While it is true that manufacturers and suppliers have invested hundreds of billions of dollars in research and development and in production facilities to bring fuel-saving technologies with impressive efficiencies to market over the last decade, scaling up the production of these technologies will take additional time and investment. Manufacturers and suppliers are working hard to grow automotivegrade battery production and other production capacities for fuel-saving technologies. Compliance with portions of this proposal require breaking new ground. Many elements of the supply chain are at capacity (consider the semiconductor shortage, for instance). Even if technologies are currently in production on some vehicles, future, unforeseen innovations are still required to meet the projected technology costs assumed in the EPA analyses (consider, for example, how quickly the Agencies assume battery costs are reduced through learning), and these cost-saving innovations are not guaranteed. The EPA analyses also include technologies that have not yet been produced (with projected effectiveness estimates that may not be technologically feasible), and these are assumed to be adopted quickly, and broadly in the EPA compliance pathways.142 [EPA-HQ-OAR-2021-0208-0571-A1, p. 46-47]

Commenter: American Honda Motor Company (Honda)

Modeling Technology Pathways

Over the past decade, Honda has expressed concern that regulatory methodologies for assessing costs and benefits under vehicle GHG and fuel economy programs result in an underestimation of actual compliance costs. While we understand an agency’s need to define regulatory boundaries, we believe this issue is increasingly important given the pace of transformation facing the automobile industry in the coming years. We believe that modeling technology pathways that are substantially different from actual plans will result in a policy discussion unnecessarily disconnected from key business decisions.

Pursuit of a pathway consistent with lowest-cost technology walks could, in theory, result in a fleet capable of meeting MY2026 standards. However, because coming regulatory regimes dictate broader strategic decisions, manufacturers today cannot simply plan to achieve 2026 targets. The Biden administration has publicly declared a desire to, in the near future, go well beyond stringencies considered in the MY2023-2026 rule. Meanwhile, California is in the process of setting its own ambitious GHG and electrification requirements as part of its Advanced Clean Car II regulations. Manufacturers and suppliers must plan for these transformations.

Pursuit of a lowest-cost technology path (capable of meeting MY2026 standards, and no further) would likely necessitate abandoning technology in the face of more stringent future requirements, stranding assets before their costs could be meaningfully recouped. More succinctly put, the cheapest path to 2026 could be the most expensive path to 2035.

Today, modeled lowest-cost pathways for bringing a fleet into compliance (such as those conducted in regulatory modeling exercises) are, for all intents and purposes, not viable options to manufacturers that must set their sights further into the future. As such, it is our view that actual compliance costs are, on the whole, typically higher than those estimated by the agency – a challenge exacerbated by the pace and magnitude of investment over a relatively brief window of time. Honda raises this point not as rationale for relaxing proposed standards, but rather to underscore the continued importance of regulatory flexibilities and complementary measures necessary to drive the transition to a cleaner fleet. [EPA-HQ-OAR-2021-0208-0565-A1, p. 11]

Agency Modeling Data

Honda has observed inconsistencies between computer model data files associated with this proposal, and data published in EPA’s Trends Report.21 Honda has not attempted to assess the breadth of this issue, but flags it as an item for further examination by the agency prior to final rule publication.

Two examples are given. First, EPA’s modeling assumes that use of off-cycle credits will be fully maximized by automobile manufacturers in MY2020 and later. By contrast, Trends Report data indicate that off-cycle credits delivered 5.4 g/mi in MY2017, climbing to just 7.5 g/mi in MY2019, an increase of roughly 1 g/mi per year. Given this pace, we believe it is unlikely that industry as a whole will adopt at a quadrupled-rate pace to reach the off-cycle cap in MY2020, as appears to be assumed in the agency’s modeling.

On a separate but related note, Honda noticed that while the 'postproc_model_runs' tool includes some aggregate off-cycle technology cost information, technology-specific costs could not be located. Honda welcomes further discussion with the agency on this topic. The agency may also wish to consider constraining off-cycle technology application to product refresh and redesign years, consistent with how it approaches application of other technologies.

Second, the total volume of banked GHG credits assumed by the agency in its CCEMS Market Data input file do not match publicly available data on EPA’s website.22 Differences between these files is, in some cases, quite significant, especially for model years 2015 and 2016. It is unclear how credit volumes included in the CCEMS Market Data input file were derived, so we simply flag the issue here for further agency examination. [EPA-HQ-OAR-2021-0208-0565-A1, pp. 11-12]

Commenter: California Attorney General Office, et al.

However, two key threshold points are relevant to all model years. First, the cost of compliance for all of the standards included in EPA’s Proposal—including the most stringent ones—is modest and very reasonable. EPA projects average, per-vehicle costs of its preferred alternative to be approximately $500 in MY2023 and $1,000 in MY2026, Draft Regulatory Impact Analysis

(‘DRIA’) 4-14 (Table 4-16), and those costs are similar for the more stringent Alternative 2, id. at 4-16 (Table 4-20). These per-vehicle costs for MY2026 are similar to the per-vehicle costs EPA estimated for the MY2025 standards it promulgated in 2012 and to the costs EPA determined remained appropriate in 2017. DRIA 1-10 (Figure 1-4). Indeed, the projected pervehicle costs are now similar to, and even lower than, they were in 2012. Compare id. (2012 estimate for MY2025) with id. at 4-16 (more stringent MY2026). The per-vehicle costs EPA estimates here for the outer model years are also in line with EPA’s earlier (2010) projections for its MY2016 GHG standards. 75 Fed. Reg. at 25,348. EPA’s 2010 actions were challenged by numerous parties in the D.C. Circuit, but none of those challengers alleged the standards were too costly or required more lead time to address compliance costs.121 Put simply, EPA correctly concluded, in 2010, 2012 and 2017, that per-vehicle compliance costs like these are reasonable and would not cause undue disruption, and there is no basis for any other conclusion here.122 No additional lead time, for any model year, can be justified on the basis of compliance costs. [EPA-HQ-OAR-2021-0208-0245-A1, pp.24-25]

Fourth, and finally, automakers can reduce fleetwide emissions by marketing and incentivizing the purchase of certain vehicles they already produce. For example, even in their current (MY2021) fleets, automakers offer a range of packages for many models.134 GHG emissions can vary, for a single model, by as much as 30% (and sometimes more) across these packages, even where, in most applications, the differently packaged vehicles will perform similarly.135 For example, in MY2021, Ford offers six versions of its popular Explorer sport utility vehicle (SUV), and the lowest-emitting Explorer has GHG emissions 27.2% below the highest-emitting one.136 And Ford’s range of Escape SUVs varies even more—by 35.7% from the highest- to lowest-emitting.137 Ford can, thus, reduce its fleetwide average emissions by leveraging its marketing, pricing, and other incentives to encourage consumers looking to buy an Explorer or an Escape to buy a lower-emitting one. And it (and other automakers) can do that with next-tono lead time, since all of these packages are already being manufactured. [EPA-HQ-OAR-2021-0208-0245-A1, p, 28]

Commenter: Consumer Federation of America

Fortunately, the agency has continued with the approach to regulation that we call 'command-but-not-control,' which was very much at the core of EISA. One challenge here is that the agency must accelerate a transition in technology to an all-electric fleet, a transformation to which many of the automakers have already committed. Therefore, the agency is not 'mandating' a technology; it is seeking to smooth and accelerate its adoption. [EPA-HQ-OAR-2021-0208-0297-A1, p. 24]

Commenter: E2 - Environmental Entrepreneurs

Costs: EPA’s cost analysis of Alternative 2 shows that compliance with the stronger rule would cost automakers less per vehicle. In 2026, the fleet average cost per vehicle is $1,044 under the Proposal and $1,030 for Alternative 2. DRIA, Tables 4-16, 4-20. It goes on to show that any higher costs of Alternative 2 are more than offset by Alternative 2’s higher benefits. EPA projects that through 2050, the Proposal has a net benefit of $140 billion, compared with Alternative 2's net benefit of $180 billion. [EPA-HQ-OAR-2021-0208-0604-A1, p. 3]

Commenter: Institute for Policy Integrity

IV. EPA Has Begun to Make Appropriate Changes to Its Modeling Approach; Further Adjustments in the Future Would More Fully Capture the Benefits of Strong Standards

In this rulemaking, EPA has chosen to rely on the same CCEMS model used by EPA and NHTSA to develop the SAFE 2 standards. Policy Integrity previously provided comments on the SAFE proposal and issued public reports on the final SAFE 2 Rule analyzing technical and economic flaws that cause this model to overestimate the costs and undervalue the benefits of strong standards.130 While EPA has begun to make appropriate adjustments to address some of these flaws, Policy Integrity recommends EPA make further changes to its model for the final rule, to work closely with NHTSA to maintain consistency in analysis with the companion fuel economy standards where appropriate, and to continue to develop its new OMEGA2 model for future rulemakings. In general, the below suggestions would not change the direction of EPA's cost-benefit analysis (i.e., the proposal and alternatives would continue to have net benefits), but rather could significantly increase the magnitude of estimated net benefits of these and future standards by more properly estimating the effects of stronger standards.

Policy Integrity provides the following comments to support EPA's proposed changes in input choices for the CCEMS model, as well as to encourage EPA to consider further changes for the final rule and in future rulemakings.131 [EPA-HQ-OAR-2021-0208-0299-A1, pp. 18-19]

Commenter: International Council on Clean Transportation

As detailed in the technology sections of ICCT's comments, above, there are many technology efficiency improvements and cost reductions that have not been incorporated into EPA's modeling, plus how the model handles off-cycle credits artificially increases the total cost of compliance. Given the very modest increases in conventional technology penetration from the SAFE rule to the proposed rule, it is clear that additional technology can easily be added to the fleet by 2026 that is more effective and lower cost than modelled in the proposed rule. [EPA-HQ-OAR-2021-0208-0522-A1, p. 18]

Commenter: Tesla

Tesla notes in supporting the proposal EPA errantly asserts that Tesla can make use of all on-menu off-cycle credits and then assigns a cost to Tesla vehicle manufacturing for utilizing off-cycle technologies that are not applicable to EVs. See, EPA, Revised 2023 and Later Model Year Light Duty Vehicle GHG Emissions Standards, Regulatory Impact Analysis (Aug 2021) at 134. ('As shown in Table 4-14, Tesla incurs nearly $400 per vehicle despite being a pure electric vehicle maker (0 grams/mile) and despite there being no upstream emissions accounting under the proposal. The costs shown for Tesla represent the costs of 15 grams/mile of off-cycle credit that we estimate Tesla would incur to generate additional GHG credits which it could sell to other manufacturers.'). EPA's modeling needs to correct this error. 185 See 77 Fed. Reg. at 62650. 186 See ICCT, How Will Off-Cycle Credits Impact U.S. 2025 Efficiency Standards? (March 2018).

Commenter: Union of Concerned Scientists (UCS)

Results – Preferred Alternative

Results for the modeled compliance scenario for the Preferred Alternative are shown in Figure 1. As can be seen in the figure, manufacturers are projected to continue to run net deficits on an annual basis until at least 2024 and as late as 2026. The crediting provisions of the greenhouse gas program allow for such deficit running, and it would be disadvantageous for a manufacturer not to take advantage of such flexibilities if they had sufficient banked credits to do so. [EPA-HQ-OAR-2021-0208-0277-A1, p.8] [[Figure 1 can be found on p. 9 of EPA-HQ-OAR-2021-0208-0277-A1]]

Both Framework OEMs and SAFE OEMs can meet the MY2023 standards without any increase in technology adoption above that in the projected baseline. For the Framework OEMs, there is not a substantial increase in technology adoption in MY2024, owing to the sufficient availability of credits and relatively small deviation between the California agreements and the NPRM in this timeframe. Already by MY2025 a small adjustment in technology can be made, and the Framework OEMs adjust then to annual compliance with the regulation. [EPA-HQ-OAR-2021-0208-0277-A1, pp.8-9]

For the SAFE OEMs, who potentially had planned for a far less stringent standard to be in place in MY2024, there is a substantial change in technology from the baseline scenario (and the previous model year). In this case, this reduction in emissions is largely the result of a modeled increase in deployment of electric vehicles (EVs) between MY2023 and MY2024, from 3.7 percent to 7.7 percent of the fleet. This is consistent with the large number of new EV models expected to be made available in this timeframe.19 Moreover, this year-over-year increase is much less than the 8 percent increase seen in the European market between 2019 and 2020, when manufacturers were similarly responding to new regulatory incentives.20 Finally, while the model determined this was the most cost-effective pathway, it is simply one technology available to manufacturers in this timeframe—there are significant available internal combustion engine technologies for most of the manufacturers at the level of certification required in MY2024 in these scenarios such that there are pathways with lower EV penetration which would still comply with the regulation, and the model was simply selecting for the most efficient within its algorithmic framework. [EPA-HQ-OAR-2021-0208-0277-A1, pp.9-10]

Because credits are a critical part of the compliance strategy, we've paid special attention to ensuring that the model replicates the credit banks in a reasonable manner.21 Figure 2 compares two different possible credit strategies considered in our modeling, one in which manufacturers are preferential toward the use of credits not ready to expire (left), and one in which industry as a whole utilizes available credits perfectly in order of vintage (right). Even with suboptimal credit usage, Figure 2 shows clearly that manufacturers can choose not to deviate at all from their compliance plans for MY2023 and comply with the NPRM with modifications to their plans consistent with technology adoption available to all manufacturers in MY2024 and later. In fact, in these modeling runs, industry runs a net deficit in MY2023, MY2024, and MY2026 and yet has sufficient credits to comply largely through carryforward of its banked credits, even in our suboptimal trading run.[EPA-HQ-OAR-2021-0208-0277-A1, pp.10-11] [[Figure 2 can be found on p. 10 of EPA-HQ-OAR-2021-0208-0277-A1]]

Results – Alternative 2

In the preamble to the proposed rule, EPA noted that lead-time was part of its consideration in rejecting Alternative 2.22 Our modeling does not support this assessment. Rather, even in our conservative assumptions on manufacturer product plans for MY2023, there is sufficient credit availability for manufacturers to comply, even without resorting to additional technology deployment or credit carryback from improvements made post-MY2024. As such, we believe there is sufficient lead-time argument for industry to comply with Alternative 2 in MY2023 and beyond [EPA-HQ-OAR-2021-0208-0277-A1,p.11]

Figure 3 illustrates manufacturers' response to Alternative 2. SAFE OEMs again respond to the rule primarily through additional electrification, this time with an increase of 7.3 percent, from 3.7 to 11.0 percent.23 Because Alternative 2 is more stringent than the California framework in MY2023 and MY2024, even the Framework OEMs choose to deviate from their baseline production plans with additional technology adoption. Though a small change, this helps the industry overall comply through the modeled timeframe. [EPA-HQ-OAR-2021-0208-0277-A1, p.11] [[Figure 3 can be found on p. 12 of EPA-HQ-OAR-2021-0208-0277-A1]]

Figure 4 illustrates the credit bank for industrywide compliance with Alternative 2. Because manufacturers make more adjustments to their fleet in MY2024, the credit bank overall is not that different entering MY2027 than it was under the compliance modeled for the Preferred Alternative. The fact that further adjustment in MY2024 is possible also further illustrates the ease with which manufacturers can comply with the Preferred Alternative, even with limited lead-time.[EPA-HQ-OAR-2021-0208-0277-A1, p.11] [[Figure 4 can be found on p. 14 of EPA-HQ-OAR-2021-0208-0277-A1]]

Additional strategies by manufacturers to handle lead-time

The Volpe model is limited in its ability to consider all of the possible paths to compliance accessible to manufacturers. Below we highlight a couple of those strategies which can and have been used by manufacturers previously, indicating that our modeling is, again, a conservative picture of how the industry could respond in a short timeframe to increases in standards with relatively little lead-time. [EPA-HQ-OAR-2021-0208-0277-A1, p.13]

One obviously potential strategy is the use of pricing changes to shift the sales mix of a manufacturer's fleet. There is extensive literature on this subject, and in fact General Motors themselves published its own internal economic model for pricing with regards to compliance with CAFE standards.24 There continues to be recent anecdotal evidence in support of this as well, such as pricing of the Fiat 500e to ensure Stellantis sold the prescribed volume of electric vehicles required under state ZEV regulations.25 Because EVs are so much more efficient than either the Preferred Alternative or Alternative 2 require, small shifts in fleetshare for those vehicles result in dramatic shifts in a manufacturer's average fleet performance. Given the large number of new EV models offered in the MY2023-2025 timeframe, it is highly likely that manufacturers concerned about short-term compliance with the newly finalized standards could make last-minute adjustments to pricing in order to compensate for any unforeseen shortfalls. Smaller pricing decisions such as the relative costs between a given model's more efficient base powertrain offering and the high-performance package could also help a manufacturer alter its average performance without making any adjustments to the technology offered in its fleet. [EPA-HQ-OAR-2021-0208-0277-A1,pp.13-14]

Another tool at manufacturers' disposal is the use of "carryback" credits. The Volpe model only looks at carrying forward credits for compliance, but manufacturers can use overcompliance credits earned from as many as three years after a deficit is generated to offset it.26 While the Volpe model does not consider this as a compliance possibility, EPA allows it, automakers' trade associations have acknowledged its use,27 and the National Automobile Dealers Association and Volkswagen both commented that credit carryback supports annual compliance with the greenhouse gas program.28 Manufacturers like Volvo and Jaguar-Land Rover have carried forward deficits under this provision for purposes of complying with the current greenhouse gas program.29 While this may not be an option preferred by manufacturers, shifts in the market and/or adjustments to the standards themselves are precisely the reason for such credit flexibilities, and it should be a viable option for compliance considered by EPA in its consideration of lead-time requirements. [EPA-HQ-OAR-2021-0208-0277-A1,p.14]

Support for setting stronger greenhouse gas emissions standards in 2026

EPA has requested comment on strengthening the standards beyond the Preferred Alternative or Alternative 2 in 2026, noting the significant amount of lead-time and information on manufacturers' plans that suggests industry is more than capable of meeting increasing stringency in this timeframe.30 Not only is such an increase feasible, but it is critical in order to rapidly confront the issue of climate change and limit warming. [EPA-HQ-OAR-2021-0208-0277-A1, p.14]

EPA's own modeling shows how much more can be done in this timeframe, not just through electrification but through improvements to gasoline-powered vehicles. Our modeling supports this and indicates the significant additional benefits increasing stringency provides. [EPA-HQ-OAR-2021-0208-0277-A1,p.14]

Building on the modeling effort detailed in § I., we examine three standards more stringent than the proposal: Alternative 2, and Alternative 2 with targets 5 and 10 g/mi lower in 2026. In all cases, manufacturers are able to comply, through both an increase in electrification and further penetration of internal combustion engine technologies, leading to significant benefits. [EPA-HQ-OAR-2021-0208-0277-A1,p.14]

Achieved fleetwide greenhouse gas emissions levels

Figure 5 shows the respective fleet average standards and the levels achieved in the scenarios examined by UCS. Even the strongest of these alternatives does not achieve an emissions level below what the initial 2012 standards were supposed to achieve in 2025 until 2026.31 While these rules are, by design, flexible to fleet mix, the dramatic shift towards crossover- and sport-utility vehicles has significantly eroded much of the emissions reductions which were initially anticipated—setting a strong standard for MY2023-2026 is the only way to put us back on that trajectory. However, EPA will need to accelerate the rate of improvement beyond even the strongest alternative modeled by UCS in order to meet our estimate for a 2030 target consistent with what is needed to address climate change (Figure 6).32 [EPA-HQ-OAR-2021-0208-0277-A1, p.15] [[Figure 5 can be found on p. 15 of EPA-HQ-OAR-2021-0208-0277-A1]] [[Figure 6 can be found on p. 16 of EPA-HQ-OAR-2021-0208-0277-A1]]

Electric vehicle penetration for different regulatory scenarios

EV marketshare for our modeling is shown in Figure 7.33 Here we also include an alternative scenario matching the proposal but excluding EV multipliers, to illustrate the adverse impacts of EV multipliers (§ III.a.). [EPA-HQ-OAR-2021-0208-0277-A1,p .16] [[Figure 7 can be found on p. 17 of EPA-HQ-OAR-2021-0208-0277-A1]]

The results are clear and systematic—the more stringent the rule, the more EVs which are projected to penetrate the fleet. While the three variants of Alternative 2 match in the early years, the increase in stringency in 2026 has a significant impact on EV penetration in the MY2025-2026 timeframe. There is nearly a 50 percent increase in MY2026 EV sales between the proposal and the most stringent scenario examined, from 10.8 percent up to 15.5 percent. These figures are more than double and triple, respectively, the 4.8 percent EV marketshare achieved in MY2026 in the baseline compliance scenario. [EPA-HQ-OAR-2021-0208-0277-A1, p.16]

While the proposal would result in more than 5.5 million EVs sold according to our analysis, more than doubling the total sold in the baseline, our strongest alternative would result in an additional 1.3 million EVs on the road. For context, 1.9 million EVs have been sold in the United States since 2010.34 However, it is further worth noting that our modeling runs do not consider compliance with state ZEV standards—this will likely impact the assumed baseline level of EV adoption, particularly by MY2026. [EPA-HQ-OAR-2021-0208-0277-A1,p.17]

California's Air Resources Board is developing the Advanced Clean Car II rule, which will include revisions to the Zero Emissions Vehicle (ZEV) regulations. The Air Resources Board initial draft of the ZEV regulation targets would require approximately 25 percent of new vehicles in California to be EVs.35 New vehicle sales in California over the previous 5 years (calendar years 2016-2020) averaged 2.06 million vehicles, and the ZEV regulation would likely require over 500,000 EVs in California alone.36 [EPA-HQ-OAR-2021-0208-0277-A1,pp.17-18]

It is clear from our modeling that EV adoption is at the heart of any discussion of stringency. Setting the strongest rule possible in the near-term sends a stronger signal to industry and will better enable industry to respond to a post-MY2026 regulation consistent with EO 14037. For example, this could be the difference in requiring a five-fold increase in EV sales in a four-year span, compared to just a three-fold increase. While the transition to electrification will happen rapidly as vehicles not just reach cost parity but convenience parity, prodding manufacturers to pull forward the front edge of that transition will help solidify investments in the United States in support of this transition that will enable EPA to set as robust a rule as possible in order to address climate change. [EPA-HQ-OAR-2021-0208-0277-A1,p.18]

Internal combustion engine vehicle technology under different regulatory scenarios

While manufacturers' EV plans will be a key piece to addressing the increase in stringency beginning in MY2023, internal combustion engine vehicles will continue to improve in this timeframe and show no sign of exhausting their potential. While our modeling suggests that manufacturers will deploy EVs due to the significant improvement they can make in a fleet's performance, this is by no means the only path available, as indicated by the relatively low levels of vehicle technology modeled as being deployed in the remaining gasoline-powered fleet, which leave many other options open (Figure 8). [EPA-HQ-OAR-2021-0208-0277-A1,p.18] [[Figure 8 can be found on p. 19 of EPA-HQ-OAR-2021-0208-0277-A1]]

The strongest gains come in the adoption of high compression ratio (HCR) engines, and especially an advanced HCR engine with a cooled exhaust gas recirculation and dynamic cylinder deactivation (HCR2). As has been highlighted previously by EPA, HCR2 remains a cost-effective technology.37 However, our modeling also shows an increase in advanced cylinder deactivation, as well as an increasing use of cylinder deactivation with turbocharged engines. [EPA-HQ-OAR-2021-0208-0277-A1,p.18]

While not shown, we saw across all scenarios a significant shift to more advanced transmissions, both for continuously variable transmissions (CVTs) moving to more advanced variants, and for a marked shift to more 10-speed automatic transmissions. Both of these are consistent with ongoing trends in the industry.38 [EPA-HQ-OAR-2021-0208-0277-A1,p.18]

Interestingly, apart from the differences in plug-in electric vehicles, there is little difference between the four modeled scenarios when it comes to hybridization of conventional vehicles. Shares of stop-start/mild hybrids, as well as strong hybrids, only see marginal changes in all scenarios (Figure 9). [EPA-HQ-OAR-2021-0208-0277-A1, p.19] [[Figure 9 can be found on p. 20 of EPA-HQ-OAR-2021-0208-0277-A1]]

The relatively small changes in marketshare across different compliance scenarios illustrates one of the challenges with a model like the Volpe model—it can get stuck in particular pathways that act as a local minimum and may not necessarily fully reflect all of the compliance pathways utilized by manufacturers. There will always be examples of a model such as Volpe not quite accurately reflecting reality—for example, Figure 9 shows little change in strong hybridization, and our modeling observed no strong hybrid pick-up trucks, yet both Ford and Toyota are moving forward with full-size hybrid pick-up trucks (§ III.d.). EPA's own modeling exhibits a similar level of stability in overall technology deployment across all regulatory scenarios and sensitivity cases.39 [EPA-HQ-OAR-2021-0208-0277-A1, pp.20-21]

At the same time, while our model may not perfectly replicate the industry's eventual path forward, it indicates that there are many viable pathways for compliance, since large numbers of vehicles remaining in relatively low-technology configurations like a lack of start-stop or large remaining share of 18-bar BMEP turbocharged engines (Turbo1). [EPA-HQ-OAR-2021-0208-0277-A1, p.21]

EPA Response

The comments by the Alliance for Automotive Innovation encouraged EPA to rethink whether the compliance modeling is reasonable considering significant events since 2017. The Alliance also commented on EPA's battery cost estimates and statement that all technologies included in the analysis are already in production. Although the comment is unclear, we believe this latter claim is directed at the HCR2 technology that was projected for wide application in the NPRM analysis. However, the FRM analysis does not include that technology in our primary analysis as we discuss in RIA 2.3.2 and 4.1.1.3. Further, we discuss our updated battery costs in Preamble III.A with more detail in RIA 2.3.4 and 4.1.1.2 where we note that our updated battery costs are in-line with Department of Energy and third-party estimates and projections.

In response to comments by Honda with respect to EPA's modeling of off-cycle credits in the NPRM, we agree that our approach in the NPRM could be improved, and we have updated our approach for the final analysis. We discuss our updated approach in RIA 4.1.1.1. Honda also commented that the banked credits that were used for modeling in our NPRM appeared to be out-of-date. We agree with the commenter and have updated our banked credits for the final analysis based on the most recent manufacturer compliance data submitted to EPA. We appreciate Honda's comment that flexibilities in the program are important because automakers may want to adopt a compliance strategy for model year 2026 with an eye towards developing products that could meet future standards that may be more stringent. We agree that the flexibilities built into the program mean that compliance costs for a given time period are often in effect spread over a wider time period, depending on a manufacturer's choice of strategy. Our modeling is intended to be a reasonable illustration of potential costs for automakers to comply with the standards under consideration in the proposal, and those adopted in this final rule. Although the flexibilities in the program offer manufacturers different options for technology paths to compliance over different time periods, which may make it more difficult, or uncertain, to accurately predict costs for a specific manufacturer in a specific year, we believe the modeling represents a reasonable estimation of costs to meet the standards, and the flexibilities adopted overall reduce costs.

EPA agrees with the comment from the Consumer Federation of America that we are not mandating a technology with these final standards. We are establishing performance-based standards which are technology neutral.

Regarding the comment from Environmental Entrepreneurs, we note that we do not set standards to maximize net benefits under the Clean Air Act, but rather EPA considers many factors including technology feasibility, lead time considerations, and costs.

Tesla commented that we erroneously show them earning off-cycle credits in our NPRM analysis. We have corrected this issue in our final analysis.

In response to comments from the Institute for Policy Integrity recommending that EPA make further changes to its model for the final rule and to work closely with NHTSA to maintain consistency in analysis with the companion fuel economy standards where appropriate, and to continue to develop its updated OMEGA2 model for future rulemakings, EPA did coordinate with NTHSA for this rulemaking. We also plan on the continued development of our OMEGA2 model and plan to make the final model available to all stakeholders in the future.

Commenter: Agortsas, George

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 189.]

I believe it's difficult to thrive when you're dealing with health issues related to air pollution. It's difficult to thrive when the extremes in weather create dangerous environment. It's difficult to thrive when economically we're burdened with the aftereffects, including increased medical costs, increased costs to address more and more disasters, and costs to address displaced families due to climate change, and other disasters.

That's my main motivation. I really, really want to leave a better planet for our children and grandchildren and those that follow

Commenter: Allergy & Asthma Network, et al.

The Biden Administration action to review and revise existing GHG standards for light-duty vehicles for model years 2023-2026 represents a crucial public health and equity opportunity. This rule must be finalized in 2021 so the rules will be implemented Model Year 2023. The American Lung Association's State of the Air 2021 report made clear that more than 40 percent of all Americans - 135 million people - live in communities impacted by unhealthy air quality. 1 Exposures to poor air quality can result in a wide range of negative health outcomes including asthma attacks, worsening COPD, heart attacks and strokes, lung cancer and premature death. Children, seniors, people of color and low-income communities are at far greater risk of harm from unhealthy air. [EPA-HQ-OAR-2021-0208-0296-A1, pp. 1-2]

Transportation is the number one source of climate pollution in the United States and a leading source of our air quality challenges. Climate change driven by fossil fuel combustion is threatening decades of clean air progress made through US EPA, state, and local actions to reduce harmful emissions. Climate change is a health emergency, amplifying many present-day threats to public health, including extreme heat impacts, degraded air and water quality, and increased destruction and displacement due to wildfires, flooding and other extreme events, among many other tolls taken on Americans' physical and mental health. US EPA acknowledges the significant public health burdens posed by climate change, and that 'scientific assessments continue to be released that further advance our understanding of the climate system and the impacts that GHGs have on public health and welfare both for current and future generations.'2 The revised standards must meet the climate challenge head-on and set the stage for future standards that transition the fleet to zero-emissions as rapidly as possible. [EPA-HQ-OAR-2021-0208-0296-A1, p. 2]

Commenter: Alliance of Nurses for Health Environments

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 21-22.]

If we do not make significant cuts in greenhouse gas emissions as soon as possible, the worst impacts of climate change will be unavoidable.

As nurses serving on the front lines of communities and caring for impacted populations, we are already seeing the very real effects of climate change on health.

Commenter: American Council for an Energy-Efficient Economy (ACEEE)

Transportation is now the largest source of greenhouse gas emissions in the United States and the light-duty sector makes up 58% of those emissions (EPA 2020b). Reducing carbon emissions is critical to tackling climate change but increasing light-duty vehicle efficiency will also have significant benefits to air quality and reduce driver fueling costs. Vehicles are a significant contributor to local air pollution and the associated health impacts, such as increased rates of asthma, increased risk of heart attacks or strokes, and lung cancer (Doyle 2021). [EPA-HQ-OAR-2021-0208-0251-A1, p.2]

Commenter: American Honda Motor Company (Honda)

Meaningful GHG Reductions

Standards developed in the 2012 Final Rule (covering MY2017-2025 vehicles) were designed to deliver significant environmental benefits. That program called for roughly 4.5% year-over-year improvement to help avoid the worst consequences of climate change. Honda supported the goals of the MY2017-2025 rule and remains convinced of the importance of further action. Due to a variety of reasons, including changing regulatory winds and shifts in consumer preference, industry as a whole did not progress at that pace. According to the latest EPA Trends Report, the combined (car/truck) fleet improved approximately 4.2% in total between model years 2016 and 2020 (the most recent year of data available), well below levels targeted in 2012.8

Societal inaction is not an option. Impacts of climate change can be seen with increased frequency, and scientists continue to warn of even more adverse consequences.9 While the burden of responsibility lies well beyond the automobile sector alone, transportation is a critical part of the solution set. According to recent statistics, light duty transportation is responsible for roughly 22% of all U.S. GHG emissions.10 It is only appropriate that our industry shoulder its portion of responsibility to lower our nation’s contribution to global climate change. [EPA-HQ-OAR-2021-0208-0565-A1, p.4]

Commenter: American Lung Association

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp.18-19]

First, climate change is a health emergency. The Intergovernmental Panel on Climate Change found that the planet is on a path towards catastrophic destruction if we do not make serious cuts to greenhouse gas emissions as soon as possible.

From deadly floods in Tennessee to wildfires in the West destroying communities and blanket the continent with unhealthy particle pollution, no one can escape the lethal consequences and the urgent need to act.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp.87-88]

The need for action on climate change could not be more urgent. Earlier this month a report from the UN Intergovernmental Panel on Climate Change found that there is an extremely narrow window of time to act on climate change after which point the worst impacts will be unavoidable.

Climate change is a public health emergency and the sooner we act the more lives we will save. Strong standards for cars are a critical step needed to slash greenhouse gas emissions.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p.89]

The bottom line: Americans across the political spectrum support specific policies to achieve a pollution-free transportation future. We must take action at every level to address climate change and reduce greenhouse gas emissions in order to protect health and save lives and that includes cleaning up transportation pollution using the strongest possible standards.

Climate change poses unprecedented threats to the health of every American now and for every future generation. There is no time to delay.

The Biden Administration must use all available tools to promote the climate pollution reductions we so desperately need. Please make this propose as beneficial for health as possible and finalize it quickly and then move forward with bold future greenhouse gas standards for light- and heavy-duty vehicles that accelerate the critical transition to zero emission vehicles.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 167-168.]

Pollution from cars is helping to drive climate change which can lead to more excessive heat like what we've seen across the country and the globe in recent months and the rise in intensity of extreme weather events and wildfires.

Setting strong greenhouse gas standards for cars and light trucks is only part of the solution towards a healthier future.

A report released by the American Lung Association in September of 2020 found that transitioning the nation to electric light- and heavy-duty vehicles powered by non-combustion renewable energy would lead to a $113 million in climate benefits annually by 2050.

Greenhouse gases are not the only pollutant released by tailpipes. Air pollutants released from cars contribute to ozone and particulate matter pollution which both have direct health impacts, particularly for vulnerable populations, like those with existing lung disease.

Our Road to Clean Air Report also found that a transition to electric vehicles would yield $72 billion in health benefits annually by 2050.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 170-173.]

Climate change is a health emergency. I imagine many of you on the line today are personally experiencing some of those impacts right now, just like millions of Americans across the country.

We know that these impacts will get dramatically worse without strong federal action. In fact, we often hear from physicians and nurses that they are seeing the impacts of climate change on their patients right now.

We hear about direct lung health concerns with student athletes who are exposed too often to wildfire smoke or parents who have to choose to keep their kids from playing outside at all on hazardous air days, and we hear about a whole array of other impacts affecting everything from cardiovascular health to mental health.

That's why health and medical organizations have been spending years rallying support for cleaner cars. In 2017, the Lung Association wrote a letter to EPA and NHTSA signed by more than 700 medical and health professionals from across the nation urging both agencies to implement strong state and federal advanced clean car regulations to protect public health.

In 2018, we joined more than 90 national, state, and local health and medical organizations in commenting against the SAFE Rule Act.

Earlier this year, the Lung Association and 13 national health and medical organizations, including the American Public Health Association, the National Association of County and City Health Professionals, the Medical Society, Consortium on Health, and the American Psychological Association all sent a letter to President Biden calling on him to set the strongest possible emissions standards to protect public health.

We asked the Administration to act urgently to ensure the same or better greenhouse gas emissions reductions scheduled to be achieved under the Obama-era standards and then set stronger standards through at least Model Year 2030.

And just last month, a robust contingent of the health community submitted commented to EPA in support of state authority to set stronger cleaner car standards, including 28 national, state, and local health and medical organizations and dozens of health professionals. In fact, some of the organizations represented are testifying today and tomorrow.

Climate change is a health emergency but it's also a health opportunity. That's why the health community supports cleaning up our nation's vehicles because it not only addresses climate change but also provides immediate benefits to health by eliminating dangerous tailpipe pollution.

The nation urgently needs to reduce greenhouse gases from transportation to avoid the worst health impacts of climate change. A nationwide transition to zero emission vehicles has the potential to provide immediate benefits to health and to equity.

Commenter: American Lung Association (Sacramento, CA)

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 253-254.]

We believe this provision is a vital response to the alarming public health risks posed by climate change in every corner of our nation and especially in communities already most at risk due to poor air quality.

The climate crisis is on full display today. Like many Americans, Californians have faced extreme heat warnings, air quality alerts, and red flag warnings for wildfire risk.

As I speak to you today, EPA's Air Now website shows very unhealthy and even hazardous air quality impacting residents of multiple states due to Western wildfires. Lives have been lost, homes have been lost, entire communities have been lost.

With each extreme event, we become more acutely aware of and concerned by the many connections between climate change and public health.

We call on you as EPA to use all the tools available to respond to this crisis and these standards really represent one of the most powerful levers available.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 255.]

These actions support cleaner air, healthier climate, and relief for communities most burdened by both on-road transportation sources and fossil fuel infrastructure that threatens health on a daily basis.

Commenter: Anderson, Laurie

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 104-105.]

The transportation sector is the largest sector of carbon pollution in the U.S. Cleaning up vehicle pollution is one of the most important things we can do to fight climate change.

I am also concerned about the impacts of climate change. Last year Colorado experienced the three worst wildfires in our state's history which impacted air quality across the state and Colorado remains in severe drought on the Western Slope and that is where our water supply comes from.

We are also facing abnormal weather patterns, such as two tornadoes over the past couple months have touched down in this area, and this is an area where we rarely even have a tornado watch.

Additionally, Colorado relies on our winter snowpack for our water supply and it is down substantially from years prior. These impacts are serious and we must reduce our pollution now.

Commenter: Asthma and Allergy Foundation of America (AAFA)

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 214-216.]

25 million Americans have asthma, including over six million children, and over 3,600 people die each year from asthma. That's about 10 people a day. It's a chronic disease that causes your airways to become inflamed, making it hard to breathe, and there is no cure for asthma.

In the United States the burden of asthma falls disproportionately on the black, Hispanic, American Indian, and Alaska Native populations, and especially on children. These groups have disproportionately high rates of poor asthma outcomes, including hospitalizations and deaths.

In fact, as documented in our 2020 Asthma Disparities Report, black Americans are three times more likely to die from asthma than white Americans and five times more likely to be treated in an emergency room, and black women have the highest death rates from asthma versus any other group.

Poor air quality and exposure to air pollution is a very significant risk factor, both for developing asthma and for those who already have an asthma diagnosis.

That's why clean air and addressing the climate crisis are particularly important to the asthma and allergy community and especially those in racial and ethnic minorities.

As the leading contributor to air pollution and the largest source of climate pollution in the U.S., cleaning up the transportation sector represents immense opportunity for public health benefits.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 217.]

We must make haste to finalize the rule this year and we must make haste to set up even more health protective standards beyond that. Climate change is a public health emergency and we cannot afford to delay action.

Commenter: Bay Area Air Quality Management District

Government regulation that encourages innovative air pollution control is critical for combatting the current climate crisis. California experiences compelling and extraordinary conditions due to air pollution, climate change, wildfires, and extreme heat. We need strong greenhouse gas standards to serve as a key tool to help prevent and address these challenges. As noted earlier, the light duty sector is a significant source of greenhouse gas emissions. Cultivating innovation in passenger car and light duty vehicle technologies is an opportunity for great impact.[EPA-HQ-OAR-2021-0208-0283-A1, p.3]

Commenter: Bednar, Valencia

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 209.]

I am wanting today to have a healthy climate and not have pollution from cars.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 210.]

We live close to busy roads and car pollution isn't good for us. We are trying to do our part. We want to ride our bikes but cars make it harder. Cars create a lot of pollution and are a big part of the climate change problem. We need EPA to help cars pollute less.

Commenter: Begley, Amanda

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 246-248.]

I'm here because I'm concerned about climate change. The latest IPCC report, the Intergovernmental Panel on Climate Change, the first part of the sixth assessment was recently released, and the assessment details in stark and clear language that climate change is widespread, rapid, and intensifying. It is here, it is now, it is us.

The assessment detailed that warming will increase over the next three decades because nations have delayed curbing fossil fuel emissions for so long. In almost all emissions scenarios contained in the latest assessment, global warming is expected to hit 1.5 degrees C in the early 2030s. That is so soon.

The global temperature average has already risen one degree C or about two degrees Fahrenheit since the Industrial Revolution, and with that two degrees of additional warming we've had record breaking heat waves, California's ever-increasing and intense wildfire season, Australia fires, China flooding. I could go on and on.

We have a window of opportunity to avoid things getting worse. The slower we act, the worse the consequences will be, and the faster we act, the less severe the consequences will be.

Transportation is the largest source of carbon emissions in the United States and it is critical that we both make our gasoline-powered cars and trucks more efficient and we must shift rapidly to electric vehicles.

Commenter: Beitzel Snow, Stephanie

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 239-240.]

Without immediate action to address the root causes of climate change, carbon pollution from burning fossil fuels, our communities are facing increasingly frequent and severe weather events causing the kind of destruction, death, and damage that swept across our lands last year.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 240.]

Transportation sector is the largest source of carbon pollution in the United States and cleaning up vehicle pollution is one of the most important things that we can do to fight climate change.

Commenter: Bjork, Deb

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 36-37]

The sobering and terrifying Sixth Intergovernmental Panel on Climate Change Report released two weeks ago clearly describes our hellish future unless we take immediate and bold action to curb fossil fuel emissions.

We must mitigate the worst of climate change. We need the EPA to enact strong standards. I have a Ph.D. in clinical psychology. Research shows that the effects of climate change place children at risk of mental health consequences, including PTSD, depression, anxiety, phobias, sleep disorders, attachment disorders, and substance abuse. These in turn can lead to problems with emotional regulation, cognition, learning, behavior, language development, and academic performance. Together, these predispose adverse mental health outcomes.

Climate change also affects adults with mental health impacts and significant stress. Two recommended coping strategies that reduce psychological impacts of climate change are staying informed and taking positive action towards change.

Of note, one suggested action is to buy an energy-efficient or electric car. Because the transportation sector is the largest source of carbon pollution in the U.S., reducing vehicle pollution is essential for the fight for climate change and clean air. Reducing pollution from cars and light-duty trucks is crucial to improving air quality.

Commenter: Brandt, Dorothy

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 207-208]

We all know pollution from cars causes breathing problems. California's air is so much better today than it was in the past because the government recognized the auto emissions problem and worked to improve clean air.

California is still leading the way to limit dangerous auto emissions. Federal leadership is needed. Please help us by minimizing dangerous greenhouse gas emissions for passenger cars and light trucks for the Model Years 2023 through 2026. This is a necessary short-term first step in addressing climate pollution from the transportation sector. If we do, our future could be much brighter with cleaner air to breathe and to my knowledge smog pollution is getting worse in America.

This is because of climate change and auto emissions. We are already experiencing rising temperatures and more intense heat waves because of climate change. High heat creates the perfect conditions for ozone to form.

As climate change continues to erode the progress we've made on cleaning up air pollution, we need strong standards to follow the science and protect our health.

Commenter: Brandt, Elizabeth

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 196-197.]

Pollution from the transportation sector is the nation's leading source of climate warming carbon pollution. Tackling pollution from cars and trucks is one of the most important ways we can fight climate change.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 199.]

In order to prevent our worse case climate scenario, we must take strong action now to reduce pollution from cars. Climate change is disrupting our livse. So we need to disrupt our approach to reducing climate pollution. Bold action is needed.

Commenter: Buzzelli, Melanie

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 122-124.]

Recently, the professor asked us to look at the concentration of carbon dioxide in the atmosphere when we entered the program and compare it to the concentration now. In June of 2019 the concentration level was approximately 414.1 parts per million, and in June of 2021 the concentration level was approximately 418.94 parts per million.

The professor then asked us to compare these numbers to the point of no return, generally recognized as 450 parts per million, and reflect on how we felt. I had a hard time attempting to describe my myriad of emotions at the time and I don't think I've become any more articulate since then, but I think the word I ultimately ended up landing on to suffice for now which was terrified.

I know these numbers aren't a surprise for you and they weren't necessarily a surprise to me either, but I think it is nonetheless important to constantly remind ourselves of what we face.

Working in policy myself, I know how easy it is for politics and bureaucracy to chip away at big change, but on the issue of climate change we simply cannot afford for that to happen.

We need to be doing as much as we can at every opportunity we have and in that vein, while this proposal is a step in the right direction, much more is needed.

The transportation sector is the largest source of greenhouse gas emissions in the United States. Gasoline and diesel-powered cars, SUVs, trucks, buses, vans, and more pollute the air we breathe and drive climate change.

Climate change is terrifying. It's truly an existential crisis and I hope it's one that we're willing to meet.

Commenter: California Air Resources Board (CARB)

We strongly support urgent action to protect public health and stabilize the climate. The wildfires, drought, declining air quality, and extreme heat we face due to the climate crisis are becoming increasingly extreme and frequent. They confirm the assessments of climate scientists that we must act quickly to stave off the worst effects of climate change. Indeed, America's most vulnerable communities – and communities in California in particular – face very serious public health and economic threats without swift action. [EPA-HQ-OAR-2021-0208-0643-A6, p.1]

The mandate to protect the environment, climate, and public health has never been stronger. We must not delay any further reducing the pollution of greenhouse gases to maintain a stable climate. The imperatives to meet the health-based National Ambient Air Quality Standards, reduce toxic emissions, and alleviate the disparate impacts of pollution on certain communities are likewise urgent and overdue. Wildfire, drought, harmful air quality, and extreme heat are more extreme and frequent because of a changing climate. The leading climate scientists continue to stress that we must act quickly to avoid the worst effects of climate change. [EPA-HQ-OAR-2021-0208-0643-A6, p.6]

The Proposal is Urgently Needed to Mitigate a Deteriorating Climate and Protect Public Health - Especially Those Most Exposed to Pollution

Transportation is one of the main causes of air pollution that threatens our health and our climate. Climate change brought on by continued emissions of greenhouse gases is an existential threat. As CARB's Chair testified on this proposal, these emission standards are sorely needed. California's skies are darkened by wildfire ash and smoke and our reservoirs are alarmingly low.6 The recent report from the Intergovernmental Panel on Climate Change on the physical science basis for human-caused climate change underscores the urgency.7 The extensive drought striking California and other parts of the West, and the resulting wildfires, are likely exacerbated by greenhouse gas emissions from human activities. As U.S. EPA recognized in its proposal, these standards would avoid the release of billions of tons of greenhouse gases.8 [EPA-HQ-OAR-2021-0208-0643-A6, p.8]

Commenter: California Attorney General Office, et al.

Strong standards are necessary now to stave off the worst effects of human-induced climate change and to confront inequitably distributed threats to public health and the environment from climate change as well as other pollution. From droughts to floods and from wildfires to hurricanes, our States and Cities are already experiencing the devastating impacts of climate change, which will continue to mount and compound with rising concentrations of GHGs in the atmosphere. [EPA-HQ-OAR-2021-0208-0245-A1, p.1]

Our States and Cities are currently experiencing the devastating effects of climate change. Just this summer, multiple deadly2 heatwaves with record-breaking high temperatures ravaged the western United States. The West is also experiencing extreme drought conditions that threaten water security and fuel wildfires that have displaced thousands.3 Meanwhile hurricanes of historic force swept across the southern and eastern United States—testing energy resilience and producing record-breaking rainfall and fatal flash floods.4 These types of impacts have been linked to climate change caused by anthropogenic emissions of GHGs,5 and they are projected to worsen.6 As average surface temperatures rise and the intensity and frequency of these types of extreme weather events increases,7 our States and Cities face direct and compounding challenges to protect the health and welfare of our residents, our economies, and our natural resources. [EPA-HQ-OAR-2021-0208-0245-A1, pp.2-3]

'The past six years, including 2020, have been the six warmest years on record,' 8 an already concerning statement only amplified by the Intergovernmental Panel on Climate Change's (IPCC) warning that '[g]lobal warming of 1.5°C and 2°C [above pre-industrial averages] will be exceeded during the 21st century unless deep reductions in CO2 and other greenhouse gas emissions occur in the coming decades.'9 See Figure 1 [Figure 1 can be found on p. 3 of Docket number EPA-HQ-OAR-2021-0208-0245-A1].

The IPCC has found that GHG emissions from human activities are already responsible for about 1.1°C of warming since 1850-190010 and that '[h]uman influence has warmed the climate at a rate that is unprecedented in at least the last 2000 years.'11 In other words, the world is getting hotter due to increased concentrations of GHGs in the atmosphere that are 'unequivocally caused by human activities.'12 As temperatures rise, threats to public health and the environment in our States and Cities continue to mount. For example, '[w]ith higher temperatures, [hospital] admissions for acute renal failure, appendicitis, dehydration, ischemic stroke, mental health, noninfectious enteritis, and primary diabetes were significantly increased.'13 And '[m]ortality effects are observed even for small differences from seasonal average temperatures.'14 These types of heat-related health and mortality risks are not equally distributed.[EPA-HQ-OAR-2021-0208-0245-A1, pp. 3-4]

'Warmer temperatures [also] contribute to the severity of drought conditions by leading to more precipitation falling as rain rather than snow, faster melting of winter snowpack, greater rates of evaporation, and drier soils.'17 This can result in, among other impacts, the degradation of water security18 and ecological vulnerabilities.19 As shown in Figure 2 [Figure 1 can be found on p. 6 of Docket number EPA-HQ-OAR-2021-0208-0245-A1], a significant portion of the western U.S. is currently experiencing extreme or exceptional drought. Drought conditions are particularly severe in California, where nearly 90% of the State is facing at least extreme drought and about 45% of the State is experiencing exceptional drought.20 The 2021 year-to-date statewide average temperature in California is almost the warmest on record,21 and precipitation and snowpack levels in the State are well below average.22 These conditions are impacting the State's water supply at major reservoirs, nearly all of which have far less water than the historical average as of September 2021.23 Moreover, '[f]orests are especially vulnerable to drought in a warming world.'24 For example, California's 2012-2015 drought killed more than 100 million trees, mainly in the Sierra Nevada forest.25 The forest density and warmer temperatures 'compound[ed] die-off by an estimated 55%,' and 'climate change is expected to . . . increas[e] Sierran tree death during drought by 15-20%' for each additional degree of warming.26 And '[w]hen a drought drives changes within ecosystems, there can be a ripple effect through human communities that depend on those ecosystems for critical goods and services.'27 [EPA-HQ-OAR-2021-0208-0245-A1, pp.4-5]

Rising temperatures combined with drier conditions are also increasing the risk of wildfires.28 '[T]he number of hot days is climbing; forests and grasslands are dried out by increased evaporation; the growing season is lengthening (providing available fuel for longer periods); and snowpack is melting earlier.'29 These conditions have significantly enhanced the size of wildfires and length of the wildfire season. '[S]ince 1984, human-induced climate change is responsible for doubling the cumulative area of forest fires across the western United States.'30 'Since the 1970s, the annual average wildfire season in the Western United States has expanded from five months to 8.5 months long.'31 'It now burns six times as many acres and consists of three times as many large fires—those defined as more than 1,000 acres.' 32 And '[c]limate models project a continued increase in the frequency and intensity of wildfires with rising temperatures.'33

Consistent with this projection, the 2020 wildfire season was unprecedented. For example, wildfires in Colorado burned more than 665,000 acres—more than in any previous year—and the State's record for largest wildfire was broken twice.34 Historic wildfires also burned 10.2 million acres across California, Oregon, and Washington.35 With 4.1 million acres blazed, California more than doubled its previous annual record for area burned.36 The State also experienced five of the top six largest wildfires on record in 202037—a record already broken in 2021.38

These massive wildfires have broad impacts across our States and Cities. The 2020 wildfires—which conservatively cost an estimated $16.5 billion39—put 500,000 Oregonians (more than 10% of the state's population) under evacuation warnings or orders,40 led to the displacement of about 100,000 people in California,41 and killed 46 people in California, Oregon, and Washington.42 In the Pacific Northwest, more than 17 million people experienced air quality deemed 'very unhealthy' or 'hazardous' for an average of 4 days,43 a worrisome statistic given that 'wildfire-specific PM2.5 is up to 10 times more harmful on human health than PM2.5 from other sources.'44,45 This public health concern grows as the frequency and intensity of wildfires increase and is not limited to States where the wildfires are burning. The rising heat from the wildfires takes particulate matter and toxic gases in the smoke into the jet stream, which can carry those hazardous substances thousands of miles and cause harmful air pollution across the country. This happened during the 2020 wildfire season and again in July of 2021, when smoke from wildfires burning on the West Coast caused New York City to experience some of the worst air quality in the world.46 [EPA-HQ-OAR-2021-0208-0245-A1, pp.6-8]

Extreme weather events pose innumerable threats to our States and Cities—from increased health risks and death, damage to infrastructure, and water scarcity,47 to economic damage and impacts to the energy system that 'threaten[] more frequent and longer-lasting power outages and fuel shortages.'48 And '[w]ith every additional increment of global warming, changes in extremes continue to become larger.'49 'For example, every additional 0.5°C of global warming causes clearly discernible increases in the intensity and frequency of hot extremes, including heat waves (very likely), and heavy precipitation (high confidence), as well as agricultural and ecological droughts in some regions (high confidence).'50 'The proportion of intense tropical cyclones (categories 4-5) and peak wind speeds of the most intense tropical cyclones are projected to increase at the global scale with increasing global warming (high confidence).'51 [EPA-HQ-OAR-2021-0208-0245-A1, p.8]

These costs, which are partially borne by our affected States and Cities, reflect the breadth of impacts and rippling effects of extreme weather events. For example, in 2020, Hurricane Isaias made landfall in North Carolina, producing storm surge inundation levels of 3 to 6 feet above ground level along the southern coast of North Carolina57 before accelerating up the East Coast. After unleashing 5-8 inches of rainfall across Virginia, Maryland, Delaware, and western New Jersey, causing flooding across those states,58 the storm's winds cut power to nearly 3.5 million customers—affecting roughly 1.4 million customers in New Jersey, 512,000 in New York, 380,000 in Pennsylvania, 264,000 in Connecticut, 218,000 in Virginia, 134,000 in North Carolina, 76,000 in Maryland, 51,000 in Delaware, 12,000 in Massachusetts, 6,000 in Vermont, and 4,000 in Rhode Island.59 Hurricane Isaias also spawned 39 confirmed tornadoes from North Carolina to New Jersey60 and killed a total of 9 people.61 More recently, in June 2021, a heat dome described as 'virtually impossible without human-caused climate change'62 descended upon the Pacific Northwest and brought record-shattering temperatures as high as 108°F in Seattle, Washington, 116°F in Portland, Oregon, and 118°F in Dallesport, Washington—the highest temperature ever recorded in Washington.63 The extreme heat not only killed billions of intertidal species along the Pacific Northwest coast,64 but it also resulted in the confirmed deaths of at least 96 people in Oregon65 and 112 people in Washington.66 'Extreme heat is already a leading cause of mortality in the United States, but without adaptation, deaths could increase more than sixfold.'67 [EPA-HQ-OAR-2021-0208-0245-A1, pp.9-10]

Our States and Cities face mounting threats from a climate crisis that is primarily caused by anthropogenic emissions of GHGs. As the transportation sector accounts for about 29% of the GHG emissions in the United States,70 that sector must be rigorously addressed. [EPA-HQ-OAR-2021-0208-0245-A1, p.10]

GHG Reductions from Light Duty Vehicles are Particularly Necessary Now. It is critically important to reduce GHGs from light-duty vehicles and to do so now. Transportation is the single leading source of GHG emissions in the country, accounting for approximately 29% of total GHG emissions. 86 Fed. Reg. at 43,746 (citing U.S. GHG Emissions Inventory), 43,779 (same). Light-duty vehicles account for nearly 60% of those transportation sector emissions, or approximately 17% of total U.S. GHG emissions. Id. Reductions of these emissions from light-duty vehicles are crucial for the United States to take meaningful steps to keep the rise in global mean temperatures below 1.5°C to 2°C.99

Immediate emissions reductions are necessary because GHGs can remain in the atmosphere for long time periods. Carbon dioxide in particular remains in the atmosphere longer than the other major GHGs emitted as a result of human activities: once emitted, 40% will remain in the atmosphere after 100 years and 20% will reside after 1000 years; only after about 10,000 years will the remainder break down.100 As explained in the Fourth National Climate Assessment, '[w]aiting to begin reducing emissions is likely to increase the damages from climate-related extreme events (such as heat waves, droughts, wildfires, flash floods, and stronger storm surges due to higher sea levels and more powerful hurricanes).'101

One of the ways in which scientists calculate and express what it will take to hold the increase in temperatures to a certain level is by using a 'carbon budget.' The carbon budget calculates the amount of cumulative GHG emissions from human activity (starting in late 1800s) that models show will result in a specified likelihood of not exceeding a particular increase in global mean temperatures. The budget is expressed either in billions of tons or 'gigatons' of carbon (GtCO2).102 Between 1850 and 2019, a total of approximately 2,390 GtCO2 of anthropogenic CO2 was emitted, resulting in a global surface temperature increase of approximately 1.1°C.103 The IPCC recently calculated that only 400 GtCO2 of the world's carbon budget remains, if we are to retain a two-thirds chance of limiting the global average temperature increase to 1.5°C.104 The IPCC further estimated that the carbon budget is being depleted by approximately 42 GtCO2 per year.105 Thus, if global emissions continue at the current pace, the carbon budget will be exhausted in less than 10 years. And that timeframe could be optimistic because, as cumulative emissions increase, the portion of those emissions in the atmosphere also increases due to ocean and land carbon sinks becoming less effective at absorbing carbon dioxide.106

There may be 'tipping points' in the climate system such that even a small incremental change in temperature could push Earth's climate into catastrophic runaway global warming.107 Indeed, a recent commentary in the journal Nature warned that nine major climate tipping points (including the accelerating ice loss from the West Antarctic ice sheet) are 'dangerously close' to being triggered.108 Therefore, serious efforts to reduce GHG emissions are needed now to avoid scenarios where steeper (and vastly more expensive) emission reductions are needed later. Delaying efforts to mitigate carbon dioxide emissions will have negative—and potentially irreversible—consequences for global warming and its impacts, including more extreme wildfires, rising sea levels, greater ocean acidification, and increased risks to food security and public health. Moreover, the uneven distribution of these impacts demands urgent action to protect our most vulnerable populations from additional climate harms and to prevent the exacerbation of existing climate injustices.109

The States and Cities agree that, in light of the 'increased urgency of the climate crisis,' the United States needs 'to achieve far deeper GHG reductions from the light-duty sector in future years.' 86 Fed. Reg. at 43,785. EPA's proposal is an important step toward those deeper reductions. By incentivizing production and deployment of lower-emitting and zero-emission vehicles, EPA's proposal will promote longer-term deeper emissions reductions critical to avoiding catastrophic impacts of climate change. [EPA-HQ-OAR-2021-0208-0245-A1, pp.20-21]

2 Sergio Olmos and Shawn Hubler, Heat-Related Deaths Increase as Temperatures Rise in the West, New York Times (July 9, 2021, updated July 28, 2021), https://www.nytimes.com/2021/07/09/us/heat-wave-deaths.html; Thomas Frank, Heat Wave Death Toll Will rise with Thorough Count, E&E News (July 23, 2021), https://www.scientificamerican.com/article/heat-wave-death-toll-will-rise-with-thorough-count/; Victoria Bekiempis, Record-breaking US Pacific north-west heatwave killed almost 200 people, The Guardian (July 8, 2021), https://www.theguardian.com/us-news/2021/jul/08/pacific-northwest-heatwave-deaths.

45 Smoke from wildfires has also been found to exacerbate risks associated with the COVID-19 virus, and one study found that '[t]housands of COVID-19 cases and deaths in California, Oregon, and Washington between March and December 2020 may be attributable to increases in fine particulate air pollution (PM2.5) from wildfire smoke.' Karen Feldscher, Link Between Wildfires and COVID cases established, The Harvard Gazette (Aug. 13, 2021), https://news.harvard.edu/gazette/story/2021/08/wildfire-smoke-linked-to-increase-in-covid-19-cases-and-deaths/.

We need your support. Now in Nevada, heat and wildfire smoke are becoming a yearly occasion. It's no longer from June to September. The vehicle pollution has always been a Number 1 part of our air pollution.

Commenter: Caudill, Gregory

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 312.]

My grandchildren are inheriting a planet I barely recognize. Global warming has already produced hotter summers and warmer winters from 50 years ago.

The ice caps and glaciers are melting. Our freshwater supplies are threatened. Homes are coming apart in the Midwest because of excessive groundwater removal by commercial and farm interests.

Commenter: Center for Biological Diversity

The excess methane emissions are particularly alarming. Immediate, deep reductions in methane emissions are critical for lowering the rate of global warming in the near-term, preventing the crossing of irreversible planetary tipping points, and avoiding harms to species and ecosystems from methane's intensive near-term heating effects and ground-level ozone production.31 Methane is a super-pollutant 87 times more powerful than CO2 at warming the atmosphere over a 20-year period, 32 and is second only to CO2 in driving climate change during the industrial era.33 Methane also leads to the formation of ground-level ozone, a dangerous air pollutant, that harms ecosystems and species by suppressing plant growth and reducing plant productivity and carbon uptake.34 Because methane is so climate-damaging but also comparatively short-lived with an atmospheric lifetime of roughly a decade, cutting methane has a relatively immediate effect in slowing the rate of temperature rise in the near-term. Critically, deep cuts in methane emissions of ~45% by 2030 would avoid 0.3°C of warming by 2040 and are considered necessary to achieve the Paris Agreement's 1.5°C climate limit and prevent the worst damages from the climate crisis.35 Deep cuts in methane emissions that reduce near-term temperature rise are also critical for avoiding the crossing of planetary tipping points—abrupt and irreversible changes in Earth systems to states wholly outside human experience, resulting in severe physical, ecological and socioeconomic harms.36 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 5-6]

EPA's decision to finalize its proposal will allow cars and light trucks to emit millions of metric tons of greenhouse gases and tens of thousands of tons of criteria pollutants—even though EPA has the discretion to reduce them. These emissions will affect climate change, air quality, and species and their habitats in ways that are direct and predictable. [EPA-HQ-OAR-2021-0208-0726-A1, p. 7]

An overwhelming international scientific consensus has established that human-caused climate change is already causing severe and widespread harms to life on Earth, and these threats are becoming more dangerous as greenhouse gas emissions continue unabated.

An overwhelming international scientific consensus has established that human-caused climate change is already causing severe and widespread harms and that climate change threats are becoming increasingly dangerous. The Intergovernmental Panel on Climate Change (IPCC), the international scientific body for the assessment of climate change, concluded in its Climate Change 2021: The Physical Science Basis report that: '[i]t is unequivocal that human influence has warmed the atmosphere, ocean and land. Widespread and rapid changes in the atmosphere, ocean, cryosphere and biosphere have occurred,' and further that '[t]he scale of recent changes across the climate system as a whole and the present state of many aspects of the climate system are unprecedented over many centuries to many thousands of years.'44 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 7-8]

The U.S. federal government has repeatedly recognized that human-caused climate change is causing widespread and intensifying harms across the country in the authoritative National Climate Assessments, scientific syntheses prepared by hundreds of scientific experts and reviewed by the National Academy of Sciences and federal agencies. Most recently, the Fourth National Climate Assessment, comprised of the 2017 Climate Science Special Report (Volume I)45 and the 2018 Impacts, Risks, and Adaptation in the United States (Volume II),46 concluded that 'there is no convincing alternative explanation' for the observed warming of the climate over the last century other than human activities.47 It found that 'evidence of human-caused climate change is overwhelming and continues to strengthen, that the impacts of climate change are intensifying across the country, and that climate-related threats to Americans' physical, social, and economic well-being are rising.'48 The Fourth National Climate Assessment warns that 'climate change threatens many benefits that the natural environment provides to society,' and that 'extinctions and transformative impacts on some ecosystems' will occur 'without significant reductions in global greenhouse gas emissions.'49 [EPA-HQ-OAR-2021-0208-0726-A1, p.8]

As detailed in the National Climate Assessments, the widespread, intensifying, and often long-lived harms from climate change include soaring air and ocean temperatures; more frequent and intense heat waves, floods, and droughts; more destructive hurricanes and wildfires; coastal flooding from sea level rise and increasing storm surge; declining food and water security; accelerating species extinction risk; melting Arctic sea ice, glaciers, and ice sheets; the collapse of Antarctic ice shelves; ocean acidification; and the collapse of coral reefs. 50 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 8-9]

Fossil fuels are the dominant driver of the climate crisis. The National Climate Assessments decisively recognize the dominant role of fossil fuels in driving climate change. As stated by the Third National Climate Assessment: 'observations unequivocally show that climate is changing and that the warming of the past 50 years is primarily due to human-induced emissions of heat-trapping gases. These emissions come mainly from burning coal, oil, and gas.'51 In parallel, the Fourth National Climate Assessment reported that 'fossil fuel combustion accounts for approximately 85 percent of total U.S. greenhouse gas emissions,'52 which is 'driving an increase in global surface temperatures and other widespread changes in Earth's climate that are unprecedented in the history of modern civilization.'53 [EPA-HQ-OAR-2021-0208-0726-A1, p. 9]

The choices made now on reducing greenhouse gas pollution will affect the severity of the climate change damages that will be suffered in the coming decades and centuries. The National Climate Assessments make clear that the harms of climate change are long-lived, and the choices we make now on reducing greenhouse gas pollution will affect the severity of the climate change damages that will be suffered in the coming decades and centuries: '[t]he impacts of global climate change are already being felt in the United States and are projected to intensify in the future—but the severity of future impacts will depend largely on actions taken to reduce greenhouse gas emissions and to adapt to the changes that will occur.'54 As the Fourth National Climate Assessment explains: '[m]any climate change impacts and associated economic damages in the United States can be substantially reduced over the course of the 21st century through global-scale reductions in greenhouse gas emissions, though the magnitude and timing of avoided risks vary by sector and region. The effect of near-term emissions mitigation on reducing risks is expected to become apparent by mid-century and grow substantially thereafter.'55 Similarly, a 2014 White House report found that the cost of delay on reducing emissions is not only extremely steep but also potentially irreversible, and the costs rise exponentially with continued delays. 56 As summarized by the National Research Council:

Emissions of carbon dioxide from the burning of fossil fuels have ushered in a new epoch where human activities will largely determine the evolution of Earth's climate. Because carbon dioxide in the atmosphere is long lived, it can effectively lock Earth and future generations into a range of impacts, some of which could become very severe. [E]mission reduction choices made today matter in determining impacts experienced not just over the next few decades, but in the coming centuries and millennia.57 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 9-10]

The IPCC 2018 Special Report, as reinforced by the 2021 IPCC Sixth Assessment Report, make clear that global greenhouse gas emissions must be halved by 2030 to avoid catastrophic damages of climate change.

In 2018, the IPCC issued a Special Report on Global Warming of 1.5°C that quantified the devastating harms that would occur at 2°C warming, highlighting the necessity of limiting warming to 1.5°C to avoid catastrophic impacts to people and life on Earth.58 The IPCC 2018 Special Report provides overwhelming evidence that aggressive reductions in emissions within this decade are essential to avoiding catastrophic climate change harms. [EPA-HQ-OAR-2021-0208-0726-A1, p. 10]

The Special Report quantifies the harms that would occur at 2°C warming compared with 1.5°C, and the differences are stark. According to the IPCC's analysis, the damages that would occur at 2°C warming compared with 1.5°C include dramatically increased species extinction risk, including a doubling of the number of vertebrate and plant species losing more than half their range, and the virtual elimination of coral reefs; significantly more deadly heatwaves, drought and flooding; 10 centimeters of additional sea level rise within this century; a greater risk of triggering the collapse of the Greenland and Antarctic ice sheets with resulting multi-meter sea level rise; 1.5 to 2.5 million more square kilometers of thawing permafrost area with the associated release of methane, a potent greenhouse gas; and a tenfold increase in the probability of ice-free Arctic summers.59 [EPA-HQ-OAR-2021-0208-0726-A1, p. 10]

The IPCC report concludes that pathways to limit warming to 1.5°C with little or no overshoot require 'a rapid phase out of CO_2 emissions and deep emissions reductions in other GHGs and climate forcers.' 60 In pathways consistent with limiting warming to 1.5°C, global net anthropogenic CO_2 emissions must decline by about 45 percent from 2010 levels by 2030, reaching net zero around 2050.61 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 10-11]

Similarly, the IPCC Climate Change 2021 report concludes that global warming will exceed 1.5°C and 2°C by 2100 unless we make immediate, deep reductions in CO_2 and other greenhouse gas emissions.62 Only the most stringent emissions reduction scenario—SSP1-1.9 in which global emissions fall steeply in the near-term, reach net zero in 2050, and become net negative afterward—is consistent with a 1.5°C climate target. In this low emissions SSP1-1.9 scenario, global average surface temperature is projected to reach 1.5°C above pre-industrial in the near-term (2021-2040), overshoot and peak at 1.6°C in the mid-term (2041-2060), and drop down to 1.4°C in the long-term (2081-2100).63 [EPA-HQ-OAR-2021-0208-0726-A1, p. 11]

In short, the IPCC Assessment Reports, U.S. National Climate Assessments, and tens of thousands of studies make clear that fossil-fuel driven climate change is a 'code red for humanity,'64 and that every additional ton of CO_2 and fraction of a degree of temperature rise matters. As warned by the IPCC, 'every tonne of CO_2 emissions adds to global warming.'65 [EPA-HQ-OAR-2021-0208-0726-A1, p. 11]

Climate change has clear and documented adverse impacts on biodiversity. The best available science shows that anthropogenic climate change is causing widespread harm to life across the planet, disrupting species' distribution, timing of breeding and migration, physiology, vital rates, and genetics—in addition to increasing species extinction risk.66 Climate change is already affecting 82% of key ecological processes that underpin ecosystem function and support basic human needs.67 Climate change-related local extinctions are widespread and have occurred in hundreds of species, including almost half of the 976 species surveyed.68 Nearly half of terrestrial non-flying threatened mammals and nearly one-quarter of threatened birds are estimated to have been negatively impacted by climate change in at least part of their range. 69 Furthermore, across the globe, populations of terrestrial birds and mammals that are experiencing greater rates of climate warming are more likely to be declining at a faster rate.70 Genes are changing, species' physiology and physical features such as body size are changing, species are moving to try to keep pace with suitable climate space, species are shifting their timing of breeding and migration, and entire ecosystems are under stress.71 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 11-12]

Species extinction risk will accelerate with continued greenhouse gas pollution. One million animal and plant species are now threatened with extinction, with climate change as a primary driver.72 At 2°C compared with 1.5°C of temperature rise, species' extinction risk will increase dramatically, leading to a doubling of the number of vertebrate and plant species losing more than half their range, and a tripling for invertebrate species.73 Numerous studies have projected catastrophic species losses during this century if climate change continues unabated: 15 to 37% of the world's plants and animals committed to extinction by 2050 under a mid-level emissions scenario74; the potential extinction of 10 to 14% of species by 210075; global extinction of 5% of species with 2°C of warming and 16% of species with business-as-usual warming76; the loss of more than half of the present climatic range for 58% of plants and 35% of animals by the 2080s under the current emissions pathway, in a sample of 48,786 species77; and the loss of a third or more of animals and plant species in the next 50 years.78 [EPA-HQ-OAR-2021-0208-0726-A1, p. 12]

As summarized by the Third National Climate Assessment, ‘landscapes and seascapes are changing rapidly, and species, including many iconic species, may disappear from regions where they have been prevalent or become extinct, altering some regions so much that their mix of plant and animal life will become almost unrecognizable.'79 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 12-13]

The loss of sea ice is one of the clearest and most obvious consequences of global warming. As highlighted by the Fourth National Climate Assessment, Alaska and the Arctic have experienced some of the most severe and rapid warming associated with climate change, with temperatures rising at twice the rate of the rest of the globe on average.81 Arctic summer sea ice extent and thickness have decreased by 40% during the past several decades,82 with each metric ton of CO_2 emissions causing a sustained loss of three square meters of summer sea ice area.83 The Arctic lost 95% of its oldest and thickest sea ice during the past three decades, and the remaining thinner, younger ice is more vulnerable to melting.84 Sea ice loss has accelerated since 2000, with Alaska’s coast suffering some of the fastest losses.85 The length of the sea ice season is shortening as ice melts earlier in spring and forms later in autumn.86 Along Alaska’s northern and western coasts, the sea ice season has already shortened by more than 90 days.87 As summarized by the Fourth National Climate Assessment:

Since the early 1980s, annual average arctic sea ice has decreased in extent between 3.5% and 4.1% per decade, become thinner by between 4.3 and 7.5 feet, and began melting at least 15 more days each year. September sea ice extent has decreased between 10.7% and 15.9% per decade (very high confidence). Arctic-wide ice loss is expected to continue through the 21st century, very likely resulting in nearly sea ice-free late summers by the 2040s (very high confidence).’88 [EPA-HQ-OAR-2021-0208-0726-A1, p. 14]

It is precisely this sea ice loss, and the lack of adequate regulatory mechanisms addressing greenhouse gas pollution, that led FWS to list the polar bear (Ursus maritimus) as a threatened species in 2008.89 As a top Arctic predator, the polar bear relies on sea ice for all its essential activities, including hunting for prey, moving long distances, finding mates, and building dens to rear cubs. 90 Separately, recognizing the critical importance of sea ice for polar bear survival, FWS designated sea ice habitat off Alaska as critical habitat for the polar bear in 2010.91 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 14-15]

Federal documents acknowledge that shrinkage and premature breakup of sea ice due to climate change is the primary threat to the species, leaving bears with vastly diminished hunting grounds, less time to hunt, and a shortage of sea ice for other essential activities such as finding mates and resting.92 As summarized in FWS’s 2017 5-year review, sea ice loss and a shorter sea ice season makes hunting calorie-rich seals more difficult for polar bears, leading to nutritional stress, reduced body mass, and declines of some populations.93 As the sea ice retreats, polar bears have been forced to swim longer distances,94 which is more energetically costly,95 and they are spending more time on land where they have reduced access to food.96 Females are denning more often on land than on ice, increasing the potential for conflicts with humans.97 Because polar bears have high metabolic rates, increases in movement resulting from loss and fragmentation of sea ice result in higher energy costs and are likely to lead to reduced body condition, recruitment and survival.98 [EPA-HQ-OAR-2021-0208-0726-A1, p. 15]

In the southern Beaufort Sea of Alaska, polar bears declined by 40 percent over a recent 10-year period,99 and this decrease has been attributed to sea ice loss that limited access to prey over multiple years. 100 For the bears in this population, research has linked sea ice loss to decreases in survival,101 lower success in rearing cubs,102 shrinking body size,103 and increases in fasting and nutritional stress.104 The loss of sea ice also jeopardizes the polar bear's sea-ice dependent prey species—the ringed seal and bearded seal—which were listed as threatened in 2012 due to sea ice loss from climate change.105 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 15-16]

If current greenhouse gas emissions trends continue, scientists estimate that two-thirds of global polar bear populations will be lost by 2050, including the loss of both of Alaska's polar bear populations, while the remaining third will near extinction by the end of the century due to the disappearance of sea ice.106 However, aggressive emissions reductions will allow substantially more sea ice to persist and increase the chances that polar bears will survive in Alaska and across their range.107 Highlighting the importance of reducing greenhouse gas emissions to protect sea ice and sea-ice dependent species, one recent study estimated that each metric ton of CO_2 emission results in a sustained loss of 3 ± 0.3 m^2 of September Arctic sea ice area based on the robust linear relationship between monthly-mean September sea ice area and cumulative CO_2 emissions.108 Similar to other research,109 the study concluded that limiting warming to 2°C is not sufficient to allow Arctic summer sea ice to survive, but that a rapid reduction in emissions to achieve a 1.5°C global warming target gives Arctic summer sea ice 'a chance of long-term survival at least in some parts of the Arctic Ocean.'110 [EPA-HQ-OAR-2021-0208-0726-A1, p. 16]

As such, FWS's 2016 Final Polar Bear Conservation Management Plan clearly stated that the polar bear cannot be recovered without significant reductions in the greenhouse gas emissions driving Arctic warming and sea ice loss: 'It cannot be overstated that the single most important action for the recovery of polar bears is to significantly reduce the present levels of global greenhouse gas (GHG) emissions, which are the primary cause of warming in the Arctic.'111 [EPA-HQ-OAR-2021-0208-0726-A1, p. 17]

If the Rule is finalized as proposed, greenhouse gases emitted will exacerbate the loss of sea ice, causing the likelihood of survival and recovery of the polar bear to diminish appreciably. The EPA must consult on how the Rule would affect sea ice loss for a listed species like the polar bear. [EPA-HQ-OAR-2021-0208-0726-A1, p. 17]

Ocean warming and ocean acidification, two incontrovertible environmental impacts caused by greenhouse gas pollution, are wreaking havoc on marine ecosystems and causing a global collapse of coral reefs. The world's oceans have absorbed more than 90 percent of the excess heat caused by greenhouse gas warming, resulting in average sea surface warming of 1.3°F

(0.7°C) per century since 1900.117 Marine heat waves—periods of extreme warm surface temperature—have become longer-lasting and more frequent due to climate change, with the number of heat wave days doubling between 1982 and 2016 and projected to increase 23 times under 2°C warming. 118 At present, 87 percent of marine heat waves are attributable to human-induced warming.119 Global average sea surface temperature is projected to rise by 4.9°F (2.7°C) by the end of the century under a higher emissions scenario, with even greater warming in the coastal waters of the Northeastern U.S. and Alaska.120 Rapid ocean warming has widespread impacts on species and ecosystems, contributing to rising sea levels, declining ocean oxygen levels, increasing rainfall intensity, and ice loss from glaciers, ice sheets and polar sea ice, and is the primary driver of mass coral bleaching events that are devastating coral reef ecosystems.121 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 17-18]

Exacerbating the harms from rising temperatures, the global oceans have absorbed more than a quarter of the CO2 emitted to the atmosphere by human activities, which has significantly increased the acidity of the surface ocean in a process called ocean acidification, and has reduced the availability of key chemicals—aragonite and calcite—that many marine species use to build their shells and skeletons.122 Ocean acidification caused by the ocean's absorption of anthropogenic CO2 has already resulted in more than a 30 percent increase in the acidity of ocean surface waters, at a rate likely faster than anything experienced in the past 300 million years.123 Ocean acidity could increase by 150 percent by the end of the century if CO2 emissions continue unabated.124 In the United States, the West Coast, Alaska, and the Gulf of Maine are experiencing the earliest, most severe changes due to ocean acidification,125 although regions of the East and Gulf Coasts are also vulnerable.126 [EPA-HQ-OAR-2021-0208-0726-A1, p. 18]

Ocean acidification negatively affects a wide range of marine species by hindering the ability of calcifying marine creatures like corals, oysters, and crabs to build protective shells and skeletons and by disrupting metabolism and critical biological functions.127 The adverse effects of ocean acidification are already being observed in wild populations, including reduced coral calcification rates in reefs worldwide, 128 severe shell damage to pteropods (marine snails at the base of the food web) along the U.S. west coast,129 and mass die-offs of larval Pacific oysters in the Pacific Northwest.130 A U.S. expert science panel concluded in 2016 that 'growth, survival and behavioral effects linked to OA [ocean acidification] extend throughout food webs, threatening coastal ecosystems, and marine-dependent industries and human communities.'131 As stated by the 2018 IPCC Special Report on Global Warming of 1.5°C, '[t]he level of ocean acidification due to increasing CO2 concentrations associated with global warming of 1.5°C is projected to amplify the adverse effects of warming, and even further at 2°C, impacting the growth, development, calcification, survival, and thus abundance of a broad range of species, e.g., from algae to fish (high confidence).'132 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 18-19]

Rising ocean temperatures and ocean acidification driven by greenhouse gas pollution threaten the continued survival of corals and coral reef ecosystems due to the increasing frequency of mass bleaching events and the dissolution of corals due to ocean acidification.133 Scientific research has definitely linked anthropogenic ocean warming to the catastrophic, mass coral bleaching events that have been documented since 1980 and are increasing in frequency and intensity as atmospheric CO_2 increases.134 Severe bleaching events have increased five-fold in the past several decades and now occur every six years on average, which is too frequent to allow full recovery of coral reefs.135 The global coral bleaching event that lasted from 2014 to 2017 was the longest, most widespread, and almost certainly most destructive on record, affecting more reefs than any previous mass bleaching event and causing mass bleaching of reefs that had never bleached before, with U.S. reefs particularly hard-hit.136 For example, in Papah-naumoku-kea Marine National Monument in Northwestern Hawaiian Islands, a 2017 study concluded that 'heat stress in 2014 was unlike any previous event and that the exposure of corals to the bleaching-level heat stress has increased significantly in the northern PMNM since 1982, highlighting the increasing threat of climate change to reefs.' 137 In the Caribbean, many important reef-building corals have not recovered from repeated bleaching events due to climate change.138 According to a 2021 study that projected changes in coral reef growth (net carbonate production) under ocean warming and acidification across 183 reefs worldwide, 94% of coral reefs globally will be eroding by 2050 if greenhouse gas emissions continue unabated. In contrast, if emissions are immediately and drastically reduced (i.e., RCP 2.6 emissions scenario), coral reef growth will still decline dramatically, but 63% of reefs will still be able to grow at the end of the century.139 A 2017 scientific review concluded that 'unless rapid advances to the goals of the Paris Climate Change Agreement occur over the next decade' that 'coral reefs are likely to degrade rapidly over the next 20 years, presenting fundamental challenges for the 500 million people who derive food, income, coastal protection, and a range of other services from coral reefs.'140 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 19-20]

Scientific research and federal documents conclude that greenhouse gas emissions must be immediately and rapidly reduced—with the target of keeping global average temperature rise below 1.5°C and returning atmospheric CO_2 levels below 350 ppm—to prevent catastrophic loss and degradation of corals. For example, a 2012 study concluded that protecting at least half of the world's coral reefs requires limiting global average temperature rise to 1.2°C, while preserving greater than 10 percent of the world's reefs would require limiting warming to below 1.5°C. 145 Similarly, a 2014 study projected that under the low emissions pathway (RCP 2.6) that limits temperature rise below 2°C, the vast majority (88%) of global reef locations would still experience severe bleaching events annually by the end of the century, indicating that 2°C of warming would be devastating for corals. 146 The 2018 IPCC Special Report on Global Warming of 1.5°C stated that coral reefs 'are projected to decline by a further 70–90% at 1.5°C (high confidence) with larger losses (>99%) at 2ºC (very high confidence).'147 As summarized by a 2018 study:

Even the aspirational Paris Agreement target of constraining global warming to 1.5°C above pre-industrial levels is unlikely to be sufficient to prevent drastic modifications and reconfigurations of the community structure and make-up of coral reefs. For the 100 reef locations examined here and given current rates of warming, the 1.5°C global warming target represents twice the thermal stress they experienced in 2016. The 2°C global target would result in 3 times the 2016 level of thermal stress and 3 °C, which is currently being tracked with the NDCs, would be over 6 times the 2016 level of stress.148 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 21-22]

Based on this evidence, coral scientists have recommended returning the atmospheric CO2 concentration to less than 350 ppm to protect coral reefs, and have suggested a target of 320 ppm which is the level that pre-dates the onset of mass bleaching events.149 [EPA-HQ-OAR-2021-0208-0726-A1, p. 22]

NMFS' 2015 Final Recovery Plan for Elkhorn and Staghorn Corals states that ocean warming and acidification are 'among the greatest threats' to these corals, and recommends actions to reduce greenhouse gas emissions to reduce these threats: 'the combination of rising temperature and ocean acidification both resulting primarily from anthropogenic increases in atmospheric CO2, are likely to have synergistic effects and are among the greatest threats to elkhorn and staghorn coral recovery'150 and 'therefore, actions must be taken to address ocean warming and acidification impacts on these species.'151 NMFS's recovery plan includes a recovery criterion with specific targets for ocean surface temperatures and ocean acidification levels152 that are lower than today's levels and are consistent with a return to an atmospheric CO2 concentration of less than 350 ppm,153 as recommended by numerous scientific studies that have examined coral species viability in response to ocean warming and ocean acidification. 154 The Recovery Plan also recognizes that a primary threat to listed corals is the inadequacy of existing regulations to control greenhouse gas emissions. It specifies a recovery criterion calling for the adoption of 'adequate domestic and international regulations and agreements' to abate threats from increasing atmospheric CO2 concentrations,155 including a recovery action to 'develop and implement U.S. and international measures to reduce atmospheric CO2 concentrations to a level appropriate for coral recovery.'156 As acknowledged by the Recovery Plan:

The final listing rule (NMFS 2006) identified inadequacy of regulatory mechanisms as a threat contributing to the threatened status of elkhorn and staghorn corals. Additionally, the 2014 final rule maintaining the threatened status of elkhorn and staghorn corals (NMFS 2014) identifies the inadequacy of existing regulations to control greenhouse gas emissions, and thus the high importance threats linked to climate change, as contributing to the status and risk of extinction of these two species. Because existing regulatory mechanisms are insufficient to provide appropriate threat abatement for elkhorn and staghorn corals, they are impeding recovery of these species. The threat posed by inadequacy of existing regulatory mechanisms is high (4) throughout the region (see Table 1) because several of the major threats affecting these species are amenable to regulation, albeit with difficulty. National and international efforts are needed to address global climate change while additional international protections are needed to protect populations of elkhorn and staghorn corals throughout their ranges.157 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 22-23]

Since the ocean has absorbed more than 90 percent of the excess heat caused by greenhouse gas warming and more than a quarter of the CO2 emitted by human activities,158 it is critical for the survival of the elkhorn and staghorn corals to prevent many additional millions of tons of CO2 from being released. At a minimum, EPA must assess how the increases in carbon dioxide emissions will affect these climate-sensitive ocean species. [EPA-HQ-OAR-2021-0208-0726-A1, p. 24]

Other Coastal Species and Sea Level Rise. Global average sea level rose by seven to eight inches (0.2 m) since 1901 as the oceans have gotten hotter and land-based ice has melted.159 Global average sea level has risen faster since 1900 than in any other century in at least the last 3,000 years.160 Sea level rise is accelerating in pace: the recent rate of sea level rise has nearly tripled compared with the rate between 1901-1971 (3.7 mm per year from 2006-2018 versus 1.3 mm per year from 1901-1971).161 The Fourth National Climate Assessment estimated that global sea level is very likely to rise by 1.0 to 4.3 feet by the end of the century relative to the year 2000, with sea level rise of 8.2 feet possible.162 Sea level rise will be much more extreme without strong action to reduce greenhouse gas pollution. By the end of the century, global mean sea level is projected to increase by 0.8 to 2.6 feet under a lower emissions RCP 2.6 scenario, compared with 1.6 to 6 feet under a high emissions RCP 8.5 scenario.163 [EPA-HQ-OAR-2021-0208-0726-A1, p. 24]

According to the IPCC's Climate Change 2021 report, even under a very low GHG emissions scenario, it is likely that global sea level rise by 2100 will be about one to two feet (0.28-0.55 m) compared to 1995-2014. Under an intermediate scenario, sea level rise is likely to be as high as 2.5 feet (0.44-0.76 m), and under a very high GHG emissions scenario it is likely to be close to three feet (0.37-0.86 m). Sea level rise above the likely range, approaching seven feet (2 m) by 2100 under a very high GHG emissions scenario cannot be ruled out due to uncertainty around the melting of ice sheets. Regardless, the impacts of sea level rise will be long-lived: under all emissions scenarios, sea levels will continue to rise for many centuries.164 [EPA-HQ-OAR-2021-0208-0726-A1, p. 24]

Research and federal documents have also highlighted sea-level rise as a primary threat to sea turtles by eroding nesting beaches and reducing nesting success.172 For example, most (87 percent) loggerhead sea turtle (Caretta caretta) nesting occurs on the east coast of Florida,173 where 43 percent of the turtle's nesting beaches are projected to disappear with just 1.5 feet of sea level rise.174 The listing rules for the green sea turtle175 and loggerhead sea turtle176 conclude that sea level rise is likely to have negative effects on these species through beach loss and reduced nesting success. [EPA-HQ-OAR-2021-0208-0726-A1, pp. 25]

Finalizing the Rule is likely to result in a significant increase of CO2 emissions and worsen sea level rise. The proposed Rule thus triggers the EPA's legal duty under the ESA to consult on how continued habitat loss due to sea level rise will adversely affect the loggerhead sea turtle and other listed species threatened by sea level rise. [EPA-HQ-OAR-2021-0208-0726-A1, p. 26]

Commenter: Center for Biological Diversity, et al.

Just this year, one out of three Americans from coast to coast experienced the disastrous effects of the escalating climate crisis firsthand. The U.S. was battered by a never-ending stream of extreme and disastrous weather events, from unrelenting heat waves and droughts to raging wildfires and extreme rainfall and flooding. Many of these events are now clearly attributable to the deteriorating climate. Also this year, the Intergovernmental Panel on Climate Change (IPCC) reached the shocking conclusion that some of the drastically changed conditions have already become irreversible – for centuries and millennia to come. It projects that by the end of the century, warming on the current trajectory would cost the U.S. economy hundreds of billions of dollars each year and up to 10% of U.S. gross domestic product.

These are the appalling circumstances under which EPA must comply with its mandate to reduce the harmful pollution at its root. Vehicle emissions are the primary contributor to this nation's greenhouse gases: their steep reduction and elimination must be EPA's top priority to prevent even more irreversible calamitous outcomes. Yet, the 2020 Final Rule set out to increase their emissions and double down on the consequences. EPA must replace that rule and rectify its fundamental mistakes. These comments discuss many of them in detail – including that the 2020 Final Rule's "balancing" of factors listed in Section 202(a) of the Clean Air Act was so vastly off the mark that it ascribed more importance to "up front" costs to consumers than to the catastrophic events playing out in front of our eyes. [EPA-HQ-OAR-2021-0208-0651-A1, p. 6]

As EPA Has Repeatedly Found, Vehicular Emissions of Greenhouse Gases Gravely Endanger Public Health and Welfare.

Emissions of greenhouse gases from the transportation sector pose mortal dangers to public health and the environment; EPA's exercise of its responsibilities under the Clean Air Act must take account of and mitigate these dangers.[1] Commenters here summarize the voluminous scientific evidence on climate change published since 2018, when many of the same organizations submitted comments in connection with the Safer Affordable Fuel-Efficient Vehicles Rule (the 2020 Final Rule), submitted to the docket at EPA-HQ-OAR-2018-0283 on October 26, 2018.[2] These comments incorporate by reference and supplement the earlier submission with an overview of peer-reviewed, climate change-related scientific studies released since then. These studies amplify EPA's conclusion that greenhouse gases (GHG) (including carbon dioxide (CO_2)) endanger public health and welfare by driving increasingly dangerous climate change. This year alone, devastating harm to people, property and the environment has been experienced from coast to coast. Indeed, the scientific record is clear that since the earlier comments, the climate has continued to deteriorate.

The full effects of climate change will depend on how much we limit warming. In 2018, the IPCC issued a Special Report on Global Warming of 1.5°C. It quantified the devastating harms that would occur at 2°C warming, highlighting the necessity of limiting warming to 1.5°C to avoid catastrophic impacts to people and life on Earth.[3] The IPCC 2018 Special Report provides overwhelming evidence that climate hazards are more urgent and more severe than previously thought, and that aggressive reductions in emissions within the next decade are essential to avoiding the most devastating climate change harms.

The IPCC Special Report concluded that pathways to limit warming to 1.5°C with little or no overshoot require "a rapid phase out of CO_2 emissions and deep emissions reductions in other GHGs and climate forcers."[4] In pathways consistent with limiting warming to 1.5°C, global anthropogenic CO_2 emissions must decline by about 45 percent below 2010 levels by 2030 and reach near zero around 2050.[5]

In the IPCC Climate Change 2021: The Physical Science Basis report, five scenarios are considered, ranging from a very low GHG emissions scenario to a very high GHG emissions scenario, and in all of them warming of at least 1.5°C has already become unavoidable. Between 2021 and 2040, 1.5°C temperature increase is very likely to be exceeded under the very high GHG emissions scenario (CO_2 emissions double by 2050), likely to be exceeded under the intermediate and high GHG emissions scenarios (CO_2 emissions stay current until 2050 and CO_2 emissions double by 2100, respectively), more likely than not to be exceeded under the low and very low GHG emissions scenarios (CO_2 emissions reach net zero around 2050). In all scenarios except for the very low and low GHG scenarios, global warming of 2°C is likely to occur.

In short, both the IPCC Climate Change 2021 report and the 2018 IPCC Special Report provide overwhelming scientific evidence for the necessity of immediate, deep greenhouse gas reductions across all sectors. The Climate Change 2021 report estimates that, for a 67% chance of limiting warming to 1.5°C, total global emissions from January 2020 onward must not exceed 400 $GtCO_2$. 6 Global emissions are currently about 40 $GtCO_2$ per year, so this emissions cutoff would be passed around 2030 without immediate and drastic action to reduce global emissions.

Greenhouse gas emissions have made the Earth's climate hotter and more extreme. According to the IPCC's Climate Change 2021 report, "[i]t is unequivocal that human influence has warmed the atmosphere, ocean and land. Widespread and rapid changes in the atmosphere, ocean, cryosphere and biosphere have occurred," and "[t]he scale of recent changes across the climate system as a whole and the present state of many aspects of the climate system are unprecedented over many centuries to many thousands of years."7

As human emissions continue to rise, the average global atmospheric CO_2 concentration in 2019 reached 410 parts per million (ppm), a level not seen for at least 2 million years.8 The last time CO_2 in Earth's atmosphere was at 400 ppm, global mean surface temperatures were 2 to 3°C warmer and the Greenland and West Antarctic ice sheets melted, leading to sea levels that were 10 to 20 meters higher than today.9 The current atmospheric CO_2 concentration is 47 percent larger than the pre-industrial level of 280 ppm, and much greater than levels during the past 800,000 years.10 The atmospheric concentrations of methane (CH_4) and nitrous oxide (N_2O), two other potent greenhouse gases, have increased by 156 percent and 23 percent respectively, relative to pre-industrial levels.11

As a result, it is now an irrefutable fact that humans are drastically changing Earth's climate with unprecedented increases in temperature. Globally, each of the last four decades has been successively warmer than any preceding decades since 1850, which is the first year with reliable temperature measurements. Average global surface temperature from 2001 to 2020 was 1.8°F (0.99°C) higher than in 1850 to 1900, with larger increases over land than over the ocean. The best estimate for the human-caused global surface temperature increase from 1850 to 2019 is 1.9°F (1.07°C). 12 Since 2012, global warming has been especially pronounced, with the past five years (2016-2020) being the hottest five-year period since 1850 (Figure 1).13 [EPA-HQ-OAR-2021-0208-0651-A1, p. 7-9] [Figure 1 can be found on p. 10 of Docket number EPA-HQ-OAR-2021-0208-0651-A1]

Extreme weather events are becoming the new normal. Human-induced climate change is now affecting weather and climate extremes observed around the globe. Many events such as heatwaves, heavy precipitation, droughts, and tropical cyclones are not only changing in severity but are also now clearly attributable to human actions.15 In a truly alarming conclusion, the IPCC states that many of the changes we are imposing on our climate “due to past and future greenhouse gas emissions are irreversible for centuries to millennia, especially changes in the ocean, ice sheets and global sea level.”16

Extreme weather events are striking with increasing frequency, most notably heat waves and heavy precipitation events.17 In the contiguous United States, extreme temperatures are expected to increase even more than average temperatures, with more intense heat waves and 20 to 30 more days per year above 90°F by mid-century for most regions under a higher emissions scenario.18 Heavy precipitation has become more frequent and intense in most regions of the U.S. since 1901.19 This is both because increasing temperatures cause more evaporation from soils, which places more water vapor in the atmosphere,20 and because warmer air holds more water vapor, resulting in more extreme rain and snowstorms.21 Climate warming also has exacerbated recent historic droughts by reducing soil moisture and contributing to earlier spring melt and reduced water storage in snowpack.22 As conditions become hotter and drier, climate change is contributing to an increase in area burned by wildfire and a lengthening of the wildfire season in recent decades.23 In addition to the toll on human lives from the fires themselves, airborne soot from wildfire smoke was linked to over 33,000 deaths a year globally between 2000 and 2016, causing 0.62% of all worldwide deaths yearly, according to a recent study.24

Climate change has contributed to increasing North Atlantic hurricane activity since the 1970s.25 Hurricane-generated storm surge events—the enormous walls of water pushed onto the coast—have also become more frequent and severe.26 One study found that the frequency of large storm surge events of Hurricane Katrina magnitude has already doubled in response to warming during the 20th century.27 Studies of Hurricane Harvey concluded that climate warming made the storm’s record rainfall more likely and intense.28

Global average sea level rose by seven to eight inches (0.2 m) between 1901 and 2018 as the oceans have warmed and land-based ice has melted.29 Global average sea level has risen faster since 1900 than any other preceding century in the last 3,000 years.30 Sea level rise is accelerating in pace, from an average rate of 1.3 mm yr-1 between 1901 and 1971 to 3.7 mm yr-1 between 2006 and 2018.31 The combination of intensifying storm surge and sea level rise is leading to increased flooding risks in coastal regions.32

These events are ubiquitous in present-day America, and Americans of all stripes suffer their consequences on a regular basis. As of July 9, 2021, there have been eight climate disasters this year with losses over $1 billion in the United States: one drought event, two floods, four severe storms, and one winter storm.33 There were 22 of these disasters in 2020, the most on record. Every single state has had at least one climate disaster with losses over $1 billion; Texas has had 124 since 1980.34 According to a Washington Post analysis of federal disaster declarations, nearly 1 in 3 Americans live in a county hit by a weather disaster between June and August

2021.35 On top of that, 64 percent live in places that experienced a multi-day heat wave. During the summer of 2021 alone, these disasters claimed the lives of at least 388 Americans.36

To cite just one recent example, last month Hurricane Ida became the second-most damaging hurricane to strike Louisiana, after Hurricane Katrina. It dumped record amounts of rain in several Mid-Atlantic and Northeast states for days after making landfall. Climate change exacerbated the damage from the storm in several compounding ways. Because background temperatures in parts of the Gulf of Mexico are 3-5°F warmer than at the end of the 20th century, the storm drew more energy from the ocean, which increased its wind speed.37 Further, because hotter air holds more moisture, the severity and volume of precipitation was far more deadly.38 When the storm hit land, it dragged a greater amount of water onto land with its storm surge, due in part to higher existing sea levels linked to global warming. This flooding can be the most destructive part of a major hurricane: one study found that 76 percent of fatalities from hurricanes between 1963 and 2021 were caused by storm surge or flooding.39 Finally, after the storm caused power outages for millions of people, which could last up to a month,40 residents who stayed faced heat indices of 105-107°F—without air conditioning.41 These intersecting dangers show just one example of how a changing climate can increase the intensity, damage, and human suffering from the same weather event.

The effects of climate change will be felt well into the future. Surface temperatures will continue to increase until at least mid-century. In a worstcase high-emissions scenario, the global average temperature in 2100 could end up 5.7°C (10.2°F) higher than in 1900.42 Even in a best-case low-emissions scenario, we are likely committed to slightly overshooting 1.5°C, but with a drop back below that threshold by the end of the century.43 Only a best-case scenario keeps warming to 1.5°C, demonstrating the need for stringent and immediate global reductions of greenhouse gas emissions. In a startling new report, the United Nations recently reported that the global average temperature will increase 2.7 °C by 2100 even if all countries meet their currently promised emission targets.44

Even under a very low GHG emissions scenario, it is likely that global sea level rise by 2100 will be about one to two feet (0.28-0.55 m) compared to 1995-2014. Under a very high GHG emissions scenario it is likely to be close to three feet (0.37-0.86 m). Sea level rise above the likely range, approaching seven feet (2 m) by 2100 under a very high GHG emissions scenario, cannot be ruled out due to deep uncertainty around the melting of ice sheets. Regardless, the impacts of sea level rise will be long-lived: sea levels will continue to rise for many centuries, in addition to the lasting effects of ocean warming and acidification.45

Heavy precipitation events are projected to continue to increase in frequency and intensity across the United States, with the number of extreme events rising by two to three times the historical average by the end of the century under a higher emissions scenario.46 Further, as the climate warms, Atlantic and eastern North Pacific hurricane rainfall and intensity are projected to increase, making hurricanes more destructive.47

The effects of climate change could be even worse than conservative predictions. The Fourth National Climate Assessment concluded with very high confidence that large-scale shifts in the climate system, known as tipping points, and the compound effects of simultaneous extreme climate events have the potential to create unanticipated and potentially abrupt and irreversible "surprises" that become more likely as warming increases.48 The IPCC Climate Change 2021 report similarly concluded that "abrupt changes and tipping points are not well understood, but the higher the warming level and the longer the duration of overshoot [beyond 1.5°C], the greater the risk of unexpected changes."49 The crossing of tipping points could result in climate states wholly outside human experience and result in severe physical and socioeconomic impacts.50

In short, these studies provide overwhelming scientific evidence for the necessity of immediate, deep greenhouse gas reductions across all sectors to avoid devastating climate change-driven damages, and underscore the high costs of inaction or delays. The enactment of strong emissions standards that require all light-duty vehicles to be electric by at least 2035, and all vehicles by at least 2050, is a non-negotiable necessity for averting the worst harms of climate change. [EPA-HQ-OAR-2021-0208-0651-A1, p. 10-15]

The effects of climate change are being felt economically. The climate crisis is exacting a heavy economic toll, already costing the U.S. economy more than $1 trillion dollars in damages, with economic losses worsening with each additional ton of carbon pollution.51 Each 1°C temperature rise is estimated to decrease U.S. gross domestic product (GDP) by 1.2%, with the poorest regions of the U.S. suffering most.52 A 2021 study of the health costs in the U.S. of air pollution from fossil fuel combustion and resulting climate change estimated the costs already exceed $800 billion per year and are expected to become even more expensive without rapid action to curb fossil fuel pollution.53 At the global scale, warming of 2°C versus 1.5°C is projected to decrease global GDP by an additional 1.5 to 2% and cause $7.7 to 11.1 trillion in damages by mid-century.54

The Fourth National Climate Assessment similarly concludes that human-caused climate change is already leading to substantial economic losses in the U.S. and that these losses will be much more severe under higher emissions scenarios, impeding economic growth:

In the absence of more significant global mitigation efforts, climate change is projected to impose substantial damages on the U.S. economy, human health, and the environment. Under scenarios with high emissions and limited or no adaptation, annual losses in some sectors are estimated to grow to hundreds of billions of dollars by the end of the century. It is very likely that some physical and ecological impacts will be irreversible for thousands of years, while others will be permanent.55

According to the Fourth National Climate Assessment, the number of extreme weather events per year costing more than one billion dollars per event has increased significantly since 1980, with total costs from those events exceeding $1.1 trillion.56 The 2017 Atlantic Hurricane season alone is estimated to have caused more than $250 billion in damages and hundreds of deaths throughout the U.S. Caribbean, Southeast, and Southern Great Plains.57

By the end of the century, the Fourth National Climate Assessment estimates that warming on our current trajectory would cost the U.S. economy hundreds of billions of dollars each year and up to 10% of U.S. gross domestic product due to damages including lost crop yields, lost labor, increased disease incidence, property loss from sea level rise, and extreme weather damage.58Ultimately, the magnitude of financial burdens imposed by climate change depends on how effectively we curb emissions. Across sectors and regions, significant reductions in emissions will substantially lower the costs resulting from climate change damages.59

Because vehicular emissions are the nation's leading source of emissions, these undisputed facts leave no doubt that steep reductions in vehicle emissions must occur now to avoid truly catastrophic outcomes. [EPA-HQ-OAR-2021-0208-0651-A1, p. 15-16]

1 The nongovernmental organizations submitted detailed comments on climate change in their comments in the rulemaking for the 2020 Final Rule. See Joint Comments of Center for Biological Diversity, Earthjustice, Environmental Defense Fund, Natural Resources Defense Council, Sierra Club, and Public Citizen, Inc., Regarding the Proposed Greenhouse Gas Emissions and Fuel Efficiency Standards for Light-Duty Vehicles, Model Years 2021- 2026 Comments Specific to Climate Change (Oct. 26, 2018) (Joint NGO Climate Change Comments). Attached as Exhibit 1.

Commenter: Center for Climate and Energy Solutions (C2ES)

Climate change caused by greenhouse gas emissions from the extraction and burning of fossil fuels poses a direct and intensifying threat to global ecosystems, human health, and the global economy. To avert the most catastrophic impacts of the climate crisis, the world must reach economy-wide net-zero emissions by 2050. Decarbonizing the U.S. transportation sector is an essential element required to reach net-zero goals, and the United States must make all light-duty vehicles on the roads zero-emissions by 2050. [EPA-HQ-OAR-2021-0208-0287-A1, p.2]

To avert increasingly severe impacts from climate change, the United States must reach economy-wide netzero emissions by 2050. Presently, transportation is the largest-emitting sector, accounting for 29 percent of U.S. greenhouse gas emissions; of that, light-duty vehicles are responsible for 58 percent of U.S. transportation emissions.1 To meet mid-century decarbonization goals, all on-road light-duty vehicles must be zero-emitting by 2050.2 Correspondingly, to reflect average lifespans and stock turnover, all new light-duty vehicle sales must be zero emission around 2035.

This target is consistent with goals already put into place by several states and companies in the private sector. In September 2020, California Governor Gavin Newsom issued an executive order requiring the end of new internal combustion engine sales by 2035, which other states including Massachusetts may follow if EPA reinstates its Advanced Clean Car waiver.3 In the private sector, General Motors announced a goal in January 2021 to be carbon neutral by 2040 including the elimination of tailpipe emissions from new light-duty vehicles by 2035, and Honda, Volvo, and Mercedes-Benz have similar goals to go all-electric in the next two decades.4 Other companies, including Ford, Stellantis, Toyota, and Volkswagen, expect low- or zero-emission vehicles to make up at least 40 percent of light-duty sales by 2030.5 The market is moving toward zeroemissions transportation. Greenhouse gas emissions regulations should reflect the real-world market and capitalize on the opportunity to provide regulatory certainty to accelerate this trend toward cleaner vehicles, with significant positive implications for the climate crisis, economic productivity, and public health. [EPA-HQ-OAR-2021-0208-0287-A1, p. 3]

Commenter: CERES

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 83.]

Transportation emissions-related health care are also major cost centers for companies. Establishing higher standards for vehicle emissions will help to substantially lower emissions-related health care costs while simultaneously lowering their fuel costs.

Commenter: Collins, Molly

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 230-231.]

I'd also like to thank this Administration for acknowledging the importance of tackling climate pollution from transportation which, as others have mentioned today, is an important step in the right direction.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 232.]

Earlier this month, a report from the UN Intergovernmental Panel on Climate Change found that we are on the path towards catastrophic destruction if we do not make serious cuts in our greenhouse gas emissions as soon as possible.

We must act with the urgency our situation requires. We are seeing the effects of our indifference in the news every day as extreme storms, wildfires, earthquakes, etcetera, and I hate that I'm leaving our planet in this state to my children.

Commenter: Connecticut Department of Energy and Environmental Protection

Connecticut needs emission reductions from the transportation sector. Reducing GHG emissions from the transportation sector is required to achieve Connecticut's economy-wide GHG reduction targets of at least 45 percent below 2001 levels by 2030, and 80 percent below 2001 levels by 2050, as required by the 2008 Global Warming Solutions Act (GWSA) and the 2018 Act Concerning Climate Change Planning and Resiliency.[5] Connecticut's transportation sector is the largest source of statewide GHG emissions, responsible for 37.4 percent in 2018, the most recent year for which data is available.[6] Connecticut will not meet its GHG reduction targets without increasingly more protective national vehicle emission standards.[EPA-HQ-OAR-2021-0208-0264-A1, p.2]

[5] Public Act 18-82, An Act Concerning Climate Change Planning and Resiliency, sec. 7, codified at Conn. Gen.Stat. § 22a200a. Public Act 08-98, An Act Concerning Global Warming Solutions, sec. 2, codified at Conn. Gen. Stat. § 22a-200a.

Commenter: Cooper, Almeta

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 76-77.]

There is a direct connection between climate change, clean air, and health. In the last month United Nations Intergovernmental Panel on Climate Change reported out that climate change is widespread, rapid, and intensifying, painting a grim picture of our world's future unless swift and strong intervention is taken immediately to curb the pollution causing global climate change.

Protecting public health means keeping everyone's air clean and safe to breathe and cutting greenhouse gas pollution. Because climate change affects us all, whether we live and work in suburban, rural, or urban areas, we must unite in protecting clean air for our children.

Commenter: Davidson, William

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 206.]

I am very concerned about climate change, forest fires, floods, storms, etcetera, are causing hundreds of billions of damage and devastating lives here and abroad. We need automakers to bring more electric cars and hybrids to market.

Commenter: Davis, Darien

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 161.]

There is, however, a practical way to begin tackling climate change: focusing on clean transportation. Since the transportation sector is the largest source of emissions, bold car standards to help accelerate the transmission from cars with internal combustion engines to pollution-free vehicles. Now the EPA has the opportunity to both reinstate and strengthen clean car standards.

Commenter: Dream Corp Green for All

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 305.]

In a short time I'd like to focus on two main points. First, strong greenhouse gas emissions standards for passenger vehicles are essential to meet climate and racial equity goals,

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 306-307.]

We may be beyond the point of being able to truly fix the climate disaster that burning fossil fuels has reaped but every fraction of a degree matters. As the Number 1 contributor to the highest emitting sector in the United States, light-duty vehicles present an opportunity, indeed an obligation, to reduce emissions as quickly as feasible so that other human needs can be met.

For example, increasing extreme heat means that we will need to add air conditioning for people to avoid heat stroke which can cook people's organs without a place of reprieve. Transportation has the highest potential to reduce emissions and we can do this without losing mobility. We can still get where we need to go with lower emissions and can make these cuts in transportation emissions far easier than in other essential sectors.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 308.]

Given the risks of abrupt changes from global temperature rise identified in the 2021 IPCC Report, the benefits of reducing emission are very likely underestimated in the government's analysis.

Commenter: Dream Corps Green for All et al.

Strong GHG emission standards for passenger vehicles are essential to meet climate and racial equity goals.[EPA-HQ-OAR-2021-0208-0285-A1, p.1]

As the number one contributor to the highest emitting sector in the United States, light duty vehicles present an opportunity--indeed an obligation--to reduce emissions as quickly as feasible so that other human needs can be met that will continue to require GHG emissions for the near future. For example, increasing extreme heat means that we will need to add air conditioning in more places in order to provide reprieve from heat-related illness or death.[4] As the biggest emitter in the United States, the transportation sector has the highest potential to reduce emissions, and thanks to existing technology, passenger vehicles can do so without sacrificing the mobility and economic benefits that transportation provides. We can still get where we need to go with lower emissions and can do this far easier in passenger vehicles than in aviation or shipping and other essential sectors.[5] [EPA-HQ-OAR-2021-0208-0285-A1, p.2]

Commenter: E2 - Environmental Entrepreneurs

Furthermore, the costs and dangers of the climate crisis has never been more apparent. In 2020, climate-related disasters cost the U.S. economy $95 billion. That is double the cost from 2019 and more than any other country. This year one out of three Americans from coast to coast experienced the disastrous effects of climate change first hand. The U.S. was battered unrelenting heat waves and droughts to raging wildfires and extreme rainfall and flooding. These events are consistent with the harms that scientists predict will grow as we continue to emit carbon dioxide pollution. The IPCC predicts that the harms we see today are just a prelude to what will come if we do not cut emissions. The IPCC's scientists project that by the end of the century, warming on the current trajectory would cost the U.S. economy hundreds of billions of dollars each year and up to 10% of U.S. gross domestic product. Strong standards to reducing carbon emissions from transportation and other sources are essential to reduce the rising costs of climate change. [EPA-HQ-OAR-2021-0208-0604-A1, p. 2]

E2 business leaders see climate change as a business risk and a threat to our broader economy. From direct impacts of stores closing from climate driven extreme weather to major disruptions in supply chains, the impacts are real and they are costly. They will only grow if America does not dramatically reduce emissions. [EPA-HQ-OAR-2021-0208-0604-A1, p. 3]

[1] This and the following calculations in this section assumes a 3% discount rate, as calculated by EPA.

Commenter: Elders Climate Action (ECA)

The science is clear: stabilizing the climate before it becomes too hot to support human civilization and attaining the ozone NAAQS in all of America's 230 nonattainment counties requires that GHG emissions from on-road vehicles be reduced to zero as soon as possible. In his Climate Executive Order President Biden declared that the policy of the United States is to 'put the United States on a path to achieve net-zero emissions, economy-wide, by no later than 2050.'1 [EPA-HQ-OAR-2021-0208-0521-A1, p. 1]

The President's declared policy responds to and is supported by the science which makes clear that the climate will continue to heat up so long as humanity continues to increase GHG levels in the atmosphere. The global mean temperature reached 1.2 o C above the pre-industrial baseline in 20202 which has produced massive damage and destruction to property and natural systems, and caused hundreds of deaths, displacement, homelessness and loss of livelihoods for tens of thousands of Americans from extreme floods, drought, wildfires, hurricanes and tornadoes.

The latest report (AR6) from the Intergovernmental Panel on Climate Change (IPCC) now makes clear that exceeding 1.5o C before 2050 is 'more likely than not' even with implementation of the most aggressive GHG reduction scenario, but that the excursion above 1.5o C can be limited to a few decades if we reduce GHG emissions by half before 2030, and achieve net zero emissions by 2050. But if we fail to meet either of those targets, it is 'more likely than not' that global temperatures will reach 2.0 o C with dire consequences for humanity.

To achieve net-zero emissions economy wide by 2050, zero emission technologies currently available must be deployed as soon as possible to put GHG emissions from our largest source of emissions – transportation – on the path toward zero. [EPA-HQ-OAR-2021-0208-0521-A1, pp. 1-2]

The IPCC Findings. Since the Endangerment Finding, EPA's catalogue of risks have been augmented by much more comprehensive modeling of warming trends, the warming expected from a range of global emission scenarios, and a description of the emission limitations that must be implemented to avoid more catastrophic climate outcomes.

The IPCC's 2018 report reviews and analyzes the then-available scientific literature to provide the best information available to answer two critical questions posed by world leaders at the Paris Climate conference:

1) What are the differences between the consequences of allowing the planetary climate system to rise 1.5o C compared to 2o C above the pre-industrial background?

2) What limitations on CO2 and other GHG emissions must be achieved to avoid overshooting a 1.5o C or a 2o C rise in global temperature?

Consequences of 1.5o C and 2o C rise in global temperatures are both unacceptable, but 2o C is significantly worse.

The IPCC's 2018 report catalogues numerous expected adverse consequences of both a 1.5o C and a 2o C rise and in global mean temperature.6 Some of the effects of greatest concern are –

1) increases in mean summer temperatures and the frequency of hot days above the 99th%ile of the baseline temperature range, and the increased duration of the summer dry season that, together, will more quickly desiccate the coastal and Cascade forests each year, increase the ignitability of forest fuels, increase the frequency and intensity of wildfires, increase the production of hazardous concentrations of fine particle pollution (smoke), and increase the adverse health consequences of public exposure to multi-day extreme hazard pollution episodes;

2) diminished summer stream flows that force curtailment of water for agricultural operations dependent on irrigation water, and contribute to warmer surface water temperatures that interfere with the survival of cold water fish species (e.g., salmonids) and contribute to algal blooms that produce toxic contamination of municipal and agricultural water supplies and fishery habitats;

3) increasing ocean acidification and ocean temperatures that together prevent reproduction and survival of some marine species, cause some native local species to abandon Oregon waters in search of cooler waters, and diminish productivity of species remaining in the local water column which in turn will reduce the catch, make commercial fishing unprofitable, and further reduce the food supply for human populations dependent on marine sources of protein and resident coastal orca populations that are now starving because of diminished food supply;

4) the frequency and duration of extreme precipitation events that cause flooding, erosion, displacement of human populations in flood-prone areas, the destruction of freshwater and anadromous fish spawning habitat and contamination of municipal water supplies;

5) warmer winter temperatures that convert winter snow precipitation events to rainfall thereby reducing the high altitude storage of water which diminishes water resources available for agriculture and municipal uses during the spring and summer, and increases the severity of

drought by reducing stream flows, causing crop loss, loss of fishery habitat, and inadequate water supplies for residential and industrial users and fire fighting.

6) longer wildfire seasons and expanded burn zones that increase human exposure to hazardous levels of air pollution, including multi-week exposure to levels of fine particles (smoke) known to cause pre-mature death and other adverse health outcomes among vulnerable populations, and elevated concentrations of ground level ozone harmful to public health exacerbated by warmer summer temperature regimes that govern the chemistry of ozone formation in the atmosphere.[7]

All of these effects are occurring now, and are expected to increase in severity as the climate warming accelerates.

Expanding Wildfire Destruction and Smoke Mortality Correlates with Warming Climate.

The IPCC found that global mean temperature was about 1.0^{o} C above the pre-industrial baseline in 2010. By 2010, the climate regime had not yet triggered large increases in wildfire conditions compared to historical fire patterns in the American West. But as the global mean advanced from 1.1 ^{o} C to 1.2 ^{o} C, new records were being set. The World Meteorological Organization (WMO) concluded that '[i]n 2020 – one of the three warmest years on record – the global average temperature was 1.2 °C above the pre-industrial baseline.'[8]

As the global temperature approached 1.2 °C, the frequency, intensity, areal extent and duration of wildfires have increased significantly in the last five years. In 2020 burns set records across the American West. California's burn area grew to nearly 5 million acres, and the total area burned in the 11 Western states exceeded 10 million acres: 2020 Western United States wildfire season - Wikipedia. The increasing area burned by wildfire in the American West tracks the Australian experience where annual fire zones expanded rapidly in response to drought leading to a massive wildfire season burning 46 million acres (an area equal to the State of Washington) during their 2019-20 austral summer.[9]

During the 2017 fire season, wildfire in Oregon destroyed one-half million acres for the first time in the State's history. In 2018 wildfire consumed 660,000 acres of forest. In 2020 Oregon wildfires consumed 1.2 million acres,[10] forced 500,000 Oregonians to evacuate their homes ahead of the flames, incinerated 4,000 homes displacing 10,000 Oregonians, leaving many families homeless, and killed 11. The 2020 burn area doubles the 2017 burn area, and is an order of magnitude greater than the statewide average of 120,000 acres burned during the 1990-2010 period.

The 2018 IPCC report states that the global mean temperature is rising about 0.2^{o} C per decade,[11] twice the warming rate during the 20th Century. This accelerated warming rate suggested in 2018 that 1.5^{o} C rise would be reached about 2035 unless large reductions in GHG emissions were achieved before 2030. New modeling performed for the 2021 IPCC report, AR6, indicates that 1.5^{o} C above the pre-industrial baseline will be reached by 2030 if GHG emissions are held to current rates, and 2^{o} C rise reached by 2050.[12,13] WMO has since announced its estimate that the first annual 1.5^{o} C rise in global temperature will likely occur by 2026.[14]

Given that the frequency and ferocity of wildfire in the American West began to increase significantly after 2015 under the climate conditions associated with 1.1° C to 1.2° C rise above the 1850–1900 baseline, the march higher toward a 1.5o C rise between 2025 and 2030 can be expected to accelerate the frequency, severity and areal extent of damage caused by wildfire.

The Oregon Climate Assessment (OCAR5.pdf | Powered by Box, January 5, 2021) anticipates that the destruction of property, disruption of daily life, large costs to the economy, pollution of the atmosphere and water supplies, impairment of human health, and damage to wildlife, the environment and habitats will worsen in coming years as the climate continues to warm more rapidly. The Assessment cites studies predicting the effects of warming on seasonal heat causing a six-fold increase in hot days (>90o F) in Oregon counties west of the Cascades during future Oregon summers (pp. 12-13), and reductions in summer precipitation (Table 2). Summers will be hotter and drier, and summer heat will start earlier and persist longer.15 The Assessment concludes that these conditions are conducive to 'high-severity' wildfires:

High-severity fires dominate wet, cool forests, including remnant old growth forests, in Oregon's Coast Range and western Cascade Range. High-severity wildfires in wet, cool forests typically are … facilitated by extremely dry and warm springs and summers or high winds.

As these conditions become more extreme, the area incinerated by wild fires is expected to increase (pp. 48-54). A 2017 forest modeling analysis 'projected a 200% increase in median annual area burned in Oregon' during the 2010-2039 period compared to 1961-2004.16 Another 2017 study looking at fires across the American West estimates a 200-400% increase in the 'annual probability of very large fires.'17 Going forward, the Assessment makes clear that all 'empirical models … consistently project that the area burned in Oregon will increase.'18

The fire zone doubled between 2017 and 2020. As predicted by forest science modeling, another doubling of the acres burned annually by 2025-30 is highly plausible as global temperature approaches 1.5° C above the pre-industrial baseline.

If fire zones expand to predicted levels in the Pacific NW, 25% to 40% of Oregon (15 to 25 million acres) and Washington (11 to 20 million acres) will be incinerated during this decade, economic activity will collapse and hazardous air quality will make the Northwest inhospitable to human habitation for most residents during the fire season.

The data and modeling estimates presented in the Oregon Climate Assessment and other sources predict a future in which the destruction of Oregon's forest resources by wildfire will continue until either 1) the cool and wet conditions that sustained Cascadia's forests during the 8,000 years before 1980 are restored, or 2) most of the standing forests are reduced to shrub or grasslands.

Impacts of Climate Warming on Public Health are Significant and Widespread.

Fire smoke and unprecedented hot temperatures are having a significant impact on human health as an example of the regional impact of heat waves, drought and wildfires.

The heat dome that raised temperatures above 110 F for three days in the Pacific NW in June 2021 caused over 200 heat-related deaths in Oregon and Washington.

Recent research demonstrates that emissions from wildfire are the largest source of fine particle pollution in large regions of the U.S., and contributed to thousands of pre-mature deaths. Wildfire in the western U.S. now accounts for half of all fine particle pollution in some areas of the West, doubling the exposure to PM2.519 from non-fire sources including motor vehicles, power plants and industrial operations.20

A warming climate is responsible for roughly half of the increase in burned area in the United States (4), and future climate change could lead to up to an additional doubling of wildfire-related particulate emissions in fireprone areas (36) or a many-fold increase in burned area (37, 38). Costs from these increases include both the downstream economic and health costs of smoke exposure, as well as the cost of suppression activities, direct loss of life and property, and other adaptive measure (e.g., power shutoffs) that have widespread economic consequences.21

Using satellite measurements of smoke plumes integrated with ground level monitored PM2.5 (fine particle) concentration data, Burke et al. estimate that between 7,000 and 14,500 deaths per year (depending on the dose/response curve used to estimate mortality from observed exposures) are attributable to fire smoke in the contiguous U.S.

Mortality and other health impacts such as asthma attacks and exacerbating COPD will be experienced most severely by communities already burdened by the adverse health effects of daily exposure to fine particle pollution emitted from tailpipes, power plants and industrial sources. Exposure to fire smoke in the American West during the 2020 fire season was universal. No communities were spared. But fire smoke at least doubled the annual exposure routinely suffered by BIPOC and low income communities living near major highways and industrial sources.

In Oregon, mortality attributed to fire includes many hundreds more deaths than the lives lost directly to fires. Statewide smoke pollution during the 2020 fires threatened lives and well-being with extreme hazard concentrations of particles known to cause pre-mature death and cancer, exacerbate asthma, COPD and other respiratory conditions, and cardio-vascular diseases.

The Oregon Health Authority (OHA) reports that '[t]he most severe recent air quality events in Oregon are due to wildfire smoke…'22 OHA cited a study finding that fire smoke in 2012 'caused hundreds of premature deaths, nearly 2,000 emergency room visits and more than $2 billion in health costs.'23 OHA points to the longer fire season as increasing the harm from exposure to smoke. 'Fire seasons in Oregon are roughly 100 days longer than they were in the 1970s. Longer seasons mean more smoke in Oregon communities.'24 The greater density of smoke and longer duration of smoke exposure in 2020 likely at least doubled the mortality caused by smoke exposure compared to 2012.

In addition, low income families without air conditioning are much less able to escape smoke pollution by closing doors and windows during the summer heat to keep themselves safe. Workers cannot avoid exposure to smoke pollution if required to work outdoors.

Beyond the economic and environmental damage, social disruption, and harm to health that will result from a longer fire season and expanded fire zones, more deadly air quality will likely make parts of the American West uninhabitable during the fire season for the most vulnerable populations such as the elderly, children and those with existing respiratory and cardiovascular conditions.

These recent data and other sources published since 2009, including the data discussed at length in the Administrator's 2009 Endangerment Finding, 74 Fed. Reg. 66,496 (December 15, 2009), confirm the finding that EPA made 12 years ago: 'The Administrator finds that the elevated atmospheric concentrations of the well-mixed greenhouse gases may reasonably be anticipated to endanger the public health and welfare of current and future generations.' Id., at 66,523.

Net-Zero Emissions Must be Achieved as Soon as Possible to Protect Public Health and the Public Welfare.

The climate will need to be stabilized as soon as possible to –

• protect public health from the deadly effects of heat waves and wildfire smoke particles;

• preserve the health, safety and quality of life in the American West from the devastation caused by massive uncontrollable wildfires;

• preserve the health, safety and quality of life for millions of Americans living along the Gulf Coast from the devastation caused by super hurricanes, o preserve the health, safety and quality of life for hundreds of millions of Americans living in the Mid-West and Northeast from the deaths and devastation caused by massive flooding,

• to protect the health, safety and quality of life for millions living in Tornado Alley from the Great Plains to the upper South;

• to protect forests so that they may serve as a sink for CO2 rather than as an emission source;

• preserve habitat for wildlife and a resource for forest products and other industries dependent on them, and

• protect the vitality of the marine web of life from collapse as a result of acidification.

The IPCC provided clear guidance in its 2018 report that to stop the warming and stabilize the climate, the economy must transition to a zero carbon (CO2 and methane) emission energy system, and forests must be expanded to extract CO2 from the atmosphere. Climate stability can be achieved only by reducing GHG emissions to net-zero.

To stabilize global temperature at any level, ‘net’ CO2 emissions would need to be reduced to zero. This means the amount of CO2 entering the atmosphere must equal the amount that is removed. Achieving a balance between CO2 ‘sources’ and ‘sinks’ is often referred to as ‘net zero’ emissions or ‘carbon neutrality’.25

Limiting warming to 1.5°C implies reaching net zero CO2 emissions globally around 2050 and concurrent deep reductions in emissions of non-CO2 forcers, particularly methane26 (high confidence). Such mitigation pathways are characterized by energy-demand reductions, decarbonization of electricity and other fuels, electrification of energy end use, deep reductions in agricultural emissions, and some form of CDR [carbon dioxide reduction] with carbon storage on land or sequestration in geological reservoirs.27

Zero GHG emissions to stabilize the climate must be achieved sooner than later to minimize the losses and deaths associated with devastating warmer climate effects. Zero emissions cannot be achieved without transforming transportation which is the largest source of GHG emissions. For most transportation sources such as on-road vehicles, zero emissions can be cost-effectively achieved by electrification with batteries or fuel cells.

The latest IPCC report (2021) concludes based on the latest climate data and updated modeling that –

Under the five illustrative [GHG emissions] scenarios, in the near term (2021-2040), the 1.5°C global warming level is very likely to be exceeded under the very high GHG emissions scenario (SSP5-8.5), likely to be exceeded under the intermediate and high GHG emissions scenarios (SSP2-4.5 and SSP3-7.0), more likely than not to be exceeded under the low GHG emissions scenario (SSP1-2.6) and more likely than not to be reached under the very low GHG emissions scenario (SSP1-1.9).28

The opportunity to stay below 1.5°C and to prevent the additional devastation that such level of warming will cause, has been frittered away by inaction and delay. At the current global mean temperature, the climate has warmed enough to endanger public health, cause devastating destruction of homes and businesses, loss of life and the disruption of natural systems by extreme floods, drought, wildfires, hurricanes and tornadoes. The harm we will experience above 1.5°C will be orders of magnitude greater.

But the IPCC offers the hope that ‘for the very low GHG emissions scenario (SSP1-1.9), it is more likely than not that global surface temperature would decline back to below 1.5°C toward the end of the 21st century, with a temporary overshoot of no more than 0.1°C above 1.5°C global warming.’29

That hope turns on cutting global CO2 emissions in half by 2030, and to net-zero by 2050 along with large reductions in non-CO2 climate forcers such as methane. EPA has not set out a regulatory path for achieving those reductions. [EPA-HQ-OAR-2021-0208-0521-A1, pp. 4-11]

Petition for Finding --

Based on these data and other available evidence, we petition the Administrator to find that –

1) climate warming already caused by GHG emissions harms the public health and is causing unacceptable adverse impacts on public welfare and the human environment, and

2) the expected increase in the severity and frequency of harms to health and the public welfare that will be caused by more extreme events that will occur as the global mean temperature advances toward and above the 1.5°C level resulting from growing GHG concentrations in the atmosphere, establish the need for a zero GHG emissions standard for light duty vehicles pursuant to section 202(b)(1)(C) of the Clean Air Act. [EPA-HQ-OAR-2021-0208-0521-A1, p. 12.]

As a proximate cause of death, air pollution from fossil fuel combustion would rank as the third-leading cause of death in the U.S. contributing to eight of the top ten causes—heart disease; cancer; chronic lower respiratory diseases; stroke (cerebrovascular diseases); Alzheimer's disease; diabetes; influenza and pneumonia; and nephritis, nephrotic syndrome, and nephrosis.34 Shindell estimates that ending the combustion of carbon fuels will save 1.4 million American lives between now and 2040.

The EPA staff researchers estimated that roughly 20% of the mortality attributed to carbon combustion is caused by emissions from on-road vehicle emissions. Depending on the total mortality estimate used, eliminating carbon fuels to power motor vehicles could save 20,000 to 40,000 lives annually in the U.S.

In the last three decades the average incidence of asthma among children has increased from 1 in 15 to 1 in 10 children, with higher rates among children of color and in polluted neighborhoods near refineries, power plants or major highways. As of 2018, the U.S. Census estimates that 22.4% of the U.S. population are under 18 years of age: https://www.census.gov/quickfacts/fact/table/US/PST045218. [EPA-HQ-OAR-2021-0208-0521-A1, p. 14]

1 Executive Order to Tackle Climate Change (January 27, 2021). Sec. 201. Policy. Even as our Nation emerges from profound public health and economic crises borne of a pandemic, we face a climate crisis that threatens our people and communities, public health and economy, and, starkly, our ability to live on planet Earth. Despite the peril that is already evident, there is promise in the solutions — opportunities to create well-paying union jobs to build a modern and sustainable infrastructure, deliver an equitable, clean energy future, and put the United States on a path to achieve net-zero emissions, economy-wide, by no later than 2050.

We must listen to science — and act. We must strengthen our clean air and water protections. We must hold polluters accountable for their actions. We must deliver environmental justice in communities all across America. The Federal Government must drive assessment, disclosure, and mitigation of climate pollution and climate-related risks in every sector of our economy, marshaling the creativity, courage, and capital necessary to make our Nation resilient in the face of this threat. Together, we must combat the climate crisis with bold, progressive action that combines the full capacity of the Federal Government with efforts from every corner of our Nation, every level of government, and every sector of our economy. It is the policy of my Administration to organize and deploy the full capacity of its agencies to combat the climate crisis to implement a Government-wide approach that reduces climate pollution in every sector of the economy; increases resilience to the impacts of climate change; protects public health; conserves our lands, waters, and biodiversity; delivers environmental justice; and spurs well-paying union jobs and economic growth, especially through innovation, commercialization, and deployment of clean energy technologies and infrastructure. Successfully meeting these challenges will require the Federal Government to pursue such a coordinated approach from planning to implementation, coupled with substantive engagement by stakeholders, including State, local, and Tribal governments.

Commenter: Energy Innovation Policy and Technology LLC

The EPA is an integral federal agency that can help unlock substantial GHG and other pollution reductions in the transportation sector, which remains the largest contributor to U.S. GHG emissions (29 percent of total emissions).[ii] The imperative to reverse course on increasingly volatile and damaging climate change is well documented, including in the most recent Intergovernmental Panel on Climate Change report.[iii] [EPA-HQ-OAR-2021-0208-0605-A1, pp. 2]

Commenter: Energy Strategy Coalition

In conclusion, reducing emissions from the transportation sector will be critical to meeting our states' mid- and long-term criteria and GHG emissions reductions obligations. The Proposed Standards will help to create a process to cost-effectively make adjustments and investments to set states on this path. [EPA-HQ-OAR-2021-0208-0533-A1, p.3]

Commenter: Environment America

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 237-238.]

Transportation is now the Number 1 source of climate emissions in the U.S. and the majority of those emissions come from every-day cars and trucks.

These emissions also cut short an estimated 58,000 American lives every year. We've already seen the damage climate change can do this year. Where I live in Philadelphia, we've entered our sixth heat wave of the summer this week and experienced intense flash flooding and rainfall for the last few months.

Scientists are saying that these impacts are coming even faster than they previously expected. So it's imperative that we do everything we can to clean up how we get around to curb the progression of the climate crisis.

Commenter: Environmental Defense Fund (EDF)

Standards that eliminate tailpipe pollution from new passenger cars and light trucks by 2035 could reduce more than 11 billion tons of climate pollution by 2050, prevent nearly 100,000 premature deaths [EPA-HQ-OAR-2021-0208-0688-A1, p. 2]

Saving Americans $88 billion annually by 2040 in economic and pollution benefits and nearly $1.6 trillion cumulatively by 2050, almost 10% of current U.S. GDP. [EPA-HQ-OAR-2021-0208-0688-A1, p. 37]

Protective pollution standards for new vehicles are urgently needed to help address the climate crisis and protect public health. We must respond to the climate crisis with urgency. The latest climate assessments are dire. According to the most recent Intergovernmental Panel on Climate Change (IPCC) Report, human-induced climate change is already affecting weather and climate extremes in every region in the world and across the whole climate system.5 Each of the last four decades has been successively warmer than any decade that preceded it since 1850. And the report concludes that in the coming decades climate changes will increase in all regions, including increased heat waves, longer warm seasons and shorter cold seasons with significant changes to wetness and dryness, winds, snow and ice, coastal areas and oceans. We must respond to the climate crisis with urgency.

The transportation sector is the nation's single largest source of climate pollution, responsible for more than 1.9 billion tons of climate pollution every year – nearly a third of U.S. emissions. 6 Passenger cars and light trucks are the largest transportation-related source of emissions, contributing nearly 60 percent of emissions. We cannot meet the climate crisis without transitioning to ZEVs. America's clean car standards are among our most effective policies for reducing pollution exposure and cutting climate emissions. EPA's proposed rule would eliminate an estimated 2.2 billion tons of climate pollution from vehicles sold in MY 2023 to 2026 by 2050. And adding a pathway to secure an additional 10 g/mi in 2026 will further enhance those reductions. Standards that deliver ZEVs in the near term, combined with longer term standards consistent with eliminating tailpipe pollution from new motor vehicles by 2035, will save lives and put us on a path to averting the worst impacts of climate change. [EPA-HQ-OAR-2021-0208-0688-A1, p. 4]

• Avoiding more than 600 million metric tons of greenhouse gas (GHG) emissions in 2040 – roughly the annual climate emissions from Canada – and eliminating more than 11.5 billion tons cumulatively by 2050 – far more than the carbon emissions from China last year, which is responsible for more than a quarter of the world's climate pollution; [EPA-HQ-OAR-2021-0208-0688-A1, p. 37]

Commenter: Environmental Law & Policy Center (ELPC), et al.

Reducing emissions from America's cars and light trucks is critical to mitigating climate change and achieving President Biden's goals and commitment in rejoining the Paris Climate agreement.[3] The transportation sector is currently the leading source of U.S. climate-changing pollution, contributing 29% of total U.S. greenhouse gas emissions.[4] As a result of the prior administration's rollback, the United States has lost years of emissions reductions as the urgency for action on climate change mounts daily. EPA must act urgently now to achieve emissions reductions.

The climate crisis currently playing out across the country and the world demands urgent, strong action. [EPA-HQ-OAR-2021-0208-0567-A1, pp. 1-2]

The sixth assessment report recently issued by the United Nations' Intergovernmental Panel on Climate Change makes clear both climate change's human causes and its devastating impacts.6 The report notes that human influence has warmed the climate at a rate that is unprecedented in at least the last 2,000 years.[7] Climate change is already affecting every inhabited region across the globe, with central and eastern North America experiencing increased heavy precipitation and western North America experiencing increases in extreme heat and drought.[8]

The undersigned organizations are specifically concerned about the threat climate change poses to the Midwest and the Great Lakes. The region is home to 61 million people and to the auto industry; it is also a significant engine for agriculture. Temperatures in the Midwest are rising due to climate change. Warmer temperatures impact public health with increased frequency of deadly heat waves and worsening air quality.[9]

In 2019, ELPC sponsored a report by leading Midwest climate scientists that detailed the impacts of climate change on the Great Lakes region. [10] Climate change threatens the Great Lakes ecosystem, fresh water supplies, and the economies that depend on them.

The Great Lakes are an international gem with enormous ecological, cultural, and economic value. The Great Lakes are the largest freshwater ecosystem on earth, containing 21% of the world's freshwater supply and providing drinking water for over 42 million people.[11] The available water supply helps to drive the regional economy.[12] Commercial and recreational fishing, alone, in the Great Lakes injects over $5 billion into the economies of the surrounding states.[13]

The changing climate brings increased storm intensity, changes to water temperatures, flooding, runoff, and algal growth—all presenting a significant and increasing threat to the Great Lakes. Costly weather-related disasters, like the recent devastating flooding in Detroit, have been linked to climate change. [14]

EPA must do all it can to avert the worst impacts of the climate crisis. [EPA-HQ-OAR-2021-0208-0567-A1, pp.2-3]

Commenter: Environmental Law and Policy Center (ELPC)

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 287-289.]

First, we need to act with urgency. The Six IPCC Report makes clear both the human causes of climate change and its devastating impact.

EPA's reminder in the NPRM that greenhouse gases endanger public health and welfare is important, but EPA fails to capture the scope of the tragic impacts we are seeing almost daily across the U.S. and around the world and the absolute urgency of strong standards.

ELPC is specifically concerned about the threat climate change poses to the Midwest and the Great Lakes which contain 21 percent of the world's freshwater supply and provide drinking water for over 42 million people.

In 2019, ELPC sponsored a report by leading Midwest climate experts and scientists that detailed the harmful impacts of climate change on the Great Lakes and our region.

The change in climate brings increased storm intensity, changes in water temperatures, flooding, runoff, and algal growth, all presenting a significant increasing threat to the Great Lakes.

In the region, the boundary waters has been evacuated due to the threats of wildfire and costly weather-related disasters, like the recent devastating flooding in Detroit, have been linked to climate change.

Commenter: Environmental Protection Network (EPN)

Section II describes the compelling need for achieving this goal, given the current understanding of the increasing threats presented by emissions of GHGs and criteria pollutants from vehicles powered by fossil fuels. Achieving the GHG and criteria emissions reductions from this kind of transformation would achieve very substantial benefits to the public’s health and welfare, and especially for those segments of society at risk for the greatest harms from climate change and criteria air pollution. Section II also discusses the confluence of several critical trends that show this goal is both practical and achievable. Section III [EPA-HQ-OAR-2021-0208-0213-A1, p.1]

While the standards proposed for these MYs would promote a real increase in zero-emissions vehicles from current levels, it is at best modest progress towards 50% electric power by MY 2030 and near 100% electric power by MY 2035. As we will discuss in Section II, there is no time to lose given the dire need to reduce GHGs from the transportation sector as part of addressing climate change and the compelling need for large reductions in nitrogen oxides (NOx) and particulate matter (PM).[EPA-HQ-OAR-2021-0208-0213-A1, p.1]

The Climate Emergency Alarms are Deafening. The recent report by 234 of the world’s top climate scientists for the Intergovernmental Panel on Climate Change (IPCC)—declaring a 'Code Red for Humanity'—is the most recent and powerful declaration of our existential climate crisis.[3] As summarized by United Nations Secretary-General Antonio Guterres, 'the alarm bells are deafening, and the evidence is irrefutable.'[4] In every corner of our country—devastating hurricanes in the southeast, massive droughts and wildfires in the west, unthinkable temperature extremes in the northwest, and more intense storms and floods in the northeast and midwest—we are seeing clear consequences of the climate crisis far faster than predicted just a few years ago. If the global community fails to 'move fast and move big' to reduce GHG emissions, the tragic impacts from today's 1.1 degrees C average global temperature rise will be dwarfed by a future 2 or 3 degrees C average rise. Accordingly, the Paris Climate Agreement established a goal of keeping the average global temperature rise to well below 2 degrees C, while urging efforts to limit the increase to 1.5 degrees C.[5] [EPA-HQ-OAR-2021-0208-0213-A1, p. 2]

Transportation is the largest U.S. GHG-emitting sector. Cars and light trucks are responsible for well over half of overall domestic transportation GHG emissions, and it takes about 15 years to turn over the U.S. car and light-truck fleet to new vehicles. Accordingly, achieving the dual economy-wide Biden administration climate goals of a 50-52% GHG reduction from 2005 levels in 2030 and net zero GHG emissions by no later than 2050 requires a bold transformation of new-car and light-truck sales from fossil fuels to zero-emissions technologies by 2035, and in-use car and light-truck fleet to zero-emissions technologies by 2050. [EPA-HQ-OAR-2021-0208-0213-A1, p.3]

EDF projects that GHG emissions would be reduced by 600 million metric tons (MMT) in 2040 and nearly 900 MMT in 2050, with cumulative GHG savings through 2050 of 11.5 billion metric tons. [EPA-HQ-OAR-2021-0208-0213-A1, p. 8]

Two, fully half of the societal benefits described above are environmental and public health benefits derived from emissions reductions that are classic textbook examples of market externalities where the societal benefits can only be accounted for through governmental regulation. [EPA-HQ-OAR-2021-0208-0213-A1, p. 8]

Commenter: Exxon Mobil

In 2019, transportation accounted for 29% of total GHG emissions in the U.S., followed by the electricity power sector at 25%[3]. [EPA-HQ-OAR-2021-0208-0734-A1, p. 1]

Commenter: Filippelli, Garbirel

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 42.]

So, of course, the IPCC report that landed last week was a shock to the world, but it was not a shock to scientists like myself. I've been studying climate change and climate change impacts for about 30 years, and I've not only read most of the studies summarized in that but produced many of them.

And so for us scientists, it's been very clear for quite some time that climate change is a critical global issue and we also know that transportation, of course, is a large contributor to climate change, but it is also a contributor to something that I study here even locally Indianapolis and that's air pollution.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 43-44.]

Now wouldn't it be nice if we were intentional about that and that's exactly what some of these air quality standards have to be written for, written not to just look at climate change in a global sense but also to improve the air for our children in cities like mine in Indianapolis and across this country, and I think that that will require some significant sharpening of some of these standards perhaps even beyond what was stated initially as preferred solutions.

So I encourage you to do this. I encourage you to do this for global climate, but I encourage you to do this for kids' right here in Indianapolis.

Commenter: Gallagher, James A.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 263.]

I watched the escalating extreme climate events, such as wildfires, droughts, and extreme heat, in the Northwest where my brother Gary has had to evacuate his home from the fires and my brother Tom died July 15th of lung cancer. He never smoked.

Meanwhile, we have tornadoes, hurricanes, and extreme flooding throughout our country and throughout the world. We have to change our ways but there are rich and powerful industries that do not want to change the status quo.

Commenter: Gersten, Dana

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 280-281.]

I see the effects of climate change on my patients almost daily as it directly causes some health emergencies and makes others worse. Many of my patients have lung conditions, like asthma or COPD, as well as heart conditions. We live in a large city with truck and air pollution. This year, like last year, large wildfires make air quality even worse, sending many to the hospital. They breathe unrelenting smoke this time of year, and the poor air quality exacerbates their health condition, sending many to the hospital for intensive care. I think because so many of my patients are living on the edge of making it and not making it, these health exacerbations can send them over the edge into poverty. For example, when I was doing training in Oregon, I had a patient who was a farm worker who worked with the grape harvest. Wildfires destroyed the harvest, and he was not able to make any money. His electricity bill went unpaid, and his electricity was turned off. He couldn't keep his insulin cold, and then he went into a dangerous hyperglycemia. He became acutely ill, and when he returned back, he was unable to work. So, I think the cycle of poverty and ill health just keeps on going, affecting people who take care of my patients and also the people they take care of, like their spouses and their children. Our health care system can't afford to keep covering the costs of weak auto pollution standards. Especially with COVID, our hospital is near capacity, and there simply isn't room to treat all of the incoming patients with respiratory issues.

Commenter: Haines, Meredith

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 112-114.] in Virginia, we recognize that addressing transportation's outsized contribution to greenhouse gas emissions is critical to climate policy. And in February, the state legislature passed clean car standards, joining other forward-looking states, such as our neighbor Maryland, and we need the action of this Administration to lead all states to swift and effective change

The vast capacity of the ocean has buffered out pollution's impact enormously, directly absorbing greenhouse effects and excess heat and tempering atmospheric warming and yet we have reached ecosystem limits largely within my lifetime. Now ocean life suffers stresses of marine heat waves on top of generally warmer and more acidic waters with less oxygen. However, it seems until the impacts show up on our coasts affecting real estate and impacting our summer beach trips, then it's a problem happening somewhere else. So I don't need to remind the panel that there is no Plan B at least for today.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 114-115.]

And to briefly touch on where regulation meets policy, I note that the regulatory analysis does not appear to consider the impact of the carbon tax and given that a carbon price is considered by economists and scientists and I advocate for it, the best policy for rapid emissions reductions and is broadly implemented worldwide should be part of the conversation and consumers will use their climate action incentive payments or carbon cash back and the known schedule of carbon price increases and want to further benefit economically by making more fuel-efficient/less-carbon-intensive choices.

Commenter: Hauptman, Elizabeth

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 242-243.]

Air pollution from the transportation sector not only harms the health of our children but it also contributes to the climate crisis. Pollution harms all of us but disproportionately impacts children. Kids are smaller, living closer to the ground than the rest of us, standing just about tailpipe high where concentrations from pollution from cars, trucks, and buses is coming directly at them.

Children's still developing hearts and lungs are being exposed to the dirty exhaust from vehicles that spew carcinogenic poisons into the air. This tailpipe pollution causes poor air quality that can exacerbate asthma, causing more asthma attacks, resulting in millions of missed school days, games, and outdoor family activities for kids across the country.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 244-245.]

Michigan has some of the worst asthma rates in the country, according to the American Lung Association. Childhood asthma rates are significantly higher for children of color. Latino children are twice as likely to die from asthma and black children are 10 times more likely to die from asthma than white non-Hispanic kids.

These statistics make it abundantly clear that strong clean standards or a shift to zero emission vehicles is an environmental and social justice issue. Our children deserve justice in every breath. Because my son and over 166,000 children in Michigan who suffer from asthma need tougher air quality standards to protect their children from the nation's largest source of carbon pollution, tailpipe pollution.

In addition, we need these strong EPA standards to address the urgent climate crisis now. This climate crisis is not something you'll see impacts some day in the future. We're seeing climate impacts right now, extreme weather events, like excessive rainfall, storms like we had last night, floods, heat waves.

Currently the strong clean standards are the best tool we have in our toolbox to fight climate change. Addressing pollution from the transportation sector will fight climate change cannot wait. Michiganders and kids deserve the strongest clean car standards EPA has proposed.

Commenter: Hewes, Celerah

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 107.]

Climate change is impacting New Mexico and the Southwest with drought and longer more intense wildfire seasons as well as increased heat waves that threaten the health of New Mexico's families. We've seen rising heat and climate impacts, including wildfires, that are causing air pollution from places over 400 miles away. This summer the wildfires burning in Arizona put Albuquerque as public health alert of smoke and particulates traveled hundreds of miles.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 108.]

Over the past few weeks, we've had numerous days where air quality officials have told us the air outside is unhealthy to breathe due to smoke and ozone and our skies are so thick with particulate matter we cannot see the Sandia Mountains. We cannot address the climate crisis without moving decisively to zero pollution vehicles and this proposal is a step in the right direction.

The pollution from cars not only causes climate change but it degrades air quality and threatens our health.

Commenter: Interfaith Power & Light (IPL)

At this moment in time, we have a choice. The just-released IPCC report makes it startlingly clear: there is no time to waste in half-measures, or catering to the interests of industry and manufacturing. We have already locked our children and grandchildren in to a future on this planet that will have more heat waves, more drought, more extreme weather, and more fires than we are experiencing right now.

We have an actual opportunity here with vehicle standards that can make a difference in lowering the amount of air pollution that is impacting people's health, and in lowering greenhouse gas emissions that are driving the climate crisis. But we can't wait. We can't grant loopholes to auto manufacturers [EPA-HQ-OAR-2021-0208-0224-A1, pp. 1-2]

Commenter: International Council on Clean Transportation

Decarbonizing the transportation sector, which is the largest contributor to climate pollution in the United States, is of the utmost urgency. While other major economies (e.g., Europe, China) have been acting on that crucial realization by taking steps to facilitate a transition to electric vehicles, the United States has lagged. That represents not only a setback for the climate but also a looming crisis for the American manufacturing economy. [EPA-HQ-OAR-2021-0208-0522-A1, p. 4]

Commenter: Kimmel, Julie

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 98-101.]

In fact, the transportation sector is responsible for 48 percent of carbon pollution in Virginia. We clearly cannot address the climate crisis without moving decisively to zero pollution vehicles. In the last year the Virginia General Assembly passed some important legislation for reducing tailpipe pollution in the Commonwealth, establishing an advanced clean cars program and electric vehicle rebate program and a grant fund for electric school buses and heavy-duty vehicles, but Virginia can't do this work to cut climate pollution alone and neither can any other state.

Climate change is already affecting my community in Reston. Over the last decade we've had several severe wind storms, a phenomenon I don't recall from my childhood here. We've also seen multiple so-called 100-year rain storms, and the annual number of days when temperatures soar past 90 degrees is growing. Families across the country are losing so many valuable play and school days to extreme storms, extreme heat, and wildfires, thanks to climate change, and this on top of the education crisis we're facing because of COVID.

As a parent worried about the impacts of climate change on our children's education, health, and future, I want EPA to finalize the strongest possible national greenhouse gas emissions standards for passenger cars and light trucks. To stall the climate catastrophe threatening our kids, we must get ourselves on the path to 100 percent zero emissions new vehicle sales by 2035 and that means the near-term standards for climate pollution that we're talking about today not only should be as strong as possible but also should avoid loopholes and put automakers on track to hit that 100 percent zero emissions by 2035 target.

Commenter: Klein, Stephanie

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 280-281.]

We also know that cars are one of our major sources of greenhouse gases. Ground transportation accounts for 22 percent of our climate pollution here. Like communities across the country, Washington, D.C., is experiencing the effects of climate change today. We are living through record-breaking heat waves, snowstorms, and floods caused by rising sea levels and heavy rain events. Our famous cherry blossoms are even blooming earlier as the planet warms.

Commenter: Kuntz, Laurie

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 208-209.]

As a biology graduate, I've been learning about the dangers of climate change and ecological degradation since the 1990s. Now in the 2020s, we are close to losing an entire class of species, anthozoa, commonly known as coral, because of the acidification and warming of ocean water that occurs with higher amounts of carbon in the atmosphere.

If we lose coral, an entire class of marine invertebrates, that's the equivalent of losing all mammals on the planet since mammals are an equivalent class of land vertebrates. If we lost coral or any other class of species, I'm confident that we would see worldwide ecological collapse.

If ecosystems can't function properly, the web of life will be untangled and humans will suffer and die. In my own area in Idaho, I've seen extreme drought. I've seen a wildfire come within two miles of my home, and I've seen reductions in wildlife populations over the past five years. I've seen birds die of heat stroke this year. I haven't seen any rusty catch bumble bees for the past two years, and I've seen chipmunks and birds with tumors caused by a degraded environment.

Reducing greenhouse gas emissions is the only way to change this path and prevent ecological collapse.

Commenter: Levison, Laura

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 234.]

Stronger clean car standards will give us greater reductions in climate pollution which we desperately need and will save us consumers money, as well.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 235.]

Thanks to Speaker Pelosi and the advocates for greater fuel efficiency inside and outside of Congress, you have the authority to make auto emissions cleaner. You should not squander this opportunity to tackle the climate crisis and save consumers money.

Commenter: Lish, Christopher

Our country faces deadly heatwaves, devastating drought, extreme storms, massive wildfires and unprecedented flooding caused by climate change. Transportation is the largest source of climate pollution in the U.S., accounting for nearly 30% of greenhouse gas emissions. Air pollution from cars and trucks harms people’s health—especially in low-income communities and communities of color. Vehicle emissions cause thousands of premature deaths and billions in health care costs every year. To fight climate catastrophe and protect public health, the United States must reduce the massive amount of pollution produced by passenger cars.

Climate change is also the single biggest threat to our national parks. Nearly all 423 units of America’s national park system are endangered by climate change-related impacts, including heat waves, drought, sea level rise, coastal flooding, and wildfires. Parks such as Glacier, Everglades, Sequoia, and Joshua Tree are even at risk of permanently losing their namesake features if we don’t act quickly. [EPA-HQ-OAR-2021-0208-0218-A1, p. 1]

Commenter: Lynch, Vanessa

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 192-193.]

The latest Intergovernmental Panel on Climate Change Report summarizes the State of the Science on Climate Change confirming climate change is widespread, rapid, and intensifying. The report paints a grim picture of our world's future unless swift and strong action is taken immediately to curb the pollution causing global climate change. The transportation sector is the largest source of carbon pollution in the U.S. We cannot address the climate crisis without moving decisively to zero pollution vehicles electrified by zero pollution electric power sources.

In Pennsylvania, climate change is clearly making an impact. The Pennsylvania Department of Environmental Protection reports the state has the highest number of Lyme disease cases in the nation, triple the number of cases from 10 years ago. If you talk to families in Southwest PA, it's not if you know someone who's been impacted but, rather, how severe were those impacts. From short-term antibiotic treatment to long-term joint pain and swelling, inflammation of the brain and spinal cord and nerve pain, my neighbors and friends have experienced them all.

In my local community, landslides and major rain events are becoming much more frequent. Our family was recently forced to install an interior French drain in our basement due to major flooding. Mold and mildew growth caused major home repair issues and health concerns as a result of the increase in rain to our region and these impacts are felt by each of us, regular American citizens across the country. From 2010 to 2020, Pennsylvania experienced 37 extreme weather events, costing the state up to $10 billion in damages, those creating the increasing financial burden climate change is becoming to Pennsylvania's families.

Commenter: Maine Department of Environmental Protection

Climate change poses a real and present danger to the to public health, the environment, and the economy. From increasing land and ocean temperatures, to rising sea levels, more frequent severe storms, shortened winters and disrupted agricultural seasons, and more prevalent public-health risks, scientists have cataloged, and continue to catalog, the current and expected harms of climate change. As greenhouse gas (GHG) emissions drive dramatic changes in Earth’s climate systems, the warming trends documented in Maine are even more prominent than those observed globally. Since 1895, Maine’s statewide annual temperatures have risen by 3.2°F (1.8°C), with coastal areas warming more than the interior of the state. Extreme weather conditions in Maine, such as drought and large rain events, are harming agriculture, shellfisheries, and freshwater and coastal ecosystems susceptible to climate change effects. Human and animal health are affected by climate change and will continue to be into the future as temperature extremes, extreme weather, tick- and mosquito-borne diseases, food- and water-borne infections, and pollen pose increasing risks to Mainers’ health. In Maine, as in much of the nation, the transportation sector is the largest source of climate-warming GHG emissions in Maine and across the nation. As we move forward to substantially reduce GHG emissions, strong standards for the transportation sector will be critical to the success of our efforts to reduce both GHG and criteria pollutants. [EPA-HQ-OAR-2021-0208-0225-A1, p.1]

Commenter: Maryland Department of Environment

This proposal has the potential to offer substantial benefits and emission reductions that are needed for Maryland to attain and/or maintain clean air, mitigate the effects of climate change, and continue to make progress reducing nitrogen deposition to the Chesapeake Bay. [EPA-HQ-OAR-2021-0208-0241-A1, p.1]

Commenter: Mass Comment Campaign sponsored by American Lung Association (121)

Climate change puts everyone at risk, including my family. To help protect our health from the impacts of air pollution and climate change, the nation needs to transition to zero-emission transportation. [EPA-HQ-OAR-2021-0208-0559-A1,p.1]

Commenter: Mass Comment Campaign sponsored by Center for Biological Diversity (77,692)

Our country faces deadly heatwaves, devastating climate change is real. drought, extreme storms, massive wildfires and unprecedented flooding caused by climate change. To fight climate catastrophe and protect public health, the United States must reduce the massive amount of pollution produced by passenger cars. [EPA-HQ-OAR-2021-0208-0560-A1, p.1]

Commenter: Mass Comment Campaign sponsored by Environment America (11,080)

Over five years ago, the Obama-Biden administration took the strongest federal action to reduce global warming pollution in history. Unfortunately, this progress was undone under the Trump-Pence administration. This is particularly concerning since the effects of climate change only continue to worsen. [EPA-HQ-OAR-2021-0208-0557-A1, p.1]

As pollution increased over the past half-decade, the wildfire season has lengthened and grown more intense, coastal communities have been torn apart by destructive hurricanes fueled by warmer oceans, and inland communities have seen more than their fair share of 100-year floods. We cannot turn back the clock five years, which makes it all the more urgent for us to zero out emissions from our cars and trucks to help solve this climate crisis. [EPA-HQ-OAR-2021-0208-0557-A1, p.1]

Commenter: Mass Comment Campaign sponsored by Interfaith Power & Light (1,093)

The window for meaningful action to address climate change is closing and we ask the EPA to do its part to address climate pollution starting with the largest sources like transportation. Stronger and more protective car standards can also reduce health care costs and protect our health, particularly the health of the most vulnerable in our communities. [EPA-HQ-OAR-2021-0208-0553-A1, p.2]

Commenter: Mass Comment Campaign sponsored by Interfaith Power and Light et al. (1,599)

As faith leaders from many diverse religious and spiritual traditions, we believe that humanity shares a responsibility to be stewards of Creation. All of us must work together to reduce pollution and implement just and equitable solutions to the climate crisis, and our national leaders have a sacred role in helping to achieve these goals. [EPA-HQ-OAR-2021-0208-0192-A1, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-1 (7,010)

With so many of us are experiencing unhealthy wildfire smoke, deadly floods, and other effects of global warming, the time has come for us to move to more responsible transportation that also happens to be better. I have driven a plug-in for nearly a decade and am happy to report that the experience is far superior to gas-powered cars. Please help us be on the right side of history.[EPA-HQ-OAR-2021-0208-0545, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-11 (1,667)

Climate change is the single biggest threat to our national parks, as well as to many local communities. Nearly all 423 units of America's national park system are endangered by climate change-related impacts, including heat waves, drought, sea level rise, coastal flooding, and wildfires. Parks such as Glacier, Everglades, Sequoia, and Joshua Tree are even at risk of permanently losing their namesake features if we don't act quickly. [EPA-HQ-OAR-2021-0208-0642-A1, p.1]

Enacting more stringent clean car standards will provide numerous co-benefits for people and parks — from saving American's billions at the pump, to preventing unhealthy vehicle air pollution that severely harms public health and the wellbeing of park ecosystems. [EPA-HQ-OAR-2021-0208-0642-A1, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-6 (39)

Climate change is the single biggest threat to our national parks, as well as to many local communities. [EPA-HQ-OAR-2021-0208-0550, p.1]

Nearly all 423 units of Americas national park system are endangered by climate change-related impacts, including heat waves, drought, sea level rise, coastal flooding, and wildfires. Parks such as Glacier, Everglades, Sequoia, and Joshua Tree are even at risk of permanently losing their namesake features if we don't act quickly. [EPA-HQ-OAR-2021-0208-0550, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-7 (37)

The transportation sector is the largest contributor to climate pollution in the US. Cleaner, more efficient vehicles reduce air pollution and combat climate change -- helping to prevent harmful health impacts like asthma attacks. We need the strongest possible clean car standards to protect health now and for future generations. [EPA-HQ-OAR-2021-0208-0551, p.1]

We experienced the better quality of air in 2020 when we had to minimize our travel including air travel. Low emission cars will create a healthier environment for all our future generations. [EPA-HQ-OAR-2021-0208-0551, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-8 (25)

Dedicated to protecting life and a sustainable future, I join the majority of Americans who want bold federal action now to stop the climate crisis from destroying our children's and grandchildren's future. I'm old enough to remember bright blue skies, a clear view of distant mountains, plentiful water, a father who could earn a house, and a mother who could stay home to care for her children. A generation has changed dramatically, and the next will be far worse -- unless you act. [EPA-HQ-OAR-2021-0208-0552, p.1]

The climate crisis has brought death, injury and destruction to millions of Americans this summer. The CODE RED for humanity issued by the International Panel on Climate Change's (IPCC) 6th Assessment underscores the urgent need for strong action NOW. Reducing GHG emissions years from now will be too late. EPA must adopt emissions standards to move the nation to zero emission vehicles as soon as possible. [EPA-HQ-OAR-2021-0208-0552, p.1]

The IPCC report has told us unequivocally that we have exhausted the time in which we might have acted to avert catastrophic change, and yet we have a very small window of time remaining to reduce the severity of the coming consequences of our inaction. Half measures are unacceptable in this moment. [EPA-HQ-OAR-2021-0208-0552, p.1]

For the sake of our children and grandchildren, the time to act, and to act boldly, is now. [EPA-HQ-OAR-2021-0208-0552, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-9 (3,219)

To date, the transportation sector has been the largest source of climate pollution in the U.S., accounting for nearly one third of our nation's greenhouse gas emissions. Cars and light trucks in particular, account for about 45 percent of all U.S. oil consumption and about 20 percent of all U.S. greenhouse gas emissions. [EPA-HQ-OAR-2021-0208-0640-A1,p.1]

Commenter: Mathews, Mary

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 256.]

As transportation is the largest source of carbon emissions, restricting the emission of heat-trapping gases will help mitigate climate change and combat deadly air pollution.

Air pollution caused by emissions has been proven to increase the risk of heart disease, lung cancer, and asthma. The requirement for transition to zero emission cars within a short time frame will greatly improve public health.

Commenter: Melton, Karen

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 253-254.]

With transportation as the largest source of carbon emissions in the U.S., it's critical that we both make our gasoline=powered trucks and cars more efficient and that we shift rapidly to electric vehicles if we are to achieve a hundred percent zero emission vehicle sales by 2035 and net zero greenhouse gas emissions economy by 2050.

Commenter: Metropolitan Mayors Caucus

In July 2021, we released the first climate action plan for the region identifying equitable goals for climate mitigation and adaptation.https://mayorscaucus.org/climate-change/ Our plan calls for a 19% reduction in transportation emissions by 2030. This target is only achievable with the strongest possible standards from the US EPA. Our mitigation objective 'Decarbonize Transportation' specifically identifies, 'Support strong national fuel efficiency standards' as a strategy. [EPA-HQ-OAR-2021-0208-0504, p.1]

Commenter: Metropolitan Washington Air Quality Committee (MWAQC)

Strengthening the GHG emissions standards will also provide considerable support for metropolitan Washington and communities across the United States to meet their GHG emissions reduction goals. Unfortunately, our region is already experiencing the impacts of climate change. Observations in metropolitan Washington show that temperatures and the water surface level in the Potomac River are rising and will continue to rise. Extreme weather events and increases in the number of days with extreme heat or extreme cold will increase risks to health, energy usage patterns, plant and animal habitats, and infrastructure. These changes in our weather patterns are also affecting stormwater, drinking water, and wastewater. Broad-based climate change mitigation and adaptation strategies, such as national rules, are necessary to reduce the impacts of climate change and fight the adverse effects of climate change on our region and planet. [EPA-HQ-OAR-2021-0208-0208-A1] [p.2]

In 2008, the National Capital Region Climate Change Report established regional climate goals to reduce GHG emissions by 20% below 2005 levels by 2020, and 80% below 2005 levels by 2050. In October 2020, the COG Board of Directors adopted new 2030 climate goals to supplement the previous goals, including a goal to reduce GHG emissions by 50% below 2005 levels by 2030. [EPA-HQ-OAR-2021-0208-0208-A1][p.2]

The metropolitan Washington region has implemented emissions reduction measures across all sectors, including on-road transportation, which contributes approximately 34% and 38% of the region’s GHG and NOx emissions, respectively. The region relies heavily on federal control programs for a significant amount of additional GHG and NOx emissions reductions since these programs provide benefits across the marketplace. The federal government's leadership in delivering effective regulatory limits on GHG emissions from motor vehicles could also help reduce ozone and fine particle precursors and is a critical component of our ability to meet adopted environmental objectives and standards. [EPA-HQ-OAR-2021-0208-0208-A1] [p.3]

Commenter: MI Air MI Health

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 195.]

We believe that everyone deserves to breathe clean and healthy air.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 196-197.]

We are in the midst of a climate crisis and emissions contributing to climate change need to be eliminated as quickly as possible. The time to act was yesterday and we are already seeing these effects as evidenced by the floods in Detroit this summer, most recently in Tennessee over this past weekend, wildfires along the Western Coast, extreme heat events, severe drought. The list of examples goes on and on. Climate change poses very serious threats to public health and to the lives of all Americans, especially our most vulnerable, our kids, older adults, low-income communities, BIPOC communities, and people living with chronic diseases which is who I see in the hospital.

This is a public health emergency and we need to do everything we can to drive down these emissions from all sectors but especially the transportation sector. Research from Harvard University demonstrated this link between long-term exposure to air pollution and increased mortality from COVID-19.

Commenter: Mid-America Regional Council (MARC)

The Air Quality Forum commends the EPA for returning to a strong pathway towards emission reductions from light duty vehicles. With the transportation sector as the largest contributor of total greenhouse (GHG) emissions and light duty vehicles contributing to 58% of transportation sector GHG emissions in the United States, the proposed reductions are essential to curbing overall GHG emissions and are urgently needed. [EPA-HQ-OAR-2021-0208-0265-A1, p.1]

Commenter: Minault, Kent

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 241.]

Here in Knoxville, the city is attempting to take some strong measures to deal with the climate crisis and I was privileged to sit in on the Mayor's Climate Council a year ago when they started meeting and we received some information, graphs showing the greenhouse gas reductions from building efficiency and especially dramatic greenhouse gas reductions that came from changing all the street lights to LED, but it was another slide that really shocked us all because it showed that a spike in transportation emissions was four times greater than all those other reductions. In other words, despite our city's best efforts to this point, we were actually going backwards and transportation was the reason.

Throughout the United States, utilities are making strides at greenhouse gas reductions and so are municipalities and counties and I sat in yesterday on a webinar hosted by the previous speaker about school bus adoption, as well, and we're starting to take steps on that in Tennessee.

Commenter: Minnesota Pollution Control Agency (MPCA) and Minnesota Department of Transportation (MnDOT)

The need for strong, immediate action to reduce transportation GHG emissions. Minnesota is already feeling the effects of climate change. Our state is getting warmer and wetter, including more frequent intense, damaging rainfalls. Our winters are getting warmer, including especially noticeable declines in the frequency of our coldest days.1 Wildfires are becoming larger and more frequent in the United States and Canada, in part due to the influence of climate change. Wildfires in Minnesota and across the region can impact Minnesota's air quality.2 Just this year, Minnesota experienced a record-breaking 17 air quality alert days due to wildfire smoke, including the state's first daily Air Quality Index reading above 200, which happened six times during July and August.3

These changes impact the health of Minnesotans, our economy, and our ways of life.4 [EPA-HQ-OAR-2021-0208-0211-A1, pp.1-2]

The recently published Intergovernmental Panel on Climate Change report, 'Climate Change 2021: The Physical Science Basis,' states 'it is unequivocal that human influence has warmed the atmosphere, ocean and land' and that 'global warming of 1.5°C and 2°C will be exceeded during the 21st century unless deep reductions in CO2 and other greenhouse gas emissions occur in the coming decades.'6 Immediate and aggressive action is needed to reduce emissions and develop resiliency to climate impacts. Transportation is the largest emitter of GHG emissions in Minnesota7 and nationally8. [EPA-HQ-OAR-2021-0208-0211-A1, p.2]

EPA's current proposal has the potential to offer substantial benefits in terms of emissions reductions, both of GHGs and criteria pollutants, as well as economic strength. [EPA-HQ-OAR-2021-0208-0211-A1, p.2]

Commenter: Moore, Cinthia

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 116-117.]

Cleaning up vehicle pollution is one of the most important things we can do to fight climate change.

Commenter: Moore, Kenneth

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 321-322.]

The latest report by the IPCC has rightly called a Code Red for Humanity, but the climate scientists who prepared the report also offered the hopeful assessment that if the top emitting countries respond to the report's alarm bells with aggressive efforts to curb carbon pollution, the worst climate outcomes remain avoidable. This year's dreadful fire season has come about in part because of our use of fossil fuels has warmed the planet by one degree Celsius. The scientists predict that the intensity of extreme weather will be twice as bad compared to today's conditions if temperatures reach two degrees and quadruple as bad if global warming reaches three degrees.

AS Texas Climate Scientist Katherine Hague put it, "Again and again assessment after assessment, the IPCC has already made it clear climate change puts at risk every aspect of human life as we know it. We're already starting to experience those risks today, but we know what we need to do today to avoid the worst future impacts. The difference between a fossil fuel versus a clean energy future is nothing less than the future of civilization as we know it."

Commenter: Mothers and Others for Clean Air

Vehicle emissions cause health problems and death, and are a major source of greenhouse gases. The world is already experiencing dramatic effects of climate change, and lower emissions can prevent it from getting worse. [EPA-HQ-OAR-2021-0208-0491-A1, p. 1]

In addition, the most recent IPCC report declared that climate change is a Code Red for humanity. We need major action in reducing greenhouse gases, immediately. The U.S. is already seeing major effects of climate change, including heatwaves, intense hurricanes, wildfires, flooding, and more. There is no time to delay, it's a health emergency. Reducing vehicle emissions will have a rapid and sustained reduction in greenhouse gases, and will keep climate change from being so harmful. [EPA-HQ-OAR-2021-0208-0491-A1, p. 1]

Commenter: National Association of Clean Air Agencies (NACAA)

In its August 9, 2021, report, Climate Change 2021: The Physical Basis, a working group of the United Nations' Intergovernmental Panel on Climate Change (IPCC) concludes, 'It is unequivocal that human influence has warmed the atmosphere, ocean and land' and '[h]uman influence has warmed the climate at a rate that is unprecedented in at least the last 2000 years.' Further, it finds that '[g]lobal surface temperatures will continue to increase until at least the mid-century under all emission scenarios considered. Global warming of 1.5°C and 2°C will be exceeded during the 21st century unless deep reductions in CO2 and other greenhouse gas emissions occur in the coming decades.'3 Consistent with EPA's 2009 Endangerment Finding for GHGs, the authors of the IPCC report emphasize that the impacts of climate change go far beyond temperature increases, to include such things as extreme heat, marine heatwaves, heavy precipitation, droughts, tropical cyclones and reductions in Arctic sea ice, snow and permafrost – all of which will increase in frequency and intensity 'in direct relation' to intensifying global warming. They further report that under scenarios in which CO2 emissions increase, ocean and land carbon sinks are anticipated to be less effective at slowing the accumulation of CO2 in the atmosphere and, moreover, that many changes attributable to past and future GHG emissions 'are irreversible for centuries to millennia,' particularly those in the ocean, ice sheets and global sea level. No region of the world appears to be immune from the harmful effects of these future increases in climate change.

In NACAA's January 15, 2021 transition paper to the Biden-Harris Administration, the association wrote that 'state and local agencies in NACAA have implemented programs that made meaningful progress towards reducing GHGs, but a strong, comprehensive federal approach is essential for providing lasting nationwide reductions, regulatory certainty and a more protective baseline for all states to meet.' This proposed rule offers an opportunity for the federal government to take a step to advance this goal. [EPA-HQ-OAR-2021-0208-0255-A1, pp.2-3]

Commenter: National Coalition for Advanced Transportation (NCAT)

Air Quality and Climate Benefits of Federal Vehicle Standards and Electric Vehicles. Federal vehicle standards are central to addressing climate change as well as state, regional, and local air pollution problems, which in many cases are severe. It is clear that action is needed and, in the U.S., the transportation sector generates the largest share of GHG emissions (29 percent of 2019 GHG emissions).96 The transportation sector is also responsible for a significant share of criteria pollutant emissions, including over 55% of the nitrogen oxides (NOx) total emissions inventory in the U.S.,97 17.9 million tons per year of carbon monoxide, 133,000 tons per year of fine particulate matter (PM) PM2.5, 287,000 tons per year of PM10, and 1.8 million tons per year of volatile organic compounds (VOCs).98 These emissions have significant effects on communities around the country. In 2020, approximately 97 million people nationwide lived in counties with pollution levels above the primary National Ambient Air Quality Standards (NAAQS).99 In many areas of the country, pollution from vehicles is also the leading source of poor air quality. Further, PM2.5 and other transportation emissions are not evenly distributed and raise environmental justice concerns.100 Studies have shown that low-income and historically marginalized communities live disproportionately close high-traffic roads and highways, exposing these communities to greater levels of transportation emissions and associated impacts.101

Electric and other zero emission vehicles are a critically important, cost-effective strategy to reduce such air pollution, particularly in areas with severe air quality problems. All-electric vehicles produce zero direct emissions since these vehicles lack a tailpipe and thus have zero tailpipe emissions of GHGs or other pollutants. As a result, use of these vehicles in place of internal combustion engine vehicles can significantly improve air quality in urban areas. On average across the United States, annual life cycle emissions per vehicle are substantially lower for all electric vehicles as compared to gasoline vehicles. The emissions reductions are even greater in geographic areas that use relatively low-polluting energy sources for electricity generation.102 The share of electricity generated from renewable energy resources (e.g., wind, solar, geothermal, hydroelectric, and biomass) has dramatically increased in recent years to about 20% of total U.S. electricity generation in 2020.103 And the U.S. Energy Information Administration (EIA) predicts that this trend of significant increases in generation from renewable resources will continue.104 As the sources of electricity generation become cleaner, GHG and criteria pollutant emissions related to use of electric vehicles will further decline. Electric vehicles also emit less heat and produce less noise.105 Researchers from Harvard studied emissions from electric vehicles and conventional vehicles in large metropolitan statistical areas and concluded that in each area, air pollution mortality was significantly less from electric vehicles. 106 Others have found that, regardless of the electric vehicle adoption scenario they considered, ozone and PM2.5 concentrations declined with the adoption of electric vehicles. 107 A number of states are requiring that electric vehicle infrastructure be deployed in disadvantaged communities to ensure that those communities can reap the environmental and public health benefits of these technologies.108 [EPA-HQ-OAR-2021-0208-0239-A1, p. 15-16]

Commenter: National Parks Conservation Association (NPCA)

Nearly all 423 national park units are harmed by climate change impacts, including runaway heat waves, drought, sea level rise, coastal flooding, and wildfires. If we do not act quickly to mitigate emissions driving and exacerbating the climate crisis, we could very well lose many of our national park system's treasured namesake features, such as the glaciers in Glacier National Park, the Joshua trees in Joshua Trees National Park, the everglades in Everglades National Park, the saguaro cacti in Saguaro National Park, and the sequoias in Sequoia National Park. The myriad natural and cultural resources found within America's national parks system are priceless. We must do all we can to protect this heritage from climate change and pass on the legacy of our national parks unimpaired. [EPA-HQ-OAR-2021-0208-0291-A1, pp. 1-2]

To meet our national climate goals, protect our communities, and preserve our beloved public lands for generations to come, NPCA firmly believes we must move forward with standards that achieves a greater total tonnage GHG emission reduction than what would have been achieved under the previous Obama-era rules. Strong standards will help contribute to keeping global temperatures below a 1.5°C change from pre-industrial levels, which climate scientists believe is the key threshold necessary to prevent the worst climate impacts to our planet. [EPA-HQ-OAR-2021-0208-0291-A1, p. 2]

Commenter: Natural Resources Defence Council (NRDC)

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 24-25.]

This proposal comes at a critical moment. The recent Comprehensive Climate Assessment from IPCC shows that fossil fuel pollution, the burning of coal, oil, and gas, is driving a rapid and widespread destabilization of our planet. According to that science, levels of carbon dioxide in the atmosphere haven't been this high in two million years. We are in dangerous uncharted territory in terms of the human experience because of our continued reliance on dirty fossil fuels.

In this country the transportation sector is the top contributor to climate pollution and the window of time for us to slow further warming and limit the likelihood of dangerous tipping points is quickly closing. Maximizing those pollution reductions is critical and urgent because the climate crisis is here and now and it is fueling and a escalating public health emergency and endangering people all across the country.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 25-27.]

It's contributing to more severe wildfires, exacerbating dangerous heat waves and drought, spiking levels of air pollution from ozone, smog, and wildfire smoke, and super-charging rainfall and flooding. If we continue down this path without cutting harmful emissions, climate hazards will only worsen in frequency, intensity, duration, and reach in the future, and the costs of those hazards, which broke a new record last year, according to federal data, will skyrocket out of control.

Climate hazards have profound consequences that are in vivid display right now, both in people's pain and suffering and in the costly need for medical care. These health costs are difficult to track and quantify and so they are largely absent from public accounting of climate damages. For that reason, the health-related costs savings of climate pollution reductions are not included in the accounting of benefits from the proposed rule being considered today. Because of these missing savings, the reality is that the net benefits of a strong cars plan are even higher than those currently estimated by EPA.

I led a peer-reviewed analysis that estimated the health costs of 10 climate-sensitive events across the U.S. that occurred during just one recent year and using public data and EPA's valuation methods, we found that just those 10 events inflicted huge health harms, about 900 deaths, 21,000 hospitalizations, and 18,000 ER visits, took a total financial toll of $10 billion in damage.

Commenter: New Mexico Environment Department

The more stringent standards will help improve the air quality in those areas of New Mexico where ambient ozone concentrations are climbing. Reducing ozone precursors by reducing emissions from mobile sources, such as automobiles, will improve public health and protect the most vulnerable populations in overburdened New Mexican communities, including children, the elderly, and those with respiratory conditions. The more stringent standards help New Mexico address global warming as swiftly as possible. New Mexico has already been experiencing the impacts of climate change. Over the past half-century New Mexico has experienced a 2.0-degree Fahrenheit average rise in temperature and a 15 percent reduction in Rio Grande surface water flows leading to heavier reliance on mined groundwater.6 Surface water flows in the Rio Grande are projected to decrease by an additional 30% by mid-century.7 Increased temperatures combined with altered precipitation amounts will create conditions for catastrophic, landscape-scale vegetation changes, including hotter droughts, woody plant dieback, increased forest fires, and intrusion of invasive plants.8 [EPA-HQ-OAR-2021-0208-0205-A1][p.2]

Commenter: New York State Department of Environmental Conservation

Combatting climate change is the preeminent environmental challenge of our time. In the last two decades, the impacts of climate change have become indisputable. We are witnessing rising average temperatures, recording-setting high temperatures, as well as increasing frequency and severity of extreme weather events. Across the western United States and globally we are experiencing record breaking wildfires in terms of number and size, driven by prolonged drought and intense heat waves resulting from climate change. The'wildfires in the West have affected the entire nation as the smoke is carried across the United States resulting in harmful levels of air quality. Last month, New York. State, like much of the eastern United States, experienced several high intensity rainfall events leading to flash flooding and significant destruction of property and infrastructure in several regions of the state. Given the profound impacts of climate change, it is essential that efforts to combat climate change and reduce emissions are supported by strict federal programs and standards. Recognizing the urgency of the climate crisis, New York enacted the. Climate Leadership and Community Protection Act (CLCPA) in 2019, which codified the most aggressive emissions targets in the country, including reducing statewide carbon emissions 40% from 1990 levels by 2030 and achieving a carbon neutral economy by 2050. [EPA-HQ-OAR-2021-0208-0238-A1, p.1]

The proposed rule would not only achieve substantial greenhouse gas reductions but, when fully implemented, will also reduce the pollution that causes harmful ozone levels across the country, providing substantial public health benefits, particularly to communities overburdened by air pollution. [EPA-HQ-OAR-2021-0208-0238-A1, p.3]

Commenter: Northeast States for Coordinated Air Use Management (NESCAUM)

The Earth's climate is changing faster than it has in thousands of years, driven primarily by GHG emissions from human activities. Atmospheric concentrations of carbon dioxide are at their highest levels in at least two million years. Every region across the globe is experiencing extreme weather and climate-related events and devastating economic impacts. In the United States, severe drought and wildfires plague the western states, while more intense precipitation events and Atlantic cyclones are wreaking havoc in the South and Northeast states. Across the country, heat waves, associated with increased illness and death, are more widespread and more intense. Snow and ice are retreating. Seas are rising at an increasing rate and becoming more acidic. Ecosystems are being irreparably altered at an unprecedented rate and scale. Entire communities are being displaced. According to the Intergovernmental Panel on Climate Change (IPCC), unless there are immediate, rapid, and large-scale reductions in GHG emissions from all sectors, limiting global warming to 1.5 degrees Celsius or even 2 degrees Celsius, consistent with the goals of the Paris Agreement, will be impossible.3

Transportation is the largest source of GHGs in the nation and in the Northeast. Light-duty cars and trucks are the largest contributor to those emissions. LDVs are also a major source of particulate matter, air toxics, and ozone-forming pollutants that harm public health. Significant portions of the Northeast are not in attainment with federal ozone standards, and climate change is expected to exacerbate tropospheric ozone levels. Low-income communities, communities of color, and indigenous populations in the Northeast are particularly vulnerable to the effects of climate change and are disproportionately impacted by air pollution. Mitigating the climate crisis will require deep reductions in GHG emissions from motor vehicles. [EPA-HQ-OAR-2021-0208-0259-A1, pp. 2-3]

Commenter: Oliver, Shaina

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 71-72.]

As a tribal member, I have seen the devastation of the degraded lands and the dwindling of birds, butterflies, bees. Our ancestral lands continue to be sacrificed for mining, drilling, and infrastructure of all sorts. Pollution from cars and trucks, including heavy-duty vehicles, degrades quality air and threatens our health.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 73-74.]

I've been living with asthma since my infancy and worsening air quality due to heat and wildfires related to climate change have a direct impact on my ability to breath. Protective clean car standards will save lives in communities like mine because over 26 million people in the United States are burdened with asthma, including more than six million children.

With recent reports from the Intergovernment Panel on Climate Change confirms that climate change is widespread, rapid, and intensified, reconfirming the warnings Indigenous knowledge-keepers have been raising for years.

We must rethink of our next generation's future and livability standards and access to clean air, water, soil and health. President Biden has promised to address climate change and fight for environmental justice. By acting swiftly on clean cars, the Administration has taken an important step to tackling climate pollution from transportation.

Commenter: Pennoyer, Marguerite

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 29.]

The transportation sector is the largest source of greenhouse gas emissions in the United States. Gasoline- and diesel-powered cars, SUVs, and the increasingly-powerful pickup trucks pollute the air we breathe and drive climate change.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 32.]

Stronger standards are desperately needed. According to the Lung Association's Road to Clean Air Report, a nationwide transition to zero emission vehicles, including passenger cars, buses, and heavy-duty vehicles, will provide $72 billion in health benefits and a $113 billion in climate benefits annually by 2050. It would reduce dangerous air pollution, especially for communities that live near major roads, and in June, the Lung Association released a poll showing that 70 percent of American voters are in support of the Federal Government advancing policies to encourage a nationwide transition to electric vehicles. So in conclusion, climate change is threatening the health of my patients and my family. The Biden Administration must use all available tools to reduce carbon pollution. We must take immediate action at every level to address climate change and reduce greenhouse gas emissions.

Commenter: Pruitt, Katherine

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 156.]

As you know, earlier this month the world got some sobering news from the UN"s Intergovernmental Panel on Climate Change that affirmed in the starkest terms that we are in a deepening climate crisis. The UN Secretary General described the report as a Code Red for Humanity.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 157.]

The transportation sector is the largest source of greenhouse gas emissions in the United States. Gasoline and diesel-powered cars, SUVs, and pickup trucks pollute the air we breathe and drive climate change.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 158.]

Again, climate change is a health emergency and the Biden Administration must use all available tools to promote carbon pollution reductions. There is no time to delay.

Commenter: Rauch, Molly

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p.34.]

The transportation sector is the largest source of climate pollution in the U.S. Cleaning up this pollution is one of the most important things we can do to fight climate change.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp.35-36.]

The latest IPCC report, as you've heard, released earlier this month has affirmed that we are living in an unequivocal climate crisis, but we don't need a UN report to tell us what so many of us are experiencing in our own communities. Searing heat waves, staggering wildfires, terrible floods, unprecedented rainfall, choking drought, this affects us all. My teenage son is an athlete who trains outside in the summer. He's playing football here in D.C. where we live and his team started daily practices last week. We've had several heat emergency days and today is a Code Orange air day for ozone.

We have historical average of 11 dangerously hot days each year in D.C., but in the 2020s, in this decade, we're projected to have 18 every year and by the 2050s heat emergencies in D.C. are projected to increase to 30 to 45 days each and every year. This is hard on my son's body and it will harm the health of athletes like him in the future.

At Moms Clean Air Force, we appreciate that the Biden Administration is prioritizing climate action and has pledged a 50 percent reduction of climate pollution from 2005 levels by 2030. Now EPA must finalize the strongest possible standards to cut pollution from cars.

Commenter: Remilien, Sandra

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 119.]

Transportation is the biggest source of greenhouse gas emissions and makes up 20 percent of emissions. (Audio glitch) makes up about 4.6 metric tons of carbon monoxide. (Audio glitch) creates about 8,887 rems of CO2.

Commenter: Sainz, Columba

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 226.]

It is a step in the right direction to address the climate emergency. Pollution from cars not only causes climate change, it harms my family's health and my community's. It threatens our health without mentioning families with no insurance, undocumented immigrants with no health access, low-wealth, and BIPOC communities experience disproportionate harm from dirty vehicle pollution, living through racial disparities in rates of asthma and other respiratory illnesses.

Commenter: Shevelew, Jonathan

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 116.]

We need to recognize that we are faced with a climate crisis and therefore need to act as if this is a crisis and not a minor inconvenience that we can address gradually over a period of time. These initiatives should have been implemented 20 years ago. To now decide to accept the 20-year transition like GM is proposing is foolhardy and will have devastating results, especially when we already have manufacturers that have demonstrated that achieving a 100 percent reduction in GHG is possible today.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 118.]

There is also a political reality to consider. While currently the government is recognizing the climate crisis we are faced with, those positions can change with future administrations. In order to assure that we don't waver from this path, the EPA needs to put rules in place that are aggressive and which need to be acted on immediately.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 119.]

We will be held accountable and we'll be judged for our actions in this crisis by subsequent generations. What we do today will affect the quality of life for this planet for many years and it's time for us to be the adults in the room.

Commenter: Sierra Club

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 31-32.]

I want to go into the why behind these standards. This rule would be our nation's strongest climate tool if EPA gets it right. This summer has been devastating for our communities. Our friends, family and neighbors have been on the front lines of heat waves, of wildfires, flooding, and more, and many times, you know, people speak about climate action for future generation. While the well-being of children growing up in this decade is of big importance, the reality of that we're experiencing the impacts of climate crisis right now and while all generations are impacted, not all communities are impacted the same way. All too often the communities least responsible for our climate pollution are facing the burdens of the crisis and suffering from toxic air pollution, as well. So the latest IPCC report states in the strongest way ever that the climate crisis will continue to rapidly worsen unless the world slashes climate= disrupting pollution as quickly as possible in the next decade.

Transportation pollution is our nation's worst offender when it comes to the climate crisis and this rulemaking, if strengthened, can put us back on track and to have strong standards and offer protection for communities in New York and across the nation. As proposed, this rule would result in much less pollution reduction than the auto industry agreeing to in 2012, despite the enormous progress that's occurred on electric vehicles and the climate disasters we have seen since then.

Commenter: Smith, Rita L.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 103.]

My testimony is about my granddaughter Marnie born with asthma. Clean air is a good start by allowing the car industry to build more efficient cars. The transportation industry pollutes the air, causing my granddaughter to keep an asthma pump with her and one at school.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 104.]

The change I would like to address is for the automotive industry, the manufacturers of cars, trucks, military vehicles, farm machinery, actually all vehicles to eliminate gas emission from fossil fuel.

Commenter: Southern Environmental Law Center

The transportation sector is the largest source of climate change-driving GHG emissions in the U.S. and is causing tremendous harm. As noted in the Federal Register notice, "[t]he transportation sector is the largest U.S. source of GHG emissions, representing 29 percent of total GHG emissions. Within the transportation sector, light-duty vehicles are the largest contributor, at 58 percent, and thus comprise 17 percent of total U.S. GHG emissions."9 This is also true for most states in the South. The transportation sector is the largest source of carbon dioxide (CO2)—a significant component of GHGs10—in every state in SELC's region except for Alabama, where it is the second largest source.11

GHG emissions are a major driver of climate change, and the U.S. is already experiencing climate change impacts. Sea level rise is affecting coastal communities around the country, and the South is particularly vulnerable. For example, the Hampton Roads region in Virginia has one of the highest rates of sea level rise on the East Coast, with scientists predicting a rise of 1.5 to 2 feet by 2050.12 The frequency of extreme weather events, including heavy precipitation, high tides, storm surges, and heat waves, also continue to increase.13 These weather events can lead to public emergencies and infrastructure disruptions, stressing health services and communities. [EPA-HQ-OAR-2021-0208-0244-A1, pp. 2-3]

There is also an economic cost to climate change. Studies have found that climate change could cost the U.S. approximately 1.2 percent of the gross domestic product for every additional degree of warming, with the South expected to experience greater impacts than other parts of the country.[16] [EPA-HQ-OAR-2021-0208-0244-A1, p. 3]

In Virginia, for example, it has been estimated that the widespread adoption of zero-emission vehicles by 2050 would yield more than $1.3 billion in avoided annual health costs—including costs of 115 premature deaths, more than 1,780 asthma attacks, and nearly 8,190 lost work days.[38] Similar or better avoided annual health costs have been estimated for other states in South if zero-emission vehicles are widely adopted.[39] [EPA-HQ-OAR-2021-0208-0244-A1, p. 6]

[39] For example, Georgia could see almost $1.7 billion in avoided annual health costs by 2050, including costs of 147 premature deaths, 2,665 asthma attacks, and over 12,200 lost work days. Id. North Carolina could see over $1.6 billion in avoided annual health costs by 2050, including costs of 141 premature deaths, 2,384 asthma attacks, and over 10,000 lost work days. Id.

Commenter: Spencer, Sam

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 150.]

Charlotte's growth is generating over 25 million new car trips every year and that's only from rezoning, not by buy-right development. Conservatively, that's tens of millions of kilograms of new carbon dioxide emissions in the Charlotte region every year. It's a major equity issue for Charlotte.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 151-152.]

The Number 1 source of carbon emissions in Charlotte is vehicle trucks. We can't make significant progress on emissions reductions without a strong federal rule and, unfortunately, the EPA's proposed rule doesn't go far enough.

Commenter: Spirit of the Sun

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 134.]

The transportation sector is the largest source of carbon pollution in the U.S. We need to clean up vehicle pollution. Honestly, it's one of the most important things we can do for climate change and the climate impacts that disproportionately impact the communities.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 135.]

We need to strengthen proposals from the EPA and we need clean car standards now. In all honesty, President Biden has promised to address climate change and fight for environmental justice, but that needs to have radical and revolutionary actions now.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 136.]

We need to address climate change by protecting our children's future and little lungs. In any way that you can have clean car standards, I advise you to do this now for future generations.

Commenter: Stein, Karen

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 276-277.]

Iowa has lost shade and wildlife habitat for decades to come. This year, we have endured an extremely hot summer. People's electric bills due to air conditioning usage are high and this is especially difficult for communities in low-wealth neighborhoods. Iowa's skies have been hazy most of the summer due to the wildfires in the Western United States and I am experiencing breathing difficulties for the very first time in my life.

I know children with asthma in the Latino communities in Iowa who have hardly been able to play outdoors this summer due to the haze and the heat and they badly needed to be able to play in the midst of this pandemic. I said that all of what I'm describing is due to the climate crisis which we're experiencing, which is made worse by vehicular pollution and many times Latino communities are not aware of the causes and don't have access to the tools that would allow them to take action while at the same time they are being among the most affected by climate change and pollution.

Commenter: Stout, Linda

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 119.]

Additional cars means more days with unhealthy air quality and more hazardous greenhouse gases and increased health problems.

Commenter: Sturza, Taisia

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 170.]

Transportation is the largest source of carbon emissions in the U.S. and it's critical that we both make our gasoline-powered cars and trucks more efficient and that shift rapidly to electric vehicles. If the vehicles themselves had stricter emissions standards and thus lower emissions, then the health impacts on the community would be much lower, as well.

Commenter: Trombetta, Nick

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 216-217.]

In light of the recent report from IPCC, it is clear more than ever that climate change poses a significant threat to human existence on earth and must be addressed in the strongest way possible. This means that the EPA must take a strong stance on climate change, and clean cars standards is a great way to start. This will send a message to the rest of the world that America is ready to be a climate leader.

Commenter: Uberuaga, Michelle

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 284.]

Montana's drought is killing farmers. Climate change is impacting every part of our lives, our economy, and our way of life, and our kids are counting on you to take action to protect their future.

Commenter: United Methodist Women

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 131.]

The most recent IPCC report notes that human-caused climate change is fueling cataclysmic changes to our planet and warns that limiting global warming will be beyond reach in the next two decades without immediate, rapid, and large-scale reductions in greenhouse gas emissions. The U.S. has a moral responsibility to drastically reduce our own emissions. We must do our fair share. While we are only four percent of the world's population, the U.S. has contributed more than 25 percent of cumulative greenhouse gas emissions and is the biggest contributor.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 132.]

Because transportation is the largest climate-polluting sector in the U.S., by implementing the strongest possible fuel economy standards, EPA can ensure that automakers and bus and technology to make more efficient vehicles rapidly shift to electric vehicles significantly reduce greenhouse gas emissions and reduce co-pollutants that will protect the planet and our health.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 133.]

Passing the strongest standards to reduce tailpipe emissions will not only protect my father's life but the 103,000 people living with COPD and over 36,600 children living with pediatric asthma and the 1.6 million people of color in Queens County alone.

Commenter: Valentine, Lucia

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 265.]

Growing up on the basic of the Potomac River, I experienced exacerbated climate disasters, such as flooding, due to the negative impacts that greenhouse gases have on our environment. This is in major part due to the lack of clean vehicle standards. The pollution from cars not only causes climate change but it also (audio glitch) the future of our children, families, and communities all across our beautiful state of West Virginia.

Commenter: Verdin, Langston

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 265-266.]

The transportation sector is the largest source of greenhouse gas emissions in the state -- in the United States. Gasoline and diesel-powered cars, SUV, and pickup trucks pollute the air we breathe and drive climate change.

Commenter: Whyte, Yolanda

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 142-143.]

As you know, Atlanta is reported to have amongst the worst urban sprawl in the nation and we're known for our traffic congestion. We have so many highways around and through the city that it's hard to avoid traffic pollution. Right about now it's hot, humid, and it also has an odor particular to the more rural areas that I frequently visit. Many parts of the city are considered urban heat islands which are disproportionately affected by our changing climate. We are learning more about heat-related illnesses in which some, like heat stroke, are fatal, especially for babies and teen athletes, and some heat-related illnesses increase the risk of pregnancy complications and adverse birth outcomes, like prematurity, low birth weight, and stillbirths, thus worsening health disparities of maternal mortality and infant mortality.

This morning's Air Quality Index for the part of the city where I live was 108. This is in the orange range considered unhealthy for sensitive groups. Unfortunately, there are no public health warnings informing vulnerable residents, such as babies, seniors, those with heart or lung disease, of this risk or the need to stay indoors, close the windows, and take measures to improve indoor air quality.

Commenter: Wisconsin Department of Natural Resources

EPA’s rule would provide critical support to Wisconsin’s efforts to reduce GHG emissions and address climate change. Transportation emissions are responsible for a significant percentage (24%) of GHG emissions in Wisconsin. Through executive action, Governor Tony Evers has committed Wisconsin to fulfill the carbon reduction goals of the 2015 Paris Climate Accord,1 and the state’s December 2020 climate change report includes numerous actions that address the impacts of GHG emissions from transportation, such as development of a statewide electric transportation plan.2 However, state authority to address GHG emissions from vehicles and other mobile sources remains very limited. EPA’s action is therefore critical to ensure Wisconsin can achieve its climate-related goals. [EPA-HQ-OAR-2021-0208-0223-A1, p.1]

1 See Gov. Evers’ Executive Order 38 and Executive Order 52, available at: https://dnr.wisconsin.gov/climatechange/solutions.

2 Report is available at: https://climatechange.wi.gov/Pages/Home.aspx.

Commenter: Wiste, Leah

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 85-86.]

This summer, the climate crisis brought another thousand-year flood to Detroit where I live, our second since 2014. In June, an overnight rainfall of seven inches, twice the amount of rain Detroit receives for the whole month. It shut down I-94 for days and flooded thousands of basements. $96 million in relief has been approved by FEMA as of July 15th. Beyond the immediate loss in damages, those whose homes were impacted are likely to experience health consequences from lingering mold and sewage which are especially dangerous for those already made vulnerable by asthma, COVID, and other diseases. Since transportation emissions are the largest source in U.S. climate pollution, clean car standards must be commensurate with the climate emergency we are experiencing right now.

Commenter: Zewadski-Bricker, Edith

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 228-230.]

As leaders, you have the grave responsibility to alleviate the climate crisis, to protect the poor here and around the world, to protect generations to come, to protect our nation's sovereignty, and ultimately to save the planet. The current Administration has recognized the urgent need for increased vehicle efficiency and limited vehicle planet-warming emissions is the very reason. The Environmental Protection Agency must do no less.

Please remember the climate crisis is the Number 1 issue facing the nation and the world. Unfortunately, only the policymakers, not individual citizens, can tackle these issues in a significant way. I am here because global warming is slated to flood the Florida Keys, my home. Here in South Florida, the Miami-Herald headline reads Sea Rise under Scrutiny in Condo Collapse. How many condos will collapse as the changing climate exacerbates the damage from hurricanes? How much will state and local governments spend uselessly fighting sea level rise?

I implore you to see past the politics, past the powerful, past the profits, and even past the present to the impact of your decisions on the future. As long as I'm here now, consider the poor and inner city Miami whose children are already dying from asthma and pneumonia and COVID-19 as a direct or indirect result of diesel fuel bus and gasoline vehicle emissions. Just today in our local paper, we read about the farmers in Homestead concerned with saltwater intrusion into South Florida's water supplies from sea level rise and an increase in pests and disease that thrives in warmer climates. In the Herald yesterday, we read about outdoor workers subject to increased temperatures.

EPA Response

The comments above in section 14 did not necessitate individual responses as they did not request changes to the proposed rule, nonetheless EPA acknowledges these comments expressing concern for health and climate impacts associated with GHG and non-GHG emissions from the transportation sector. Many of the commenters note studies linking harm to human health and the environment from these emissions.

EPA notes that this rule will result in significant reductions in air pollutants and substantial benefits for public health. As described in the preamble Section 1, the benefits include climate-related economic benefits from reducing emissions of GHGs that contribute to climate change, reductions in energy security externalities caused by U.S. petroleum consumption and imports, the value of certain particulate matter-related health benefits, the value of additional driving attributed to the rebound effect, and the value of reduced refueling time needed to fill a more fuel-efficient vehicle. Through 2050 the program will achieve more than 3.1 billion tons of GHG emission reductions.

Commenter: American Enterprise Institute (AEI)

Even under the assumptions and analytic/quantitative estimates provided in the Proposed Rule and the accompanying Regulatory Impact Analysis, the Proposed Rule cannot satisfy any plausible benefit/cost test, for two central reasons. First: The reduction in GHG emissions Asserted by EPA attendant upon implementation of the Proposed Rule would yield a global temperature reduction in 2100 of 0.0013 degrees C at most, applying the EPA climate model under a set of assumptions that exaggerates the effects of the Proposed Rule. Second: In economic terms, again under the explicit EPA analysis and assertions, the annual increase in global real GDP would be a maximum of 0.075 percent, a figure that cannot be statistically significant given the normal variation in global GDP growth. [EPA-HQ-OAR-2021-0208-0254-A1, p. 2]

The use of asserted global rather than domestic environmental benefits of the Proposed Rule is illegitimate, and would yield an obvious free-rider effect and important inefficiencies. [EPA-HQ-OAR-2021-0208-0254-A1, p. 2]

The Near-Zero Climate and Economic Benefits of the Proposed Rule

Table 2 in the draft Regulatory Impact Analysis2 asserts that the carbon dioxide (CO2) target in the Proposed Rule for MY 2026 is a reduction of 5.0 percent combined for cars and light trucks, as opposed to the 1.7 percent target in the SAFE rule to be replaced. Because the national fleet will evolve over time, in particular after MY 2026, let us quadruple the former parameter to 20 percent as the assumed long run reduction in GHG emissions attendant upon the Proposed Rule. The EPA reports that U.S. GHG emissions from the transportation sector overall are 29 percent of all U.S. GHG emissions.3 Let us assume for discussion purposes that all such emissions from the transportation sector are produced by cars and light trucks, ignoring heavy vehicles, airplanes, and sea transport. The notional 20 percent reduction in U.S. GHG emissions would represent a decline — other parameters held constant — of 5.8 percent in total U.S. GHG emissions. Because U.S. GHG emissions are 12.6 percent of global GHG emissions, the global emissions effect would be seven tenths of 1 percent.4

Let us apply the EPA climate model so as to derive an estimate of the global temperature impact of that reduction in GHG emissions, under a set of assumptions that exaggerate the future temperature/climate effects of reductions in GHG emissions.5 The predicted temperature effect in 2100 would be about 13 ten-thousandths of one degree C. For purposes of policy analysis, that number is effectively zero; and because the standard deviation of the surface temperature record is 0.11 degrees C, that notional effect would not be measurable.6 Nor can the Proposed Rule be justified as one component of a larger effort to reduce GHG emissions: The effect of a net-zero emissions policy implemented immediately by the U.S. would be 0.173 degrees C, under an identical set of assumptions. Accordingly, even if the assumption of a 20 percent long run reduction in U.S. GHG emissions proves to be understated by some large factor, the same benefit/cost analytic conclusion would be warranted. Nor would an international perspective change this conclusion: The national promises (‘Nationally Determined Contributions’) incorporated into the Paris agreement adopted at the 2016 21st Conference of the Parties, if taken seriously (they are not7), would yield a temperature reduction in 2100 of 0.178 degrees C. A GHG emissions reduction of 50 percent by China, under the same set of favorable assumptions, would yield a temperature reduction in 2100 of 0.184 degrees C. [EPA-HQ-OAR-2021-0208-0254-A1, pp. 3-4]

In the larger context, the claim of nontrivial climate benefits from reductions in GHG emissions must be based upon assertions of nontrivial climate effects — a climate ‘crisis’ either upon us or looming — from such emissions. But there is no evidence — none — of a climate ’crisis’ attendant upon increasing atmospheric concentrations of GHG, which can be expected to create effects both adverse and positive, the net effects of which are highly uncertain.

That anthropogenic climate change is ‘real’ — that increasing GHG concentrations are having detectable effects — is incontrovertible, but that does not tell us the magnitude of the observable impacts, which must be measured empirically. Temperatures are rising, but as the Little Ice Age ended no later than 1850, it is not easy to separate natural from anthropogenic effects on temperatures and other climate phenomena.19 The latest research in the peer-reviewed literature suggests that mankind is responsible for about half a degree of the global temperature increase of about 1.5-1.7 degrees C of global warming observed since 1850.20

The ‘crisis’ assertions are unsupported by the evidence reported in the peer-reviewed, official, or scientific literature. There is little trend in the number of ‘hot’ days for 1895–2017; 11 of the 12 years with the highest number of such days occurred before 1960.21 NOAA has maintained since 2005 the U.S. Climate Reference Network, comprising 114 meticulously maintained temperature stations spaced more or less uniformly across the lower 48 states, 21 stations in Alaska, and two stations in Hawaii.22 They are placed to avoid heat island effects and other such distortions as much as possible; the reported data show no trend over the available 2005–20 reporting period.23 A reconstruction of global temperatures over the past one million years, using data from ice sheet formations, shows that there is nothing unusual about the current warm period.24

Global mean sea level has been increasing at about 3.3 mm per year since satellite measurements began in 1992. The tidal-gauge data before then show annual increases of about 1.9 mm per year, but that comparison does not show an acceleration in sea-level rise because the two datasets are not comparable. The tidal gauges do not measure sea levels per se; they measure the difference between sea levels and ‘fixed’ points on land that in reality might not be fixed due to seismic activity, tectonic shifts, land settlement, etc. Accordingly, the data are unclear as to whether there is occurring an acceleration in sea level rise; it is reasonable to hypothesize that there has been such an acceleration simply because temperatures are rising due to both natural and anthropogenic influences, as noted above, and such increases should result in more melting ice and the thermal expansion of water. But because rising temperatures are the result of both natural and anthropogenic causes, we do not know the relative contributions of those causes to any such acceleration.25

The Northern and Southern Hemisphere sea ice changes tell different stories; the arctic sea ice has been declining, while the Antarctic sea ice has been stable or growing.26 U.S. tornado activity shows either no trend or a downward trend since 1954.27 Tropical storms, hurricanes, and accumulated cyclone energy show little trend since satellite measurements began in the early 1970s.28 The number of U.S. wildfires shows no trend since 1985, and global acreage burned has declined over past decades.29 The Palmer Drought Severity index shows no trend since 1895.30 U.S. flooding over the past century is uncorrelated with increasing GHG concentrations.31 The available data do not support the ubiquitous assertions about the dire impacts of declining pH levels in the oceans.32 Global food availability and production have increased more or less monotonically over the past two decades on a per capita basis.33 The IPCC itself in the Fifth Assessment Report was deeply dubious about the various severe effects often asserted to be looming as impacts of anthropogenic warming.34

Any rigorous analysis of the future effects of GHG emissions clearly should incorporate both adverse and beneficial impacts. The adverse effects of such emissions may prove serious, but there is a very large literature on the important benefits of slightly or moderately warmer temperatures. Examples are planetary greening, increased agricultural productivity, increased water use efficiency by plants, and reduced mortality from cold.35 [EPA-HQ-OAR-2021-0208-0254-A1, pp. 6-9]

EPA Response

EPA disagrees with many of the commenters’ contentions. EPA did not conduct climate modeling in support of this rulemaking and thus has no basis to evaluate the commenter’s estimate of temperature change. EPA notes that it is required to establish standards to reduce air pollution that endangers public health and welfare, taking into consideration the cost of compliance and lead time. As discussed in Section VI of the preamble, this is the approach EPA took in setting these standards. EPA did take note of the results of the benefit-cost analysis in the RIA, prepared under E.O. 12866, including the possibility that the net benefits could be higher or lower than presented, and finds that the estimated benefits exceeding costs reinforces the conclusion that the standards are appropriate. Thus, EPA disagrees that a change in the estimated benefits would have necessarily resulted in a meaningful change in how the impacts of the final standards compare to the alternatives, or in selection of different standards.

Commenter: Hill, Pablo

To Whom it may concern, my name is Pablo Hill and I would like to present my ideas and comments for EPA-HQ-OAR-2021-0208-0116. My goal today is to present peer-review confirmed data to better assist with the proposed rule for light duty vehicle with regards to GHG emissions. As the proposed rule relies on data with respect to weather, health, climate, etc. I will reference these topic and these topic only. And while the EPA uses the IPPC data to help draw its conclusion as to why it's position should be taken, policy and decision makers must make the best decision based on proven ideas that completes the stated goal(s) for the society while carefully considering the cost with those actions, not political ideology. I would recommend the readers please see the link provide:

https://www.visualcapitalist.com/how-much-oil-electric-vehicle/.

Each one of these links offer detail analysis necessary for all to make a proper comparison with respect to the EPA Proposed Rule and data. I will remind you all that while the EPA draws on IPPC and several other climate and weather agencies, institutions, think tanks, advice groups, etc. The issue at hand is not about climate change, climate science, or climate propaganda. The issue at hand is the stringiness of light duty emission rules for the future and the cost associated with implementation of the EPA rules to achieve a reduction in GHG. The links provided are use as reference for comparison and education purposes only and nothing more. Now I will state that I am not in favor of further regulations as defined by the EPA for GHG standards. The cost analysis are extremely optimistic. While the EPA does make references to health cost, which appears to be the main cost factor used to justify their proposed rule, the is no examples or real world analysis of this just inferences. Take from example Nox, Volkswagen emissions scandal of 2015 cost the shareholder and stakeholders over 9 billions dollars in fines, fees, and penalties, yet A peer reviewed study published in Environmental Research Letters estimated that approximately 59 premature deaths will be caused by the excess pollution produced between 2008 and 2015 by vehicles equipped with the defeat device in the United States, the majority due to particulate pollution (87 percent) with the remainder due to ozone (13 percent). The study also found that making these vehicles emissions compliant by the end of 2016 would avert an additional 130 early deaths. America has 330 million inhabitants, 59 deaths is not even a rounding error when compare with the benefits associated with Volkswagen companies and products they produce. [EPA-HQ-OAR-2021-0208-0515, p. 1]

EPA Response

While hard to follow, it appears that the commenter contends that the benefit-cost analysis has an inadequate benefit basis, however the commenter only cites the VW defeat device case to support that claim which is not relevant to our analysis. EPA notes that it determined what standards were appropriate in light of the need for emissions reductions, the cost of compliance and lead time, and found the results of the benefit-cost analysis in the RIA provide additional support for its conclusions. See Preamble Section VI.

Commenter: Taxpayers Protection Alliance

For those added expenses there would be little environmental benefit. American Action Forum regulatory policy director Dan Bosch notes, 'The EPA's analysis projects greenhouse gas emissions reductions of 2,200 million metric tons (MMT) if the proposed rule is finalized…According to the most recent calculation by the EPA, the United States emitted more than 6,500 MMT of greenhouse gases in 2019, with about 1,900 MMT from transportation sources. The projected reductions from the proposed rule, therefore, are about one-third of the annual nationwide total but spread over 28 years.'[EPA-HQ-OAR-2021-0208-0202-A1, p.1]

EPA Response

EPA disagrees with the commenter and believes there are substantial environmental benefits, as discussed in the Regulatory Impact Analysis and Preamble to the Final Rule. As described in those documents, this rule will result in significant reductions in air pollutants and substantial benefits for public health. The benefits include climate-related economic benefits from reducing emissions of GHGs that contribute to climate change (3.1 billion tons of GHG emissions through 2050), reductions in energy security externalities caused by U.S. petroleum consumption and imports, the value of certain particulate matter-related health benefits, the value of additional driving attributed to the rebound effect, and the value of reduced refueling time needed to fill a more fuel-efficient vehicle.

Commenter: Tesla

Protecting the Public Health and Welfare Requires 100% EV Sales By 2030. Recently, President Biden has acknowledged that we are at 'code red' because of the increasing impacts of climate change.34 He has further asserted:

Climate change has had a growing effect on the U.S. economy, with climate-related costs increasing over the last 4 years. Extreme weather events and other climate-related effects have harmed the health, safety, and security of the American people and have increased the urgency for combatting climate change and accelerating the transition toward a clean energy economy.35

And as the EPA confirms in its proposal, 'the transportation sector is the largest U.S. source of GHG emissions, making up 29 percent of all emissions. Within the transportation sector, light-duty vehicles are the largest contributor, 58 percent, to transportation GHG emissions in the U.S.'36 Indeed, there are compelling and extraordinary air pollution, climate change, and public health and welfare impacts to the country that result from these emissions, and they necessitate the rapid and complete electrification of the nation's transportation system.37 [EPA-HQ-OAR-2021-0208-0278-A1][pp.5-6]

Newer and Greater Urgency to Act in Addressing the Climate Crisis. As EPA notes, 'addressing the climate crisis will require substantial reductions in GHG emissions from the transportation sector.'75 In 2009, the EPA made its Endangerment Finding76 and subsequently established LDV standards at the requisite level of stringency to meet its statutory mandate to protect the public health and welfare demanded by the finding.77 The agency's failure to improve upon the stringency of a standard than what was proposed in 2012 is made more befuddling by the admission that the science about endangerment from climate change has significantly deepened and reveals more immediate and dire warning about the impact it will have on the nation.

As EPA recognizes 'major scientific assessments continue to be released that further advance our understanding of the climate system and the impacts that GHGs have on public health and welfare both for current and future generations.'78 Among the most recent of these studies is the new Intergovernmental Panel on Climate Change's (IPCC) peer reviewed science findings that, inter alia: '[h]uman influence has warmed the climate at a rate that is unprecedented in at least the last 2000 years;'79 'global warming of 1.5°C and 2°C will be exceeded during the 21st century unless deep reductions in CO2 and other greenhouse gas emissions occur in the coming decades;'80 and that 'every tonne of COâ‚‚ emissions adds to global warming.'81 Other recent reports have confirmed the imperative to act and reduce GHG emissions82 and include the agency's own analysis of the disproportionate vulnerability of racial and ethnic minority communities to the greatest impacts on underserved and pre-dominantly non-White communities.83 One recent study found that for each 4,434 metric tons of carbon dioxide emitted in 2020 one excess death will be caused globally between 2020 and 2100.84 Indeed, in early September, leading medical and public health professionals released an emergency call to action addressing the public health impacts of climate change.85

Embedded within these scientific findings is the heightened imperative to reduce GHG emissions and to 'dramatically reduce and electrify energy demand for transportation'86 and include 'the expansion of electric vehicles.'87 Indeed, as the UN has recently highlighted, '[i]n terms of specific technologies that Parties intend to use for achieving their adaptation and mitigation targets, the most frequently identified were energy efficient appliances and processes, renewable energy technologies, low- or zero-emission vehicles and hydrogentechnologies.'88 These findings only add to the overwhelming scientific consensus that the endangerment is accelerating and the U.S. and other countries need to set performance standards that utilize EV technology to mitigate the endangerment and GHG emissions rapidly.89[EPA-HQ-OAR-2021-0208-0278-A1][pp.10-11]

34 President Biden, Remarks by President Biden on the Administration's Response to Hurricane Ida (Sept. 7, 2021) ('They all tell us this is code red; the nation and the world are in peril. And that's not hyperbole. That is a fact. They've been warning us the extreme weather would get more extreme over the decade, and we're living it in real time now.'); Remarks by President Biden Before the 76th Session of the United Nations General Assembly (Sept. 21, 2021)('This year has also brought widespread death and devastation from the borderless climate crisis. The extreme weather events that we have seen in every part of the world — and you all know it and feel it — represent what the Secretary-General has rightly called 'code red for humanity.' And the scientists and experts are telling us that we're fast approaching a 'point of no return,' in the literal sense.').

EPA Response

EPA acknowledges these comments, and notes that this rule will result in significant reductions pollutants and substantial benefits for public health. Through 2050 the program will achieve more than 3.1 billion tons of GHG emission reductions. Regarding the comment about improving upon the 2012 standard, the final standards are more stringent than the 2012 standards in MY 2026 and beyond, as discussed in the preamble section I and in response to comments in section 2.2 of this response to comments document. In addition, EPA set the standards, as required under section 202, taking into account lead time.

GHG Emissions Benefits

The proposed rulemakings do not include recent advances in scientific analysis of the social cost of carbon ("SCC"). Before the Agencies consider any changes in the SCC, we urge the Administration to undertake a rigorous process that includes independent scientific peer review and ample opportunity for public comment. The Agencies should also use consistent discount rates for costs and benefits in any given calendar year.

From a societal perspective, Auto Innovators believes that GHG control is the most compelling benefit category that supports stricter CAFE and GHG standards.182 However, the proposed rulemakings do not include recent advances in scientific analysis of the social cost of carbon.183 We are aware that the Administration intends to update estimates of the social cost of carbon emissions based on new scientific developments. However, before the Agencies consider any changes in the SCC, and we urge the Administration to undertake a rigorous process that includes independent scientific peer review and ample opportunity for public comment.

In reviewing how the SCC was applied in the RIAs, Auto Innovators noticed an inconsistency in how SCC is applied to future benefits and costs. A basic principle of benefit- cost analysis is that the same rate of discount should be applied to any future benefit or cost that is experienced in the same calendar year. However, in some of the analyses reported, the discount rate for a climate-related benefit (in, for example, 2040) is discounted at a smaller rate (e.g., 2.5%) than the discount rates (3% or 7%) applied to local-air quality benefits and energy- security benefits in 2040. There may be a valid rationale for applying a smaller discount rate for long-term climate-related impacts, but coherence demands that the lower rate should be applied to all impacts that occur in those distant years. This discrepancy could be resolved by applying the 2.5% rate only in those years that transcend the analytic time horizon for the other benefit and cost streams (e.g., post-2050 or 2060). Alternatively, if a lower discount rate is applicable after a specific year (say) 2040, when multiple benefit and cost items are affected, then that lower discount rate should apply to all benefit and cost items that occur starting 2040.

One important step to clarifying the confusion is for both RIAs to provide a clear statement of the analytic time horizon for benefit and cost accounting. The RIAs state clearly that model years through 2050 are included in some of the modeling but the year 2050 is not the end of the analytic time horizon. The SCC estimates used by the Agencies presume that a ton of CO_2 emitted in 2020 can have welfare impacts far into the future, as IPCC estimates that most released CO_2 remains in the atmosphere between 5 and 200 years.184

Thus, the reader needs to know how long the analytic time horizon is, and what procedures for discounting are employed throughout the time horizon. Publishing the undiscounted time streams for each benefit and cost category as an appendix to the RIA would allow readers to perform their own sensitivity analyses with different rates. Whatever decision is made, benefit and cost impacts in the same calendar year should be subjected to the same discount factor. [EPA-HQ-OAR-2021-0208-0116]

EPA Response

EPA follows applicable guidance and best practices when conducting its benefit-cost analyses, including OMB Circular A-4 and EPA's Guidelines for Preparing Economic Analyses. We therefore consider our analysis methodologically rigorous and a best estimate of the projected benefits and costs associated with the final rule.

With respect to the social cost of greenhouse gases, EPA recognizes the limitations and uncertainties associated with the current interim IWG estimates and underlying methodology. EPA participated in the IWG and has carefully reconsidered for this rulemaking the February 2021 TSD,[58] the underlying studies discussed in the TSD and the issues raised by commenters. EPA concludes that, as noted in Section 3.3 of the RIA and elsewhere in this RTC, the discussions in the TSD represent appropriate consideration of the various issues (e.g., appropriate discount rate and scope) and the resulting estimates of the TSD represent appropriate, if conservative, estimates for purposes of this rulemaking.

With respect to the application of discount rates, EPA notes that it used the same discount rate as the rate used to discount the value of damages from future GHG emissions, for internal consistency. That approach to discounting follows the same approach that the February 2021 TSD recommends "to ensure internal consistency—i.e., future damages from climate change using the SC-GHG at 2.5 percent should be discounted to the base year of the analysis using the same 2.5 percent rate." EPA has also consulted the National Academies' 2017 recommendations on how SC-GHG estimates can "be combined in RIAs with other cost and benefits estimates that may use different discount rates." The National Academies reviewed "several options," including "presenting all discount rate combinations of other costs and benefits with [SC-GHG] estimates."

Commenter: American Enterprise Institute (AEI)

The EPA estimates of the climate benefit of the Proposed Rule obviously is based upon the interim estimates of the 'social cost of carbon,' which analytically are fundamentally flawed, combined with the asserted reduction in GHG emissions attendant upon the Proposed Rule. This methodology is illegitimate.

---

[58] *Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates under Executive Order 13990*

‘Fuel savings’ are asserted by the EPA to be roughly twice the purported environmental benefits of the Proposed Rule. But fuel savings, even if the asserted magnitudes are correct, are illegitimate as an economic benefit of the Proposed Rule, as the purported environmental benefits of reduced fuel use are reported separately, and thus there remains no further divergence between the market price and the social cost of petroleum fuels. Moreover, the EPA fails to consider the adverse consumer effects of a forced reduction in fuel consumption. Were the use of petroleum motor fuels to be proscribed entirely, the EPA methodology would yield a ‘benefit’ calculation of $357 billion annually, based upon data for 2019 reported by the Energy Information Administration. The EPA methodological approach is fundamentally unserious.

The discount rate analysis presented in the Proposed Rule and the RIA is not correct because the use of resources for future environmental improvement is an investment by definition; the historical evidence shows that the appropriate discount rate is a minimum of 7 percent. The use of different discount rates for the asserted benefit and cost streams engendered by the Proposed Rule is illegitimate. With respect to the ‘intergenerational equity’ question, the interests of future generations are served by a bequest of the most valuable possible capital stock, an outcome dependent upon the use of a correct and consistent discount rate by the current generation. [EPA-HQ-OAR-2021-0208-0254-A1, p. 2]

This reality — the ostensible effect of the Proposed Rule as a climate policy — alone demonstrates that the Proposed Rule cannot satisfy any plausible benefit/cost, and thus is not appropriate and should not be finalized in its present form or any alternative even remotely approximating it. That inescapable conclusion is demonstrated as well by the economic benefits asserted in the Proposed Rule, which are between $4.2 billion and $7.3 billion (in year 2018 dollars) annually through 2050. Global GDP in 2019 was about $97.5 trillion, also in year 2018 dollars.8 Accordingly, the EPA is asserting that this Proposed Rule will increase global GDP annually by an absolute maximum of about 0.075 percent, an effect that would decline over time as global GDP grows. Given the variation in global GDP growth rates over time, that effect cannot possibly be statistically significant. Accordingly, the EPA claim that ‘the total benefits far exceed the total costs of the program’ is not to be taken seriously.

Note also that the available independent analyses suggest that the prospective economic benefits of policies to reduce GHG emissions are much smaller than many assert. Consider the economic predictions from the integrated assessment models, the central one of which in this context is the Dynamic Integrated Climate and Economy Model, for which William D. Nordhaus won the Nobel Prize in Economics in 2018.9 Under DICE, global gross domestic product (GDP) in 2100 varies by about 3 percent across policy scenarios, including no climate policies at all, a figure that is both very small and almost certainly not statistically significant given the vagaries of economic forecasting and the number of years remaining before the end of this century. (I exclude here Nordhaus’ ‘Stern discounting’ policy scenario, as it assumes a discount rate effectively equal to zero, a fundamental analytic error.10) Per capita consumption varies only by about 1.3 percent across policy scenarios, also a very small number and almost certain not to be statistically significant.

The IPCC — even in its most alarmist analyses — arrives at a conclusion very close to that reported in the DICE analysis. In its 2018 report, it finds that the damage from anthropogenic climate change unmitigated by policy initiatives will reduce global GDP by 2.6 percent by 2100.11 By that year, IPCC projects that individual incomes on average will be at least 400 percent greater than is the case today.12 [EPA-HQ-OAR-2021-0208-0254-A1, pp. 4-5]

The discount rate analysis in the Proposed Rule is illegitimate. [EPA-HQ-OAR-2021-0208-0254-A1, p. 5]

Climate-related benefits. It is obvious that the EPA analysis in the Proposed Rule arrives at its calculation of the (global) benefits of reduced GHG emissions by multiplying its (interim) estimate of the social cost of carbon (SCC) by the asserted reductions in GHG emissions attendant upon implementation of the Proposed Rule.16 The interim estimates of the SCC are deeply problematic for a number of reasons,17 the most important of which is that they are divorced from the actual evidence and science of anthropogenic climate change. The mainstream estimates of the SCC, derived from three major integrated assessment models, ignore the actual evidence on the climate effects of increasing atmospheric concentrations of GHG, relying instead upon models that have overstated the historical record on global surface and tropospheric temperatures by a factor of over two, and upon a future scenario of increasing GHG concentrations that is almost impossible.18 (The IPCC in the Sixth Assessment Report describes RCP8.5 as ‘a low probability scenario.’) They ignore also the benefits of small or moderate warming. [EPA-HQ-OAR-2021-0208-0254-A1, p. 6]

Note also that the Interagency Working Group in its SCC analysis used the assumed global benefits of reductions in GHG emissions as the basis for the SCC analysis, while the CPP net benefits largely or wholly are created by assumed reductions in domestic pollutants, as just discussed. This is an inconsistency that has gone largely unnoticed in the Washington policy community.43 [EPA-HQ-OAR-2021-0208-0254-A1, p. 11]

The Inconsistent Use of Discount Rates and the Intergenerational Equity Question. By definition ‘climate policy’ is the allocation of resources away from current consumption and from productive activities that yield consumption goods during the current time period, in favor of a reduction in GHG emissions/concentrations that purportedly would increase the production of consumption goods during some series of future time periods. That is why EPA asserts that the Proposed Rule would increase the present value of the consumption stream increased. Accordingly, that use of resources during the current time period — again, by definition — is an investment, and it must be evaluated in comparison with the social return to alternative investments.

Therefore, it is the opportunity of cost of capital that is the appropriate discount rate to be applied to the evaluation of the Proposed Rule, because the allocation — the investment — of resources to such endeavors imposes an opportunity cost in the form of other forgone investments. Because the use of scarce resources for reductions in GHG emissions is an investment, whether promising returns low or high, the appropriate discount rate is the opportunity cost of capital for the economy as a whole. For the period 1928-2020, the average annual before-tax return to investment in the Standard and Poor 500, in real (inflation-adjusted) terms was 8.5 percent.53 For the period 1960-2020, the figure was 7.61 percent. Such long-run historical figures are consistent with the directive in OMB Circular A-4 that a discount rate of 7 percent be the baseline parameter applied to regulatory analysis by the federal government.54

The RIA proceeds to justify a ‘consumption rate of interest’ defined alternatively at 2.5 percent, 3 percent, or 5 percent, as follows.55

Second, the IWG found that the use of the social rate of return on capital (7 percent under current OMB Circular A-4 guidance) to discount the future benefits of reducing GHG emissions inappropriately underestimates the impacts of climate change for the purposes of estimating the SC-GHG. Consistent with the findings of the National Academies and the economic literature, the IWG continued to conclude that the consumption rate of interest is the theoretically appropriate discount rate in an intergenerational context… and recommended that discount rate uncertainty and relevant aspects of intergenerational ethical considerations be accounted for in selecting future discount rates. As a member of the IWG involved in the development of the February 2021 TSD, EPA agrees with this assessment and will continue to follow developments in the literature pertaining to this issue.

That analytic argument is fundamentally flawed. First: The ‘consumption rate of interest’ is not the correct conceptual discount rate for analysis of the Proposed Rule because the use of resources for purposes of reductions in GHG emissions is obviously an investment, the opportunity cost of which is the marginal social return to investment. Even if we assume that the ‘consumption rate of interest’ conceptually is the correct parameter for discounting purposes, the relevant metric is the real market rate of interest on intertemporal consumption shifts, one crude measure of which is the market rate of interest on unsecured consumer loans. Even given the recent years of low interest rates maintained by the Federal Reserve, that market rate appears to be over 7 percent in real terms.56 For secured loans (new autos), the real interest rate appears to be at least 3 percent,57 but that is not the correct parameter because there is no collateral insuring against the possibility that government policies mandating reductions in GHG emissions prove uneconomic. The discount rate argument presented in the RIA is fundamentally flawed analytically, and is inconsistent with the data for the U.S. credit market.

Note also that the use of a (low) ‘consumption rate of interest’ for the evaluation of climate policy only would introduce an important bias in the allocation of resources among government policies and between government and private-sector resource use. The RIA does not argue that the ‘consumption rate of interest’ should be applied to the benefit/cost analysis of all government investment and regulatory activity; only climate policies are to be so treated, on the grounds of ‘intergenerational equity,’ discussed below. Nor would the private sector choose to use an artificially-low discount rate for the evaluation of alternative resource uses. If it is only the climate dimension of investment and consumption choice dynamics that is to be shaped by the use of a low ‘consumption rate of interest,’ it is obvious that important distortions would be the central outcome, with a smaller capital stock resulting.

Second: The implicit premise in the EPA discussion of intergenerational analysis and the discount rate is straightforward: Future generations prefer to avoid the damages that they ostensibly will bear because of the climate effects of resource allocation decisions made by the current generation, and because future generations cannot vote during the current time period, it is equitable to force the current generation to bear the costs of anthropogenic climate change that otherwise would be inflicted upon future generations.

However seemingly straightforward, that argument is not correct. Future generations prefer to receive a bequest of an aggregate capital stock more- rather than less valuable, an objective very different from a maximization of the value of one dimension — climate phenomena — of that aggregate capital stock. This requires efficient resource allocation by the current generation, and therefore the application of the correct discount rate. Consider a homo sapiens baby borne in a cave some 50,000 years ago. Despite the fact that at birth that child would have enjoyed environmental quality effectively unaffected by mankind, and a fortiori climate phenomena determined by natural processes only, the baby at birth would have had a life expectancy of only about ten years.58

Accordingly it is obvious that given the opportunity to choose, that child would opt for less environmental quality and greater climate risk in exchange for a longer life expectancy engendered by a more valuable aggregate capital stock yielding improved shelter, expanded food supplies, a cleaner water supply, better medical care, ad infinitum. Greater wealth is the central objective of any generation, a reality shunted aside by the focus in the RIA upon only the climate dimension of the aggregate capital stock to be bequeathed to future generations.

There is the further matter that the application of differing discount rates to the benefit and cost streams asserted by EPA in defense of the Proposed Rule is deeply problematic. EPA discounts the purported benefit stream at 2.5, 3, and 5 percent discount rates — for presentational purposes, the 3 percent rate is used in the summary argument — but a 7 percent discount rate for the purported cost stream.59 Because the economic costs of the Proposed Rule would be borne almost immediately, while the asserted climate benefits would be obtained only after many decades at the earliest, it is not difficult to hypothesize that the use of inconsistent discount rates represents an effort to bias the analysis in favor of the Proposed Rule. Note that EPA in the RIA reports estimated global climate benefits through 2050 (year 2018 dollars) in present value terms of $140 billion, $91 billion, and $22 billion, at discount rates of 2.5 percent, 3 percent, and 2.5 percent, respectively.60 It is obvious that the application of a 7 percent discount rate would have yielded a climate benefit calculation close to zero. [EPA-HQ-OAR-2021-0208-0254-A1, pp. 14-16]

Inclusion of Global Rather Than Domestic Purported Benefits of GHG Emissions

OMB Circular A-4 directs federal agencies conducting benefit/cost analysis of regulatory measures as follows: 'Your analysis should focus on benefits and costs that accrue to citizens and residents of the United States. Where you choose to evaluate a regulation that is likely to have effects beyond the borders of the United States, these effects should be reported separately.'50 The Proposed Rule, however, incorporates explicitly in its benefit/cost calculation the purported global climate benefits from reductions in U.S. GHG emissions, presumably on the grounds that the assumed GHG externality is global in nature.

This argument is fundamentally flawed, in substantial part because the global climate effect of all U.S. GHG emissions is very close to zero, as discussed above in section I. Accordingly, the global 'benefit' of the Proposed Rule is effectively zero. EPA cannot dispute this because it is the EPA climate model used directly or indirectly through the IAMs applied to the analysis of the Proposed Rule. More generally, it is the EPA climate model that is used throughout the federal government for analysis of climate and energy policies.51

Furthermore, the inclusion of purported global benefits in the benefit/cost analysis of U.S. GHG policies would create a very large distortion in terms of an efficient international adoption of climate policies. An efficient promulgation of climate policies internationally would attempt to achieve both an equation of the global marginal benefits and costs of GHG emission reductions, and an allocation of emissions reductions that equates the marginal cost of such reductions across economies. If the U.S. is to promulgate domestic policies that equate domestic marginal costs with global marginal benefits, then other countries would have powerful incentives to obtain free rides on U.S. efforts. Given that the marginal cost function for reductions in GHG emissions almost certainly is upward sloping — the marginal cost of GHG reductions rises as such reductions increase — the outcome would be a global effort to reduce GHG emissions more costly than an international effort equating marginal costs across economies.52 That is the central implication of the imperative asserted in the Proposed Rule of including the purported global benefits of reductions in GHG emissions, rather than only the domestic ones. Under any assumption about the global benefits of reduced GHG emissions, that cannot be an efficient outcome unless the U.S. is the low-cost source of all reductions in GHG emissions, an assumption that simply is not plausible. [EPA-HQ-OAR-2021-0208-0254-A1, p. 13]19 On the surface (land/ocean) temperature record, see UK Met Office, Hadley Centre/University of East Anglia Climatic Research Unit, 'Tim Osborn: HadCRUT4 Global Temperature Graphs,' https://crudata.uea.ac.uk/~timo/diag/tempdiag.htm. On the Little Ice Age, see Michael E. Mann, 'Little Ice Age,' in Encyclopedia of Global Environmental Change, Volume 1: The Earth System: Physical and Chemical Dimensions of Global Environmental Change, ed. Michael C. MacCracken, John S. Perry and Ted Munn (Chichester, England: John Wiley & Sons, 2002), http://www.meteo.psu.edu/holocene/public_html/shared/articles/littleiceage.pdf.

52 This is true whether the marginal cost functions across economies are identical or differ.

EPA Response

EPA disagrees with many of the commenters' contentions. EPA follows applicable guidance and best practices when conducting its benefit-cost analyses, including OMB Circular A-4 and EPA's Guidelines for Preparing Economic Analyses. We therefore consider our analysis methodologically rigorous and a best estimate of the projected benefits and costs associated with the final rule. EPA has carefully reconsidered for this rulemaking the Technical Support Document, the underlying studies discussed in the TSD and the issues raised by commenters. EPA concludes that, as noted in Section 3.3 of the RIA and elsewhere in this RTC, the discussions in the TSD represent appropriate consideration of the various issues (e.g., appropriate discount rate and scope) and the resulting estimates of the TSD represent appropriate, if conservative, estimates for purposes of this rulemaking.

With respect to the use of consumption rate of interest for SC-GHG based estimates of climate benefits, the February 2021 IWG TSD discusses in detail why the social rate of return to capital is not appropriate for use in calculating the SC-GHG and climate benefits in general where benefits occur for decades or longer into the future. In this analysis, to calculate the present and annualized values of climate benefits, EPA uses the same discount rate as the rate used to discount the value of damages from future GHG emissions, for internal consistency. That approach to discounting follows the same approach that the February 2021 TSD recommends "to ensure internal consistency—i.e., future damages from climate change using the SC-GHG at 2.5 percent should be discounted to the base year of the analysis using the same 2.5 percent rate." EPA has also consulted the National Academies' 2017 recommendations on how SC-GHG estimates can "be combined in RIAs with other cost and benefits estimates that may use different discount rates." The National Academies reviewed "several options," including "presenting all discount rate combinations of other costs and benefits with [SC-GHG] estimates."

With respect to discount rates, EPA recognizes the limitations and uncertainties associated with the current interim IWG estimates and underlying methodology. The limitations were outlined in the February 2021 TSD and include that the current scientific and economic understanding of discounting approaches suggests discount rates appropriate for intergenerational analysis in the context of climate change are likely to be less than 3 percent, near 2 percent or lower. Additionally, the IAMs used to produce these estimates do not include all of the important physical, ecological, and economic impacts of climate change recognized in the climate change literature, and the science underlying their “damage functions” – i.e., the core parts of the IAMs that map global mean temperature changes and other physical impacts of climate change into economic (both market and nonmarket) damages – lags behind the most recent research.

The modeling limitations do not all work in the same direction in terms of their influence on the SC-GHG estimates. However, as discussed in the February 2021 TSD, the IWG has recommended that, taken together, the limitations suggest that the SC-GHG estimates likely underestimate the damages from GHG emissions. Therefore, as a member of the IWG involved in the development of the February 2021 TSD, EPA agrees that the interim SC-GHG estimates represent the most appropriate estimate of the SC-GHG until revised estimates have been developed reflecting the latest, peer reviewed science. The 2021 TSD previews some of the recent advances in the scientific and economic literature that the IWG is actively following and that could provide guidance on, or methodologies for, addressing some of the limitations with the interim SC-GHG estimates.

Regarding the distinction between global and domestic SC-GHG estimates, to correctly assess the total climate damages to U.S. citizens and residents, an analysis must account for impacts that occur within U.S. borders, climate impacts occurring outside U.S. borders that directly and indirectly affect the welfare of U.S. citizens and residents, and spillover effects from climate action elsewhere. The SC-GHG estimates used in regulatory analysis under revoked E.O. 13783 were an approximation of the climate damages occurring within U.S. borders only. EPA included the application of these domestic SC-GHG estimates to the reductions estimated in the analysis in Section 3.3 of the RIA. As discussed at length in the IWG's February 2021 TSD, estimates focusing on the climate impacts occurring solely within U.S. borders are an underestimate of the benefits of GHG mitigation accruing to U.S. citizens and residents, as well as being subject to a considerable degree of uncertainty due to the manner in which they are derived. EPA disagrees that using global estimates creates an incentive for foreign countries to "free ride" on U.S. GHG reduction efforts. As discussed in the February 2021 TSD, a wide range of scientific and economic experts have emphasized the issue of reciprocity as a reason for considering global damages of GHG emissions. Further, EPA agrees with commenter Institute for Policy Integrity's points on this issue (see comment in Section 14.1 of this document).

See Section 17 of this document for the response to AEI's comment on inclusion of the fuel savings in the benefit-cost analysis.

Commenter: Attorney General of Missouri et al.

Before addressing the EPA's request for public comment on the 'Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards,' it is important to reaffirm our objections to the process that has led us to this place. The Interagency Working Group on the Social Cost of Greenhouse Gases (IWG) and its actions violate the separation of powers by exercising quintessentially legislative authority without a valid delegation of authority from Congress, and violate the Administrative Procedure Act by failing to engage in ordinary rulemaking procedures.[1] They also violate federal statutes that delegate rulemaking authority to specific agencies, not the IWG. Separation-of-powers principles safeguard individual liberty, and the APA is Congress's blueprint to ensure reasoned decision-making by the Executive Branch. The IWG's failure to comply with these basic principles constitutes fundamentally lawless action that threatens the freedom of all Americans. [EPA-HQ-OAR-2021-0208-0288-A1, p.2]

The actions of the Interagency Working Group violate these fundamental principles. The adoption of specific, binding, numerical values for 'social costs ' of greenhouse gases is an inherently legislative function. Thus, the IWG purports to exercise quintessentially legislative authority without citing any delegation of authority whether valid or purported from Congress. The IWG reflects the Executive Branch's naked arrogation of legislative power to itself. 'Frequently,' a threat to the separation of powers 'will come ... clad, so to speak, in sheep's clothing .... But this wolf comes as a wolf.' Morrison u. Olson, 487 U.S. 654, 699 (1988) (Scalia,J .,dissenting). [EPA-HQ-OAR-2021-0208-0288-A1, p.3]

Moreover, the Interagency Working Group's 'request for comment ' earlier this year invoked the label for AP A procedures while purporting to deny Americans a critical benefit of notice and comment procedures: access to the judicial review to ensure that the Executive Branch meaningfully considers and addresses these concerns. We have previously objected to the Interagency Working Group dressing up substantive executive edicts in the parlance of good government. [EPA-HQ-OAR-2021-0208-0288-A1, pp.3-4]

On May 6, 2021, Deputy OIRA Administrator Mancini submitted a notice that the Co-Chairs requested comment on five issues impacting the SC-GHG. In addition to the legal and constitutional deficiencies in the IWG's formulation and process, we responded as follows to bullet points about 'general advances in science and economics included in' the 2021 TSD, approaches to implementing the recommendations of the National Academies of Science, Engineering, and Medicine (NASEM) published in its 2017 Valuing Climate Damages report, and using discount rates for intergenerational analysis. The Interagency Working Group's current approach to potential climate-related damages is deeply and irretrievably flawed, and yet more baseless modeling, speculative assumptions, and artificially manufactured numbers are not the solution. [EPA-HQ-OAR-2021-0208-0288-A1, p.4]

The 2021 TSD sets forth a substantive, legislative rule [3] because it is a final agency action imposing new rights or duties. Iowa League of Cities v. EPA, 711 F.3d 844, 873 (8th Cir. 2013); see 5 U.S.C. § 551(4). 'Expanding the footprint of a regulation' by imposing new requirements ... is the hallmark of legislative rules.' Id. As JudgeFriendly recognized, 'when an agency wants to state a principle 'in numerical terms,'terms that cannot be derived from a particular record, the agency is legislating and should act through rulemaking.' Catholic Health Initiatives v. Sebelius, 617 F.3d 490, 495 (D.C. Cir. 2010) (quoting Henry J. Friendly, Watchman, What of the Night?, in Benchmarks 144 45 (1967)). '[A]n agency performs a legislative function' when it promulgates 'a rule that turns on a number.' Id. In other words, rules that . promulgate specific numerical values for policy problems are quintessentially legislative in nature. The task of promulgating specific numerical values for 'social costs' of greenhouse gases is 'a legislative function.' Id. It can be exercised only by Congress, or through a valid delegation of authority from Congress (if a delegation of such enormous authority is even permissible, which is doubtful at best). [EPA-HQ-OAR-2021-0208-0288-A1, pp.4-5]

The IWG's promulgation of such rules for the 'social costs' of gases raises several problems. First, '[i]t is axiomatic that an administrative agency's power to promulgate legislative regulations is limited to the authority delegated by Congress.' Bowen v. Georgetown Univ. Hosp., 488 U.S. 204, 208 (1988). So when 'there is no statute conferring authority, a federal agency has none.' Michigan v. EPA, 268 F.3d 1075, 1081 (D.C. Cir. 2001). Neither the 2021 TSD nor the vehicle that created the Interagency Working Group, Executive Order 13990, cites any statutory authority authorizing them to promulgate such rules, and none exists. As a result, the Interagency Working Group lacks authority to issue rules in this area at all, and its attempts to do so violate both the separation of powers and the statutes that properly delegate such authority. See supra. [EPA-HQ-OAR-2021-0208-0288-A1, p.5]

Second, the IWG violated the APA in promulgating interim values for SCGHG because it failed to provide any opportunity to comment. 'Notice of a proposed rule must include sufficient detail on its content and basis in law and evidence to allow for meaningful and informed comment.' Am. Med. Ass'n v. Reno, 57 F.3d 1129, 1132 (D.C. Cir. 1995). 'The purpose of the comment period is to allow interested members of the public to communicate information, concerns, and criticisms to the agency during the rule-making process.' Connecticut Light & Power Co. v. Nuclear Regul. Comm'n, 673 F.2d 525, 530 (D.C. Cir. 1982). The Interagency Working Group, however, did not seek any public comment to before issuing the 2021 SCGHG estimates.

Instead, it formulated different SCGHG estimates for future use preventing the public from commenting on the 2021 SCGHG estimates that the rule at issue uses. [EPA-HQ-OAR-2021-0208-0288-A1, p.5]

These administrative procedures reflect important fairness principles and sound decision-making-and that is why Congress requires them. The Interagency Working Group effectively denied the American public the opportunity to meaningfully contribute to its decision-making process. Now, the IWG's unlawful process forms the foundation for the Revised Light Duty Vehicle Greenhouse Gas Emissions Standards, and EPA has used these interim estimates in this rule without determining whether the estimates comply with the statute or whether estimates are reasonable. [EPA-HQ-OAR-2021-0208-0288-A1, pp.5-6]

Basing the Revised Light-Duty Vehicle Greenhouse Gas Emissions Standards on Fla wed Social Costs of Greenhouse Gas Estimates while Failing to Account for Negative Externalities Would Be Arbitrary and Capricious.

To the extent that EPA relies on the IWG's SC-GHG analysis, the Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards result from a scientifically unreliable process that is unnecessarily experimental, non-scientific and harmful. As outlined above, the Eiden Administration's calculation of the 'social costs' of gases such as carbon dioxide and methane is arbitrary and capricious. This abstract and speculative policy-making causes substantial harms when applied to real-world industries that sustain thousands of American workers. [EPA-HQ-OAR-2021-0208-0288-A1, p.14]

This EPA proposed rule is the latest in what promises to be a series of evermore- stringent sweeping executive fiats intent on dramatically reshaping the automotive industry in the United States by a top-down conversion from the internal combustion engine to zero or near-zero emissions (i.e., all-electric) vehicles beginning in 2023. (86 FR 43728). Auto-manufacturing has formed an integral part of the national economy for generations, the economies of many states, and American life. The economic impact of vehicle manufacturing to the State of Missouri alone is estimated to be over $3.8 billion per year.[9] Furthermore, this economic activity employs over 20,000 Missourians. [10] [EPA-HQ-OAR-2021-0208-0288-A1, pp.14-15]

Failure to Adequately Consider Negative Impacts. This proposed rule compounds errors in the IWG's defective processes and is internally inconsistent. For example, the EPA fails to consider the negative environmental effects of its aggressive mandate which aims to convert a sizeable percentage of American auto manufacturing to electric vehicles on an expedited timeframe. Far from the panacea the EPA describes,[11] such heavy-handed meddling by federal bureaucrats in the functioning of the free market is bound to have negative upstream effects, which the SC-GHG analysis fails to consider. [EPA-HQ-OAR-2021-0208-0288-A1, p.15]

Inexorably linked to the move away from abundant, easy-to-reach fossil-fuels to electric light vehicles, are a host of technical, ecological, diplomatic and ethical issues. Phasing out internal combustion engines causes a dramatic increase in the demand for batteries. Significant challenges still remain before this technology can replace gasoline engines. [EPA-HQ-OAR-2021-0208-0288-A1, p.15]

The most common fuel cells to be used in electric vehicles rely on 'rare earth' metals such a lithium and cobalt. These important resources are often difficult to attain in adequate quantities for a number of reasons.[12] First, these metals are primarily located in regions of the world such as China, Chile, Bolivia, and Argentina, in the case of lithium. Extracting these resources have hidden costs such as extensive use of scarce water during the mining process in arid regions such as Chile. Such practices may have damaging effects on local agriculture.[13] Even more concerning is the supply of cobalt which is predominately located in the Democratic Republic of the Congo. Mining is conducted with little regard to human rights concerns, resulting in widespread exploitation. Child labor in these mining operations is estimated to impact up to 40,000 children who work in dangerous conditions.[14] [EPA-HQ-OAR-2021-0208-0288-A1, pp.15-16]

The rule is also internally inconsistent, and therefore arbitrary, because it only considers the 'global damages' from the emissions of new light duty vehicles, but not the global damages from upstream GHG emissions used to create and scale these new technologies. By only focusing on end-point GHG emissions, the rule increases perceived benefits in the lower emissions of these vehicles without considering, let alone measuring, whether upstream manufacturers emit more GHG, or in the case of rare earth metals, the other countries will emit more GHG emissions mining these materials. If the global damages from GHG must be considered, and EPA insists they must do so, failing to consider how adopting new technologies that require mining rare materials in other countries will produce GHG emissions is arbitrary. [EPA-HQ-OAR-2021-0208-0288-A1, p.16]

By offloading GHG emissions to other countries, the rule encourages 'carbon colonialism' that provides 'benefits' to first world countries at the expense of less developed ones. [EPA-HQ-OAR-2021-0208-0288-A1, p.16]

[3] A 'rule' is ' the whole or part of an agency statement of general or particular applicability and future effect designed to implement, interpret, or prescribe law or policy' 'includ[ing] the approval or prescription ... of valuations, costs, or accounting, or practices bearing on any of the foregoing.' 5 U.S.C. § 551(4). In its executive summary, the 2021 TSD makes clear that the 'SC-GHG is the monetary value of the net harm to society associated with adding a small amount of that GHG to the atmosphere in a given year.' Whether used in a cost-benefit analysis or for any other purpose, the 2021 TSD sets forth a value to be used in agency statements designed to implement law or policy, and as a result it is a rule.

EPA's use of the Biden Administration's Interagency Working Group's interim estimates for the 'social costs of greenhouse gases' (SC-GHG) to determine global damages of the present-day greenhouse emissions for light-duty vehicles is inappropriate. The interim estimates are the product of unreliable analysis, speculative projections, and naked policy judgements that have an outsize impact on perceived benefits from reducing GHG emissions. The selection of a discount rate, in particular, involves not science but a legislative judgement that Congress has not delegates to a regulatory agency like the EPA, And the IWG, by purporting to dictate binding values for such calculations that agencies like EPA must use in regulatory actions, is acting without any statutory authority and in violation of the fundamental separation of powers.

The federal government has previously and correctly recognized that this SC-GHG analysis is a fatally flawed concept when it refused ' to use social cost of carbon' analysis or a similar analytical tool to analyze the environmental impacts of greenhouse gas emissions from the construction and operation of the converted [natural gas] facilities.' EarthReports, Inc. v. Fed. Energy Regul. Comm'n, 828 F.3d 949, 956 (D.C. Cir. 2016). In that instance, the Federal Energy Regulatory Commission (FERC) did so because it concluded that the SCC would not be 'appropriate or informative' due to three factors: 'the lack of consensus on the appropriate discount rate leads to significant variation in output,' the SCC 'tool does not measure the actual incremental impacts of a project on the environment,' and 'there are no established criteria identifying the monetized values that are to be considered significant for NEPA purposes.' Id. (internal quotation marks omitted). The Commission further observed that 'there is no standard methodology to determine how a project's incremental contribution to [greenhouse gas emissions] would result in physical effects on the environment, either locally or globally.' Id. The D.C. Circuit upheld the Commission's reasoning and decision on this point. Id. All these concerns remain true today. The EPA should not rely on such a 'Social Cost of Carbon' metric for any rulemaking or other regulatory proceeding. [EPA-HQ-OAR-2021-0208-0288-A1, pp. 1-2]

Promulgating the Social Costs of Greenhouse Gases Violates the Separation of Powers and the APA, and Exceeds the Executive's Statutory Authority. Congress, not the President, controls the substance and sets the procedure for writing substantive rules. 5 U.S.C. § 553. The Interagency Working Group has violated those principles by issuing the 2021 TSD establishing the Social Costs of Greenhouse Gases (SCGHG) without engaging in notice and comment.[2] Id. at § 553(b). This deprives the American people of a meaningful opportunity to comment.[EPA-HQ-OAR-2021-0208-0288-A1, p.4]

The Current Social Costs of Greenhouse Gases Are Deeply Flawed and Cannot Be Fixed by Making More Wild Guesses. Beyond the fatal constitutional and legal deficiencies in these procedures, the IWG's approach to calculating ‘social costs’ of various gases is deeply flawed. The previous notice for comment expressly requested ways to implement the 2017 NASEM report's recommendations, recent advances in science and economics, and how to reflect the best understanding of discount rates for intergenerational analysis. The 2017 NASEM report, in turn, touches on most elements of the Interagency Working Group's process for developing a TSD, from the accounting of global versus domestic damages, the selection of the discount rate, and moving away from the incomplete and flawed averaging of the Integrated Assessment Models (IAMs). Though we agree with the 2017 NASEM report's general findings that the 2016 TSD[4] and Addendum are highly deficient, we disagree with the report's recommendations that more speculative modeling and more speculative probability distributions will right the ship. NASEM's findings confirm what MIT economist Robert Pindyck has found: ‘an IAM-based analysis suggests a level of knowledge and precision that is nonexistent, and allows the modeler to obtain almost any desired result because key inputs can be chosen arbitrarily.’ Robert S.

Pindyck, Climate Change Policy: What do the Models Tell Us?, National Bureau of Economic Research Working Paper 19244, at 16 (2013) (emphasis added). [5]

The 2021 TSD provides SCGHG estimates that are completely arbitrary for the reasons discussed below. As the Interagency Working Group's ! AM-based estimates fail to show a reasonable basis for the factual inputs and modeling assumptions, the estimates cannot survive arbitrary and capricious review. Sierra Club v. Castle, 657 F.2d 298, 333 (D.C. Cir. 1981).

2017 NASEM Report. NASEM's recommendations touch on virtually every aspect of the !AM-driven estimates promulgated by the Interagency Working Group. The NASEM report repeatedly criticizes the lack of transparency and consistency in the modeling processes, as well as the Interagency Working Group's failure to use more recent science. For example, in discussing the climate module, NASEM recommended that any ‘module should strive for transparency and simplicity so that the central tendency and range of uncertainty in its behavior are readily understood, reproducible, and amenable to improvement over time.’ Recommendation 4-1 at 13. NASEM concluded that averaging three IAMs fell short of achieving ‘transparency and consistency of key assumptions with the peer reviewed science' and aggravated 'the uncertainty representations, including structural uncertainty.' 2017 NASEM Report at 46 (Conclusion 2-1). It also found that the approach failed to provide an 'a transparent identification of the inputs, outputs, uncertainties, and linkages among the different steps of the SC-CO2 estimation process.' Id. (Conclusion 2-2).

NASEM also determined that estimated damages to the 'United States alone, beyond approximations done by the IWG ... is limited in practice by the existing SCIAM methodologies.' Id. at 9 (Conclusion 2-4). The report noted that the first Interagency Working Group made 'rough estimates of the proportion of global damages attributable to impacts within U.S. borders' even though it had departed from past agency practices by focusing on global damages. Id.[EPA-HQ-OAR-2021-0208 0288-A1, pp.6-7]

In various recommendations, NASEM stated that any new model should provide for more transparent reporting of individual sectors. E.g., Recommendations 3-2 at ll(‘Develop projections of sectoral and regional GDP and regional population’), 3-3 at 12 (socioeconomic module with ‘probabilistic regional and sectoral projections’), and 5-1 at 17 (damage functions).

The report and its recommendations identify other problems involving the time horizon, climate effects (ocean acidification, ice-sheet warming), the lack of reliable projections for population and GDP, the variability and non-comparability of the three different IAMs used by the Interagency Working Group, the need to account for feedback and adaptation, and the selection of discount rates. In nearly all cases, NASEM recommends more explicit modeling, more projections through expert elicitation and probability distributions, and improving the data sets for the modeling. And even NASEM doubts the viability of any socioeconomic module past the year 2100 an understatement to say the least. 2017 NASEM Report at 74 77. These significant issues and uncertainty counsel against relying on modeling to take government actions that impose pocketbook costs on the American people today. Unfortunately, the EPA with its currently proposed regulation on light duty vehicles is going down this very path.

IAM-based damages analyses are arbitrary. The IAM-based analyses provide a scientific veneer for the modeler's own policy preferences, instead of applying high quality data to measurable and reproducible phenomena. Because the DICE, PAGE, and FUND Models are all IAMs and the sole inputs for every estimate of social costs, averaging the results does nothing to make up for the lack of theoretical and empirical bases for the SCGHGs. See NERA, A Review of the Damage Functions Used in Estimating the Social Cost of Carbon (Feb. 20, 2014) (attached as Exhibit A).6 No matter how many times one guesses, the mean of three wild guesses is still a wild guess.

The IAMs ‘have crucial flaws that make them close to useless as tools for policy analysis’ and their ‘descriptions of the impact of climate change are completely ad hoc, with no theoretical or empirical foundation.’ Pindyck, Climate Change Policy (abstract). As one colleague put it, ‘I can make a model tie my shoe laces.’ Id. at 5 n.7. A 2014 NERA report, submitted to an earlier iteration of the Interagency Working Group, found the same thing. A Review of the Damage Functions, at 1. Specifically, it explained ‘that possible damage estimates at a given point in time can differ by a factor of 20 or more within the range of parameters and range of temperature changes found in the IAM literature.’ Id.

The NERA report explains that the IAMs' damages function predicts economic loss to show the change in GDP directly as a function of the projected change in temperature. Id. at 13. The FUND model projects monetary loss directly from the temperature change, the rate of temperature change, or carbon dioxide concentration. Id. at 14. This direct function from temperature change means that for all IAMs ‘global GDP is always reduced as global temperature increases.’ Id. at 15. Additionally, because of this relationship, all of the IAMs also have built in ad hoc ‘safety rails’ that prevent damages from exceeding 100% GDP. Id. at 16. In evaluating the theoretical basis for this damage function, the NERA team reviewed Weitzman's articles and ultimately credited his assessment that while he preferred one functional form over another, he could not ‘prove that my favored choice is the more reasonable of the two.’ Id. at 24.

The NERA report found that the IAMs had no empirical basis either. The team explained that the IAMs suffered from a lack of high quality data to properly calibrate their damage functions. Id. at 27 28. It also noted that these IAMs are set to one benchmark point that is a judgment each modeler makes, resulting in ‘damage functions [that] can differ dramatically from model to model, but each is ad hoc and with no well-defined empirical standards to resolve which might be more reliable than another.’ Id. at 26. As a result of these two issues, the report notes that the ‘modelers clearly recognize and readily concede the limitation in the empirical evidence’ with the creator of FUND noting that the lack of evidence ‘does not result in a climate change impact model that is adequate.’ Id. at 30.

All of this leads to the inevitable conclusion that the ‘model is unreliable and should not be used by lawmakers or regulators.’ Declaration of Kevin Dayaratna ,¶ 5 (Dayaratna Deel.) (attached as Exhibit B). As one economist noted, ‘[t]he bottom line here is that the damage functions used in most IAMs are completely made up.’ Pindyck, Climate Change Policy, at 13.[EPA-HQ-OAR-2021-0208-0288-A1, pp. 7-8]

Using an Improper Time Horizon. The Interagency Working Group's centuries-long time horizon further dilutes any perceptible causal chain and reflects an arbitrary decision that has an outsize impact on the SCGHGs. Purporting to predict global impacts 300 years into the future is an inherently speculative task- akin to an observer in the year 1721 predicting the invention of nuclear weapons and smart phones. And if the project had any non-speculative basis, the IAMs' time horizon was chosen arbitrarily and the Working Group injected their own assumptions into the models beyond their design.

The choice to run the IAMs to year 2300 originated in the first TSD and occurred because '[m]any consider 2200 too short a time horizon because it could miss a significant fraction of damages under certain assumptions about the growth of marginal damages and discounting.' 2010 TSD at 25 (emphasis added). In other words, without going to the year 2300, the Working Group reasoned, there was a risk costs would be lower. Notably, the Working Group made this decision even though one IAM and all of the EMF-22 climate scenarios ended before year 2300. To accomplish this task, the Working Group arbitrarily 'adjusted' the PAGE Model because it was designed to end in the year 2200. Id. The EMF-22 models (the five climate scenarios) also did not have projections for GDP, population, and greenhouse gas emission trajectories after the year 2100, so the Working Group also made those assumptions for the next 200 years that were used in all three IAMs. Id. In other words, it made up a model that would yield its pre-determined result.

The changes had the desired effect: the longer time horizon increased damages significantly. Dayaratna Deel. 30. This was a predictable change because '[t]he longer the horizon, the more years are summed into the damages and those years have greater and greater damages in a future that is difficult if not impossible to predict.' 34. To illustrate this effect, when the DICE Model (at a 3 percent discount rate) is only run until the year 2150 (roughly half the Working Group's time period) the damages are 13.43% to 20.28% less. 35-36. Although categorized as uncertainty, those additional damages assume what will happen centuries into the future and solely reflect the Interagency Working Group's assumptions for an additional 200 years. The Interagency Working Group did not submit these assumptions for peer review, expert elicitation, or public comment. It is virtually impossible to account for dynamic changes such as those caused by now commonplace technological innovations such as internet, smartphones, and GPS technology that were mere science fiction 300 years ago. 29. And the models provide no meaningful attempt to account for future technological changes that might mitigate the putative climate effects of gases, nor any other future mitigation attempts by the United States or any other country.

The SC-GHG estimates offer no justification why the IAMs were run to 2300 versus 2280 or an even 300 years to 2310. And if the reason is that damages were not fully accounted by the year 2100, the SC-GHG does not explain its arbitrary selection of a 300-year horizon for future damages. The Interagency Working Group also does not explain why the data it used is relevant to predicting GDP and population in the year 2300. All of these issues show that the selected end-dates are arbitrary and reflect a naked result-driven policy judgment. [EPA-HQ-OAR-2021-0208-0288-A1, pp.10-11]

Fails to Include 7% Discount Rate Baseline. The selection of the relevant discount rate is another consequential policy choice that the Interagency Working Group admits ‘has a large influence on the present value of future damages’ and ‘raises highly contested and exceedingly difficult questions of science, economics, ethics, and law.’ 2021 TSD at 17 (emphasis added). The 2021 TSD notably excludes the use of the 7 percent discount rate that the longstanding guidance in the peerreviewed 0MB Circular A-4 recommends for regulatory analysis. 0MB recognized that a 7 percent discount rate measures the cost of government regulation displacing investment (it is what a government project must ‘earn’ (pre-tax) to justify the cost, else it would have been better to invest in the market); and a 3 percent rate measures the opportunity cost of government regulation that displaces future consumption (for example, a person considers $1.03 tomorrow (post-tax) equal to a $1.00 today). See 0MB Circular A-4. The Interagency Working Group chose to use the consumption rate of return, alleging that it calculated the Social Cost of Carbon in terms of consumption. The Working Group, however, conceded that its analysis only works if it can convert ‘displaced investment . . . into a flow of consumption equivalents’ something it suggested it had yet to do fully. See 2021 TSD at 18; see also id. at 19 (needing ‘a more complete measure of costs, accounting for displacement of investment’). In other words, there is no rational explanation for the Working Group's transition from investment-based to consumption-based discounting.

To illustrate the influence of the selection of discount rate, the average social cost of carbon in the FUND Model for 2020 goes from a range of $21 to $39, 2016 TSD App. A Table A3, to negative 37 cents. Dayaratna Deel. 23. Adjusted for inflation, the FUND Model at a 7 percent discount rate equals negative 45 cents. This means that under the different (investment-based) discount rate, the social ‘cost’ of emitting an extra ton of carbon dioxide becomes a net benefit to society. The average social cost of carbon in the DICE Model for 2020 goes from a range of $28 to $48, 2016 TSD App. A Table A2, to $5.87 when the discount rate changes to 7 percent. Dayaratna Deel. 22. Adjusted for inflation, the social cost of carbon under the DICE Model at a 7 percent discount rate equals $7.21. Adjusted for inflation, the values for methane and nitrous oxide show similar sensitivity in the DICE Model for 2020 at the 7 percent rate are $331.76 (methane) and $2,312.44 (nitrous oxide). 25 26.

It is also noteworthy that in the Revised Light Duty Vehicle Rule's Summary of Costs and Benefits of the Proposed Program, EPA represents the present value of benefits under a 7 percent discount rate. Yet, Notes b & c to Table 4 explain that EPA has only used the IWG's estimates to discount the value of future GHG emissions, ‘while all other costs and benefits are discounted at either 3% or 7%.’ 86 FR 43735. EPA is not comparing benefits on an apples-to-apples basis, and does not comply with 0MB Circular A-4. EPA has failed to comply because it did not perform its own analysis, but blindly accepted the IWG's analysis as binding.

In short, the selection of a discount rate has an enormous impact on the actual projected costs generated by the SCGHG estimates. But this selection is not a scientific decision; even the 2021 Working Group admits that it ‘raises highly contested and exceedingly difficult questions of science, economics, ethics, and law.’ 2021 TSD at .17. Further, the 2021 Working Group admits that it has no clear scientific or economic justification for its abandonment of the investment mdisplacement discount rate provided in 0MB Circular A-4, and its adoption of the much lower consumption-based discount rates provided in the 2021 TSD-other than the naked policy preference for increased calculations of the ‘social costs’ of the relevant gases. Indeed, the 2021 Interagency Working Group's arbitrary selection of discount rates especially rates contrary to long-accepted pre-existing regulatory policy embodied in Circular A-4 constitutes a policy judgment that Congress did not delegate to any federal agency.[EPA-HQ-OAR-2021-0208-0288-A1p. 11-12]

2021 TSD Improperly Relies on Outdated Science. The SCGHG relies on assumptions and science used in the IAMs that do ‘not reflect the tremendous increase in the scientific and economic understanding of climate-related damages that has occurred in the past decade.’ 2021 TSD at 22; id. at 32. Contrary to the IWG's assumptions, however, such scientific advances reduce the calculations for SCGHGs; they do not inflate them. As a threshold issue, the NERA report notes that the IAMs are plagued by data availability issues for calibration. NERA Report at 28 30 (noting DICE 2013R and early 2000 FUND rely on studies from the 1990s). The report notes that even when new information is added, sometimes it makes relatively little difference if the IAM continues to use older studies. Id. There are at least three other considerations.

First, the Equilibrium Climate Sensitivity distribution (Roe and Baker (2006)) used in all the IAMs is out of date, and the Working Group does not explain why it has not considered newer ECSs. An ‘ECS is a distribution that probabilistically quantifies the earth's temperature response to a doubling of carbon dioxide concentrations.’ Dayaratna Deel. 39. For each IAM, the ECS shows the carbon dioxide impacts on climate, and the ‘[s]econdary effects, such as sea-level rise, all depend on a reliable ECS.’ The current ECS used is more than a decade old, and it vastly overstates the probability of high-end global warming compared to a more recent distribution.

A number of more recent ECS distributions suggest lower probabilities of extreme global warming in response to higher carbon dioxide concentrations.41. Failing to consider these alternatives has a big impact on the SC-GHG. Using newer ECS distributions, the average social cost of carbon (at the 3% discount rate in 2020 dollars) can be reduced by as much as 45% for the DICE Model and 80% for the FUND Model. Dayaratna Decl. 43 46. For example, the Lewis and Curry (2015) ECS that controls for observed ocean heat uptake efficiency causes the DICE Model’s value to go from $46.43 to $34.15 in 2020, $55.47 to $28.95 in 2030, $65.43 to $38.25 in 2040, and $75.83 to $39.94 in 2050. 43. The FUND Model’s values are affected even more : $23.75 to $4.09 in 2020, $26.76 to $4.79 in 2030, $29.93 to $5.52 in 2040, and $33.25 to $6.25 in 2050. 45. Instead of reviewing these alternatives, the 2016 and 2021 TSDs simply apply an ECS that is 15 years old and sorely outdated, without any adequate justification or explanation.

Second, four of the five EMF-22 scenarios ‘represent the modelers’ judgement of the most likely pathway absent mitigation policies to reduce greenhouse gas emissions, rather than the wider range of possible outcomes. ‘ 2010 TSD at 16 (emphasis added). These four scenarios continue to drive the outputs in the 2021 TSD and are hopelessly outdated. In addition to climate and emissions policies and rules in the last decade, President Biden announced ‘that America would aim to cut its greenhouse gas emissions 50 percent to 52 percent below 2005 levels by 2030.’ Brad Plumer and Nadja Popovich, The U.S. Has a New Climate Goal. How Does it Stack up Globally? N.Y. TIMES (Apr. 22, 2021). [8] Other nations similarly pledged to cut emissions compared to 2005 emissions: The EU nations by 51%, Britain by 63%, Canada by 45%, Japan by 44%, and Australia by 28%. All of these countries have pledged to achieve zero net emissions by 2050. And China , the world's largest emitter of greenhouse gases, has pledged that it will aim to get down to zero net emissions by 2060. To be sure, many nations such as China may not comply or fully comply with their pledges to reduce emissions. But it is implausible to assume as the IWG plainly does that no effective mitigation measures will occur over the upcoming decades. Even before these pledges, the United States and the EU nations had all been decreasing their emissions. The continued use of the four business-as-usual scenarios cannot be justified, and it has criticized as ' not just badly out of date, but reflecting a set of fictional worlds.'Roger Pielke Jr, The Biden Administration Just Failed its First Science Integrity Test, February 28, 2021 (available at https://rogerpielkejr.substack.com/p/thebidenadministraction-just-failed). And this process of implausibly adopting the worst-case scenario while refusing to give any weight to possible positive or mitigating effects pervades the IWG's entire analysis.

Third, the SCGHG analysis fails to fairly account for agricultural benefits caused by increased carbon dioxide concentrations, such as increasing plants' internal water use efficiency and raising the rate of net photosynthesis. Only one IAM, the FUND model, includes some quantification of these benefits. Indeed, the DICE model as utilized by the Working Group explicitly presumes that only damages will result from more CO2 in the atmosphere and there will be no benefits.Dayaratna Deel. 52. This limitation is arbitrary and only serves to overstate damages. For example, even using the outdated Roe Baker (2006) ECS distribution, the FUND Model (at a 3 percent discount rate) has a greater than 10 percent chance to generate a negative social cost of carbon each year through 2040. Dayaratna Deel. 49. Changing the discount rate to 7 percent raises that probability significantly. If an updated ECS distribution is used, there is a greater than 50 percent chance the social cost of carbon is negative through the year 2050. And there is good reason to believe that if the DICE Model was permitted to account for these benefits, then it would generate some negative values for the SCC as well. 52.

The Interagency Working Group, and by extension the EPA, should stop relying on data and projections that are not accurate and that only inflate the values for the SCGHGs. They should adhere to the best science showing that the IWG's analysis of future greenhouse gas emissions has no basis in sound science or reality. [EPA-HQ-OAR-2021-0208-0288-A1, pp.11-14]

Calculating Global Damages Is Inappropriate. The SC-GHGs allegedly monetize predicted global damages from the emission of an additional ton of carbon dioxide. The Interagency Working Group cited a number of reasons why it believes global damages are appropriate: 'GHG emissions contribute to damages around the world regardless of where they are emitted'; global impacts 'will have a direct impact on [overseas] U.S. citizens and the investment returns on those assets owned by U.S. citizens and residents'; global issues 'impact the welfare of individuals and firms that reside in the United States through their effect on international markets, trade, tourism, and other activities'; and 'allow[ing] the U.S. to continue to actively encourage other nations, including emerging major economies, to take significant steps to reduce emissions.' 2021 TSD, at 15 16. But these reasons have nothing to do with the CAA and whether Congress intended that costs (or benefits) include damages allegedly incurred in other countries in hundreds of years. [EPA-HQ-OAR-2021-0208-0288-A1, pp.8-9]

The Interagency Working Group's promulgation of purportedly binding numerical values for the ‘social costs’ of gases constitutes a quintessentially legislative activity, and its decision to do so without any valid delegation of authority from Congress violates the separation of powers and threatens the liberty of all Americans. Further, the 2021 TSD IAM-based methodology is deeply flawed, as highlighted by the 2017 NASEM report, and the resulting social costs estimates are arbitrary and capricious. [EPA-HQ-OAR-2021-0208-0288-A1, p.17]

EPA Response

EPA disagrees with many of the commenters’ contentions. EPA notes that it determined what standards were appropriate in light of the need for emissions reductions, the cost of compliance and lead time, and found the results of the benefit cost analysis in the RIA provide additional support for its conclusions. Under Section 202 of the CAA, EPA is required to establish standards to reduce air pollution that endangers public health and welfare, taking into consideration the cost of compliance and lead time. EPA is not required to conduct formal cost benefit analysis to determine the appropriate standard under Section 202. EPA weighed the relevant statutory factors to determine the appropriate standard and the analysis of monetized GHG benefits was not material to the choice of that standard. EO 12866 requires EPA to perform a cost-benefit analysis, including monetizing costs and benefits where practicable, and the EPA has conducted such an analysis. The monetized GHG benefits are included in the cost-benefit analysis. That cost-benefit analysis provides additional support for the EPA’s final standards. EPA notes that while it finds the results of the benefit-cost analysis supportive, it recognizes that some costs and benefits may be difficult to quantify. Indeed, the benefit -cost analysis for this rulemaking plainly omits certain benefits (as noted by several commenters and EPA’s responses in this document). After considering the February 2021 TSD, and the issues and studies discussed therein, EPA finds the SC-GHG estimates in the TSD, while likely an underestimate, are the best currently available SC-GHG estimates and appropriate for use in the RIA for this rulemaking. Note EPA has also assessed an estimate of benefits from climate impacts within U.S borders based on SC-GHG estimates used in regulatory analysis under revoked E.O. 13783, including in the RIA for the SAFE rule. As discussed at length in the February 2021 TSD and the RIA for this rule, estimates focusing on the climate impacts occurring solely within U.S. borders are an underestimate of the benefits of GHG mitigation accruing to U.S. citizens and residents, as well as being subject to a considerable degree of uncertainty due to the manner in which they are derived. However, regardless of the method used in quantifying the benefits of GHG reductions for purposes of this rulemaking, EPA would still adopt the standards of this final rule pursuant to its statutory obligation to set standards for pollutants that contribute to air pollution that endangers public health and welfare, taking into consideration the cost of compliance and lead time and other relevant factors as discussed in Preamble section VI. As a result, the decisions reached and standards put in place do not depend on the 2021 SC-GHG interim estimates

The commenter contends that the Interim SC-GHG values did not satisfy requirements of the Administrative Procedure Act (APA). First, Section 307(d) of the Clean Air Act generally specifies the procedural requirements applicable to this rulemaking and EPA has fully complied with those requirements. The question of whether the Interim SC-GHG values constitute a rule is beyond the scope of this action, but in any case, EPA does not view them to be or constitute a rule subject to the APA, or which the EPA is bound to follow in all cases. These estimates serve as one analytical input to EPA's evaluation of the overall economic effects of the rule. Nonetheless, EPA has independently evaluated (and indeed, contributed to) the development and methodology for these estimates and believes they reflect an appropriate valuation of the social benefits of GHG reduction based on currently available information. These estimates were used in the proposal, and commenters had the opportunity to comment on them (as they have).

With respect to the comment regarding consideration of negative impacts of requirements of the rule, EPA notes that the Final rule is fuel neutral and does not mandate a particular technology.

Please see the response to AEI in Section 14.1 in this document to similar comments on the distinction between global and domestic SC-GHG estimates, modeling uncertainties and the NASEM recommendations for the SC-GHG models and estimates, and the choice of discount rate and intergenerational discounting. With respect to the comments citing findings made by MIT economist Robert Pindyck on IAM-based analysis, as discussed by the commenter Institute for Policy Integrity, Professor Pindyck himself has noted that his writings on the subject have been taken out of context and that the damage functions in the IAMs are generally reflective of two to three degrees of warming (See comment from Institute for Policy Integrity in Section 14.1 of this document). With respect to the comments on the IAM modeling factors including time horizon, climate effects, projections for population and GDP, and variability of the three different IAMs used by the Interagency Working Group, EPA notes that the 2017 National Academies report makes near and longer-term updating recommendations regarding these issues. For example, the National Academies report provided methodological recommendations for addressing the challenges involved in developing the long run socioeconomic projections necessary for estimating the SC-GHG and recommended "In the context of the socioeconomic, damage, and discounting assumptions, the time horizon needs to be long enough to capture the vast majority of the present value of damages." Additionally, the 2021 TSD previews some of the recent advances in the scientific and economic literature that the IWG is actively following and that could provide guidance on, or methodologies for, addressing some of the limitations with the interim SC-GHG estimates. As noted above, taken together, the limitations suggest that the SC-GHG estimates likely underestimate the damages from GHG emissions and EPA agrees that the interim SC-GHG estimates represent the most appropriate estimate of the SC-GHG until revised estimates have been developed reflecting the latest, peer reviewed science.

With respect to the comment that the Clean Air Act does not provide authority to EPA to consider the global costs of climate change and the social cost of carbon, EPA disagrees with this comment. Even assuming it is possible to make a reasonable estimate of "domestic" costs of climate change, whether EPA considers global costs or domestic costs of climate change would not change anything about who is subject to these standards, and thus the canon against extraterritoriality does not resolve this question. Moreover, as the commenter notes, Congress has demonstrated its awareness in the Clean Air Act that air pollution can have effects beyond international borders so there is no reason to believe Congress expected EPA to ignore those effects, much less that it barred EPA from considering them, in making decisions under the Clean Air Act. In light of the well-recognized global nature of the climate problem, it would be odd if Congress did not intend EPA to consider the costs and benefits of addressing the problem at a global scale. This is particularly true when, in the agency's expert judgment, it is difficult and inappropriate to assess a "domestic" cost of climate change, both because of the nature of available modeling tools and the diverse ways in which U.S. interests, businesses, and residents may be impacted by climate change beyond U.S. borders. To the extent Congress was silent on this specific question, it is "eminently reasonable to conclude that [the statute's] silence is meant to convey nothing more than a refusal to tie the agency's hands." *Entergy Corp. v. Riverkeeper, Inc.*, 556 U.S. 208, 222 (2009).

Commenter: California Attorney General Office, et al.

Not only are the frequency and intensity of extreme weather events increasing, but so too are the costs. See Figure 3 [Figure 1 can be found on p. 9 of Docket number EPA-HQ-OAR-2021-0208-0245-A1]. On average, there were 7 billion-dollar extreme weather events per year in the United

States between 1980-2020 with an average annual cost of $45.7 billion; however, over the past 5 years, the average number of events per year increased to 16, with an average annual cost of $121 billion.52 In 2020—'a historic year of extremes'53—'[t]here were 22 separate billion-dollar weather and climate disasters across the United States, shattering the previous annual record of 16 events' and 'cost[ing] the nation a combined $95 billion in damages.'54 And these costs 'do not take into account losses to natural capital or assets, health care related losses, or values associated with loss of life,'55 meaning these estimates 'should be considered conservative.'56 [EPA-HQ-OAR-2021-0208-0245-A1, p.8]

As to the social cost of greenhouse gases ('SC-GHG') analysis in EPA's proposal, we: (1) applaud the use of a global rather than domestic analysis; (2) urge the use of a discount rate lower than 3%; and (3) recommend EPA explain that its analysis is based on its independent conclusions based on the best available science, including any additional updates that may further improve upon the interim SC-GHG values offered by the Interagency Working Group on Social Cost of Greenhouse Gases ('IWG').[EPA-HQ-OAR-2021-0208-0245-A1, p.33]

While we applaud improvement over SAFE 2, we strongly urge EPA to use a lower discount rate in its SC-GHG analysis than the 3% discount rate in EPA's proposed reference case. Recalculating social costs using a lower discount rate can be implemented immediately, especially given that EPA's proposal offers a sensitivity study that uses a 2.5% discount rate.159 As explained in both the SAFE 2 litigation and rulemaking,160 as well as multi-state comments161 regarding the interim SC-GHG values offered by the IWG, state experience and recent economic evidence shows a lower discount rate better accounts for the long-term, intergenerational impacts of climate change.

In addition, and to the extent possible, EPA should update its SC-GHG models to include any significant climate change-related impacts that have become quantifiable since EPA released its proposed standards.162 We also encourage EPA to identify some of the significant impacts it was unable to quantify in its SCC—including some impacts our States are experiencing this year, such as the combined effects of storm surges and rising sea levels and the human health costs of increased wildfires. While we recognize that EPA cannot quantify all climate impacts, and that EPA need not do so, we nonetheless believe it is important to acknowledge that the SCC figure used is almost certainly understated due to this constraint.

Finally, we urge EPA to explain that, while its SC-GHG analysis is consistent with the interim values offered by the IWG, EPA has reached its independent conclusions using the best available science, especially given that EPA's proposal uses SC-GHG analysis that reflects some updates from the IWG's analysis. Doing so would not diminish the SC-GHG analysis offered by the IWG, whose analysis is based on peer-reviewed literature and economic models.163 Rather, any updates by EPA based on agency expertise merely recognizes that federal agencies must use the best available science—which includes SC-GHG—when setting vehicle standards.164 [EPA-HQ-OAR-2021-0208-0245-A1, pp.33-34]

EPA Response

EPA acknowledges the commenter's input and notes that it determined what standards were appropriate in light of the need for emissions reductions, the cost of compliance and lead time, and found the results of the benefit-costs analysis in the RIA provide additional support for its conclusions.

With respect to the social cost of greenhouse gases, EPA recognizes the limitations and uncertainties associated with the current interim IWG estimates and underlying methodology. EPA participated in the IWG and has carefully reconsidered for this rulemaking the February 2021 TSD, the underlying studies discussed in the TSD and the issues raised by commenters. EPA concludes that, as noted in Section 3.3 of the RIA and elsewhere in this RTC, the discussions in the TSD represent appropriate consideration of the various issues (e.g., appropriate discount rate and scope) and the resulting estimates of the TSD represent appropriate, if conservative, estimates for purposes of this rulemaking. The 2021 TSD previews some of the recent advances in the scientific and economic literature that the IWG is actively following and that could provide guidance on, or methodologies for, addressing some of the limitations with the interim SC-GHG estimates.

Commenter: Center for Climate and Energy Solutions (C2ES)

Finally, with regards to the proposed input changes, C2ES supports the replacement of the domestic values for the social cost of greenhouse gases with global values. However, the interim values and discount rates used in the proposal are insufficient to capture the expected damages of climate change and should be adjusted to take into account the significant marginal costs of future emissions as the world approaches critical climate thresholds. [EPA-HQ-OAR-2021-0208-0287-A1, pp.2-3]

Input Changes – Global Social Cost of Carbon. C2ES supports the replacement of domestic values of the social cost of greenhouse gases with global values in the proposal but believes these values should be adjusted to more sufficiently capture the harms of marginal emissions now and in the future.

The social cost of carbon translates the future harm inflicted by the release of one additional ton of carbon dioxide into a present monetary value. The proposed rule uses the interim global estimates of the social cost of carbon published by the interagency working group (IWG) in February 2021. These values represent a significant improvement over the values EPA used in the analysis of the 2020 SAFE rule following the disbanding of the IWG, which considered only domestic climate-related damages and used a discount rate of 3 to 7 percent. The proposed rule considers global climate-related damages and uses average discount rates of 2.5 percent, 3 percent, and 5 percent, as well as the 95th-percentile of the 3 percent discount rate.

However, as EPA notes in the Draft Regulatory Impact Analysis (DRIA), these estimates are insufficient to capture the expected damages of climate change, particularly as the world approaches critical climate thresholds and each additional ton of greenhouse gases emitted represents significantly greater threats to the global climate. As the world warms, the value of avoiding future emissions becomes ever more important relative to avoiding present-day emissions and puts downward pressure on the discount rate. A discount rate of 2 percent or lower, based on the most up-to-date scientific and economic evidence, should be employed to reflect this.25

EPA recognizes the shortfalls of these interim values in the DRIA, including highlighting that a discount rate of 2 percent or lower would be more appropriate. However, as EPA plans to maintain the interim social cost of greenhouse gas emissions in its analysis and lists no plans to update the values once official ones are released by the IWG, the costs and benefits used to inform EPA's analysis of the proposal will significantly underestimate the actual marginal damages of greenhouse gas emissions.

The Intergovernmental Panel on Climate Change's (IPCC) Sixth Assessment Report highlights the extreme value of each marginal unit of warming avoided.26 It demonstrates that even if the global aspirational target of 1.5 degrees C of warming is exceeded, the relative severity of impacts of warming between 1.5 and 2.0 degrees C is significantly lower than that of the impacts of warming between 2 and 3 degrees C, and so on. The values used to determine the marginal cost of each ton of emissions should correspond to these marginal dangers of increased warming.

EPA and the IWG should adjust the values used for the social cost of greenhouse gases and lower the discount rates used in the analysis of this proposal to better reflect the increasing urgency of the climate crisis, and to more accurately capture the most recent scientific and economic evidence to analyze the damages of its present and future compounding impacts as emissions increase. [EPA-HQ-OAR-2021-0208-0287-A1, p.8]

EPA Response

EPA acknowledges the commenter's input and notes that the 2021 TSD previews some of the recent advances in the scientific and economic literature that the IWG is actively following and that could provide guidance on, or methodologies for, addressing some of the limitations with the interim SC-GHG estimates. For the reasons described in section 3.3 of the RIA and in the

February 2021 TSD, EPA believes that the estimates of the TSD are conservative (i.e., likely underestimates) but are nonetheless appropriate for use in this rulemaking.

Commenter: Competitive Enterprise Institute et al.

Our comments challenge the plausibility of the EPA's climate benefit estimates. The EPA estimates that, during calendar years 2023-2050, the proposal's GHG emission reductions will deliver $91 billion in climate change mitigation benefits.6 Those benefits are a mirage. Our comments may be summarized as follows.

The EPA's climate benefits estimate is based on the Biden administration Interagency Working Group's (IWG) social cost of carbon (SCC) estimates.7 Whatever its value as an academic pursuit, SCC estimation is too speculative and assumption-driven to inform policy decisions. The seeming objectivity and precision of official SCC estimates are illusory.

Indeed, SCC estimates are easily manipulated for political purposes. The IWG exercise is a case in point. All of the IWG's methodological decisions have the effect of increasing SCC values.

Those dubious decisions include the use of below-market discount rates, an analysis period extending far beyond the limits of reasonable speculation, outdated climate sensitivity assumptions, unscientific depreciation of carbon dioxide fertilization benefits, unjustified pessimism regarding human adaptive capabilities, implausible 'return to coal' baseline emission scenarios, and net-benefit calculations that misleadingly compare domestic costs to global benefits. Absent those biases, the IWG's SCC estimates could fall to zero dollars or below during 2023-2050 and beyond.

Even if the IWG's methodology were not biased in multiple ways, the EPA's $91 billion climate benefit estimate would still defy common sense. The proposed motor vehicle GHG standards are projected to avoid 0.001°C-0.002°C of global warming by 2050. That hypothetical change would be far too small for scientists to detect. It would make no discernible difference in weather patterns, crop yields, polar bear populations, or any other environmental condition people care about. Benefits no one can experience are 'benefits' in name only.

Section 1: Social Cost of Carbon Basics

The SCC is an estimate in dollars of the cumulative long-term damage caused by one ton of CO2 emitted in a specific year. That number also represents an estimate of the benefit of avoiding or reducing one ton of CO2 emissions.

The computer models used to project SCC values are called integrated assessment models (IAMs) because they combine aspects of a climate model, which estimates the physical impacts of CO2 emissions, with an economic model, which estimates the dollar value of climate change effects on agricultural productivity, property values, and other economic variables. The IWG uses three IAMs—abbreviated DICE, FUND, and PAGE—to estimate SCC values.8

In federal agency analyses, the cumulative damage of an incremental ton of CO_2 emissions is estimated from the year of the emission's release until 2300. SCC estimates are highly sensitive to:

• The discount rates chosen to calculate the present value of future emissions and reductions.

• The climate sensitivity assumptions chosen to estimate the warming impact of projected increases in atmospheric GHG concentration.

• The choice of socioeconomic pathways used to project future GHG emissions and concentrations.

• The timespan chosen to estimate cumulative damages from rising GHG concentration.

• The extent to which the SCC reflects empirical information about the agricultural and ecological benefits of carbon dioxide fertilization.

• The assumptions chosen regarding the potential for adaptation to decrease the cost of future climate change impacts.

In addition, from a political perspective, it matters a great deal whether the net benefits of climate policy proposals are calculated by comparing the domestic costs of GHG-reduction policies to the IAM-estimated global climate benefits or to the much smaller domestic benefits.

What this all means is that, if a modeler intends to make climate change look economically catastrophic and make GHG regulations appear essential, the modeler:

• Runs the IAMs with below-market discount rates.

• Uses IAMs that assume high climate sensitivity.

• Calculates cumulative damages over a 300-year period—i.e., well beyond the limits of informed speculation about how the global economy will evolve and how adaptative technologies will develop.

• Runs the models with implausible emission scenarios that assume the world repeatedly burns through all fossil fuel reserves absent aggressive climate policies.

• Minimizes the immense agricultural benefits of atmospheric CO_2 fertilization by, for example, averaging the results of three IAMs, two of which effectively assign a dollar value of zero to carbon dioxide's positive externalities.

• Includes at least one IAM that assumes adaptation cannot mitigate the cost of climate change impacts once 21st century global warming and sea-level rise exceed 2°C and 0.25 meters, respectively

• Calculates climate policy net benefits by comparing apples (domestic costs) to oranges (global benefits).

In other words, the modeler does exactly what the Obama IWG did in its 2010, 2013, and 2016 technical support documents (TSDs), and what the Biden IWG proposes to do in its 2021 interim TSD.9

Section 2: Artifactual Benefits No One Will Ever Experience

What will be the proposed regulation's measurable effects on global average surface temperature, compared to the existing SAFE Rule standards, and what benefits can be expected to accrue from the proposed changes?

In a word, the answer to both is simple: None.

It is a standard procedure for the EPA to assess the temperature effects of proposed or existing policies using the Model for the Assessment of Greenhouse-Gas Induced Climate Change. Developed at the National Center for Atmospheric Research, the model's official acronym is MAGICC.10

That subtle humor aside, one can use MAGICC to determine the effects of continuing the current vehicle standards versus those now proposed (which are roughly equivalent in stringency to the Obama-EPA standards rescinded by the SAFE Rule).

Using standard MAGICC assumptions, which include an equilibrium climate sensitivity of 3.0°C, MAGICC calculates the net 'savings' of global warming to be 0.003°C by the year 2100.11 That is roughly the average temperature difference between the air surrounding your knees and the air surrounding your midsection.

According to the National Oceanic and Atmospheric Administration, the inherent error in current calculations of annual global average surface air temperature is 0.08°C, which is nearly 27 times the calculated effect of the new standards.12

Yet when the EPA multiplies projected emission reductions by the IWG's SCC estimates, it comes up with climate benefits of $91 billion by 2050. Given that the MAGICC-calculated temperature change is a mere 0.003°C by 2100, the 2050 temperature 'savings' has to be far less than half of this value, rounding to some value between 0.001°C and 0.002°C.

It simply defies logic to calculate the benefits of a regulation that will have impossible-to-detect effects on surface temperature, because it is those same temperature changes that drive cost estimates.

In short, the proposed vehicle standards will have an undetectable effect on surface temperature, which means the standards will produce undetectable climate 'benefits.' In pursuit of such digital artifacts, the EPA will foist enormous costs on automakers, forcing some consumers to purchase vehicles they would otherwise not choose to buy while pricing others out of the market for new motor vehicles.

Qui bono? The only interest groups with tangible benefits are the administering agencies and the dominant automakers. Tightening GHG/fuel economy standards perpetuates and expands regulatory control over the auto industry. It also further cartelizes the industry. All automakers must comply or incur penalties. None is free to beat competitors on price, ride height, crashworthiness, or other vehicle attributes by producing fleets that fall short of the EPA's GHG reduction requirements.

Section 3: How the Discount Rate Affects the SCC13

Models used to estimate the SCC rely on the specification of a discount rate. Discounting is essential in benefit-cost analysis because compliance costs are best viewed as investments intended to yield benefits in the future. Applying discount rates enables agencies to compare the projected rate of return from CO2-reduction expenditures to the rates of return from other potential investments in the economy.

Office of Management and Budget (OMB) guidance in Circular A-4 specifically stipulates that agencies discount the future costs and benefits of regulations using both 3.0 percent and 7.0 percent discount rates.14 The IWG suggests that a 7 percent discount rate is an affront to intergenerational equity, apparently on the theory that discount rates higher than 1-2 percent imply that people living today are more valuable than people living decades or centuries from now.15

We respectfully disagree. The point of discounting is not to rank the worth of different generations but to have a consistent basis for comparing alternate investments. Only then can policymakers determine which investments are most likely to transmit the most valuable capital stock to future generations. In other words, discounting clarifies the opportunity cost of investing in climate mitigation, for example, rather than medical research, national defense, or trade liberalization.

Not only is it reasonable to include a 7 percent discount rate in SCC estimation, it is arguably the best option because 7 percent is the rate of return of the New York Stock Exchange over the last hundred and twenty-five years.16 Only by using a 7 percent discount rate can policymakers assess the wealth foregone when government invests in GHG reduction rather than other policy objectives or simply allows companies and households to invest more of their dollars as they see fit.

Institute for Energy Research economist David Kreutzer illustrates the point as follows. Suppose an emission-reduction investment produces $100 in benefits by 2171 (150 years from now). That is equivalent to investing $5.13 today with a 2 percent annual ROI. But if the same $5.13 is invested in stock that appreciates at 7 percent annually, the investment yields $131,081 in 2171. Clearly, that is a much larger bequest to future generations.

Kreutzer also notes that all baseline scenarios assume future generations are richer than current generations. He comments:

It is a terrible policy to make investments that return $100 instead of $131,081, but it is virtually brain-dead to argue the bad return is justified on equity grounds. Those alive centuries from now are almost certain to be much wealthier, healthier, and possessed of technology to better overcome any adversity—including climate change.17

It is hard to shake the suspicion that the IWG has never used a 7 percent discount rate, even as a sensitivity case analysis, because doing so would spotlight the comparatively low rates of return of GHG-reduction policies.

The IWG hints that its final TSD, to be published in 2022, may use discount rates as low as 1 percent.18 However, as in the IWG's 2010, 2013, and 2016 TSDs, the February 2021 interim TSD uses discount rates of 2.5 percent, 3.0 percent, and 5.0 percent. Accordingly, the remainder of this section examines how those rates affect SCC values.

At the Heritage Foundation, Dayaratna and colleagues ran DICE and FUND using a 7.0 percent discount rate to quantify how much the IWG's lower discount rates increases SCC estimates.

Below is the 2016 TSD's SCC estimates19 followed by the Heritage analysts' results published in the peer-reviewed journal Climate Change Economics:20 [Table ES-1, Table DICE Model Average SCC, and Table FUND Model Average can be found at docket number EPA-HQ-OAR-2021-0208-0292-A1, pp.7-8]

As the above tables illustrate, the SCC estimates are drastically reduced when the models are run with a 7.0 percent discount rate. In fact, under the FUND model, the estimates are negative. Using a 7.0 percent discount rate can cause the SCC to drop by as much as 80 percent or more.

The EPA should not use SCC analysis for policymaking, as it depends on too many unknowns. However, if the agency is going to use SCC analysis, it should include SCC discounted at 7 percent as part of its benefit-cost analysis, because only on that basis can the public compare climate policy 'investments' to other capital expenditures. And only through such comparisons can policymakers reasonably assess which investments will best position future generations to inherit the most productive capital stock.

Section 4: How the Time Horizon Affects the SCC

Human beings use technology to adapt to environmental conditions. Consequently, the loss functions in IAMs depend on assumptions about how adaptive technologies will be developed and deployed as the world warms. It is essentially impossible to forecast technological change decades, let alone centuries, into the future. Regardless, the IWG bases its SCC estimates on projections of climate change damages over a 300-year period (2000-2300). Dayaratna and his former Heritage Foundation colleague David Kreutzer ran the DICE model with a significantly shorter, albeit still unrealistic, time horizon of 150 years into the future.21

Here are the DICE-estimated SCC values with a baseline ending in 2300: [Tables 1 and 3 can be found at docket number EPA-HQ-OAR-2021-0208-0292-A1, p. 9]

The SCC estimates drop substantially—in some cases by more than 25 percent—as a result of ending the SCC estimation period in 2150. If the EPA is going to use the SCC in policymaking, it should underscore the highly-speculative nature of long-term economic and technology forecasting. In addition, the EPA should include sensitivity case analyses using timespans shorter than 300 years.

Section 5: How the Equilibrium Climate Sensitivity (ECS) Distribution Affects the SCC

The key climate specification used in estimating the SCC is the equilibrium climate sensitivity (ECS) distribution. Such distributions probabilistically quantify the earth's temperature response to a doubling of CO2 concentrations.

ECS distributions are derived from general circulation models (GCMs), which attempt to represent physical processes in the atmosphere, ocean, cryosphere and land surface. The IWG uses the ECS distribution from a study by Gerard Roe and Marcia Baker published 14 years ago in the journal Science.22 This non-empirical distribution, calibrated by the IWG based on assumptions it selected in conjunction with IPCC recommendations,23 is no longer scientifically defensible.24

Since 2011, a variety of newer and empirically-constrained distributions have been published in the peer-reviewed literature. Many of those distributions suggest lower probabilities of extreme global warming in response to CO2 concentrations. Below are three such distributions:25 [Figure (2007) can be found at docket number EPA-HQ-OAR-2021-0208-0292-A1, p.10]

The areas under the curves between two temperature points represent the probability that the earth's temperature will increase between those amounts in response to a doubling of CO2 concentration. For example, the area under the curve from 4°C onwards (known as right-hand 'tail probability') represents the probability that the earth's temperature will warm by more than 4°C in response to a doubling of CO2 concentrations. Note that the more up-to-date ECS distributions (Otto et al., 2013; Lewis, 2013; Lewis and Curry, 2015) have significantly lower tail probabilities than the outdated Roe-Baker (2007) distribution used by the IWG.

Here, again, is the IWG's 2016 SCC estimates for 2020-2050: [Table ES-1, Table DICE Model Average SCC, and Table FUND Model Average can be found at docket number EPA-HQ-OAR-2021-0208-0292-A1, pp.11-12]

In Climate Change Economics, Dayaratna and colleagues re-estimated the DICE and FUND models' SCC values using the more up-to-date ECS distributions and obtained the following results:26

Using the more up-to-date ECS distributions dramatically lowers SCC estimates. The IWG's outdated assumptions overstate the probabilities of extreme global warming, which artificially inflates their SCC estimates. The EPA should not to use SCC estimation for policymaking, as it is highly susceptible to user manipulation. However, if it must be used, the agency should utilize realistic estimates of climate sensitivity.

Lest the EPA assume we prefer the empirically-constrained ECS estimates just because they are lower, we would note that so-called state-of-the-art GCMs repeatedly overshoot observed warming—a clear indication the models overestimate climate sensitivity.

In its Fifth Assessment Report (AR5), the IPCC used the Coupled Model Intercomparison Project Phase 5 (CMIP5) models to project future warming and the associated climate impacts.27 The figure below compares predicted and observed average tropospheric temperature over the tropics.28 The observations come from satellites, weather balloons, and reanalyses.29

A careful look at the figure reveals that only one of the 102 model runs correctly simulates what has been observed. This is the Russian climate model INM-CM4, which also has the least prospective warming of all of them, with an ECS of 2.05°C, compared to the CMIP5 average of 3.2°C. [Figure 1. can be found at docket number EPA-HQ-OAR-2021-0208-0292-A1, p.13]

Best scientific practice uses models that work and does not seriously consider those that do not. This is standard when formulating the daily weather forecast, and should be standard with regard to climate forecasts.

The IPCC's recently released Sixth Assessment Report (AR6) uses a new suite of models, designated CMIP6. Is it an improvement?

No. As shown by McKitrick and Christy (2020), the CMIP6 models are even worse.31 Of the two models that work, the Russian INM-CM4.8, has even less warming than its predecessor, with an ECS of 1.8°C, compared to the CMIP6 community value of around four degrees.32 The other one is also a very low ECS model from the same, group, INM-CM5. The model mean warming rate exceeds observation by more than four times at altitude in the tropics. [Figure McKitrick and Christy (2020) can be found at docket number EPA-HQ-OAR-2021-0208-0292-A1, p.14]

Quoting from McKitrick and Christy's conclusion:

The literature drawing attention to an upward bias in climate model warming responses in the tropical troposphere extends back at least 15 years now (Karl et al., 2006). Rather than being resolved, the problem has become worse, since now every member of the CMIP6 generation of climate models exhibits an upward bias in the entire global troposphere as well as in the tropics.

Zeke Hausfather, hardly a climate skeptic, has noted that while the CMIP6 models are warmer than the previous generation, the warmer they are, the more they over-forecast warming in recent decades, confirming what McKitrick and Christy found.33

Zhu, Poulsen, and Otto-Bliesner (2020) used a CMIP6 model called CESM2 to project warming from an emission scenario that reaches 855 parts per million by 2100—roughly three times the pre-industrial concentration. Despite being tuned to match the behavior of 20th century climate, CESM2 produced a global mean temperature '5.5°C greater than the upper end of proxy temperature estimates for the Early Eocene Climate Optimum.' That was a period when CO2 concentrations of about 1,000 ppm persisted for millions of years.34 Moreover, the modeled tropical land temperature exceeded 55°C, 'which is much higher than the temperature tolerance of plant photosynthesis and is inconsistent with fossil evidence of an Eocene Neotropical rainforest.'35

The bottom line is that Row-Baker ECS distribution inflates the IWG's SCC estimates, which will become even more unrealistic if updated with CMIP6.

Section 6: Negative SCC Values

Policymakers and the media often assume carbon dioxide emissions have only harmful impacts on society. However, CO2 emissions have enormous direct agricultural36 and ecological benefits,37 global warming lengthens growing seasons,38 and warming potentially alleviates cold-related mortality, which may exceed heat-related mortality by 20 to 1.39

Of the three IAMs used by the IWG, only the FUND model estimates CO2 fertilization benefits. Dayaratna and colleagues investigated whether a model with CO2 fertilization benefits could produce negative SCC estimates. A negative SCC means that each incremental ton of CO2 emissions produces a net benefit.

The researchers calculated the probability of a negative SCC under a variety of assumptions. Below are some of the results published both at the Heritage Foundation as well as in the peer-reviewed journal Climate Change Economics:40 [Table FUND Model Probability, can be found at docket number EPA-HQ-OAR-2021-0208-0292-A1, pp.15-16]

As the above statistics illustrate, under a variety of reasonable assumptions, the SCC has a substantial probability of being negative. In fact, in some cases, the SCC is more likely to be negative than positive, which implies—if one adopts the perspective of a central planner—that the EPA should, in fact, subsidize (not limit) CO2 emissions. We, of course, oppose such interventionism.

Our purpose here is to illustrate the extreme sensitivity of these models to reasonable changes in assumptions. Although we advise the EPA not to use SCC analysis as a policymaking tool, if it does so, it should also present the probabilities of negative SCC values—i.e., the chance that the direct benefits of CO2 emissions will exceed climate-related damages.

Section 7: Updated Agricultural Benefits and Benefit-Cost Analysis

It is a well-established fact that increases in CO2 concentration enhance plant growth by increasing their internal water use efficiency as well as raising the rate of net photosynthesis.41

As discussed in the previous section, the FUND model attempts to incorporate those benefits; however, this aspect of the model is grounded on research that is one-to-two decades old. Even so, as discussed in the preceding section, Dayaratna et al. (2017) found substantial probabilities of negative SCC using the outdated assumptions in FUND. Dayaratna et al. (2020) summarized more recent CO2 fertilization research in a peer-reviewed study published in Environmental Economics and Policy Studies and re-estimated the FUND model's SCC values upon updating those assumptions.[42] To facilitate the EPA's review of that research, we excerpt several paragraphs from Dayaratna et al. (2020):

Three forms of evidence gained since then indicates that the CO2 fertilization effects in FUND may be too low. First, rice yields have been shown to exhibit strong positive responses to enhanced ambient CO2 levels. Kimball (2016) surveyed results from Free-Air CO2 Enrichment (FACE) experiments, and drew particular attention to the large yield responses (about 34 percent) of hybrid rice in CO2 doubling experiments, describing these as 'the most exciting and important advances' in the field. FACE experiments in both Japan and China showed that available cultivars respond very favorably to elevated ambient CO2. Furthermore, Challinor et al. (2014), Zhu et al. (2015) and Wu et al. (2018) all report evidence that hybrid rice varietals exist that are more heat-tolerant and therefore able to take advantage of CO2 enrichment even under warming conditions. Collectively, this research thus indicates that the rice parameterization in FUND is overly pessimistic.

Second, satellite-based studies have yielded compelling evidence of stronger general growth effects than were anticipated in the 1990s. Zhu et al. (2016) published a comprehensive study on greening and human activity from 1982 to 2009. The ratio of land areas that became greener, as opposed to browner, was approximately 9 to 1. The increase in atmospheric CO2 was just under 15 percent over the interval but was found to be responsible for approximately 70 percent of the observed greening, followed by the deposition of airborne nitrogen compounds (9 percent) from the combustion of coal and deflation of nitrate-containing agricultural fertilizers, lengthening growing seasons (8 percent) and land cover changes (4 percent), mainly reforestation of regions such as southeastern North America …

Munier et al. (2018) likewise found a remarkable increase in the yield of grasslands. In a 17-year (1999-2015) analysis of satellite-sensed LAI, during which time the atmospheric CO2 level rose by about 10 percent, there was an average LAI increase of 85 percent. A full 31 percent of earth's continental land outside of Antarctica is covered by grassland, the largest of the three agricultural land types they classified. Also, for summer crops, such as maize (corn) and soybeans, greening increased an average of 52 percent, while for winter crops, whose area is relatively small compared to those for summer, the increase was 31 percent. If 70 percent of the yield gain is attributable to increased CO2, the results from Zhu et al (2016) imply gains of 60 percent, 36 percent and 22 percent over the 17-year period for, respectively, grasslands, summer crops and winter crops, associated with only a 10 percent increase in CO2, compared to parameterized yield gains in the range of 20 to 30 percent for CO2 doubling in FUND.

Third, there has been an extensive amount of research since Tsingas et al. (1997) on adaptive agricultural practices under simultaneous warming and CO2 enrichment. Challinor et al. (2014)

surveyed a large number of studies that examined responses to combinations of increased temperature, CO2 and precipitation, with and without adaptation. In their metanalysis, average yield gains increased 0.06 percent per ppm increase in CO2 and 0.5 percent per percentage point increase in precipitation, and adaptation added a further 7.2 percent yield gain, but warming decreased it by 4.9 percent per degree C. In FUND, 3°C warming negates the yield gains due to CO2 enrichment. However, based on Challinor et al.'s (2014) regression analysis, doubling CO2 from 400 to 800 pm, while allowing temperatures to rise by 3°C and precipitation to increase by 2 percent, would imply an average percent yield increase ranging from 2.1 to 12.1 percent increase, indicating the productivity increase in FUND is likely too small.

Based on that literature, Dayaratna et al. (2020) updated the FUND model's coefficients to increase its agricultural benefits by 15 percent and 30 percent. In addition, the authors used an updated ECS distribution—that of Lewis and Curry (2018).43 In the charts below, the last three columns show the mean SCC as well as the associated probability of negative SCC values under different discount rates. [Table FUND Model Average SCC (2.5%), Table FUND Model Average SCC (3%), Table FUND Model Average SCC (5%), Table FUND Model Average SCC (7%) can be found at docket number EPA-HQ-OAR-2021-0208-0292-A1, pp.19-20]

As the results illustrate, under more realistic assumptions regarding agricultural productivity and climate sensitivity, the mean SCC essentially drops to zero and in many cases has a substantial probability of being negative. At a minimum, Dayaratna et al. (2020) further demonstrates that the SCC is highly sensitive to very reasonable changes in assumptions and is thus readily prone to user manipulation.

Indeed, we could not help noticing that the concepts of CO2 fertilization and global greening do not occur in the IWG's February 2021 interim TSD. Similarly, although Dayaratna et al. (2020) was published in January 2020, it is not included among the TSD's 115 references.44

Section 8: Unreasonable Pessimism Regarding Human Adaptive Capabilities

Other things being equal, the more pessimistic an IAM's view of human adaptive capabilities, the higher the SCC estimates it will produce. Climate impact assessments often ignore, assume away, or depreciate mankind's remarkable capacity for adaptation.45 Prominent examples include:

• The 2018 Fourth National Climate Assessment, which estimates that global warming could reach 8°C and reduce U.S. GDP by 10 percent in the 2090s.46 As revealed in the fine print, the estimate assumes no adaptive measures beyond those already deployed 'in the historical period,' i.e., during 1980-2010.47

• The Assessment's high-end estimate of $505 billion in climate damages in 2090. That estimate similarly assumes 'limited or no adaptation.'48

• The EPA's 2015 Benefits of Global Action report, which projects 12,000 annual heat-stress deaths and 57,000 annual air pollution deaths in 49 U.S. cities in 2100.49 As revealed in the fine print, the heat mortality estimate assumes no further progress in adaptation after 2015. As revealed in a key underlying study,50 the air pollution mortality estimate assumes no further reduction in air pollutant emissions after 2000, even though fine particle (PM2.5) emissions and precursors in 2015 were already significantly lower than in 2000.51

The 2021 TSD says little about adaptation other than to acknowledge the IAMs' 'incomplete treatment of adaptation and technological change' and 'uncertainty' about the adaptation costs.52 The 2016 TSD has a subsection on the PAGE model's treatment of adaptation. Here is the gist. In PAGE2002, 'Beyond 2°C, no adaptation is assumed to be available to mitigate the impacts of climate change.' And in PAGE09, 'adaptation is assumed to alleviate 25-50 percent of the damages from the first 0.20 to 0.25 meters of sea level rise but is assumed to be ineffective thereafter.'53

Those assumptions are not reasonable. Industrial civilization's virtuous circle of wealth creation and technological innovation endlessly updates mankind's adaptive capabilities, including our ability to make earth's naturally dangerous climate more livable.54 Since the 1920s, global CO2 concentrations increased from about 305 parts per million to more than 410 ppm, and average global temperatures increased by about 1°C.55 Yet, globally, the individual risk of dying from weather-related disasters such as hurricanes, floods, and drought decreased by 99 percent.56 If we are in a 'climate crisis' today, what words can adequately describe the climate regime of the 1920s?57 [Figure 8 can be found at docket number EPA-HQ-OAR-2021-0292-A1, P. 22]

It is not possible to discern a social cost of carbon in those data. Nor is an SCC detectable in several other trends of fundamental relevance to human survival and flourishing. The past 70 years have been marked by unprecedented improvements in global life expectancy,58 per capita income,59 food security,60 and various health-related metrics.61 Yields of all major food crops keep increasing,62 nearly 3 billion people gained access to improved water sources since 1990,63 and deaths from malaria (the most consequential climate-sensitive disease) declined by 52 percent during 2000-2015.64 [EPA-HQ-OAR-2021-0208-0292-A1, pp. 2-23]

Even in recent decades, the warmest in the instrumental record, mortality and economic loss data point to an increasingly sustainable civilization. A recent peer-reviewed study finds that climate-related hazards show a 'clear decreasing trend in both human and economic vulnerability, with global average mortality and economic loss rates that have dropped by 6.5 and nearly 5 times, respectively, from 1980–1989 to 2007–2016.'65 Similarly, data buried in the appendix of a 2019 study in the Lancet reveal that disaster losses as a percentage of GDP are declining, with the greatest declines occurring in low-income countries.66

It is thus fundamentally important to pursue policies that will make the United States and other countries wealthier, which will make humanity better able to handle whatever climate-related hazards occur in the future. SCC-based regulations, on the other hand, are likely to make nations less wealthy, while providing negligible climate change mitigation.67

A useful counterpoint to the PAGE model's pessimism about the futility of adaptation beyond 2°C of warming and 0.20-0.25 meters of sea-level rise is Hinkel et al. (2014), a study published in Proceedings of the National Academy of Sciences and reviewed by Bjorn Lomborg in his recent book False Alarm. The study includes an RCP8.5 warming scenario in which sea levels rise up to six feet and flood 350 million people every year by century's end, with costs reaching $100 trillion or 11 percent of global GDP annually.68 However, those extraordinary damages are projected to occur only if people do nothing more than maintain current sea walls.

If 'enhanced' adaptive measures are taken, annual flood costs increase from $11 billion in 2000 to $38 billion in 2100. Similarly, annual dike costs increase from $13 billion to $48 billion. However, Lomborg notes, 'the total cost to the economy will actually decline, from 0.05 percent of GDP to 0.008 percent.' Moreover, the number of people experiencing flood damages drops from 3.4 million in 2000 to 15,000 in 2100—a 99.6 percent reduction in flood victims! In other words, with reasonable adaptation, people are projected to be much safer, and the global economy much less affected by sea-level rise in 2100, despite high-end warming.69

If the EPA continues to use SCC estimates, it should eschew those produced by models that assume humanity is powerless to mitigate the costs of even modest levels of warming and sea-level rise. Visionaries have been predicting doomsday for millennia and none has ever been correct.

Section 9: Implausible Emission Baselines

We have discussed several ways modelers can inflate SCC estimates: run the models with below-market discount rates, project social costs far beyond the limits of informed speculation, assume climate sensitivities derived from general circulation models that repeatedly overshoot observed warming, use models that depreciate (or simply ignore) CO2 fertilization benefits, and use models that lowball human adaptive capabilities. Another way is to run the IAMs with implausibly high baseline emission scenarios. University of Colorado professor Roger Pielke, Jr. recently spotlighted this fatal flaw in the IWG exercise.70

To estimate the incremental impact of one ton of CO2 emissions, SCC modelers must first estimate how global emissions and concentrations will change over time. Such estimates are only as credible as the socio-economic development scenarios on which they are based. The IWG calculates SCC values with five emission trajectories. Four are no-climate-policy emission trajectories projected by four socio-economic models participating in a 2009 Stanford Energy Modeling Forum study known as EMF-22.71 The fifth, a climate policy scenario, is the average trajectory produced by the same four models run with a CO2 stabilization target of 550 parts per million. For more detail, see the Electric Power Research Institute's (EPRI) 2014 technical assessment report.72

Here is the gist. The EMF models estimated emissions growth through 2100. The IWG took those trajectories and extended them out to 2300. According to EPRI, 'the extensions lack a coherent, viable, and intuitive storyline (or set of storylines)' that could explain the emission pathways after 2100. That is not surprising. As noted above, nobody can foresee how the global economy will evolve centuries into the future. The IWG did not even try to guess how economies would develop after 2100, yet nonetheless plotted emissions growth over the next 200 years. Based on what assumptions? Apparently, the IWG assumed that, absent specific climate change mitigation policies, the global economy would burn through all fossil fuel reserves and do so repeatedly.

As EPRI put it, all four 'reference' (no-climate-policy) scenarios (USG1 – USG4) 'result in post-2100 cumulative CO2 emissions in excess of estimated fossil reserves.' [Table 4-6 can be found at docket number EPA-HQ-OAR-2021-0292-A1, p. 25]

For example, in the USG2 scenario, cumulative CO2 emissions reach 22,024 gigatons in 2200 and 33,023 gigatons in 2300—multiples of the estimated reserves (3,674 – 7,113 gigatons).

Thus, the IWG's SCC estimates 'envision cumulative carbon dioxide emissions that are far, far in excess of any plausible current expectation about the future,' Pielke, Jr. observes. 'In fact,' he continues, 'to even approach these massive amounts of cumulative emissions, the world would have to make it a policy goal to burn as much coal as possible over the coming centuries. That seems unlikely.'

The IWG's 300-year emission baselines are even more implausible than RCP8.5,73 the so-called business-as-usual (BAU) emission scenario used in the U.S. National Climate Assessment, IPCC AR5, AR6 (updated as SSP5-8.5), and literally thousands of other climate impact studies.74 For RCP8.5 to be a realistic projection of future CO2 emissions and concentrations, coal consumption would have to increase ten-fold during 2000-2100,75 achieving market shares not seen since the 1940s.76 [Figure 5 can be found at docket number EPA-HQ-OAR-2021-0292-A1, p. 26]

That is not happening, and emission trends increasingly diverge from those projected in RCP8.5. See the chart below by Zeke Hausfather and Glenn Peters. The chart shows that RCP8.5-projected CO2 emissions in 2050 are more than double those projected by the International Energy Agency in its baseline (current and pledged policies) emission scenarios.77 [Figure International Energy Agency can be found at docket number EPA-HQ-OAR-2021-0292-A1, p. 27]

One point that should leap out at attentive readers is that no-policy scenarios such as RCP8.5 are no longer 'reference case' or 'business-as-usual' baselines. Climate policies have been proliferating since the IWG's first SCC report in 2010. Yet the IWG continues to treat the obsolete EMF-22 'no policy' scenarios as BAU baselines.

More importantly, the EMF-22 no-policy scenarios would be unrealistic even if governments were not adopting climate policies. In 'The 1000 GtC coal question: Are cases of vastly expanded future coal combustion still plausible?'78 Justin Ritchie and Hadi Dowlatabadi show that all of the IPCC's five assessment reports 'use business-as-usual (BAU) scenarios that combust most or all coal reserves before the year 2100.' The basic idea is that coal is the inexpensive backstop energy source for the global economy, with reserve-to-production (R-P) ratios that increase over time as technological progress decreases extraction costs. Ritchie and Dowlatabadi further note that DICE, FUND, and PAGE 'adopt similar reference case assumptions for coal,' as do the EMF baseline scenarios underpinning the IWG's technical support documents.

Such scenarios are no longer plausible projections for the 21st century. The current coal R-P ratio is about 100 years—an order of magnitude lower than 1960s vintage assessments (>900 years) and two-thirds lower than the 300-year R-P ratio estimated in 1990. [Figure 1d can be found at docket number EPA-HQ-OAR-2021-0292-A1, p. 28]

Moreover, instead of real coal prices falling, as assumed in the IPCC, IAM, and EMF reference scenarios, prices in 2016 were about the same as in 1990, and have risen since 2000. In fact, coal prices today ($177 per metric ton) are more than double the average price in 2016.79 [Figure 1a can be found at docket number EPA-HQ-OAR-2021-0292-A1, p. 29]

Ritchie and Dowlatabadi comment: 'All else equal, conventional resource economists theorize that higher sustained commodity prices lead to a reclassification of marginal geologic deposits as economically recoverable reserves. Yet, since the doubling of coal prices and production in 2000, reserves declined by roughly 15 percent.' [Figure 1c can be found at docket number EPA-HQ-OAR-2021-0292-A1, p. 29]

In short, 'today's [coal] reserves are now more costly and less abundant than assumed 30 years ago.' That is due to several factors including constraints on extraction related to air and water quality regulations, declining social acceptance of mining operations near populated areas, the replacement of human labor with excavation machines too large to access smaller deposits, the absence (despite decades of R&D) of significant markets for coal-to-liquid motor fuel and coal syngas electricity fuel, and increased competition from unconventional oil and natural gas.

It is therefore no longer reasonable to view 'all geologic coal resources as eventual reserves' that sooner or later will be combusted. That is akin to assuming that 'all oceans should be on a supply curve for drinkable water' just because 'the total quantity of ocean water is vast and existing technology could theoretically convert all saltwater to replace fresh water.'

Ritchie and Dowlatabadi acknowledge that 'technological breakthroughs' may reverse the rise in coal prices and decline in coal R-P ratios. 'However, to assume [such breakthroughs] as constituting a plausible reference case is a tall ask.' To sum up, there is no evidence that, absent stringent new climate policies, coal will dominate global energy for centuries to come.80

Section 10: Comparing Apples and Oranges

In addition to stipulating that agencies should use both 3 percent and 7 percent discount rates in benefit-cost analysis, OMB Circular A-4 states:

The analysis should focus on benefits and costs that accrue to citizens and residents of the United States. Where the agency chooses to evaluate a regulation that is likely to have effects beyond the borders of the United States, these effects should be reported separately.81

Comparing domestic benefits to domestic costs makes obvious sense. It is Americans who chiefly bear the costs of domestic GHG regulations, so quantification of the associated U.S. climate benefits (to the extent that the SCC is quantifiable at all) is reasonable and appropriate.

Nonetheless, the IWG only estimates the global benefits of GHG emission reductions and suggests domestic benefit estimation is foolish or worse. We're admonished that GHG emissions are global externalities; that climate damages abroad have 'spillover' effects in the United States; that there are relatively few region- or country-specific SCC estimates in the literature; that IAMs were not calibrated to estimate domestic climate damages; and that presenting global SCC estimates facilitates U.S.-led international policy coordination.82

Whatever the merits of those points, they do not rebut the fact the agencies' current practice misleads the public by comparing apples to oranges. It encourages the public to mistakenly infer that it will reap most or all of the net benefits calculated by subtracting domestic regulatory costs from global climate change mitigation benefits. However valid it may be to present global SCC-based benefits, those should be reported separately, as Circular A-4 directs. There is no scientific or ethical justification for hiding U.S. domestic SCC estimates from the public.

The IWG discussed domestic SCC estimation in its 2010 TSD.83 The continuing dearth of country-specific SCC estimates and IAMs calibrated to estimate domestic SCC values strongly suggests agencies are not funding such research. Is that because domestic SCC estimates, even when inflated by all the methodological biases discussed above, are not large enough to support the 'climate crisis' narrative?

According to the 2010 TSD, the FUND model indicates the U.S. benefit of reducing CO2 emissions is about 7-10 percent of the global benefit.84 Based on such speculation (and, to repeat, all SCC estimation is speculation), the Trump administration estimated the domestic SCC in 2020 to be $7 per ton—about 86 percent lower than the IWG's 2016 estimate.85 [Table GAO-20-254 can be found at docket number EPA-HQ-OAR-2021-0292-A1, p. 31]

This much is clear. Failure to compare domestic climate policy costs and benefits injects a pro-regulatory bias into American politics. But then, so do all the IWG methodological decisions discussed above.

Section 11: Conclusion

The EPA's estimate of $91 billion in climate benefits from the proposed GHG motor vehicle standards does not withstand scrutiny. It depends on so many questionable and biased methodological choices there is no good reason to believe the projected emission reductions have any actual monetary value.

The studies by Dayaratna and colleagues reviewed above show that reasonable alternative assumptions substantially drive down SCC estimates, even pushing SCC values into negative territory. Replacing the obsolete EMF-22 baselines with realistic emission scenarios would further decrease SCC values during 2023-2050 and beyond.

However small (or negative) the global SCC would be after all reasonable adjustments are made to assumptions regarding discount rates, time horizons, climate sensitivity, CO2 fertilization, adaptive capabilities, and baseline emission trajectories, the SCC would be smaller still (or increasingly negative) if calculated on a domestic (U.S.-only) basis.

Finally, because the proposal's $91 billion climate benefits estimate is an inference from undetectably small hypothetical changes in global temperature with no discernible or verifiable environmental impacts, those benefits are not real enough to be netted against the tens of billions of dollars in annual costs the proposal would indisputably impose on automakers and consumers. [EPA-HQ-OAR-2021-0208-0292-A1, pp. 23-32]

EPA Response

EPA acknowledges the commenter's input and notes that it determined what standards were appropriate in light of the need for emissions reductions, the cost of compliance and lead time, and found the benefit-costs results of the RIA provide additional support for its conclusions. Under Section 202 of the CAA, EPA is required to establish standards to reduce air pollution that endangers public health and welfare, taking into consideration the cost of compliance and lead time. EPA is not required to conduct formal cost benefit analysis to determine the appropriate standard under Section 202. EPA weighed the relevant statutory factors to determine the appropriate standard and the analysis of monetized GHG benefits was not material to the choice of that standard. EO 12866 requires EPA to perform a cost-benefit analysis, including monetizing costs and benefits where practicable, and the EPA has conducted such an analysis. The monetized GHG benefits are included in the cost-benefit analysis. That cost-benefit analysis provides additional support for the EPA's final standards.

With respect to the social cost of greenhouse gases, EPA recognizes the limitations and uncertainties associated with the current interim IWG estimates and underlying methodology. EPA participated in the IWG and has carefully considered for this rulemaking the February 2021 TSD, the underlying studies discussed in the TSD and the issues raised by commenters. EPA concludes that, as noted in Section 3.3 of the RIA and elsewhere in this RTC, the discussions in the TSD represent appropriate consideration of the various issues (e.g., appropriate discount rate and scope) and the resulting estimates of the TSD represent appropriate, if conservative, estimates for purposes of this rulemaking.

Please see the response to AEI in Section 14.1 on modeling uncertainties and the NAESM recommendations for the SC-GHG models and estimates. Please see the response to AEI in Section 14.1 of this document on the choice of discount rate and intergenerational discounting.

Commenter: Institute for Policy Integrity at NYU Law et al.

EPA appropriately applies the social cost estimates developed by the Interagency Working Group on the Social Cost of Greenhouse Gases (Working Group') and rejects the faulty numbers that EPA applied from 2017 until early 2021. The Working Group developed its social cost estimates through a rigorous and transparent process incorporating the best available science. Those values though widely agreed to underestimate the full social costs of greenhouse gas emissions4 are appropriate to use as conservative estimates and have been applied in dozens of previous rulemakings 5 and upheld in federal court.6 In contrast, the estimates that EPA and other federal agencies applied during the Trump administration disregarded the best available science and were rejected by a federal court as arbitrary and capricious.7

EPA provides several compelling justifications for readopting the Working Group's estimates. But while the legal challenges that have already been brought against the Working Group's estimates are unfounded,8 EPA should anticipate similar legal challenges to its application of the social cost of greenhouse gases and so provide additional justifications for its policy choices on this consequential issue.9 In particular, EPA should expand upon its justifications for adopting a global damages valuation and for the range of discount rates it applies to climate effects. As detailed herein, there are many additional legal, economic, and policy justifications for such methodological decisions that can further bolster EPA's support for these choices. EPA should also strongly consider conducting supplemental sensitivity analyses to further confirm that strengthening the vehicle emissions standards will deliver significant net benefits to society under a range of analytical assumptions.

These comments are organized into five sections. First, as Section I recommends, EPA should both explicitly affirm that, in EPA's own expert judgment, those estimates are appropriate but conservative lower bounds that omit significant categories of climate damages. [EPA-HQ-OAR-2021-0208-0268-A1, pp. 1-2]

Section II recommends that EPA provide additional justification for adopting a global framework for valuing climate impacts. These include legal justifications based on the Clean Air Act, the National Environmental Policy Act's broad government-wide policy mandates, the Administrative Procedure Act's requirement to consider all important factors, and executive orders and international agreements. EPA can similarly strengthen its economic and policy justifications, such as by explicitly concluding that the theory and evidence for international reciprocity justify a focus on the full global values. Section II also recommends that EPA modify its discussion of domestic-only estimates. The RIA currently uses, in a footnote, the flawed domestic-only values developed under the now-revoked Executive Order 13,783.10 Though EPA correctly judges those values to be underestimates, they are actually fatally incomplete11 and should not be used. EPA should instead consider conducting sensitivity analysis using a sounder domestic-only estimate as a backstop to minimize legal risk. [EPA-HQ-OAR-2021-0208-0268-A1, pp.2-3]Section III recommends that EPA provide additional justification for adopting the range of discount rates endorsed by the Working Group and for appropriately deciding not to apply a 7% capital-based discount rate to climate impacts. In particular, EPA should provide additional justification for combining climate effects discounted at an appropriate consumption-based rate with other costs and benefits discounted at a capital-based rate. Besides climate effects presenting special legal, economic, and policy considerations for the discount rate, EPA should also argue that it is appropriate generally to focus its analysis of this rule on consumption-based rates given that most costs and benefits are projected to fall to consumption rather than to capital investments. We also urge EPA to consider providing additional sensitivity analysis using discount rates of 2% or lower for climate impacts, as recently suggested by the Working Group.

Section IV recommends that EPA bolster its justification for relying on the Working Group's other methodological choices, including the fact that the Working Group applied a transparent and rigorous process that relied upon the best-available and most widely-cited models for monetizing climate damages. This section also provides detailed rebuttals to common criticisms of the Working Group's methodology from opponents of climate regulation.

Finally, Section V encourages EPA to apply the social cost of greenhouse gases estimates that it developed through 2070, to coordinate with the Working Group (of which EPA is a member) to adopt social cost values through at least that time period, and more broadly to extend its analytical time frame to capture all significant benefits. [EPA-HQ-OAR-2021-0208-0268-A1, p.3]

EPA Should Affirm That, in Its Expert Judgment, the Working Group's Social Cost of Greenhouse Gas Estimates Are Appropriate But Conservative.

Both the Proposed Rule12 and the RIA13 cite and quote the Working Group's February 2021 Technical Support Document as support for the methodological choices underlying the social cost of greenhouse gas values that EPA applies in its analysis. In particular, EPA cites the Working Group's conclusion that the values likely underestimate' climate damages.14 Such references provide compelling justifications for applying the Working Group's estimates as appropriate lower bounds. However, EPA should take the additional steps of explicitly incorporating the Working Group's entire Technical Support Document by reference, and then affirming that in EPA's own judgment, the values it endorses are conservative underestimates.

These additional steps will serve two important goals. First, they will help shield EPA from any attacks that the agency's reliance on the Working Group's guidance or its justification for the values is in any way incomplete. Second, they will bolster the case that stronger vehicle emission standards will deliver significant net benefits to society. Notably, the Working Group's estimates do not currently reflect (due to data limitations) climate damages from many significant effects that EPA has a statutory responsibility to consider, including ocean acidification, wildfires, public health effects from methane emissions, abrupt ecosystem disruptions, and many potentially catastrophic outcomes, to name just some categories of omitted damages. 15 Because of such omitted damages and other limitations of the current estimates, the Working Group's central estimates of global damages calculated at a 3% discount rate are most likely severe underestimates of the full climate effects from greenhouse gas emissions. EPA should note in all its presentations of net benefits that its estimates of climate benefits are conservative underestimates that do not currently include many significant categories of climate damages.16 [EPA-HQ-OAR-2021-0208-0268-A1, pp. 3-4]

EPA Should Provide Additional Justification for Its Reliance on Global Climate Damage Valuations, While Considering Additional Analysis of Domestic Effects

In the Proposed Rule, EPA appropriately focuses on a global estimate of climate benefits, returning to its historical approach and correcting its recent, temporary, and arbitrary practice of disregarding all climate effects that occur outside the physical borders of the United States.

While EPA offers persuasive justifications for this decision,17 it should provide additional analysis on this front.18 In particular, EPA should emphasize the concern for the impacts of U.S. pollution on foreign welfare in the Clean Air Act and other sources of law, further highlight the significance of U.S. strategic interests and reciprocity, discuss the importance of extraterritorial impacts and spillovers, and highlight the inconsistency that would occur if the agency considered only domestic benefits while focusing on global costs. At the same time, since reliance solely on a global valuation carries some legal risk, EPA may wish to conduct additional sensitivity analysis around a domestic-only valuation.

Relevant Statutes and Executive Orders Compel, And Certainly Permit, a Global Perspective on Climate Damages.

The Clean Air Act, National Environmental Policy Act, Administrative Procedure Act, and other key sources of law not only permit, but in fact require EPA to consider international effects. EPA should highlight these legal requirements as justification for its focus on global climate impacts.

Section 202 of the Clean Air Act, under which EPA issues the Proposed Rule, charges EPA with regulating 'air pollutant[s] which may be reasonably anticipated to endanger public health or welfare,'19 where 'welfare' is defined to include 'effects on . . . weather . . . and climate.'20 When interpreting Section 202, the Supreme Court found 'there is nothing counterintuitive to the notion that EPA can curtail the emission of substances that are putting the global climate out of kilter.'21 And when industry challenged another EPA climate program by arguing that the Clean Air Act 'was concerned about local, not global effects,' the U.S. Court of Appeals for the D.C. Circuit had 'little trouble disposing of Industry Petitioners' argument that the [Clean Air Act's prevention of significant deterioration] program is specifically focused solely on localized air pollution,' finding instead that the statute was 'meant to address a much broader range of harms,' including 'precisely the types of harms caused by greenhouse gases.'22

Environmental and administrative law scholar Richard Revesz, who also directs the undersigned Institute for Policy Integrity, has exhaustively reviewed the legislative history of the Clean Air Act's definition of 'welfare' and has concluded that 'when Congress included the 'effects on . . . climate' language in the statute, it understood that adverse climate effects could occur on a global scale.'23 For instance, Senator Caleb Boggs, a Republican from Delaware and ranking minority member of the Public Works Subcommittee on Air and Water Pollution, which was considering the Clean Air Act in 1970, entered a report into the record stating that air pollution 'alters climate and may produce global changes in temperature.'24 Senator Jennings Randolph of West Virginia likewise submitted a statement into the record explaining that U.S. air pollution could 'produce unacceptable worldwide climate changes.'25 Congress's clear concern for the effects of domestic pollution on the global climate—many more examples of which are discussed in Professor Revesz's article—demonstrates that a global perspective is appropriate, if not required, when EPA regulates under the Clean Air Act. [EPA-HQ-OAR-2021-0208-0268-A1, pp. 4-5]

This interpretation is further compelled by the National Environmental Policy Act ('NEPA'). Though best known for requiring agencies to prepare environmental impact statements before taking certain actions (a requirement that does not apply to Clean Air Act actions),26 NEPA also much more broadly declares a national environmental policy and requires of all agencies that ‘to the fullest extent possible[,] the policies, regulations, and public laws of the United States shall be interpreted and administered in accordance with the policies set forth in this chapter,’ including the need to ‘recognize the worldwide and long-range character of environmental problems’ and to ‘lend appropriate support’ to help ‘maximize international cooperation.’28 In other words, especially because adopting a global perspective on climate damages will advance U.S. foreign policy goals (see the next subsection), NEPA requires EPA to interpret all of its laws, including the Clean Air Act, in ways that recognize the worldwide character of environmental problems. Using global social cost of greenhouse gas estimates helps fulfill that requirement.

Other key legal commitments compel this same conclusion. For instance, the United Nations Framework Convention on Climate Change—to which the United States is a party—declares that national ‘policies and measures to deal with climate change should be cost-effective so as to ensure global benefits at the lowest possible cost.’30 The Convention further commits parties to evaluating global climate effects in their policy decisions, by ‘employ[ing] appropriate methods, for example impact assessments . . . with a view to minimizing adverse effects on the economy, on public health and on the quality of the environment, of projects or measures undertaken by them to mitigate or adapt to climate change.’31 The unmistakable implication of the Convention is that parties—including the United States—must account for global economic, public health, and environmental effects in their impact assessments. In 2008, a group of U.S. senators—including then-Senator John Kerry, who helped ratify the framework convention on climate change—agreed with this interpretation of the treaty language, saying that ‘[u]pon signing this treaty, the United States committed itself to considering the global impacts of its greenhouse gas emissions.’

And under the Administrative Procedure Act, it is arbitrary and capricious for agencies to ‘entirely fail[] to consider an important aspect of the problem’—an obligation that a federal court held requires federal agencies to consider international climate impacts. Specifically, a recent ruling from the U.S. Court for the Northern District of California struck down as arbitrary the Bureau of Land Management’s (‘BLM’) rescission of the Waste Prevention Rule in part because the agency had abandoned the Working Group’s peer-reviewed, global estimates of the social cost of greenhouse gases in favor of flawed estimates (the same estimates that EPA applied under the Trump administration) that looked only at effects within the U.S. borders. The court found that the global values developed by the Working Group reflected ‘the best available science about monetizing the impacts of greenhouse gas emissions,’ whereas ‘focusing solely on domestic effects has been soundly rejected by economists as improper and unsupported by science.’ The court reminded BLM that relevant executive orders, including Executive Order 12,866, require consideration of ‘all’ costs and benefits, based on the ‘best reasonably obtainable scientific, technical, economic, and other information,’ and concluded that ‘no[] . . . regulatory rules or orders require exclusion of global impacts.’ More recently, Executive Order 13,990 instructed agencies to ‘tak[e] global damages into account,’ because ‘[d]oing so facilitates sound decision-making, recognizes the breadth of climate impacts, and support the international leadership of the United States on climate issues.’ This language again reinforces the instructions from NEPA that, whenever not precluded by statute from doing so, agencies should account for the environmental impacts of their actions on foreign nations.

EPA should draw upon these legal authorities in justifying its reliance on global climate-damage valuations. [EPA-HQ-OAR-2021-0208-0268-A1, pp.5-7]

26 While actions taken under the Clean Air Act 'shall [not] be deemed a major Federal action significantly affecting the quality of the human environment within the meaning of [42 U.S.C. § 4332(2)(C)],' 15 U.S.C. § 793(c)(1), the other provisions of NEPA—including those quoted and cited in this paragraph—continue to apply.

28 Id. § 4332(2)(F); see also EDF v. Massey, 986 F.2d 528, 536 (D.C. Cir. 1993) ('Section 102(2)(F) further supports the conclusion that Congress, when enacting NEPA, was concerned with worldwide as well as domestic problems facing the environment. . . . Compliance with one of the subsections can hardly be construed to relieve the agency from its duty to fulfill the obligations articulated in other subsections.'); NRDC v. NRC, 647 F.2d 1345, 1387 (D.C. Cir. 1981) (J. Robinson, concurring; J. Wilkey wrote for the Court, but there was no majority opinion) (concluding that even if a conflict with another statute prevents the agency from conducting an environmental impact statement, that 'does not imply that NRC may ignore its other NEPA obligations,' including the 'provision for multinational cooperation' and the 'policy of the United States with respect to the ecological well-being of this planet'; rather, the agency 'should remain cognizant of this responsibility'); Greene County Planning Bd. v. Federal Power Comm'n, 455 F.2d 412, 424 (2d Cir. 1972) ('The Commission's 'hands-off' attitude is even more startling in view of the explicit requirement in NEPA that the Commission 'recognize the worldwide and long-range character of environmental problems' and interpret its mandate under the Federal Power Act in accordance with the policies set forth in NEPA.').

30 U.N. Framework Convention on Climate Change art. 3(3), May 9, 1992, 1771 U.N.T.S. 107 (emphasis added); see also id. art. 3(1) ('The Parties should protect the climate system for the benefit of present and future generations of humankind, on the basis of equity and in accordance with their common but differentiated responsibilities and respective capabilities.') (emphasis added); id. art. 4(2)(a) (committing developed countries to adopt policies that account for 'the need for equitable and appropriate contributions by each of these Parties to the global effort').

Focusing on Global Climate Damages Furthers U.S. Strategic Interests by Facilitating Reciprocity, Mitigating International Spillover Effects, and Protecting U.S. Extraterritorial Interests.

EPA explains that the Working Group selected a global perspective because climate impacts occurring outside U.S. borders can directly and indirectly affect U.S. welfare through spillovers and foreign reciprocity, and that EPA is readopting that global perspective consistent with its approach from 2009 2016.39 EPA should expand on this justification. In particular, EPA should explicitly explain why the theory and evidence for reciprocity by itself justifies a focus on the full global values, and that additional strategic and practical justifications provide further support.

Use of the Global Values Facilitates International Reciprocity. Because the world's climate is a single interconnected system, the United States benefits greatly when foreign countries consider the global externalities of their greenhouse gas pollution and cut emissions accordingly. It therefore promotes the strategic interests of the United States to encourage all other countries to think globally in setting their climate policies. The United States can advance this objective by itself adopting the full global social cost of greenhouse gases as numerous leading climate economists and experts have explained.40 Indeed, basic economic principles demonstrate that the United States stands to benefit greatly if all countries apply global social cost of greenhouse gas values in their regulatory decisions and project reviews41 likely trillions of dollars in direct benefits from foreign action to combat climate change.42

The Biden Administration has clearly made such a strategic choice, to adopt a global valuation of climate damages as part of its diplomatic strategy. Executive Order 13,990 unequivocally states that [i]t is essential that agencies capture the full costs of greenhouse gas emissions as accurately as possible, including by taking global damages into account . . . [to] support the international leadership of the United States on climate issues.'43 The Order later elaborates: Our domestic efforts must go hand in hand with U.S. diplomatic engagement. Because most greenhouse gas emissions originate beyond our borders, such engagement is more necessary and urgent than ever. The United States must be in a position to exercise vigorous climate leadership in order to achieve a significant increase in global climate action and put the world on a sustainable climate pathway.'44

There is already evidence that the U.S. strategy of combining its domestic efforts including the global valuation of climate damages with its diplomatic engagement is spurring foreign reciprocity. During the April 2021 Leaders' Summit on Climate' hosted by the United States, following the announcement of a new U.S. commitment to reduce emissions to 50 52% below 2005 levels by 2030, multiple other countries reciprocally increased the ambition of their own climate targets. Notably, Japan accelerated its reduction goal from 26% to 46 50%; Canada strengthened its target from 30% to 40 45%; the European Union set a target of at least 55%; the United Kingdom set a new target for the year 2035; South Korea strengthened its target to achieve net zero emissions by 2050; China promised to peak coal use by 2025 and phase down coal consumption after that, and to join the Kigali Amendment to reduce hydrofluorocarbon emissions; Argentina pledged to strengthen its goal by 2.7% and make previously conditional' targets unconditional' instead; Brazil committed to a net zero target by 2050 (ten years earlier than its previous 2060 goal) and pledged to end illegal deforestation by 2030; South Africa shifted its emission peak ten years earlier, to 2025; and New Zealand, Bhutan, and Bangladesh all committed to submit more ambitious plans in the near future.45

This flurry of activity is just the latest evidence of reciprocity in international climate actions. Some past reciprocity has been explicit. The Kigali Amendment, for example, is the latest internationally negotiated climate treaty, with more than 120 parties so far committing to common but differentiated responsibilities to phase down hydrofluorocarbons. 46 Previously, under the Copenhagen Accord and the Paris Agreement, some parties, including the European Union and Mexico, have at times explicitly made conditional pledges, promising to ratchet up their efforts if other countries make comparable reductions.47 By contrast, when the United

States failed to take action to reduce greenhouse gas emissions during the George W. Bush Administration and during the Trump Administration,’ as economist Michael Greenstone has testified before the U.S. House of Representatives, both periods were characterized by little [international] progress, and indeed many instances of backsliding, in reducing emissions globally.’48 By failing to take international climate damages into account, in other words, EPA and other U.S. agencies would incentivize other countries to do the same, which in turn would cause greater greenhouse gas pollution originating in other countries that causes climate damage within the United States.

In January 2021, Trevor Houser and Kate Larsen published a conservative estimate of the number of tons of greenhouse gases that the rest of the world has committed to reduce for each ton that the United States has pledged to reduce: a figure they call the Climate Reciprocity Ratio.’49 Using only the quantifiable, unconditional pledges that 51 countries have made since 2014 to cut emissions through 2030, Houser and Larsen conservatively estimate that for every ton the United States pledged to reduce, these other countries have pledged 6.1 6.8 tons in return.50 While implementation of all these foreign policies is not guaranteed, Houser and Larsen cite evidence that several large emitters are on track to meet their goals, and that the ratio should grow over time as the U.S. share of global emissions falls.51

In short, both empirical evidence and economic theory strongly support a strategic choice for U.S. agencies to adopt the full global estimates of the social cost of greenhouse gases, as this facilitates international reductions in greenhouse gas pollution that directly benefits the United States. EPA should therefore explicitly make the case that current evidence of foreign reciprocity supports a focus on the full global valuations of the social cost of greenhouse gases. [EPA-HQ-OAR-2021-0208-0268-A1, pp.7-10]

Use of the Global Values Recognizes Spillover Impacts from Climate Change. Significant costs to trade, human health, and security will inevitably spill over’ to the United States as other regions of the planet experience climate change damages.52 Due to its unique place among countries both as the largest economy with trade- and investment-dependent links throughout the world, and as a military superpower the United States is particularly vulnerable to effects that will spill over from other regions of the world. Use of global damage values recognizes these spillover effects, which were ignored under the Trump administration’s domestic-only valuation.

These spillover effects take many forms. In terms of trade-related impacts, for one, as climate change disrupts the economies of other countries, decreased availability of imported inputs, intermediary goods, and consumption goods will cause supply shocks to the U.S. economy, causing particularly damaging disruptions in sectors such as agriculture and technology. Similarly, the U.S. economy will experience demand shocks as climate-affected countries decrease their demand for U.S. goods. U.S. trade and businesses that rely on foreign-owned infrastructure, services, and resources will suffer.53 Financial markets will also suffer as foreign countries become less able to loan money to the United States and as the value of U.S. firms declines with shrinking foreign profits. As seen historically, economic disruptions in one country can cause financial crises that reverberate globally at a breakneck pace.54

Climate change is also predicted to exacerbate existing security threats and possibly catalyze new security threats to the United States.55 Besides threats to U.S. military installations and operations at home and abroad from flooding, storms, extreme heat, and wildfires,56 climate change is also a source[] of conflict around the world'57 and a threat multiplier' that, as recognized by the Department of Defense, will aggravate stressors abroad such as poverty, environmental degradation, political instability, and social tensions conditions that can enable terrorist activity and other forms of violence.'58 Climate change will create and exacerbate new conflicts and humanitarian crises that will require a U.S. response, even as climate change also complicates the logistics of deploying forces and achieving missions.

Climate change will also very directly cause spillover damages across transboundary resources. The United States has already begun to experience increased smoke from Canadian wildfires and drought conditions that spread along the U.S.-Mexico border.59 The United States shares a maritime border with 21 other countries, shares water resources like the Columbia River with our neighbors, and shares ecosystems including the oceans through which migratory species with high economic and ecosystem-service values, like the Pacific hake, travel and live.60

All of these individual spillover effects can also interact and trigger feedback loops that will propagate additional spillover damages.61 Economic shocks around the world can make it more difficult for other countries to continue investing in mitigation and abatement, thus hastening the pace of climate change.62 Conflict and political instability caused by climate change can further reduce the willingness or ability of countries to engage in domestic climate policy or international cooperation.63 Spillover effects can chain together: if climate change accelerates migration, the attendant economic ripple effects and spread of health risks may cause political instability, which in turn can cause more migration and further economic ripple effects, thus starting the feedback loop again.64

Some experts on the social cost of greenhouse gases have therefore concluded that, because the integrated assessment models that underlie the Working Group's social cost valuations currently do not capture many of these key inter-regional costs, use of the global values can be further justified as a proxy for capturing all spillover effects.65 Though not all climate damages will spill back to affect the United States, many will, and together with other justifications, the likelihood of significant spillovers makes a global valuation the better, more transparent accounting of the full range of costs and benefits that matter to U.S. policymakers and the public. EPA can therefore highlight spillover impacts as further justification for relying on global social cost valuations. In addition to the spillover effects that EPA already mentions,66 EPA should argue that transboundary spillovers, feedback loops, information spillovers, and other effects justify a focus on the full global values, either independently or in combination with other strategic and ethical considerations.67 [EPA-HQ-OAR-2021-0208-0268-A1, pp.10-12]

Use of the Global Values Preserves Extraterritorial Interests. The RIA mentions direct and indirect impacts to U.S. citizens and assets located abroad as a justification for a global valuation,68 but U.S. extraterritorial interests are even more extensive and significant. A domestic-only estimate of the social cost of greenhouse gases based on some rigid conception of geographic borders or U.S. share of world GDP will fail to capture all the climate-related costs and benefits that matter to U.S. citizens, including impacts to significant U.S. ownership interests in foreign businesses, properties, and other assets, as well as U.S. consumption abroad including tourism,69 and even effects to the millions of Americans living abroad.70 The United States also has military personnel and assets located in almost every nation across the globe, and many if not all installations abroad including those with high replacement costs or irreplaceable strategic value face imminent climate risks.71 Because no methodology for estimating a domestic-only' value would capture these impacts to extra-territorial interests, focusing on the global values can be further justified in part as a proxy for these important considerations.

The Office of Management and Budget's Circular A-4 guidance on conducting regulatory impact analysis requires agencies to count all significant costs and benefits, including use' values as well as non-use' values like bequest and existence values.72 Circular A-4 cautions that ignoring these values' may cause analyses to significantly understate the benefits and/or costs' involved.73 Similarly, Circular A-4 recognizes that U.S. citizens may have altruism for the health and welfare of others,' and instructs agencies that when there is evidence of selective altruism, it needs to be considered specifically in both benefits and costs.'74 U.S. citizens will experience costs because of their use values, non-use values, and altruistic values attached to climate effects occurring outside the U.S. borders.

Such non-use and altruistic values take many forms. For one, the United States and its citizens have a willingness to pay as well as a legal obligation to protect the global commons of the oceans and Antarctica from climate damages. Furthermore, a quarter of the U.S. population consists of either foreign-born immigrants or second-generation residents,75 and subsequent generations of Americans retain significant familial, cultural, economic, and religious ties to their ancestors' home nations across the world.76 U.S. citizens and residents have a significant willingness to pay to protect their relatives, ancestral homes, and cultural and religious sites located abroad.77 Similarly, U.S. citizens value natural resources and plant and animal lives abroad even if they never see or use those resources and care about the health and welfare of unrelated foreign citizens78 and cultural and world heritage sites threatened by climate change.79 This altruism is selective altruism,' consistent with Circular A-4, because the United States is directly responsible for a huge amount of the historic emissions contributing to climate change.80

Both strategic considerations and the need to account for spillovers already provide independent justifications for focusing on the full global social cost of greenhouse gas estimates. But the global values can also be at least partly justified as a proxy for these extra-territorial interests that otherwise would be overlooked using a domestic-only damage estimate. EPA can therefore highlight U.S. extraterritorial interests as further justification for relying on global social cost valuations, and should specifically call attention to climate-vulnerable U.S. military instillations abroad with high replacement costs or irreplaceable strategic value, U.S. willingness to pay to protect relatives, ancestral homes, cultural and religious sites, and natural resources located abroad, and U.S. altruism toward the people, animals, and natural habitats across the globe. [EPA-HQ-OAR-2021-0208-0268-A1, pp.12-14]

Focusing on Global Climate Damages Is Consistent With EPA's Consideration of Global Costs. EPA can further justify its focus on global climate benefits as necessary for consistency with the rest of its analysis. To begin, EPA decided to treat monopsony impacts as an international transfer payment, rather than as potential benefits to U.S. consumers at the expense of foreign oil producers.81 As Circular A-4 suggests, an analysis adopts a global rather than U.S.-centered perspective when it treats such international flows as transfers rather than as costs or benefits.82 And while a global perspective on climate damages can be justified on strategic grounds that would not necessarily compel also treating monopsony effects as transfers rather than as U.S. benefits, adopting a global perspective on such monopsony effects is consistent with adopting a global perspective on climate effects.

More broadly, EPA's analysis implicitly takes a global perspective on technology costs, and so it would be arbitrary not to take a global perspective on climate effects as well. All industry compliance costs ultimately fall on the owners, employees, or customers of regulated and affected firms. Whether the Proposed Rule's technology costs are passed to consumers or investors, or some combination thereof, a significant portion of the Proposed Rule's alleged compliance costs will ultimately accrue to foreign customers or foreign investors. Regulated manufacturers include major corporations that are headquartered abroad or that are publicly traded with investors across the globe.83 Consumers similarly include corporate fleets of passenger vehicles and light-duty trucks owned by foreign entities or by public corporations with foreign shareholders.84 In general, about 29% of U.S. corporate debt and 14% of equities are foreign-owned,85 and adding foreign direct investment to portfolio stock ownership suggests that foreigners own about 40% of U.S. corporate equity.86 Thus, a significant share of technology costs may fall on foreign entities, but EPA never distinguishes between those costs that would accrue to foreign entities as opposed to U.S. citizens or U.S. entities, and so its calculations of cost implicitly include all global effects. Considering global climate benefits is consistent with that approach.

In a few recent analyses, agencies including EPA have admitted that some portion of the costs or cost savings calculated for publicly-traded corporations will accru[e] to entities outside U.S. borders' through foreign ownership, employment, or consumption.87 Yet much like in the Proposed Rule, these analyses do not attempt to separate out such effects to foreign interests, nor attempt to exclude such effects from consideration altogether. Indeed, splitting corporate effects into subparts based on ultimate ownership much like separating climate benefits geographically could be extremely complicated.88 Thus, as a practical matter, agencies typically count all costs or benefits to corporations, no matter how those effects may be passed through to foreign owners, foreign employees, or foreign customers.

Since EPA analyzes the Proposed Rule's costs globally without distinguishing between U.S. and foreign effects it would be inconsistent and arbitrary for the agency to attempt to separate out and disregard climate benefits that occur abroad, as doing so would put a thumb on the scale' by treating costs globally but benefits domestically.89 EPA can therefore highlight its consistent treatment of costs and benefits as further justification for relying on global social cost of greenhouse gas valuations. [EPA-HQ-OAR-2021-0208-0268-A1, pp.14-15]

EPA Should Replace Its References to the Interim' Domestic-Only Values Created Under Executive Order 13,783, and Instead Consider a Different Sensitivity Analysis as a Backstop to Minimize Legal Risks. While EPA correctly relies on global social cost of greenhouse gases values to assess the Proposed Rule's benefits, it should modify its limited discussion of the rule's domestic climate impacts. In a footnote, EPA applies the flawed domestic-only values developed under the now-revoked Executive Order 13,783. But those numbers are fatally incomplete and thus should not be used. Instead, EPA should consider conducting sensitivity analysis using a sounder domestic-only estimate as a backstop to minimize legal risk.

To begin, EPA should delete a stray reference in its RIA to social cost of greenhouse gas values created under the now-revoked Executive Order 13,783 that could be misinterpreted. In note j on page 3-29, the RIA writes: The values used in the SAFE rule RIA were interim values developed under E.O. 13783 for use in regulatory analyses. EPA followed E.O. 13783 by using SC-CO2 estimates reflecting impacts occurring within U.S. borders and 3% and 7% discount rates in our central analysis for the proposal RIA.'90 Though likely intended to refer only to the values EPA used in the proposed and final RIA for the SAFE Rule, the wording of the final phrase is ambiguous and could be misinterpreted as suggesting EPA is continuing to use such domestic-only values in its central analysis of this proposed RIA. To avoid such confusion, EPA should delete that unnecessary reference.

EPA does in fact use those domestic-only estimates in yet another footnote in the RIA. Specifically, note n on page 3-36 explains that those values were incomplete underestimates that ignored how climate impacts occurring outside U.S. borders can directly and indirectly affect U.S. welfare.91 Nevertheless, EPA presents what the Proposed Rule's climate benefit would be according to those values, highlighting climate benefits in the years 2023 and 2050. EPA perhaps intended to show that even under such misleadingly low valuations, the proposed standards will still achieve billions of dollars in climate benefits. However, the domestic-only values calculated under the now-revoked Executive Order 13,783 were not simply incomplete and misleading underestimates: they have been ruled by a federal court to be illegally arbitrary values inconsistent with the best available science and economics.92 EPA should make even clearer that these values are arbitrary and invalid and should not be relied upon.

At the same time, given past legal challenges to agencies' reliance on global valuations of the social cost of greenhouse gases, EPA should anticipate there may likely be litigation over its use of the global values in its main analysis here. For example, last year, a judge in the U.S. Court for the District of Wyoming faulted the Bureau of Land Management for not separately analyzing and reporting the United States' domestic share of [climate] benefits' resulting from a rule to reduce methane waste.93 Even after the agency had explained to the court that there was no suitable methodology for estimating domestic damages, the court opined that there is no reason to think that a domestic analysis cannot also be performed.'94 Thus, notwithstanding all the compelling legal, economic, and policy justifications for focusing on the global values, and despite previous caselaw favorable to the global valuation,95 some legal risk remains if EPA relies on global values without conducting a sensitivity analysis using domestically-oriented calculations. Additionally, because EPA included some domestic-only calculations of the social cost of greenhouse gases in its proposed RIA,96 erasing any domestic-only calculation from its final RIA could also raise legal challenges.

To further minimize legal risk, therefore, EPA should consider conducting a sensitivity analysis using a domestic-only valuation. The Working Group may in the future release guidance on an appropriate range for such a valuation, and considerable evidence suggests that after weighing strategic benefits, spillover effects, and extraterritorial interests any reasonable attempt to estimate the U.S. share of climate benefits would be quite a high proportion of global benefits.97 In the meantime, however, the best existing guidance available to EPA for a domestic-only estimate is not the arbitrary values calculated under the now-revoked Executive Order 13,783. Rather, EPA should look to the Working Group's past technical support documents for guidance.

In 2010, the Working Group provided an approximate, provisional, and highly speculative' range of up to 23% of the global value as a domestic-only estimate, but admitted even that was likely a significant underestimate. 98 Though an imprecise and gross underestimate, those values at least have the virtue of some regulatory precedent, as the Department of Energy has repeatedly used them for sensitivity analyses.99 EPA should therefore consider 23% of the global value to be the absolute minimum used for a domestic-only sensitivity analysis. EPA should emphasize that such values are still gross underestimates, as they disregard most of the domestic impacts discussed above including international reciprocity, spillover impacts, and extraterritorial interests. EPA should also note that the integrated assessment models used to estimate the social cost of greenhouse gases were not designed for such localized, non-global estimates. EPA should confirm that, while the Proposed Rule would be cost-benefit justified using such domestic-only values, the agency maintains that the global perspective is the correct focus for its main analysis. [EPA-HQ-OAR-2021-0208-0268-A1, pp.15-17]

EPA Should Provide Additional Justification for Its Discount Rates Choices and Conduct Sensitivity Analysis Using Lower Rates. EPA applies the social cost of greenhouse gas estimates calculated at discount rates of 2.5%, 3%, and 5%,100 consistent with the Working Group's current recommendations, and justifies its decision to return to its prior conclusion that a 7% capital-based discount rate is inappropriate for climate effects. While EPA's return to a reasonable range of discount rates to assess climate impacts is well supported, in anticipation of specious but inevitable legal challenges, EPA should provide additional justifications for its discounting choices.101 [EPA-HQ-OAR-2021-0208-0268-A1, p.17]

EPA should also work to promote consistent language on discounting with the National Highway Traffic Safety Administration's analysis of its now-proposed vehicle standards and, per the Working Group's recommendation, EPA should strongly consider providing additional sensitivity analysis around discount rates lower than 2.5% such as a 2% discount rate. [EPA-HQ-OAR-2021-0208-0268-A1, p.17]

EPA Should Provide Additional Justifications for Its Discount Rate Range. The RIA cites the Working Group's arguments that, for long-term policies with intergenerational effects, uncertainty and ethical considerations make a 7% capital-based discount rate inappropriate.102 Though these arguments provide sufficient reason for EPA's approach to discount rates, because the Working Group's approach to discount rates and in particular the reversal of the prior administration's irrational application of a 7% rate to climate effects has already been challenged in court, 103 EPA should provide additional justifications for its focus on consumption-based rates and its approach to discounting climate effects as compared to other costs and benefits. [EPA-HQ-OAR-2021-0208-0268-A1, pp. 17-18]

A 7% Discount Rate Is Inappropriate for Climate Effects, as Considerable Evidence Points to Substantially Lower Discount Rates in Intergenerational Settings. Although Circular A-4 provides discount rates of 3% and 7% as a default assumption, it also requires agency analysts to do more than rigidly apply default assumptions.104 As such, analysis must be based on the best reasonably obtainable scientific, technical, and economic information available,'105 and agencies must [u]se sound and defensible values or procedures to monetize benefits and costs, and ensure that key analytical assumptions are defensible.'106 Rather than assume that a 7% discount rate should be applied automatically to every analysis, Circular A-4 requires agencies to justify the choice of discount rates for each analysis.107 Based on Circular A-4's criteria, there are numerous reasons why applying a 7% discount rate to climate effects that occur over a 300-year time horizon would be unjustifiable and that discount rates of 3% or lower are appropriate.

First, basing the discount rate on the consumption rate of interest (which the 3% rate represents) is the correct framework for analysis of climate effects, whereas a discount rate based on the private return to capital (which the 7% rate represents) is inappropriate. While Circular A-4 suggests that 7% should be a default position' that reflects regulations that primarily displace capital investments, it also explains that [w]hen regulation primarily and directly affects private consumption . . . a lower discount rate is appropriate.'108 The 7% discount rate is based on a private sector rate of return on capital, as private market participants typically have short time horizons. By contrast, climate change concerns the public well-being broadly rather than market participants narrowly. Rather than evaluating an optimal outcome from the narrow perspective of investors alone, economic theory requires analysts to make the optimal choices based on societal preferences and social discount rates. Moreover, because climate change is expected to mostly affect large-scale consumption, as opposed to capital investment,109 a 7% rate is inappropriate. Crucially, as the Working Group recognizes, the social cost of greenhouse gas estimates present climate damages in consumption-equivalent units, and therefore, Circular A-4's guidance in fact dictates application of consumption-based discount rates.110 The National Academies of Sciences has agreed that a capital-based rate would be inappropriate for use with the social cost of greenhouse gases, given that climate damages are estimated in consumption-equivalent units.111 There is also strong consensus through the economic literature that a capital discount rate like 7% is inappropriate for climate change.112

Second, uncertainty over the long time horizon of climate effects should drive analysts to select a lower discount rate. As an example of when a 7% discount rate is appropriate, Circular A-4 identifies an EPA rule with a 30-year timeframe of costs and benefits.113 By contrast, greenhouse gas emissions generate effects stretching out across approximately 300 years. As Circular A-4 notes, [p]rivate market rates provide a reliable reference for determining how society values time within a generation, but for extremely long time periods no comparable private rates exist.'114 Circular A-4 discusses how uncertainty over long time horizons drives the discount rate lower.115 Circular A-4 cites the work of renowned economist Martin Weitzman and concludes that the certainty-equivalent discount factor . . . corresponds to the minimum discount rate having any substantial positive probability.'116 The National Academies of Sciences makes the same point about discount rates and uncertainty.117

Third, a 7% discount rate also ignores catastrophic risks and the welfare of future generations. As EPA showed in a recent cost-benefit analysis, the 7% rate truncates the long right-hand tail of social costs relative to the 3% rate's distribution. 118 The long right-hand tail represents the possibility of catastrophic damages. Thus, the 7% discount rate effectively assumes that present-day Americans are barely willing to pay anything at all to prevent medium- to long-term catastrophes. [EPA-HQ-OAR-2021-0208-0268-A1, pp.18-20]

Given that Congress expressed its overall goal for the Clean Air Act Amendments of 1977 to insure the protection of the public health and the environment, both of this and future generations, while at the same time considering the energy and economic needs of this Nation,' it would not be reasonable for EPA to discount climate impacts at such a high rate as to effectively ignore the welfare of future generations. .119 [EPA-HQ-OAR-2021-0208-0268-A1, p.20]

Fourth, long-term time horizons in general counsel strongly against application of a capital-based rate. The Working Group's latest guidance cites Li and Pizer's work on how the capital-based rate is generally inappropriate in many longer-term contexts.120 Specifically, Li and Pizer find that, given their best estimate of the shadow price of capital, the appropriate social discount rate collapses to the consumption-based rate relatively quickly, in the span of just several decades.121 Given the long time horizon that analysis of climate policies demands, the capital-based rate is simply inapplicable.

Fifth, several standard justifications for capital-based discount rates break down given the particular threats of climate change. For example, one argument for capital-based discount rates is that spending capital on climate abatement policies has opportunity costs and so, in policy analysis, future costs and benefits should be discounted at the rate of return to capital. However, the irreversible, uncertain, and catastrophic risks of climate change may disrupt this opportunity cost' rationale: while it may seem, for instance, that future, wealthier generations might have better opportunities to address climate change for themselves, irreversible or catastrophic damages could arise that make future mitigation efforts more expensive or impossible.122 Similarly, if climate damages are non-marginal,' such that climate change significantly affects the very natural resources needed to drive economic growth, growth could plummet or even turn negative.123

Sixth, a 7% discount rate is inappropriate because it is based on outdated data and diverges from the current economic consensus. Circular A-4 requires that assumptions including discount rate choices are based on the best reasonably obtainable scientific, technical, and economic information available.'124 Yet Circular A-4's own default assumption of a 7% discount rate was published 18 years ago and was based on data from even earlier.125 Circular A-4's guidance on discount rates is in need of an update, as the Council of Economic Advisers (CEA) detailed recently after reviewing the best available economic data and theory. 126 CEA gave two reasons to revise the 7% rate, both of which are generally applicable but may have particular force in the context of climate change. The first argument is that the market data clearly shows that the long-term interest rates used to derive the consumption-based discount rates have fallen, such that the 3% consumption-based rate instead should be at most 2 percent.'127 Because of the relationship between long-term, tax-free interest rates and rates of return on capital (i.e., the divergence between those rates is caused largely by taxation), a 1% drop in the consumption-based discount rate strongly suggests a corresponding drop in the capital-based rate.128 This may be especially true for longer-term context like climate change, because of the lack of reliable market data to measure expected rates of return on assets held inter-generationally.129 The second argument why the 7% rate is too high is that market rates of return are artificially increased by returns associated with unpriced externalities, rents associated with market power, and private (as opposed to social) risk premiums.130 For example, a market return on an oil and gas investment is increased because the oil and gas operation can externalize some of the costs of its pollution onto society. Yet especially when crafting long-term climate policies, it would be inappropriate to discount future welfare based on the fact that the current generation of investors prefers the high market returns that are now available partly because of such externalities.131 As such, the 7% capital-based rate is not only out of date and too high, but especially inappropriate for climate policy.

Finally, Circular A-4 recognizes that intergenerational contexts raise unique ethical issues that further counsel for lower discount rates. Specifically, it recognizes that [i]t may not be appropriate for society to demonstrate a similar preference when deciding between the well-being of current and future generations' as it does in the intragenerational setting.' 132 Circular A-4 thus recommends that agencies conduct additional analysis at using a lower [than 3%] but positive discount rate' for impacts with important intergenerational effects.133 Most market data reflects at best individual's current preferences for their own welfare over time and so simply does not capture society's preferences toward or ethical obligations to future generations. Basing a discount rate solely on market data ignores such important inter-generational considerations. Executive Order 13,990 instructs agencies to ensure that the social cost of greenhouse gas values adequately account for intergenerational equity.'134 A 7% rate ignores much of future generations' welfare and so would be inconsistent with that mandate. Notably, even in the SAFE rule, EPA and NHTSA explained that the 7% capital rate did not adequately account for tradeoffs between improving the welfare of current and future generations.' 135 [EPA-HQ-OAR-2021-0208-0268-A1, pp.20-22]

EPA Should Further Justify Its Distinct Approach to Discounting Climate Effects. As explained above, EPA's choice to use the social cost of greenhouse gas values calculated with consumption-based discount rates is fully justified. Two additional discounting choices then arise: how to discount back to present value the application of a future social cost of greenhouse gas value to monetize the climate benefits of future emissions reductions (e.g., bringing the $85 per ton of carbon dioxide in climate benefits generated by an emissions reduction in the year 2050 back to present value in 2021), and then how to compare those discounted climate effects to other costs and benefits.

EPA has chosen to ensure that all climate benefits are discounted in an internally consistent way, by applying the same discount rate used to estimate the underlying social cost values (e.g., 2.5%, 3%, or 5%) to calculate the present values of future climate benefits.136 That approach is consistent with the Working Group's guidance.137 But it also means EPA is calculating the present value of reduced greenhouse gas emissions differently than the present value of other costs and benefits (which, per Circular A-4's current default recommendations, are calculated at 3% and 7% discount rates).138

In the future, EPA should consider working with OMB and the Working Group to move toward a declining discount rate framework that can straightforwardly resolve all these issues of consistent discounting, by adopting a single schedule of applicable discount rates that steadily declines over time.139 In the meantime, EPA should expand on its justification to its current approach to discounting. EPA should consider two approaches: (1) explaining why a general focus on discounting all costs and benefits at consumption-based rates, rather than at a 7% capital-based rate, is appropriate in this particular rulemaking; and (2) explaining why special legal, economic, and policy considerations justify a different approach to discounting climate effects as distinct from other costs and benefits.

To begin, EPA can explain that given the nature of the Proposed Rule's costs and benefits, it is more appropriate to discount all effects using consumption-based rates, and so the present value calculations that include some costs and benefits discounted at a 7% rate can be viewed as lower-bound sensitivity analyses. The capital-based discount rate theoretically assesses whether the net benefits from government action will exceed the returns that society could earn by instead investing the same resources in the private sector. But this framework for discounting and comparing benefits and costs makes sense only under the extreme' assumption that all the costs of government action would fully displace' (i.e., crowd out) private investment. 140 In this way, the capital-based rate at best creat[es] a lower bound on the estimate of net benefits,' by applying a maximum discount rate that reflects an extreme case not likely to apply to many government actions.141

In general, there is less of a chance now that U.S. government actions will crowd out private investments than there was in 1992 when OMB first set its 7% capital-based discount rate, because the U.S. economy is relatively more open now.142 Additionally, the magnitude of the costs and benefits involved in many agency actions will be relatively small compared to the overall U.S. debt, again making it unlikely that agency actions will significantly crowd out private U.S. investment.143 Some agency actions may also induce more private investment than they displace.144 And if the costs of agency actions will be more borne through displaced consumption rather than displaced investment, the crowding-out theory for a capital-based discount rate further breaks down. In this rulemaking, the upfront technology costs and long-term fuel savings will be felt primarily by individual consumers, as will rebound value and refueling time savings; other effects, like health effects, climate benefits, energy security, and congestion, will be felt by society as a whole. In other words, because of the nature of the rule, the theory for a capital-based discount rate has a tenuous application at best. EPA therefore would be justified in arguing for a focus on cost-benefit comparisons using consumption-based rates, with the application of a 7% rate treated like a lower-bound sensitivity analysis.

Separately, EPA would also be justified in taking a distinct approach to discounting climate effects, and EPA should elaborate on the special legal, economic, and policy considerations. While effects like fuel savings and energy security will play out over the course of the next several decades, the climate effects of this rule are undeniably much longer term, affecting the welfare of future generations over centuries. Therefore, the arguments in favor of lower consumption-based discount rates based on long-term uncertainty, ethics, declining economic growth, inapplicable market data, and other considerations apply much more strongly to climate effects than to other costs and benefits. [EPA-HQ-OAR-2021-0208-0268-A1, pp.22-23]

And because a high capital-based rate, like 7%, will effectively ignore the welfare of future generations (e.g., over the course of just 80 years, a 7% rate discounts away 99.5% of a future effect's value145) legal requirements to consider the welfare of future generations caution much more strongly against the application of a 7% rate to long-term climate effects than to other costs and benefits. Notably, the Clean Air Act Amendments of 1977 expressed the congressional goal to insure the protection of the public health and the environment, both of this and future generations, 146 and NEPA broadly instructs147 all agencies to interpret all their laws to the fullest extent possible to advance the national environmental policies, 148 including to fulfill the responsibilities of each generation as trustee of the environment for succeeding generations.' 149 Multiple Executive Orders, including Executive Order 13,563 and 13,990, also call for agencies to appropriately and accurately weigh the interests of future generations. [EPA-HQ-OAR-2021-0208-0268-A1, pp.23-24]

Consequently, as the National Academies of Sciences has recognized, some differences in the application of discount rates may be warranted when only some categories [of costs and benefits] have an intergenerational component.'151 The National Academies has offered recommendations for how agencies can best apply different annualized discount rates to climate impacts versus other costs and benefits,152 and EPA can rely on the National Academies' guidance to support its approach to discounting here.

Case law on the social cost of greenhouse gases also offers support for EPA's discounting approach. Specifically, in Zero Zone v. Department of Energy, the plaintiffs argued that the Department of Energy had arbitrarily considered hundreds of years of climate benefits while limiting its assessment of employment impacts and other effects to just a thirty-year time horizon. The court upheld the regulatory analysis, concluding that the difference in time horizons was justified because the rule would have long-term effects on the environment but . . . would not have long-term effects on employment.'153 The choice of time horizons is related to the choice of discount rate: any cost or benefit occurring beyond the end of the analytical time horizon is effectively discounted at an infinitely high (or 100 percent) rate.154 Analogizing from this precedent, a court may similarly defer to an agency's finding that the long time horizon of climate change justifies a lower discount rate than the rate applied to shorter-term costs and benefits. EPA should explain the special economic, legal, and ethical considerations that justify selecting a different annual discount rate for climate effects than for other costs and benefits. [EPA-HQ-OAR-2021-0208-0268-A1, p.24]

EPA Should Conduct Additional Sensitivity Analysis Around Lower Discount Rates for Climate Impacts. In its regulatory impact analysis for the Proposed Rule, EPA assesses climate benefits using discount rates of 2.5, 3, and 5 percent for the social cost of greenhouse gases. In its most recent technical support document, however, the Working Group suggested that agencies conduct[] additional sensitivity analysis using discount rates below 2.5 percent.'155 And while EPA repeatedly references the fact that considering discount rates at 2 percent and lower' is warranted,'156 EPA's list of sensitivity analyses does not include a run using a 2% or lower discount rate for the social cost of greenhouse gases.157 Because of the considerable evidence that the most appropriate discount rate should be below 2%, and in anticipation of potential future updates to the Working Group's recommendations, EPA should conduct additional sensitivity analysis around lower discount rates for the social cost of greenhouse gases, including discount rates of 2% or lower.

As the Working Group explained in its recent technical support document, there is considerable evidence from market data that the default estimate of the consumption-based discount rate should be revised down from 3% to 2%. In the context of long-term, intergenerational effects like climate damages, the case for a lower discount rate is even stronger, in light of ethical considerations and other factors.158 Multiple expert elicitations show a growing consensus around a discount rate below 2%,159 and factors like uncertainty, negative economic growth correlations, risk aversion, and the scarcity and non-substitutability of environmental goods all point strongly toward even lower discount rates.160

For this reason, among others, the Working Group acknowledged in its latest technical support document that its social cost valuations presented at discount rates of 2.5%, 3%, and 5% 'likely underestimate societal damages from [greenhouse gas] emissions.'161 The Working Group will evaluate the discount rate (among other issues) as it performs a full assessment of its social cost valuations to reflect the latest scientific and economic research a task that it has been ordered to complete by January 2022.162 In the meantime, the Working Group has recommended that agencies apply additional sensitivity analysis around lower discount rates.163 To do so, EPA could look to the value of carbon' estimates from the New York State Department of Environmental Conservation (DEC'), which applied a 2% discount rate as its central value.164 Pursuant to DEC's estimates, at a discount rate of 2% social cost valuations for year 2020 emissions equal $125 per ton of carbon dioxide, $2,782 per ton of methane, and $44,727 per ton of nitrous oxide.165 DEC also recommended using a 1% discount rate for climate impacts, and provided annual social cost values for doing so.166 Because these valuations are based off of the Working Group's methodology, and differ only through the discount rate, EPA can apply these valuations if it applies additional sensitivity analysis around lower discount rates. [EPA-HQ-OAR-2021-0208-0268-A1, pp. 24-26]

EPA Should Ensure Analytical Consistency With the Treatment of Climate Benefits in NHTSA's Concurrent Fuel-Economy Rulemaking Though Consistent Approaches Need Not Be Identical Approaches. While EPA and NHTSA both assess global climate benefits using discount rates of 2.5%, 3%, and 5% in their recently proposed vehicle rules,167 there is a slight difference in the analyses between the two agencies. Many but not all of EPA's summary tables focus on the social cost of greenhouse gas values calculated at a 3% discount rate,168 though

EPA does caution against interpreting the 3% values as its central' estimates.169 By comparison, NHTSA tends to focus more on climate benefits calculated at a 2.5% discount rate in its summary tables, though again NHTSA does apply the Working Group's full range of values. These two approaches are consistent with each other and with the Working Group's guidance, which reminds agencies of their discretion to focus on lower discount rates.170 Nevertheless, because the approaches are not identical, they could be misinterpreted in ways that could wrongly cast doubt on the social cost of greenhouse gas values. To reduce legal risk, EPA and NHTSA should strive for analytical consistency in the treatment of climate benefits as they finalize their regulations.

Although there are few cases addressing an agency's discount rate in a cost-benefit analysis, courts have usually been reluctant to second-guess an agency's discounting choice in the instances where it has been challenged. In one case, for example, the U.S. Court of Appeals for the District of Columbia Circuit deferred to an agency's discount rate selection as first and foremost a policy choice,' and explained that the agency was free to revisit its discount rates in future rulemakings so long as it sets forth a reasonable justification for doing so.'171 This decision fits squarely within the judiciary's deferential approach to reviewing the more technical aspects of an agency's cost-benefit analysis.172

Given all of the evidence discussed above pointing to relatively low discount rates in intergenerational contexts, agency reliance on a 3% or 2.5% discount rate for the social cost of greenhouse gases or even a lower discount rate consistent with the latest evidence should easily meet the applicable standard of review. Agencies generally are given broad deference in selecting technical valuations, as noted above, and different agencies have sometimes used different inputs for key metrics such as the statistical value of life (i.e. the monetary value placed on mortality risks). 173 Consistent with this precedent, EPA and NHTSA should be able to rationally justify reliance on different discount rates for the social cost of greenhouse gases.

But such a strategy does not come without risk. Though deference to technical valuations is broad, a court may invalidate a regulation if a key analytical input is insufficiently explained or inconsistent with evidence and practice. Should EPA and NHTSA apply different discount rates in their analyses, critics could point to such an alleged inconsistency in an attempt to misleadingly argue that the social cost of greenhouse gases is indeterminate or arbitrary. More problematically, critics could point to statements made by each agency to justify its preferred discount rate to argue that the other agency's choice is irrational. To the extent that EPA and NHTSA can agree on more consistent presentations and discussions about the discount rate, it may help minimize the risk of such misinterpretations. EPA should especially be careful not to use any language that could be taken out of context to misleadingly criticize NHTSA's approach.

But ultimately, consistency does not require identical approaches. Both agencies have considered the full range of values recommended by the Working Group, and the choice to focus in some summary tables on the values calculated either at 3% or 2.5% or even at lower values, like 2% can be fully justified. [EPA-HQ-OAR-2021-0208-0268-A1, pp. 26-27]

EPA Should Defend Against Common Criticisms of the Working Group's Methodology. While the Working Group developed its social cost valuations through a rigorous process that incorporated the best scientific and economic modeling available at the time, its assumptions have sometimes been criticized by opponents of climate regulation. Such objections lack legal merit, and do not supply bases for EPA to reject the Working Group's expert valuations. Nonetheless, in order to minimize legal risk, EPA should provide additional defense of the Working Group's process and modeling assumptions, and be prepared to respond to common criticisms of its work. This section offers a defense of the Working Group's process and methodology, and offers responses to common criticisms that have been offered by opponents of strong climate policy. [EPA-HQ-OAR-2021-0208-0268-A1, p.27]

The Working Group's Methodology Is Rigorous, Transparent, and Based on a Range of Assumptions Reflecting the Best Available Data. Although the term social cost of greenhouse gases' is often used synonymously with the valuations developed by the federal Working Group, economic research and modeling on the social cost of greenhouse gases predate federal efforts to monetize incremental climate damages. Several of the most celebrated economic models of climate damages such as models by William Nordhaus174 and Chris Hope175 that have since been integrated into the federal government's damage valuations were first released in the early 1990s.

Owing to the availability of these damage models, the U.S. Court of Appeals for the Ninth Circuit held in 2008 that the federal government must monetize climate impacts when it conducts a cost-benefit analysis. In Center for Biological Diversity v. National Highway Traffic Safety Administration, the Ninth Circuit remanded a fuel economy rule to the Department of Transportation (DOT') for failing to monetize the benefits of carbon dioxide reductions in its regulatory analysis.176 The Court recognized the presence of uncertainty in the valuation of climate damages, but explained that the value of carbon emissions reduction is certainly not zero.'177 By failing to value the benefit of greenhouse gas emission reductions in its analysis, the Court continued, DOT effectively ignored the adverse impacts of greenhouse gas emissions and thus put a thumb on the scale by undervaluing the benefits and overvaluing the costs of more stringent standards.'178

Following this decision, federal agencies began applying different valuations of the social cost of greenhouse gases in their regulatory analyses.179 To harmonize those damage valuations across agencies, the Obama administration convened an interagency working group comprised of members of twelve federal agencies and departments, including EPA, the Council of Economic Advisors, Office of Management and Budget, the Department of Energy, and DOT.180 The Working Group also released damage estimates for two other greenhouse gases methane and nitrous oxide in 2016.186 These additional metrics used the same economic models, the same treatment of uncertainty, and the same methodological assumptions that the Working Group applied to the social cost of carbon, and underwent peer review.187 [EPA-HQ-OAR-2021-0208-0268-A1, pp.27-29]

EPA Is Required to Value Climate Damages, and Doing So Provides Balance to EPA's Cost-Benefit Analysis. One objection to agency usage of the Working Group's estimates is that

Congress, not the executive branch, should set policy with respect to climate change. But EPA has broad authority to assess climate impacts, and judicial precedent suggests that it must value climate-change impacts as part of its regulatory impact analysis. In fact, assessing climate damages as part of its regulatory impact analysis provides rationality and balance to EPA's approach and does not, as critics have suggested, inappropriately skew the analysis. [EPA-HQ-OAR-2021-0208-0268-A1, p. 29]

EPA Must Monetize Climate Impacts as Part of Its Analysis. It is widely established that federal agencies may and often must consider effects on climate change when those effects flow from the agency's actions. With EPA, this is especially well-established. Perhaps most relevant here, in Massachusetts v. EPA, the Supreme Court held that EPA may regulate greenhouse gas emissions from new motor vehicles.188 Because the purpose of the Proposed Rule is to limit greenhouse gas pollution from new motor vehicles directly in line with the Massachusetts precedent EPA should naturally and obviously consider impacts on climate when deciding upon the stringency of its regulation.

Since EPA must account climate impacts, therefore, the only relevant question is how it should account for those impacts. Monetizing climate impacts is the best available option. Indeed, it is well accepted in regulatory practice and precedent that agencies should monetize regulatory impacts to the extent feasible, in order to compare costs and benefits along a common metric and select the alternative that maximizes net benefits.189 In a decision that sparked the federal government to develop consensus valuations of climate damages in the first place the Center for Biological Diversity case discussed above the Ninth Circuit held that the Department of Transportation acted arbitrarily and capriciously by failing to monetize potential climate benefits when assessing the costs and benefits of various alternative fuel-economy standards for new automobiles.190 And EPA monetized climate damages both in the SAFE Rule and in the Section 202 emissions standards promulgated under the Obama administration. [EPA-HQ-OAR-2021-0208-0268-A1, pp. 29-30]

Monetizing Climate Benefits Does Not Skew the Analysis, but Rather Provides Balance Since EPA Also Monetizes Costs. Another objection to the use of the social cost of greenhouse gases from critics of climate action is that these valuations account only for the damages from climate change, but do not take account of the economic benefits from fossil-fuel production and usage, such as economic development and employment. But this argument is unpersuasive for two key reasons.

First, the economic benefits of fossil-fuel extraction are far more limited than its proponents suggest, since the broader benefits that society derives from power and electricity are attributable to energy production in general and are not unique to fossil fuels.191 Accordingly, controls on fossil fuels will hasten a transition to a greener economy, and so have limited net economic impacts.192 Second, while there are of course some economic impacts from reductions in fossil-fuel production and usage, including effects on revenues and jobs, those impacts should not be included in any calculation of climate damages, but rather considered separately by regulators on the costs side of the ledger in individual determinations.

In the Proposed Rule, EPA monetizes not only the expected benefits of the proposal including, but not limited to, climate benefits but also the expected compliance costs from industry as well as other costs of the rule such as expected fatalities, forgone consumer surplus, and even noise costs. EPA then compares quantified cost and benefit estimates in determining whether and how to regulate, as instructed by federal guidance and executive order.193 Capturing climate benefits is thus essential to ensuring a balanced analysis. As the Ninth Circuit has held, failure to monetize the most significant benefit of more stringent [vehicle-emission] standards: reduction in carbon emissions' while continuing to value estimated compliance costs would put a thumb on the scale by undervaluing the benefits and overvaluing the costs of more stringent standards.'194 [EPA-HQ-OAR-2021-0208-0268-A1, p. 30]

Common Criticisms of the Working Group's Methodology from Opponents of Climate Policy Lack Merit. EPA should also provide detailed responses to any objections lobbed against the Working Group's methodology and valuations during this comment period. The Working Group, of course, has already responded to criticisms of its methodology that were offered during the public comment period that it held in 2013,195 and EPA should draw from that document where relevant in responding to objections offered through this notice-and-comment process. But some objections are now being raised that were not offered during the 2013 comment period, while some of the responses that the Working Group provided can be supplemented with more recent information. Below, we provide brief responses to common objections that are now being presented by opponents of climate reforms. [EPA-HQ-OAR-2021-0208-0268-A1, p.31]

The Social Cost Valuations Are Not Too Uncertain to Apply. While critics argue that there it too much uncertainty to rely on the Working Group's social cost valuations, this argument is incorrect on multiple levels. As a legal matter, the presence of some uncertainty in the social cost valuations should not preclude agencies from using the best numbers available. And as a factual matter, the Working Group rigorously considered uncertainty and accounted for it in numerous ways. If anything, the presence of continued uncertainty suggests that the social cost valuations should be higher than presently valued not that climate damages should be ignored.

Federal courts have repeatedly recognized that agency analysis necessitates making predictive judgments under uncertain conditions, explaining that [r]egulators by nature work under conditions of serious uncertainty' 196 and are often called upon to confront difficult administrative problems armed with imperfect data.'197 As the Ninth Circuit has explained, the proper response' to the problem of uncertain information is not for the agency to ignore the issue but rather for the [agency] to do the best it can with the data it has.'198 Courts generally grant broad deference to agencies' analytical methodologies and predictive judgments so long as they are reasonable, and do not require agencies to act with complete certainty.199

Use of the Working Group's social cost estimates is precisely the type of reasonable analysis of uncertain information that courts endorse. The Working Group rigorously considered various sources of long-term uncertainty through a combination of a multi-model ensemble, probabilistic analysis, and scenario analysis.'200 As the Working Group explained, the three IAMs account for uncertainty themselves by spanning a range of economic and ecological outcomes.201 Additionally, the use of three separate models all developed by different experts spanning a range of views accounts for uncertainty by integrating a diversity of viewpoints and structural and analytical considerations.202

In addition to the use of three distinct damage models with differing inputs and assumptions, the Working Group integrated various sources of uncertainty into its damage valuations. For instance, the Working Group applied an equilibrium climate sensitivity that is, an estimate of how much an increase in atmospheric greenhouse gas concentrations affects global temperatures that reflects a broad distribution of possible outcomes.203 The Working Group also applied five different socioeconomic and emissions trajectories from the published literature reflecting a range of possible outcomes for future population growth, global gross domestic product, and greenhouse gas emission baselines all important inputs that affect long-term climate damage estimates.204 The Working Group ran each integrated assessment model 10,000 times per scenario (and per greenhouse gas) for a total of 150,000 draws per greenhouse gas, and then averaged across those results to develop its recommended estimates.205 In addition to reporting the average valuations, the Working Group published the results of each model run under each scenario.206

Moreover, experts broadly agree that the presence of uncertainty in the social cost valuations counsels for more stringent climate regulation, not less.207 This is due to various factors including risk aversion, the informational value of delaying climate change impacts, and the possibility of irreversible climate tipping points that cause catastrophic damage.208 In fact, as discussed above, uncertainty is a factor justifying lowering the discount rate, particularly in intergenerational settings.209 Furthermore, current omission of key features of the climate problem such as catastrophic damages and certain cross-regional spillover effects further suggests that the true social cost values are likely higher than the Working Group's current estimates.210 [EPA-HQ-OAR-2021-0208-0268-A1, pp. 31-32]

The Working Group Did Not Bias Its Estimates by Ignoring Positive Impacts of Climate Change. Critics further claim that the Working Group's social cost values ignore important positive impacts of a warming climate. Examples that have been offered to support this argument include alleged agricultural benefits from higher temperatures and decreased wintertime mortality. But these arguments are legally and factually dubious, and miss the forest for the trees.

Mere omission of some impacts does not counsel for abandoning the social cost estimates, particularly since independent experts widely agree that those estimates likely undervalue true climate damages because they omit far more negative effects than positive ones. For instance, the Working Group has explained that several of the underlying economic models omit certain major damage categories such as catastrophic damages and certain cross-regional spillover effects.211 These effects can be massive: One paper, for instance, finds that the inclusion of tipping points doubles the social cost estimates, 212 with another paper concluding that the effect is even greater and thus the Working Group's existing values may be significantly underestimating the needs for controlling climate change.'213 The current consensus of experts puts damages for a 3Â°C increase at roughly 5% to 10% of gross domestic product,214 which is substantially higher than the damages estimated by the IAMs.215 And as the Ninth Circuit has explained, the presence of some omitted damages does not provide a legal basis to ignore established methodologies to monetize climate damages, since while there is a range of [plausible] values, the value of carbon emissions reduction is certainly not zero.'216

In addition to its legal shortcomings, arguments about the impact of positive externalities are also factually suspect. For instance, while agricultural benefits have become a flashpoint in this debate, the IAMs in fact do account for the potential agricultural benefits of carbon dioxide fertilization from a warming planet.217 And evidence suggests that, if anything, these models overvalue agricultural benefits from a warming planet and thus undervalue the social cost of greenhouse gases.218 One paper, for instance, concludes that estimates of net agricultural impacts produced an undervaluation of the social cost of carbon by more than 50%, explaining that new damage functions reveal far more adverse agricultural impacts than currently represented' in the IAMs used by the Working Group.219 And a comprehensive investigation of the impacts of climate change on agriculture has rejected the hypothesis that agricultural damages over the next century will be minimal and indeed that a few degrees Celsius of global warming would be beneficial for world agriculture,' concluding that climate change will have at least a modest negative impact on global agriculture in the aggregate.'220

Other arguments focusing on omitted positive impacts are equally misguided. For example, while some critics of the Working Group's methodology misleadingly point out that one of the models, DICE, focuses on increased heat-related mortality and does not account for reductions in wintertime mortality, consideration of the many damages omitted from the IAMs (such as particulate matter from wildfires, deaths from flooding, Lyme and other tick-based diseases), including certain mortality effects, consistently point toward a higher social cost value.221 One recent study, in fact, concludes that the IAMs, on net, undervalue mortality from climate change.222 Focusing on the omission of reductions in wintertime mortality thus misses the forest for the trees, and does not supply a basis to disregard the Working Group's valuations. [EPA-HQ-OAR-2021-0208-0268-A1, pp. 33-34]

The Working Group Did Not Overstate the Pace of Climate Change. Critics further allege that the chosen Equilibrium Climate Sensitivity (ECS') distribution that is, the amount of warming that is expected to result from a doubling of the atmospheric carbon dioxide concentration is outdated and fails to account for recent evidence showing that sensitivity to be lower than previously believed. But these arguments rely on cherry-picked data and ignore the scientific consensus.

In 2016, the National Academies of Sciences dedicated an entire report to whether the Working Group should update the social cost metrics to reflect more recent science on the ECS. The National Academies decided that such an update was unnecessary, recommend[ing] against a near-term change in the distributional form of the ECS' and explaining that any reasonable revisions on this front would have a minimal impact on estimates of the [social cost of greenhouse gases].'223

On top of the National Academies' rejection of this argument, there is little support for the claim that the Working Group overstated the pace of climate change. The most recent estimate from the Intergovernmental Panel on Climate Change (IPCC') which reflects consensus estimates from the worldwide scientific community projects an ECS range from 2.5°C to 4°C, with 3°C as a best estimate.'224 This is consistent with the range applied by the Working Group based off of Roe & Baker which uses 3°C as its median and 3.5 °C as its mean ECS value.225 In evaluating the ECS, the Working Group assessed estimates from a wide range of experts and selected consensus values. In fact, as the Working Group acknowledged, some ECS estimate ranges go as high as 10º C, making its selected ECS distribution substantially lower than these high-end estimates and a reasonable middle range.226

Critics further argue that the ECS distribution applied by the Working Group inappropriately skews rightward, meaning that its mean ECS value exceeds the median value of 3º C that the IPCC has indicated. But that decision is a feature, not a bug. As the National Academies explained, the IPCC has found that there is a positively skewed distributional form for [the ECS] parameter' similar to the ECS distribution applied by the Working Group.227 In other words, the mean ECS value should be higher than the median ECS value, and the Working Group applied an appropriate distribution. Criticisms to the contrary are meritless. [EPA-HQ-OAR-2021-0208-0268-A1, pp. 34-35]

The Working Group Applied a Reasonable Range of Emission Baselines. Critics further argue that the Working Group's valuations are an overestimate because they apply outdated emission scenarios that exaggerate the baseline level of atmospheric greenhouse gas levels. Using a higher baseline level of emissions raises the social cost estimates because the harm from an additional unit of emissions increases with the baseline atmospheric emissions level. However, the Working Group used a reasonable emissions baseline that reflects different possible mitigation scenarios.

While the Working Group assumed a baseline emissions range of 13 118 gigatons of carbon dioxide emitted per year by 2100,228 recent projections from the Climate Action Tracker indicate that baseline emissions will reach between 14 175 gigatons of carbon dioxide by 2100 under a range of scenarios reflecting different levels of mitigation.229 Thus, the baselines used by the Working Group potentially understate baseline emissions rather than overvalue them as opponents argue. In fact, several of the Working Group's supposedly business-as-usual' scenarios are actually more consistent with baseline estimates reflecting policy projections.230 Accordingly, the criticism that the Working Group overestimated future greenhouse gas concentrations in the atmosphere falls flat.

Moreover, this choice does not particularly affect the social cost valuations. In comparison to the Working Group's central social cost of carbon estimate in 2020 of $51 per ton, the average social cost of carbon under the Working Group's supposed business-as-usual emissions scenarios is $53 per ton and $41 per ton under the emissions scenario that is consistent with sustained and widespread mitigatory action.231 While relying less on the Working Group's supposed business-as-usual scenarios would therefore modestly decrease the interim social cost valuations in a vacuum, more holistic updates to the metrics as recommended by the National Academies of Sciences would very likely increase the social cost valuations overall due to the omitted damages discussed above and recent evidence regarding intergenerational discount rates.232 At best, therefore, this argument makes a mountain out of a molehill. [EPA-HQ-OAR-2021-0208-0268-A1, pp. 35-36]

The Working Group Applied Scientifically-Based Damage Models. Critics further claim that the IAMs the damage functions for translating climate impacts into economic losses are flawed and arbitrary. In reality, however, the damage functions are based on reasonable assumptions made by a range of experts.233 They have also withstood scientific scrutiny, and while opponents of climate reform frequently highlight criticism of the damage functions by a notable economist, they take this criticism out of context.

The Working Group selected three models of climate damages that were the most widely used and cited models in the economics literature linking physical climate impacts to economic damages234: the DICE, FUND, and PAGE models.235 These models were developed by outside experts, published in peer-reviewed economic literature,236 and were the product of extensive scholarship and expertise. One of the models, DICE, was developed by William Nordhaus, an economics professor and former provost of Yale university who won a Nobel Memorial Prize in Economic Sciences for developing the model. And PAGE developer, Chris Hope, was a lead author and review editor for the Third and Fourth Assessment Reports of the IPCC, which shared the Nobel Peace Prize in 2007 with former U.S. Vice President Al Gore.237

The three models reflect a wide diversity of methodological assumptions about a range of key parameters and inputs.238 This reflects, in part, different judgments about the experts who developed the models. For instance, Richard Tol, who developed the FUND model, has stated that [t]he impact of climate change is relatively small,’ and dismissed much of the research behind climate change as scaremongering’ rather than sound science.’239 Unsurprisingly, his model produces the lowest damage estimates of the three models incorporated by the Working Group.240 William Nordhaus, who developed the DICE model, is widely credited with popularizing the goal that global temperatures increase no more than 2Â° Celsius (or 3.6Â° Fahrenheit) below pre-industrial levels241 a goal now considered conservative by the global community.242 His model produces higher damage estimates that are close to the Working Group’s average damage valuations.243

Opponents of climate mitigation policy frequently point to criticisms from Robert S. Pindyck, a noted climate economist who has been critical of the Working Group’s choice of damage functions. But as Professor Pindyck has himself stated, his writings continue to be taken out of context by some to unfairly attack the Interagency Working Group’s methodology and its interim estimates.’244 While Professor Pindyck has questioned the shape of the models’ damage functions,245 he has acknowledged that the damage functions reflect common beliefs’ about the effects of two or three degrees of warming.

And Pindyck states that uncertainty about the social cost estimates, including the damage functions, does not imply that [their] value should be set to zero until the uncertainty is resolved.’246 In fact, he actually advocates for an even higher social cost value than that produced by the Working Group,247 and has emphatically declared that the federal government should continue to use the [Working Group’s] interim estimates . . . as lower bound estimates.’248 In other words, the best critic of the Working Group’s methodology that opponents could find supports continued use of the Working Group’s estimates and considers them to be conservative underestimates of the true cost to society of greenhouse gas emissions. [EPA-HQ-OAR-2021-0208-0268-A1, pp. 36-38]

EPA Should Apply the Social Cost Estimates That It Has Developed Through 2070, and Coordinate With the Working Group to Adopt Climate-Damage Valuations Through at Least that Time Period

Although the Working Group's latest guidance presents calculations of the social cost of greenhouse gases only through year 2050, the marginal damages caused by an additional ton of emissions will continue to rise over time after 2050.249 EPA has used the Working Group's methodology to extend estimates of the social cost of greenhouse gases through year 2070.250 However, despite writing in the RIA that Table 3-14 through Table 3-16 shows the combined total climate benefits expected to occur over 2023-2070,'251 those tables' titles suggest they only cover the years 2023-2050,252 and all of EPA's cumulative cost-benefit comparison tables similarly end in 2050.253

EPA does not give a clear reason why it stops its analysis in year 2050. As early as its 2009 analysis of vehicle emission standards, EPA had already been projecting the net benefits for its proposed vehicle standards through the year 2050;254 yet now, twelve years later, EPA has not extended its time frame any further. Notably, NHTSA has suggested that some model year 2029 vehicles could still be in service as late as 2068.255 And while regulated vehicles' technology costs decline over the course of the analysis,256 many key benefits257 including climate benefits258 grow over the course of the analysis and may continue to grow after 2050. According to Circular A-4, EPA should select a time frame long enough to encompass all the important benefits and costs likely to result from the rule.'259

EPA should urge the Working Group to adopt social cost of greenhouse gas estimates through at least 2070, if not further into the future, for all agencies to use as appropriate. EPA should identify how far into the future it believes the Proposed Rule will continue to generate significant costs or benefits. If the rule will have significant effects after 2050, EPA should either extend its time frame or else state its reasons for not doing so. If EPA is trying to match the time frame from the SAFE Rule, it could still include a longer time frame as a sensitivity analysis. If EPA lacks sufficient data to fully project costs and benefits beyond 2050, it should explain the data limitations. But given that costs are likely to decrease over time while benefits may continue into the distant future, EPA should state whether it believes that the net effects of stronger vehicle standards after 2050 will increase total net benefits. If so, this fact further highlights that EPA's cost-benefit projections, especially around climate benefits, are conservative, and that stronger vehicle emissions standards will deliver significant net benefits to society. [EPA-HQ-OAR-2021-0208-0268-A1, pp.38-39]

For the foregoing reasons, it is appropriate for EPA to continue to rely on the Working Group's valuations of the social cost of greenhouse gases in the Proposed Rule as conservative estimates. To bolster the legal justification for that reliance as it finalizes its regulation, EPA should provide additional explanation for its methodological choices and conduct additional sensitivity analysis around different social cost values. [EPA-HQ-OAR-2021-0208-0268-A1, p. 39]

40 Most generally, it is individually rational for a country to fully internalize the global social cost of greenhouse gases ‘if a country expects a decrease in its own emissions to decrease that of all others in proportion to the ratio of its external cost of emissions to its internal costs.’ Matthew J. Kotchen, Which Social Cost of Carbon? A Theoretical Perspective, 5 J. ASSOC. ENV’T. & RES. ECON. 673, 683 (2017). Other economists have justified use of the global social cost estimates on more intuitive grounds. See, e.g., Tamma Carleton & Michael Greenstone, Updating the United States Government’s Social Cost of Carbon at 26-27 (Becker Friedman Institute Working Paper 2021-04, Jan. 2021), https://perma.cc/H9EU-XWBX (‘The global SCC . . . is an ingredient in efforts to procure the necessary international action. . . . Even if policymakers decide that the effects of regulations on U.S. citizens are what matter (in terms of both law and policy), it would make sense to use the global measure, as it would protect U.S. citizens against a range of adverse effects from unmitigated climate change.’); William Pizer et al., Using and Improving the Social Cost of Carbon, 346 SCIENCE 1189, 1190 (2014) (explaining that the ‘potential to leverage foreign mitigation,’ combined with moral, ethical, and security issues, provide ‘compelling reasons to focus on a global SCC but, more important, to make a strategic choice.’); Robert S. Pindyck, Comments on Proposed Rule and Regulatory Impact Analysis on the Delay and Suspension of Certain Requirements for Waste Prevention and Resource Conservation, Nov. 6, 2017, available at https://perma.cc/HG8Q-MT6H (‘[W]hat treatment of international damages is in the United States’ self-interest? . . . The simplest answer is to find the value of the [social cost of carbon] that maximizes global welfare. . . . I continue to think that the global value is the appropriate provisional value for use as research on this topic continues.’).

50 The estimate is conservative because it omits any conditional pledges, any pledges that are not readily quantified into specific reductions, any actions from countries that have not formally submitted Nationally Determined Contributions to the United Nations, any reductions occurring after 2030, and any foreign actions already achieved before 2014 that may have motivated U.S. pledges in the first place. Id.

52 Though some positive spillover effects are also possible, such as technology spillovers that reduce the cost of mitigation or adaptation, see S. Rao et al., Importance of Technological Change and Spillovers in Long-Term Climate Policy, 27 ENERGY J. 123–39 (2006), overall climate spillovers are likely strongly negative, see Jody Freeman & Andrew Guzman, Climate Change and U.S. Interests, 109 COLUM. L. REV. 1531 (2009).

72 A bequest value captures willingness to pay to preserve a resource for a future generation. Existence value captures willingness to pay to preserve a resource even with no intention to ever use or bequeath the resource. Off. of Mgmt. & Budget, Circular A-4: Regulatory Analysis 22 (2003).

76 Over $100 billion is sent from the United States to other countries in remittances every year. See Pew Res. Ctr., Remittance Flows Worldwide in 2017, Apr. 3, 2019, https://perma.cc/D684-7ZA8.

77 Many cultural sites are located near water because of how civilization developed, Yu Fang & James W. Jawitz, The evolution of human population distance to water in the USA from 1790 to 2010, 10 NATURE COMMUNICATIONS 1 (2019), and so such sites may be especially vulnerable to climate change, see Lee Bosher et al., Dealing with multiple hazards and threats on cultural heritage sites: an assessment of 80 case studies, 29 DISASTER PREVENTION AND MANAGEMENT: AN INTERNATIONAL JOURNAL 109 (2019). More broadly, there are clear cultural costs of climate change, W. Neil Adger et al., Cultural dimensions of climate change impacts and adaptation, 3 NATURE CLIMATE CHANGE 112 (2013), and a willingness to pay to protect culture, Ali Ardeshiri et al., Conservation or Deterioration in Heritage Sites? Estimating Willingness To Pay for Preservation (Working Paper, 2019).

83 Stellantis, which has been subject to the largest penalties in recent years for noncompliance, is based in the Netherlands. Volkswagen, Mercedes-Benz, and BMW are based in Germany. Mazda, Honda, Toyota, and Nissan are based in Japan. Yet in the Proposed Rule, EPA does not distinguish between compliance costs that would fall upon Japanese investors, German investors, Dutch investors, or American investors.

84 Agrium, for example, a subsidiary of Canadian-based Nutrien, operates one of the largest corporate fleets of pickup trucks operating in the United States, 6 FleetTrax, The Largest Fleets in America, https://fleettrax.net/largest-fleets-america/ ('Agrium also owns and operates a staggering 7,627 pickup trucks and cargo vans—a record number for this list.'; reporting on 'the largest private fleets operating in the United States'). Large fleets are also owned by public companies like Hertz. Norway's Government Pension Fund, for example, owns 1% of Hertz. https://www.nbim.no/en/the-fund/investments/#/2019/investments/equities/3799/Hertz%20Global%20Holdings%20Inc.

100 Note that just as there is growing evidence that the discount rate should be below 2%, there is growing evidence that 5% is much too high a discount rate. The values at 5% should be considered a very conservative lower bound.

167 NHTSA's proposed rule was published in the Federal Register earlier this month, with comments due October 26. Corporate Average Fuel Economy Standards for Model Years 2024–2026 Passenger Cars and Light Trucks, 86 Fed. Reg. 49,602 (Sept. 3, 2021).

174 The earliest versions of Nordhaus's DICE model were published starting in 1992. See William Nordhaus, An Optimal Transition Path for Controlling Greenhouse Gas Emissions, 258 SCIENCE 1315 (1992).

175 Chris Hope first released his PAGE model in 1991. See Memorandum by Dr Chris Hope, Judge Institute of Management, University of Cambridge, ¶1 (Jan. 14, 2005), https://publications.parliament.uk/pa/ld200506/ldselect/ldeconaf/12/5011805.htm (document describing the development and results of the PAGE model submitted to the Select Committee on Economic Affairs of the U.K. House of Lords).

191 Renewable energy, like fossil fuels, generates revenue, supports jobs, and vitalizes local economies. See, e.g., Katie Siegner et al., Rocky Mtn. Inst., Seeds of Opportunity: How Rural America Is Reaping Economic Development Benefits from the Growth of Renewables 6–16 (2021), available at https://perma.cc/DWH9-D4L7.

192 Environmental regulation typically has limited impacts on total employment or other macroeconomic indicators, but rather shifts production from one sector to another. See Inst. for Pol'y Integrity, Does Environmental Regulation Kill or Create Jobs (2017), available at https://policyintegrity.org/files/media/Jobs_and_Regulation_Factsheet.pdf. Meanwhile, the sharp decline in the cost renewable energy is already expected to crowd out the demand for gas-fuel electricity in the coming years and decades. See, e.g. Energy Info. Admin., Annual Energy Outlook 2021 Narrative 18 tbl. 11 (projecting doubling of renewables as a share of domestic energy consumption—from 21% to 42%—by 2050 under reference case, while share of coal and natural gas declines); Charles Teplin et al., ROCKY MTN. INST., The Growing Market for Clean Energy Portfolios 8 fig. ES-2 (2019), available at https://perma.cc/P5YJ-WARJ (showing precipitous decline in cost of clean energy to being cheaper than fossil fuels).

208 The undersigned organizations have filed comments in numerous regulatory proceedings highlighting the various forms of uncertainty that increase the social cost of greenhouse gases, and providing numerous references. See, e.g., Environmental Defense Fund et al., Improper Valuation of Climate Effects in the Proposed Revised Cross-State Air Pollution Rule Update for the 2008 Ozone NAAQS, Technical App'x: Uncertainty (Dec. 14, 2020), https://policyintegrity.org/documents/Joint_SCC_comments_EPA_revised_CSAPR_Ozone_NAAQS_2020.12.14.pdf.

242 For instance, the Paris Agreement calls for governments to 'hold[] the increase in the global average temperature to well below 2°C above pre-industrial levels and pursu[e] efforts to limit the temperature increase to 1.5°C above pre-industrial levels, recognizing that this would significantly reduce the risks and impacts of climate change.' Paris Agreement to the United Nations Framework Convention on Climate Change, Art. 2(1)(a), Dec. 12, 2015, T.I.A.S. No. 16-1104.

EPA Response

EPA acknowledges the comment and thanks the commenter for the detailed comments on the application of the SC-GHG estimates from the February 2021 TSD, *Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates under Executive Order 13990*. For the reasons described in section 3.3. of the RIA and in the February 2021 TSD, EPA believes that the estimates of the TSD are conservative (i.e., likely underestimates) but are nonetheless appropriate for use in this rulemaking.

With respect to extending the analysis beyond 2050, EPA constrained the analysis to an out year of 2050 due to limitations in sales projections and other input assumptions beyond that year, though EPA expects impacts such as GHG emissions reductions will continue into the future.

Commenter: Kreucher, Walter

EVEN AFTER ALL THE COSTS AND DISRUPTIONS TO THE SUPPLY CHAIN, THERE WILL BE A DE MINIMIS EFFECT ON CLIMATE CHANGE

The Environmental Impact Statement 17 conducted in association with this rulemaking concludes that implementing the most stringent alternative (Alternative 3) would decrease global mean temperature by 0.003° C (0.006° F) over the next 100 years. Implementing the preferred alternative would decrease global mean temperature by 0.002° C (0.003° F). The predicted sea-level rise would decrease by 0.06 centimeters (0.03 inches) under the most stringent alternative. The global precipitation rate would be unaffected and the ocean ph level would change by about 0.0004 under the most stringent alternative. [EPA-HQ-OAR-2021-0208-0199-A1, p. 10]

EPA Response

The commenter appears to be citing the EIS for the NHTSA rulemaking, as EPA did not conduct climate modeling in support of this rulemaking. Rather, EPA estimated the climate benefits of the rule by using an estimate of the social cost of greenhouse gases, which resulted in an estimate of $31-$390 Billion in climate benefits. For more information regarding the estimated climate benefits see section 3.3 of the RIA. Moreover, as the Supreme Court recognized, "Agencies, like legislatures, do not generally resolve massive problems in one fell regulatory swoop. ... And reducing domestic automobile emissions is hardly a tentative step."[59] Thus, EPA disagrees that the estimates cited by the commenter provide a basis for not adopting these standards.

Commenter: Ohio Attorney General Office, et al.

The proposed rule is irrational, as it rests on a baseless benefit analysis. EPA describes that an 'essential' factor to the proposed rule is reducing carbon emissions, 'given the urgency of the climate crisis.' [49] According to the proposed rule, '[t]he monetized benefit of these GHG reductions is estimated at $22 billion to $280 billion across a range of discount rates and values for the social cost of carbon. '[50] That's a broad enough range to deduce that the monetized benefit is fantasy, not reality.

The proposed rule takes its estimate range from numbers produced by the Interagency Working Group on Social Costs of Greenhouse Gases in February 2021.[51] The February 2021 document is merely a recitation of estimates produced in 2016, using 2020 dollars. [52] And despite their importance to regulatory decisionmaking, the 2021 estimates were not subjected to notice-and-comment procedures. The 2016 estimates, [53] which include average estimates from three 'integrated assessment models' and one unlikely but doomsday scenario, do not provide a reasonable basis for decisionmaking.

---

[59] *Massachusetts v. E.P.A.*, 549 U.S. 497, 524 (2007)

The 2016 estimates purport to predict the amount of warming that all greenhouse gases now and in the future will create, the effects that warming will have on society, and the costs of those effects. But in doing so, the 2016 estimates incorporate unreliable assumptions rather than data. As one economist described the integrated assessment models, they allow ‘the modeler to obtain almost any desired result because key inputs can be chosen arbitrarily. [54]

For example, the 2016 estimates result from the integrated assessment models being run through the year 2300, and calculate present day costs based on that speculative future harm. To put this absurdity into context, three hundred years ago, in the era of Sir Isaac Newton, social-cost evaluators may well have recommended the wholesale abolishment of cities, considering the costs of horse waste (unimaginably high, if today we all still rode horses) [55] and rampant disease (like smallpox and dysentery). But today we have automated transportation, running water, modern medicine, and advanced farming. There is simply no scientific way to fasten a 2021 rule around 2300 predictions. Nor do the 2016 estimates attempt to explain why a 300-year time horizon is scientifically appropriate. 56

The assumptions underlying EPA’s benefit guess are also badly out of date, and thus don’t reflect updated realities that conflict with inputs to the predictive models. [57] The predicted climate future scenarios (the amount of carbon that would otherwise be emitted) were established in 2010.[58] These assumptions incorporate four ‘business as usual’ scenarios and one that incorporates a ‘lower-than’ business as usual potential—and each scenario is weighted equally in estimating the social cost of carbon. Thus the trendline the EPA uses to calculate savings is based on an alternate reality where the world continues to burn immense amounts of coal and engage in other energy policies that are becoming obsolete. Reality since 2010 shows a different likelihood. Since 2007, for example, energy-related carbon emissions in the United States declined eight out of 12 years, [59] not counting 2020 where global energy-related carbon emissions declined by almost 6 percent.[60] [EPA-HQ-OAR-2021-0208-0258-A1, pp.7-8]

[56] This time horizon also conflicts with standard Executive Branch regulatory analyses, which generally do not consider effects beyond fifty years. See, e.g., Arden Rowell, Foreign Impacts and Climate Change, 39 HARV. ENVTL. L. REV. 371, 386 (2015).

[57] For example, the estimates incorporate the findings of the Fourth Assessment Report of the Intergovernmental Panel on Climate Change. But that Panel has since published a Fifth Assessment Report that increases the probabilities associated with a lower average temperature increase. See The Intergovernmental Panel on Climate Change, Climate Change 2014 Synthesis Report at 43, 62 (2015), https://perma.cc/C55X-EYP9.

[60] The Covid-19 pandemic resulted in the largest-ever decline in global emissions, International Energy Agency (Mar. 2, 2021), https://perma.cc/G5G4-UXNL.

EPA Response

EPA disagrees with many of the commenters’ contentions. EPA notes that it determined what standards were appropriate in light of the need for emissions reductions, the cost of compliance and lead time, and found the results of the cost-benefit analysis in the RIA provide additional support for its conclusions. Under Section 202 of the CAA, EPA is required to establish standards to reduce air pollution that endangers public health and welfare, taking into consideration the cost of compliance and lead time. EPA is not required to conduct formal cost benefit analysis to determine the appropriate standard under Section 202. EPA weighed the relevant statutory factors to determine the appropriate standard and the analysis of monetized GHG benefits was not material to the choice of that standard. EO 12866 requires EPA to perform a cost-benefit analysis, including monetizing costs and benefits where practicable, and the EPA has conducted such an analysis. The monetized GHG benefits are included in the cost-benefit analysis. That cost-benefit analysis provides additional support for the EPA's final standards. EPA follows applicable guidance and best practices when conducting its benefit-cost analyses, including OMB Circular A-4, EPA's Guidelines for Preparing Economic Analyses. We therefore consider our analysis methodologically rigorous and a best estimate of the projected benefits and costs associated with the final rule.

Please see the response to AEI in Section 14.1 of this document to similar comments on SC-GHG modeling uncertainties and limitations, and the use and application of the 2021 TSD SC-GHG estimates. Please see the response to the Missouri Attorney General in Section 14.1 to a similar comment on IWG notice and comment and the use of global estimates.

14.2. Comments on Impacts on Endangered Species

<u>Commenters Included in this Section:</u>

Center for Biological Diversity, Earthjustice, and Sierra Club
Center for Biological Diversity

Commenter: Center for Biological Diversity, Earthjustice, and Sierra Club

This rulemaking would benefit from consultation under the Endangered Species Act. Finally, EPA's rule would benefit from consultation under Section 7 of the Endangered Species Act. For every discretionary action, Section 7(a)(2) of the Endangered Species Act ('ESA') requires each federal agency, in consultation with the National Marine Fisheries Service and the U.S. Fish and Wildlife Service (collectively, the 'Services'), to 'insure that any action authorized, funded, or carried out by the agency is not likely to jeopardize the continued existence of any threatened or endangered species, or result in the destruction or adverse modification of the critical habitat of such species' using the best scientific data available.61 Undergoing consultation under the ESA assists EPA in making discretionary decisions—such as regarding stringency levels and uses of credits and other flexibilities—that mitigate harmful effects on species. Consultation is also consistent with President Biden's 'whole of government' approach to addressing the climate crisis, as well as Executive Order 13990, which states that all federal agencies 'must be guided by the best science and be protected by processes that ensure the integrity of Federal decision-making.' For these reasons, we encourage EPA to consult with the Services in rulemakings such as this and future ones that have vast potential effects on biodiversity. [EPA-HQ-OAR-2021-0208-0270-A1, p.10]

EPA Response

EPA acknowledges the comment. Please see the response to the following comment from Center for Biological Diversity.

Commenter: Center for Biological Diversity

Should EPA finalize the Rule, the Center urges you to undertake interagency consultation as required pursuant to Section 7 of the Endangered Species Act, 16 U.S.C. §§ 1531-44 ('ESA') ('Section 7 consultation'). Because the Rule will have an appreciable, cumulative impact on climate-threatened species as wells as species susceptible to criteria air pollution, EPA must consult with both the National Marine Fisheries Service and the U.S. Fish and Wildlife Service (collectively the 'Services').1 EPA's failure to undertake such consultation would violate both the procedural requirements of Section 7(a)(2) of the ESA as well as EPA's substantive duty to ensure against jeopardy of federally-listed species and the adverse modification of their habitats.

As explained below, while EPA's Rule reduces the total amount of greenhouse gas and other emissions that would have been emitted under the previous administration's Safer Affordable Fuel Efficient ('SAFE') Vehicles Rule, EPA's decision to finalize this Rule will nonetheless allow cars and light trucks to emit millions of metric tons of greenhouse gases and tens of thousands of tons of criteria pollutants. The impacts may be somewhat less harmful than those under the SAFE Rule, but they still exist. And by undergoing consultation under the ESA, EPA could make discretionary decisions—such as regarding stringency levels and uses of credits and other flexibilities—that mitigate these effects. Consultation is also consistent with President Biden's 'whole of government' approach to addressing the climate crisis, as well as Executive Order 13990, which states that all federal agencies 'must be guided by the best science and be protected by processes that ensure the integrity of Federal decision-making.' [EPA-HQ-OAR-2021-0208-0726-A1, pp. 1-2]

II. THE ENDANGERED SPECIES ACT REQUIRES INTERAGENCY CONSULTATION ON THE ADOPTION OF THE REVISED VEHICLES RULE

A. EPA's adoption of the Rule triggers its duty to consult under Section 7 of the ESA.

The proposed Rule triggers EPA's procedural duty to undergo Section 7 consultation. First, the Rule is a discretionary federal action. Section 7 consultation is required on an agency action 'so long as the agency has 'some discretion' to take action for the benefit of a protected species.'22 If 'an agency has any statutory discretion over the action in question, that agency has the authority, and thus the responsibility, to comply with the ESA.'23 Second, as explained above, 'action' is broadly defined to include 'all activities or programs of any kind authorized, funded, or carried out, in whole or in part' by federal agencies.24 The ESA's implementing regulations provide that actions triggering ESA consultation include those that ‘directly or indirectly caus[e] modifications to the land, water, or air.’25

Here, EPA’s adoption of the Rule is a discretionary government action that directly causes modifications to the air, and indirectly modify land and water, thus triggering the ESA Section 7 consultation requirement. For instance, EPA is making the discretionary decision to adopt the proposal rather than a more stringent alternative, and in doing so, is making the discretionary decision to allow millions of metric tons more greenhouse gases to be emitted than if it chose a different alternative. What is more, EPA is making the discretionary decision to include a number of different regulatory flexibilities and credits, which allow manufacturers to avoid or delay producing vehicles that would reduce their emissions.26 Each of these discretionary decisions affects the greenhouse gas and criteria emissions over the next several years, and thus ‘may affect’ endangered species or their habitat. [EPA-HQ-OAR-2021-0208-0726-A1, pp. 4-5]

According to the Rule’s Draft Regulatory Impact Analysis, while the proposal projects a reduction in greenhouse gas emissions compared to Trump’s SAFE Rule rollback, it would still allow millions of metric tons of greenhouse gases and other criteria pollutants to be emitted. This is especially stark when the proposal is compared to EPA’s suggested Alternative 2, which would save 293 million metric tons CO2 and 426,545 metric tons of methane compared with the proposal through 2050.27 Similarly, compared to the proposal, Alternative 2 would reduce emissions of NOx by approximately 30,000 tons and SO2 by over 100,000 tons through 2050.28 In other words, by making the decision to adopt the proposal instead of Alternative 2, EPA is, in its discretion, authorizing an addition 293 million metric tons of CO2 and 426,545 metric tons of methane, in addition to other greenhouse gases and increased criteria pollution. Of course, EPA could have analyzed other alternatives stronger than Alternative 2, which would have made these emissions savings even higher.

These numbers are not insignificant, and they can be directly tied to harm to species or critical habitat, such as to precise losses of sea ice and sea ice days in the Arctic. For instance, the greenhouse gas emissions can be tied to precise losses of sea ice and sea ice days in the Arctic;29 the excess 293 million metric tons of CO2 alone—not including the other greenhouse gases—that will be emitted if EPA decides to adopt the proposal instead of Alternative 2 will lead to a sustained loss of sea ice of 879 square kilometers,30 larger than the area of New York City. This loss will have devastating consequences for polar bears, as described below. [EPA-HQ-OAR-2021-0208-0726-A1, p. 5]

The excess methane emissions are particularly alarming. Immediate, deep reductions in methane emissions are critical for lowering the rate of global warming in the near-term, preventing the crossing of irreversible planetary tipping points, and avoiding harms to species and ecosystems from methane’s intensive near-term heating effects and ground-level ozone production.31 Methane is a super-pollutant 87 times more powerful than CO2 at warming the atmosphere over a 20-year period, 32 and is second only to CO2 in driving climate change during the industrial era.33 Methane also leads to the formation of ground-level ozone, a dangerous air pollutant, that harms ecosystems and species by suppressing plant growth and reducing plant productivity and carbon uptake.34 Because methane is so climate-damaging but also comparatively short-lived with an atmospheric lifetime of roughly a decade, cutting methane has a relatively immediate effect in slowing the rate of temperature rise in the near-term. Critically, deep cuts in methane emissions of ~45% by 2030 would avoid 0.3°C of warming by 2040 and are considered necessary to achieve the Paris Agreement's 1.5°C climate limit and prevent the worst damages from the climate crisis.35 Deep cuts in methane emissions that reduce near-term temperature rise are also critical for avoiding the crossing of planetary tipping points—abrupt and irreversible changes in Earth systems to states wholly outside human experience, resulting in severe physical, ecological and socioeconomic harms.36 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 5-6]

Accordingly, EPA's discretionary actions meet the broad—and extremely low—'may affect' threshold under the ESA and its implementing regulations that trigger the EPA's Section 7 consultation duty.37 The 'may affect' standard includes '[a]ny possible effect, whether beneficial, benign, adverse or of an undetermined character.'38 As discussed below, the increases in greenhouse gas and criteria emissions—associated with the agency decisions described above—may impact the hundreds of federally protected species and their critical habitats that are imperiled due specifically to exacerbated climate change, nitrogen deposition, and greater levels of particular air pollutants from vehicle emissions. Courts have found that similar agency actions resulting in increases of criteria air pollutants may impact federally-listed species and result in environmental harms.39

In light of the Rule's effects, '[i]n no uncertain terms, the [ESA] mandates that [EPA] shall engage in consultation before taking any action that could jeopardize the continued existence of any endangered species or threatened species.' 40 Separately, the finalization of the proposed Rule also triggers EPA's substantive duty under Section 7(a)(2) of the ESA to 'insure' against a likelihood of jeopardizing federally-listed species which would be impacted by the Rule's adoption.41 Agencies are required to give the benefit of the doubt to federally-listed species, thus placing the ultimate burden of protecting species against risk and uncertainty on the agency itself.42 Accordingly, should EPA adopt the Rule without undergoing Section 7 consultation, EPA will have failed its substantive duty to insure that the Rule will not jeopardize listed species or adversely modify their critical habitat. [EPA-HQ-OAR-2021-0208-0726-A1, pp. 6-7]

EPA's decision to finalize its proposal will allow cars and light trucks to emit millions of metric tons of greenhouse gases and tens of thousands of tons of criteria pollutants—even though EPA has the discretion to reduce them. These emissions will affect climate change, air quality, and species and their habitats in ways that are direct and predictable. [EPA-HQ-OAR-2021-0208-0726-A1, p. 7]

i. Climate change has clear and documented adverse impacts on federally protected species.

This section describes the hundreds of federally-listed species—including the iconic polar bear43—whose very existence is jeopardized by increasing GHG emissions and exacerbated climate change—as legally determined by the Services in response to these species' listing petitions. The proposal, if finalized, would directly contribute to significantly higher GHG emissions and exacerbate climate change, and thus jeopardize the endangered and threatened species, as well as their critical habitats, that are specifically at risk due to exacerbated climate change. [EPA-HQ-OAR-2021-0208-0726-A1, p. 7]

a. An overwhelming international scientific consensus has established that human-caused climate change is already causing severe and widespread harms to life on Earth, and these threats are becoming more dangerous as greenhouse gas emissions continue unabated.

An overwhelming international scientific consensus has established that human-caused climate change is already causing severe and widespread harms and that climate change threats are becoming increasingly dangerous. The Intergovernmental Panel on Climate Change (IPCC), the international scientific body for the assessment of climate change, concluded in its Climate Change 2021: The Physical Science Basis report that: '[i]t is unequivocal that human influence has warmed the atmosphere, ocean and land. Widespread and rapid changes in the atmosphere, ocean, cryosphere and biosphere have occurred,' and further that '[t]he scale of recent changes across the climate system as a whole and the present state of many aspects of the climate system are unprecedented over many centuries to many thousands of years.'44 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 7-8]

The U.S. federal government has repeatedly recognized that human-caused climate change is causing widespread and intensifying harms across the country in the authoritative National Climate Assessments, scientific syntheses prepared by hundreds of scientific experts and reviewed by the National Academy of Sciences and federal agencies. Most recently, the Fourth National Climate Assessment, comprised of the 2017 Climate Science Special Report (Volume I)45 and the 2018 Impacts, Risks, and Adaptation in the United States (Volume II),46 concluded that 'there is no convincing alternative explanation' for the observed warming of the climate over the last century other than human activities.47 It found that 'evidence of human-caused climate change is overwhelming and continues to strengthen, that the impacts of climate change are intensifying across the country, and that climate-related threats to Americans' physical, social, and economic well-being are rising.'48 The Fourth National Climate Assessment warns that 'climate change threatens many benefits that the natural environment provides to society,' and that 'extinctions and transformative impacts on some ecosystems' will occur 'without significant reductions in global greenhouse gas emissions.'49 [EPA-HQ-OAR-2021-0208-0726-A1, p.8]

As detailed in the National Climate Assessments, the widespread, intensifying, and often long-lived harms from climate change include soaring air and ocean temperatures; more frequent and intense heat waves, floods, and droughts; more destructive hurricanes and wildfires; coastal flooding from sea level rise and increasing storm surge; declining food and water security; accelerating species extinction risk; melting Arctic sea ice, glaciers, and ice sheets; the collapse of Antarctic ice shelves; ocean acidification; and the collapse of coral reefs. 50 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 8-9]

b. Fossil fuels are the dominant driver of the climate crisis.

The National Climate Assessments decisively recognize the dominant role of fossil fuels in driving climate change. As stated by the Third National Climate Assessment: 'observations unequivocally show that climate is changing and that the warming of the past 50 years is primarily due to human-induced emissions of heat-trapping gases. These emissions come mainly from burning coal, oil, and gas.'51 In parallel, the Fourth National Climate Assessment reported that 'fossil fuel combustion accounts for approximately 85 percent of total U.S. greenhouse gas emissions,'52 which is 'driving an increase in global surface temperatures and other widespread changes in Earth's climate that are unprecedented in the history of modern civilization.'53 [EPA-HQ-OAR-2021-0208-0726-A1, p. 9]

c. The choices made now on reducing greenhouse gas pollution will affect the severity of the climate change damages that will be suffered in the coming decades and centuries.

The National Climate Assessments make clear that the harms of climate change are long-lived, and the choices we make now on reducing greenhouse gas pollution will affect the severity of the climate change damages that will be suffered in the coming decades and centuries: '[t]he impacts of global climate change are already being felt in the United States and are projected to intensify in the future—but the severity of future impacts will depend largely on actions taken to reduce greenhouse gas emissions and to adapt to the changes that will occur.'54 As the Fourth National Climate Assessment explains: '[m]any climate change impacts and associated economic damages in the United States can be substantially reduced over the course of the 21st century through global-scale reductions in greenhouse gas emissions, though the magnitude and timing of avoided risks vary by sector and region. The effect of near-term emissions mitigation on reducing risks is expected to become apparent by mid-century and grow substantially thereafter.'55 Similarly, a 2014 White House report found that the cost of delay on reducing emissions is not only extremely steep but also potentially irreversible, and the costs rise exponentially with continued delays. 56 As summarized by the National Research Council:

Emissions of carbon dioxide from the burning of fossil fuels have ushered in a new epoch where human activities will largely determine the evolution of Earth's climate. Because carbon dioxide in the atmosphere is long lived, it can effectively lock Earth and future generations into a range of impacts, some of which could become very severe. [E]mission reduction choices made today matter in determining impacts experienced not just over the next few decades, but in the coming centuries and millennia.57 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 9-10]

d. The IPCC 2018 Special Report, as reinforced by the 2021 IPCC Sixth Assessment Report, make clear that global greenhouse gas emissions must be halved by 2030 to avoid catastrophic damages of climate change.

In 2018, the IPCC issued a Special Report on Global Warming of 1.5°C that quantified the devastating harms that would occur at 2°C warming, highlighting the necessity of limiting warming to 1.5°C to avoid catastrophic impacts to people and life on Earth.58 The IPCC 2018 Special Report provides overwhelming evidence that aggressive reductions in emissions within this decade are essential to avoiding catastrophic climate change harms. [EPA-HQ-OAR-2021-0208-0726-A1, p. 10]

The Special Report quantifies the harms that would occur at 2°C warming compared with 1.5°C, and the differences are stark. According to the IPCC's analysis, the damages that would occur at 2°C warming compared with 1.5°C include dramatically increased species extinction risk, including a doubling of the number of vertebrate and plant species losing more than half their range, and the virtual elimination of coral reefs; significantly more deadly heatwaves, drought and flooding; 10 centimeters of additional sea level rise within this century; a greater risk of triggering the collapse of the Greenland and Antarctic ice sheets with resulting multi-meter sea level rise; 1.5 to 2.5 million more square kilometers of thawing permafrost area with the associated release of methane, a potent greenhouse gas; and a tenfold increase in the probability of ice-free Arctic summers.59 [EPA-HQ-OAR-2021-0208-0726-A1, p. 10]

The IPCC report concludes that pathways to limit warming to 1.5°C with little or no overshoot require 'a rapid phase out of CO2 emissions and deep emissions reductions in other GHGs and climate forcers.' 60 In pathways consistent with limiting warming to 1.5°C, global net anthropogenic CO2 emissions must decline by about 45 percent from 2010 levels by 2030, reaching net zero around 2050.61 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 10-11]

Similarly, the IPCC Climate Change 2021 report concludes that global warming will exceed 1.5°C and 2°C by 2100 unless we make immediate, deep reductions in CO2 and other greenhouse gas emissions.62 Only the most stringent emissions reduction scenario—SSP1-1.9 in which global emissions fall steeply in the near-term, reach net zero in 2050, and become net negative afterward—is consistent with a 1.5°C climate target. In this low emissions SSP1-1.9 scenario, global average surface temperature is projected to reach 1.5°C above pre-industrial in the near-term (2021-2040), overshoot and peak at 1.6°C in the mid-term (2041-2060), and drop down to 1.4°C in the long-term (2081-2100).63 [EPA-HQ-OAR-2021-0208-0726-A1, p. 11]

In short, the IPCC Assessment Reports, U.S. National Climate Assessments, and tens of thousands of studies make clear that fossil-fuel driven climate change is a 'code red for humanity,'64 and that every additional ton of CO2 and fraction of a degree of temperature rise matters. As warned by the IPCC, 'every tonne of CO2 emissions adds to global warming.'65 [EPA-HQ-OAR-2021-0208-0726-A1, p. 11]

e. Climate change has clear and documented adverse impacts on biodiversity.

The best available science shows that anthropogenic climate change is causing widespread harm to life across the planet, disrupting species' distribution, timing of breeding and migration, physiology, vital rates, and genetics—in addition to increasing species extinction risk.66 Climate change is already affecting 82% of key ecological processes that underpin ecosystem function and support basic human needs.67 Climate change-related local extinctions are widespread and have occurred in hundreds of species, including almost half of the 976 species surveyed.68 Nearly half of terrestrial non-flying threatened mammals and nearly one-quarter of threatened birds are estimated to have been negatively impacted by climate change in at least part of their range. 69 Furthermore, across the globe, populations of terrestrial birds and mammals that are experiencing greater rates of climate warming are more likely to be declining at a faster rate.70 Genes are changing, species' physiology and physical features such as body size are changing, species are moving to try to keep pace with suitable climate space, species are shifting their timing of breeding and migration, and entire ecosystems are under stress.71 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 11-12]

Species extinction risk will accelerate with continued greenhouse gas pollution. One million animal and plant species are now threatened with extinction, with climate change as a primary driver.72 At 2°C compared with 1.5°C of temperature rise, species' extinction risk will increase dramatically, leading to a doubling of the number of vertebrate and plant species losing more than half their range, and a tripling for invertebrate species.73 Numerous studies have projected catastrophic species losses during this century if climate change continues unabated: 15 to 37% of the world's plants and animals committed to extinction by 2050 under a mid-level emissions scenario74; the potential extinction of 10 to 14% of species by 210075; global extinction of 5% of species with 2°C of warming and 16% of species with business-as-usual warming76; the loss of more than half of the present climatic range for 58% of plants and 35% of animals by the 2080s under the current emissions pathway, in a sample of 48,786 species77; and the loss of a third or more of animals and plant species in the next 50 years.78 [EPA-HQ-OAR-2021-0208-0726-A1, p. 12]

As summarized by the Third National Climate Assessment, 'landscapes and seascapes are changing rapidly, and species, including many iconic species, may disappear from regions where they have been prevalent or become extinct, altering some regions so much that their mix of plant and animal life will become almost unrecognizable.'79 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 12-13]

f. Greenhouse gas pollution has clear and documented adverse impacts on federally protected species.

Greenhouse gas emissions harm endangered species in ways that are not only measurable but also causally understood. Climate change impacts such as sea ice loss, ocean heat stress and ocean acidification, sea level rise, the increasing frequency of extreme weather events, decreasing snowpack, and elevational and latitudinal shifts in habitat are several of the ways that greenhouse gas emissions harm hundreds of federally protected species--and has been recognized as such in federal listing determinations under the Endangeered Species Act. [EPA-HQ-OAR-2021-0208-0726-A1, p. 13]

The Polar Bear (Ursus maritimus) and Loss of Sea Ice. In 2008, the FWS listed the polar bear (Ursus maritimus) as a threatened species due to climate change and the loss of sea ice. 80 See also In re Polar Bear Endangered Species Act Listing, 709 F.3d 1 (D.D. Dir. 2013) (affirming FWS's decision to federally list the polar bear as threatened due to the effects of global climate change on polar bear habitat). [EPA-HQ-OAR-2021-0208-0726-A1, p. 13]

The loss of sea ice is one of the clearest and most obvious consequences of global warming. As highlighted by the Fourth National Climate Assessment, Alaska and the Arctic have experienced some of the most severe and rapid warming associated with climate change, with temperatures rising at twice the rate of the rest of the globe on average.81 Arctic summer sea ice extent and thickness have decreased by 40% during the past several decades,82 with each metric ton of CO2 emissions causing a sustained loss of three square meters of summer sea ice area.83 The Arctic lost 95% of its oldest and thickest sea ice during the past three decades, and the remaining thinner, younger ice is more vulnerable to melting.84 Sea ice loss has accelerated since 2000, with Alaska's coast suffering some of the fastest losses.85 The length of the sea ice season is shortening as ice melts earlier in spring and forms later in autumn.86 Along Alaska's northern and western coasts, the sea ice season has already shortened by more than 90 days.87 As summarized by the Fourth National Climate Assessment:

Since the early 1980s, annual average arctic sea ice has decreased in extent between 3.5% and 4.1% per decade, become thinner by between 4.3 and 7.5 feet, and began melting at least 15 more days each year. September sea ice extent has decreased between 10.7% and 15.9% per decade (very high confidence). Arctic-wide ice loss is expected to continue through the 21st century, very likely resulting in nearly sea ice-free late summers by the 2040s (very high confidence).'88 [EPA-HQ-OAR-2021-0208-0726-A1, p. 14]

It is precisely this sea ice loss, and the lack of adequate regulatory mechanisms addressing greenhouse gas pollution, that led FWS to list the polar bear (Ursus maritimus) as a threatened species in 2008.89 As a top Arctic predator, the polar bear relies on sea ice for all its essential activities, including hunting for prey, moving long distances, finding mates, and building dens to rear cubs. 90 Separately, recognizing the critical importance of sea ice for polar bear survival, FWS designated sea ice habitat off Alaska as critical habitat for the polar bear in 2010.91 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 14-15]

Federal documents acknowledge that shrinkage and premature breakup of sea ice due to climate change is the primary threat to the species, leaving bears with vastly diminished hunting grounds, less time to hunt, and a shortage of sea ice for other essential activities such as finding mates and resting.92 As summarized in FWS's 2017 5-year review, sea ice loss and a shorter sea ice season makes hunting calorie-rich seals more difficult for polar bears, leading to nutritional stress, reduced body mass, and declines of some populations.93 As the sea ice retreats, polar bears have been forced to swim longer distances,94 which is more energetically costly,95 and they are spending more time on land where they have reduced access to food.96 Females are denning more often on land than on ice, increasing the potential for conflicts with humans.97 Because polar bears have high metabolic rates, increases in movement resulting from loss and fragmentation of sea ice result in higher energy costs and are likely to lead to reduced body condition, recruitment and survival.98 [EPA-HQ-OAR-2021-0208-0726-A1, p. 15]

In the southern Beaufort Sea of Alaska, polar bears declined by 40 percent over a recent 10-year period,99 and this decrease has been attributed to sea ice loss that limited access to prey over multiple years. 100 For the bears in this population, research has linked sea ice loss to decreases in survival,101 lower success in rearing cubs,102 shrinking body size,103 and increases in fasting and nutritional stress.104 The loss of sea ice also jeopardizes the polar bear's sea-ice dependent prey species—the ringed seal and bearded seal—which were listed as threatened in 2012 due to sea ice loss from climate change.105 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 15-16]

If current greenhouse gas emissions trends continue, scientists estimate that two-thirds of global polar bear populations will be lost by 2050, including the loss of both of Alaska's polar bear populations, while the remaining third will near extinction by the end of the century due to the disappearance of sea ice.106 However, aggressive emissions reductions will allow substantially more sea ice to persist and increase the chances that polar bears will survive in Alaska and across their range.107 Highlighting the importance of reducing greenhouse gas emissions to protect sea ice and sea-ice dependent species, one recent study estimated that each metric ton of CO_2 emission results in a sustained loss of 3 ± 0.3 m^2 of September Arctic sea ice area based on the robust linear relationship between monthly-mean September sea ice area and cumulative CO_2 emissions.108 Similar to other research,109 the study concluded that limiting warming to 2°C is not sufficient to allow Arctic summer sea ice to survive, but that a rapid reduction in emissions to achieve a 1.5°C global warming target gives Arctic summer sea ice 'a chance of long-term survival at least in some parts of the Arctic Ocean.'110 [EPA-HQ-OAR-2021-0208-0726-A1, p. 16]

As such, FWS's 2016 Final Polar Bear Conservation Management Plan clearly stated that the polar bear cannot be recovered without significant reductions in the greenhouse gas emissions driving Arctic warming and sea ice loss: 'It cannot be overstated that the single most important action for the recovery of polar bears is to significantly reduce the present levels of global greenhouse gas (GHG) emissions, which are the primary cause of warming in the Arctic.'111 [EPA-HQ-OAR-2021-0208-0726-A1, p. 17]

If the Rule is finalized as proposed, greenhouse gases emitted will exacerbate the loss of sea ice, causing the likelihood of survival and recovery of the polar bear to diminish appreciably. The EPA must consult on how the Rule would affect sea ice loss for a listed species like the polar bear. [EPA-HQ-OAR-2021-0208-0726-A1, p. 17]

Elkhorn, Staghorn and other Coral Species & Ocean Heat Stress and Ocean Acidification. As of the date of this letter, 22 species of corals are listed under the Endangered Species Act due primarily to threats from ocean warming and ocean acidification, direct consequences of climate change. In 2006, NMFS listed elkhorn and staghorn corals (Acropora palmata and A. cervicornis) as threatened, citing ocean warming as a key threat to these species.112 In 2014 NMFS reaffirmed that ocean warming due to climate change and ocean acidification are primary threats to these species.113 In 2014 NMFS listed 20 additional corals as threatened, including five Caribbean coral species and fifteen Indo-Pacific coral species,114 determining that the most important threats contributing to extinction risk for these species are ocean warming, disease (as related to climate change), and ocean acidification.115 NMFS stated that 'these impacts are currently occurring, and are expected to worsen, posing increasingly severe effects on the species considered in this final rule.'116 [EPA-HQ-OAR-2021-0208-0726-A1, p. 17]

Ocean warming and ocean acidification, two incontrovertible environmental impacts caused by greenhouse gas pollution, are wreaking havoc on marine ecosystems and causing a global collapse of coral reefs. The world's oceans have absorbed more than 90 percent of the excess heat caused by greenhouse gas warming, resulting in average sea surface warming of 1.3°F (0.7°C) per century since 1900.117 Marine heat waves—periods of extreme warm surface temperature—have become longer-lasting and more frequent due to climate change, with the number of heat wave days doubling between 1982 and 2016 and projected to increase 23 times under 2°C warming. 118 At present, 87 percent of marine heat waves are attributable to human-induced warming.119 Global average sea surface temperature is projected to rise by 4.9°F (2.7°C) by the end of the century under a higher emissions scenario, with even greater warming in the coastal waters of the Northeastern U.S. and Alaska.120 Rapid ocean warming has widespread impacts on species and ecosystems, contributing to rising sea levels, declining ocean oxygen levels, increasing rainfall intensity, and ice loss from glaciers, ice sheets and polar sea ice, and is the primary driver of mass coral bleaching events that are devastating coral reef ecosystems.121 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 17-18]

Exacerbating the harms from rising temperatures, the global oceans have absorbed more than a quarter of the CO2 emitted to the atmosphere by human activities, which has significantly increased the acidity of the surface ocean in a process called ocean acidification, and has reduced the availability of key chemicals—aragonite and calcite—that many marine species use to build their shells and skeletons.122 Ocean acidification caused by the ocean's absorption of anthropogenic CO2 has already resulted in more than a 30 percent increase in the acidity of ocean surface waters, at a rate likely faster than anything experienced in the past 300 million years.123 Ocean acidity could increase by 150 percent by the end of the century if CO2 emissions continue unabated.124 In the United States, the West Coast, Alaska, and the Gulf of Maine are experiencing the earliest, most severe changes due to ocean acidification,125 although regions of the East and Gulf Coasts are also vulnerable.126 [EPA-HQ-OAR-2021-0208-0726-A1, p. 18]

Ocean acidification negatively affects a wide range of marine species by hindering the ability of calcifying marine creatures like corals, oysters, and crabs to build protective shells and skeletons and by disrupting metabolism and critical biological functions.127 The adverse effects of ocean acidification are already being observed in wild populations, including reduced coral calcification rates in reefs worldwide, 128 severe shell damage to pteropods (marine snails at the base of the food web) along the U.S. west coast,129 and mass die-offs of larval Pacific oysters in the Pacific Northwest.130 A U.S. expert science panel concluded in 2016 that 'growth, survival and behavioral effects linked to OA [ocean acidification] extend throughout food webs, threatening coastal ecosystems, and marine-dependent industries and human communities.'131 As stated by the 2018 IPCC Special Report on Global Warming of 1.5°C, '[t]he level of ocean acidification due to increasing CO2 concentrations associated with global warming of 1.5°C is projected to amplify the adverse effects of warming, and even further at 2°C, impacting the growth, development, calcification, survival, and thus abundance of a broad range of species, e.g., from algae to fish (high confidence).'132 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 18-19]

Rising ocean temperatures and ocean acidification driven by greenhouse gas pollution threaten the continued survival of corals and coral reef ecosystems due to the increasing frequency of mass bleaching events and the dissolution of corals due to ocean acidification.133 Scientific research has definitely linked anthropogenic ocean warming to the catastrophic, mass coral bleaching events that have been documented since 1980 and are increasing in frequency and intensity as atmospheric CO2 increases.134 Severe bleaching events have increased five-fold in the past several decades and now occur every six years on average, which is too frequent to allow full recovery of coral reefs.135 The global coral bleaching event that lasted from 2014 to 2017 was the longest, most widespread, and almost certainly most destructive on record, affecting more reefs than any previous mass bleaching event and causing mass bleaching of reefs that had never bleached before, with U.S. reefs particularly hard-hit.136 For example, in PapahÄ□naumokuÄ□kea Marine National Monument in Northwestern Hawaiian Islands, a 2017 study concluded that 'heat stress in 2014 was unlike any previous event and that the exposure of corals to the bleaching-level heat stress has increased significantly in the northern PMNM since 1982, highlighting the increasing threat of climate change to reefs.' 137 In the Caribbean, many important reef-building corals have not recovered from repeated bleaching events due to climate change.138 According to a 2021 study that projected changes in coral reef growth (net carbonate production) under ocean warming and acidification across 183 reefs worldwide, 94% of coral reefs globally will be eroding by 2050 if greenhouse gas emissions continue unabated. In contrast, if emissions are immediately and drastically reduced (i.e., RCP 2.6 emissions scenario), coral reef growth will still decline dramatically, but 63% of reefs will still be able to grow at the end of the century.139 A 2017 scientific review concluded that 'unless rapid advances to the goals of the Paris Climate Change Agreement occur over the next decade' that 'coral reefs are likely to degrade rapidly over the next 20 years, presenting fundamental challenges for the 500 million people who derive food, income, coastal protection, and a range of other services from coral reefs.'140 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 19-20]

As discussed, 22 species of corals are listed under the Endangered Species Act due primarily to threats from ocean warming and ocean acidification. Specifically, listed elkhorn and staghorn corals—once abundant throughout the Caribbean Sea—precipitously declined by 92 to 97 percent, largely due to disease. Research indicates that the outbreaks of white-band disease that decimated these corals were driven by heat stress from rising ocean temperatures.141 Research has also documented that ocean warming increases the susceptibility to disease, fragmentation, and mortality of elkhorn and staghorn corals, while ocean acidification decreases their fertilization, settlement success, growth and calcification.142 For listed pillar corals (Dendrogyra cylindrus) which have suffered catastrophic declines in Florida in recent years, research indicates that black band disease first emerged following bleaching events in 2014 and 2015 spurred by abnormally high water temperatures. 143 The three listed star corals in the Caribbean—boulder star coral (Orbicella franksi), mountainous star coral (Orbicella faveolata), and lobed star coral (Orbicella annularis)—have experienced long-term declines in reproduction following bleaching events caused by high water temperatures, which scientists warned 'may be catastrophic for the long-term maintenance of the population.'144 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 20-21]

Scientific research and federal documents conclude that greenhouse gas emissions must be immediately and rapidly reduced—with the target of keeping global average temperature rise below 1.5°C and returning atmospheric CO_2 levels below 350 ppm—to prevent catastrophic loss and degradation of corals. For example, a 2012 study concluded that protecting at least half of the world's coral reefs requires limiting global average temperature rise to 1.2°C, while preserving greater than 10 percent of the world's reefs would require limiting warming to below 1.5°C. 145 Similarly, a 2014 study projected that under the low emissions pathway (RCP 2.6) that limits temperature rise below 2°C, the vast majority (88%) of global reef locations would still experience severe bleaching events annually by the end of the century, indicating that 2°C of warming would be devastating for corals. 146 The 2018 IPCC Special Report on Global Warming of 1.5°C stated that coral reefs 'are projected to decline by a further 70–90% at 1.5°C (high confidence) with larger losses (>99%) at 2ºC (very high confidence).'147 As summarized by a 2018 study:

Even the aspirational Paris Agreement target of constraining global warming to 1.5°C above pre-industrial levels is unlikely to be sufficient to prevent drastic modifications and reconfigurations of the community structure and make-up of coral reefs. For the 100 reef locations examined here and given current rates of warming, the 1.5°C global warming target represents twice the thermal stress they experienced in 2016. The 2°C global target would result in 3 times the 2016 level of thermal stress and 3 °C, which is currently being tracked with the NDCs, would be over 6 times the 2016 level of stress.148 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 21-22]

Based on this evidence, coral scientists have recommended returning the atmospheric CO2 concentration to less than 350 ppm to protect coral reefs, and have suggested a target of 320 ppm which is the level that pre-dates the onset of mass bleaching events.149 [EPA-HQ-OAR-2021-0208-0726-A1, p. 22]

NMFS' 2015 Final Recovery Plan for Elkhorn and Staghorn Corals states that ocean warming and acidification are 'among the greatest threats' to these corals, and recommends actions to reduce greenhouse gas emissions to reduce these threats: 'the combination of rising temperature and ocean acidification both resulting primarily from anthropogenic increases in atmospheric CO2, are likely to have synergistic effects and are among the greatest threats to elkhorn and staghorn coral recovery'150 and 'therefore, actions must be taken to address ocean warming and acidification impacts on these species.'151 NMFS's recovery plan includes a recovery criterion with specific targets for ocean surface temperatures and ocean acidification levels152 that are lower than today's levels and are consistent with a return to an atmospheric CO2 concentration of less than 350 ppm,153 as recommended by numerous scientific studies that have examined coral species viability in response to ocean warming and ocean acidification. 154 The Recovery Plan also recognizes that a primary threat to listed corals is the inadequacy of existing regulations to control greenhouse gas emissions. It specifies a recovery criterion calling for the adoption of 'adequate domestic and international regulations and agreements' to abate threats from increasing atmospheric CO2 concentrations,155 including a recovery action to 'develop and implement U.S. and international measures to reduce atmospheric CO2 concentrations to a level appropriate for coral recovery.'156 As acknowledged by the Recovery Plan:

The final listing rule (NMFS 2006) identified inadequacy of regulatory mechanisms as a threat contributing to the threatened status of elkhorn and staghorn corals. Additionally, the 2014 final rule maintaining the threatened status of elkhorn and staghorn corals (NMFS 2014) identifies the inadequacy of existing regulations to control greenhouse gas emissions, and thus the high importance threats linked to climate change, as contributing to the status and risk of extinction of these two species. Because existing regulatory mechanisms are insufficient to provide appropriate threat abatement for elkhorn and staghorn corals, they are impeding recovery of these species. The threat posed by inadequacy of existing regulatory mechanisms is high (4) throughout the region (see Table 1) because several of the major threats affecting these species are amenable to regulation, albeit with difficulty. National and international efforts are needed to address global climate change while additional international protections are needed to protect populations of elkhorn and staghorn corals throughout their ranges.157 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 22-23]

Since the ocean has absorbed more than 90 percent of the excess heat caused by greenhouse gas warming and more than a quarter of the CO2 emitted by human activities,158 it is critical for the survival of the elkhorn and staghorn corals to prevent many additional millions of tons of CO2 from being released. At a minimum, EPA must assess how the increases in carbon dioxide emissions will affect these climate-sensitive ocean species. [EPA-HQ-OAR-2021-0208-0726-A1, p. 24]

Other Coastal Species and Sea Level Rise. Global average sea level rose by seven to eight inches (0.2 m) since 1901 as the oceans have gotten hotter and land-based ice has melted.159 Global average sea level has risen faster since 1900 than in any other century in at least the last 3,000 years.160 Sea level rise is accelerating in pace: the recent rate of sea level rise has nearly tripled compared with the rate between 1901-1971 (3.7 mm per year from 2006-2018 versus 1.3 mm per year from 1901-1971).161 The Fourth National Climate Assessment estimated that global sea level is very likely to rise by 1.0 to 4.3 feet by the end of the century relative to the year 2000, with sea level rise of 8.2 feet possible.162 Sea level rise will be much more extreme without strong action to reduce greenhouse gas pollution. By the end of the century, global mean sea level is projected to increase by 0.8 to 2.6 feet under a lower emissions RCP 2.6 scenario, compared with 1.6 to 6 feet under a high emissions RCP 8.5 scenario.163 [EPA-HQ-OAR-2021-0208-0726-A1, p. 24]

According to the IPCC’s Climate Change 2021 report, even under a very low GHG emissions scenario, it is likely that global sea level rise by 2100 will be about one to two feet (0.28-0.55 m) compared to 1995-2014. Under an intermediate scenario, sea level rise is likely to be as high as 2.5 feet (0.44-0.76 m), and under a very high GHG emissions scenario it is likely to be close to three feet (0.37-0.86 m). Sea level rise above the likely range, approaching seven feet (2 m) by 2100 under a very high GHG emissions scenario cannot be ruled out due to uncertainty around the melting of ice sheets. Regardless, the impacts of sea level rise will be long-lived: under all emissions scenarios, sea levels will continue to rise for many centuries.164 [EPA-HQ-OAR-2021-0208-0726-A1, p. 24]

Scientific research and federal documents recognize that many coastal listed species are threatened by sea level rise driven by climate change. According to a 2013 analysis, on the current emissions trajectory, rising seas driven by warming temperatures threaten at least 17 percent of our nation’s federally protected species, totaling 233 species in 23 coastal states.165 For example, more than half of Florida’s endangered species are threatened by rising sea levels and associated groundwater contamination.166 Recent FWS listing rules for Florida coastal species have determined that sea level rise resulting from climate change, and the inadequacy of existing regulatory mechanisms to address climate change, are primary threats endangering these species, including the Florida bonneted bat (Eumops floridanus), 167 Cape

Sable thoroughwort (Chromolaena frusrata),168 Florida semaphore cactus (Consolea corallicola),169 aboriginal prickly-apple (Harrisa aboriginum),170 and Florida bristle fern (Trichomanes punctatum ssp. floridanum).171 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 24-25]

Research and federal documents have also highlighted sea-level rise as a primary threat to sea turtles by eroding nesting beaches and reducing nesting success.172 For example, most (87 percent) loggerhead sea turtle (Caretta caretta) nesting occurs on the east coast of Florida,173 where 43 percent of the turtle's nesting beaches are projected to disappear with just 1.5 feet of sea level rise.174 The listing rules for the green sea turtle175 and loggerhead sea turtle176 conclude that sea level rise is likely to have negative effects on these species through beach loss and reduced nesting success. [EPA-HQ-OAR-2021-0208-0726-A1, pp. 25]

Finalizing the Rule is likely to result in a significant increase of CO2 emissions and worsen sea level rise. The proposed Rule thus triggers the EPA's legal duty under the ESA to consult on how continued habitat loss due to sea level rise will adversely affect the loggerhead sea turtle and other listed species threatened by sea level rise. [EPA-HQ-OAR-2021-0208-0726-A1, p. 26]

Sample of Recent Species Listed Due to Climate Change. In addition, the Environmental Groups' analysis of federal listing rules found that FWS and/or NMFS determined that human-caused climate change was a current or potential threat for more than 70 percent of all species listed during 2012 to 2015. The table below includes examples of species listed during 2006 to 2015 for which climate change was a listing factor. Climate change is also a growing threat to many threatened and endangered species that were first listed for other reasons. [EPA-HQ-OAR-2021-0208-0726-A1, pp. 26; Table 1 can be found on pp. 26-31 of Docket number EPA-HQ-OAR-2021-0208-0726-A1]

In sum, the single most important action to avoid further jeopardizing climate-threatened species is achieving emissions reductions that keep warming below 1.5°C and meaningfully lessens carbon dioxide-induced ocean acidification. 177 Section 7 consultation under the ESA is the critical first step to preventing the worst impacts of climate change and ocean acidification on endangered species. As described above, the Rule, if finalized, would directly contribute to significantly higher emissions and their attendant climate change and ocean acidification effects, and thus triggers the duty to consult on those impacts to climate-threatened species—including polar bears and corals—to ensure that any final agency is not likely to jeopardize these and other species or result in the adverse modification of their critical habitat. Failure to conduct this consultation would render any final Rule unlawful. [EPA-HQ-OAR-2021-0208-0726-A1, pp. 31-32]

ii. Nitrogen pollution from vehicle exhaust has documented adverse impacts on federally protected species, and EPA's adoption of the proposed Rule will allow cars and light trucks to emit nitrogen pollution and impact these federally-listed species.

This section describes the numerous federally-listed species whose existence is jeopardized by increases in nitrogen oxide (NOx) emissions. The proposal would emit approximately 30,000 more tons of NOx than Alternative 2, and increasing stringency while reducing available credits could save even more NOx than Alternative 2 alone. Consequently, the Rule, if finalized, would directly contribute to NOx emissions from vehicle exhaust and increase nitrogen deposition in the areas where such vehicles are operating. Accordingly, increased levels of nitrogen deposition may impact critically imperiled species, including the bay and quino checkerspot butterflies and desert tortoise, whose populations are at heightened risk of extinction directly due to increased nitrogen pollution in their locations and critical habitats. [EPA-HQ-OAR-2021-0208-0726-A1, p.32]

Fossil fuel combustion from vehicles produces nitrogen oxide (NOx) air pollutants including nitrous oxide (N2O), as well as nitric acid (HNO3), nitrate (NO3-), and ammonia (NH3), which have contributed to the significant increase in nitrogen deposition globally and in many parts of the United States,178 resulting in widespread impacts to species and ecosystems.179 [EPA-HQ-OAR-2021-0208-0726-A1, p.32]

A recent study of the effects of nitrogen pollution on federally-listed species, based on analysis of USFWS and NMFS documents, found that this threat is ‘substantial’ and ‘geographically widespread.’180 The study found evidence for harm from nitrogen pollution for at least 78 federally protected taxa.181 This includes at least 50 invertebrates such as mollusks and anthropods, at least 18 vertebrate species of fish, amphibians, and reptiles, and at least 8 plants.182 Harms from nitrogen pollution fell into four main categories: (1) direct toxicity or lethal effects of nitrogen, (2) eutrophication lowering dissolved oxygen levels in water or causing algal blooms that alter habitat by covering up substrate, (3) nitrogen pollution increasing nonnative plant species that directly harm a plant species through competition, and (4) nitrogen pollution increasing nonnative plant species that indirectly harm animal species by excluding their food sources.183 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 32-33]

Bay checkerspot butterfly (Euphydryas editha bayensis) Nitrogen deposition from vehicle exhaust is a well-documented threat to the bay checkerspot butterfly (Euphydryas editha bayensis), which is restricted to patches of low-nutrient serpentinite soil in the San Francisco Bay area.184 Nitrogen deposition has allowed exotic grasses to replace native forbs, including the bay checkerspot’s larval host plant, leading to butterfly population declines and local extirpations.185 USFWS in its most recent 5-year review for the bay checkerspot butterfly found that nitrogen deposition from smog created soil conditions that allowed for invasion of non-native plants, where the level of impact increased with proximity to a major interstate highway:

Weiss (1999, p. 1476) determined that while the initial cause of the butterfly declines were the result of rapid invasion by nonnative annual grasses that crowded out the butterfly’s larval host plants, the evidence indicated that dry nitrogen deposition from smog was responsible for creating soil conditions that allowed the observed grass invasion. Weiss (1999, p. 1482) estimated nitrogen deposition rates south of San Jose to be 10-15 kg of nitrogen per hectare per year (kg-N/ha/yr). Weiss (2002, p. 31) further demonstrated these effects by analyzing the pattern of non-native grass invasion resulting from nitrogen deposition at Edgewood Park, and observed that the cover of non-native Italian ryegrass (Lolium multiflorum) decreased with distance from Interstate Highway 280 (I-280), while Plantago erecta cover increased with distance. Plantago erecta cover was also higher upwind of I-280 than downwind. 186 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 33-34]

In its 5-year review, USFWS concluded that ‘the butterfly is still at great risk from invasion of non-native vegetation, exacerbated by nitrogen deposition from air pollution.' 187 [EPA-HQ-OAR-2021-0208-0726-A1, p. 34]

Presidio clarkia (Clarkia franciscana) Endangered plant species such as the Presidio clarkia (Clarkia franciscana)--a beautiful flowering plant native to California serpentine grasslands--are also being harmed by nitrogen deposition from vehicle pollution which gives a competitive advantage to nonnative plants. 188 USFWS in its most recent 5-year review for the Presidio clarkia identified nitrogen deposition from air pollution as a principal threat, explaining that ‘elevated inputs of atmospheric nitrogen deposition from air pollution have further accelerated the encroachment of native shrubs and nonnative shrubs and nonnative grasses and forbs...into Clarkia franciscana habitat.' 189 The USFWS 5-year review specifically highlights vehicle pollution as a key contributor to the nitrogen deposition harming the Presidio clarkia:

Elevated atmosphere nitrogen deposition from air pollution is particularly harmful to the nutrient-poor serpentine grasslands where the Clarkia franciscana occurs because nitrogen is the primary limiting nutrient for plant growth on serpentine soils (Weiss 1999). The use of catalytic converters on vehicles has increased the availability of nitrogen in a form that is directly absorbed by plants (EBRPD 2009a). The excess nitrogen deposited leads to increases in nonnative annual grasses which outcompete the native flora (Fenn et al. 2003, Weiss 1999). [EPA-HQ-OAR-2021-0208-0726-A1, p. 34]

The displacement of Clarkia franciscana and native bunchgrasses from serpentine soils in the Oakland hills is attributed to the dry deposition of 10-15 kilograms nitrogen per hectare per year from smog allowing for the invasion of nonnative annual grasses, especially Italian ryegrass at Redwood Regional Park (EBRPD 2009a, Tonnesen et al. 2007). … Thus, Clarkia franciscana in the serpentine grasslands in the Oakland Hills continues to be threatened by elevated atmospheric nitrogen deposition from air pollution enabling the invasion of nonnative annual grasses into otherwise nutrient-poor soils.190 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 34-35]

The USFWS 5-year review identifies other potential harms to the Presidio clarkia from nitrogen deposition such as decreased diversity of mycorrhizal communities and predisposing plants to environmental stresses such as elevated concentrations of ozone, drought, frost, or insect attacks.191 [EPA-HQ-OAR-2021-0208-0726-A1, p. 35]

Other Species Threatened by Nitrogen Pollution. Similarly, USFWS has determined that nitrogen pollution threatens the federally protected Quino checkerspot butterfly (Euphydryas editha quino) and the desert tortoise (Gopherus agassizii) by facilitating the spread of non-native species that displace the butterfly’s host plants192 and the tortoise’s forage plants, reducing the nutritional quality of available food for the desert tortoise.193 [EPA-HQ-OAR-2021-0208-0726-A1, p. 35]

A review on the effects of nitrogen deposition in the western United States highlighted the need for policy changes at the national level for reducing air pollution to protect endangered species from nitrogen deposition: 'local land management strategies to protect these endangered species may not succeed unless they are accompanied by policy changes at the regional or national level that reduce air pollution.'194 [EPA-HQ-OAR-2021-0208-0726-A1, p. 35]

i. Sulfur dioxide pollution has clear and documented adverse impacts on federally protected species, and EPA's adoption of the proposed Rule will allow cars and light trucks to emit sulfur dioxide pollution and impact these federally-listed species.

This section describes the myriad federally-listed species whose existence is jeopardized by increases in sulfur dioxide ('SO2') emissions. As with NOx, the proposal would emit over 100,000 more tons of SO2 than Alternative 2, and increasing stringency while reducing available credits could save even more SO2 than Alternative 2 alone. Consequentially, the Rule, if finalized as proposed, would directly contribute to SO2 emissions and jeopardize numerous critically imperiled bird species and plant species, whose populations are at heightened risk of extinction directly due to increased sulfur dioxide pollution in their locations and critical habitats. [EPA-HQ-OAR-2021-0208-0726-A1, pp. 34-36]

Strong evidence shows that SO2, as well as precursors such as sulfur oxides ('SOx'), harm endangered plant and animal species as well as aquatic and terrestrial ecosystems. As reviewed by EPA, the negative ecological effects of SO2 pollution include acidification of aquatic and terrestrial ecosystems, nutrient enrichment of aquatic and terrestrial ecosystems, and facilitation of mercury methylation in aquatic ecosystems.195 Acute and chronic exposure to SO2 also leads to phytotoxic effects on plants, including foliar injury, decreased photosynthesis, and decreased growth.196 [EPA-HQ-OAR-2021-0208-0726-A1, p. 36]

In its 2017 final Integrated Review Plan for Secondary Standards for Oxides of Sulfur, EPA acknowledged that there is 'sufficient evidence to infer causal relationships' between exposure to SO2 and SOx and (a) aquatic acidification and the loss of acid-sensitive species, where more species are lost with greater acidification;197 (b) changes in terrestrial biota due to acidifying sulfur deposition, such as decreased growth and increased susceptibility to disease and injury in sensitive tree species;198 (c) increased mercury methylation in aquatic environments;199 and (d) injury to vegetation, including decreased photosynthesis, decreased growth, and visible foliar injury.200 [EPA-HQ-OAR-2021-0208-0726-A1, p. 36]

In terms of harms to endangered species, EPA acknowledged that acidifying sulfur deposition in aquatic ecosystems can cause the loss of acid-sensitive species, such as salmonids (many of which are endangered), and that disruption of food web dynamics can cause changes to the diet, breeding distribution and reproduction of bird species.201 EPA further stated that current rates of acidifying SOx deposition are still well above pre-acidification conditions in areas such as the Adirondacks and Shenandoah, and that sulfur and nitrogen deposition loadings of many Adirondack lakes and streams are at levels that can harm aquatic biota (e.g., levels associated with loss of fitness in species such as the Blacknose Dace).202 EPA also acknowledged that there is a 'causal relationship between Sulfur deposition at current levels and increased Hg methylation in aquatic environments,'203 which is problematic because mercury is highly neurotoxic and, once methylated, can be taken up by zooplankton and macroinvertebrates, and bioaccumulate up the food web. 204 [EPA-HQ-OAR-2021-0208-0726-A1, pp. 36-37]

Indeed, EPA's Integrated Review Plan acknowledges that SO2 has the potential to negatively affect endangered species. The Risk and Exposure Assessment (REA) identified a range of ecosystem services that are affected by terrestrial acidification including 'decreased habitat for threatened and endangered species.,' 205 [EPA-HQ-OAR-2021-0208-0726-A1, p. 37]

At-risk Plant Species. Federal wildlife agencies, and in particular FWS, have identified numerous federally endangered and threatened species that are negatively affected by atmospheric pollution from SO2 and SOx. Federally protected plant species identified by FWS as threatened by or susceptible to acidification and atmospheric pollution include the Harperella (Ptilimnium nodosum), 206 Zuni Fleabane (Erigeron rhizomaxs), 207 Mancos Milkvetch (Astragalus humillimus), 208 Blue Ridge Goldenrod (Solidago spithamaea), 209 Heller's Blazing Star (Liatris helleri), 210 Rock Gnome Lichen (Gymnodema lineare), 211 and Roan Mountain Bluet (Hedyotis purpurea var. montana). 212 For example, Heller's Blazing Star is a rare plant endemic to a limited area in the Blue Ridge Mountains of North Carolina, with only a few populations currently known to exist. The recovery plan for this species names acid precipitation as a 'pervasive' threat. 213 The FWS recovery plan for the Rock Gnome Lichen, which is endemic to the Southern Appalachians, flags that 'there is a high likelihood that current and previous air pollution levels, especially from sulfates, may be contributing to the decline of this species.' 214 [EPA-HQ-OAR-2021-0208-0726-A1, p. 37]

At-risk Animal Species. FWS has also identified numerous animal species as being threatened by or susceptible to acidification and atmospheric pollution, including the Shenandoah Salamander (Plethodon shenandoah),215 Cheat Mountain Salamander (Plethodon neftiigi),216 Chiricahua Leopard Frog (Rana chiricahuensis),217 Whooping Crane (Grus americana),218 Roanoke Logperch (Percina rex),219 Dwarf Wedge Mussel (Alasmidonta heterodon),220 Mobile River Basin mussels,221 and seven species of Southeast mussels.222 For example, the recovery plan for the Chiricahua Leopard Frog states that acid rain has been found to adversely affect Chiricahua Leopard Frog populations,223 likely through reduced hatching of eggs and reduced growth rates.224 [EPA-HQ-OAR-2021-0208-0726-A1, p. 38]

Consultation under the ESA about impacts to species is essential. EPA's Proposal, if finalized, would directly contribute to higher emissions of SO2, and thus triggers the duty to consult on those impacts to species at risk from atmospheric pollution from SO2 and SOx. Failure to conduct this consultation would render any final repeal unlawful. [EPA-HQ-OAR-2021-0208-0726-A1. p.39]

The scientific evidence demonstrates that the Rule, if adopted as proposed, may affect hundreds of threatened and endangered species, and their critical habitats, due to the Rule's resulting increase in emissions of GHG, NOx, SO2 and other criteria air pollutants. [EPA-HQ-OAR-2021-0208-0726-A1. pp 39]

EPA Response

EPA notes that its rulemaking will result in emissions reductions that are expected to have beneficial effects on the environment with respect to global climate change, criteria pollutants, listed species, critical habitats, and associated impacts. EPA has reviewed the information submitted in comments noting the additional cumulative greenhouse gas and criteria pollutant emissions associated with the proposed standards as compared to Alternative 2, and attempting to quantify alleged impacts on certain threatened and endangered species from adopting the proposed standards in place of Alternative 2. EPA agrees that standards even more stringent than the proposal would provide additional reductions in emissions of greenhouse gases and criteria pollutants. As discussed in Section II of the Preamble, EPA has decided to finalize standards that are 10 g/mi more stringent than Alternative 2 in MY 2026 and beyond, resulting in a cumulative emissions reduction of 3.1 billion metric tons of CO_2 and, similarly, additional methane and criteria pollutant reductions. By comparison, in our NPRM, the proposed standards resulted in 2.2 billion metric tons of CO_2 reductions while Alternative 2 resulted in 2.5 billion metric tons of CO_2 reductions. This stringent path forward results in greater emissions reductions than either the proposal or Alternative 2 and beneficial climate effects on listed species and habitats.

Commenter: American Lung Association

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp.17-18]

Air pollution causes tens of thousands of people to die each year in the United States and motor vehicles are a leading source of emissions that create ozone or smog and particle pollution. Transportation is also the nation's leading contributor to climate change.

The American Lung Association's most recent State of the Air Report found that more than a 135 million people in the United States, more than four in 10, live in counties with unhealthy levels of air pollution. Let me repeat this. Climate change is making air quality worse.

Commenter: American Lung Association in the Mid-Atlantic

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 110-112.]

According to the American Lung Association's most recent State of the Air Report in just this service area, not a mere handful but 20 counties, home to 13 million people, accounting for one-third of that region's population, earned failing grades for ozone smog, and a clear majority of these counties average at least five days a year when ozone levels were high enough to pose clear risks for people in sensitive groups, children and seniors as well as people with chronic lung and heart disease, risks severe enough to send people to emergency rooms and hospitals.

Despite many years of improvement in emissions and efficiency standards for vehicles and fuels, we in the Mid-Atlantic still face a serious problem. Transportation-related air pollution, including significant contributions from light-duty vehicles, continues to be a major source of both greenhouse gases and ambient air pollution. According to the most recent emission inventories, highway vehicles alone account for about 17 percent of the Mid-Atlantic's contributions to volatile organic compounds and for fully 39 percent, the largest share for any emissions tier, for nitrogen oxides, the primary driving precursor of ozone formation in the Mid-Atlantic.

Commenter: Anderson, Laurie

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 104.]

Additionally, by reducing tailpipe pollution which includes NOX, a precursor to ozone, we thereby help reduce ground level ozone pollution and our hope of getting out of ozone non-attainment so we can breathe easier along Colorado's Front Range.

Commenter: Brandt, Dorothy

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 205-206.]

I call on the EPA to strengthen clean car standards. One of my daughters has asthma and I insist that our government protect her and the health of all Americans. No one should struggle to breathe due to preventable car pollution.

Commenter: California Air Resources Board (CARB)

U.S. EPA's proposed GHG emission standards will also decrease emissions of criteria pollutants, including particulate matter (PM) and the pollutants that form ground-level ozone: volatile organic compounds and oxides of nitrogen (NOx). Reducing particulate matter pollution and the constituents of smog are especially important in California. The interaction of population, geography, and climate present the most acute challenges in the nation to meeting the health-based standards for this pollution. CARB agrees with U.S. EPA that more stringent greenhouse gas emission standards will reduce criteria pollutants. [EPA-HQ-OAR-2021-0208-0643-A6, p.8]

Reducing this pollution will deliver a range of important public health benefits, especially for communities that have been disproportionately impacted by pollution. [EPA-HQ-OAR-2021-0208-0643-A6, pp. 8-9]

In addition, exposure to elevated pollution levels has been found to increase vulnerability to other types of illnesses. Studies in the U.S. and Europe have demonstrated associations between chronic elevated PM2.5 exposure and increased COVID-19-related premature death and illness. Wu et al., found long-term exposure to PM2.5 was associated with a significant increase in COVID-19 mortality in the U.S. Additionally, a study by Pozzer and colleagues found that PM2.5 air pollution contributed to COVID-19 mortality: approximately 15% worldwide, and 17% in North America. These results suggested that air pollution is an important cofactor increasing COVID-19 mortality risk. [EPA-HQ-OAR-2021-0208-0643-A6, pp. 13-14]

Commenter: California Attorney General Office, et al.

Reducing other forms of pollution—including criteria air pollution (such as fine particulate matter (PM2.5) and ozone) and emissions of toxic air pollutants—is also critical. Our States and Cities are committed to those reductions, but federal involvement is necessary to help States attain the National Ambient Air Quality Standards (NAAQS) and to reduce emissions that are outside our control. As EPA projects, more stringent standards will decrease criteria pollutant and air toxic emissions, as well as GHG emissions, and these reductions are critical to meeting our States' and Cities' public health and environmental justice goals and protecting our residents. [EPA-HQ-OAR-2021-0208-0245-A1, pp.10-11]

EPA projects overall reductions in PM2.5 and reductions in upstream nitrogen oxides (NOx) (an ozone precursor) beginning in 2023, and overall (net) reductions in NOx from 2028 on. 86 Fed. Reg. at 43,779–43,780. All of these reductions are crucial to avoid adverse health consequences, including premature mortalities. Short- and long-term PM2.5 exposures result in mortality risk, cardiovascular harms and adverse respiratory effects. In California alone, over 5,000 premature deaths and hundreds of illnesses and emergency room visits for respiratory and cardiovascular disease are linked to PM2.5 pollution. Even in areas presently attaining the NAAQS, two studies showed that long-term PM2.5 exposures are associated annually with up to 45,000 deaths, and 14,600 ischemic heart disease deaths, respectively, and thus, even a modest reduction of PM2.5 pollution will have beneficial impacts. For example, decreases in PM2.5 are significantly associated with lower asthma incidence. Recent studies also show that air pollution, including long-term PM2.5 exposure, may increase the vulnerability of individuals to contracting COVID-19 and may increase the severity and mortality risk from the virus. Ozone pollution leads to similar negative health effects, especially for respiratory health.

The mobile source sector is a major cause of these health impacts because it is one of the largest contributors of PM2.5 and ozone-forming emissions in the United States. In some urban areas, mobile sources account for 13 to 30% of the total primary PM2.5 emissions. In California, more than half of the PM2.5 pollution is produced by mobile sources. Mobile sources are also the number one contributor to high ozone levels in the Ozone Transport Region. The mobile source pollution concentrated near major roadways exposes nearby communities to additional health risks, including by contributing to and exacerbating asthma, impairing lung function, and increasing cardiovascular mortality. [EPA-HQ-OAR-2021-0208-0245-A1, pp.11-12]

EPA also projects that its proposed standards would result in the reduction of emissions of air toxics. 86 Fed. Reg. at 43,729, 43,781, 43,785. These reductions will benefit public health and welfare, in part because toxic air pollutants cause cancer and other serious health effects. Id. at 43,781; 72 Fed. Reg. 8,428, 8,430 (Feb. 26, 2007). Of all the outdoor air toxics, benzene contributes the most to nationwide cancer risk, and most of the nation's benzene emissions come from mobile sources. Id. at 8,432. In New Jersey, mobile sources are the largest contributors of air toxic emissions. In Allegheny County in Pennsylvania, mobile sources account for over 9% of the estimated cancer risk from hazardous air pollutants, mostly due to gasoline-powered cars. [EPA-HQ-OAR-2021-0208-0245-A1, p.13]

Reductions in Other Pollution Are Also Urgently Needed to Protect Public Health. EPA's proposal will also advance another important and urgent objective of our States and Cities and of Congress: reductions in criteria and toxic air pollution. See Background, Section B. It will do so by reducing GHG emissions, and laying the groundwork for deeper reductions to come, which is important for the reasons outlined above and because the effects of climate change will result in worse air quality even if criteria emissions remain the same. More stringent standards will also directly reduce criteria and toxic pollution, and even small reductions will have a significant impact, especially in nonattainment areas and communities living near refineries or near roadways. [EPA-HQ-OAR-2021-0208-0245-A1, pp.21-22]

More stringent standards will help protect public health and support NAAQS attainment. Various locations throughout our States and Cities have been unable to attain, or face difficulty maintaining, the NAAQS—designed to protect public health—for ozone and PM2.5. 42 U.S.C. § 7409(b). For example, multiple counties in California are registering severe, serious, or extreme nonattainment with the 8-Hour Ozone NAAQS. Reductions in ozone due to the proposed standards would provide critical clean air benefits to these locations. Nonattainment areas outside of California will experience similar benefits. For example, more stringent standards may result in a reduction of ozone precursors in Colorado's Denver Metro/North Front Range, which includes a major transportation corridor and a refinery. Based on 2018–2020 ozone monitoring data, this area is expected to shift from serious to severe nonattainment for the 2008 8-Hour Ozone NAAQS, and, thus, any and all reductions in ozone precursors are needed. Likewise, counties in Connecticut and New York are in serious nonattainment with the 2008 8- Hour Ozone NAAQS and are in moderate nonattainment with the 2015 8-Hour Ozone NAAQS, and their challenges in attaining the NAAQS are due in part to ozone-forming pollution from out-of-state upwind sources which EPA's standards could help reduce. 84 Fed. Reg. 44,223, 44,248, 44,251–44,252 (Aug. 23, 2019) ('EPA acknowledges the role interstate transport of precursors to ozone pollution plays in the efforts of downwind areas to attain and maintain the NAAQS.') New Jersey has taken action to reduce NOx and VOC emissions from mobile sources and from stationary sources, including power plants and refineries, in an attempt to attain the NAAQS. But New Jersey and other States cannot attain or maintain the NAAQS alone, and EPA's standards may provide important emissions reductions in upwind states and across the country.

In addition, PM2.5 exposure at any level is associated with adverse health impacts, so reductions in PM2.5 emissions will bring public health benefits to our States and Cities regardless of whether our regions have attained the NAAQS. Indeed, because PM2.5 exposure below the current NAAQS is clearly harmful, a multi-state coalition, which includes many of the signatories to this comment, petitioned EPA to reconsider its 2020 decision not to strengthen the current NAAQS for Particulate Matter. On June 10, 2021, EPA acknowledged that the current standards may not be adequate to protect public health and welfare, and announced its decision to reconsider its prior decision. [EPA-HQ-OAR-2021-0208-0245-A1, pp.22-23]

Commenter: Center for Climate and Energy Solutions (C2ES)

From a public health perspective, reduced vehicle emissions will contribute significantly to reducing urban smog and supporting healthier communities. In addition to the contribution of greenhouse gas emissions to global climate change, particulate pollution, ground-level ozone, and nitrous oxides are linked to asthma, heart disease, and premature death. Avoiding these health impacts will save the American economy billions in healthcare and lost productivity costs and will improve quality of life for many Americans. [EPA-HQ-OAR-2021-0208-0287-A1, p.3]

Commenter: City of Albuquerque, NM

As the largest metropolitan area and the major transportation hub in the State of New Mexico, the City and Bernalillo County are faced with the challenge of maintaining attainment status for the National Ambient Air Quality Standards ('NAAQS') for ground-level ozone. In Albuquerque/Bernalillo County ozone pollution is high and rising. Ground-level ozone can cause coughing, sore throats, inflame and damage the airways, and aggravate lung diseases such as asthma, emphysema, and chronic bronchitis. Local asthma rates are of particular concern to AQP as Albuquerque is listed as the 38th 'Most Challenging Places to Live with Asthma' in the United States according to the Asthma and Allergy Foundation of America.[EPA-HQ-OAR-2021-0208-0535-A1, p.2]

Although the Proposed Emission Standards are designed to reduce greenhouse gas emissions, if implemented, they will have co-benefits of also reducing criteria and ozone pre-cursor pollutants from mobile sources. [EPA-HQ-OAR-2021-0208-0535-A1, pp.2-3]

Commenter: Collins, Molly

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 231-232.]

Dylan has been pretty impacted by air quality and like a lot of people in our community here in Milwaukee, which is on the American Lung Association's list of the 25 Cities with the Worst Ozone Pollution, getting those air quality alerts on your phone can impact a lot about how you live your life that day and what you're able to do and as I'm sure you know, the increasing temperatures due to climate change make ozone more likely to form and that impacts a lot of people. People should have the freedom to move through their day not worrying about whether or not they're going to be able to breathe.

Commenter: Connecticut Department of Energy and Environmental Protection

The transportation sector was also responsible for 66 percent of the emissions of nitrogen oxides (NOx) in 2017, a key component of ground level ozone (smog). Connecticut fails to meet both the 2008 and 2015 National Ambient Air Quality Standards (NAAQS) for ozone. Poor air quality exposure exacerbates acute and chronic respiratory problems such as asthma, Chronic Obstructive Pulmonary Disease, and other lung diseases. Furthermore, the immediate health impacts of mobile source related air pollution (both direct and indirect) are felt in areas within and along transportation corridors that have borne a disproportionate impact from this pollution for decades. A recent national report, Asthma Capitals 2019, ranked New Haven (#11) and Hartford (#13) among the 100 largest U.S. cities where it is most challenging to live with asthma. [EPA-HQ-OAR-2021-0208-0264-A1, p.2]

Commenter: Cooper, Almeta

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 75-76.]

I'm speaking to you today from Downtown Atlanta where I have lived for seven years. Metro Atlanta is notoriously known for some of the worst traffic congestion in the nation. According to the U.S. Bureau of Transportation, from the outer edges of Fulton County commuters can average traveling as much as 80 miles each work day. Additionally, about 80 percent of the Fulton County's thousands of commuters travel by car daily and many are single occupants driving their vehicles.

Driving is the most harmful mode of transportation to the health of communities and is directly related to air quality. Therefore, it's no surprise that Fulton County was again flagged with a failing grade by the American Lung Association in its 2021 State of the Air Report. So you can easily understand why clean car standards are important to me. Cleaning up vehicle pollution is one of the most important actions we can take as citizens to improve air quality and to fight the adverse impact of climate change.

Commenter: Elders Climate Action (ECA)

In addition, the failure to attain the ozone NAAQS in 230 urban counties where 135 million Americans reside is a perpetual air pollution pandemic that has burdened millions of children with a lifetime of asthma and shortened millions of American lives over the last 50 years. This public health crises will continue to make our cities unhealthy places to raise our children and for elders to reside for decades to come.

In most nonattainment areas, the nitrogen oxides and reactive organic compounds emitted from internal combustion engines (ICEs) are the primary cause of ozone formation and a major contributor to PM2.5 nonattainment. Replacing ICEs as quickly as possible is the solution to urban smog and soot pollution that impairs the health and quality for life for millions of urban Americans. [EPA-HQ-OAR-2021-0208-0521-A1, p. 2-3]

Emissions from ICEs are a Primary Cause of Urban Smog and the Public Health Burden Imposed on Urban Dwellers by Air Pollution. The combustion of carbon fuels in ICEs produces, in addition to CO2, a complex array of hazardous pollutants that U.S. EPA has found cause deadly and debilitating effects on human health, including premature death, cardiovascular disease, chronic obstructive pulmonary disease, lung cancer, impaired fetal development, low birthweight babies, autism, childhood asthma, impaired lung development, and impaired cognitive function among children and adults.

The actions needed to stabilize the climate and prevent the accelerated worsening of the adverse effects on human health from a hotter climate will also provide other substantial public health benefits. The most important health benefits will flow from eliminating the exposures of over one hundred and thirty million Americans to life-shortening air pollutants by not burning carbon fuels. Other health benefits will be achieved by not poisoning the air with toxic pollutants emitted from oil and gas well fields, oil refineries and fuel transport terminals, by not poisoning water supplies now being contaminated by fracking fluids and ruptured oil pipelines, and by not risking the contamination of the oceans and the marine web of life with crude oil released from off-shore drilling and tanker wrecks.

LDVs vehicles are a primary source of nitrogen oxides (NOx) and organic compounds that contribute to the formation of ozone in more than 230 urban counties designated by U.S. EPA as nonattainment for the national ambient air quality standards (NAAQS) for ozone (also known as smog), or particulate matter smaller than 2.5 μm in diameter ("fine particles" regulated as PM2.5), or both.31

Health effects research estimates that air pollution from burning carbon was expected to take an estimated 242,000 lives in 2020 assuming normal economic activity not slowed by the COVID pandemic.32 Earlier work by EPA staff scientists using mortality risk factors derived from health effects research available in 2016 estimated 110,000 deaths annually.33 [EPA-HQ-OAR-2021-0208-0521-A1, p. 13]

Ozone-Caused Asthma Attacks Linked to Daily Exposures. For both ozone and PM2.5 EPA has established national ambient air quality standards (NAAQS) for short-term exposures (8 hours for ozone, and 24 hours for PM2.5) because the health effects research demonstrates that adverse health effects are associated with short-term exposure to these pollutants.

EPA's Clean Air Science Advisory Committee found that every day when ozone concentrations reach the level of the national ambient air quality standard (70 ppb), 8 to 20% of all children will experience a reduction in lung function deemed adverse to the health of an asthmatic child. 35 When ozone concentrations reach 75 ppb, only 5 ppb above the standard, from 11% to 22% of all school aged children will experience at least one such an event, and 1 to 6% of children will experience such adverse health events on 6 or more days.36 Both the percentage of children experiencing harmful effects and the number of days when exposures produce harmful effects continue to increase as ozone concentrations are elevated further above the level of the NAAQS. In most nonattainment cities, peak ozone levels routinely exceed 80 ppb. In Denver peak concentrations are at 90 ppb, and in the South Coast and San Joaquin air districts in California, peak 8 hour concentrations reach 110 ppb.

In its review of the health effects research, EPA found compelling evidence that populations exposed to elevated ozone will experience other adverse health effects in addition to the incidence of asthma attacks discussed in the CASAC letter, including both respiratory and cardiovascular disease outcomes. When the high frequency of asthma attacks is added to the expected frequency of other adverse health outcomes, the best estimates are that ozone pollution days exceeding the NAAQS will cause from 1% to 3% of the entire exposed population to experience an adverse health outcome that interferes with personal health to the degree that normal daily activity is disrupted and some medical intervention is required. As a pollutant formed in the atmosphere miles away from the primary sources of emissions, elevated ozone levels exceeding the NAAQS affect most of the residents of a metropolitan population.

For children, the proportion of the population adversely affected by ozone exposure is likely greater than for the entire population since children have been found to be more sensitive to pollution because of higher ventilation rates, greater air volume to body mass ratios, and higher activity levels when outdoors.

Both asthma attacks and these other adverse health outcomes often require resort to medications, and many require urgent or emergency medical care. Adults who require care suffer pain and impaired capacity to perform daily tasks, often miss work, lose income and incur medical costs. Children miss school. If they miss many days, their education is disrupted and students fall behind which contributes to high school dropout rates. Childhood asthma, autism and impaired cognitive development linked to pollutant exposures all contribute to failed educational achievement, which in turn is strongly correlated with lower lifetime income, poor health histories and shorter lifespans.

Daily NAAQS exceedances in these nonattainment counties create an air quality regime that is harmful to children born into it. Children raised in polluted air sheds develop lungs, bodies and nervous systems in an environment where the air is not safe to breathe. In some cities air is not safe to breathe for weeks out of the summer. In these nonattainment areas children who have no choice in where to live are exposed for the first two decades of their lives to an environment where venturing outdoors during the summer is often a high risk activity. The odds are high that children raised in this environment will develop childhood asthma, suffer impaired lung development, spend many days each year in urgent or emergency care, and experience lost school time that interferes with their education in ways that can result in poor achievement, delayed advancement, and ultimately in limited employment opportunities and diminished lifetime income.

Commenter: Environmental Defense Fund (EDF)

We must treat air pollution as the public health and equity crisis that it is. In addition to being the largest source of climate pollution in the U.S., the transportation sector is also one of the biggest sources of other harmful tailpipe pollutants. It generates over half of the nation's total nitrogen oxide (NOx) emissions, which form harmful ground-level ozone pollution and particle pollution. And our passenger cars and light trucks are responsible for more than half of the NOx and almost all of the volatile organic compound (VOC) pollution from all highway vehicles. Hundreds of studies over multiple decades have found that exposure to vehicle pollution causes adverse health impacts in utero, in infants and children, and in adults [EPA-HQ-OAR-2021-0208-0688-A1, p. 4 - 5]

More than 40 percent of all Americans live in counties with unhealthy levels of ozone or particle pollution. And more than 20,000 Americans die prematurely every year as a result of the motor vehicle pollution on our roads and highways. A recent study by researchers at George Washington University and the Environmental Defense Fund (EDF) found that, in the Bay Area alone, more than 2,500 lives are lost and 5,200 children develop asthma every year due to trafficrelated air pollution exposure. And researchers from the University of North Carolina and the Harvard T.H. Chan School of Public Health found that ozone and fine particulate matter from vehicle emissions in 2016 led to an estimated 7,100 deaths in eleven northeast states and the District of Columbia. Regionwide, light-duty trucks and SUVs were responsible for the largest number of premature deaths. [EPA-HQ-OAR-2021-0208-0688-A1, p. 5]

Significantly reducing ozone forming pollution and harmful particulate pollution that disproportionately burdens people of color, avoiding as many as 5,000 premature deaths and 281,000 lost workdays each year by 2040 and preventing as many as 98,000 premature deaths cumulatively by 2050; [EPA-HQ-OAR-2021-0208-0688-A1, p. 37]

Commenter: Environmental Protection Network (EPN)

Section II describes the compelling need for achieving this goal, given the current understanding of the increasing threats presented by emissions of GHGs and criteria pollutants from vehicles powered by fossil fuels. Achieving the GHG and criteria emissions reductions from this kind of transformation would achieve very substantial benefits to the public's health and welfare, and especially for those segments of society at risk for the greatest harms from climate change and criteria air pollution. Section II also discusses the confluence of several critical trends that show this goal is both practical and achievable. Section III [EPA-HQ-OAR-2021-0208-0213-A1, p.1]

135 million Americans Continue to Suffer from High Air Pollution Levels. Non-GHG air pollution continues to be a major problem in much of the country. The most intractable air pollutants are ground-level ozone and fine PM, both of which can cause a wide range of lung and heart conditions, such as asthma, bronchitis, and heart disease, which can contribute to premature death. Researchers estimate that fine particulate alone is responsible for nearly 48,000 premature deaths in the United States every year. Recent research shows that exposure to elevated levels of air pollution is linked to worse health outcomes from COVID-19, including higher death rates.

According to the American Lung Association's annual 'State of the Air' report, about 40% of Americans—more than 135 million people—live in the 217 counties across the nation with unhealthy levels of ozone, short-term particle pollution, or year-round particle pollution. Around 20.7 million people, or 6.3% of Americans, live in the 13 counties that have unhealthy levels for all three pollutants. [EPA-HQ-OAR-2021-0208-0213-A1, p.3]

Through 2050, the projected cumulative criteria emissions reductions are 5.5 million tons of NOx, 5.3 million tons of volatile organic compounds, and 390,000 tons of fine PM. Using EPA's own screening and mapping tool, EDF projects that the PM savings alone would avert between 43,000 and 99,000 cumulative premature deaths through 2050. [EPA-HQ-OAR-2021-0208-0213-A1, p. 8]

Commenter: Filippelli, Garbirel

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 42-43.]

Now I think COVID, the horrors of COVID also brought an important window for us to view some of these climate and air quality impacts through. The COVID shutdowns markedly cleared the air around the world, but it also cleared the air right here in the U.S. in cities and towns and we just published a study in the Journal Sustainability that shows how much that clearance was. In the two major months of COVID shutdowns, the concentration of NO2 dioxides, which is a severe lung irritant, the concentration in the atmosphere dropped by 20 to 40 percent in major cities across the country.

This drop wasn't because of a reduction in energy production. It was a reduction in transportation. This was the lockdown which kept people at home and those are people largely with the light vehicles and light-duty truck sectors. So what we saw was a very clear shutdown which inevitably resulted in a significant, although only temporary, improvement in public health in cities and towns around this country.

Commenter: Gillet, Victoria

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 288-289.] Particle pollution, we know that there's no specific safe amount, right? Even a small amount of exposure to air pollution can cause health consequences across the life spectrum, from preterm birth to dementia and everything in between. And particularly, it's been shown to decrease COVID outcomes, in particular, for people who become infected. They're more likely to have severe outcomes and even death. So, it's important to me that my patients have access to clean air regardless of where they live, even if they happen to be near locations where there are larger vehicles going by.

Commenter: Kansas Senator Marci Francisco

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 293-294.]

As has been testified to today, vehicle emissions not only constitute one of the largest sources of greenhouse gas emissions in the United States but cars and trucks also emit deadly air pollutants, such as PM 2.5. By strengthening pollution standards for passenger vehicles and light-duty trucks as proposed, it would mean significant gains in both public health and our environment, all while providing consumers with opportunities for lower vehicle costs and economic savings.

Commenter: Klein, Stephanie

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 280.]

Washington, D.C., has one of the highest ground level ozone pollution rates in the country. The American Lung Association grades our city at an F in its State of the Air Ozone Pollution Ratings. One in 10 kids in D.C. suffers from asthma which is exacerbated by ground level ozone pollution, and in some parts of the city, particularly our low-wealth and BIPOC communities, the childhood asthma rate is as high as one in three. Cars are one of the major sources of ground level ozone pollution and our kids are living with the impacts.

Commenter: Mass Comment Campaign sponsored by Environment America (11,080)

Not only do America's cars account for the majority of greenhouse gas emissions, but the pollution they emit also cuts short an estimated 58,000 American lives each year. Without stronger action, air pollution from our cars and trucks will continue to rise and threaten our health with more asthma attacks, cancer, and other negative health outcomes. [EPA-HQ-OAR-2021-0208-0557-A1, pp.1-2]

Commenter: Mass Comment Campaign sponsored by Evangelical Environmental Network (15,748)

After the release of the proposed rule, The Evangelical Environmental Network circulated the following petition among members of our community in support of the rule change:

As pro-life Christians, we want the air that we breathe to be safe for our children. But cars are spewing dangerous amounts of soot and smog into our air. These emissions put God's creation and our families—especially children, pregnant mothers, and the unborn—in harm's way. They cause premature birth, increase asthma, and are linked to serious brain diseases. We can fix this. And we can do it in a way that creates millions of new jobs and lowers Americans' monthly fuel bills. That's why we call upon The United States Environmental Protection Agency (EPA) to quickly complete the 2021, EPA's Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards (SAFE 2-Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule). The sooner we can make the air safer for our children and the unborn, the better. [EPA-HQ-OAR-2021-0208-0561-A1, p.1]

We collected 15,748 signatures of support, and have included them with this letter. Pro-life Christians understand that reducing tailpipe emissions is a crucial part of defending the health of our kids—both born and unborn—from toxic pollution. Asthma, preterm labor, and other respiratory illnesses are all preventable epidemics that Americans have suffered under for far too long. Our children are in danger every day that vehicle pollution continues to choke their air. [EPA-HQ-OAR-2021-0208-0561-A1, p.1]

We are grateful that you also recognize the scale of the problem and are taking bold steps to address it. As you do, please know that tens of thousands of pro-life Christians stand with you. We are ready to use our voices to demand action for the health and life of all people—especially those made most vulnerable by air pollution. Our faith requires it. [EPA-HQ-OAR-2021-0208-0561-A1, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-9 (3,219)

Beyond this, the transportation sector contributes significantly to health-harming particulates and smog-forming nitrogen oxides, exacerbating respiratory illnesses like asthma and resulting in premature deaths. These health impacts are felt disproportionately by low-income communities and communities of color. [EPA-HQ-OAR-2021-0208-0640-A1, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-11 (1,667)

Enacting more stringent clean car standards will provide numerous co-benefits for people and parks — from saving American's billions at the pump, to preventing unhealthy vehicle air pollution that severely harms public health and the wellbeing of park ecosystems. [EPA-HQ-OAR-2021-0208-0642-A1, p.1]

Commenter: McQuire, Terry

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 223-224.]

Studies make very clear that communities near major roadways are exposed to higher levels of dangerous air pollution. We know that this is true in my house because every six months or so we have to wash the front of the house off that's not covered by the porch roof. A layer of black soot builds up on the exterior of our home wherever the rain cannot reach it to be washed away. In more moderate months when we leave our windows open to get fresh air and avoid having to run the air conditioning, a layer of soot also develops on the window sills. So I know that we're breathing that in.

As a clean air advocate, I know how dangerous soot pollution is, especially for sensitive populations, like children and seniors. Directly across the street from my house is a small park, Argonne Circle, where groups of children play whenever the weather permits. I think about the pollution they are breathing and wonder if this will result in avoidable sickness or health harms.

Also across from the park is a senior rehabilitation and hospice center. I also think about those elderly residents and I wonder if our proximity to Intestate 581 shortens what little time they may have left with their loved ones.

Commenter: Metropolitan Washington Air Quality Committee (MWAQC)

Poor air quality affects the residents living and working in metropolitan Washington. The region is currently designated as being in nonattainment of federal National Ambient Air Quality Standards (NAAQS) for ozone. Nitrogen Oxides (NOx) are a precursor pollutant of ground-level ozone. In addition, NOx is a precursor to secondary particulate matter, such as particulate matter 2.5 micrometers in diameter and smaller (PM2.5). Exposure to PM2.5, along with ground-level ozone, is associated with premature death, increased hospitalizations, and emergency room visits due to exacerbation of chronic heart and lung diseases and other serious health impacts. Some communities in metropolitan Washington face higher rates of illnesses such as asthma than the national average, and these illnesses are aggravated by these pollutants. As such, reductions in NOx emissions will provide health benefits from both reduced ozone and PM2.5 pollution. [EPA-HQ-OAR-2021-0208-0208-A1] [p.2]

While significant progress has been made in metropolitan Washington to reduce NOx emissions, addressing sources of NOx, including those from on-road vehicles, is critical to continuing to deliver cleaner air for the residents of the region. Over the last five ozone seasons, the region recorded an annual average of seven unhealthy air days, which are in part caused by emissions transported into the region, making this not only a regional issue but a national one. In the short term, strengthening the national GHG emissions standards for passenger cars and light trucks will likely have minimal impact on our region's ability to realize the reductions in NOx emissions needed to comply with the 2015 Ozone NAAQS. However, in the long term, strengthening these standards will reduce NOx and PM2.5 emissions as shown by EPA's forecasts in Table 44 and Table 45 of the Federal Register Notice. [EPA-HQ-OAR-2021-0208-0208-A1] [p.2]

Commenter: Mitchell, Milton

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 318.]

First, let me say that the air quality right now is tragically toxic and it's only getting worse.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 319.]

So what I ask today is that the EPA do everything it can within its power to do everything it can to reduce any pollution or toxicity because myself, along with millions, almost two to three percent of the population is immuno-compromised, transplant recipients. Some have transplanted hearts, some liver, whatever the case may be. It could be heart, could be liver, could be kidneys, and at this particular time what we're looking for is help and support and direction from the leadership.

Commenter: Mothers and Others for Clean Air

Studies show that PM2.5 from fossil fuels cause 13.1% of all deaths in the U.S. Nitrogen oxides cause 1.6% of all deaths in the U.S. Vehicle emissions are also a major source of substrates for ozone formation, which also causes many deaths in the U.S. Every death is preceded by illness and suffering, too many trips to medical offices, and too many admissions into a hospital. From lung disease, to heart conditions, strokes, cancer, dementia, and many other illnesses, air pollution is horrendous for human health. Significant reductions in vehicle emissions would save many lives and prevent much suffering. Air pollution also causes low birthweight, preterm birth, it affects children's performance in school, and causes increased needs for mental health care.

Here in the Southeast, air pollution has been shown to increase admissions for dementia, and in Atlanta we know that reducing air pollution prevented many episodes of asthma, congestive heart failure, and other heart and lung conditions.

Because air pollution has such a dire effect on health, the World Health Organization recently strengthened standards for all air pollutants, lowering the standard for annual PM2.5 from 35µg/m3 to 5µg/m3, and lowering the standard for nitrogen oxides from 40µg/m3 to 10µg/m3. Reducing vehicle emissions significantly would help meet these standards. Studies show that reducing air pollution will yield major health improvements within the first year. [EPA-HQ-OAR-2021-0208-0491-A1, p. 1]

Commenter: National Coalition for Advanced Transportation (NCAT)

Federal vehicle standards are central to addressing climate change as well as state, regional, and local air pollution problems, which in many cases are severe. It is clear that action is needed and, in the U.S., the transportation sector generates the largest share of GHG emissions (29 percent of 2019 GHG emissions). The transportation sector is also responsible for a significant share of criteria pollutant emissions, including over 55% of the nitrogen oxides (NOx) total emissions inventory in the U.S., 17.9 million tons per year of carbon monoxide, 133,000 tons per year of fine particulate matter (PM) PM2.5, 287,000 tons per year of PM10, and 1.8 million tons per year of volatile organic compounds (VOCs). These emissions have significant effects on communities around the country. In 2020, approximately 97 million people nationwide lived in counties with pollution levels above the primary National Ambient Air Quality Standards (NAAQS). In many areas of the country, pollution from vehicles is also the leading source of poor air quality.

Electric and other zero emission vehicles are a critically important, cost-effective strategy to reduce such air pollution, particularly in areas with severe air quality problems. All-electric vehicles produce zero direct emissions since these vehicles lack a tailpipe and thus have zero tailpipe emissions of GHGs or other pollutants. As a result, use of these vehicles in place of internal combustion engine vehicles can significantly improve air quality in urban areas. On average across the United States, annual life cycle emissions per vehicle are substantially lower for all electric vehicles as compared to gasoline vehicles. The emissions reductions are even greater in geographic areas that use relatively low-polluting energy sources for electricity generation. The share of electricity generated from renewable energy resources (e.g., wind, solar, geothermal, hydroelectric, and biomass) has dramatically increased in recent years to about 20% of total U.S. electricity generation in 2020. And the U.S. Energy Information Administration (EIA) predicts that this trend of significant increases in generation from renewable resources will continue. As the sources of electricity generation become cleaner, GHG and criteria pollutant emissions related to use of electric vehicles will further decline. Electric vehicles also emit less heat and produce less noise. Researchers from Harvard studied emissions from electric vehicles and conventional vehicles in large metropolitan statistical areas and concluded that in each area, air pollution mortality was significantly less from electric vehicles. Others have found that, regardless of the electric vehicle adoption scenario they considered, ozone and PM2.5 concentrations declined with the adoption of electric vehicles. A number of states are requiring that electric vehicle infrastructure be deployed in disadvantaged communities to ensure that those communities can reap the environmental and public health benefits of these technologies. [EPA-HQ-OAR-2021-0208-0239-A1, p. 15-16]

Commenter: National Parks Conservation Association (NPCA)

Passenger vehicles contribute high levels of traditional air pollutants impacting many of our most beloved national parks. These include pollutants such as nitrogen oxides, particulate matter, ozone, and sulfur dioxide, all of which directly harm the health and wellbeing of park visitors, staff, wildlife, and ecosystems, as well as significantly impair visibility in our parks. Nearly 90% of national parks are plagued by haze pollution. On average, park visitors miss out on 50 miles of scenery across our national parks, with haze cutting down on as many as 90 miles of average visibility in the parks most impacted by vehicle pollution, such as Sequoia and Kings Canyon. With 48 national parks listed as Class 1 areas under the Clean Air Act's Regional Haze Rule, strong action is needed by the federal government to help restore visibility to natural levels in all Class 1 areas. This is especially relevant as states are currently in the midst of the regional haze state implementation planning process through which reductions to improve visibility are required by 2028. [EPA-HQ-OAR-2021-0208-0291-A1, p. 1]

A strong clean cars standard will provide clear benefits for these communities across the nation—from improving localized health outcomes in hot spot communities, to saving average American's billions at the pump. [EPA-HQ-OAR-2021-0208-0291-A1, p. 2]

Commenter: Oliver, Shaina

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 72.]

As a Colorado resident, myself and my family have experienced the worst air quality this past summer of air quality levels above a 120 levels according to the IQ Air Report by 9News Colorado.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 74.]

Colorado State of the Air Report by the American Lung Association just gave us an F for ozone pollution. So we cannot stand by and lose another opportunity to strengthen a path to a hundred percent zero emissions new vehicle sales by 2035.

Organization: Pien, Natalie

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 44.]

Where I live, Northern Virginia is now an air quality marginal non-attainment area due to excessive ozone. Internal combustion engine vehicles, ICEs, emit ozone precursors as well as other pollutants that harm human health. I vividly recall the time I walked my now 33-year-old daughter in a stroller down a sidewalk in Leesburg. I became anxious and almost distraught realizing that I was exposing her to car exhaust. Zero emission vehicles would eliminate this experience and restore clean air and improved health to our communities, especially communities of color disproportionately exposed to air pollution.

Commenter: Program for Public Consultation

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 95-96.]

Overall, we find that large majority support the government taking action to reduce air pollution. In a September 2020 survey, 78 percent of voters assigned a very or somewhat high priority to the government working to reduce air pollution that causes negative health effects. This included 54 percent of Republicans, eight in 10 Independents, and 98 percent of Democrats. A survey in 2016 on the clean power plants proposal from the Obama Administration was a proposal to require all cars and trucks by 2025 to emit half the CO2 emissions of the 2010 model elicited support from 73 percent of voters, including 86 percent of Democrats, 71 percent of Independents, and 57 percent of Republicans. This also had bipartisan support in the states we oversampled, including Texas, Florida, and Oklahoma, and Ohio.

Commenter: Remilien, Sandra

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 120.]

Particulate matter worsens asthma and causes premature death. Tailpipes cause air pollution. Electric cars do not emit tailpipe emissions or the gases that come from gasoline-powered cars. Fuel-efficient cars lower air pollution and emissions from cars. Fuel-efficient cars emit less carbon dioxide.

Commenter: Sabetta, Tracy

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 100-101.]

We know that pollution from the transportation sector accounts for about 29 percent of the total U.S. greenhouse gas emissions, making it the largest contributor. Between 1990 and 2019, transportation sector pollution increased more in absolute terms than any other sector.

I'm fortunate that my daughter was not born with a respiratory illness but many of her friends were not that lucky. Pollution increases the frequency and severity of their asthma attacks and robs them of the opportunity to be a kid enjoying the outdoors the way most of us did as children. Extreme heat here in Columbus has closed 20 buildings in our city school district today, slated to be the first day of school for these kids.

Commenter: San Joaquin Valley Air Pollution Control District

The San Joaquin Valley faces one of the most significant air quality challenges in the country due to its unique meteorology, topography, and geography, and is currently in nonattainment of the latest federal ozone and PM2.5 standards. Near-term criteria pollutant emission reduction strategies are critical to achieve federal health-based standards within the timeframes called for by the San Joaquin Valley’s clean air attainment plans.

The San Joaquin Valley is one of the most heavily regulated air basins in the nation. After decades of implementing stringent stationary and mobile source emission reduction control strategies by the San Joaquin Valley Air Pollution Control District (District) and California Air Resources Board (CARB), over 85% of the San Joaquin Valley's emissions of oxides of nitrogen (NOx), the major precursor for both ozone and PM2.5 formation in the Valley, come from mobile sources. The presence of two major transportation corridors connecting Northern and Southern California and vehicle activity from one of the fastest-growing populations contribute significantly to the Valley's air quality and public health challenges. [EPA-HQ-OAR-2021-0208-0566-A1, p.1]

Building on past air quality improvement efforts, the District, in partnership with CARB, recently adopted the 2018 Plan for the 1997, 2006, and 2012 PM2.5 Standards (2018 PM2.5 Plan) that outlines the actions necessary for furtherimproving the Valley's air quality and meeting the federal air quality standards for PM2.5 by the applicable deadlines of 2024 and 2025. Additionally, District and CARB recently adopted the 2016 Ozone Plan to address the 2008 federal air quality standard for 8-hour ozone.

Since mobile source emissions contribute the majority of NOx emissions in the Valley, California action, made possible by the waiver of preemption process, along with supporting federal action to accelerate mobile source emissions reductions, are critical to the Valley's attainment of federal ambient air quality standards. Moving forward with these attainment efforts will be a major endeavor only achievable through a collaborative approach with Valley residents and businesses, and significant support and action at the local, state, and federal level.

The District's 2016 Ozone Plan and 2018 PM2.5 Plan both rely on emission reductions from California's Advanced Clean Cars regulation and other mobile source measures to support the Valley's attainment of the federal health-based NAAQS. Regarding the standards addressed in these specific plans, the Valley is classified as extreme non-attainment for the 2008 8-hour ozone standard, and serious non-attainment for the 1997 and 2006 PM2.5 standards (proposed Serious nonattainment for the 2012 PM2.5 standard). These plans demonstrate the critical importance of emission reductions from all mobile sources. The importance of state and federal agencies doing their fair share to address pollution sources under their control cannot be understated.[EPA-HQ-OAR-2021-0208-0566-A1, pp.1-2]

Commenter: Southern Environmental Law Center

Many major metropolitan areas in the U.S., including many in the South like Washington, D.C., Atlanta, and Birmingham, already suffer from elevated concentrations of ozone, nitrogen oxides (NOx), particular matter (PM), and volatile organic compounds (VOCs) and hotter temperatures can make air quality even worse. [EPA-HQ-OAR-2021-0208-0244-A1, p. 3]

Commenter: Spirit of the Sun

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 134.]

I live in Palmer City, Colorado. We deal with several different forms of particulate pollution, mainly the transportation sector, and also other extractive industries, like Suncor fully-leased hydrogen cyanide, hydrogen sulfide, and benzene. We live with issues of respiratory and circulatory issues far before COVID. In Indigenous spaces, urban and rural, that does mean a death sentence.

Commenter: Tafoya, Ian

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 189.]

But this is really about people. We can talk about numbers all day, but saving people money, yes, also important, that's a co-benefit, but reducing the amount of pollution into our community, reducing the long-term impacts of carbon dioxide into our community, and other VOCs is going to help, and what we've seen is a direct connection between small particulate matter and COVID deaths.

Commenter: Tomcik, Patrice

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 258-259.]

Studies have shown that the highest daytime exposures of traffic pollution are within 500 feet of a busy road. On an average day, at least 10,000 vehicles and 500 light-duty trucks travel this heavily-congested roadway. Closing school windows and doors can help lessen the traffic pollutant exposures but the reality is, is that fine particles, ultrafine particles, gases, and vapors are able to readily penetrate the indoors where they can be breathed in by very young lungs.

many schools across the nation are built near busy roadways because the land is cheap. I know that children are especially impacted by pollution since their lungs and brains are still developing until early adulthood. Toxic air pollution exposures have deleterious effects that can last a lifetime.

Commenter: Uberuaga, Michelle

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 284-286.]

I'm also testifying because my family, like many Montana families, is impacted from air pollution from cars and trucks. Livingston is a small town in a rural county on the Northern edge of Yellowstone National Park, and you might imagine that we have pretty good air quality, but like every other place, we experience local pollution from vehicles. It's inescapable. In fact, pollution from vehicles can create serious air quality concerns even in Yellowstone National Park where cars often get lined up back-to-back sometimes for miles. The air pollution when that happens is visible as it sits in the air in remote river valleys.

In our little town, we experience pollution from vehicles regularly. Livingston, like many towns, sits right off I-90. When the freeway closes for bad weather, heavy truck traffic is rerouted right through our downtown, right down Main Street, past our elementary school. Sometimes traffic gets backed up for several miles, semis, cars, trucks, slowly inc through town, past schools, restaurants, and sidewalks. We can and we must do better for our kids and for our communities. An estimated six million children under 18 suffer from asthma.

We need your help. Local families and communities can work together to protect themselves from dangerous pollution, but we shouldn't have to, and many especially vulnerable communities just don't have the resources or time. We need your leadership to protect vulnerable children across our country from air pollution and climate change.

Commenter: Venner, Marie

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 18-19.]

There has been an avalanche of research this past decade on the harms from vehicle emissions and their connection to every physical, cognitive, and emotional condition where inflammation is a component because fossil fuel emissions of all types cause this inflammation, cause 21 percent of dementia and Alzheimer's cases and vastly increase the risk of asthma and autism. My kids have asthma and my son is on the spectrum. Denver was the worst polluted city in the world one day this summer and has had over 50 days of dangerous air pollution, keeping us all indoors. As a public servant and public policy researcher, I was shocked at the extent of the health effects evidence, deaths from cancer, organ damage, as well as the most severe impacts to quality of life, learning, anxiety, depression, illness, cognitive declines, suicide, that I knew were not being considered in decisions to fund projects.

Commenter: Wisconsin Department of Natural Resources

The WDNR has identified several areas of EPA's proposal that can be improved or should be addressed in its final rule, which are described below. WDNR notes that the National Highway Transportation Safety Administration (NHTSA)'s companion rule to EPA's proposal also contains analyses of anticipated GHG and criteria pollutant emissions impacts, in some cases in more detail than EPA has provided. When appropriate, WDNR has referenced NHTSA's information in these comments. [EPA-HQ-OAR-2021-0208-0223-A1, p.1]

Table 45 in the preamble should be corrected. The columns in Table 45 of EPA's proposal (p. 43780), entitled 'Upstream (U.S. tons)' and 'Tailpipe emissions (U.S. tons),' appear to be mislabeled. EPA provides the referenced upstream and tailpipe emissions in Table 44. Table 45 would appear to be showing net annual emissions (in U.S. tons) and the percent change in emissions from baseline. While EPA's intention with this table could be assumed by the associated discussion in text, EPA should provide an appropriate correction in its final rule. [EPA-HQ-OAR-2021-0208-0223-A1, p.4]

EPA Response

EPA acknowledges comments of general support for the proposed program in the preamble to this rule, Section II.F.1, and Section 1.1 of this RTC document. EPA also acknowledges and agrees with comments in this RTC section stating that reductions in air pollutant emissions, are important to address ongoing threats to human health and the environment. The commenters supported the projected non-GHG emissions reductions from the proposal for many reasons, including: health effects associated with exposure to ozone, particulate matter (including increased rates of covid mortality in areas with higher $PM_{2.5}$ concentrations), and air toxics, and contributing to efforts to attain and maintain the ozone and $PM_{2.5}$ NAAQS and environmental effects like haze caused by emissions of NO_X and $PM_{2.5}$. EPA's final rule (see Section V.A of the preamble) will over time result in reductions of non-GHG tailpipe emissions and emissions from upstream refinery sources. We also project that the rule will result in small increases of non-GHG emissions from upstream EGU sources.

EPA agrees with the commenter who noted the issue with the table heading for Table 45 in the preamble of the proposed rule and has corrected the table headings, see Tables 35 through 37 in Section V of the preamble for the final rule.

15.2. Comments on Non-GHG Benefits Methodology

Commenter: American Enterprise Institute (AEI)

The asserted health benefits of reduced emissions of particulate matter are not consistent with the available scientific analysis, and represent double counting given other regulatory measures promulgated under the Clean Air Act to reduce ambient particulate concentrations to levels that 'protect the public health' 'with an adequate margin of safety.' [EPA-HQ-OAR-2021-0208-0254-A1, p. 2]

Health benefits of reductions in particulates. EPA claims that reductions in particulate emissions would be an ancillary effect ('co-benefit') of the Proposed Rule, and so would provide additional benefits in the form of improved health. I mention here only in passing the highly speculative nature of such asserted health benefits: In a 2019 report, the EPA Clean Air Science Advisory Committee (CASAC) argued as follows.

The Draft PM PA depends on a Draft Particulate Matter (PM) Integrated Science Assessment (ISA) that, as noted in the April 11, 2019, CASAC Report on the Draft PM ISA, does not provide a sufficiently comprehensive, systematic assessment of the available science relevant to understanding the health impacts of exposure to PM, due largely to a lack of a comprehensive, systematic review of relevant scientific literature; inadequate evidence and rationale for altered causal determinations; and a need for clearer discussion of causality and causal biological mechanisms and pathways. Given these limitations in the underlying science basis for policy recommendations, and diverse opinions about what quantitative uncertainty analysis and further analysis of all relevant data using the best available scientific methods would show, some CASAC members conclude that the Draft PM PA does not establish that new scientific evidence and data reasonably call into question the public health protection afforded by the current 2012 PM2.5 annual standard. Other members of CASAC conclude that the weight of the evidence, particularly reflecting recent epidemiology studies showing positive associations between PM2.5 and health effects at estimated annual average PM2.5 concentrations below the current standard, does reasonably call into question the adequacy of the 2012 annual PM2.5 National Ambient Air Quality Standards (NAAQS) to protect public health with an adequate margin of safety. The CASAC also finds, in agreement with the EPA, that the available evidence does not reasonably call into question the adequacy of the current 24-hour PM2.5 standard, PM10 standard, or secondary PM standards and concurs that they should be retained.

The more important observation to be made for purposes of regulatory analysis is that the 'co-benefit' approach is deeply problematic because the Clean Air Act explicitly requires the EPA, upon making an 'endangerment' finding for a given criteria pollutant, to promulgate a National Ambient Air Quality Standard that 'protects the public health' with 'an adequate margin of safety.' Accordingly, the inclusion of the purported health benefits of reductions in particulate emissions as a benefit of the Proposed Rule is appropriate only if (1) the existing NAAQS for particulates fails to satisfy the requirements of the law, or if (2) the law itself creates a standard that is inefficiently lax.

If neither of those conditions is true, then the co-benefits analysis (3) will reduce emissions of the other pollutants to levels that are inefficiently low, that is, to levels at which the marginal costs of reductions exceed the marginal benefits. This is the case for criteria pollutants in particular, in that the establishment of the NAAQS must exclude cost considerations; this means that the NAAQS is likely already to reduce emissions of such pollutants to levels that are inefficiently low. At least one of these three conditions must be true. If a given region is in 'nonattainment,' that presumably is evidence that achievement of the NAAQS is more costly than is the case on average, so that imposition of a standard even more stringent is unlikely to be appropriate.

Note that the EPA during the Obama administration used the same co-benefit analysis for the Clean Power Plan, for the ozone rule,40 for the fine particulate (PM 2.5) rule, and for the Utility Mercury and Air Toxics Standards. [EPA-HQ-OAR-2021-0208-0254-A1, pp. 10-11]

The central reality is that the co-benefits approach for estimating the benefits of a given proposed rule has proven replete with abuse and political and bureaucratic gameplaying designed to support as 'appropriate and necessary' the adoption of rules that could not satisfy any honest benefit/cost analysis. This is no small matter. Consider the 2011 Obama EPA benefit/cost analysis of its Mercury and Air Toxics Standards (MATS) aimed at coal-fired powerplants. The EPA cost estimate for the intended reduction of mercury and other hazardous air pollutants (HAP) was $9.6 billion (year 2007 dollars); the estimated benefits were $1 million to $6 million, thus yielding estimated costs exceeding estimated benefits by at least 1600 to 1.

That was the finding for the 'direct' objectives of MATS. EPA argued that the rule was 'appropriate and necessary' because other CAA requirements failed to control powerplant HAP emissions adequately and because effective control technologies were available. EPA also declined to consider costs, arguing that it was not required to do so and should not. The Supreme Court in 2015 in Michigan v EPA ruled that 'EPA interpreted [section 112 of the CAA] unreasonably when it deemed cost irrelevant to the decision to regulate power plants' as appropriate and necessary in the context of HAP. The Court: 'One would not say that it is even rational, never mind 'appropriate,' to impose billions of dollars in economic costs in return for a few dollars in health or environmental benefits. ….. No regulation is 'appropriate' if it does significantly more harm than good.'

But EPA proceeded in 2016 to justify the rule by including indirect 'co-benefits,' over 90 percent of which were the asserted health benefits of reductions in emissions of fine particulates (PM2.5). Using a deeply dubious methodology, the health benefits of the PM2.5 reductions were estimated at between $33 billion and $90 billion, thus yielding benefits per dollar of costs between $4 and $9. Note that fine particulates are a criteria pollutant, as distinct from a HAP; EPA already limits ambient levels of PM2.5 in a separate regulation, and is required under the CAA to determine every five years whether that standard 'accurately reflects the latest scientific knowledge' on the health effects of exposure to particulates. It is inappropriate for EPA to include in the Proposed Rule the purported health benefits of reductions in a pollutant already regulated under a separate section of the Clean Air Act. [EPA-HQ-OAR-2021-0208-0254-A1, p. 12]

Commenter: Competitive Enterprise Institute (CEI)

The claim of harms by particulate matter smaller than 2.5 microns ('PM2.5') in the proposal are vastly overstated. EPA claims harms even in areas where EPA says emissions are low enough to protect public safety with an adequate margin of safety.

The Clean Air Scientific Advisory Committee ('CASAC'), established in 1977 under the Clean Air Act Amendments of 1977, 42 U.S.C. §7409(d)(2), provides independent scientific evaluation of EPA's air quality claims. The chairman of CASAC criticized EPA's analysis for having 'unstated, untested, unverified, or mistaken assumptions' and for failing 'to distinguish between true exposure values and estimated exposure values in analyzing and presenting information.' See attached. Rather than address these problems, EPA fired him and the rest of CASAC's independent experts. EPA is now relying on an older analysis that includes these same errors.2 These errors must be corrected if EPA's analysis is to be relied upon as an accurate account of the harms of PM2.5. [EPA-HQ-OAR-2021-0208-0652-A1, p. 2]

II. EPA Continues to Overstate the Harms of PM2.5 Emissions, Despite the Fact that It Has Full Notice of the Problems in Its Approach. The health effects of PM2.5 emissions play a major role in the EPA's new cost-benefit calculations. As is shown below, however, those effects were arbitrarily overstated and thus skewed EPA's calculations.

PM2.5 emissions are one of six criteria pollutants that are regulated under EPA's National Ambient Air Quality Standards (NAAQS). The Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021-2026 Passenger Cars and Light Trucks, 85 FR 24854 (2020). Each of those NAAQS standards have been set by EPA at a level that 'allow[s] an adequate margin of safety' and is 'requisite to protect the public health.' 42 U.S.C. § 7409(b)(1).

In analyzing the changes in these emissions that would occur under the various alternatives considered, EPA viewed PM2.5 as raising the most serious health concerns. This was broken down by emission type in both the most recent prior rulemaking, 85 FR 24202, and in the NHTSA analysis, 86 FR 49773, but the current proposal doesn't directly compare the total emissions harms. Instead, EPA discusses the benefit-per-ton of each of the emissions. EPA finds that, at a 3% discount rate, PM2.5 harms start at $600,000 per ton while harms from SO2 start at $150,000 per ton and those from NOx start at $64,000. 86 FR 43791, Table 48.

PM thus ranks as the most harmful of the criteria pollutants, according to EPA. Because most particulates in vehicle emissions are on the order of 2.5 microns in diameter, a category known as PM2.5, it is this class of particulates that is the focus of the agency's attention. See The Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Year 2021 – 2026, Final Environmental Impact Statement at S-7 (2020) ('Almost all of the PM in motor vehicle exhaust is PM2.5; therefore, this analysis focuses on PM2.5 rather than PM10.').

The agency based its assessments of PM2.5 on a 2009 Integrated Scientific Assessment for Particulate Matter (ISA). 86 FR 43790. The 2009 ISA categorized a series of human ailments based on their association with acute (short-term) or chronic (long- term) exposure, evaluating each ailment in terms of the strength of its causal relationship with ambient particulate matter. Id. As is shown below, these estimates are highly questionable.

One problem is that the agency relied on a 'benefits per ton' approach to evaluate the risk of premature deaths due to increases in emissions. 85 FR 24886-87. EPA has admitted in the past that this simplified approach could exaggerate the benefits of reducing emissions by 'as much as 10 percent' over more accurate modeling. 85 FR 24887.

However, there is a more basic problem with this per-ton approach: it overlooks the fact that PM2.5 emissions are a problem only in nonattainment areas, which are regions where concentrations of criteria pollutants exceed Federal standards. This follows from the fact that EPA itself has set NAAQS at levels that already provide 'an adequate margin of safety.' 42 U.S.C. § 7409(b)(1). According to EPA, only 6 counties in the country are currently in nonattainment, and yet EPA counts harms for PM2.5 in areas where it says they are at safe levels. EPA has presented no information to believe that other counties will go above this level.

As for the possibility that there is some health benefit in reducing PM2.5 to levels below NAAQS, EPA itself has noted the lack of evidence for that claim. In fact, EPA has concluded 'important uncertainties in the evidence for adverse health effects below the current standards and in the potential for additional public health improvements from reducing ambient PM2.5 concentrations below those standards.' EPA, Final Action: Review of NAAQS for Particulate Matter, 85 FR 82684, 82685 (Dec. 2020). This cuts against EPA's benefits-per-ton approach, which is not limited to the small number of nonattainment areas in the country.

Even more importantly, there are fundamental questions about how significant a threat PM2.5 is at any level encountered in everyday life. As demonstrated in a study by Steve Milloy, there are reasons to doubt that it is—reasons that EPA has ignored. S. Milloy, Will the Trump Fuel Economy Reform Proposal Create Deadly Air Pollution? (Oct. 2018), attached hereto.

Milloy examined the basic contention that the alleged deaths from PM2.5 emissions should be viewed on the same basis as traffic deaths. '[T]raffic deaths are real. No one disputes that they happen. But can the same be said for the claim that PM in outdoor air kills people?' 2018 Milloy at 2. In his view, the answer is no, and certainly not on the scale claimed by the agency.

Milloy bases his conclusion on several lines of evidence: epidemiological and clinical studies of humans; animal studies; and real-word experiences. Some of those doubts about the effects of PM2.5 first arose in 1996, shortly after EPA first proposed to regulate PM2.5. At that time EPA's CASAC—a statutorily required panel of experts selected by EPA to peer review its findings on PM2.5—determined that 'there was insufficient evidence to support the claim that PM2.5 was associated with death.' 2018 Milloy at 4.

EPA largely relies on what are known as the Six City and Pope studies for its claims of premature deaths from PM2.5. Id. Nonetheless, several recent studies have found no association between deaths and PM2.5. One is a 2015 study by Anthony Cox, who subsequently became chairman of CASAC, that found no drop in death rates despite a 30 percent decline in PM2.5 levels; another is a 2017 analysis of over two million deaths in California over a 12-year period, finding no association with PM2.5. 2018 Milloy at 5.

Among the studies highlighted by Milloy was one by epidemiologist James Enstrom that 'reanalyzed the Pope study with improved exposure data and reported no association between PM2.5 and death.' Id.

Given that startling finding, one would expect it to be extensively discussed in EPA's analysis, but it has not been discussed at all. However, the 2019 ISA dismissed all of this in two sentences: 'A recent reanalysis of early …ACS [American Cancer Society] results observed a null association between county-level averages of PM2.5 measured by the Inhalable Particle Network between 1979 and 1983 and deaths between 1982 and 1988 … Enstrom (2017)]. Inconsistencies in the results could be due to the use of 85 counties in the ACS analysis by Enstrom (2017) and 50 metropolitan statistical areas in the original ACS analysis (Pope et al., 1995).' EPA, 2019 ISA for PM, 11-67.

This ‘could be’ explanation, however, is no explanation at all. It says nothing about why Pope’s conclusion should be favored over Enstrom’s. If anything, Enstrom’s focus on a larger geographical area (in Milloy’s words, ‘improved exposure data’) is a point in his favor. 2018 Milloy at 5. This is far from the sort of reasoned analysis required on this issue.

The 2019 ISA took a similar approach in dismissing a 2017 Smith and Young study discussed by Milloy, which analyzed the over two million deaths that occurred in California in 2000-12 and found no association with PM2.5. Id. Once again, the ISA explained away that study’s findings largely on the ground that it analyzed a multi-county air basin, rather than the single county analyzed in the 2006 study that found a positive association. ISA at 11-9, comparing the Smith and Young 2017 study with that 2006 study. But this difference is no reason to discount the Smith and Yong study.

The problems that Milloy identified received no mention in any of the 2020 SAFE Final Rule’s decision that EPA now proposes to amend—not in the Rule itself, nor in the Final Regulatory Impact Analysis, nor in the Final Environmental Impact Statement, nor the 2019 ISA for particulate matter, nor in EPA’s proposed rule or its draft Regulatory Impact Analysis.

Many of Milloy’s contentions are supported by two subsequent reports from CASAC to EPA in 2019. EPA’s NAAQS proposal notes the importance of CASAC’s advice in the agency’s formulation of its PM2.5 policy. 86 FR 43790. In an April 2019 report to EPA, CASAC reviewed the agency’s draft ISA on particulate matter. Its major conclusion was that ‘the Draft ISA does not provide a sufficiently comprehensive, systematic assessment of the available science relevant to understanding the health impacts of exposure to particulate matter (PM).’ Cover letter from Dr. L.A. Cox, CASAC Chair, to EPA Administrator A.R. Wheeler (April 11, 2019) 1 (‘CASAC April 2019 Report’), attached and quoted in part at 85 FR 24099. Among its reasons for this conclusion were:

• ‘Lack of comprehensive, systematic review - some of the relevant and important scientific literature is not reviewed and study quality is not systematically considered. …’

• ‘Inadequate evidence for altered causal determinations - the CASAC finds that the Draft ISA does not present adequate evidence to conclude that there is likely to be a causal relationship between long-term PM2.5 exposure and nervous system effects; between long-term ultrafine particulate (UFP) exposure and nervous system effects; or between long-term PM2.5 exposure and cancer.’

• Need for ‘Clearer discussion of causality and causal biological mechanisms and pathways - specifically including pulmonary inflammation.’

Milloy has re-examined EPA’s claims for this rulemaking. See 2021 Comments by Steve Milloy, attached hereto. He notes that EPA has not cited any evidence that is more recent than 2014. In short, EPA cites nothing new to undercut Milloy’s 2018 analysis.

The CASAC April 2019 report, in its Consensus Responses, pointed to a number of basic weaknesses in EPA's approach: 'Some members of the CASAC think that the EPA must better justify their determination that short-term or long-term exposure to PM2.5 causes mortality.' April 2019 CASAC Report, Consensus Responses at 1, attached; 'The EPA's mortality causality determination appears to be based almost exclusively on epidemiology studies, which cannot be used in isolation to determine causation.' Id., Consensus Responses at 2, see attached.

In his individual comments, CASAC Chairman Cox identified certain errors that should exclude consideration of studies unless they were corrected, such as 'unstated, untested, unverified, or mistaken assumptions' and the failure 'to distinguish between true exposure values and estimated exposure values in analyzing and presenting information.' Id. at A-36-37. Cox pointed out that the Draft ISA omitted some studies 'that appear to be discordant with conclusions in the Draft ISA' and that the ISA needed to be 'meticulous in reporting negative results accurately.' Id. at A-27, A-31. He warned that the ISA 'should not uncritically accept results based on poor-quality or speculative quasi-experimental studies' (id. at A-32) and that some studies in the Draft ISA 'misrepresent estimated exposures as if they were true exposures, leading to false statements about what has been found.' Id. at A-45.

Cox also emphasized that researchers' estimates of human exposure to PM2.5 could be seriously erroneous. 'In general, studies that treat estimated exposures as true exposures and that ignore exposure estimation errors … do not support valid inferences about the shape of the C-R [concentration-response] curve for PM2.5. … Studies that do not address exposure measurement and estimation errors should not be used or cited as 'evidence' but should be excluded, unless they can be retroactively reanalyzed and corrected to model the effects of realistic exposure estimation errors.' Id. at A-43; see also December 2019 CASAC report at 4-5, whose 'Overarching Recommendations' include EPA's need to deal with such errors. Dr. L.A. Cox to EPA Administrator A.R. Wheeler 1 (Dec. 16, 2019).

To determine if a study properly accounted for such measurement errors, Chairman Cox recommended that EPA ask, 'Did the study use appropriate errors-in-variables methods or other techniques to correct for differences between true and estimated exposure values and between true and estimated values of other variables?' April 2019 CASAC Report at A-56.

The failure to account for measurement error is especially important in determining whether a threshold exists below which harm does not occur. EPA itself recognized that the 'possible influence of exposure measurement error, and variability among individuals with respect to air pollution health effects, tend to smooth and 'linearize' the concentration-response function, and thus can obscure the existence of a threshold or nonlinear relationship.' EPA, Preamble to the Integrated Science Assessments 29 (Nov. 2015), https://bit.ly/3nLdMoW.

But EPA has entirely ignored such errors-in-variables methods to account for measurement error. Errors-in-variables analysis was not even mentioned in any of the ISAs nor in this proposed rule. Instead, EPA continues to use studies which only estimate exposure to PM2.5 without correcting for measurement error. One instance among many is the 2017 Di et al. studies of Medicare patients, relied upon by EPA in the 2019 ISA. See ISA at 11-61, 11-70, and 11-72. In fact, EPA described the study as among its ‘strongest evidence’ (ISA at 11-97), despite the fact that Chairman Cox characterized it as treating ‘guesses … as if they were error-free measurements – a clear violation of sound statistical analysis for error-prone exposure estimates.’ CASAC December 2019 Report, p. B-21.

In EPA’s NAAQS Proposal, issued a year after the April 2019 CASAC Report, the agency stated that while it had not followed CASAC’s recommendation that a second draft ISA be prepared, it did address CASAC’s comments in the final ISA by expanding its text and by downgrading one causality determination. 85 FR 24099. But neither CASAC’s recommendations nor EPA’s responses had any apparent effect on the agency’s calculations of the alleged PM2.5 health impacts. The agency’s use of such methods as the ‘benefits-per-ton’ approach was essentially based on across-the-board modeling that largely ignored the numerous problems raised by CASAC.

EPA has arbitrarily failed to discuss why it rejected so many of its key recommendations and problems identified. These problems apply just as much to the 2009 PM ISA as the 2019 PM ISA. As Milloy said in his most recent comments, ‘This utter rebuke of the 2019 PM ISA and EPA’s scientific assessment of PM2.5 also applies to the 2009 PM ISA.’ See 2021 Milloy, attached. Because EPA has been put on notice of these problems by CASAC, it has a duty to consider them before continuing to rely on either the 2009 PM ISA or the 2019 PM ISA.

If the agency had properly assessed the health risks of PM2.5 emissions, its large estimate of health-related costs might well have been lower. This would likely have shifted the outcome of the decision-making process, which involved ‘balancing the factors considered in our assessment that the proposed standards are appropriate, and how this balancing of factors differs from that used in the SAFE rule.’ 86 FR 43781. And that shift would have been in the direction of a more lenient standard than the one proposed by the agency. [EPA-HQ-OAR-2021-0208-0652-A1, pp. 2-6]

EPA Response

EPA disagrees with the commenters’ contentions regarding the analysis of costs and benefits for this rulemaking. EPA’s analysis is consistent with applicable guidance and best practices for conducting benefit-cost analyses, including OMB Circular A-4, EPA’s Guidelines for Preparing Economic Analyses, and the Interagency Working Group (IWG) on Social Cost of Greenhouse Gases Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates under Executive Order 13990. Guidance in both Circular A-4 and EPA’s Guidelines directs the Agency to quantify and monetize all impacts associated with a particular rulemaking to the extent feasible, including those that may be ancillary to the statutory purpose of the regulation. We consider our analysis consistent with the guidance, methodologically rigorous, and a best estimate of the projected benefits and costs associated with the final rule.

In addition, the following responses to comments are contained in Preamble Section VII.E:

EPA received comments asserting that quantifying and monetizing the health benefits of reduced emissions of particulate matter is not consistent with the available scientific evidence and that EPA did not consider the advice made by some members of CASAC that reviewed the 2019 PM ISA. We disagree that our estimates are not consistent with the available scientific evidence and the advice of the Clean Air Science Advisory Committee. In determining which health outcomes to quantify and monetize, EPA relies on the weight-of-evidence evaluation of relationships between $PM_{2.5}$ exposure and health effects conducted within the ISAs, which are the scientific basis of the NAAQS review process. ISAs represent thorough evaluations and syntheses of the most policy-relevant science. EPA uses a structured and transparent process for evaluating scientific information and determining the causal nature of relationships between air pollution exposures and health effects. The ISA development process is detailed in the *Preamble of the Integrated Science Assessments*,[60] which describes approaches for literature searches, criteria for selecting and evaluating relevant studies, and a framework for evaluating the weight of evidence and forming causality determinations. EPA quantifies and monetizes health effects that the ISA determines are "causal" or "likely to be causal." The focus on categories identified as having a "causal" or "likely to be causal" relationship with the pollutant of interest allows for the estimation of pollutant-attributable human health benefits in which the Agency is most confident.

As part of the process of developing an ISA, the Clean Air Scientific Advisory Committee (CASAC) is statutorily required to review the science underlying decisions about the NAAQS. CASAC provides independent review of draft ISA documents for scientific quality and sound implementation of the causal framework that informs the ISA before it is finalized. The 2020 PM NAAQS review was completed without the benefit of a PM-specific panel supporting the CASAC, as had been done in prior reviews. However, CASAC did have access to a pool of consultants who were available to respond in writing to questions from CASAC members. With limited access to relevant expertise, CASAC did not reach consensus on the determination that there is a causal relationship for $PM_{2.5}$ exposure (i.e., both short- and long-term) and mortality presented within the draft PM ISA. After the disbandment of the 20-member CASAC PM panel, CASAC noted that "Additional expertise is needed for [CASAC] to provide a thorough review of the [PM NAAQS] documents" and recommended the Administrator reappoint "the previous CASAC PM panel or panel with similar expertise."[61] In his final decision to retain the PM standards, after considering CASAC's advice, the EPA Administrator, "placing the greatest weight on evidence of effects for which the ISA determined there is a causal or likely causal relationship with long- and short-term $PM_{2.5}$ exposures,"[62] concluded that the current PM NAAQS are necessary to protect public health. Thus, the Administrator fully considered CASAC's recommendations with respect to assessing the health risks of PM in the review of the

[60] See https://cfpub.epa.gov/ncea/isa/recordisplay.cfm?deid=310244
[61] In the time since the previously chartered CASAC, EPA has recognized the significant accumulation of new scientific studies since the cutoff date of the 2019 PM ISA (January 2018) and published a draft supplement to the 2019 PM ISA. The Supplement found that recent studies further support, and in some instances extend, the evidence that formed the basis of the causality determinations presented within the 2019 PM ISA that characterizes relationships between PM exposure and health, including mortality.
[62] 85 FR 82715. The effects for which the 2019 ISA determined there is a causal or likely causal relationship with long- and short-term $PM_{2.5}$ exposures include respiratory effects, cardiovascular effects, and mortality.

PM NAAQS and EPA is being consistent with the conclusions of the PM NAAQS review in this action.

Commenters also asserted that health benefits from reductions in human exposure to ambient concentrations of $PM_{2.5}$ only occur above the level of the primary health-based NAAQS, and that accounting for the health benefits of $PM_{2.5}$ at all represents double counting given other regulatory measures promulgated under the Clean Air Act to reduce ambient concentrations of $PM_{2.5}$. The EPA disagrees with this assertion. First, it is important to recognize that the NAAQS "shall be ambient air quality standards…which in the judgment of the Administrator" are "requisite" to protect public health with an "adequate margin of safety" (CAA Section 109). "Requisite" means sufficient but not more than necessary while an "adequate margin of safety" is intended to address uncertainties associated with inconclusive evidence and to provide a reasonable degree of protection against hazards that research has not yet identified. The CAA does not require eliminating all risk, and therefore, the NAAQS does not represent a zero-risk standard. Additionally, EPA is reconsidering the 2020 decision to retain the PM standards because available scientific evidence and technical information suggests that the current standards may not be adequate to protect public health and welfare, as required by the Clean Air Act.

As detailed in the 2019 PM ISA and previous assessments in support of the PM NAAQS, EPA's review of the science has consistently found no evidence of a threshold below which exposure to $PM_{2.5}$ yields no health response. Specifically, the 2019 PM ISA found that "extensive analyses across health effects continues to support a linear, no-threshold concentration-response (C-R) relationship." This conclusion in the 2019 PM ISA is supported by the more recent evaluation of the health effects evidence detailed in the recently released Draft Supplement to the PM ISA which found "continued evidence of a linear, no-threshold concentration-response (C-R) relationship."

Regarding double-counting, the emissions attributed to this final rulemaking are incremental to all other currently promulgated air pollution regulations and can therefore be monetized without double-counting previously achieved benefits from mobile source emissions reductions. However, EPA also notes that while it takes costs and benefits into consideration in selecting standards, it is not required, and historically has not sought, to set standards based on the results of the benefit-cost analysis in an attempt to maximize net benefits. EPA is required to establish standards to reduce air pollution that endangers public health and welfare, taking into consideration the cost of compliance and lead time. As discussed in Section VI of the preamble, this is the approach EPA took in setting these standards. EPA did take note of the results of the RIA, finding that the fact that benefits exceed costs substantially reinforced the conclusion that the standards were appropriate, but also noting that the net benefits could be higher or lower than presented, given the reasonable range of potential costs and benefits. Thus, EPA disagrees that a change in the estimated benefits would have necessarily resulted in a meaningful change in how the impacts of the final standards compare to the alternatives, or in selection of different standards.

Commenter: Alliance for Automotive Innovation

Regarding uncertainty analysis, EPA and NHTSA are using simplified benefit per ton multipliers for PM2.5 emissions without including sensitivity analysis of each of the key inputs identified by the EPA Science Advisory Board ("SAB"). SAB recommended sensitivity analyses of alternative values of the dose-response function, differential toxicity by type of particle, and spatially-dependent VSL values.189

Commenter: California Air Resources Board (CARB)

The Benefits of the Standards Outweigh the Costs and are Likely Greater Than U.S. EPA Estimated. As described above, CARB agrees that more stringent standards will deliver significant benefits to society that far outweigh their costs. CARB supports the work of U.S. EPA to reconsider its approach to estimating the impacts of the proposed standards. But CARB believes the standards are more beneficial than U.S. EPA estimates and encourages the agency to improve its analysis of the costs and benefits of more stringent emission standards in several respects.

The Proposed Standards Will Reduce Harmful Particulate Pollution. The proposed standards will also reduce particulate matter (PM) pollution, another serious threat to public health, and will have greater benefits than the proposal acknowledges. The Benefits-per-Ton (BPT) analysis for the proposal, corroborated by U.S. EPA's Integrated Science Assessment and Policy Assessment, demonstrate the harmful human health effects of PM and, accordingly, the human health benefits of reducing PM emissions and exposures. CARB agrees the BPT method used by U.S. EPA is a well-established approach to estimating the health benefits from reductions in PM2.5 due to the proposed rule. However, U.S. EPA has noted that the BPT method is currently being updated, and CARB also agrees that this update is needed to ensure it is based upon the most updated Integrated Science Assessments and expanded health endpoints. For instance, U.S. EPA has acknowledged that it is currently using BPT estimates based on the 2009 PM ISA, including the Krewski et al. 2009 study for mortality, although there are newer studies available for mortality and other endpoints. Additional health endpoints that could be included in the BPT methodology include: lung cancer, Alzheimer's disease, and Parkinson's disease, among others, that show important associations with PM2.5 exposure in the 2019 PM ISA.

Recent evidence adds to the wealth of literature showing the harmful human health effects of PM at levels below the federal health-based air quality standards. In its review of the National Ambient Air Quality Standards (NAAQS) for PM, U.S. EPA's Integrated Science Assessment document found strong associations between short and long-term PM2.5 exposure and mortality and cardiovascular and respiratory effects. As stated in CARB and OEHHA's June 29, 2020 letter to the U.S. EPA Administrator, many epidemiological research studies and U.S. EPA's own scientists reported that health effects have been demonstrated below the current NAAQS standards.

Significant associations have been found between PM2.5 levels below the current EPA annual NAAQS standard and premature mortality in multicity epidemiological studies in the U.S. and Canada. These studies are representative of the overwhelming body of research that demonstrates adverse health impacts at PM2.5 levels below the current National Ambient Air Quality Standard. Therefore, even areas currently in attainment for the PM2.5 NAAQS would see health benefits from decreased PM levels, including the benefits from this proposal.

Commenter: Center for Biological Diversity, et al.

Finally, EPA recognizes that certain non-GHG health and environmental benefits are difficult to quantify, and would be even more significant under Alternative 2 than the Proposal. As mentioned above, some of these benefits include: increased visibility from less particulate matter in the ambient air (DRIA 7.1.3.1), the diverse effects of ozone on ecosystems (DRIA 7.1.3.2), the multifaceted impacts on biogeochemistry from nitrogen and sulfur deposition (DRIA 7.1.3.3), and the environmental effects of air toxics (DRIA 7.1.3.4). Combined with scientific uncertainty about the full extent of the effects of air toxics on human health, these environmental factors further tip the scale in favor of stronger protections. While it may be difficult to quantify these benefits precisely, they no doubt signal the irreparable harm that would occur to the environment and human health from adopting a weaker standard. [EPA-HQ-OAR-2021-0208-0651-A1, p. 21]

EPA undercounts the benefits of the PM2.5 reductions from more stringent standards and understates other air quality benefits. While EPA improves its monetization of health benefits attributable to tailpipe PM2.5 emission reductions, its process for monetizing upstream PM2.5 health benefits remains flawed. Fine particulate matter is a harmful criteria air pollutant that has been found to cause a variety of adverse human health impacts ranging from cardiovascular effects to premature mortality. EPA, Integrated Science Assessment for Particulate Matter (Dec. 2019) at ES-9 to ES-11, Tbl. ES-1 (2019 PM2.5 ISA). PM2.5 is emitted both by vehicles' tailpipes themselves as well as from upstream sources such as refineries and power plants. Although EPA updated the resources it relied on in monetizing the impact of reductions in PM2.5 attributable to the Proposal, it replicated errors it made in monetizing upstream PM2.5 health benefits and therefore understated the rule's benefits.

In its 2020 Final Rule, EPA relied on a 2018 technical support document from the Office of Air and Radiation to estimate benefits per ton (BPT) attributable reductions in PM2.5. EPA, Technical Support Document: Estimating the Benefit per Ton of Reducing PM2.5 Precursors from 17 Sectors (Feb. 2018) (2018 PM2.5 TSD). These sectors include on-road mobile sources, electric generating units, and refineries. 2018 PM2.5 TSD at 7, Tbl. 1.

The 2018 PM2.5 TSD utilized a three-step process to generate estimates of the BPT for each of 17 emissions sectors. Id. at 4-5. First, as relevant to direct PM2.5 emissions, EPA conducted photochemical modeling to predict annual average ambient concentrations of primary PM2.5 attributable to each of the 17 emission sectors. Id. at 4. Second, EPA used its 2017 Benefits Mapping and Analysis Program—Community Edition to estimate and monetize the health impacts associated with the attributable ambient concentrations of PM2.5. Id. Finally, EPA calculated BPT for PM2.5 by dividing the monetized benefits and avoided impacts of the emissions from each sector by the sector-specific emissions. Id. at 5.

The 2018 PM2.5 TSD found that the BPT for a ton of PM2.5 differed significantly between source categories. This is due to factors such as proximity to populations, geographic distribution of sources, and information about where emissions are released (e.g., stack height). Id. at 6. Most pertinently, EPA found that PM2.5 emission reductions from refineries provide significantly greater health benefits on a per-ton basis than those from electric generation: $430,000-980,000/ton (2015$) for refineries versus $180,000-410,000/ton (2015$) in 2030 using a 3 percent discount rate. Id. at 20, Tbl. 11. The relative results hold across years and discount rates. Id. at 14-21, Tbls. 5-12.

In the Proposal, EPA no longer relies on the 2018 PM2.5 TSD to monetize the benefits of PM2.5 reductions from tailpipe emissions. Instead, EPA utilizes a BPT estimate from Wolfe et al. (2019) that improves the accuracy of the Agency's tailpipe health benefit assessment. Specifically, EPA explains that the BPT values from Wolfe et al. (2019) "provide better resolution by mobile sector and geographic area, two features that make them especially useful for quantifying the benefits of reducing emissions from the onroad light-duty sector." Proposal, 86 Fed. Reg. at 43,790.

While the use of the BPT estimates from Wolfe et al. (2019) will likely improve EPA's monetization of tailpipe PM2.5 emission benefits from the Proposal, for upstream emissions, EPA continues to rely on the 2018 PM2.5 TSD, id., and in doing so, replicates a fundamental error with its monetization of upstream emissions from the 2020 Final Rule.

EPA recognizes that upstream emission changes would result from a variety of sources including electricity generating unit sources, petroleum extraction, storage and transport sources, as well as sources upstream from the refinery. Id. These impacts are countervailing: more protective vehicle emission standards will reduce fuel consumption and therefore reduce refinery production; however, they will increase vehicle electrification and therefore increase electric generation. Nevertheless, EPA used a simplification that all upstream emission reductions were due to refining emission reductions, id., effectively netting increases in power plant emissions against decreases in refinery emissions without accounting for the differential health benefits.

EPA justified its simplification by pointing to its estimate that "the fleet penetration of electric vehicles attributed to the proposed standards is relatively small (i.e., the change in electric vehicle penetration is projected to change from 4 percent in the No Action case to 8 percent under the proposed standards)." Id. In the final rule, EPA should instead separately quantify and monetize upstream emission impacts for both refineries and power plants before netting those impacts. However, we note that correcting this error would only further support the case for stronger standards, as it causes the benefits of the PM2.5 reductions from the rule to be understated. [EPA-HQ-OAR-2021-0208-0651-A1, p. 45-47]

EPA's failure to quantify and monetize health benefits resulting from reductions in ozone and air toxics attributable to more stringent standards results in an understatement of the benefits of the rule. Although EPA recognizes the importance of quantifying the health and environmental benefits of the Proposal "because a failure to adequately consider ancillary impacts could lead to an incorrect assessment of a program's costs and benefits," Proposal, 86 Fed. Reg. at 43,789- 90, EPA further understates the non-GHG benefits of more stringent standards by failing to quantify benefits associated with reductions of several pollutants.

One source of underestimate is EPA's exclusion of benefits attributable to ozone and air toxics. Ground-level ozone is a widespread criteria air pollutant that inflames lung tissue and is associated with a number of respiratory and cardiovascular health impacts. Motor vehicles contribute to ozone formation through their emissions of both nitrogen oxides and volatile organic compounds, either of which can catalyze the formation of ozone depending on the relative amounts of each in the ambient air. DRIA at 7-2. EPA notes that, "the complex, nonlinear photochemical processes that govern ozone formation prevent us from developing reduced-form ozone BPT values," which EPA recognizes as "an important limitation" when using the BPT approach. Proposal, 86 Fed. Reg. at 43,790. EPA similarly acknowledges that there "would [] be impacts associated with reductions in air toxic pollutant emissions that result from the proposed program" that the agency did not attempt to monetize. DRIA at 7-24. According to EPA, "[t]his is because currently available tools and methods to assess air toxics risk from mobile sources at the national scale are not adequate for extrapolation to incidence estimation or benefits assessment." Id. Incorporation of these categories would have increased the net benefits of the Proposal. [EPA-HQ-OAR-2021-0208-0651-A1, p. 47-48]

EPA Response

EPA agrees with CARB that the use of benefit-per-ton (BPT) values to estimate the PM-related health benefits of the program "is a well-established approach" that nonetheless omits a number of other health and environmental benefits, such as ozone-related benefits. Commenters expressed concern that because the BPT approach leaves these benefits unquantified, the analysis undercounts air quality benefits. EPA believes that using the reduced-form BPT approach to benefits estimation approach was reasonable for the analysis conducted for this rulemaking though less robust than an analysis based on photochemical air quality modeling. EPA continues to refine our reduced form methods. We note that criteria pollutant-related health benefits are typically driven by reductions in PM-related mortality risk, which are reflected in the BPT-based analysis of benefits associated with the final rule. We would expect that monetizing the full suite of health and environmental benefits associated with the final rule would increase total benefits, and benefits would increase in proportion to the criteria pollutant emissions reductions achieved, for both the final program and the alternatives that were considered. However, as explained in Preamble Section VII.E, we are limited to the use of $PM_{2.5}$-related BPT values for this analysis. We do not expect that the omission of unquantified benefits would meaningfully change how the impacts of the final program compare to the alternatives, though the rule would be even more beneficial on net (compared to costs) if all benefits were quantified and monetized. Regarding uncertainty in the BPT estimates, the Alliance for Automotive Innovation referenced recommendations made by the Science Advisory Board in its review of EPA's Reduced Form Tools.[63] EPA is considering the SAB's recommendations in future work concerning reduced

[63] U.S. EPA – Science Advisory Board (U.S. EPA-SAB). 2020. Review of EPA's Reduced Form Tools Evaluation. EPA-SAB-21-001.

form benefits tools, but believes the current approach is reasonable, is consistent with applicable guidance and best practices for conducting benefit-cost analyses, and provides a best estimate of PM-related health benefits.

Regarding the request that EPA improve its analysis of benefits, and as discussed in Preamble Section VII.E and RIA Chapter 7.2, we note that EPA bases its benefits analyses on peer-reviewed studies of air quality and health effects and peer-reviewed studies of the monetary values of public health and welfare improvements. Very recently, EPA updated its approach to estimating the benefits of changes in $PM_{2.5}$ and ozone.[64,65] These updates were based on information drawn from the recent 2019 $PM_{2.5}$ and 2020 Ozone Integrated Science Assessments (ISAs), which were reviewed by the Clean Air Science Advisory Committee (CASAC) and the public.[66,67] EPA has not updated its mobile source BPT estimates to reflect these updates in time for this analysis. Instead, we use $PM_{2.5}$ BPT estimates that are based on the review of the 2009 PM ISA[68] and 2012 PM ISA Provisional Assessment[69] and include a mortality risk estimate derived from the Krewski et al. (2009)[70] analysis of the American Cancer Society (ACS) cohort and nonfatal illnesses consistent with benefits analyses performed for the analysis of the final Tier 3 Vehicle Rule,[71] the final 2012 PM NAAQS Revision,[72] and the final 2017-2025 Light-

Available on the internet: http://www3.epa.gov/ttnecas1/regdata/RIAs/finalria.pdf.

duty Vehicle GHG Rule.[73] We expect this lag in updating our BPT estimates to have only a minimal impact on total PM benefits, since the underlying mortality risk estimate based on the Krewski study is identical to an updated $PM_{2.5}$ mortality risk estimate derived from an expanded analysis of the same ACS cohort.[74] The Agency is currently working to update its mobile source BPT estimates to reflect these recent updates for use in future rulemaking analyses.

Regarding comments about the use of refinery-related BPT values as a surrogate for the monetization of all upstream emissions impacts, EPA agrees with the commenters that sector-specific BPT values are preferable to monetize sector-specific emissions. For the final rule, upstream emissions have been apportioned to the refinery and EGU sectors and we apply corresponding BPT values to monetize those emissions impacts. More information on non-GHG emissions impacts of the final rule can be found in Preamble Section V and RIA Chapter 5.1.

Commenter: American Council for an Energy-Efficient Economy (ACEEE)

EPA has the authority under the Clean Air Act to set technology-forcing standards. At this critical juncture, it is imperative that EPA adopt emissions standards to catalyze investments in technological advancements and accelerate electrification beyond what is likely to occur in the absence of new standards. [EPA-HQ-OAR-2021-0208-0251-A1, p. 13]

Commenter: American Fuel & Petrochemical Manufacturers (AFPM) et al

While the American Fuel & Petrochemical Manufacturers (AFPM) and the Western States Petroleum Association (WSPA) support increased fuel efficiency, the proposed rule misinterprets EPA's and the National Highway Transportation Safety Administration's (NHTSA's) respective roles in establishing light-duty vehicle (LDV) fuel economy standards, neglects to apply a full life-cycle analysis (LCA), and overstates the benefits and understates the costs of electric vehicles (EVs). Consequently, this proposed rule does not conform to statutory requirements and should be revised. [EPA-HQ-OAR-2021-0208-0286-A1, p. 1]

Congress Tasked NHTSA, not EPA, to Establish Fuel Economy Standards. Both NHTSA and EPA have a role to play in increasing efficiency and reducing GHG emissions harmoniously, but EPA's proposal ignores NHTSA's role.9 The Energy Policy and Conservation Act (EPCA) designates NHTSA as the lead in setting fuel economy standards. The Clean Air Act (CAA), on the other hand, authorizes EPA to regulate motor vehicle emissions that 'may reasonably be anticipated to endanger public health or welfare.'10 For the past eleven years, these authorities were exercised through joint rulemakings11 to ensure harmonization. This was necessary because the agencies acknowledged that 'the relationship between improving fuel economy and reducing carbon dioxide (CO2) tailpipe emissions is a very direct and close one.'12

The Supreme Court also determined that while NHTSA's and EPA's obligations to regulate CO2 emissions from motor vehicles may overlap, 'there is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency.'13 EPA should thus defer to NHTSA's fuel economy standards and focus on motor vehicle GHG emissions other than from the tailpipe, such as regulating automotive air conditioning refrigerant leakage (HFCs) or the use of reflective glass, coatings, and paints to reduce air conditioning usage. At the very least, EPA and NHTSA should conduct a joint, coordinated rulemaking that respects each agency's statutory limits on its authority in this overlapping area. The approach EPA embraced in the proposed rule renders NHTSA's fuel economy standards moot and is thus contrary to Congress's intent.

Congress designated NHTSA to set fuel economy standards using a particular process while considering relevant factors. As part of that process, EPCA requires NHTSA to consult with EPA and the Department of Energy.14 EPCA limits NHTSA's standard-setting authority, requiring NHTSA to set the 'maximum feasible average fuel economy' in light of 'technological feasibility, economic practicability, the effect of other motor vehicle standards of the Government on fuel economy, and the need for the United States to conserve energy.'15 None of these express procedural and substantive checks would have meaning if EPA could circumvent them by unilaterally issuing a CO2 tailpipe standard under CAA Section 202(a), as it attempts to do in this proposal.16

Unfortunately, the gap between the Agencies' programs continues to widen. EPA here intends to alter NHTSA's existing maximum feasible average fuel economy standards, via CO2 standards, for MY 2023 without NHTSA making any changes for that model year. They do not even attempt to 'avoid inconsistency.'17

Promulgating a duplicative and inconsistent tailpipe emissions program, like the Agency proposes here, thwarts Congressional direction, creates uncertainty, imposes unnecessary costs, and wastes scarce government resources. [EPA-HQ-OAR-2021-0208-0286-A1, pp. 2-3]

EPA Must Utilize a Life-Cycle Analysis to Quantify Emissions. It is critical to employ a life-cycle analysis, based on sound science, that accounts for each vehicle's emissions, regardless of powertrain, over its lifetime, including emissions associated with its production, recharging/refueling, drivetrain replacements, required infrastructure modifications, and end-of-life disposal options. Every transportation mode uses energy and impacts the environment. Highlighting only tailpipe emissions with misleading euphemisms like 'zero emissions vehicles' results in a distorted view of actual environmental impacts of motor vehicle technologies that have no basis in the regulatory process.

Section 202 of the CAA requires EPA to perform LCAs when setting vehicle emissions standards. Section 202(a)(1) requires EPA to 'prescribe…standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which…cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare.'18 While tailpipe emissions are the most obvious emissions from new motor vehicles or their engines, emissions from electricity generation, too, are emissions 'from' EVs because operating EVs are the 'source, cause, agent, or basis' for such emissions.19 Likewise, emissions relating to battery mining, production, and disposal or recycling of batteries or power sources like coal emissions 'from' EVs because EVs are the 'source, cause, agent, or basis' for such emissions. LCA ensures that these emissions 'from' EVs are addressed by EPA's vehicle emissions standards, as they are required to be, rather than ignored by focusing on tailpipe emissions. Without LCA, the Agency cannot reasonably assess the stringency or GHG reduction benefits of its proposed standards, nor can it reasonably assess the costs and benefits; thus, EPA cannot assure that its standards appropriately and justifiably protect public health or welfare without LCA.

EPA projects that the proposed standards could be met by gradually increasing sales of plug-in electric vehicles in the U.S., up to about 8 percent market share (including both EVs and plug-in hybrids) by MY 2026. In its analysis, the Agency accounted for slight increases in emissions from electric generation units (EGUs)20 due to increased EV penetration rates but did not account for any emissions, or other environmental impacts, associated with battery mining, production, and disposal, or recycling of batteries or power sources like coal. Significant GHGs are emitted during an EV's lifecycle. As EPA takes steps towards implementing its planned transition to widespread EVs, the Agency must consider that such a transition would require a massive reconfiguration of the electric power system, including distribution transformers, conductors, and substations, which would lead to a significant increase in mining of minerals and production of steel, generating significant additional GHG emissions compared to a business-as-usual scenario. As such, a lifecycle perspective is required to understand any potential GHG emissions reductions achieved by EVs. Quantifying lifecycle GHG emissions is an issue of central relevance to this rulemaking and such a quantification must be undertaken before advancing the rulemaking.

EPA should review the underlying research collected and highlighted in a recent paper published by ConservAmerica, which we incorporate by reference into these comments.21 Each study ConservAmerica reviewed used an LCA approach to analyze the vehicles emissions based upon 'vehicle size and performance, battery size and lifetime, the carbon intensity of electricity generation and fuel production, and the state of technology advancements.' Recognizing these relevant parameters, the review concludes that 'a variety of automotive technologies and powertrains deliver comparable GHG emission reductions,'22 and that all vehicle technologies should be examined based on the entire lifecycle of the vehicle and their energy sources, as all vehicles produce GHG emissions.

Scientists confirm that the carbon intensity of battery manufacturing has a large contribution to the lifecycle carbon emissions of EVs, which typically start with a GHG emissions deficit.23, 24 EPA must also consider the effect of increasing battery needs worldwide. For instance, increased demand for components of EVs (including the minerals needed to produce Li-ion batteries), all other things being equal, increases prices. Some observers have predicted that EV production will become more carbon intensive as it becomes more difficult to obtain the materials needed for battery production.25, 26, 27 [EPA-HQ-OAR-2021-0208-0286-A1, pp. 3-5]

Congress designated NHTSA to set fuel economy standards. NHTSA is the agency that through EPCA can maintain one national program while respecting Congress's procedural and substantive considerations. EPA's actions bypass the statutory guardrails included in EPCA. EPA must also more fully and accurately account for the costs and benefits in this rule, including carbon reductions and fuel savings, by evaluating all vehicles technologies on a lifecycle basis and based on identical emissions and fuel economy tests of real-world driving conditions. [EPA-HQ-OAR-2021-0208-0286-A1, pp. 7-8]

Commenter: Americans for Prosperity

The Proposed Rule Violates Section 202(a) of the Clean Air Act. Under Section 202(a) of the CAA, '[t]he Administrator shall by regulation prescribe (and from time to time revise) in accordance with the provisions of this section, standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in his judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare.'2 The Administrator must exercise reasonable judgment and decision-making under Section 202(a).

For this proposed rule, EPA is 'changing its 2020 position and restoring its previous approach by proposing to find, in light of the statutory purposes of the Clean Air Act and in particular of section 202(a), that it is more appropriate to place greater weight on the magnitude and benefits of reducing emissions that endanger public health and welfare, while continuing to consider compliance costs, lead time and other relevant factors.'3 The Agency has broad authority under Section 202(a), 'EPA is afforded considerable discretion under section 202(a) when assessing issues of technical feasibility and availability of lead time to implement new technology. Such determinations are 'subject to the restraints of reasonableness,' which 'does not open the door to 'crystal ball' inquiry.'' NRDC, 655 F.2d at 328, quoting International Harvester Co. v. Ruckelshaus, 478 F.2d 615, 629 (D.C. Cir. 1973).'4 The proposed rule violates this requirement, relying almost entirely on EPA's vehicle standards finalized in 2012 and the voluntary commitments of five automakers as the justification for compliance costs and lead time.

The 2012 final rule set standards for model years 2017-2025. As part of the 2012 vehicle standards a Mid-term Evaluation (MTE) was required, EPA began this process in 2016. The process was rushed, giving stakeholders and the public only thirty days to comment. EPA signed off on the MTE one week prior to President Trump taking office and more than one year before the midterm review was scheduled to be completed. In 2017, automakers asked the Trump administration for relief from the stringent standards knowing it would be difficult to meet the targets by 2025.5 The automakers knew the rules would impose significant costs and were not aligned with consumer preferences.6

In December 2017, Mitch Bainwol, then-President and CEO of Alliance of Automobile Manufacturers, testified before the House Energy and Commerce Committee Subcommittee on Digital Commerce and Consumer Protection that:

'[M]uch has changed since the agencies issued the final rulemaking for the MY 2017-2025 vehicle fuel economy/GHG emission standards in 2012… I pointed out how several of the assumptions – such as gas prices, technology effectiveness and cost, and the consumer acceptance of advanced technology vehicles – on which the agencies determined that automakers would be able to comply with the current MY 2022-2025 standards have drastically shifted since 2012. That pattern has only continued, making compliance with the more aggressive later year standards very challenging.'7

The other assertion EPA relies on to satisfy Section 202(a) requirements is the readiness of automakers to meet the stringency, compliance cost, and lead time being proposed. This hinges on the five automakers that joined the California Framework and other automakers who have recently stated their commitment to lowering vehicle emissions and moving toward EVs. These public relations representations from consistently noncompliant manufacturers are in no way binding or enforceable. The five automakers that joined the California Framework represent only one-third of automakers and in 2017 they were petitioning the federal government for less stringent standards. Even the Center for Biological Diversity recognizes these statements are empty, '[a]utomakers tore up the last promise they made to cut pollution, so why would anyone trust their new one . . . . Voluntary pledges from auto companies make a New Year's resolution to lose weight look like a legally binding contract.'8

The use of the 2012 standard as Section 202(a) justification is not reasoned decision-making. Automakers have not been compliant with stringent standards set during the Obama administration and will not be able to achieve the even more stringent standards being proposed.

According to EPA's 2020 Automotive Trends Report, out of 14 large vehicle manufacturers, only three achieved regulatory compliance based on emission performance without help from banked credits. All other large manufacturers used a combination of banked or purchased credits, along with technology improvements, to achieve compliance in model year 2019.9 EPA acknowledges, 'In the last four years, the industry GHG performance has been above the industry-wide average standard, resulting in net withdrawals from the bank of credits to maintain compliance.'10 EPA has created its authority to establish a greenhouse gas credit trading program, as well as the retroactive commandeering of credits from model year 2021 and 2022, from whole cloth. This absence of statutory authority is underscored by the explicit delegation of authority to the Department of Transportation/NHTSA under EPCA for related trading programs. Section 202(a) requires reasoned decision-making, this reliance on non-binding voluntary statements from noncompliant automakers is a clear violation of Section 202(a). Put differently, automakers have failed to achieve EPA's stringent vehicle standards technologically, raising fundamental questions about the reasonability of the agency's decision-making. [EPA-HQ-OAR-2021-0208-0226-A1, pp. 1-3]

The Proposed Rule Violates Key Provisions of CAA Sections 307(d). EPA's proposed rule is subject to CAA Section 307(d), as published in the Federal Register EPA does not acknowledge its statutory and legal authority in this rulemaking being subject to Section 307(d). Section 307(d) establishes unique docketing and procedural requirements, Senator Carper raised serious concerns regarding these requirements last year when EPA promulgated the SAFE rule.16 Under Section 307(d)(4)(b)(ii) '[t]he drafts of proposed rules submitted by the Administrator to the Office of Management and Budget for any interagency review process prior to proposal of any such rule, all documents accompanying such drafts, and all written comments thereon by other agencies and all written responses to such written comments by the Administrator shall be placed in the docket no later than the date of proposal of the rule.'17

During the SAFE rulemaking the docketing concerns raised by Senator Carper brought on an Inspector General evaluation. As stated in the Office of Inspector General report 'OGC attorneys said that in joint rulemakings in 2010 and 2012, as well as for the final SAFE Vehicles Rule in 2020, the Agency's practice was to treat [National Highway Traffic Safety Administration] NHTSA as a coauthor both before and after initiating interagency review. Using this interpretation, NHTSA would not be considered an 'other agency' for purposes of the docketing provision.'18 EPA's current proposed rule is not a joint rulemaking with NHTSA and is subject to Section 307(d)(4)(b)(ii).

EPA has violated this provision; the proposed rule and 12866 interagency comments speak of a collaborative process with NHTSA. 'EPA has coordinated with NHTSA, both on a bilateral level as well as through the interagency review of the EPA proposal led by the Office of Management and Budget.'19 There is no evidence in the docket of their bilateral or interagency coordination, EPA is using NHTSA's updated modeling and has a shared interest in this area. The Agency 'notes that EPA may coordinate with NHTSA, and has done so, regardless of the formality of joint rulemaking. EPA has consulted significantly with NHTSA in the development of this proposal. Consultation is the usual approach Congress specifies when it recognizes that EPA and another agency share expertise and equities in an area.'20 As stated in the proposed rule, if EPA has consulted significantly with NHTSA throughout the development process this should be seen in the docket to remain transparent, this is not a joint rulemaking and NHTSA is not considered a coauthor. [EPA-HQ-OAR-2021-0208-0226-A1, pp. 4-5]

Commenter: Bay Area Air Quality Management District

We applaud President Biden for directing EPA to reconsider the dangerously flawed SAFE Vehicles Rule and appreciate EPA's efforts that have resulted in proposal of the Revised Model Year (MY) 2023 and Later GHG Standards. The SAFE Rule used analyses that were unsound, relying on bad data; relaxed 2012 National Clean Car Standards ('Obama-era standards') already shown to be feasible; and, by significantly weakening the standards, ignored the opportunity to phase in readily achievable technological advancements over time. The Bay Area Air District agrees with EPA's assessment in the NPRM that 'in light of the significant contribution of light-duty vehicles to transportation sector GHG emissions, standards more stringent than those relaxed in the SAFE rule are appropriate under the Clean Air Act'. [EPA-HQ-OAR-2021-0208-0283-A1, pp.1-2]

EPA's Proposal in spirit addresses many of the Air District's previous concerns with the greenhouse gas standards portion of the SAFE Vehicles Rule. All options in the NPRM are improvements over the SAFE standards [EPA-HQ-OAR-2021-0208-0283-A1, p.2]

Commenter: California Air Resources Board (CARB)

U.S. EPA has a legal obligation to follow the science and the Clean Air Act and cut emissions as deeply as possible. [EPA-HQ-OAR-2021-0208-0643-A6, p.1]

As CARB and many others explained in multiple comments on the SAFE proposal3 and subsequent briefing in the litigation challenging the Final SAFE standards,4 U.S. EPA's decisions, actions, and supporting analyses were deficient and fundamentally wrong in many respects. The SAFE rules and actions also failed to meet U.S. EPA's fundamental obligation under the Clean Air Act to protect public health and welfare, as they allowed continuing dangerous emission levels despite U.S. EPA's determination that these emissions threaten public health and welfare and the availability of feasible reductions. [EPA-HQ-OAR-2021-0208-0643-A6, p.7]

The Proposal Meets the Statutory Direction to Protect Public Health by Reducing Pollution. CARB welcomes the Administrator's recognition that Congress enacted Section 202 of the Clean Air Act to address the threats to public health and welfare from pollution by new motor vehicles.75 As the proposal discusses, Congress directed U.S. EPA to adopt motor vehicle pollution control standards at levels to address all manner of air pollutants that may reasonably be anticipated to endanger public health and welfare.

The current standards do not properly respond to this core mandate. CARB supports the Administrator's proposal to adhere to Congress's direction to reduce the threat to public health and welfare by limiting, in the near- and far-terms, harmful greenhouse gas emissions. Notably, these more stringent standards will bestow significant net benefits on society, even if they impose some cost on automakers.

The preferred alternative, Alternative 2, and the requirement for further emission reductions in model year 2026 all meet U.S. EPA's obligations under the Clean Air Act when exercising its authority to establish emission standards. CARB supports and agrees with the comments of the California Attorney General and multi-state coalition that this range of standards advances the objectives of Section 202(a) of the Clean Air Act. They will significantly reduce pollution from motor vehicles. In the time available, they can be met with existing technology at a cost that is reasonable, particularly considering their benefits for protecting public health and welfare. [EPA-HQ-OAR-2021-0208-0643-A6, p.28]

As U.S. EPA correctly recognizes,81 and as further explained in the accompanying comments of the California Attorney General, manufacturers have had a decade to plan for the National Program standards. In contrast, the SAFE Vehicles Rule is a recent concoction that has been nothing but uncertain throughout its existence.

The SAFE Vehicles Rule proposal was extensively panned in voluminous, detailed, well-reasoned comments. And because so much of the criticism was valid, the final analysis for the SAFE Vehicles Rule deviated in many significant ways from the proposal. But it remained deficient. The final rules were immediately challenged by multiple petitioners; those consolidated cases are in abeyance pending the outcome of this proposal,82 in response to the President's direction to reconsider it.83 The federal agencies have realized the Final SAFE Rule standards were inappropriate and proposed to restore more stringent standards. At no time have the Final SAFE Rule standards provided a stable platform for automakers to plan their products.

Commenter: California Attorney General Office, et al.

EPA has long recognized that GHG emissions from new motor vehicles and new motor vehicle engines endanger public health and welfare, and, under Section 202(a) of the Clean Air Act, this recognition triggers a mandatory duty to reduce such emissions. [EPA-HQ-OAR-2021-0208-0245-A1, p.1]

There is, thus, every reason for EPA to act quickly to replace the unlawful and woefully inadequate SAFE 2 standards with more stringent ones that satisfy the agency's statutory mandate to reduce emissions of harmful air pollution. [EPA-HQ-OAR-2021-0208-0245-A1, p.1]

We urge EPA to quickly adopt the rigorous standards that the circumstances, its statutory mandate, and the record demand. [EPA-HQ-OAR-2021-0208-0245-A1, p.2]

In 2018, EPA and NHTSA ('the Agencies') proposed to freeze their respective standards at model year 2020 levels for six years, meaning no increase in stringency would be required in model years 2021-2026 (although model year 2021 had not been part of the Mid-Term Evaluation). 83 Fed. Reg. 42,986 (Aug. 24, 2018). In April 2020, the Agencies published final SAFE 2 standards that increase in stringency by approximately 1.5% each year, 85 Fed. Reg.

24,174 (April 30, 2020), a rate far lower than the annual increase (approximately 5%) required by the standards promulgated in 2012. Id. at 25,106. The Agencies' analysis projected that EPA's SAFE 2 standards will increase GHG emissions by up to 923 million metric tons, id. at 24,176, and will cause up to 1,000 premature deaths, and other adverse health impacts, due to increases in criteria pollutant emissions, id. at 25,119. Notably, the Agencies also acknowledged and reaffirmed that technologies sufficient to comply with the more stringent standards promulgated in 2012 had 'already been developed, have been commercialized, and are in-use on vehicles today.' Id. at 25,107. The Agencies also confirmed that the SAFE 2 standards will cost consumers money overall, because increases in fuel expenditures will exceed estimated decreases in vehicle prices. Id. at 24,180-81.95

Many of the undersigned (and other parties) challenged the SAFE 2 standards in the D.C. Circuit Court of Appeals. Although briefing had commenced, those cases were placed in abeyance after President Biden's January 20, 2021 Executive Order directed EPA and NHTSA to reconsider the standards. [EPA-HQ-OAR-2021-0208-0245-A1, pp.17-18]

Section 202(a) of the Clean Air Act demands nothing less. We urge EPA to adopt the most stringent standards it concludes are feasible, commensurate with the undeniable need for urgent and rigorous action. [EPA-HQ-OAR-2021-0208-0245-A1, p.18]

Section 202(a) Requires EPA to Reduce Threats to Public Health and Welfare from Harmful Air Pollution. Under Section 202(a)(1) of the Clean Air Act, EPA 'shall by regulation prescribe . . . standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles . . ., which in [its] judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare.' 42 U.S.C. § 7521(a)(1). 'By employing the verb 'shall,' Congress vested a non-discretionary duty in EPA,' Coalition for Responsible Regulation, Inc. v. EPA, 684 F.3d 102, 126 (D.C. Cir. 2012), rev'd in part on alternative grounds, the purpose of which is clear: reduce or eliminate the threats to public health and welfare of deleterious air pollutants. See 42 U.S.C. § 7401(b)(1) (declaring a goal of the Clean Air Act 'to protect and enhance the quality of the Nation's air resources so as to promote the public health and welfare and the productive capacity of its population'); Massachusetts, 549 U.S. at 532 (explaining that 'EPA has been charged with protecting the public's 'health' and 'welfare'' in Section 202(a)).

In SAFE 2, EPA disregarded its statutory mandate and Congress's objective of reducing harmful emissions. The agency adopted standards that, by its own estimate, would increase GHG emissions by 923 million metric tons, 85 Fed. Reg. at 24,176, and thereby exacerbate the long recognized and well-documented threats to public health and welfare posed by the climate crisis.96 97 EPA also projected that its SAFE 2 standards would increase criteria pollution, 85 Fed. Reg. at 25,059-60, and result in adverse public health impacts such as premature deaths, asthma exacerbation, and non-fatal heart attacks, id. at 25,112-13. These preventable increases in harmful air pollution needlessly enhanced known threats to public health and welfare, and the Administrator failed to 'square [] [this] with the statutory objectives that Congress specified.' See Independent U.S. Tanker Owners Comm. v. Dole, 809 F.2d 847, 854 (D.C. Cir. 1987). Rather, the Administrator improperly prioritized 'reducing the cost of compliance on the regulated industry and the upfront (but not total) cost to consumers,' 86 Fed. Reg. at 43,786, over the reduction in harmful air pollution that Section 202(a) expressly demands.98 See Independent U.S. Tanker Owners Comm., 809 F.2d at 854 (Administrator 'is not free to substitute new goals in place of the statutory objectives without explaining how these actions are consistent with [his] authority under the statute'). See also Proof Brief of State and Local Government Petitioners at 43-45, Competitive Enterprise Institute, et al. v. NHTSA, No. 20-1145 (D.C. Cir. Jan. 14, 2021).

Unlike the SAFE 2 standards, EPA's Proposal comports with its congressional mandate in Section 202(a). EPA properly recognizes that it is required to reduce harmful air pollution. The Proposal, and particularly the more stringent alternatives included therein, will further the statutory objective and reduce, rather than exacerbate, threats to public health and welfare. EPA projects that the proposed standards will reduce GHG emissions by more than 2,200 million metric tons of CO_2, 2.7 million metric tons of CH_4, and 71,000 metric tons of N_2O through 2050, in addition to reductions in criteria pollutant emissions. 86 Fed. Reg. at 43,785. And the more stringent standards in Alternative 2 would reduce harmful emissions even more. Id. at 43,739 (Table 8). EPA correctly describes these emissions reductions as an 'essential factor' in its determination of the appropriate level of the proposed standards, id., and properly places greater weight than in its SAFE 2 rule on the statutory goal of reducing harmful pollution, id. at 43,786. We support EPA's return to a proper balancing of factors in setting vehicle emission standards—including the proper emphasis on reducing harmful air pollution and mitigating threats to public health and welfare. [EPA-HQ-OAR-2021-0208-0245-A1, pp.18-20]

The only express statutory constraint on EPA's mandate to control harmful air pollution is the requirement that EPA determine there is sufficient lead time for the standards it promulgates—that the standards provide 'such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.' 42 U.S.C. § 7521(a)(2). As the D.C. Circuit held not long after this section was enacted, this requires EPA to 'provide the requisite lead time to allow technological developments' while avoiding 'undue economic disruption' in the auto industry, such as the 'doubling or tripling the cost of motor vehicles.' Motor & Equip. Mfrs. Ass'n, Inc. v. EPA (MEMA I), 627 F.2d 1095, 1118 (D.C. Cir. 1979). EPA may find that lead time is sufficient where there are 'plausible reasons for [EPA's] belief that the industry will be able to solve … problems in the time remaining.' NRDC v. EPA, 655 F.2d 318, 333–34 (D.C. Cir. 1981). [EPA-HQ-OAR-2021-0208-0245-A1, p.24]

Measures—such as the standards in EPA's proposal—that reduce pollution in these communities are urgently needed, and addressing that need (and others described above) is mandatory under Section 202(a). [EPA-HQ-OAR-2021-0208-0245-A1, p. 24]

EPA can more than plausibly find that lead time would be sufficient for each of the model-year standards it is considering here (including Alternative 2 and an additional 10 grams/mile of stringency in MY2026), and there is no reason to conclude that any of these standards would cause undue economic disruption. Because lead-time considerations can vary by model year, we address each year (or small group of similar years) separately below. And, as discussed in more detail below in Subsection D, we urge EPA to do the same in its final rule both because of variability in the facts associated with different model years and to support severability should one or more model-year standards be stayed or vacated. [EPA-HQ-OAR-2021-0208-0245-A1, p.24]

Thus, here, the only lead time question is whether automakers have sufficient time to develop and implement a compliance strategy for each of the model years at issue. And, under the longstanding design of this regulatory program (which EPA is not proposing to change), compliance strategies involve not only the fleet an automaker plans to sell in a given model year but also strategic decisions concerning whether and when to earn, purchase, bank, and use credits. See 86 Fed. Reg. at 43,733. Consideration of both of these aspects of automaker compliance strategies leads to only one conclusion: there is sufficient lead time for all the standards included in EPA's proposal. As we explain further below, EPA should consider adopting its Alternative 2 standards for MY2023 and should not finalize standards for that year that are less stringent than its preferred alternative. Regardless of where EPA sets the standards for MY2023, it should finalize Alternative 2's standards for MYs 2024-2026 with the proposed additional 10 grams/mile of stringency in MY2026. Finally, EPA should also make separate lead-time findings for each model year (or group of similar model years) to support severability of the model-year standards should that be necessary. [EPA-HQ-OAR-2021-0208-0245-A1, p.25]

Indeed, any changes in plans automakers made in reliance on the SAFE 2 standards remaining in place for MY2023 would have been unreasonable. There was only a very 'limited period' between when SAFE 2 was finalized and President Biden's direction to reconsider, and the SAFE 2 standards have been vigorously challenged since their adoption. See Mozilla Corp. v. FCC, 940 F.3d 1, 64 (D.C. Cir. 2019) (holding reliance interests unreasonable where rule was in effect for 'barely two years' and 'faced persistent legal challenges'). In those challenges, vacatur of SAFE 2 and reinstatement of the standards promulgated in 2012 was an available remedy. See, e.g., Nat'l Parks Conservation Ass'n v. Semonite, 925 F.3d 500, 501 (D.C. Cir. 2019) (describing vacatur as 'default remedy to correct defective agency action'); Sugar Cane Growers Co-op. of Fla. v. Veneman, 289 F.3d 89, 97 (D.C. Cir. 2002) (characterizing vacatur as 'restor[ing][the status quo ante'). Where, as here, 'agency orders on which the [parties] claim to have relied not only had never been judicially confirmed, but were under unceasing challenge,' 'reliance is typically not reasonable.' Verizon Tel. Companies v. FCC, 269 F.3d 1098, 1110 (D.C. Cir. 2001). [EPA-HQ-OAR-2021-0208-0245-A1, pp.26-27]

Each Model Year's Standards Should Be Severable. Whatever standards EPA adopts, it should include a severability provision for each model year indicating that it would adopt each model year's standards even if other model-year standards are stayed or vacated.152 EPA should also support severability by making independent lead-time (and any other necessary) findings for each model year. In other words, EPA should make it clear that 'the agency would have adopted' each model year's standards on their own and that each model year's standards could function even if earlier model years' standards were stayed or vacated.153 For example, EPA should find that the MY2024 and later-year standards it adopts would provide adequate lead time even if the MY2023 standards EPA finalizes are stayed or vacated. EPA should make similar findings for each year. These findings are well-supported by the existing record, as discussed above.

Moreover, if one or more early model years were stayed, automakers would have even greater opportunities to accumulate windfall credits in those years, further underscoring that more stringent standards in the outer years can and should remain in effect. [EPA-HQ-OAR-2021-0208-0245-A1, pp.31-32]

We are encouraged that EPA has drastically improved the analysis it relied on for the SAFE 2 standards, correcting multiple, serious errors as well as unrealistic input assumptions. See, e,g., 86 Fed. Reg. at 43,769 Table 30. As discussed in more detail in SAFE 2 briefing, and in the comments and appendices submitted by CARB, we agree with, among other things, EPA's decisions to allow the modeling to apply high-compression ratio technologies to far more vehicles than the SAFE 2 modeling did and to return to the 10% rebound estimate it has previously employed.154 After correcting these (and other) errors, the resulting analysis is reasonable and justified. We also support EPA's decision to use the Corporate Average Fuel Economy Compliance and Effects Modeling System (CCEMS). While EPA should continue to refine its modeling capabilities for future rulemakings, including developing OMEGA2, EPA's approach to analyzing net benefits for all its proposed standards allows for more direct comparison with the SAFE 2 Rule and clearly demonstrates the need and bases for standards more stringent than SAFE 2.

We also very much agree with EPA's conclusion that a properly conducted cost-benefit analysis, such as the one EPA has performed here, strongly supports more stringent standards—either EPA's preferred alternative or Alternative 2 (and the additional 10 grams/mile added to either for MY2026). As EPA notes, net benefits have consistently been clear for all increases in stringency to GHG standards—from the initial standards finalized in 2010 to the Phase 2 standards finalized in 2012 and to the 2016 TAR and 2017 Final Determination in the Mid-Term Evaluation process. See 86 Fed. Reg. at 43,734-35 (noting that 'results of … earlier analyses, as well as the updated analysis … performed [here], have all produced very similar results in several key metrics'). As discussed in CARB's separate comments (including attached expert analyses), EPA should consider further revisions to its cost-benefit analysis, which would cumulatively show even greater net benefits to the proposed standards. CARB Comments at 33-40. For example, EPA should change its price elasticity figure from the -1.0 it used (erroneously) in SAFE 2 to one with an absolute value much closer to zero. Id. at 38-39 (citing expert analysis from Prof. Ken Gillingham). Without such changes, EPA's cost-benefit analysis underestimates the true net benefits, though the net benefits EPA calculates clearly support its proposed action(s). Indeed, EPA's cost-benefit analysis establishes that the proposed standards would significantly benefit society, producing (as underestimated) between $86 billion and $140 billion of total net benefits. 86 Fed. Reg. at 43,735 (Table 4). EPA projects that consumers would save between $120 billion and $250 billion on fuel costs. Id. Although many of these benefits remain unquantified, the proposed standards would generate between $22 billion and $280 billion in climate benefits from greenhouse gas reductions and at least $3.6 billion to $8.8 billion in benefits from reduction in fine particulate matter. Id. at 43,795 (Tables 54-55). [EPA-HQ-OAR-2021-0208-0245-A1, pp. 32-33]

We are encouraged that EPA's SC-GHG analysis, by accounting for global climate harms, has corrected serious errors in SAFE 2's social cost of carbon ('SCC') analysis that used a scientifically and legally indefensible domestic number. As CARB and the multi-state coalition have explained,155 SAFE 2's domestic SCC ignored the best available science and failed to consider an important aspect of the problem. Indeed, agency reliance on an interim domestic SCC in lieu of the global SCC has been held arbitrary and capricious,156 whereas agency reliance on the global SCC has been upheld.157 We recommend EPA identify these errors in SAFE 2's SCC analysis and explain why EPA needed to correct them and return to its longstanding recognition—dating as far back as 2008, under the Administration of President George W. Bush—that 'GHGs are global pollutants' that require a global analysis.158 [EPA-HQ-OAR-2021-0208-0245-A1, p.33]

Commenter: Center for Biological Diversity, et al.

Standards under Clean Air Act Section 202(a) Must Give Primary Importance to the Need to Reduce Emissions to Mitigate Dangers to Public Health and Welfare. Clean Air Act section 101(b)(1) declares that the purpose of the Act is to "protect and enhance the quality of the Nation's air resources so as to promote the public health and welfare." 42 U.S.C. § 7401(b)(1). Section 202(a) in turn directs the Administrator to promulgate new motor vehicle emissions standards that address emissions of air pollutants that "in his judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare." 42 U.S.C. § 7521(a). EPA's statutory duty is to reduce the dangers it identifies through vehicular emission standards, while taking into account considerations of timing, technological feasibility and cost. See Coal. for Responsible Regulation, Inc. v. EPA, 684 F.3d 102, 122 (D.C. Cir. 2012).

Under the statute and basic requirements of reasoned decision-making, when EPA acts under Section 202(a), it must arrive at a response commensurate with the harm the vehicle emissions it regulates cause to public health and welfare and explain how its standards reduce the "endanger[ment]" that it has identified. Any "balancing" of factors—including available technology, costs, and lead time—must prioritize the principal harm-reduction mandate animating the statute. The 2020 Final Rule failed in these respects. In that rule, EPA almost completely ignored the central pollution problem caused by greenhouse gas emissions— climate change—and disregarded EPA's own findings regarding its severity and the urgent need for mitigation. Nowhere did EPA explain how weakening standards could be justified under the statute given the acknowledged dangers to health and welfare. See Competitive Enterprise Inst. v. EPA, D.C. Cir. No. 20-1145, Brief of Public Interest Organization Petitioners, at 8-12 (ECF 1880214), attached as Exhibit 45.

EPA had previously acknowledged that the preexisting standards established by the 2012 Final Rule were "the most significant federal actions ever taken to reduce GHG emissions . . . in the U.S." 2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions and Corporate Average Fuel Economy Standards, 77 Fed. Reg. at 62,630 (Oct. 15, 2012) (2012 Final Rule). And EPA has itself repeatedly documented the massive damage wrought by vehicular GHG emissions and the urgency of curtailing climate change. See Joint NGO Climate Change Comments 2-7. Yet EPA proceeded to adopt a rule that increases emissions and fuel consumption dramatically, increasing GHG emissions from affected vehicles by at least 867 million more tons. The Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years

2021-2026 Passenger Cars and Light Trucks, 85 Fed. Reg. 24,174, 24,176 (Apr. 30, 2020) (2020 Final Rule).

The 2020 Final Rule's rollback in standards defied reports from leading scientific bodies, and EPA itself, that sound the alarm for immediate action to lower GHG emissions. EPA's duty under the statute is to prescribe standards reducing the "endanger[ment]," while considering necessary lead time in light of technology and compliance costs. 85 Fed. Reg. at 24177. EPA cannot rationally perform that task without fully examining the nature, magnitude, and effects of climate-changing pollution. EPA nowhere explained why it was reasonable, in light of its own endangerment findings and the catastrophic harms documented in this record, to weaken its prior standards, vastly increasing vehicular emissions despite ready availability of effective technologies to reduce them. EPA's discussion of climate change in the 2020 rule's preamble consisted of little more than references to the National Highway Traffic Safety Administration (NHTSA) Environmental Impact Statement (EIS). 2020 Final Rule, 85 Fed. Reg. at 24,846, 24,849, 25,111 n.2480. In that document, NHTSA arbitrarily brushed off the effects of nearly a billion metric tons of climate pollution as "extremely small in relation to global emissions trajectories," [FEIS, S-13] – an arbitrary and dismissive approach irreconcilable with any serious effort to mitigate climate dangers, let alone with EPA's special statutory charge to protect public health and welfare. In the 2020 Final Rule, EPA remained conspicuously silent on the central statutory concern, and failed to explain how a dramatic weakening of standards – and adoption of standards that accomplish much less than can be achieved with readily available technologies – comported with the agency's Clean Air Act duties to protect public health or welfare.

In the 2020 Final Rule, EPA improperly attempted to recast Section 202(a)'s directive to impose standards to reduce dangerous emissions—bounded by consideration of timing, technical feasibility and cost—as an open-ended balancing test giving the agency "effectively complete discretion," Oceana, Inc. v. Locke, 670 F.3d 1238, 1242 (D.C. Cir. 2011). But Section 202 is no such blank check: As the Proposal correctly observes, "the purpose of adopting standards under CAA section 202 is to address air pollution that may reasonably be anticipated to endanger public health and welfare. Indeed, reducing air pollution has traditionally been the focus of such standards." 86 Fed. Reg. at 43,729. In developing standards under Section 202, the agency cannot disregard or slight the statute's central mandate to reduce dangers to public health and welfare. The proposal represents a positive step insofar as EPA restores public health and welfare to the center of its analysis under Section 202. And, on the record before it, EPA is clearly correct to conclude that "[g]reater reductions in GHG emissions from light duty vehicles over these model years are both feasible and warranted as a step to reduce the impacts of climate change on public health and welfare." Id. at 43,781.

The 2020 Final Rule did not result from an "alternative" balancing of statutory factors; it was an indefensible, unreasoned subordination of the statute's central objective and core requirement. EPA need not find that the 2020 Final Rule violated the statute in order to revisit the standards that the 2020 rule established. But in this rulemaking EPA should confirm that whatever room for balancing of factors Section 202(a) provides, the statute does not give the agency an open-ended authority to adopt whatever standards it wishes; to invent spurious "factors" (such as an overriding preference for avoiding "upfront costs" even when discounted fuel costs would far exceed them); or disregard the statutory mandate to reduce emissions that endanger public health and welfare. [EPA-HQ-OAR-2021-0208-0651-A1, p. 16-18]

EPA Should Acknowledge the Patent Mistakes that Underlie the 2020 Final Rule. “Agencies are free to change their existing policies as long as they provide a reasoned explanation for the change.” Encino Motorcars, LLC v. Navarro, 136 S. Ct. 2117, 2125 (2016). In order to change course, EPA does not need to demonstrate that the 2020 Final Rule was contrary to statute or arbitrary and capricious. See generally FCC v. Fox Television Stations, Inc., 556 U.S. 502, 515 (2009).

However, EPA should acknowledge that the 2020 Final Rule was marked by serious errors that require correction regardless of any changes in policy views. The 2020 Final Rule’s central reliance on a claim that consumers have an extraordinary preference for “upfront” vehicle cost savings over later fuel-cost savings, see, e.g., 85 Fed. Reg. at 25,111, 25,210, 25,171, was not just a different policy perspective; it was flat wrong. EPA and NHTSA had already accounted for the fact that purchase prices and fuel costs occur at different times (i.e., for the time value of money) by using a discount rate to convert future costs and benefits to their present value. Id. at 24,281. By later assigning even more weight to upfront costs, the Agencies “double-discounted” future cost savings, violating long-established agency practice and guidance, economic theory, and common sense. This is not a reasonable policy judgment; it has no grounding in the statute or established economic analysis.60

In the Proposal, EPA properly moves away from the 2020 Final Rule’s approach to upfront costs, 86 Fed. Reg. at 43,785. But, in doing so, EPA should make clear that the need to reject that approach is more than a “change in policy priorities.” Id. EPA should acknowledge that this aspect of the 2020 Final Rule was not only inconsistent with EPA’s current policy priorities, but was also outside the bounds of reasonable analysis. Nothing in the statute or in rational economic analysis authorized the 2020 Final Rule’s reliance on upfront costs as a basis for overriding statutory priorities and the results of conventional cost-benefit analysis.

And the double-counting of upfront costs was hardly the only patent error in the 2020 Final Rule that cannot fairly be characterized merely as a differing weighing of policy considerations. The 2020 rule was based upon numerous patent analytical errors – outright mistakes – that severely distorted the analysis underlying the decision to weaken the existing emission standards. Many of these errors are described in detail in the NGOs’ joint petition for administrative reconsideration.61 These are not debatable-but-defensible policy judgments, but patent errors that EPA should acknowledge. The multiple clear analytical mistakes further confirm that the 2020 Final Rule’s gratuitous weakening of emissions standards must be rescinded. [EPA-HQ-OAR-2021-0208-0651-A1, p. 18-19]

Commenter: Consumer Federation of America

The Trump administration, reintroduced over two dozen (28) errors in its SAFE 2 rule which had previously been corrected. By reintroducing these errors into the rule, the benefit-cost ratio calculated by CFA of the standard in place before SAFE 2 to be 5-to-1, but subsequently has been reduced to a mere 1.1-to-1. By reversing many of these errors through this proposed rulemaking and taking into account key changes, the benefit ratio has risen to 2.2-to-1. [EPA-HQ-OAR-2021-0208-0297-A1, p. 1]

Table 3.1 presents EPA's summary of changes in its analysis compared to the Trump administration's SAFE 2 Rule. We have highlighted the major changes that EPA correctly concluded the Trump administration failed to justify. The references in the Table are to the chapters in the Regulatory Impact Assessment.

The first three items involve the valuation of greenhouse gases and other pollutants. At one level, this is just an updating of the values used, although the cost of carbon is considerably large, consistent with international analyses and consensus, and the cost of methane is included. At another level, it represents a symbolically and quantitatively significant return to the treatment of externalities. Since climate change is a global problem, it takes into account the full global value of reducing emissions. The fourth item is a significant change that affects the economics of the proposed standard in two ways. EPA returns to a 10 percent rebound rate, which it had justified before the Trump administration doubled it. Increasing the rebound rate reduces the estimate of fuel savings and assumes a much larger increase in driving than is justified, which affects the 7th item, congestion. EPA has once again justified its use of a 10 percent discount rate. CFA has argued that a lower discount rate can be justified today and certainly will be more appropriate in the future.

Items 5, 6, 7 and 9, involve updates of values that increase the net benefit slightly. As discussed below, CFA believes a lower discount rate (1% to 2%) should be included to set the result in perspective. Because climate change is a long-term, global phenomenon, the 3 percent discount rate undervalues the impact on future generations. In fact, EPA uses a lower and more narrow range to assess the value of greenhouse gas reduction (2.5% to 5%).

Items 11 and 12 involve the availability of technologies, which has been updated and involves a very significant impact on the estimation of costs and net benefits. As discussed below, the Trump administration had inappropriately doubled the projected cost of the technologies. The EPA justified a much lower number in the earlier Technical Assessment Review (TAR) and did so again here. Item 13 involves the modeling of credits, which lowers the projected fuel and emission savings somewhat. [EPA-HQ-OAR-2021-0208-0297-A1, p. 11; Table 3.1 can be found at docket number EPA-HQ-OAR-2021-0297-A1, p. 12.]

These corrections to the flawed SAFE 2 rule account for the bulk of the difference in the benefit-cost ratio. They are well justified in the proposed rule and address the 'third-party' criticisms of the SAFE 2 rule.

Table 3.2 presents a summary of the CFA criticism of the SAFE 2 rule compared to other third-party evaluations. The CFA column identifies over a dozen mistakes that the Trump administration had reintroduced into its analysis. We then provide three critical articles, as well as references to other evaluations, showing the type of error. Finally, we estimate the impact of the errors on our calculation of the benefit/cost ratio. [EPA-HQ-OAR-2021-0208-0297-A1, p. 12; Table 3.2 can be found at docket number EPA-HQ-OAR-2021-0297-A1, p. 13.]

Many of the elements in Table 3.2 track with the differences EPA noted in Table 3.1 for its modeling of the benefits and costs. The three broad categories, overestimation of costs, underestimation of benefits, and the value of driving, summarize the individual elements. [EPA-HQ-OAR-2021-0297-A1, p. 14; Tables 3.1 and 3.2 can be found at docket number EPA-HQ-OAR-2021-0297-A1, p. 12 and 13]

Commenter: District of Columbia Department of Energy and Environment

DOEE supports EPA in strengthening GHG standards for light-duty vehicles under Clean Air Act § 202(a). [EPA-HQ-OAR-2021-0208-0240-A1, p.1]

Commenter: Elders Climate Action (ECA)

To Stabilize the Climate as Quickly as Possible, and Protect the Public Health, EPA Must Set a Zero Emissions Standard for GHG Emissions from New Motor Vehicles, and Begin Phasing in the Standard With the 2026 Model Year.

The Clean Air Act authorizes EPA to set emission standards for motor vehicles ‘as needed to protect public health or welfare, taking costs, energy and safety into account.’3 We ask the Administrator to make the determination that emissions of both GHGs and precursors to the criteria pollutants PM and ozone emitted from light duty vehicles must be reduced to zero to -- 1) protect the public health and welfare from the many adverse effects of climate warming, and 2) prevent the direct injury to health caused by pollutants emitted from internal combustion engines.

The Act provides that ‘[a]ny such [standard] under this subchapter may provide for a phase-in of the standard.’4 We ask the Administrator to begin phasing in a zero emission standard by establishing a sales mandate that requires each manufacturer to achieve 30% ZEV sales during the 2026 MY with the goal of achieving 100% ZEV sales by 2030 in order to achieve zero emissions from on-road light duty vehicles by 2045. [EPA-HQ-OAR-2021-0208-0521-A1, p. 3]

Urgent Need for Zero GHG Emission Standard to Achieve GHG Reductions. Harm to public health and the environmental, property and economic resources of our communities incorporated into the CAA definition of ‘public welfare’ was anticipated and comprehensively described in the Administrator’s Endangerment Finding that established the basis for regulating six GHGs under the CAA.5 All of the anticipated harms have now been demonstrated to vary degrees, and are accelerating rapidly as the planet continues to heat up. [EPA-HQ-OAR-2021-0208-0521-A1, p. 4]

In its Regulatory Impact Assessment, at 2-15, EPA acknowledges that

… long-term GHG reduction goals will require a far greater penetration of ZEVs than this proposal would require through MY2026. The need for substantial increases in fleet penetration of ZEVs over the long term is supported by the recommendations of the National Academy of Sciences, which states in its 2021 Light-duty Vehicle Technology Assessment: 'The agencies should use all their delegated authority to drive the development and deployment of ZEVs, because they represent the long-term future of energy efficiency, petroleum reduction, and greenhouse gas emissions reduction in the light-duty fleet'.

But EPA does not disclose what its 'long-term GHG reduction goals' are, how it intends to achieve them, or whether and how the current rulemaking contributes to achieving those goals. The reasonableness of the current proposal turns on whether EPA 1) is committed to achieving the GHG reductions identified by the IPCC as necessary to avoid the dire public health and environmental consequences of warming greater than 1.5°C, 2) believes that zero emissions from on-road vehicles are a necessary component of the President's national policy of transforming the U.S. into a zero emission economy by 2050, and 3) can establish how the current proposal contributes to a strategy designed to achieve those objectives.

In the absence of any consideration of these factors and an explanation by the Agency of how it has addressed those factors in developing its proposed decision in this rulemaking, the current proposal fails to consider relevant factors, fails to provide a rational basis for the proposal, and is arbitrary and capricious. [EPA-HQ-OAR-2021-0208-0521-A1, p. 12]

The expected increase in the severity and frequency of harms to health and the public welfare that will be caused by more extreme events that will occur as the global mean temperature advances toward and above the 1.5°C level resulting from growing GHG concentrations in the atmosphere, establish the need for a zero GHG emissions standard for light duty vehicles pursuant to section 202(b)(1)(C) of the Clean Air Act. [EPA-HQ-OAR-2021-0208-0521-A1, p. 12.]

NAAQS Attainment for Ozone and Particulate Matter Requires a Zero Emission Standard. In addition to the public health and welfare effects of a warming climate caused by GHG emissions, the persistent ozone nonattainment status of most American cities since the initial enactment of the CAA in 1970, the addition of new counties to the list of nonattainment areas, the worsening of ozone concentrations and the frequency of ozone exceedance days, and the demonstrated adverse health impacts of fine particles emitted by ICEs also demand that EPA issue a zero emission standard for LDVs. [EPA-HQ-OAR-2021-0208-0521-A1, p. 13]

Commenter: Energy Innovation Policy and Technology LLC

We are heartened with EPA's statement that the proposed action serves 'as a critical building block for a comprehensive, multipollutant longer-term regulatory program implementing EPA's statutory authority under the CAA.'[v] [EPA-HQ-OAR-2021-0208-0605-A1, pp. 2]

We commend the EPA for their rigorous analytical work to determine the clear shortcomings of the SAFE Vehicles Rule for Model Years MY 2021-2026 Passenger Cars and Light Trucks rules, which clearly failed to reduce GHGs and other air pollutants from the transportation sector and ignored the disproportionate impacts of tailpipe emissions on BIPOC and low-income/low-wealth populations. In addition, the proposed rules addressing MY 2023 is key to ensuring the standards take effect as soon as possible, so the U.S. does not lose yet another year in its efforts to clean up the transportation sector, mitigate climate change, and save consumers money. Yet, while the proposed rule is an improvement over the SAFE rules, the preferred option still falls short of what is needed. [EPA-HQ-OAR-2021-0208-0605-A1, p. 4]

Commenter: Energy Strategy Coalition

EPA Must Address Greenhouse Gas Emissions from Motor Vehicles, which the Proposed Rule Appropriately Does. Courts have held that EPA has a requirement to address GHG emissions from motor vehicles.5 The D.C. Circuit explained in Coalition for Responsible Regulation, Inc. v. EPA that 'in the Endangerment Finding, EPA determined that motor-vehicle emissions contribute to greenhouse gas emissions that, in turn, endanger public health and welfare; the agency therefore was in no position to 'avoid taking further action,' by deferring promulgation of the Tailpipe Rule.'6 The Court found that EPA's interpretation of its responsibilities under the Clean Air Act to set emission standards for cars and light trucks as 'unambiguously correct.' Additionally, D.C. Circuit judges who are on the en banc panel that heard oral argument in the cases concerning the Clean Power Plan reaffirmed this obligation when the Court partially granted EPA's request for abeyance of the litigation, reminding the agency that 'in 2009, EPA promulgated an endangerment finding, which we have sustained…That finding triggered an affirmative statutory obligation to regulate greenhouse gases.'7 Given the transportation sector's significant contribution to GHG emissions, EPA should not take any actions counter to this statutory obligation and the emission reduction opportunities from motor vehicles.

The Proposed Standards reflect EPA's consideration of a number of relevant factors, including the technical feasibility of the proposed standards, the moderate costs per vehicle, the savings to consumers in fuel costs over the lifetime of the vehicle, the very significant reductions in GHG emissions and fuel consumption, and the significantly greater quantified benefits compared to quantified costs. We agree with EPA's assessment in that the Proposed Standards are appropriate under EPA's section 202(a) authority. [EPA-HQ-OAR-2021-0208-0533-A1, p.2]

Commenter: Environmental Defense Fund (EDF)

Automakers' demonstrated ability to comply with EPA's GHG standards using earned or otherwise acquired compliance credits is thus an essential part of the agency's Section 202(a)(2) analysis. [EPA-HQ-OAR-2021-0208-0688-A1, p. 8]

This means that finalizing EPA's proposed MY 2023-2026 standards would comport with CAA Section 202(a)(2). No waiting "period" can be "necessary" if the pace of "application of the requisite technology" to comply, 42 U.S.C. § 7521(a)(2), will for several model years into the future roughly mirror the pace presently codified by regulation and which pace no automaker has suggested is too precipitous--and fall well short of the pace of improvement that automakers long expected the law would require of them in MY 2023-2025. [EPA-HQ-OAR-2021-0208-0688-A1, p. 8-9]

Commenter: Environmental Law & Policy Center (ELPC), et al.

Section 202 of the Clean Air Act requires the EPA to issue regulations to control motor vehicle emissions that 'in [the Administrator's] judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare.' 42 U.S.C. 7521(a)(1). As the proposed rule notes, EPA made a finding in 2009 that greenhouse gas emissions 'may reasonably be anticipated to endanger the public health and welfare of current and future generations.'[5] EPA therefore has a statutory duty to address these climate-changing, health-and-welfare-endangering emissions, and must issue vehicle emission standards that match the urgency of the crisis. [EPA-HQ-OAR-2021-0208-0567-A1, pp 2]

The Clean Air Act provides that EPA's vehicle emission standards 'shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.'42 U.S.C. § 7521(a)(2). EPA acknowledges that the automakers were already planning for the strong standards issued in 2012.[20] [EPA-HQ-OAR-2021-0208-0567-A1,p.3]

We also note that EPA clearly has the authority under the Clean Air Act to act separately from NHTSA. Even though the two agencies have jointly proposed and finalized rulemakings in the past in order to harmonize their respective vehicle emissions and fuel-efficiency standards, there is no requirement that the agencies act jointly, and their separate statutory authority and statutory duties make it logical for them to act separately here. [EPA-HQ-OAR-2021-0208-0567-A1, pp. 4]

Commenter: Environmental Protection Network (EPN)

In the past, EPA has exercised its discretion under Section 202(a) to provide some manufacturers who meet specific criteria temporary relief in the form of additional lead time, based on a careful evaluation of the circumstances for those manufacturers. For example, EPA previously provided 'Temporary Lead Time Allowance Alternative Standards' for manufacturers that met certain sales criteria to address lead time concerns in the initial years of the MY2012 to 2025 GHG program.[23] EPA carefully limited the form and scope of the temporary relief to fit the circumstances and placed various restrictions on the provision to avoid inappropriate loss of emissions reductions. [EPA-HQ-OAR-2021-0208-0213-A1, p.12-13]

Commenter: Fuels Freedom Foundation

With these goals in mind, Fuel Freedom commends the EPA for reconsidering the SAFE Rule. The rise in atmospheric CO_2 and rising temperatures reflect an increasingly urgent need to mitigate potential impacts on health and human welfare. Yet in the SAFE Rule the EPA had effectively deferred its obligation to reduce GHG emissions in light-duty transportation—not only minimizing the EPA's own endangerment finding for CO_2, but compromising global competitiveness of U.S. industry when light duty standards in the rest of the world are moving in the opposite direction.

Since 2009, the EPA has significantly reduced GHG emissions from light-duty transportation by regulating tailpipe CO_2 standards. Nonetheless, as noted in the Proposed Rule, transportation is today the biggest source of GHGs, with light-duty vehicles contributing the largest portion. For the long term, regulating vehicle technology will not be enough. To sufficiently reduce carbon intensity, our national policies need to adopt a more holistic approach.

EPA's authority to reduce CO_2 emissions, reaffirmed by the U.S. Supreme Court,1 is not limited to vehicle emissions alone.2 [EPA-HQ-OAR-2021-0208-0231-A1, p. 1]

Commenter: Growth Energy

EPA ignores the lifecycle benefits of ethanol, while not considering the full lifecycle emissions of other vehicle technologies including electric vehicles. The NPRM does not have any extended discussion regarding lifecycle analysis of vehicle greenhouse gas emissions, which includes tailpipe emissions, "upstream" greenhouse gas emissions associated with the fuel and vehicle production, and carbon uptake of biogenic materials whereby carbon is effectively "recycled" in biofuels.

In a veiled discussion, the NPRM does recognize – and then selectively ignores – upstream emissions. The NPRM say its analysis estimates the "GHG and non-GHG emission impacts (tailpipe and upstream)" of the proposal (NPRM at 43,734). Later, the NPRM emphasizes analysis of "upstream emissions associated with the fuels used to power those vehicles (both at the refinery and the electricity generating unit)." (NPRM at 43,777). However, the NPRM then says, "EPA is continuing to use tailpipe-only values to determine vehicle GHG emissions, without accounting for upstream emissions (EVs and PHEVs will continue to use 0 g/mile through MY 2026)." (NPRM at 43,746).

Thus, EPA selectively ignores lifecycle emissions associated with fuel use derived from electricity. The NPRM assumes-away the upstream emissions of EVs and PHEVs, assigning them a value of zero grams per mile, even though the NPRM assumes electric power plants – and thus EVs – will use fossil fuel electricity through 2050 (NPRM at 43,779-80).

The importance of fully considering lifecycle greenhouse gas emissions is widely recognized by EPA and other stakeholders. For instance, the credits generated under the California Low Carbon Fuel Standard (LCFS) are based on lifecycle greenhouse gas emissions.10 The United States Department of Energy and national labs have extensively assessed lifecycle greenhouse gas emissions of light duty vehicle fuels, including in conjunction with the GREET model used by EPA.11 The NPRM itself notes that "upstream emissions factors" used in its models are from the "DOE/Argonne GREET model." (NPRM at 43,779). Furthermore, materials in the interagency review materials for this docket note "The GREET model is widely recognized as a reliable tool for life cycle analysis (LCA) of transportation fuels and has been used by several regulatory agencies."12 A National Academy of Sciences report in this docket's interagency review materials finds a "full fuel cycle assessment more fully captures the total light-duty vehicle system greenhouse gas emissions and energy consumption than an onboard, in-use consumption or emissions metric, and more evenly compares vehicles using different fuels."13

The National Academy of Sciences, in these docketed materials, further finds that “use of only tailpipe rather than full-fuel-cycle GHG emissions incentivizes the deployment of zeroemission vehicles, but it misrepresents the actual carbon emissions associated with energy use in a light-duty fleet,” and “As alternative powertrain technologies continue to be adopted, considerations of life cycle environmental impacts and how vehicle policies may affect multiple sectors become especially important.”14 The National Academy of Sciences further finds:

“Notably, if deep GHG emissions reduction is a goal, then there will need to be consideration of not only onboard vehicle emissions, but also the emissions from related sectors, like electricity (for vehicle charging), and manufacturing (of vehicles and their materials and components). This motivates the need for life cycle thinking.15 ”

Other stakeholders have recognized the importance of the EPA vehicle program fully considering lifecycle greenhouse gas emissions. For instance, in a statement on release of the NPRM, NGVAmerica stated “EPA is aware of the environmental benefits of renewable [fuel], but it has resisted including credits for fuels based on upstream emission reductions. The fact that EPA is unwilling to look at the well-to-wheel benefits of different fuels and technologies and reward them with regulatory credits puts … low-carbon fuels at a significant disadvantage to electric vehicles.”16

This lifecycle greenhouse gas emissions issue is not new to EPA. In addition to the above-referenced citations to upstream emissions in the NPRM, EPA’s 2012 final rule on vehicle greenhouse gas standards stated, “EPA is glad to see the advances in research on this important topic [of lifecycle greenhouse gas emissions] and plans to monitor new work in this area,” but “the agency continues to believe that, as of the time of this rulemaking, there is too much uncertainty about the life-cycle impacts of future advanced technologies to conduct the type of detailed, vehicle-specific assessments that would be needed in a regulatory context.”17 The state of lifecycle impacts knowledge has evolved considerably since 2012, including numerous analyses, and implementation of California’s LCFS where ethanol has played a key role as one of the largest sources of greenhouse gas emission reductions under that program.18 [EPA-HQ-OAR-2021-0208-0279-A1, p. 3-5]

Commenter: Ingevity Corporation

In this NPRM, EPA maintains a narrow ‘tailpipe only’ view of GHG emissions, which does not appropriately account for the full lifecycle GHG emissions and the GHG reduction benefits of alternative technologies and fuels.

The purpose of EPA’s GHG regulation is to reduce GHG emissions, and, given the long survival period of CO2 in the atmosphere, there is little difference on the effect of GHG emissions whether they are produced during the production of the vehicle and battery, from the tailpipe, or during the production of electricity. The problem is that EPA’s well-to-wheels analysis inherently tipped the scale in favor of electric vehicles by ignoring the substantial amount of energy used to produce lithium ion batteries. Many studies are now being made on lifecycle emissions, and there are wide estimates in the magnitudes of upstream emissions.

EPA's exclusive recognition of battery electric vehicles as 'game-changing' technology and making electric vehicles the sole beneficiary of valuable 0 g/mile CO2 credit incentives have been based on a narrow well-to-wheels (tailpipe only) view of emissions. However, in 2016, Argonne National Laboratory issued a report evaluating the full life-cycle (or cradle-to-grave) emissions of several fuel pathways, including fossil natural gas and battery electric vehicles .21 The study finds that BEVs are expensive to operate and do not provide significantly larger GHG reductions than gasoline hybrid electric vehicles (HEVs) that operate at half the cost. The study also finds that CNG vehicles, utilizing fossil natural gas, provide 70% of the GHG reductions at 20% of the cost of avoidance in comparison to BEVs .22 The table below summarizes these findings. [The table can be found on p.10 of Docket number [EPA-HQ-OAR-2021-0208-0227-A1]]. [EPA-HQ-OAR-2021-0208-0227-A1, p,10]

The Manufacturers of Emission Controls Association (MECA) recently completed a comprehensive scientific analysis for cradle-to-grave (full lifecycle) greenhouse gas (GHG) emissions for traditional ICE vehicles, HEVs, PHEVs, and NGVs (including NGVs fueled by RNG). As shown in the table below, the results show a NGV crossover SUV operating on RNG has 92% lower emissions than a similar ICE version operating on gasoline and 67% lower emissions than a BEV operating on the 2030 California energy grid. Such analyses confirm that EPA's 'tailpipe only' view is limiting and restricts alternative, and in some cases more effective and lower cost, GHG reduction technologies from being adopted by OEMs and consumers. Ingevity believes the EPA should adopt a full-lifecycle approach as it is the most appropriate and effective method to evaluate alternative vehicle and fuel technologies to achieve real-world GHG reductions. [The tables can be found on p.11 of Docket number [EPA-HQ-OAR-2021-0208-0227-A1] [EPA-HQ-OAR-2021-0208-0227-A1, p.11]

Commenter: Institute for Policy Integrity

EPA should affirm that strong standards help correct market failures that prevent consumers from achieving valuable fuel savings on their own. The SAFE 2 Rule distorted its balancing of factors based on unsupported assumptions about consumer valuations. EPA now correctly balances those factors, but should go further to highlight additional market failures that interfere with consumers purchasing optimal levels of fuel economy on their own, and should conclude that standards are necessary to help correct at least some persistent market failures. [EPA-HQ-OAR-2021-0208-0299-A1, p. 1]

Section 202 of the Clean Air Act instructs EPA to balance its mandate to safeguard 'public health and welfare' with an 'appropriate' consideration of costs.4 In the Proposed Rule, EPA correctly recognizes that a finding of significant net benefits 'reinforces' its conviction that it is 'appropriate[ly] weighing . . . the statutory factors and other relevant considerations.'5 [EPA-HQ-OAR-2021-0208-0299-A1, p. 2]

EPA Should Select the Alternative That Will Maximize Net Social Welfare and Promote Distributional Justice, Consistent with Its Statutory Mandate and Executive Orders [EPA-HQ-OAR-2021-0208-0299-A1, p. 2]

Moreover, the executive order that instructed EPA to revise the SAFE 2 Rule reminded agencies to simultaneously advance the interests of public health, the environment, justice, workers, and communities. A related presidential memorandum, issued the same day, reaffirmed the principles of Executive Orders 12,866 and 13,5637—including that agencies should select regulatory alternatives that 'maximize net benefits' while also accounting for distributive impacts and equity.8 EPA should follow these principles in setting its vehicle standards. [EPA-HQ-OAR-2021-0208-0299-A1, p. 2]

EPA Can Finalize Its Proposed Standards with Adequate Lead Time for the 2023 Model Year, Consistent with Prior Standards. Under Clean Air Act Section 202(a), emission standards may take affect 'after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.'17 Thus, when setting new standards, EPA must consider—among other factors—how much lead time is necessary for automakers to comply with new standards. [EPA-HQ-OAR-2021-0208-0299-A1, pp. 3-4]

The Clean Air Act does not require a specific number of days or months for lead time. Instead, EPA has the discretion to balance what is required of manufacturers by any particular regulatory standard versus the time to comply and determine in its judgment how much lead time is necessary. When previous standards have required significant investment in new technologies and could not be achieved with existing technology, EPA has provided somewhat longer lead times in the past. But if a new standard can already be met with existing technology, without extensive redesign of powertrains and engine lines, EPA has the discretion to provide much shorter lead times. Here, EPA has properly exercised its discretion to determine how much lead time is necessary given existing compliance options, and has acted consistently with its historical regulation of vehicle tailpipe emissions.

Congress Provided EPA With Significant Discretion to Determine Appropriate Lead Time. The statutory history and structure suggest that EPA should balance lead time against how technologyforcing its standards are, so when compliance options are readily available, a shorter lead time is permissible. When drafting the Clean Air Act, Congress sought to confront the problems of an automotive industry that previously had no obligation or incentive to reduce its emissions. Congress understood that state-of-the-art pollution controls would not be developed 'until some sort of regulation took it by the hand and gave it a good pull.'21 So Congress crafted a statutory scheme that would require EPA to regulate through the 'drastic medicine' of setting stringent standards that would 'force the state of the art.'22 Through the technology-forcing structure in Title II of the Clean Air Act, Congress readily demonstrated its intent for EPA 'to project future advances in pollution control capability . . . [and] 'press for the development and application of improved technology rather than be limited by that which exists today.''23 Congress instructed EPA in 1970 that it must set standards for MY 1975 that would reduce hydrocarbons and carbon monoxide emissions by more than 90% compared to MY 1970 levels,24 and set future standards to take effect 'after such period as the Administrator finds necessary to permit the development and application of the requisite technology.'25 Congress directed EPA to consider lead time when setting standards because it expected EPA to set stringent standards that would require the development of new emissions controls. Over more than five decades of mobile source regulation since then, EPA has drastically reduced automotive emissions. And it has indeed done so by issuing standards that have sometimes asked automakers to 'do what seems to be impossible.'26

But EPA's proposed standards here do not ask the same of automakers. Instead, the current proposal seeks to remedy a misguided, arbitrary rollback27 by re-proposing standards for MY 2023 that are equivalent to, or even less stringent than, those that were set almost a decade ago28—standards with which many vehicle models already comply. This hardly presents a situation where automakers need significant lead time to rework their product lines. Given the discretion granted to EPA, the agency need not 'provide detailed solutions to every engineering problem' or 'rebut all speculation that unspecified factors may hinder [meeting the standard]' when evaluating adequate lead time.29 Rather, EPA 'need only identify the major steps necessary for development . . . and give plausible reasons for its belief that the industry will be able to solve those problems in the time remaining.'30 Here, EPA has provided a more than sufficient explanation in the Proposed Rule for why the agency expects automakers to be able to meet its proposed MY 2023 standards.

Indeed, given that a significant percentage of the MY 2021 automotive fleet already meets the MY 2023 proposed fleet average standard,31 EPA's analysis is far from a ''crystal ball' inquiry,'32 but rather is based on a reasonable assessment of the domestic automotive fleet. In addition, EPA is providing multiple new flexible compliance options for automakers, including extending the availability of credits generated in MYs 2016–2020, extending multiplier credits, and expanding the off-cycle credits program. These extended flexibilities come on top of other existing flexibilities, like credit trading, the large bank of available credits,33 and the carryback period for compliance. Further, five automakers (and more than one-third of domestic automotive sales) since 2019 have been in compliance with a framework agreement with California to voluntarily meet emission targets for MY 2023 that are equivalent to EPA's new proposed standards. Indeed, EPA could easily increase the standards' stringency, especially for MYs 2024–2026, and, if it retains sufficient flexible compliance options, still determine that 'the development and application of the requisite technology'34 already exists. [EPA-HQ-OAR-2021-0208-0299-A1, pp. 4-6.]

First, EPA should clarify that, whereas the SAFE 2 Rule distorted its balancing of long-term savings versus upfront costs in ways grossly inconsistent with economic practices, regulatory precedent, and statutory mandates, EPA now properly balances the appropriate factors consistent with best economic practices. [EPA-HQ-OAR-2021-0208-0299-A1, p. 8.]

The SAFE 2 Rule Distorted Its Balancing of Factors Based on Unsupported Assumptions About Consumer Valuations; EPA Now Correctly Balances the Factors. EPA's Proposed Rule is far too generous in characterizing the SAFE 2 Rule as merely 'balancing the[] factors' by 'plac[ing] greater weight' on upfront costs as compared to long-term fuel savings,56 public health gains, and other benefits to social welfare.57 The SAFE 2 Rule in fact relied on a distorted balancing of costs and benefits to justify a costly rollback that would increase emissions. By putting forward revised vehicle standards that will reduce emissions and generate net social welfare, EPA has now properly balanced the factors that it must consider in a way once again consistent with principles for economic analysis and rational decisionmaking, and with its statutory responsibilities. EPA should therefore explicitly justify its current approach not as a reweighing of factors, but rather as correcting the SAFE 2 Rule's distorted approach, which had broken from best practices and decades of regulatory precedent.58 Justifying the rule as following the proper approach, rather than just as a reweighing of factors, will give the rule a stronger, more durable foundation.

The Clean Air Act requires EPA to give 'appropriate consideration to the cost of compliance.'59 But when EPA tried to balance the SAFE 2 Rule's costs and benefits in 2020, it found that the rollback's net effects at best 'straddle[d] zero' or were 'directionally uncertain,' depending on the choice of discount rate; in fact, the analysis conducted at a 3% consumption-based discount rate showed that the rollback would result in billions of dollars in net costs.60 EPA therefore explicitly admitted that it could not rely on its cost-benefit analysis to justify the rollback.61 By instead increasing the 'weight' ascribed to upfront costs in order to justify the rollback,62 EPA correspondingly decreased the weight given to longer-term benefits, including fuel savings and environmental gains. But embellishing upfront costs by diminishing long-term cost savings and other effects was not an 'appropriate' consideration of costs: it violated best economic practices and decades of regulatory precedent.

In economic terms, the weight assigned to upfront versus long-term effects is determined by the discount rate.63 As the SAFE 2 Rule acknowledged, ascribing a high discount rate to consumers' valuations of future fuel savings can influence results such that fuel savings will appear not to outweigh the consumers' opportunity cost of purchasing a model with higher fuel economy.64 Yet the SAFE 2 Rule offered no persuasive theory or evidence for why consumers would selectively apply a much higher discount rate to fuel savings, let alone why society should excessively discount fuel savings.65

In promulgating the SAFE 2 Rule, EPA and NHTSA speculated without adequate support that perhaps fuel economy upgrades entailed some unidentified technology tradeoffs that resulted in hidden opportunity costs for consumers, allegedly causing consumers to discount the value of future fuel savings.66 But as Policy Integrity detailed in our 2020 report Shortchanged: How the Trump Administration's Rollback of the Clean Car Standards Deprives Consumers of Fuel Savings,67 the agencies failed to marshal adequate theoretical or empirical support for such speculations.68 Many fuel economy technologies increase performance,69 and even if manufacturers may occasionally reduce select vehicle features like weight to achieve an inexpensive boost to fuel economy, such compliance choices would significantly decrease regulatory costs in ways that the agencies did not account for in the SAFE 2 Rule.70 Given that consumers can access financing at relatively low rates to purchase additional fuel-economy technologies that will pay for themselves, there is no justification to assume that—absent market failures—rational consumers would apply exceedingly high discount rates selectively just to future fuel savings.71

Though the SAFE 2 Rule's main cost-benefit analysis did fully value fuel savings,72 the agencies' justification for the costly rollback departed from those findings. EPA wrongly claimed in 2020 that a full consideration of fuel savings 'distorts the comparison,' and the agency inappropriately focused on ‘upfront vehicle technology costs’ by assuming that consumers may rationally choose ‘to buy a new vehicle at a lower up-front price even if that vehicle will incur a more-than offsetting level of fuel costs over its lifetime.’73 This approach to balancing the factors broke from decades of prior regulatory practice of acknowledging the existence of market failures and consistently considering the full energy savings of regulatory actions.74 Ultimately, EPA got its conclusion entirely backwards in the SAFE 2 Rule: overly discounting the long-term benefits of vehicle standards is what ‘distorts’ the analysis, by ignoring an important factor.

Case law supports that it was not appropriate for the SAFE 2 Rule to overly discount future cost savings in a way that disproportionately weighted upfront costs while effectively ignoring much of the longerterm effects. As the Supreme Court ruled in Michigan v. EPA, it is unreasonable to read a statutory reference to ‘appropriate’ as ‘an invitation to ignore’ a key effect; instead, ‘[c]onsideration of cost reflects the understanding that reasonable regulation ordinarily requires paying attention to the advantages and the disadvantages of agency decisions.’75 Courts similarly have faulted agencies for ‘put[ting] a thumb on the scale by undervaluing the benefits and overvaluing the costs of more stringent standards,’76 and for ‘inconsistently and opportunistically fram[ing] the costs and benefits’ of regulatory action.77 By placing a thumb on the side of upfront costs and opportunistically ignoring longterm benefits, the SAFE 2 Rule fell far short of the statutory instructions to give ‘appropriate consideration to the cost of compliance’ and balance that factor against public welfare.78

By applying appropriate discount rates to the consideration of costs and benefits and selecting a policy choice that will deliver net benefits and advance the Clean Air Act’s purpose, EPA is now correcting the SAFE 2 Rule’s departure from best economic practices and from an appropriate balancing of statutory factors. EPA should justify its approach not as a reweighting of factors, but rather as correcting the SAFE 2 Rule’s distorted approach, which had broken from best practices and decades of regulatory precedent. [EPA-HQ-OAR-2021-0208-0299-A1, pp. 9-11]

As Executive Order 12866 requires, agencies should identify the specific market failures or other problems that their rules address and assess the significance of the problems.83 [EPA-HQ-OAR-2021-0208-0299-A1, p. 12.]

EPA’s Return to Its Prior Estimate of Rebound Effect Is Appropriate. While EPA and NHTSA previous relied on a 10% rebound estimate in the Clean Car Standards issued in 2012, the agencies used a 20% rebound estimate in the final SAFE 2 Rule in 2020.132 The agencies’ departure from prior practice in the SAFE rulemaking was arbitrary and capricious, and EPA’s return to 10% in the proposal here is more consistent with the best available evidence.

To arrive at the new estimate in the SAFE 2 Rule, the agencies in 2020 made significant changes to their assumptions about the magnitude of the rebound effect. These changes resulted in a significant increase in the costs and fatalities that the agencies attributed to the baseline standards.133 Those fatalities and costs helped serve as the agencies’ justification for the misguided 2020 rollback of those standards.134 But the agencies’ methodological changes in the

2018 SAFE proposal and 2020 final SAFE 2 Rule were inconsistent with the best available evidence regarding rebound.

Policy Integrity provided comments during the SAFE rulemaking demonstrating that EPA and NHTSA's selection of a 20% value for rebound effect was arbitrary and capricious.135 By restoring the value of rebound effect to 10%, consistent with the agency's practice prior to the SAFE rulemaking, EPA has improved the accuracy of the CCEMS model for this rulemaking by using a value supported by an appropriate meta-analysis of the academic literature.136

As Policy Integrity noted in comments on the SAFE proposal, EPA and NHTSA failed to adequately explain their departure from a 10% rebound effect. The agencies ignored studies that supported a lower rebound value, including studies relied upon by the agencies in the past and new studies published since the prior rulemaking.137 Overall, the agencies failed to present sufficient evidence in 2020 to support abandoning its prior use of a 10% rebound effect.138

In contrast, EPA has now conducted an updated and rigorous literature review that more fully presents the large body of academic literature on the rebound effect.139 This literature review includes studies that were previously considered by the agencies but ignored in the SAFE rulemaking, including Greene (2012),140 Wang and Chen (2014),141 and Gillingham (2016);142 studies that Policy Integrity recommended the agencies consider in the SAFE rulemaking, including Gillingham (2015)143 and Wenzel and Fujita (2018);144 and studies published after the SAFE rule was finalized, including Knittel and Sandler (2018),145 Gillingham and Munk-Nielsen (2019),146 and Gillingham (2020).147

Most importantly, EPA has now evaluated the available economic literature to determine which studies were most relevant to the proposed standards, weighting the analysis based on geographic/timespan relevance, time period of study, reliability/replicability, and strong statistical/methodological basis.148 In the SAFE rulemaking, the agencies calculated a simple average from the arbitrarily incomplete set of studies they considered—a flawed methodology, inconsistent with EPA's own guidelines for reaching conclusions using multiple studies, that led to an improperly inflated rebound effect.149 As Policy Integrity noted in previous comments, a meta-analysis focusing on closely matched studies—as EPA has done in the Proposed Rule—is a much more rigorous approach to evaluate results based on multiple studies.150

In addition, EPA has now offered several specific reasons why the agencies' prior rebound estimate of 20% are likely overstated. First, consumers' total VMT (vehicle miles traveled) may be more responsive to sharp increases in fuel prices as compared to the gradual decrease in fuel costs-per-mile that will result from these proposed standards, and therefore any rebound effect resulting from the standards may be smaller than some historical estimates of rebound based on price fluctuations.151 Second, consumers are likely to respond less to small changes in their costs per mile traveled as they become wealthier, and total U.S. GDP is projected to increase over time based on the latest projections.152 Together, these two considerations further suggest that an estimate of 10% or lower is appropriate, whereas the 20% estimate was much too high. And while EPA could not quantify the possible indirect and economy-wide rebound effects due to limited data,153 such effects are likely small and, to the extent they exist, they may be offset by the two consumer response factors discussed above. [EPA-HQ-OAR-2021-0208-0299-A1, pp. 19-20.]

In the regulatory proposal underlying the SAFE 2 Rule, EPA and NHTSA projected that the price elasticity for new car and light truck sales ‘ranged from -0.2 to -0.3’—meaning, in other words, that a 1 percent increase in sticker price would decrease sales by only 0.2–0.3 percent.162 Yet in the final Safe 2 Rule, the agencies abruptly rejected their earlier elasticity estimate and drastically increased the price elasticity more than three-fold. The agencies claimed that the price elasticity for new vehicles was -1—meaning that new car sales would decline by 1 percent for every 1 percent increase in sticker price.163 But the agencies offered minimal justification for this substantial revision. And by making this change in the final rule, the agencies did not provide an opportunity for comment.164

Policy Integrity provides these comments now to urge EPA not to rely on the overly conservative estimate of demand elasticity from the SAFE 2 Rule. The agency should instead conduct a full review of the relevant economic literature, which confirms that vehicles are currently an inelastic good in the long run—with a price elasticity far below -1 in absolute terms.

After EPA and NHTSA abruptly changed the demand elasticity in the final SAFE 2 Rule, Policy Integrity issued a report reviewing the relevant literature.165 As further explained in this report, the SAFE 2 Rule erroneously relied on short-run estimates of demand elasticity even though long-run estimates are more appropriate for standards that apply several years into the future,166 and even though the agencies used long-run estimates of other inputs elsewhere in their rule analysis.167 Table 1 (see appendix) demonstrates that EPA’s continued use of -1 is overly conservative compared to the most current literature. [Table 1 can be found at docket number EPA-HQ-OAR-2021-0208-0299, p. 25]

The estimate chosen for sales elasticity has a significant impact on EPA’s analysis, as it directly influences the dynamic fleet share model’s projection of sales and scrappage impacts and fleet size, thus affecting key projections such as criteria pollutant and greenhouse gas emissions.168 By continuing to use the conservative demand elasticity from the SAFE 2 Rule, EPA may be undervaluing the net benefits of its new proposed standards by as much as $10 billion.169 [EPA-HQ-OAR-2021-0208-0299-A1, pp. 22.]

Commenter: International Council on Clean Transportation

Table 4 compares technology penetration levels between the SAFE final rule (1.5% annual CO2 reductions) and the proposed rule. To match the modeling inputs used by EPA for the proposed rule, the comparison uses the sensitivity case with HCR2 available in the SAFE final rule for 2030 (FRIA Table VI-473, page 1777).31 Compared with the SAFE rule technology penetration for the HCR2 sensitivity case, the proposal increases HCR penetration by 7% and strong hybrids by 3%, but turbocharger penetration decreases by 13% and cylinder deactivation by 9%. Overall, it appears the proposed rule has little impact on pulling additional conventional technology into the fleet compared with the SAFE rule. Most of the CO2 reductions from the SAFE rule to the 2023+ proposal appear to be due to the 4.3% increase in PHEVs+BEVs combined with the multiple credits for PHEVs and BEVs and the other credit provisions adopted in the proposed rule. [EPA-HQ-OAR-2021-0208-0522-A1, p. 18; The tables can be found on p. 16 of Docket number EPA-HQ-OAR-2021-0208-0522-A1]

Commenter: International Union, United Automobile, Aerospace & Agricultural Implement Workers of America (UAW)

The Environmental Protection Agency's Revised 2023-26 Model Year (MY) Light-Duty Vehicle Greenhouse Gas (GHG) Emissions Standards by and large strike the right balance of continuing to reduce automotive GHG emissions and encourage automakers to invest in new technologies that will benefit autoworkers and the economy. In addition, UAW does not support the current SAFE Vehicles Rule put in place by the previous administration for a variety of reasons. The SAFE Rule threatened to disrupt the 'One National Program', creating uncertainty for the industry. Uncertainty undermines long-term investment. It also puts the U.S. auto industry at risk of falling behind on advanced technology vehicles and sustainable innovation, at a time when other nations were promoting increased efficiency and lower emissions. The SAFE Rule inadvertently posed risk to the U.S. economy, the domestic auto industry, our members, our retirees, and the communities that rely on a thriving auto industry. [EPA-HQ-OAR-2021-0208-0749-A1, p. 1]

Commenter: Kreucher, Walter

EPA does not have the authority to circumvent the clear meaning of the statute that prevents anyone other than the Secretary of Transportation from setting standards related to vehicle fuel economy or authorizing California to do so. Further, the proposed rule includes dedicated and dual fueled vehicles contrary to Federal statute and therefore must be withdrawn. In addition, the proposal uses arbitrary and capricious assumptions and will not provide the benefits predicted. [EPA-HQ-OAR-2021-0208-0199-A1, p. 1]

EPA is free to regulate GHGs from fuels, buildings, refineries, powerplants, and a host of point sources. It does not possess the authority to regulate GHGs from automobiles and trucks, an authority granted exclusively to the Department of Transportation. There is simply no reasonable explanation why two Federal Agencies should issue standards that regulate the same thing1. Carbon dioxide regulation is fuel economy regulation by another name as clearly acknowledged in the SAFE Rulemaking. This 'fundamental and unnecessary complication in the currently-existing regulatory framework' must cease immediately and EPA must abandon its carbon dioxide standard which by the Agencies own admission in the Supplemental Environmental Impact Analysis attached to the proposal will not impact global mean temperature, sea levels, or ocean acidity. [EPA-HQ-OAR-2021-0208-0199-A1, pp. 2-3]

By statute, only the Secretary of the Department of Transportation can regulate vehicle fuel economy. Once the Secretary issues a rule (or declines to issue more stringent standards), all other proposals and final rules related to vehicle fuel economy are void ab initio as the issuing entity does not possess the statutory authority to issue such rules. Such rules include any vehicle greenhouse gas standards and alternative or dual fuel vehicle mandates issued by EPA or any state. [EPA-HQ-OAR-2021-0208-0199-A1, p. 10]

Neither EPA nor NHTSA offers any new science that would compel a change in the stringency of the CAFE standards or greenhouse gas standards, especially one under ‘unusually condensed’ timing.

There have been no new studies since the prior rulemaking. No evidence is presented on technological breakthroughs in support of the proposals. The only thing that changed are the Administrators of the agencies.

Political ideology is not science. The will of the Administrators is not a reason for changing a rule. Instituting a rule change (or withdrawing a previous rule) because of political ideology is the definition of arbitrary and capricious rulemaking. [EPA-HQ-OAR-2021-0208-0199-A1, p. 14]

Commenter: Lucid USA, Inc. (Lucid)

EPA has the authority under the Clean Air Act (Title II, Part A) to establish nationwide ZEV requirements. Under Section 202(a) of the Clean Air Act, EPA 'shall by regulation prescribe (and from time to time revise) … standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles … which may reasonably be anticipated to endanger public health or welfare.' 42 U.S.C. § 7521. The Agency 'has clear authority to set standards under CAA section 202(a) that are technology forcing when EPA considers that to be appropriate,' 74 Fed. Reg. 49,454, 49,464–6 (Sep. 25, 2009). A national ZEV program would be a technology forcing program contemplated by § 202(a). [EPA-HQ-OAR-2021-0208-0528-A1, p.6]

Commenter: Minnesota Pollution Control Agency (MPCA) and Minnesota Department of Transportation (MnDOT)

Under the Clean Air Act, and in particular section 202(a), Congress charged EPA with protecting the public’s 'health' and 'welfare.' In light of EPA’s statutory purpose, it is entirely reasonable and consistent with congressional intent for EPA to place greater weight on the benefits of reducing harmful emissions over other factors, such as costs and lead time, that the agency considers when setting motor vehicle emission standards. Thus, the MPCA and MnDOT support EPA’s decision to change the position taken in the SAFE rule and return to its previous approach of placing greater weight on the magnitude and benefits of reducing emissions that endanger public health and welfare, while continuing to consider compliance costs, lead time, and other relevant factors. [EPA-HQ-OAR-2021-0208-0211-A1, p.3]

Commenter: National Coalition for Advanced Transportation (NCAT)

EPA’s Authority Under Clean Air Act Section 202(a). Clean Air Act Section 202(a)(1) directs EPA to promulgate standards for emissions of air pollutants from any class or classes of new motor vehicles or new motor vehicle engines which cause or contribute to air pollution that may reasonably be anticipated to endanger public health or welfare.3 Following the Supreme Court's decision in Massachusetts v. EPA, 549 U.S. 497 (2007), holding that GHGs are within the Clean Air Act's definition of "air pollutant", id. at 528- 29, EPA in 2009 issued an Endangerment Finding for GHGs.4 This finding obligated EPA to set GHG emissions standards for motor vehicles,5 which EPA has promulgated for light-duty vehicles in multiple rulemakings. 6 EPA jointly promulgated those prior rules setting GHG emissions standards along with NHTSA's rules governing corporate average fuel economy standards under NHTSA's separate Energy Policy and Conservation Act authority. However, no federal law or regulations require EPA to take such a joint approach. Rather, EPA's authority under Clean Air Act Section 202(a) fully supports the approach that EPA sets forth in this Proposed Rule to independently promulgate GHG standards.

EPA considers several factors when setting vehicle emission standards under Clean Air Act Section 202(a). These standards are technology-based and are premised on a finding of technological feasibility.7 Relatedly, EPA considers the lead time for the standards. See 42 U.S.C. § 7521(a)(2) (standards must take effect after the period EPA "finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period."). EPA has interpreted Section 202(a) to allow the agency to set technology-forcing standards.8 EPA must also consider the cost to entities directly subject to the standards.9 EPA considers safety in setting standards, and Clean Air Act Section 202(a)(4) prohibits use of emissions controls to comply with the standards if they "will cause or contribute to an unreasonable risk to public health, welfare, or safety in its operation or function."10

EPA's Prior Rulemakings Setting MY 2023-2026 GHG Standards. In 2012, EPA issued a final rule setting light-duty vehicle GHG emissions standards for MY 2017–2025 (2012 Rule) based on a robust technical record. In the 2012 Rule, EPA also promulgated regulations providing for a mid-term evaluation process through which EPA, before April 1, 2018, would determine whether the vehicle GHG emissions standards established for MY 2022-2025 are appropriate in light of the record before the EPA at that time.11 In November 2016, based on the technical assessment report, public comments, and the record before the agency, EPA issued a proposed determination that the MY 2022-2025 standards remained appropriate under CAA Section 202(a).12 In January 2017, EPA issued a final determination confirming the MY 2022-2025 standards were appropriate and would be maintained going forward.13 Then, following the change in Administration, EPA decided to reconsider the standards set in the 2012 Rule.14 In July 2020, EPA issued a final rule revising the MY 2021–2025 standards (2020 Rule) to significantly reduce their stringency, and EPA also issued a new standard for MY 2026.15

Shortly after EPA's 2020 Rule was finalized, NCAT, along with multiple groups of stakeholders—including States, air districts, public interest organizations and other industry stakeholders—challenged EPA's actions in the 2020 Rule as arbitrary and capricious and unlawful. 16 In briefing, NCAT explained how the agencies' treatment of electric vehicles and related technologies demonstrates that the 2020 Rule rollbacks are arbitrary and capricious. NCAT's brief is attached as Exhibit A to these comments [Exhibit A can be found at Docket number EPA-HQ-OAR-2021-0208-2039-A2] . These consolidated cases are currently being held in abeyance, pending the outcome of EPA's rulemaking process for the Proposed Rule (and NHTSA's separate proposed rulemaking).17 [EPA-HQ-OAR-2021-0208-0239-A1, p. 2-4]

EPA's GHG emissions standards incentivize and support investment in the development and deployment of electric vehicles, other advanced low-emission and zero-emission vehicles and the infrastructure to support them. Federal vehicle standards have helped drive investment in electric vehicle manufacturing and technology because performance standards incentivize manufacturing vehicles with lower GHG and criteria pollutant emissions and provide a mechanism by which vehicle manufacturers that deploy innovative technologies and out-perform the standards can earn and sell tradeable compliance credits. Federal standards also play a key role in catalyzing major infrastructure and economic development plans. Accordingly, EPA's reduction in the stringency of the standards in the 2020 Rule adversely affected the marketplace for transportation electrification and deployment of advanced vehicle technologies and supporting infrastructure across the country, undermining the important work and investments of manufacturers and infrastructure companies, including utilities and electric vehicle service providers. EPA's longerterm GHG emissions standards for MY 2027 and beyond will play an important role by providing benchmarks to give manufacturers, state air agencies, public utility commissions and consumers a sense of long-term clarity, as discussed further in Section VII below.

NCAT membership includes U.S. manufacturers of all-electric vehicles that are sold across the U.S., and thus are subject to EPA's standards. NCAT members also include companies engaged in electricity generation, transmission and distribution that supports electric vehicles and companies involved in manufacturing, deploying, and operating electric vehicle charging infrastructure. NCAT's members collectively have invested, or are in the process of investing, billions of dollars in manufacturing electric vehicles and deploying charging-related infrastructure. NCAT members are making those significant investments and implementing long-term business strategies, in large part, to support the implementation of vehicle GHG emissions regulations. The regulations and resulting investments will stimulate technology innovation and market competition, enable consumer choice, attract private capital investments, and create high quality jobs.

Electric vehicles and other advanced technology vehicles and supporting infrastructure play a critical role in supporting U.S. global competitiveness, economic growth, energy security, and cost-effective protection of public health and environmental quality. To remain a leader in the global automotive market, the U.S. must continue to support policies that encourage adoption of electric and other advanced technology vehicles and related infrastructure to serve the needs of American consumers. The U.S. electric vehicle market has grown and is expected to continue substantial growth into the future. See Section IV, A, 1 and 3. Electric vehicle battery costs have continued to decline, reducing the cost of electric vehicles relative to other vehicles. See Section IV, A, 4. Charging infrastructure providers continue to expand charging networks across the country and utilities are investing in the grid and transportation electrification infrastructure programs to support and complement those efforts. See Section IV, B. NCAT supports EPA adopting strong standards that continue to advance electric vehicle deployment and infrastructure investment. [EPA-HQ-OAR-2021-0208-0239-A1, p. 4-5]

Commenter: New York State Department of Environmental Conservation

New York supports EPA's proposal to remove the multiplier incentives for natural gas vehicles for MYs 2023-2026 previously provided under the SAFE Rule. [EPA-HQ-OAR-2021-0208-0238-A1, p.3]

New York urges EPA to adopt the rule to revise existing national greenhouse gas emission standards for passenger cars and trucks through model year 2026. The SAFE rule relaxed the stringency of the standards, ignored established science and technologies, and will result in increased greenhouse gas emissions as well as regulatory uncertainty for the automotive industry. [EPA-HQ-OAR-2021-0208-0238-A1, p.3]

Commenter: Northeast States for Coordinated Air Use Management (NESCAUM)

Placing Greater Weight on Emission Reduction Benefits Is Appropriate Under the Clean Air Act. Under the Clean Air Act, and in particular section 202(a), Congress charged EPA with protecting the public’s 'health' and 'welfare.' In light of EPA’s statutory purpose, it is entirely reasonable and consistent with congressional intent for EPA to place greater weight on the benefits of reducing harmful emissions over other factors, such as costs and lead time, that the agency considers when setting motor vehicle emission standards. Thus, NESCAUM concurs with EPA’s decision to reject the position taken in the SAFE Vehicles Rule and return to its previous approach of placing greater weight on the magnitude and benefits of reducing emissions that endanger public health and welfare, while continuing to consider compliance costs, lead time, and other relevant factors. [EPA-HQ-OAR-2021-0208-0259-A1, p. 4]

Commenter: Ohio Attorney General Office, et al.

Ohio and 15 other States submit these comments in opposition to the notice of proposed rulemaking entitled, 'Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards,' set forth at 86 Federal Register [EPA-HQ-OAR-2021-0208-0258-A1, p.1]

The proposed rule is transparently outcome driven, not the product of reasoned decisionmaking. The EPA repeatedly acknowledges that, in developing the proposed rule, it considered California uniquely. But California’s unconstitutional favoritism under the Clean Air Act, and attempted domination of federal policy, is not a valid basis for promulgating nationwide emissions standards. Moreover, the proposed standards rest on an overly speculative cost-benefit analysis and entirely fail to consider how reliance on China for raw materials and manufacturing will harm our national security. The proposed rule should be withdrawn [EPA-HQ-OAR-2021-0208-0258-A1, p.1]

A California partnership is not a valid basis for establishing nationwide carbon emission standards. When the EPA released its proposed rule, the White House released congratulatory statements from stakeholders—automakers, auto worker unions, climate activists, and California. 'We look forward to continuing our decades-long collaboration with federal partners to build on California's clean car leadership and deliver the investments needed to support the nationwide build-out of clean vehicle infrastructure,' Governor Newsom provided.[2] No other State is included in this partnership: not, for example, Ohio, which ranked first in car production in 2018,[3] Kentucky, which has the highest light-vehicle production per capita,[4] or Michigan, which leads the nation in auto-manufacturing jobs [5].

The proposed rule emphasizes throughout the outsized role California played in creating the proposed standards. The EPA 'coordinated extensively with the California Air Resources Board,' as it developed the proposal.[6]'California has long been a partner in reducing light-duty vehicle emissions, often leading the nation by setting more stringent standards before similar standards are adopted by EPA.'[7].

Indeed the EPA attempts to color its proposal as reasonable given existing automaker behavior pursuant to California's Framework Agreements.[8] It boasts: 'the California Framework Agreements were a key consideration in our development and assessment of the proposed EPA standards.'[9] The only reason California was able to establish 'Framework Agreements' upon which the EPA heavily relies is due to the possibility that California would regain its waiver of preemption under section 209(b)(1) of the Clean Air Act, allowing California, and only California, to set emissions standards that are more stringent than those adopted by the federal government.[10] The Framework Agreements, signed by BMW, Ford, Honda, Volvo, and Volkswagen, are largely premised on these automakers' belief, or at least uncertainty, that California would again hold outsized regulatory power through a section 209(b) waiver.[11] [EPA-HQ-OAR-2021-0208-0258-A1, p.2]

Unsurprisingly, then, the EPA has proposed standards that closely resemble the California Framework projected targets.[12] [EPA-HQ-OAR-2021-0208-0258-A1, p.3]

Section 202(a) of the Clean Air Act requires the EPA to establish national standards for emissions of pollutants from new motor vehicles which cause or contribute to air pollution which may reasonably be anticipated to endanger public health or welfare.[13] The EPA must consider technological feasibility[14] and costs to regulated entities.[15] The EPA may consider other factors reasonably allowed by Congress, like safety issues.[16] But no reasonable interpretation of the statute allows California, and California alone, to be a factor in setting national motor-vehicle emissions standards. And an agency rule is arbitrary and capricious where it 'relie[s] on factors which Congress has not intended it to consider.' Motor Vehicle Mfrs. Ass'n v. State Farm Mut. Auto. Ins. Co., 463 U.S. 29, 43 (1983). [EPA-HQ-OAR-2021-0208-0258-A1,p.3]

The EPA engages in this illegitimate partnership with California given California's special status under section 209 of the Clean Air Act. But Section 209(b)(1) violates the doctrine of equal-sovereignty—a doctrine inherent in our Constitution and express in Supreme Court precedent—by allowing California to exercise sovereign authority that the Act takes from every other State. This unequal treatment is unconstitutional, full stop. Because section 209(b) is unconstitutional, and because the EPA has embedded unequal treatment into its proposed rule, any final rule based on the EPA proposal is arbitrary, capricious, and contrary to law [EPA-HQ-OAR-2021-0208-0258-A1, p.3]

The Constitution and Supreme Court precedent require States to be treated as equal sovereigns. As just explained, the EPA's proposed rule rests largely on the idea that California has unique authority to regulate air quality under the Clean Air Act. The Act does indeed say that, in Section 209(b)(1). But the Act's special treatment of California violates the Constitution. And the EPA cannot reasonably rely on California's ability to wield unconstitutional power over her sister States.

The United States of America 'was and is a union of States, equal in power, dignity and authority, each competent to exert that residuum of sovereignty not delegated to the United States by the Constitution itself.'[17] This 'constitutional equality' among the States,'[18] derives from the Constitution's text and structure. [EPA-HQ-OAR-2021-0208-0258-A1, p.3]

Indeed, the principle is so deeply embedded in our constitutional order that the Supreme Court treats the States' sovereign equality as a 'truism.'[19] The equal-sovereignty of the States is one of those principles that, while 'not spelled out in the Constitution,' is 'nevertheless implicit in its structure and supported by historical practice.'[20] [EPA-HQ-OAR-2021-0208-0258-A1, p.4]

In using California's super-sovereign authority as a basis for the proposed rule, the EPA relied on a statute that is not even constitutional. It is inherently arbitrary and capricious, and contrary to law, to adopt a standard predicated on an unconstitutional law. [EPA-HQ-OAR-2021-0208-0258-A1, p.6]

If Congress intended for California's waiver to dictate national standards, it would have said so. Even if California exceptionalism were appropriate under our federalist system, the EPA has the appropriate inquiry exactly backwards. Under the proposed rule, California sets its desired emissions policy, and then the federal government seeks to conform. But under the statute, California may only be granted a waiver if the EPA determines its standards are 'at least as protective of public health and welfare as applicable Federal standards.'[46] This scheme shows that EPA must make its determination first—finalizing a national standard that is protective of air quality, feasible, and reasonable—and then, after it has established a standard, consider any proposals from California.

This ordering makes sense, especially because giving California special treatment up front has concrete negative effects in other States when it comes to carbon emissions. Conforming with carbon-emission standards requires vehicle manufacturers to make 'changes to the entire vehicle.'[47] Because car manufacturers make only one national fleet, whatever standard California invents becomes the national standard. This means the vehicles available to Ohioans are not governed by Ohio's standards or the Federal government's standards, but rather by California's standards. That not only offends the Constitution, but it makes bad policy. [EPA-HQ-OAR-2021-0208-0258-A1, p.6]

Ohio and California have different key industries, different commuting patterns, and different access to alternative fuel stations, and reasonably need different vehicles or different timelines to transition to new vehicles. [EPA-HQ-OAR-2021-0208-0258-A1, p.7]

Where the EPA considers the States equally in setting standards, it can assess feasibility in the manner Congress intended. Where it considers California at the outset, all other States are cut out, it creates an irrational policy that favors certain States in a manner Congress never intended [EPA-HQ-OAR-2021-0208-0258-A1, p.7]

The Clean Air Act was designed to 'protect and enhance the quality of the Nation's air resources.'[75] Since that time, technological advances from American innovators have worked to create a 78 percent drop in criteria and precursor pollutants, all while our economy remained strong.[76] But rather than advance this positive trend, the proposed rule attempts to please California, which remains the single most problematic State in attaining National Ambient Air Quality Standards.[77] The EPA has disbanded its mission of improving the air Americans breathe, and focused instead on receiving international recognition for climate leadership.[78] In doing so, it has left consumers, manufacturers, our Constitution, and American security behind. [EPA-HQ-OAR-2021-0208-0258-A1, p.11]

Commenter: Platt, Keari

With such a large impact on overall GHGs, it is wise for the EPA to target LDVs. Requiring automakers to reduce GHG emissions from LDVs will reduce the nation's overwhelming contribution to global emissions and climate change impacts. [EPA-HQ-OAR-2021-0208-0201-A1, p. 2]

Commenter: South Coast Air Quality Management District

While the proposal acknowledges the 2020 SAFE rulemaking 'significantly weakened' standards established in 2012, 86 FR at 43726, it notably omits mention that the SAFE rule was also profoundly arbitrary and capricious. Still today, that action faces legal challenges (currently in abeyance) rightly demanding its judicial invalidation. Aside from the outlandish legal defects, the SAFE rule, along with its lead-up maneuvering, was profoundly damaging to the trajectory of transportation emissions reductions that are needed to protect public health and welfare. History will take note of these points whether or not EPA should, in this regulatory action, squarely admit to the many fatal errors both procedural and substantive that pervaded the SAFE rule. At minimum, however, EPA should make clear when it states it is merely 'reaching a different conclusion,' see 86 FR at 43729, or implies that is merely weighing or balancing statutory factors differently than in the SAFE rulemaking, see 86 FR at 42786, that it is not substantively engaging with that action's many serious allegations of error, nor (despite carrying forward aspects of the technical record) is it purporting to substantively defend any of those choices. EPA should at least acknowledge the superficial irregularities of the SAFE rule lest it be credited as precedential. Anything less glosses over what was a deeply flawed rule record. [EPA-HQ-OAR-2021-0208-0215-A1, p.2]

Moving on, the South Coast AQMD applauds this proposal for putting the Clean Air Act (CAA) back to work and bringing these important standards on track. As graphically represented inFigure 1, 86 FR 43732, the current proposal stands to mitigate much of the damage made by the SAFE rule, while reinstating and recapturing much of the benefits that EPA had long ago and sensibly expected to materialize in its 2012 rule for light-duty vehicles. [EPA-HQ-OAR-2021-0208-0215-A1, p.2]

EPA errs in conflating its statutory role under section 202(a)(4)(A) with its accounting of estimated 'safety' impacts in terms of 'changes in vehicle scrappage, fleet turnover, and VMT.'

The proposal terms safety a relevant consideration. 86 FR at 43279. EPA must be cautious in carrying forward or normalizing the erroneous approaches on this subject set out in the SAFE rule. When EPA states it 'currently believes it is more appropriate to consider the risk of injuries per mile traveled,' 86 FR at 43786, it appears to suggest there was a semblance of appropriateness to how the SAFE rule purported to address vehicle safety. This is not correct or supportable. EPA could not in the SAFE rule or now in this proposal cite Clean Air Act section 202(a)(4)(A)—addressed to how EPA must handle safety-compromising design elements—as justification for its study of changes in the use of vehicles in the fleet or the turnover of the fleet to newer vehicles. While these may be allowable topics of study in terms of Executive Order compliance, they are not legally or analytically valid 'vehicle safety' considerations for purposes of setting standards. Even for the case of relative mass changes or 'mass reduction as a technology option,' see 86 FR at 43793, EPA should acknowledge that issue is only, arguably4 statutorily pertinent in regard to whether there may be some 'unreasonable risk' under the prescribed factors of section 202(a)(4)(B). But EPA nowhere in this proposal or in the prior SAFE rule addresses that provision. Instead, and regrettably, in the proposal's section titled 'Safety Considerations in Establishing GHG Standards,' 86 FR at 43793, EPA gratuitously remarks four times that it is being 'consistent' with the SAFE rule. The District objects to EPA's perpetuation of an amorphous, overarching safety consideration. This is both analytically sloppy and it papers over the cynical branding behind EPA's 'SAFE' rule that was beset with disingenuous and faulty safety claims. EPA should not finalize this proposed approach without first examining whether these supposed 'relevant' 'considerations' in 'establishing… standards' are backed by any prior implementation history,5 deemed valid by any prior judicial precedent, or are consistent with Congressional direction.6 EPA must acknowledge it only has a proper basis for considering aspects of 'safety' in setting standards when there is a basis in the statutory text and purpose or when it is backed by judicial precedent. [EPA-HQ-OAR-2021-0208-0215-A1, pp.5-6]

4 EPA is empowered to set regulations based on classes or categories, including gross vehicle weight. See CAA section 202(a)(3)(A)(i). Thus, merely having a vehicle with lower mass is arguably not any kind of cognizable "risk" for purposes of section 202(a)(4)(A).

5 Any search for 202(a)(4)(A) in the Federal Register should confirm it is not.

6 There is particularly no warrant for fleet turnover arguments. This supposed safety concept as a basis for standard setting is proved illogical by transplanting the same argument to the

hypothetical of an agency charged to set new vehicle safety standards. If, for example, both airbags and antilock brakes would be reasonable safety additions to vehicles, there should be no argument that the safety benefits of the first-intime required feature takes such precedence that boosting scrappage and turnover is more important than having, as Congress directs, overall optimal safety in new vehicles.

Commenter: Southern Environmental Law Center

Under the Trump administration, EPA substantially weakened GHG emissions standards for light-duty vehicles for model years 2021 through 2026 (the SAFE Rule). This was a significant step back for the U.S. in its efforts to address the climate crisis and protect public health, since the transportation sector is the largest source of GHG emissions nationally—as well as in most of the South—and emissions from light-duty vehicles account for a majority of that pollution. The Biden administration announced its intention to review the weakened standards on its first day in office, and has since put forward ambitious plans to promote cleaner vehicles. In August, EPA released its proposed rule to establish more stringent GHG emissions standards for light-duty vehicles. We welcome this proposal, and urge EPA to adopt the strongest standards possible under the Clean Air Act.[EPA-HQ-OAR-2021-0208-0244-A1, p. 1]

While these stronger standards would still not entirely close the cumulative GHG reduction gap between the SAFE Rule and the 2012 Rule, they are closer than the current proposal and it is critical that EPA make up this lost ground as quickly as possible. [EPA-HQ-OAR-2021-0208-0244-A1, p. 2]

EPA should adopt the strongest possible tailpipe GHG emissions standards under the Clean Air Act. [EPA-HQ-OAR-2021-0208-0244-A1, p.2]

For these and many other reasons, immediate and decisive action is needed to reduce U.S. GHG emissions. Tailpipe emissions standards are one of the most important tools available given the significant contribution of light-duty vehicles to GHG emissions. EPA should adopt the strongest possible standards under the Clean Air Act. The current proposal, however, leaves attainable GHG emissions reductions on the table. The proposed standards do not reach the compliance targets from the 2012 Rule until after model year 2025, even though the 2012 Rule[17] and subsequent 2017 Midterm Evaluation [18] provided ample justification for these more aggressive CO2 targets—despite the fact that these analyses were conducted at a time when GHG- reducing and EV technologies were more expensive and less widely available. The evidence supporting more stringent emissions standards has only grown stronger.

The pace of introduction of clean vehicle technologies has increased rapidly and the EV and PHEV manufacturing and sales landscape is quite a bit more advanced than when the 2012 Rule was promulgated. In part, decreasing costs are helping to make EVs more common. In 2010, lithium-ion battery packs cost over $1,000 per kilowatt hour (kWh); today the battery packs cost roughly $125 per kWh.[19] Hybrid EVs accounted for only about 2.4 percent of vehicles sales in model year 2015, but that figure jumped to approximately 6.5 percent of vehicle sales by model year 2020.[20] By the end of 2024, almost 100 EV and PHEV models are expected to be available to consumers.[21] Almost every major vehicle manufacturer in the U.S. has launched, or is in the process of launching, an EV line and many have publicly stated ambitious EV and PHEV manufacturing and sales goals.[22] Furthermore, as explained by EPA in its Regulatory Impact Analysis (RIA), vehicle manufacturers are believed to remain largely on track to meet the 2012 standards due to the multi-year nature of the vehicle development process.[23] [EPA-HQ-OAR-2021-0208-0244-A1, pp. 3-4]

EPA Response

EPA appreciates the comments in support of final standards as stringent or more stringent than the proposed standards, and EPA's decision to restore emissions reduction to the center of its decision making on light duty GHG standards, while at the same time taking into account cost of compliance and lead time, and considering other relevant factors. EPA disagrees with the suggestion that it is required to set standards that maximize net benefits, as calculated in the RIA. EPA is not required to take such an approach under section 202(a) of the Clean Air Act, and has not taken this approach in the past. Rather, EPA has considered the need for reductions of emissions to reduce pollution that endangers public health and welfare, and the cost of compliance and lead time. As discussed in the preamble, EPA has presented an analysis of benefits and costs in the RIA, including sensitivity analysis to examine how much results might be higher or lower than the quantified values we present. EPA seeks continually to revise and improve its methods for costs and benefits, with the updates since the SAFE rule described in the RIA.

American Fuel and Petroleum Manufacturers commented that EPA and NHTSA should be harmonizing their standards, and that EPA cannot finalize standards more stringent than NHTSA's because it would frustrate Congressional intent in the passage of the fuel economy provisions of EPCA. Similarly, other comments state that NHTSA has the sole statutory authority to regulate fuel economy.

EPA disagrees with these comments. As the Supreme Court has explicitly recognized, EPA and NHTSA have distinct sources of authority and distinct responsibilities to the public: "EPA has been charged with protecting the public's 'health' and 'welfare,' 42 U.S.C. § 7521(a)(1), a statutory obligation wholly independent of DOT's mandate to promote energy efficiency. See Energy Policy and Conservation Act, § 2(5), 89 Stat. 874, 42 U.S.C. § 6201(5)."[75] Thus, EPA considered it well-settled that the agency has authority to regulate greenhouse gas emissions from light duty vehicles separate and apart from NHTSA's authority to regulate fuel economy.

The Supreme Court further concluded that "there is no reason to think the two agencies cannot both administer their obligations yet avoid inconsistency."[76] EPA agrees that this is possible, and it has been and continues to be an important principle of EPA's light duty GHG program. However, EPA disagrees that in order to avoid inconsistency it is necessary for the agencies to

[75] *Massachusetts v. EPA*, 549 U.S. 497, 532 (2007).
[76] *Id.*

conduct joint rulemaking[77] or that the standards must be identical. Indeed, as the commenter appears to recognize, the programs have never been identical. For example, EPA's program allows credits for air conditioning refrigerant leakage which reduce hydrofluorocarbon (HFC) emissions, allows unlimited credit trading between car and truck fleets, provides multipliers for EVs and other advanced technologies, and regulates additional GHGs including methane and nitrous oxide. The NHTSA program has none of those features, but does have a backstop standard based on domestic manufacturing content and allows for payment of fines as a means of compliance, which are features not found in EPA's program. EPA does not believe these differences, which in many cases are directly attributable to differences in statutory authority between the agencies, result in "inconsistency" between the program, although in some cases they might result in automakers having a slightly different compliance strategy for each program. EPA concludes that a continuation of an approach where the agencies coordinate while adopting standards that are consistent with their respective statutory authorities is the best means of each agency complying with Congressional direction, and is not inconsistent with either EPCA or the Clean Air Act. Growth Energy and AFPM commented that EPA should conduct life cycle analysis (LCA) for fuel and vehicle production. AFPM asserted that LCA is required under the CAA. EPA disagrees that it is required to perform a life cycle analysis of vehicle and fuel production before setting vehicle standards, or to treat emissions of air pollutants attributable to electricity generation, or the mining, production or disposal of batteries for electric vehicles, as emissions "from" new motor vehicles. The Clean Air Act's entire structure evidences a clear divide between stationary sources (regulated under Title I) and mobile sources (regulated under Title II). There may be indirect impacts of stationary source regulation on mobile sources and vice versa, and it may be appropriate to consider those impacts in some circumstances, but it would be inappropriate and contrary to the plain text of the Clean Air Act to conflate the consideration of indirect impacts, when appropriate, with actually treating stationary source emissions as mobile source emissions. *Cf. Coal. for Responsible Regul., Inc. v. E.P.A.,* 684 F.3d 102, 128–29 (D.C. Cir. 2012), *aff'd in part, rev'd in part sub nom. Util. Air Regul. Grp. v. E.P.A.*, 573 U.S. 302 (2014), *and amended sub nom. Coal. for Responsible Regul., Inc. v. Env't Prot. Agency*, 606 F. App'x 6 (D.C. Cir. 2015) ("EPA was not arbitrary and capricious by not considering stationary-source costs in its analyses"). Congress directed EPA to address emissions from manufacturing fuels and vehicles under EPA's authority to reduce pollution from stationary sources and to address emissions from the operation of light duty vehicles under its authority to reduce pollution from mobile sources. It would be contrary to the purpose of the Clean Air Act if EPA declined to adopt otherwise-appropriate standards to reduce emissions from new light duty vehicles because additional reductions in pollution could be, but had not yet been, achieved by refineries, electric generating units, or vehicle manufacturers (due to vehicle production facilities). EPA interprets the Clean Air Act as directing EPA to consider regulation of emissions for each sector according to the applicable statutory requirements for each program. Congress has established and EPA intends to continue to undertake regulation of GHG consistent with those statutory requirements.

[77] See Preamble section II.A.8

With respect to consideration of the indirect impacts, it is neither feasible nor required under the Clean Air Act for EPA to estimate every indirect environmental effect of these standards, such as changes in material from steel to aluminum, or the environmental effects of additional mining of minerals to be used in battery manufacturing. Moreover, EPA finds the result of life cycle analyses depend heavily on the scope of the analysis and the data available assessed. For example, one commenter (Ingevity) cited a study that relied on outdated data with respect to road load reduction, Li-ion battery energy density, and the energy sources either currently used within the U.S. electric grid or near-term electric generation energy source trends. As a result, the cited 2016 ANL study predicts average conventional internal combustion engine (ICE), CNG, HEV, BEV90, and BEV210 life cycle GHG emissions to be approximately 350-450, 320-370, 240-345, 250-300, and 250-440 gCO_{2e}/mi, respectively. A more recent analysis based on more recent vehicle data from the 2020 EPA Trends Report, and more recent energy source data from the 2020 International Energy Agency - World Energy Outlook, shows life cycle BEV GHG emissions of 100-160 gCO_{2e}/mi, less than half that of the older ANL study despite an assumption of increased BEV range within the more recent study.[78,79,80]. The commenter (Ingevity) also cites a MECA analysis of natural gas vehicle GHG emissions, however only provided isolated data tables without either a copy of the study or a citation that would allow review of the study's methodology. Such a review would be crucial for determining whether or not the study included a full accounting of factors of critical importance to NGV life-cycle GHG emissions, such as fugitive methane emissions during extraction, refining, compression, and end-use. The GHG life-cycle emissions for BEVs within the table from MECA analysis also conflict with the life-cycle emissions from ANL study also cited by the commenter (Ingevity). BEV life cycle emissions within the table from the MECA analysis are only one-third to one-half of those cited within the ANL analysis. EPA's decision to not include the emissions associated with battery production, as the commenter recommends, is based on our current assessment of existing LCA studies, and the degree of uncertainty in the study results relative to magnitude of the impact on overall emissions. EPA is not making any determination here about the potential value of LCA for informing standards in the future, and we will continue to monitor further developments in LCA studies on the impacts of battery production.

Consistent with its past practice, EPA has sought to identify and consider the most significant indirect impacts for consideration, such as the impact of the rebound effect on production and distribution of fuel. Thus, EPA is not ignoring the upstream effects of these standards on fuel production (whether petroleum fuel or electricity). EPA has taken into consideration in setting the standards the RIA's estimated effects of the rule on reduced petroleum and increased electricity production. In fact, to monetize the $PM_{2.5}$-related impacts of upstream emissions, we apply BPT values that were developed for the refinery and electric generating unit (EGU) sectors. However, EPA is not required to structure standards in a particular way to reflect those anticipated effects, e.g., by revising the 0 g/mile provision for EVs, and EPA concluded in light

---

[79] U.S. EPA. The 2020 EPA Automotive Trends Report - Greenhouse Gas Emissions, Fuel Economy, and Technology since 1975. EPA-420-R-21-003, January 2021.

[80] International Energy Agency. (2020). World energy outlook 2020. http://www.iea.org/weo

of the ongoing industry shift towards electrification it is reasonable to maintain that provision at least as a transition provision for the model years at issue here. Altering EPA's approach to setting standards to attempt to assess a full lifecycle analysis taking into consideration fuel and vehicle production is beyond the scope of this rulemaking.

Americans for Prosperity asserted that since this is not a joint rulemaking with NHTSA, EPA violated CAA 307(d) by not docketing materials related to interagency coordination. EPA agrees that this rulemaking is subject to the provisions of section 307(d) of the Clean Air Act,[81] and is not a joint rulemaking with NHTSA. EPA disagrees, however, that it has violated the docketing provisions of section 307(d)(4)(B)(ii) related to comments received from other agencies. That provision requires, in part, docketing of written comments from other agencies on drafts of proposed rules submitted to the Office of Management and Budget (OMB) for any interagency review process prior to proposal. Nothing in that provision requires EPA to document discussions or docket any written comments arising out of consultations with NHTSA during the period when EPA was identifying and considering options for the proposal, or undertaking initial steps to draft a proposal, before EPA management concluded the draft was ready for submission to OMB. In fact, docketing such communications (when not required by section 307(d)) would be contrary to well-established principles concerning intragovernmental consultation, which is entitled to the protection of the deliberative process privilege to encourage full and frank discussion among agencies. Thus, it is entirely consistent with section 307(d) and proper for EPA to consult with NHTSA informally, to ensure coordination of the two agencies' programs, but not docket those discussions that occurred prior to interagency review. In addition, EPA did docket all written comments of other agencies (including NHTSA) that it received through the interagency review process, together with all written responses by EPA to those comments.

EPA disagrees with the assertion made by Americans for Prosperity that EPA relied "almost entirely on EPA's vehicle standards finalized in 2012 and the voluntary commitments of five automakers as the justification for compliance costs and lead time." As explained at greater length in the preamble and RIA, EPA relied on a significant technical record, including data about technologies currently deployed in the vehicle fleet and modeling about manufacturers' ability to adopt additional emissions reduction strategies for their fleets, as well as the structure of the program, incorporating important flexibilities such as averaging, banking and trading across the entire fleet, to reach its conclusions about compliance costs and lead time for this rulemaking. EPA does believe the 2012 standards are relevant, in light of automotive design cycles and the model years covered by the 2012 rule and this rule. EPA recognizes that automakers were under no legal obligation to enter into the California Framework Agreements, but the Agreements demonstrate an ability and intention by those automakers to meet more stringent standards than the SAFE 2 standards, which is likewise relevant. However, particularly in light of EPA's decision to adopt more stringent standards in this rule, the 2012 standards and the national targets under the California Framework Agreements were confirmatory to, rather than necessary elements of, EPA's analysis of lead time and compliance costs.

[81] See Section VIII.K of the preamble.

EPA also disagrees with the comment from Walter Kreucher that a change in Administration is an insufficient basis for EPA to change course, provided we acknowledge the change in course and provide good reasons for it, as we have done in Preamble VI. *See e.g, FCC v. Fox Television Stations, Inc.*, 556 U. S. 502 (2009).

EPA acknowledges the comment from the California Attorney General's Office that each model year of standards should be severable. EPA recognizes that the earlier model years for which we are setting standards will have relatively less lead time than the later model years, and finds that even in the absence of revised standards for one or more earlier model years, we would still adopt these final standards for the other model years, because there is sufficient lead time to meet those later standards (and if earlier model year standards were not revised it would only increase automakers' ability to generate and bank credits for use in compliance with later standards). Likewise, although EPA intends to undertake a subsequent rulemaking for MY2027 and beyond, EPA is setting these standards based on its assessment of appropriate standards for each of the model years 2023 through 2026 and the appropriateness of the earlier standards is not dependent on the later standards, or on EPA's upcoming rulemaking.

SCAQMD asserted that EPA has conflated statutory requirements under CAA section 202(a)(4)(A) with our projected safety impacts in terms of 'changes in vehicle scrappage, fleet turnover, and VMT'. In response, EPA acknowledges that the requirements of section 202(a)(4)(A) are not so broad as to include changes in vehicle purchase, ownership, and use decisions, but instead are more narrowly defined to evaluate an whether an 'unreasonable risk' to safety in the vehicle operation or function is caused or contributed to by an 'emission control device, system, or element of design.' We have concluded that no device, system, or element of design adopted for the purposes of complying with these standards will impact vehicle operation or function in such a way as to increase risk.

The CAA does not, however, preclude EPA from considering safety more broadly for the purpose of our benefit-cost analysis, as we describe in Preamble VII.H and RIA 5.3. While we recognize that not all metrics for characterizing safety should be given weight in promulgating standards under section 202, in our estimation of societal costs of fatal and non-fatal injuries we include consideration of any changes in risk that are projected due fleet mix changes and the relative mass differences between vehicles in collisions, and the ownership and operation of vehicles, including changes in scrappage decisions. We also include societal impacts that arise from changes in VMT due to the rebound effect, and the associated increase in projected fatal and non-fatal injuries, which are mostly offset by the societal value of that additional driving.

EPA acknowledges the comments from Institute for Policy Integrity (IPI) and the South Coast Air Quality Management District relating to errors in the SAFE rule. IPI comments that EPA should identify the market failures that this rule addresses. The primary market failure that this rule is addressing is GHG emissions, a classic case where the private benefits and costs of controlling emissions do not match the societal benefits and costs. Other market failures appear to exist, such as the failure of private markets to provide all the fuel-saving technologies that pay for themselves; we discuss those in Preamble VII.A, RIA 8.1.1, and Section 17 of the RtC, and find that the rule provides net benefits from provision of increased fuel economy.

EPA disagrees with comments from the Ohio Attorney General Office characterizing "the outsized role California played in creating the proposed standards" (and a similar suggestion from Americans for Prosperity that the proposed rule places undue emphasis on the California Framework Agreements). It is true that EPA consulted with California in considering options for the draft proposed rule, because many stakeholders expressed interest in having a "national" program, where automakers can plan to produce the same vehicle fleet and meet the applicable standards in all 50 states. In addition, as discussed in the preamble and this RTC, EPA considered the national targets under the California Framework Agreements relevant, but not dispositive, for its assessment of feasibility and lead time considerations. However, the decision about what standards to adopt was made by the Administrator based on his judgment about what standards were appropriate under Section 202(a), in light of emissions reductions, cost of compliance, lead time, and other relevant factors.

EPA also disagrees with the commenter's apparent suggestion that EPA should not consider the benefits of a potential national ("50 state car") program during the rulemaking because section 209(b) is unconstitutional. It is well-established that administrative agencies lack the authority to find statutory provisions unconstitutional. *See, e.g., Johnson v. Robison*, 415 U.S. 361, 368 (1974). Moreover, EPA does not believe that allowing California to exercise its police powers to address its longstanding and continuing "compelling and extraordinary conditions" disadvantages any state. In fact, the ability to adopt California standards has benefited many states by offering low cost means of achieving emissions reduction and attaining National Ambient Air Quality Standards without creating an unworkable patchwork of state requirements.

Commenter: Allen, Martin

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 24.] I'm going to speak to you about my personal experiences as an electric vehicle owner and the issues of upfront costs, range anxiety, and a need for improved infrastructure. [The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 25-26.] Range anxiety. Did I have range anxiety? Oh, yeah, I have range anxiety. Did I get over it? Yes, very quickly. I live in the Watchung Hills, New Jersey, and we get some inclement winter weather here. So a four-wheel drive vehicle was a requirement. My EV, which has dual motors, is set by me to get approximately 250 miles on a complete charge, and I can get over 300 miles fully charged. I charge my car around once or twice a week. I installed a Level 2 240-volt charge in my garage in my townhome house at a cost of less than $300. I get a full charge at home in around six hours, but I almost never charge from zero at home. Let me tell you a story how I got over range anxiety. Soon after getting my electric vehicle, I went on vacation and parked my car at the airport. On the way to the airport, I discovered that I had less than 60 miles left of estimated charge. What if the estimate was wrong? What if there wasn't sufficient charge to get home?

So when I left the airport, I put on the standard regenerative braking, slowed my speed, used my brakes probably a bit more frequently than I would have normally, and I arrived at home with an estimated miles of more than what I started with. As for quick charging stations, I have used a couple and within 15 or 20 minutes, any short coffee break, my car has been fully charged. I'm over anxiety, no more range anxiety.

EPA Response

EPA appreciates the commenter’s positive experience with EV range. As more charging infrastructure is developed, concerns over range anxiety are expected to ease.

Commenter: Alliance For Automotive Innovation

Helping consumers bridge near-term cost premiums with purchase incentives

There is much uncertainty regarding EV price parity with internal combustion engine (“ICE”) vehicles, and while some segments may achieve this earlier than other segments, we do not expect this to occur prior to 2030 for some more popular segments and likely later for others. Many consumers may be unable, or simply unwilling, to shoulder the higher upfront cost premiums. Purchase incentives help to close the price gap and drive EV sales. A study by Resources For the Future finds that federal income tax credits resulted in a 29 percent increase in EV sales.13 Federal, state, and local governments have the opportunity to put in place rebates and other incentives to drive market share for electric vehicles.

With the goal of significantly increasing the number of EVs on the road, purchase incentives should fully apply to the broadest range of vehicles and be available to the broadest range of consumers. Incentives should be applicable to vehicles produced by all manufacturers (including by raising or eliminating the current per-manufacturer cap), non-discriminatory between companies, and widely available to preserve consumer choice as more EVs come to the market across all models and price points. [EPA-HQ-OAR-2021-0208-0571-A1, p. 5]

Continued actions and commitments by automakers to improve the availability, variety, and affordability of EVs in the United States Manufacturers are on pace to debut almost 100 pure electric models by the end of 2024.

Metrics and milestones that align with nationwide EV sales targets

For the nine above action items, development of specific metrics to track progress and identify milestones linked to EV sales targets will be critical. This will ensure the necessary conditions for success are being developed and provide federal, state, and local governments with guidance on policies and funding needed to expand electrification across the nation. [EPA-HQ-OAR-2021-0208-0571-A1, p. 6]

Private Fuel Savings
The CAFE Compliance and Effects Modeling System ("CAFE Model") assumes manufacturers will adopt technologies, absent regulation, that pay for themselves within 2.5 years of vehicle ownership. Overall, given that the existing body of evidence about consumer valuation of fuel economy does not reach definitive findings, a sensitivity-analysis approach to the 2.5-year payback period may be warranted.

Payback Period

The largest category of benefits in the rulemakings is private fuel savings for motorists.

The amount of private fuel savings due to the standards should be based on a proper baseline characterization of the amount of fuel-saving innovation in ICE vehicles that will occur if the MY 2024-2026 vehicles are not subject to stricter standards. The Agencies have recognized this issue. The RIAs assume that innovations that pay for themselves within 2.5 years of vehicle ownership will be implemented by manufacturers voluntarily and are therefore incorporated into the baseline fleets from MYs 2024-2026.

NHTSA asks for comment on whether, instead of making this 2.5-year assumption, it should assume that the new technologies will be channeled by automakers to accomplish further improvements to performance, on the assumption that consumers value the performance gains even more than the net-beneficial fuel savings.[172] Under this scenario, all the innovation-related gains in fuel economy and GHG reduction would be assigned to the stricter standards, and none to market forces.

Auto Innovators urges caution on this point because the Agencies have not yet developed a practical analytic approach to value the private (hedonic) benefits of performance (or the opportunity costs of foregone performance gains from stricter standards). Unless and until the agencies are prepared to quantify the monetary value of performance as well as fuel savings, then an analytic move in the posited direction seems premature. Moreover, the current 2.5-year payback assumption is consistent with the reality that consumers are heterogenous (some strongly value performance, others value fuel economy, and still others value both to various degrees). And the current assumption captures the reality that the typical consumer does not account for anything close to 15 years of fuel savings when they compare alternativemodels with respect to price, fuel savings and other important attributes.

On the other hand, Auto Innovators recognizes that there is uncertainty as to whether 2.5 years is the best approximation of a complicated set of consumer and manufacturer perceptions, as explained by the Agencies in the CAFE and GHG NPRM preambles, in the NHTSA and EPA RIAs, and by the National Academies.[173] Auto Innovators supports sensitivity analysis of alternatives to the 2.5-year point estimate, possibly as low as one year and as high as four years.

A recent analysis by economists at Resources for the Future ("RFF"), which relies primarily on revealed-preference studies of changes in fuel prices, suggests that a somewhat longer payback period is supportable.[174] The RFF analysis is worthy of consideration.

The RFF analysis does not consider the stated preference studies that provide a basis for the 2.5 year estimate and that were cited by the National Research Council in 2015 and by the Agencies in previous rulemakings. One of the advantages of the stated-preference approach is that study designs can directly address consumer reaction to new technologies; the findings of the revealed preference studies are more difficult to interpret. They may offer more insight about consumer reaction to changes in fuel prices than to changes in technologies.[175] A well- known weakness of the stated-preference approach is that consumer responses to hypothetical questions are not necessarily validated when those same consumers make decisions in the marketplace.

Overall, given that the existing body of evidence about consumer valuation of fuel economy does not reach definitive findings, a sensitivity-analysis approach to the 2.5-year payback period is warranted.

Both EPA and NHTSA recognize fuel savings as significant in the benefit-cost analysis. These fuel savings accumulate to consumers based on assumed prices of fuel, fuel efficiency for combinations of technologies, and travel over the lifetime of the vehicle. Each analysis recognizes that independent of regulations, consumers will adopt fuel saving technologies that pay back quickly.180

We suggest that the Agencies also consider "attribute substitution" affects (wherein households buy and use vehicles with differing fuel economy attributes to suit their needs, e.g., a large SUV and a midsize car) in the consideration of rebound.

The Agencies have not yet incorporated another type of rebound effect, sometimes called "attribute substitution", which occurs at the vehicle purchasing stage and may also occur when households make decisions about which vehicles to use on trips (e.g., urban versus rural trips, and short trips versus long trips).

Some balancing of vehicle attributes occurs in households without any regulatory inducement. If a household owns a relatively fuel-efficient small car, they may be inclined to purchase a minivan or large SUV as their second vehicle. In Norway, households with a fully battery-operated electric vehicle – the dominant propulsion system in the market -- sometimes purchase a luxurious diesel-powered car or a premium PHEV as their second vehicle.191

As emerging economics literature suggests that attribute substitution could somewhat diminish the effectiveness and cost-effectiveness of NHTSA's CAFE standards, EPA's GHG standards and other policies aimed at boosting the fuel economy of the new-vehicle fleet.192 When regulations induce households to own a more fuel-efficient vehicle or an advanced technology vehicle, households may choose to "trade" (balance) some of the enhanced fuel economy in their new vehicle for more performance, safety, seating space, cargo space or towing capability in their next vehicle purchase. This "attribute" substitution occurs in multi- vehicle households, which account for about 75% of the households that purchase new passenger vehicles in the US.

In a long-term setting where all vehicle types are becoming more fuel efficient, the magnitude of attribute-substitution effects is attenuated. However, the U.S. faces at least a 15- year transition process, but possibly as much as 30-year, where households will be owning at least one electric vehicle and at least one internal combustion engine vehicle that could range from a small car to a pickup truck or large SUV. [EPA-HQ-OAR-2021-0208-0116]

EPA Response

EPA agrees that purchase incentives would likely speed the adoption of EVs. That said, it is not within EPA's purview to provide purchase subsidies. EPA believes the expanded variety in offerings of EVs by automakers will increase their suitability for more vehicle buyers, and thus also increase EV adoption. EPA will monitor sales of EVs as part of its compliance program.

EPA has conducted extensive analysis of the role of fuel costs in the vehicle purchase decision. Although there is no consensus on the value, the modeling in CCEMS that assumes 2.5 years of fuel consumption in the purchase decision, as discussed in Preamble Section VII.A. and RIA Chapter 8.1.1, is on the low end of the distribution of estimates of consumer valuation of reduced fuel consumption. For these reasons, EPA considers its evaluation of the impacts of the standards on vehicle purchases to be reasonable, or conservative. EPA has not conducted a sensitivity assessment of this value due to the way it is coded in CCEMS.

As discussed in RIA Chapter 8.1.1, EPA finds very wide ranges of estimates for the willingness of vehicle buyers to pay for fuel economy and for performance. EPA agrees that it is premature to incorporate the value of performance in the benefits until research is more conclusive about these values. EPA agrees that the RFF analysis cited by the Alliance is worthy of consideration within the larger literature.

Regarding attribute substitution, EPA's reviews of literature on consumer vehicle demand have found great variation in results, even among studies considered very high quality.[82] Thus,

[82] See, e.g., Helfand, G., and Wolverton, A. (2011). "Evaluating the Consumer Response to Fuel Economy: A Review of the Literature." International Review of Environmental and Resource Economics 5: 103-146; Doremus, J., et al. (2019). "Simpler is better: Predicting consumer vehicle purchases in the short run." Energy Policy 129: 1404-1415; Greene, D., et al. (2018). "Consumer Willingness to Pay for Vehicle Attributes: What Do We Know?" Transportation Research Part A 118: 258-279.

Archsmith et al. (2020)[83] may suggest an important aspect of household vehicle choice, but it is unlikely to be the last word on the topic. In addition, as the authors themselves note, “we readily acknowledge that households may be substituting an attribute that is correlated with fuel intensity, such as size or power, and not fuel intensity itself” (p. 4). That is, while their study analyzes fuel intensity, it may actually be studying households that prefer to have portfolio of different-sized vehicles, or vehicles with different power. For these reasons, EPA does not consider it appropriate to rely on this study alone to examine the effects of household attribute substitution.

Commenter: American Enterprise Institute (AEI)

The inclusion of fuel savings — roughly twice as large as the purported environmental benefits — is illegitimate as an economic benefit of a proposed regulation. [EPA-HQ-OAR-2021-0208-0254-A1, p. 5]

Fuel savings. The conceptual purpose of any proposed regulation is the correction of some set of purported inefficiencies inherent in market allocational outcomes, usually assumed to result from some social resource or other cost not reflected in market prices. This is the standard definition of an externality. (I shunt aside here the issue of whether government can be predicted to adopt policies yielding systematic allocational improvement.) Fuel savings themselves represent no such divergence between market prices and resource costs apart from the climate effects (discussed below) and other such assumed impacts not reflected in market prices. Accordingly, fuel savings are not relevant analytically, for reasons addressed immediately below, and the EPA methodologically is engaged in an obvious exercise in double counting in the Proposed Rule by including both asserted fuel savings and reductions in purported externalities created by fuel consumption.

Even shunting that observation aside, the inclusion of fuel savings is illegitimate as a component of the ‘benefits’ of the Proposed Rule because the economic benefits of fuel savings are captured fully by consumers of fuels. There is no ‘externality’ attendant upon fuel consumption per se, and if ‘fuel savings’ are to be considered relevant for purposes of benefit/cost analysis, then the adverse effects or costs of a (forced) reduction in fuel consumption must be included in the analysis. The EPA claims that the fuel savings attendant upon implementation of the Proposed Rule would yield a benefit stream through 2050 the present value of which is between $120 billion and $250 billion. That the Proposed Rule would force consumers of fuels to change their consumption patterns in ways that would not be observed without the Proposed Rule demonstrates that the ‘fuel savings,’ even if we accept the underlying calculations, must be accompanied by some explicit or implicit costs, which in turn must be greater than the value of the purported fuel savings. That obviously is why we do not observe the allocational outcomes

[83] Archsmith, J., K. Gillingham, C. Knittel, and D. Rapson (2020). “Attribute Substitution in Household Vehicle Portfolios.” https://econjim.com/pdf/WP/HHPort/HHPort.pdf , accessed 11/12/2021.

envisioned in the Proposed rule as a result of market forces. Why does market behavior not yield the fuel economy parameter for the vehicle fleet envisioned in the Proposed Rule?

In order to see this clearly, suppose that the Proposed Rule were simply to outlaw entirely the use of motor fuels by cars and light trucks, forcing consumers massively to use bicycles, horse-drawn carts, and similar substitutes backward as a technological matter. It is no answer to say that electric vehicles and the like would be substituted without loss of value in terms of consumption value; the fact that such technologies have not been adopted by markets in the aggregate, even given the subsidies embedded in current policies, demonstrates that these technologies must impose some set of disadvantages in terms of costs and/or performance. The data reported by the Energy Information Administration show that in 2019 expenditures on motor gasoline alone in the transportation sector were about $357 billion.15 Under the EPA methodology, that 'fuel saving' in total would be an annual benefit of such a hypothetical rule outlawing the use of motor fuels, and the disadvantages of bicycles, horse-drawn carts, and the like — the marginal benefits of using motor vehicles — would be irrelevant. Under the methodology underlying the Proposed Rule, the more stringent the constraint imposed upon fuel use, the greater the benefit from 'fuel savings.' Amazingly, this is the analytic framework underlying this part of the estimated benefits asserted in the Proposed Rule. It is not to be taken seriously. [EPA-HQ-OAR-2021-0208-0254-A1, pp. 5-6]

EPA Response

AEI asserts the market for fuel economy operates efficiently, and thus has no externality or other market failure; if the present value of fuel savings exceeds the technology costs, it states, then there must be "some explicit or implicit costs" associated with those technologies. AEI does not provide evidence to support this assertion.

EPA has been monitoring this area of concern since previous LD GHG rulemakings and in the Midterm Evaluation. In addition to regularly updating our estimates of technology costs and fuel savings, EPA has conducted several studies (discussed in RIA Chapter 8.1.1) that examine whether there are "explicit or implicit" (hidden) costs associated with the technologies, in addition to the financial costs. The statistical evidence for new technologies producing hidden costs is, at best, weak; in fact, fuel-saving technologies show positive associations with desirable operational characteristics far more often than they have negative associations. On that basis, as discussed in Preamble Section VII.A. and RIA Chapter 8.1.1, EPA concludes that there is in fact a failure in the market for fuel economy: there seem to have been existing fuel-saving technologies that were not commonly included in new vehicles previous to the standards that, after they were adopted, proved to have reasonable payback periods and did not reveal significant adverse effects. In other words, private markets previously failed to provide these technologies, and vehicle buyers have experienced fuel savings and not suffered known adverse effects with their adoption. This conclusion is based on the factual record rather than economic theory.

Neither EPA nor scientific literature has yet come to a conclusion on the cause of this failure. As discussed in Preamble VII.A. and RIA Chapter 8.1.1, a number of hypotheses have been suggested for both consumer and producer behavior that might contribute to this phenomenon, such as consumer undervaluation of fuel consumption and first-mover disadvantage for producers. The evidence to date is inconclusive as to which effects in fact contribute to under-adoption of cost-effective fuel-saving technologies. The studies that have sought to estimate consumer willingness to pay for fuel economy, for instance, have produced a very wide range of findings, including significant undervaluation, close-to-perfect valuation, and some overvaluation. Thus, this hypothesis remains unproven, as do others.

It is therefore appropriate for EPA to include the reduced fuel consumption resulting from our final standards in the benefit-cost analysis (BCA). The BCA compares the costs and fuel consumption in the absence of the standards with the costs and fuel consumption in the presence of the standards. This "with/without" comparison is standard in BCA; OMB Circular A-4, for instance, directs agencies "to measure the benefits and costs of a rule against a baseline. This baseline should be the best assessment of the way the world would look absent the proposed action."[84] If there were evidence of hidden costs of the technologies, EPA agrees that it would be appropriate to include those costs in the BCA. In the absence of such evidence, though, EPA considers it appropriate to value such costs at zero.

In sum, EPA considers its estimates of the technology costs and fuel savings to be appropriate, and its estimates of zero for "explicit or implicit" costs to be based on the best available evidence.

Commenter: American Fuel & Petrochemical Manufacturers (AFPM) et al

EPA Overstates the Benefits of the Rule, Particularly EVs

The proposed rule does not explicitly mandate any specific vehicle technology, however, EPA acknowledged that the stringency of the proposed standard would result in automobile manufacturers including about 8 percent EVs (including plug-in hybrids) in their fleets. Moreover, the President issued Executive Order 14037 on the same day as this proposal, 'setting a goal that 50 percent of all new passenger cars and light trucks sold in 2030 be zero-emission vehicles, including battery electric, plug-in hybrid electric, or fuel cell electric vehicles.' As such, the Agency must take special care to appropriately calculate the costs and benefits of the EVs in this rule.

According to EPA, the proposal would save American drivers $120 to $250 billion in fuel costs through 2050.29 EPA also notes that '[b]ecause the use of vehicles varies widely across vehicle owners, another way to estimate the effects of the standards is to examine the 'break even' number of miles—that is, the number of miles driven that would result in fuel savings matching the increase in up-front costs.'30 EPA calculates the aggregate value of fuel savings that result

---

[84] Office of Management and Budget (2003). "Regulatory Analysis," section E.2. https://obamawhitehouse.archives.gov/omb/circulars_a004_a-4/#e , accessed 11/10/2021.

from reductions in fleet-wide fuel use and include rebound effects, credit usage, and advanced technology multiplier use. However, research shows EVs and ICEVs are not perfect substitutes, and EVs are driven substantially fewer miles than comparable ICEVs, which EPA ignored in its calculations. Without considering this real-world implication, the Agency arbitrarily overstates avoided tailpipe emissions and potential fuel savings. [EPA-HQ-OAR-2021-0208-0286-A1, p.5]

A recent National Bureau of Economy Research (NBER) study finds that EVs are being driven less than half the annual miles driven by conventional cars, which undermines assumptions that the technology will replace a vast majority of trips currently using gasoline.35 The study finds that EVs are driven just 5,300 miles per year, less than half the average ICEV. This single omission could result in the Agency arbitrarily doubling any estimated avoided emissions. Assuming reductions in emissions based on the faulty premise that EVs are driven the same distance as ICEVs distorts the cost-benefit analysis, including total carbon emissions reductions and the fuel savings calculations. Policymakers must have a more complete picture about EVs before costly and irreversible commitments are made to the technology as the primary solution to decarbonizing transportation.36

Further research shows EV-owning consumers tend to buy larger second cars, potentially wiping out substantial fuel efficiency savings (and carbon reductions). 37 According to recent research by professors from Yale, MIT, and the University of California-Davis (UC-Davis), even consumers who have already bought EV vehicles are less likely to choose another EV vehicle as an additional car.38, 39 The Yale, MIT, and UC-Davis study used long-term data tracking households over several vehicle replacements, and found that “attribute substitution” is a common phenomenon where households buy an additional vehicle with very different attributes than the first vehicle (the “kept vehicle”).40 For example, a household may choose to prioritize cargo space or the need to be able to travel long distances over fuel economy if it already owns an electric car. Attribute substitution has: a large countervailing effect on the fuel economy of the newly purchased vehicle. For example, in our preferred specification, increasing the fuel economy of the kept vehicle by 10 percent results in a 4.8 percent decrease in the fuel economy of the purchased vehicle.41 The authors observed “significant changes in usage patterns that further reduce the net fuel savings” through increases in mileage for both vehicles that “erodes over 60% of the fuel savings from the fuel economy increase of the kept vehicle on net….”42 Attribute substitution introduces a new and previously unaccounted for phenomenon that reduces the effectiveness of higher fuel economy standards or EV mandates. EPA does not account for attribute substitution in its proposal, but should do so to more accurately quantify the benefits of the proposal. [EPA-HQ-OAR-2021-0208-0286-A1, pp.6-7]

29 This indicates that EPA recognizes this rule is related to fuel economy and should be led by NHTSA.

36 Moreover, it is notable that the above-referenced study evaluates EVs in the State of California (where more than 50% of U.S. EVs are located). Because the study does not include any colder climates, where EV performance degrades materially during winter months, it likely overestimates the average miles driven per EV in the U.S. Other studies that claim to show

higher EV miles traveled include EVs used for commercial business and cannot be considered by EPA as representative of the typical EV.

EPA Response

The Burlig et al. paper,[85] cited as evidence that EVs are driven less than ICE vehicles, uses data from the 2017 National Household Transport Survey. As noted in Chakraborty et al. (2022),[86] EVs in the 2017 NHTS, excluding Tesla, commonly had maximum range of 70-80 miles; many recent EVs have ranges greater than 200 miles. In contrast to Burlig et al., Chakraborty et al. (2022) find that EVs in California are driven about the same as ICE vehicles, displaying neither rebound effects nor range anxiety. This latter study is based on data from 2019 in California. EPA agrees that how EVs are used matters for estimates of emissions impacts, but we disagree that the Burlig et al. study should be the basis of estimates for EV VMT. Indeed, a news article about the paper[87] quotes Burlig as saying, "The fleet in 2017 is not the same as the fleet in 2021. . . . I'm not trying to say that we are predicting the future, but I do think it's important to understand what EV driving has looked like." The Chakraborty et al. study, using more recent data better reflecting improved EV ranges, suggests that EPA's assumption of EVs and ICE vehicles having similar VMT is a reasonable starting point.

Regarding attribute substitution, EPA's reviews of literature on consumer vehicle demand have found great variation in results, even among studies considered very high quality.[88] Thus, Archsmith et al. (2020)[89] may suggest an important aspect of household vehicle choice, but it is unlikely to be the last word on the topic. In addition, as the authors themselves note, "we readily acknowledge that households may be substituting an attribute that is correlated with fuel intensity, such as size or power, and not fuel intensity itself" (p. 4). That is, while their study analyzes fuel intensity, it may actually be studying households that prefer to have portfolio of

different-sized vehicles, or vehicles with different power. For these reasons, EPA does not consider it appropriate to rely on this study alone to examine the effects of household attribute substitution.

In sum, EPA's regulatory analyses rely on a broader range of literature than just the two studies cited by AFPM, and EPA believes it is inappropriate to rely specifically only on these two studies.

EPA agrees that vehicle greenhouse gas emissions affect vehicle fuel consumption, and thus incorporates those effects in its benefit-cost analysis. Nevertheless, the purpose of the rule, as discussed in Preamble Section I.A., is "revised, more stringent national greenhouse gas (GHG) emissions standards for passenger cars and light trucks under section 202(a) of the Clean Air Act (CAA), 42 U.S.C. §7521(a)."

Commenter: California Attorney General Office, et al.

The costs of these technologies are reasonable (and, in some cases, are declining), and the application of these technologies generally results in consumers saving money over the life of a new vehicle because the fuel savings substantially exceed the costs to consumers of the applied technology. [EPA-HQ-OAR-2021-0208-0245-A1, p.1]

Many of these offerings have been extraordinarily successful, with some models even completely selling out.129 These successes can be attributed, at least in part, to consumer demand for features of these vehicles that are unrelated to their GHG-reducing attributes, such as rapid acceleration, electric power output for use at remote sites or in emergencies, and increased horsepower.130 They can also be attributed, again in part, to shareholder demands.131 Automakers can, and to some extent must, continue to expand these offerings to respond to those demands, and these offerings (and their popularity) support more stringent standards as early as MY2023. [EPA-HQ-OAR-2021-0208-0245-A1, pp.27-28]

<u>EPA Response</u>

EPA agrees that EVs provide desirable attributes unrelated to their GHG-reducing attributes, and that these attributes will contribute to their adoption. EPA also agrees that the costs of EVs are expected to fall over time, increasing their financial acceptability.

Commenter: Center for Climate and Energy Solutions (C2ES)

Zero-emission vehicles represent a powerful economic opportunity for both U.S. manufacturers and vehicle owners and operators. Although average upfront vehicle costs currently remain higher for zero-emission vehicles than their combustion-engine counterparts, recent analysis projects up-front costs of electric vehicles to reach parity with internal combustion engine vehicles as early as 2025.6 Even with higher up-front costs, maintenance costs of zero-emission vehicles are up to 40 percent lower on a per-mile basis, and lifetime charging costs can save electric vehicle drivers between $3,078 and $10,445 over 15 years.7 [EPA-HQ-OAR-2021-0208-0287-A1, p.3]

C2ES recognizes that regulations and performance standards are not implemented in a vacuum; large-scale proliferation of electric vehicles in the U.S. market will require significant investment at the federal, state, and local policy levels, as well as strong ambition from the private sector, and will rely heavily on increased demand by American drivers for low- and zero-emission vehicles. Policies like electric vehicle tax credits, point-of-sale rebates for new and used vehicles, and other purchase incentives are crucial. [EPA-HQ-OAR-2021-0208-0287-A1, pp.3-4]

As price remains a significant barrier to access for many households, incentivizing further expansion of low- and zero-emissions technologies to bring down costs and improve access should be an essential goal of any transportation emissions reduction program. [EPA-HQ-OAR-2021-0208-0287-A1, p.6]

EPA Response

EPA agrees that, especially as the up-front costs of EVs decreases, the total cost of ownership of EVs will become lower than that of ICE vehicles. EPA also agrees that complementary public policies outside of EPA's authorities, such as vehicle subsidies, would facilitate their adoption, and that access for lower-income households is an important consideration. See RIA Chapter 8.4 for more discussion of the effects of the standards on vehicle affordability, and Chapter 8.4.1 in particular for effects on lower-income households.

Commenter: Competitive Enterprise Institute et al.

Motor vehicle GHG standards have three unavoidable downsides. Such policies (1) increase vehicle ownership costs,3 (2) restrict consumer choice,4 [EPA-HQ-OAR-2021-0208-0292-A1, p. 1] and (3) make the average vehicle less crashworthy than it otherwise could be. 5

3 Manufacturers spend tens of billions of dollars annually on technology to comply with GHG standards. That increases the average cost of new vehicles, which in turn can price middle-income households out of the new-car market. 'The Average New Car Price Is Now Over $40,000,' Autotrader reported in February, https://www.autotrader.com/car-news/the-average-new-car-price-is-now-over-40000. The proposed standards are projected to increase average vehicle cost by $1,022 relative to the no-action (SAFE Rule) scenario. See EPA, Draft Regulatory Impact Analysis, Revised Model Year 2023 and Later Light Duty Vehicle GHG Emission Standards, August 2021, p. 4-14, Regulatory Impact Analysis, LD GHG 2023-2026.pdf (hereafter, EPA 2021, DRIA).

4 Regulatory agencies have different priorities than consumers. If that were not so, consumers would demand the same average fuel economy the EPA deems optimal, and GHG standards would not be 'needed.' GHG standards unavoidably shift capital and engineering talent from consumer priorities to bureaucratic priorities.

EPA Response

The average price of a new vehicle depends, not only on the prices of vehicles, but also the sales mix. As discussed in RIA Chapter 8.4.4, low-priced vehicles continue to exist. EPA agrees that cost increases can affect vehicle affordability; see RIA Chapter 8.4 for further discussion of this topic. At the same time, the standards offer a desirable characteristic – reduced fuel consumption – that, over the vehicle's lifetime, exceed those up-front costs; see Preamble Section VII.J. for discussion of those effects for new and used vehicle buyers.

The footprint-based standard is intended to support the diversity of vehicle sizes in the fleet. As described in the response to American Enterprise Institute above in this chapter, EPA has not found evidence that vehicle buyers have faced losses of other attributes in their new vehicles, and neither CEI nor AEI have presented evidence of those losses. Thus, while EPA agrees with CEI that it should account for the increase in up-front costs and any losses to vehicle attributes, EPA considers its accounting for the benefits and costs of the standards to have taken into account all relevant impacts on consumers, including both the increase in up-front costs and the reduction in operating costs.

Safety impacts are discussed in Section 21 of this Response to Comments.

Commenter: Consumer Reports (CR)

However, this proposal leaves significant consumer savings on the table and does not go far enough to meet the climate challenge ahead of us. [EPA-HQ-OAR-2021-0208-0602-A1, p.4]

Commenter: Mass Comment Campaign sponsored by Consumer Reports (19,038)

and they leave billions of dollars in consumer savings on the table, as stronger standards could save drivers up to $88 billion on gas, maintenance, and costs for vehicles purchased in the next 5 years. [EPA-HQ-OAR-2021-0208-0602-A2, p.1]

EPA Response

EPA's standards are based on multiple considerations, including their feasibility, compliance cost, and lead time, as provided in section 202(a) of the CAA. As discussed in Preamble Sections II. and VI., the decisions in this final rule balances these and other factors.

Commenter: Egbert, Judi

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 177.]

I need and do use a fuel efficient vehicle, which is a hybrid Prius. I find this vehicle, which gets about 45 to 50 miles per gallon, can adequately and comfortably help me contribute to a thriving community

<u>EPA Response</u>

EPA is pleased that this commenter found a fuel-efficient vehicle that suits her needs.

Commenter: Energy Innovation Policy and Technology LLC

The companion Policy Report finds that achieving the DRIVE Clean Scenario requires a combination of policy and regulatory changes at the federal, state, local, and utility level, including:

• Strengthened EPA tailpipe emission standards that support ZEV sales and reduce overall tailpipe emissions for all ground vehicle classes to 0 g/mile by 2035;

• Continued adoption of state ZEV standards and rules;

• Incentives for EVs and charging infrastructure to help more consumers access affordable new and used EVs and convenient charging;

• Workforce programs that help streamline the transition to EVs and create new jobs;

• Incentives for domestic manufacturing to encourage the production and sale of electric cars and trucks;

• EV-friendly rules, codes, permitting, interconnection, and rates. [EPA-HQ-OAR-2021-0208-0605-A1, pp. 9-10]

<u>EPA Response</u>

These comments primarily address EV incentives that are outside EPA's authority or the scope of this rulemaking, though EPA agrees that they would facilitate adoption of EVs. As discussed in Preamble Section I.A.2, EPA is planning to initiate a rulemaking to establish multi-pollutant emission standards for MY 2027 and later.

Commenter: Environmental Protection Network (EPN)

Better and cheaper batteries have also allowed automakers to increase EV range. A decade ago, EV range was often on the order of 100 miles. Now, most EVs have ranges between 200 and 300 miles. While such EV ranges are still less than the typical highway range for gasoline cars, they are more than sufficient for most drivers who typically travel 20-50 miles per day and for others who have convenient charging access in their home garages or workplaces. Higher EV ranges are possible, of course, but there is a tradeoff between vehicle range and cost, and automakers will likely offer multiple battery sizes and costs, allowing consumers to choose the best package for their circumstances. [EPA-HQ-OAR-2021-0208-0213-A1, pp. 5-6]

EPN cannot speak on behalf of the industry, of course, but there is mounting evidence that many automakers are convinced that EVs are the future of the industry for multiple reasons: they will be higher-quality designs that consumers will prefer, they will be simpler and cheaper to build, and they will be required by countries fulfilling their commitments to the Paris Climate Agreement to protect the planet and public health. This apparent belief by multiple major automakers that there is an attractive powertrain technology ready to replace fossil fueled internal combustion engines is unprecedented in the century-plus history of the automobile industry. [EPA-HQ-OAR-2021-0208-0213-A1, p. 6]

But EVs are not superior in every way, and at least for the foreseeable future, EVs will entail some disadvantages as well: range between refueling will be shorter and they will take longer to recharge (not so important with overnight home charging, but a meaningful drawback in the middle of a long highway trip), access to public refueling stations may be more limited than to gasoline stations (at least initially), and certain types of driving, such as boat towing or steep road grades, may require additional technology and cost.

It is well accepted in the economics literature that many consumers are risk averse, especially with large expenditures. It is easy to stick with what you know and let others be the 'guinea pigs' for a new technology.

Some automakers may choose to delay their transition to EVs as long as possible, in the hopes of 'milking as much profit' as they can from their existing gasoline vehicle designs and engine/transmission/assembly plants.

Finally, EPN agrees with statements by some individual automakers and the Alliance for Automotive Innovation that there is a critical need for complementary federal policies to support a fast transition to EVs in at least three areas: the extension of federal tax credits/rebates for consumers who are willing to buy EVs in the next few years, the buildout of a nationwide public refueling infrastructure, and a modernized and more sophisticated electric grid to support widespread EV use. The Biden administration infrastructure bills include all these critical components, which are currently being debated in Congress. None of these programs would fall under the purview of EPA, of course. [EPA-HQ-OAR-2021-0208-0213-A1, p. 7]

EPA Response

As discussed in RIA Chapter 4.1.4 and Preamble Section III.B.3, EPA projects that, while 17 percent of the vehicles sold in MY 2026 will be EVs, the large majority of vehicles sold subject to these standards will use gasoline. The policies that EPN cites to promote adoption of EVs are beyond EPA’s authority or the scope of this rulemaking, though EPA agrees that they would facilitate widespread adoption of EVs.

Commenter: General Motors LLC (GM)

The 200,000 unit per manufacturer cap on the $7,500 Federal EV Tax Credit, 26 U.S.C. § 30D, should be modified to ensure that the credit does not penalize first movers in this space, currently putting companies like GM at a severe pricing disadvantage in the market for several years.

• This incentive should be available to consumers at the point of sale and should be able to be used by all retail, commercial, and government entities.

• A federally funded program should be established to drive EV adoption through federal, state, and local government fleet EV purchase commitments (recognizing that many government fleets cannot take advantage of tax credits).

• A federally funded national EV-awareness campaign should be established, including EV experience centers across the United States, K-12 education programs, and media programs that highlight the benefits of driving electric for both retail consumers and fleet operators.[EPA-HQ-OAR-2021-0208-0234-A1][p.4]

GM recognizes that increased EV charging infrastructure is necessary for battery electric vehicles to achieve scale. To support this development, GM recommends the following initiatives for federal leadership and support:

• Reestablish and reform the EVSE (Electric Vehicle Supply Equipment) Infrastructure Tax Credit, 26 U.S.C. § 30C, to convert it into a refundable tax credit that can be used by all retail, commercial, and government entities.

• Establish a federal grant program to accelerate public and private workplace charging.

• Establish a federal grant program to accelerate investment in urban and high-density DC fastcharging hubs.

• Establish a national building code that requires all new residential construction (single family homes and multi-unit dwellings) to support EV charging.

• Establish a federal program to ensure all EV charging stations in the U.S. are easily identifiable to consumers (e.g. some uniformity in appearance).

• Enactment of the provisions of EV infrastructure included in the Bipartisan Infrastructure Bill passed by the U.S. Senate on August 10, 2021 and presently pending before the U.S. House of Representatives. [EPA-HQ-OAR-2021-0208-0234-A1][p.5]

EPA Response

These comments address EV incentives that are outside EPA's authority or the scope of this rulemaking, though EPA agrees that they would facilitate adoption of EVs.

Commenter: Haines, Meredith

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 114.]

Our communities will have cleaner air benefits sooner and will be more choices in electric vehicles, and I want consumers to get a strong signal that zero emission vehicles are the future and that is the future we want with lower running costs, cleaner air to breathe, and wider ecosystem benefits.

EPA Response

EPA agrees that zero-emissions vehicles can have lower operating costs and can improve air quality and provide other ecosystem benefits.

Commenter: Hall, Marilyn

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 21-22.]

I am fortunate that I was able to purchase a plug-in hybrid car that meets my needs, is a great car that I've already taken on a few road trips. I only wish that the battery would carry my car farther between charges so that I would not need to rely on gasoline as much as I do. There's a huge market for electric cars that will become even larger as the technology improves. I have found tremendous interest in hybrid electric cars since I started driving mine. Friends have asked to check out my car to see whether it would work for them. Strangers approach me at charging stations with questions about the technology. Some folks have commented longingly that they would like to own an electric vehicle but they need prices they can afford The proposed rule can help that to happen for American consumers. People want electric cars.

EPA Response

EPA expects EV technology will improve over time, especially as automakers develop greater experience in producing them, and that costs will decrease over time; see RIA Chapters 2.3.3 and 2.3.4.

Commenter: Hyundai America Technical Center, Inc. (Hyundai)

Consumer acceptance is growing as driver exposure to EVs increases, EV model availability expands and appeals to a wider consumer base, infrastructure becomes more accessible and reliable, and incentives narrow the price gap between EVs and gasoline vehicles.

It is important to continually analyze EV sales to understand how the sales demand is being driven, and it is necessary to formulate relevant metrics to forecast whether the market can sustain continuing aggressive growth. There are a number of ways to proactively evaluate whether the EV market is healthy, as described below.

1. Consumer reasons for rejecting EVs and associated trends should be continuously monitored. Surveys providing rejection reasons can show fundamental consumer concerns with EVs. In a healthy market, rejection reasons should not be foundational (i.e. infrastructure, vehicle range, vehicle cost). Therefore, foundational concerns should decline over time.

2. The number of EV intenders (people who state future intent to purchase EVs) should be compared to the number of actual EV purchasers. Over time, the gap between these two numbers should narrow.

3. Financial incentives provided by auto manufacturers to purchase EVs should decrease over time as price parity improves between EVs and gasoline vehicles, and consumer acceptance of EVs grows.

4. As the share of gasoline vehicles declines, consumer willingness to pay premiums over Manufacturer Suggested Retail Price for gasoline vehicles may suggest consumer apprehension towards EVs. The cost differential between EVs and equivalent gasoline vehicles should be monitored for this indicator.

5. 'Days to Turn' in the industry is the average number of days vehicles remain in dealer inventory prior to sale. This metric should be monitored for both EVs and gasoline vehicles. If the number of days is decreasing for EVs and increasing for gasoline vehicles, this could indicate a healthy EV market. The opposite could indicate EV hesitancy.

6. Evaluate GHG performance by manufacturer in conjunction with the factors listed above to further assess the health of the EV market.

All of these components are vital to understanding whether the EV market expansion will be successful, and provide insight into how to proactively address any issues before they impact the goals of GHG reduction.

In addition, complementary consumer awareness programs that explain the benefits of electric vehicles are critical. Hyundai and other automakers are broadly marketing new electric vehicles on a variety of platforms. Hyundai also supports the national Drive Change Drive Electric4 campaign, a unique public-private partnership between auto manufacturers and U.S. Northeast states to improve consumer awareness, understanding, consideration and adoption of electric cars, including battery electric, plug-in hybrid electric, and fuel cell electric vehicles.

The Federal Government could supplement the efforts of manufacturers by launching a national consumer education campaign. This could include Public Service Announcements, social media posts, a consumer-focused website, and a helpline as resources for consumers to answer questions about EVs, such as charging locations, installation of home chargers, or how to access Federal and/or local EV incentives. [EPA-HQ-OAR-2021-0208-0603-A1, pp. 3-4]

As an emerging technology, electric vehicles remain more expensive than conventional gasoline vehicles. The timing of cost parity between EV and gasoline vehicles is unknown and there are numerous variables that will impact when it will occur (e.g. battery prices, cost reductions due to economies of scale, and raw material pricing).

Until then, consumer incentives are critical in reducing the price gap and accelerating EV market growth. Consumer incentives and cost parity should be monitored and incentives adjusted, as needed, to assure they bridge the price gap between electric and conventional vehicles. [EPA-HQ-OAR-2021-0208-0603-A1, p.5]

EPA Response

EPA agrees that consumer acceptance of EVs deserves monitoring, and Hyundai suggests some useful metrics that EPA will consider, taking into account the availability of such information. Nevertheless, the majority of vehicles subject to these standards that are expected to be sold through MY 2026 are not EVs, but gasoline-powered vehicles; see Preamble Section III.B.3. and RIA Chapter 4.1.4 for further information.

Consumer incentives to reduce EV costs are outside EPA's authority or the scope of this rulemaking, though EPA agrees that such measures would facilitate adoption of EVs.

Commenter: Institute for Policy Integrity

EPA should affirm that strong standards help correct market failures that prevent consumers from achieving valuable fuel savings on their own. The SAFE 2 Rule distorted its balancing of factors based on unsupported assumptions about consumer valuations. EPA now correctly balances those factors, but should go further to highlight additional market failures that interfere with consumers purchasing optimal levels of fuel economy on their own, and should conclude that standards are necessary to help correct at least some persistent market failures. [EPA-HQ-OAR-2021-0208-0299-A1, p. 1]

EPA has begun to make appropriate changes to its modeling approach, but further adjustments in the future would more fully capture the benefits of strong standards. [EPA-HQ-OAR-2021-0208-0299-A1, p. 1]

Going forward, EPA should revise the sales and scrappage models to be more consistent with real-world purchasing behaviors, such as moving to a long-run sales elasticity estimate and correcting the assumption that consumers will indefinitely continue to irrationally value only 2.5 years of fuel savings. [EPA-HQ-OAR-2021-0208-0299-A1, p. 2]

Notably, comparing technology costs to fuel savings also suggests that Alternative 2 may have greater net benefits for individual consumers.10 Given EPA's findings that lower-income families benefit more from net fuel savings,11 Alternative 2 should also advance equity goals. [EPA-HQ-OAR-2021-0208-0299-A1, p. 2.]

EPA Should Affirm that Strong Standards Help Correct Market Failures that Prevent Consumers from Achieving Valuable Fuel Savings on Their Own

In the Final Rule, EPA should offer much stronger conclusions about its approach to consumer valuation. [EPA-HQ-OAR-2021-0208-0299-A1, p. 8]

First, EPA should clarify that, whereas the SAFE 2 Rule distorted its balancing of long-term savings versus upfront costs in ways grossly inconsistent with economic practices, regulatory precedent, and statutory mandates, EPA now properly balances the appropriate factors consistent with best economic practices. [EPA-HQ-OAR-2021-0208-0299-A1, p. 8.]

Second, EPA should conclude that there is considerable evidence that multiple market failures contribute to consumers purchasing less vehicle efficiency than would benefit them, and so there is a clear role for regulations to correct these market failures. Third, EPA should reiterate that the constant performance assumption built into its analytical model obviates the need to estimate any potential lost consumer welfare from forgone attributes—which would, in any case, likely be small and offset by countervailing effects. [EPA-HQ-OAR-2021-0208-0299-A1, pp. 8-9]

EPA Should Cite Additional Evidence and Theories of Market Failures and Should Affirmatively Conclude that Standards Help Correct Market Failures

The Proposed Rule and the supporting draft Regulatory Impact Analysis ('DRIA') discuss numerous explanations for why consumers are not able on their own to achieve optimal levels of fuel savings. However, EPA should more thoroughly identify the full range of market failures and more clearly conclude that regulations are necessary to help correct such market failures and so deliver net savings to consumers.

The Proposed Rule's preamble identifies several consumer behaviors that help explain the 'energy efficiency gap,' the phenomenon that describes how consumers do not always on their own purchase levels of energy efficiency that will save them money over time. Specifically, the Proposed Rule cites 'myopic loss aversion,' incomplete understanding of fuel savings, and not prioritizing fuel consumption in the complex process of selecting a vehicle.79 In the Final Rule, EPA should connect these consumer behaviors to specific market failures, namely: myopia and loss aversion (which are two separate market failures); informational costs and asymmetries; and a variety of market failures that can affect prioritization, including salience, satisficing, positional externalities, and others.80 Similarly, the Proposed Rule cites several producer-side explanations, including the large fixed costs of investments to switch to new technologies, and the complex and uncertain processes involved in technological innovation and adoption.81 Again, the Final Rule should connect these with specific market failures, like first-mover disadvantages and network externalities.82 As Executive Order 12,866 requires, agencies should identify the specific market failures or other problems that their rules address and assess the significance of the problems.83

The Proposed Rule's conclusion—that despite the lack of 'consensus in the literature' on 'which of these hypotheses for the efficiency gap explain its apparent existence,' EPA 'cannot reject the observation that the energy efficiency gap has existed for light-duty vehicles'84—is much more lukewarm than it needs to be. In fact, there is strong evidence that multiple market failures continue to plague consumers throughout the vehicle market.85 The Final Rule should conclude that, given the broad range of potential market failures, stronger vehicle standards are clearly necessary to help consumers achieve net savings.

The DRIA offers some more details, by discussing additional market failures like positional externalities and first-mover effects.86 However, the DRIA also offers the rather subdued conclusion that ‘it is not clear whether consumer behavior is responsible for the energy efficiency gap,’ and leaves it as ‘an open question why’ the gap exists, though it concedes that ‘it appears to have happened.’87 Again, in either the Final Rule, the Final RIA, or both, EPA should make a much stronger conclusion. Even though it may not be clear which market failure is the dominant cause of the energy efficiency gap, there is considerable evidence that at least some market failures are in part responsible for consumers purchasing less vehicle efficiency than would benefit them, and so there is a clear role for regulations to correct these market failures.

To support this stronger conclusion, EPA should add descriptions of both additional market failures that exist, as well as additional evidence for the market failures that are already mentioned. EPA should also make clearer that different market failures may apply to different categories of consumers, as the market failures that affect purchases by individual consumers may be the same or different from market failures that affect small business fleets, governmental and institutional fleets, or corporate fleets of light-duty vehicles.88 The literature recognizes multiple additional market failures that EPA has not yet discussed in the Proposed Rule or DRIA. These additional failures include:

• Dealership incentives, biases, and information asymmetries. Consumers typically must purchase new vehicles from dealerships, and salespeople have significant influence on consumer purchasing decisions.89 Yet salespeople’s own incentives and biases may cause informational asymmetries that prevent consumers from purchasing optimal fuel efficiency.90 Studies have found that dealers and salespeople often believe (whether or not it is true) that electric vehicles and other highly efficient cars have lower profits for dealers than gas-powered cars,91 including less profits from dealership-provided service and maintenance opportunities on electric vehicles, lower ‘back-end’ profits on trade-ins of electric vehicles, and commission structures that may not compensate salespeople for the perceived increased paperwork and transaction costs of selling electric vehicles.92 Perhaps partly because of such incentives, consumers and ‘mystery shoppers’ conducting research have often complained of poor dealership experiences when trying to purchase electric vehicles, citing salespeople’s limited knowledge and dishonesty; misinformation about electric vehicle’s costs, range, and other attributes; inconsistent enthusiasm among salespeople for electric vehicles; dealerships’ lack of inventory for more efficient and electric vehicles; poor timeliness for completing paperwork and delivery of electric vehicles; limited promotional materials on energy efficiency; and dealerships’ inability to facilitate consumers’ cost comparisons of electric versus gas vehicles.93 Some dealerships have admitted that poor sales training is a major barrier to electric vehicle sales.94 Because consumers rely on dealerships, but dealerships have different incentives and information than consumers, market failures can occur.

• Split incentives. When the purchaser of a vehicle does not have to pay the costs of fuel usage, this can create a market failure known as ‘split incentives’ or the ‘principal-agent problem.’95

Economists have found, for example, that split incentives can lead to undervaluation of fuel economy in the shipping industry, as parties that own or operate trucks are frequently not responsible for fuel costs.96 A similar dynamic can occur in other contexts, such as in the large rental vehicle fleets of light-duty vehicles, since rental companies do not pay for fuel costs. Government intervention can ensure that purchasers make societally optimal investments in energy efficiency technologies when they receive inadequate market incentives because of principal-agent problems.97

• Network externalities. Though EPA mentions some network effects, there is additional evidence of market failures in this area. The benefits of a new technology sometimes depend on widespread adoption by others, creating a situation where ‘proven’ technologies are chosen even though others would save more money in the long run.98 Network externalities can affect investments in electric vehicle charging, maintenance facilities, natural-gas refueling, and replacement parts.99 In turn, these externalities can affect a range of consumers and vehicles, from individuals to businesses, and from passenger cars to heavy-duty trucks. Because consumers buying alternative fuel or more efficient vehicles must make predictions about the future development of these critical networks in order to estimate their long-term savings, various market failures from information asymmetries and costs, myopia, and loss aversion all come into play here. Transaction costs and principal-agent dynamics may also prevent some vehicle consumers from getting access to the charging facilities at their apartment buildings or office buildings that they would require before purchasing electric vehicles, even as those buildings’ owners may be uncertain about their tenants’ demand for such charging facilities.100 Fuel economy and vehicle emission standards help resolve the coordination, first-mover, and informational problems facing the developers of this network infrastructure, thereby providing greater certainty that consumers can achieve long-term cost savings.101

• Salience, inattention, and mental accounting. Evidence continues to show that even though consumers have access to fuel economy labels, they may not accurately or fully factor those values into their decisions. The fuel economy differences among similar vehicles tend to be small on a miles-per-gallon (MPG) basis, and so may not be particularly salient.102 Salience bias may therefore cause consumers to inefficiently undervalue fuel economy in their vehicle purchasing decisions. Consumers also continue to misunderstand that fuel costs are inversely related to fuel economy (what is known as the ‘MPG illusion’).103 Consumers may value such information only in relative rather than absolute terms,104 and so may undervalue potential fuel costs savings. Left-digit bias may also affect consumer interpretation of relative MPG values, as it does when consumers focus on only the left-most digit in prices (e.g., the 99-cent price effect) or in the odometer values on used cars.105 [EPA-HQ-OAR-2021-0208-0299-A1, pp. 12-15]

• Additional myopia and inattention, including short-termism. Though EPA refers to myopia, the evidence for such market failures is more extensive than EPA recounts.106 Though myopia and inattention may more commonly plague individual consumers, economists have also found that managers at certain companies can exhibit similar kinds of inattention and so fail to implement many energy efficiency initiatives despite positive paybacks.107 Businesses may also face a kind of myopia called short-termism, in which certain corporate employees have an incentive to favor short-term profits over long-term investments if, for example, their personal compensation or career prospects are tied to near-term earnings.108 Employees with such incentives may have reason to purchase cheaper, less efficient vehicles.109 To the extent shorttermism is exacerbated by an informational asymmetry either between employees (who know that lower vehicle purchase prices will favorably boost short-term earnings reports) and investors (who may not know that more efficient vehicle purchases could have increased their long-run returns), or is caused by myopia, the phenomenon is a market failure.110 Economic studies suggest that short-termism can affect managers' choices about energy efficiency specifically,111 and about environmental sustainability more broadly.112 [EPA-HQ-OAR-2021-0208-0299-A1, pp. 15-16.]

• Manufacturer market power. Though EPA mentions how strategic marketing choices by manufacturers can result in inefficient under-supply of fuel economy to some consumer segments (and inefficient over-supply in other market sectors),113 EPA does not fully connect this inefficient pattern to market power. Because of the limited competition in at least some segments of the vehicles market, manufacturers may be able to act strategically when pricing vehicles and when producing vehicles with combinations of different fuel economy and other vehicle features in order to push consumers towards purchases that lead to higher manufacturer profits at the expense of optimal fuel economy.114 There is a relatively small number of firms producing several types of vehicles and engines across the light-duty and heavy-duty markets.115 This market failure therefore could influence purchases by all consumer groups and across several vehicle classifications.

• Additional first-mover effects. EPA mentions the first-mover disadvantages that may cause manufacturers to under-invest in research into new fuel-efficiency technologies in the face of uncertainty, but there is additional evidence for this market failure. Economists have noted that the first-mover disadvantage can be especially pronounced when returns to society are greater than those to the investor, as is the case with fuel-efficiency technologies that reduce oil use and greenhouse gas emissions.116 Short-termism can also compound the first-mover disadvantage, as manufacturers have to balance the immediate costs and risks of research against the longer-term profits from future sales. Since each manufacturer faces muted incentives to be the first to research and deploy new technologies, without regulations, no manufacturer is likely to produce vehicles with the socially optimal level of energy efficiency.117 Because manufacturers are responding to consumer demand for fuel economy that multiple other market failures have already depressed, this first-mover dynamic can exacerbate the energy efficiency gap.118 First-mover effects can also affect vehicle consumers, including corporate and institutional purchasers.119 Without regulatory incentives, firms may underinvest in purchasing such efficiency-enhancing technology as they all wait for their competitors to go first and bear the costs of testing the implementation of new technology.

• Additional information costs and asymmetries, including experience goods. Though EPA refers to some informational costs, the evidence for market failures is more extensive than EPA recounts.120 Consumers may also lack information to fully value some benefits of more efficient vehicles—like the benefit of not having to stop as often (or at all) to refuel—until after the consumer has already purchased and experienced the good.121 Because insufficient information can mute consumer demand for fuel economy, this can also lead manufacturers to underinvest in fuel economy and in lowering greenhouse gas emissions. EPA should cite these additional market failures and evidence, and EPA should offer a clearer conclusion that there is considerable evidence that at least some market failures are responsible for consumers purchasing less vehicle efficiency than would benefit them, and so there is a clear role for regulations to correct these market failures. [EPA-HQ-OAR-2021-0208-0299-A1, pp. 16-17]

EPA Should Clearly State that Its Model's Constant Performance Assumption Obviates the Need to Estimate Lost Consumer Welfare (Which Is Likely Small)

The Proposed Rule appropriately concludes that the SAFE 2 Rule was inaccurate in finding that vehicle standards would substantially change vehicle attributes and consumer choices,122 and the Proposed Rule further notes persuasive evidence that manufacturers can implement fuel-efficiency technologies without imposing hidden costs.123 Indeed, not only has the marginal rate of substitution between power and fuel economy changed over time, such that newer technology improvements do not reduce power,124 but many fuel-efficiency technologies enhance power, performance, handling, or other attributes.125 The DRIA expands on this evidence and also notes that EPA's analytical model assumes that manufacturers will incur any additional costs necessary to hold performance constant, and yet EPA does not estimate either the cost savings that would follow if manufacturers instead chose to trade off some performance attributes for lower emissions to some extent, nor does EPA estimate the benefits from installing fuel-efficient technologies while maintaining or increasing performance attributes.126 EPA should therefore even more strongly conclude that the constant performance assumption built into the current model obviates the need to estimate any potential lost consumer welfare from forgone attributes. Moreover, not only is any such lost welfare likely small,127 but it would also be offset by countervailing effects: vehicles with slightly less horsepower, for example, would have lower risks of accidents and reduced negative positional externalities,128 and some fuel-efficient technologies indirectly but automatically improve other performance attributes in ways that would benefit consumers.129 [EPA-HQ-OAR-2021-0208-0299-A1, pp. 17-18]

EPA Should Rethink the Unrealistically Conservative Assumption that Consumers Value Only 2.5 Years of Fuel Savings

EPA compounds how conservative its sales model is by applying its elasticity estimate to the change in 'net price,' by which EPA means the difference between technology costs and the estimated fuel savings over just 2.5 years. EPA bases the 2.5-year estimate on manufacturers' assumption about the limited extent to which consumers value future fuel savings, and EPA admits that the assumption 'deserves further evaluation.'170

As explored above in the section of these comments on consumer valuation, multiple market failures and consumer behavioral patterns explain why consumers may appear—in the baseline scenario—not to fully factor future fuel savings into their current purchasing decisions; yet once fuel economy increases under future regulations, consumers will fully value the actual fuel savings that show up as extra money in their bank accounts or wallets; and, over time, consumers may therefore begin to more fully account for fuel savings in future purchasing decisions. As stronger vehicle emissions standards begin to place more vehicles with higher fuel economy into the marketplace, consumers will see more of their friends and neighbors driving fuel-efficient vehicles, more marketing materials and dealership presentations on fuel-efficient vehicles, more charging stations and maintenance facilities to service fuel-efficient vehicles, more labels with higher MPG numbers, and so forth. As the regulations begin to correct some of the market failures that currently exist, and as the marketplace changes in response, consumer behaviors will change as well, and consumers will likely begin to factor fuel economy more into their purchasing decisions over time—though so long as some market failures continue to persist, consumers will continue to need the assistance of regulations to optimize the fuel economy of their vehicles. But by assuming that consumers currently only value 2.5 years' worth of fuel savings and will never value more, even as the market changes over time, is simply not a realistic assumption and is not consistent with the best available evidence or theories. EPA should therefore rethink this unrealistically conservative assumption in the future. [EPA-HQ-OAR-2021-0208-0299-A1, p. 23]

101 Resolving the coordination and informational problems facing the developers of network infrastructure may also be an independent justification for government regulation of fuel economy, beyond its contribution to the energy efficiency gap.

108 A similar dynamic could exist in government, and so affect local, state, and federal government fleet purchases, if officials are rewarded for short-term cost savings rather than long-term fiscal health.

109 This incentive could be muted by a firm's accounting practices if costs and expenses are amortized over time.

118 Because it creates externalities and coordination issues that raise the cost of developing beneficial technologies, the first mover disadvantage facing manufacturers may also be an independent justification for government regulation of fuel economy, beyond its contribution to the energy efficiency gap.

119 For example, some focus-group studies of medium- and heavy-duty truck purchasers have found that they may hesitate to purchase more fuel-efficient vehicles because they are unsure about their reliability. See Heather Klemick, Elizabeth Kopits, Keith Sargent & Ann Wolverton, Nat'l Ctr. for Env't Econ., Heavy-Duty Trucking and the Energy Efficiency Paradox, 12, 20 (2014), https://www.epa.gov/sites/default/files/2014-12/documents/heavy-duty_trucking_and_the_energy_efficiency_paradox.pdf.

121 These kinds of 'experience goods' can create market failures. See Cass R. Sunstein, Rear Visibility and Some Unresolved Problems for Economic Analysis (with Notes on Experience Goods), 10 J. BENEFIT-COST ANALYSIS 317, 342–46 (2019). Experience goods have been associated with plug-in hybrids. See Margaret Taylor & K. Sydny Fugita, Lawrence Berkeley Nat'l Lab'y, Consumer Behavior and the Plug-In Electric Vehicle Purchase Decision Process: A Research Synthesis 9, 49 (2018).

EPA Response

See Preamble Section VII.J and RIA Chapters 8.4.1 and 8.4.2 for discussion of impacts on used vehicle buyers and low-income households. Also see Preamble Sections I.A.2 and VI. for our explanation of the appropriateness of the standards under the Clean Air Act, and how we considered statutory and other factors.

Preamble Section VII.B and RIA Chapter 8.1.2 discuss the role of fuel consumption in the vehicle purchase decision as well as the choice of demand (sales) elasticity. EPA agrees that, in its future modeling efforts, it should revisit the assumption that consumers take into consideration 2.5 years of fuel consumption in their purchase decision. See Section 18, below, for discussion of the choice of demand elasticity.

EPA has stated its conclusion that the market for fuel-saving technologies has not operated efficiently, and that there have been net benefits, including to vehicle buyers, from making vehicle greenhouse gas standards more stringent. EPA has not come to a conclusion on why there are failures in the market for fuel-saving technologies. EPA has discussed a number of hypotheses, and NYU IPI seeks to add to that list, primarily by adding more detail to existing theories. While these additional hypotheses deserve further consideration as potential explanations for the efficiency gap, EPA's approach to date has been to focus on examining whether the market failure exists, because that existence provides the basis for our approach to benefit-cost analysis; see the response above to comments from American Enterprise Institute. We have also observed that the standards in place since MY 2012 have both contributed to the adoption of fuel-saving technologies and have not to date contributed in a measurable way to additional hidden costs; thus, the standards appear to be operating as expected. EPA agrees that the constant performance assumption obviates the need to estimate losses from foregone performance. We also agree that some fuel-saving technologies improve some other vehicle attributes. EPA hopes and expects that researchers will continue to pursue reasons that the market for fuel-saving technologies operates inefficiently, because that exploration may suggest additional approaches for the effective reduction of vehicle GHG emissions.

Commenter: Maine Department of Environmental Protection

Unfortunately, while EPA's proposal acknowledges that industry can comply with the proposed standards through use of existing GHG reduction technologies, selling additional vehicles with today's technology is unlikely to 'jump-start' either further market penetration or the technical innovation necessary for truly widespread acceptance of ZEVs. [EPA-HQ-OAR-2021-0208-0225-A1, p.2]

<u>EPA Response</u>

The analysis in this FRM projects that the standards being finalized will lead to greater penetration of EVs than in the NPRM: e.g., 17 percent instead of 8 percent in MY 2026. See Preamble Sections III.B.3 and III.C. for further discussion of this topic. In addition, as discussed in Preamble Section I.A.2, EPA expects to develop a subsequent rule for MY 2027 and beyond that will build on the standards finalized here and contribute to further advances in technologies as well as further reductions in vehicle GHG emissions.

Commenter: Motor & Equipment Manufacturers Association (MEMA)

The vehicle supplier industry is committed to working toward a cleaner transportation future. The goals outlined in the pre-2026 proposal and the 50 percent ZEV goal in 2030 will require not only significant investments by suppliers but also significant coordination and long-term commitments by state, federal and local governments on complementary policies. These goals will also require actions by industries outside the vehicle industry. There must be an overall comprehensive plan that prepares the industry and the U.S. consumer for these technology advances.

While MEMA understands many of these necessary policies are not within the jurisdiction of the EPA, the success of the transition to ZEVs depends on a multi-faceted and coordinated approach from the federal government. Complementary polices will be needed for these advanced technologies to be attractive to consumers and compete among the other technologies available. This coordinated approach will be essential to support vehicle suppliers' investments, allow these advanced technologies to compete, and encourage continued innovation to meet the nation's goals.

The EO 14037, establishing the ZEV goal, outlines that the Departments of Commerce, Labor, and Energy will work together to achieve the goal by directing them to accelerate innovation and manufacturing in the vehicle sector, strengthen the domestic supply chain, and grow jobs.47 MEMA strongly supports investments to strengthen the U.S. manufacturing supply chain and preserve supplier jobs. This includes investments at the supplier level for research and development and retooling of existing facilities. Vehicle suppliers take a leadership position and take on significant risk in developing and planning these advanced technologies years in advance of deployment. The supplier industry needs to thrive if the vehicle industry is going to meet its goals.

MEMA urges policymakers at all levels to ensure there is an overall comprehensive plan to prepare U.S. consumers for this advanced transportation future. Demand-side issues that must be addressed to achieve the nation's short and long-term goals include:

1. consumer incentives allowing adoption of ZEVs and GHG-reducing technology to be more financially feasible;

2. consumer adoption and uptake of ZEVs; and

3. infrastructure to utilize and support ZEVs effectively.

These polices include consumer purchase incentives of electric and fuel cell vehicles, investments in electric and fuel cell vehicle charging and refueling infrastructure as well as consumer education.

In order to ensure our supplier manufacturing and workforce is supported, a strategic plan must include supply-side polices. Policy must aim to accelerate the development, commercialization, manufacture, and deployment of new, advanced technologies in the U.S. It is critical the supplier industry have increased access to government provided resources, including investments and incentives for the research and development, and increased manufacturing, and funding for facility retooling. Importantly for suppliers, MEMA strongly supports investments and programs to further develop and sustain our skilled workforce, including training to upskill workers, as these development needs are evolving with the transition to higher levels of electrification.

Because vehicle suppliers take significant risk in planning and committing to developing these advanced technologies years in advance of deployment, cohesive complementary policies are essential to support supply- and demand-side polices and advance the industry’s innovation and support the nation’s GHG goals. [EPA-HQ-OAR-2021-0208-0249-A1, p. 14-15]

EPA Response

These comments address ZEV incentives that are outside EPA’s authority or the scope of this rulemaking, though EPA agrees that they would facilitate adoption of ZEVs.

Commenter: National Automobile Dealers Association (NADA)

“Push” mandates do not necessarily equate to “if they build them, they will come” and NADA’s concern with EPA’s proposed mandates is premised principally on this basic fact. The critical nature of new vehicle consumer purchase behavior must be viewed properly through the lens of an ever-changing light-duty vehicle marketplace that keys on the willingness and ability of prospective purchasers to buy ever more expensive new vehicles with enhanced GHG emissions reduction performance. The current proposal is flawed and incomplete in its evaluation of these key marketplace factors because, as in EPA’s 2012 rule, key demand-side marketplace factors including whether OEMs will be able to make and deliver compliant vehicles that are both marketable and affordable have not been adequately considered.

EPA’s final rule should set mandates that maximize light-duty fleet turnover, not inhibit it as projected under the proposal. In so doing, EPA must appropriately account for the variables, data, and analyses necessary to understand how prospective purchasers behave, and thus will likely behave with respect to the MY 2023-2026 vehicles at issue. Doing so is critical to maximizing GHG reduction effectiveness given that, as noted above, regulatory benefits will not be achieved unless and until vehicles subject to new mandates are sold or leased to end-users.

EPA’s Proposed Standards Will Diminish the Ability and Willingness of Consumers to Purchase New Light-Duty Motor Vehicles. Whether vehicles with enhanced GHG performance languish on dealer lots or are successfully delivered to new light-duty vehicle customers depends on whether consumers are able and willing to purchase the performance enhancement. GHG mandates must reflect an accurate understanding by EPA of how prospective purchasers will react when new vehicles subject to new mandates are delivered to market at prices higher than similar vehicles unburdened by the costs of those mandates.

As detailed below, unlike for many regulated goods, prospective purchasers of new light-duty vehicles have transportation options which include the used vehicle marketplace, existing vehicle service and repair, and alternatives to light-duty vehicle transportation. Moreover, factors influencing the willingness of prospective purchasers to buy or lease include consumer confidence, perceived operating costs, and expected residual values. [EPA-HQ-OAR-2021-0208-0290-A1, p. 4]

Consumer Demand for Fuel Efficiency Fluctuates With Gas Prices as Does Fleet Sales Mix. Estimates of future fuel savings are not simple financial calculations, such as where one can use a discount rate as a corporation might for its cost of money when calculating the net present value of a potential project. EPA must consider the expectations of able and willing prospective purchasers because it is those expectations that ultimately determine behavior in the marketplace. Prospective purchasers form expectations of the net present value of future fuel savings that are related, but not closely related, to a standardized financial calculation.22 During dramatic upward swings in the price of gasoline followed by heavy media coverage, consumers place a large value on fuel economy, as revealed by shifts in demand to more fuel-efficient segments of the market. During slow and steady increases in the price of gasoline with little or no media attention, consumer demand reveals a diminished value for fuel economy.

Higher fuel economy performance has the potential to benefit consumers, but it is just one factor that can influence a consumer’s willingness to purchase and, like all variables, changes over time and with market conditions. If fuel prices remain at or near current levels, the TCO benefits associated with EPA’s proposal will not “pencil out” for most new vehicle prospective purchasers. Moreover, fundamental product mix shifts, such as from large cars to light-duty trucks, and from smaller footprint cars to SUVs and CUVs, must also be considered for MYs 2023-2026. Barring a sudden and prolonged spike in fuel prices, new light-duty vehicle customers are, on average, unlikely to shift to more fuel-efficient vehicles and, in fact, are likely to do the opposite. Gasoline price projections in the Annual Energy Outlook for the years covered by the proposal range from $2.55/gallon to $2.79 /gallon.23 These price projections are less than what exists today and are certainly unlikely to cause retail customers to shift their preferences from pickups, SUVs and CUVs back to cars, for example.

A Consumer’s Willingness to Purchase Based on Fuel Economy Must Be Viewed in the Context of Other Vehicle Attributes. Further, when assessing the valuation of fuel economy improvements by prospective purchasers, the financial benefits of future fuel savings cannot be separated from the utility lost by necessary reductions to other vehicle qualities and performance. For example, if a consumer values an increase in fuel economy of 1 mpg at $500 but gaining this 1 mpg forces a reduction in power or safety valued at $600, the value of the fuel economy gain is negative. Consumer behavior indicates how these tradeoffs are valued. Indeed, these tradeoffs are available today in dealership showrooms offering new light-duty vehicles with a wide variety of fuel economy performance, along with variations in safety and performance features.

A study released earlier this year examined the tradeoff between fuel economy and vehicle performance and determined that the willingness of consumers to purchase increased horsepower/acceleration is three times their willingness to purchase increased fuel economy.24

The study also found that models attempting to assess willingness to purchase for fuel economy without controlling for tradeoffs, likely suffer from omitted variables bias. Specifically, the study found that: "Economists and policy makers have focused on the energy efficiency gap under the presumption that if there is a gap, tighter standards would raise private consumer welfare."25 They argue that this inference is incorrect because policy makers have failed to consider the effects of tightening emissions and fuel economy standards on other vehicle attributes such as performance. This trade-off between fuel economy and vehicle performance has been documented in the literature, causing performance to increase less than if there was not a tightening of the standards.26 Because of this, studies that estimate the welfare benefits of increased fuel economy must also consider how consumers value other vehicle attributes as well. The study found that consumers are willing to pay 54 cents for $1 dollar of discounted fuel cost savings, in contrast to Busse, et al. (2013) who find full valuation by consumers, and Allcott and Wozny (2014) who found that consumers are willing to pay 76 cents for $1 of discounted fuel cost savings.27 It finds similar undervaluation by using Busse's methodology, suggesting that the differences in the sample period rather than methodology explain the discrepancies.28

Of course, consumers of any product will accept product improvements if they are free. Thus, fuel economy improvements are most acceptable when customers are not required to pay for them. Moreover, when consumers are asked about paying for fuel economy, they largely are unwilling to do so. The aforementioned study found that consumers are willing to pay just $94 for a 1% increase in performance arising from fuel saving technology adoption. This contrasts with a willingness to pay $1,100 for a 1-second reduction in 0-60 acceleration time. The study also notes that failing to control for the endogeneity of fuel economy and performance when modelling, will understate consumer valuation of fuel economy and performance.29

EPA Has Not Adequately Considered Consumer Behavior and Marketplace Realities. In its proposal, EPA paid some attention to the issues discussed above, but did not draw definitive conclusions and relied on analyses and papers that miss the mark.30 The studies EPA relied on were either "in progress," or focused on evaluations of vehicle operating characteristics and found only that the presence of emission reductions "more often correlated with positive evaluations than negative ones."31 EPA apparently failed to consider studies assessing how new light-duty vehicle consumers actually value emissions reduction/fuel economy technology when making purchase decisions, a failure that undermines its ability to propose GHG reduction mandates premised on realistic and accurate conclusions.

Given the deficiencies in the studies referenced in the proposal, it is incumbent upon EPA to perform a meaningful meta-analysis to account for the temporal shifting of consumer preferences. In comments responding to prior EPA rulemakings and regulatory actions, NADA provided numerous citations on consumer purchase decision-making and how new vehicle purchasers rank fuel economy in terms of other vehicle attributes. How and when consumers value fuel economy changes with time and, like most vehicle attributes, fuel economy choices are dependent on numerous factors. Because of its importance, EPA should directly address the critical importance of the temporal shifting of consumer preferences.

EPA also must never rely on simple "purchaser satisfaction" surveys or vehicle evaluations by professional automobile reviewers, especially when new vehicle purchaser survey data is readily available. EPA can and should focus on what actual new vehicle buyers want and are willing to pay for, as evidenced by actual vehicle purchasers. [EPA-HQ-OAR-2021-0208-0290-A1, p. 6-9]

EPA Response

EPA agrees that many factors affect how potential purchasers will respond to new vehicles subject to the standards. EPA disagrees that it has not appropriately analyzed these factors. It is important to distinguish between the role of fuel savings in the vehicle purchase decision, and the fuel savings that vehicle buyers experience once the vehicle is purchased. Even if, as NADA argues, vehicle buyers undervalue fuel savings in the vehicle purchase decision, or if that value fluctuates with gasoline prices, those who buy a more fuel-efficient vehicle will nevertheless spend less money on fuel and will therefore be able to use those savings for other purposes. Because benefit-cost analysis is based on a comparison of the world with vs. the world without the standards (see response to American Enterprise Institute in this section), the projected fuel savings are appropriate to use in the benefit-cost analysis. EPA includes sensitivity analysis of the effects of different fuel prices on net benefits in RIA Chapter 10.4. As RIA Table 10-19 shows, net benefits are positive even with AEO's low fuel price projections.

As discussed in Preamble Section VII.B. and RIA Chapter 8.1, EPA estimates a reduction in sales of up to 1 percent, though we also explain that this reduction may overestimate adverse effects on vehicle sales: in particular, if vehicle buyers put more value on reduced fuel and operating costs than are considered in the CCEMS modeling conducted for this rule, sales effects would be less negative or possibly even positive. EPA has conducted extensive analysis of the role of fuel costs in the vehicle purchase decision. Although there is no consensus on the value, the modeling in CCEMS that assumes 2.5 years of fuel consumption in the purchase decision, as discussed in Preamble Section VII.A. and RIA Chapter 8.1.1, is on the low end of the distribution of estimates of consumer valuation of reduced fuel consumption. For these reasons, EPA considers its evaluation of the impacts of the standards on vehicle purchases to be reasonable, or conservative.

Leard et al. (2021)[90] provides estimates of willingness to pay (WTP) for performance and fuel economy. EPA discusses the concern over tradeoffs between performance and fuel economy and consumer WTP for vehicle attributes in Preamble Section VII.A. and RIA Chapter 8.1.1. There are many estimates of these WTP values, and they cover a very wide range; this paper contributes one more set of estimates where there does not yet seem to be a consensus. It is unclear from NADA's comment whether it is concerned that WTP varies specifically due to time, or due to other factors that happen to vary, and those factors should be taken into account. EPA in fact sponsored research conducting a meta-analysis of values for willingness to pay for

[90] Leard, B., J. Linn, and Y. Zhou (2021). "How Much Do Consumers Value Fuel Economy and Performance? Evidence from Technology Adoption." Review of Economics and Statistics, in press.

vehicle attributes,[91] and took into account the different timing of the underlying studies as well as other factors. The meta-analysis was not able to account well for the wide variation in estimates for WTP, reflecting the lack of consensus over these values.

In addition, the cost estimates for the technologies are based on holding performance constant, as NYU IPI notes in its comments. Because it is possible to improve fuel economy and reduce GHG emissions without adverse effects on performance, the costs of achieving the standards take into account foregone performance impacts.

NADA does not explain its objection to purchaser satisfaction surveys, which are based on the responses of actual new vehicle buyers, which are its preferred source of data; we note that Leard et al. (2021) relies on such a dataset. Nor does it explain its resistance to evaluations from professional automobile reviewers. EPA considers both these kinds of data potentially useful.

Commenter: National Coalition for Advanced Transportation (NCAT)

Sales and Growth: Electric vehicle sales in the U.S. have continued to grow dramatically. Over two million electric vehicles (battery electric vehicles and plug-in hybrid electric vehicles) have been sold cumulatively in the U.S. from January 2010 to the present. 18 Nearly 375,000 electric vehicles have been sold in 2021 as of August. 19 In the last year, electric vehicle sales have "skyrocket[ed]."20 A total of 43,721 electric vehicles (28,460 battery electric vehicles and 15,261 plug-in hybrid electric vehicles) were sold during the month of August 2021 alone in the United States, which captured 4% of total light-duty vehicle sales that month. 21 The share of electric vehicles in new car sales grew dramatically to 4.4 percent in 2020, substantially higher than 2.5 percent in 2019.22 This increase in electric vehicle sales has continued despite low gas prices, and even as car sales generally declined due to the pandemic.23

Projected sales: President Biden's recent Executive Order on Strengthening American Leadership in Clean Cars and Trucks set a goal that 50% of all new passenger cars and light trucks sold in 2030 be zero emission vehicles (including battery electric, plug-in hybrid electric, or fuel cell electric vehicles). 24

It is clear that electric vehicle sales have and will continue to increase, and that many projections are underestimates.25 Even the very conservative U.S. Energy Information Administration (EIA) predicts that battery electric vehicle sales will increase faster than any other type of vehicle sales, growing by 6% per year on average with 200- and 300-mile range vehicles reaching almost 2 million vehicles (combined) per year in 2050.26 EVAdoption predicts that by 2030, electric vehicle sales will be nearly 30% of all new car sales nationwide and nearly 57% in California.27

---

[91] U.S. Environmental Protection Agency (2018). "Consumer Willingness to Pay for Vehicle Attributes: What is the Current State of Knowledge?" EPA-420-R-18-016, https://cfpub.epa.gov/si/si_public_file_download.cfm?p_download_id=536423&Lab=OTAQ (accessed 4/15/2021); Greene, D., A. Hossain, J. Hofmann, G. Helfand, and R. Beach (2018). "Consumer Willingness to Pay for Vehicle Attributes: What Do We Know?" Transportation Research Part A 118: 258-279.

In the nearer-term, IHS Markit estimates that electric vehicles will double their 2020 market share by the end of 2021, and make up 10% of new car sales nationwide by 2025.28 The Goldman School of Public Policy at the University of California, Berkeley has summarized the estimates of some of these projections and others, showing that electric vehicles will likely be between 5% and 35% of new vehicle sales by 2035. [Figure 3 can be found on p. 7 of Docket number EPA-HQ-OAR-2021-0208-0239-A1] [EPA-HQ-OAR-2021-0208-0239-A1, p. 5-6]]

Consumer Acceptance: Consumers increasingly know about and are interested in purchasing electric vehicles. In summer 2019, Consumer Reports found that 63% of Americans were interested in electric vehicles. 53 A year later, Consumer Reports' summer 2020 survey found that number had increased to 71% of U.S. drivers who would consider buying an electric vehicle in the future, with almost a third suggesting it would be their next purchase.54 The interest in electric vehicles is even greater among younger buyers. 55 And the trend is growing rapidly. In a recent survey, the number of U.S. adults who said they would consider buying or leasing an electric vehicle rose four percentage points in just the first four months of 2021.56 The growing acceptance may be due to increasing range,57 model availability,58 and consumer familiarity with electric vehicles owned by family and friends or operated by commercial entities.59 The drop in electric vehicle prices, driven by strong consumer demand, has also reached a "tipping point" such that more consumers are willing to consider going electric.60

Demand for electric vehicles has come out of the COVID-19 pandemic even stronger61 and can play a role in pandemic recovery. Many car owners say they intend to buy an additional car in the next three months because of COVID-19, and the pandemic has also encouraged many others to buy cars who do not currently own one.62 Consumers, particularly younger people buying their first cars, are increasingly interested in sustainable options.63 According to polling data from McKinsey, 56% of North American respondents said they are more interested in purchasing a hybrid or electric vehicle because of the pandemic, with half of them saying they were "significantly more" interested; this is driven by recent air quality improvements and increased concern about sustainability.64

Increased Electric Vehicle Fleet Demand: Fleet vehicles are shifting to electric models. Rideshare and ride hail companies, for example, are already beginning the transition. Uber and Lyft both have a 2030 target for going all-electric.65 To get there, Uber has committed $800 million over the next five years to pay drivers for the environmental attributes of their rides.66

In addition to shared mobility, Amazon ordered 100,000 small electric delivery vans from NCAT member Rivian.67 Electric vehicles represent a growing number of fleet acquisitions for DOE Clean Cities,68 states, and alternative fuel providers.69 A group of 150 mayors have come together to pool their purchasing power through the Climate Mayors EV Purchasing Collaborative, reducing the cost of procuring electric vehicles for municipalities.70 [EPA-HQ-OAR-2021-0208-0239-A1, p. 10-12]

<u>EPA Response</u>

EPA agrees that consumer interest in EVs is growing, and that this increased interest will contribute to greater adoption of EVs in coming years.

Commenter: Nissan North America, Inc.

Thanks to the leadership and early investment of Nissan and others, the EV market has steadily grown over the last 10 years, albeit slower than many expected. Transitioning from long existing and established technology takes time and significant financial investment. This responsibility must be shared among the industry, its customers, and governmental entities. Widespread adoption of EVs requires not only that the automotive industry broadly embrace investment in this technology, but also that consumers show willingness to adopt the new technology. Nissan and other industry leaders have invested billions of dollars in an effort to stimulate growth, not only investing in technology and product development but also in infrastructure and consumer outreach/education. Nissan strongly supports federal, state, and local investment in market measures to complement the efforts already in place by industry leaders such as Nissan to further encourage this shift towards EVs.

For example, Nissan believes investment in EV infrastructure and consumer incentives is essential to encouraging the growth of the EV market. In the last several years, Nissan has invested significantly in EV infrastructure and provided consumer benefits such as free public charging and credits towards charging as part of the Nissan Energy Perks program in partnership with EVgo.2 While the federal and state governments have provided some consumer incentives for purchasing and leasing EVs, these incentives are not always stable and their future availability is unpredictable. Maintaining and expanding market-based governmental efforts such as tax credits and other purchase incentives, developing infrastructure, and allowing use of HOV lanes are essential to expanding the EV market share. Nissan encourages the Administration to complement the industry's efforts by continuing to offer these and other consumer incentives, and to invest in consumer education regarding the environmental and financial benefits of transitioning to EV technology. Moreover, Nissan encourages the Administration to consider investing in incentives on the industry side, including manufacturing incentives and R&D incentives for vehicle manufacturers and their suppliers who invest time and considerable financial resources in making EV technology more reliable and cost-effective. [EPA-HQ-OAR-2021-0208-0529-A1, p. 4-5]

EPA Response

These comments address EV incentives that are outside EPA's authority or the scope of this rulemaking, though EPA agrees that they would facilitate adoption of EVs.

Commenter: Pennoyer, Marguerite

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 29-30.]

However, I wanted to share my husband's recent experience in trying to purchase a light-duty pickup truck as just one example of the need for ever-stronger standards.

He had just retired last year and was looking for a small truck to tackle a number of home construction projects and canoeing trips. He searched long and hard to try to find an acceptable option for a light truck that had zero or low greenhouse gas emissions, either hybrid or all-electric. There were almost exactly zero available options. Pressure to innovate has been stymied for pickup trucks by loopholes and lack of pressure on the industry. These wildly popular and energy inefficient pickup trucks now seem to be among the most common type of personal vehicle seen on Maine's roads and the nation's highways.

EPA Response

In coming years, as the Alliance for Automotive Innovation notes in its comments in this section, EVs will be offered in more vehicle classes. This greater variety in offerings is expected to facilitate adoption of EVs, because people like the commenter’s spouse will find them more readily available, and even those not as focused on zero or low GHG emissions may find that an EV suits their purposes.

Commenter: Pien, Natalie

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 45]

As an EV driver, I don't miss going to the gas station to buy gas. I don't miss going to the car dealer to pay for regular service and repairs.

A 2018 study by the University of Michigan found that operating an EV is less than half the cost of operating an ICE. There's so many benefits to be gained.

EPA Response

EPA agrees that low operating and maintenance costs are a valuable feature of EVs.

Commenter: Securing America’s Future Energy

President Biden has laid out a vision for an electrified transportation future. He has set a goal to make half of all new light-duty vehicle sales electric by 2030. He has called for federal investments to help build a nationwide vehicle charging network. He is advocating for an expanded and extended tax credit for the purchase of new electric vehicles. And he has sought funding to support the manufacture of an electric vehicle supply chain in the United States. But if we expect automakers to invest in this transition, they need confidence that if they build the vehicles, that customers will buy them. Perhaps the most effective tool to help expand the market for electric vehicles is the federal light-duty vehicle greenhouse gas emission and fuel economy standards. The stringency of the standards set in these programs, and the use of other tools in these programs to incentivize electric vehicles, can help expand the market. [EPA-HQ-OAR-2021-0208-0527-A1, p. 2]

EPA Response

As discussed in RIA Chapter 4.1.4 and Preamble Section III.B.3, EPA projects that 17 percent of the vehicles sold in MY 2026 will be EVs. While there is uncertainty about consumer response to EVs, as NCAT notes in its comments in this section, EV adoption has been increasing in recent years.

Commenter: Schrier, Paul

As an American consumer, I stand against the proposed rule change that would make finding affordable vehicles even more difficult because of the following reasons:

Perhaps most telling is problems galore with EVs themselves, which are being recalled due to vehicle fires, sudden losses of power, and failures to start. Within the last year recalls by General Motors, Hyundai, and Ford involved 132,500 electric vehicles and cost a combined $2.2 billion.

Unsurprisingly, these issues have resulted in a lack of consumer confidence. After all, who wants to buy a vehicle that might burst into flames at any moment, or refuse to start when youre already fifteen minutes late to work? [EPA-HQ-OAR-2021-0208-0466, p.1]

And thats only the beginning. Its proving difficult to convince drivers to re-charge their cars and trucks instead of quickly refueling them with gasoline or diesel. EVs also remain significantly more costly than gas-powered vehicles, meaning government incentives mostly help affluent buyers, not average families. And the issue of charging stations is challenging for people who live in apartments or homes without garages or an adequate electrical panel to charge electric cars. [EPA-HQ-OAR-2021-0208-0466, p. 1]

EPA Response

Concerns over EV safety are discussed in Section 12.1 of this Response to Comments. As discussed in Preamble Sections VII.A. and VII.M. and RIA Chapters 8.1 and 8.4, EVs both have higher up-front costs and lower operating costs; how vehicle buyers assess these tradeoffs will affect their purchase decisions. In addition, access to vehicle charging is a concern until more public charging stations are available. Nevertheless, the large majority of vehicles subject to these standards that are expected to be sold through MY 2026 are not EVs, but gasoline-using vehicles. Buyers who are reluctant to buy EVs will find an abundance of choices.

Commenter: Southern Environmental Law Center

In addition to lower fuel costs associated with more efficient internal combustion vehicles, stricter emission standards will also encourage manufacturers to make EVs more widely available—which will help drive the market closer to the Biden administration’s goal of having

50 percent of all new light-duty vehicles sold in the U.S. in 2030 be zero-emissions vehicles. [32] Adoption of Alternative 2 is expected to result in approximately 10 percent of the market share being EVs by model year 2026,[33] compared to only about 8 percent of the market share under the proposed standards.[34] EVs are anticipated to reach parity in upfront costs with internal combustion vehicles in a few years,[35] and increased EV sales will expand the used EV market. [EPA-HQ-OAR-2021-0208-0244-A1, p. 5]

This will help to make EVs available and affordable to more consumers. EVs have many benefits for drivers, including improved handling and lower maintenance costs. For example, owning an EV saves the typical driver between $6,000 and $10,000 over the lifetime of the vehicle as compared to a gas car due to reduced fuel and maintenance costs [36] [EPA-HQ-OAR-2021-0208-0244-A1, p. 5]

EPA Response

As discussed in RIA Chapter 4.1.4 and Preamble Section III.B.3, EPA projects that 17 percent of the vehicles sold in MY 2026 will be EVs. EPA agrees that EVs are getting less expensive over time, that their operating and maintenance costs are lower than for ICE vehicles, and that they can have additional desirable attributes, including performance.

Commenter: Steitz, Jim

Manufacturers have tremendous ability to drive purchaser preference. Their complaints about difficulties selling fuel-efficient vehicles are self-fulfilling prophecies and must be disregarded. If the auto manufacturers must accept lower profit margins to drive sales of fuel-efficient and electric vehicles, this is a trivial concern. [EPA-HQ-OAR-2021-0208-0422, p. 2]

EPA Response

As discussed in Preamble Section VII.A. and RIA Chapter 8.1.1, EPA has investigated the role of fuel economy in consumer vehicle purchase decisions. We have found a very wide range of estimates of consumers' willingness to pay for additional fuel economy, ranging from significant undervaluation of the lifetime fuel savings expected to occur, to overvaluation of those savings. EPA's sales analysis in RIA Chapter 8.1.3 suggests that adverse sales impacts are likely to be up to about 1 percent, and may be less negative or even positive.

Commenter: Stellantis

Increase Consumer Awareness Of EVs - Additional federal support for consumer education and advertising can build off success in regional campaigns, like the Veloz 'Electric for All' and the NESCAUM 'Drive Change, Drive Electric' campaigns. These programs foster collaboartion among a broad group of stakeholders to help understand and overcome critical barriers and promote the purchase of EVs nationwide. [EPA-HQ-OAR-2021-0208-0532-A1, p. 5]

As part of the Build Back Better Plan, President Biden has proposed $174B in new spending on electrification incentives for consumers, manufacturers and charging infrastructure; with $7.5B for charging infrastructure included in the bipartisan infrastructure plan that passed the Senate in August. Stellantis believes policies like these are absolutely critical to the transition and necessary for the achievement of the Administration's sales targets. We are relying on execution of the above commitment and more from the Biden Administration and U.S. policymakers to provide the full suite of supportive policies included in the Build Back Better Plan.

Upfront vehicle costs remain a barrier to consumer adoption of electrified vehicles. Based on 2018 data, a report by the National Academy of Sciences indicated, 'The incremental cost for BEVs are at least $8,500 for the medium car (i.e., $36,800 BEV150 versus $28,300 conventional) to about $26,000 for the long-range SUV (i.e., $57,000 BEV300 versus $31,000 conventional).'27 For many popular vehicle segments and for longer range plug-in electric vehicles, price parity with ICE vehicles may not be achieved until 2030 or later, and while the PHEV price differential versus conventional ICE vehicles is projected to be smaller by 2030, NAS projected no price parity points in any vehicle class. The price difference between electrified powertrains and ICEs is largely attributable to the high-cost of battery technology. The NAS Report assumptions rely on significant battery cost reductions to close the price gap, but recent research has questioned how accurate battery cost reduction predictions will be.28

Significant, consistent consumer purchase incentives are vital until the cost of electrification reaches parity with traditional ICEs. These incentives have shown to be effective in various regions. On the state level, in New York, electric car sales increased 74% when the state implemented its EV rebate, and in Georgia, sales dropped 90% when its incentive was phased out.29 30 In a 2019 survey in California, where the Clean Vehicle Rebate Program (CVRP) has provided over $900 million to California residents over the lifetime of the program, 90% of the respondents ranked the CVRP rebate as moderately, very, or extremely important, and 54% said they would not have purchased their ZEV without it.31 32

Looking towards national incentives in other countries, the trend continues. The McKinsey Electric Vehicle Index showed that 'the EV market in China declined by 31% in the second half of the year after the government cut subsidies. In the United Kingdom, sales of plug-in hybrid electric vehicles (PHEVs) fell by 15% after the government stopped subsidies for hybrids.'33 Consumer financial incentives work and have helped establish markets for EVs around the world.

The existing federal incentive in the U.S. has been similarly vital to creating a domestic EV market. The incentive does a good job of recognizing that batteries drive the cost of EVs and the dollar amount is scaled based on battery capacity, an appropriate proxy for size and relative cost. Consumers have significantly capitalized on the federal funding – at a maximum tax credit of $7,500, it was projected in 2019 that by the end of fiscal year 2022, the U.S. will have spent $9.7B on the Plug-in Vehicle Tax Credit.34

Given these concerns and the potential of a well-designed incentive to create and bolster a better EV market, the federal electric vehicle incentive should be restructured and expanded. Continue to recognize battery as the driving cost and maintain scaling based on battery size, but eliminate the manufacturer vehicle cap and make the credit refundable, ideally moving it altogether to the consumer point-of-purchase. A significant financial incentive goes beyond closing the cost gap between electrified technology and traditional ICEs – it can also help overcome barriers in addition to cost and incentivize consumers to switch to the new electrified technology. [EPA-HQ-OAR-2021-0208-0532-A1, p. 21]

Electric vehicles are a new technology for most drivers. With this in mind, there needs to be federal leadership on consumer education to familiarize vehicle buyers with the technology and how it can fit with their lifestyles. In terms of charging infrastructure, for example, an educational campaign coordinated between utilities and EV charging providers could provide planning tools for types and quantities of chargers, cost estimates, and even best practices for home or worksite upgrades. At the state level, consumer awareness campaigns such as Veloz and Drive Change. Drive Electric., funded by automakers, states, and others, seek to not only raise consumer awareness of and comfort with EV technology, but also provide an environment to identify and address barriers to EV adoption. Types of activities these groups might undertake include media campaigns, online EV explorer materials, interactive lists of available EV incentives, or even in-person ride-and-drive events. The goal is to create awareness, overcome major EV adoption barriers such access to charging, cost (incentives available), and simplify the transition from traditional internal combustion vehicles to electrified vehicles. While automakers spend significant resources promoting their individual products, alternative consumer-facing campaigns help promote EV adoption from all angles.

To date, these consumer awareness campaigns have been very limited in scope and budget. Collaboration amongst a larger group of stakeholders (government, automakers, utilities, charging station providers, NGOs, and others) could further enhance consumer awareness and education outreach efforts. The federal government should consider a consumer education program like the work being done at the state level, with an appropriately scaled and expanded level of funding to reach consumers nationwide and make sure they are aware of the steps being taken to promote vehicle electrification. [EPA-HQ-OAR-2021-0208-0532-A1, p. 32]

EPA Response

Most of these comments address EV incentives that are outside EPA's authority or the scope of this rulemaking, though EPA agrees that they would facilitate adoption of EVs. EV costs are discussed in Section 12.1 of this Response to Comments.

Commenter: Tesla

Tesla believes that the transition to a fully electrified light duty vehicle sector can and will happen quicker than EPA anticipates. As demonstrated by Model 3 being the world's best-selling premium sedan38 and the Model Y becoming one of the top selling SUVs in the country,39 consumers continue to embrace electric vehicles. As a leading automotive trade group recently touted, 'consumer interest is growing because these vehicles are reliable, efficient, safe, and particularly fun to drive.'40 Indeed, there is widespread public support for policies that support the transition to ZEVs41 and consistently growing consumer interest in EV purchases.42 A recent survey found that almost 56% of consumers are likely to buy a hybrid or electric vehicle for their next car purchase and over 40% think green-conscious cars will outnumber gas-powered cars in the U.S. by 2030. 43 Tesla believes that more stringent standards can appropriately set the pathway to encourage widespread deployment of ZEVs and set the stage for a fleet-wide light-duty vehicle standard of 0 g/mi CO2 starting in MY 2030 (i.e., 100% EV sales by 2030). [EPA-HQ-OAR-2021-0208-0278-A1][pp.6-7]

EPA Response

EPA agrees that consumer interest in EVs is increasing.

Commenter: Toyota Motor North America, Inc. (Toyota)

Electrified powertrains must become more accessible to mainstream consumers for a carbon neutral future to be realized. Toyota market research has found consumer attitudes are shifting to a greater openness about alternative powertrains as seen if Figure 2. That growth in consumer openness is also being observed in vehicle segments that have traditionally been less inclined toward alternative powertrains. The changing attitudes appear to stem from increasing consumer exposure to electrified powertrains via the growing availability of vehicle models, styles and types, and the media attention created through manufacturer and government announcements. [EPA-HQ-OAR-2021-0208-0531-A1, p. 7] [Figure 2 can be found on p. 7 of Docket number EPA-HQ-OAR-2021-0208-0531-A1]

While the openness to electrification is growing, converting that openness to purchase intent and ultimately vehicle sales remains a challenge. As mentioned previously, the market share for BEVs, PHEVs, and FCEVs has averaged 2.4% percent over the 2018 – 2021 period. Potential buyers still see obstacles to ownership because of price, range anxiety, charging time, lost utility and host of other factors presenting a more expensive and less convenient proposition compared to their current vehicle as seen below (Figure 3). A general lack of knowledge and misunderstanding contribute to these purchase barriers. [EPA-HQ-OAR-2021-0208-0531-A1, p. 7] [Figure 3 can be found on p. 8 of Docket number EPA-HQ-OAR-2021-0208-0531-A1]

Converting openness to vehicle purchases entails bolstering the value proposition of electrification with more certain refueling availability, greater cost parity, and more of a perceived overall benefit relative to today's powertrains. This will take time and requires a systems-based approach where auto companies continuously make better vehicles, our customers both want and can afford those vehicles, and the government helps with infrastructure, codes and standards, and demand-side policies during the transition. We strongly agree with AAI's comments that specify a list of ten shared responsibilities including an all-of-government effort needed to support the transition to electrified vehicles. Toyota stands ready to do its part. [EPA-HQ-OAR-2021-0208-0531-A1, p. 8]

EPA Response

EPA agrees that vehicle buyers appear to be gaining familiarity and comfort with electrified vehicles, and that this will increase adoption of vehicles with these technologies. While the “shared responsibilities” mentioned are outside EPA’s authority or the scope of this rulemaking, EPA agrees that they would facilitate adoption of EVs.

Commenter: Volkswagen Group of America, Inc. (Volkswagen)

We must note, however, we are concerned by proposals in Congress that will hurt our ability to compete in the US market by creating discriminatory purchasing incentives for EVs that would not be available to VW Groups' US produced EVs and imported EVs. Limiting consumer choice compromises our ability to meet EPA's greenhouse gas reduction and future EV goals. [EPA-HQ-OAR-2021-0208-0237-A1, p.2]

As ambitious and committed as VWGOA is to the accelerated deployment of zero-emissions battery electric vehicles, we want to underscore how critical it is that all elements of the surrounding EV ecosystem be worked equally aggressively. Otherwise, our ambitions as well as those of the Administration, will be put at significant risk.

Policies that build consumer awareness provide valuable financial and non-financial consumer incentives, and fund the deployment of new fueling infrastructure are critical to providing consumers the confidence that they will be supported at the point of sale and over the lifetime of ownership. Namely, VWGoA wants to highlight the following list of necessary activities and initiatives, a similar version of which have also been identified by the broader industry, which must occur in parallel and are of paramount importance to meet the stated national EV adoption ambitions:

• Purchase incentives fair and equitable purchase incentives which are fully available to all qualifying electric vehicles. Restricted incentives will distort the market for EVs, limit consumer choice, and impact the ability of all manufacturers to meet increasingly stringent regulations

• EV infrastructure in sufficient quantity and type to meet the EV charging needs (i.e., residential, workplace, and publicly accessible high-speed chargers) commensurate with each year's EV adoption targets; • Fleet purchase requirements that facilitate federal, state, and local governments leading by example in EV adoption that meets or exceeds consumer adoption goals.

• Inclusion of EV charging in EPA's national Renewable Fuels Program (RFS) and/or a new national Low Carbon Fuels program that provides direct incentive to OEMs to deploy EVs;

• Robust support and properly structured incentives for EV and battery manufacturing, including sourcing of critical minerals, that don't distort the consumer market;

• Research, collaboration and guidance supporting the development of a battery component and EV recycling system in the United States consistent with global standards;

• Consumer and commercial fleet EV education programs to dramatically improve technology awareness and overcome persistent misunderstanding of how electric vehicles operate, as well as their capability to meet a diverse range of use cases.

• Adopting global standards for electrification technology and design

It is worth noting that the first item in the above list, purchase incentives, are a point of intense debate at the moment, and although not within the direct purview of the agency, we would underscore the criticality of accelerating electric vehicle adoption to meet not only the Administration's climate goals, but air quality requirements that many local governments are struggling to meet. Discriminatory EV purchase incentives which are not available to all vehicles that meet the targeted environmental attributes could ultimately attenuate EV adoption by U.S. drivers through distortions in the consumer marketplace, particularly if the subset of 'qualifying vehicles' does not meet the full range of consumer needs. We believe that the stakes are too high to tinker with the market in this way -- transportation is the #1 source of greenhouse gases in the U.S. and to pursue demand side policies that distort the marketplace would put the desired EV adoption trajectory at serious risk. [EPA-HQ-OAR-2021-0208-0237-A1, pp.4-5]

EPA Response

These comments address EV incentives that are outside EPA's authority or the scope of this rulemaking, though EPA agrees that they would facilitate adoption of EVs.

17.1. Analysis of fuel consumption, fuel savings and fuel cost offsets

Commenter: Brandt, Peter

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 214.]

It's going to save American drivers between 120 to 250 billion in fuel costs to go through with the proposed enhanced emissions standards for passenger cars and light trucks.

EPA Response

EPA agrees that this rule will provide both fuel cost savings and emission reductions.

Commenter: Center for Biological Diversity, et al.

EPA's assessment of consumer impacts provides important insights into the implications of stronger GHG standards, though it understates the benefits to consumers. While not a statutory consideration in the setting of motor vehicle emission standards under CAA 202, EPA has historically considered consumer impacts in evaluating proposals to modify its standards. EPA's approach to considering consumer impacts in the Proposal differs from the 2020 Final Rule in two primary ways. First, EPA broke down consumer impacts over discrete segments of the lifespan of the vehicle to provide additional information about the equity impacts of the Proposal on vehicle owners. Second, EPA simplified its analysis to focus exclusively on technology costs and fuel savings. As discussed below, EPA's election to analyze consumer impacts over discrete segments of vehicle lifespan was appropriate and EPA provided a reasoned explanation for doing so in this rulemaking. EPA's narrowing of the consumer analysis from the 2020 Final Rule to exclude several categories of costs and benefits on balance will result in EPA understating the consumer benefits of more stringent standards. [EPA-HQ-OAR-2021-0208-0651-A1, p. 48]

EPA provided a reasoned explanation for deviating from the 2020 Final Rule in analyzing and considering vehicle costs spread over the lifetime of the vehicle, which provides important information about the equitable implications of more stringent standards. In the NPRM, EPA broke down its analysis of consumer impacts into five-year increments (viz. the first 5 years; the next 5 years; the third 5 years) and quantified the fraction of incremental technology costs and fuel cost savings that would be experienced by the owner of the vehicle during each of those 5-year periods. Proposal, 86 Fed. Reg. at 43,798. EPA also calculated a break-even number of miles that the owner or purchaser of a new, 5-year old, and 10-year old vehicle would need to drive for fuel cost savings to offset the incremental technology cost. Id.

This approach differed from the 2020 Final Rule. In that rule, EPA declined to follow comments urging it to "calculate and consider fuel savings, spread over the lifetime of the vehicle up to 39 years and experienced by multiple owners." 85 Fed. Reg. at 25,110. Rather, EPA asserted that "the upfront vehicle technology costs (and associated financing costs) are a more important factor." Id. at 25,111.

Not only was EPA's elevation of upfront vehicle technology and financing costs over customer fuel savings and other benefits arbitrary in the 2020 Final Rule, but EPA has clearly explained its basis for changing course in the NPRM and "consider[ing] the total fuel savings of the vehicle, over its lifetime," Proposal, 86 Fed. Reg. at 43,785, emphasizing the importance of understanding the broader equity implications of more stringent standards. As EPA explained, "[d]isregarding [the fuel vehicle lifespan] benefits, which often accrue to lower income households, who more often purchase used cars, would provide a less accurate picture of total benefits to society." Id. As EPA observes, less affluent individuals are frequently purchasers of used vehicles. The payback period (in miles) for incremental technology costs decreases with vehicle age (since vehicle resale value decreases in a nonlinear manner). Thus, for a 5-year old MY 2026 vehicle, technology costs would be offset by fuel cost savings after only 32,000 miles, as compared to approximately 177,000 miles for the purchaser of a new vehicle. Id. at 43,798.

Consideration of consumer impacts over different phases of the vehicle's lifetime is important for understanding the equity implications of the new standards. More stringent standards are likely to have a disproportionately beneficial effect on purchasers of used vehicles and a progressive economic effect. It is reasonable for EPA to consider these equitable impacts in determining the final standards. [EPA-HQ-OAR-2021-0208-0651-A1, p. 48-49]

EPA failed to account for the beneficial impacts of reduced fuel prices resulting from stronger GHG standards.

EPA further understates the consumer benefits of more stringent standards by ignoring the reduction such standards would cause not just in fuel consumption but also in fuel prices. Both total fuel consumption and the price per gallon of fuel will impact the consumer benefits of new standards. See, e.g., NHTSA 2021 NPRM, 86 Fed. Reg. at 49,793 ("Fuel for vehicles costs money for vehicle owners and operators, so all else equal, consumers benefit from vehicles that need less fuel to perform the same amount of work."); id. at 49,809 ("The sensitivity cases suggest that fuel prices exert considerable influence on net benefits—where higher and lower prices not only determine the dollar value of each gallon saved, but also how market demand responds to higher levels of fuel economy in vehicle offerings."). Yet, EPA considered the rule's impact only on the former.

To evaluate the consumer benefits of the Proposal, EPA used NHTSA's CCEMS model, which as NHTSA explains, treats fuel price exclusively as an input. Id. at 49,625 ("Many of these inputs are developed outside of the model and not by the model. For example, the model applies fuel prices; it does not estimate fuel prices."). Consequently, EPA did not consider the impact that the rule would have on fuel prices.

Basic principles of microeconomics affirm that reductions in fuel consumption (i.e., reduced fuel demand) decreases the price of fuel. However, EPA nowhere accounts for this fuel price reduction. EPA projects the rule will result in a reduction of 291 million barrels of oil (9.9% of 2020 U.S. consumption) through 2050. Proposal, 86 Fed. Reg. at 43,789, Tbl. 46. This substantial reduction in petroleum demand will undoubtedly have an appreciable impact on fuel prices.113 EPA's failure to account for this impact causes EPA to further understate the benefits of stronger GHG standards to consumers. [EPA-HQ-OAR-2021-0208-0651-A1, p. 50]

EPA Response

EPA appreciates CBD et al.'s support for the analysis of the consumer impacts of the standards, presented in Preamble Section VII.J. for this FRM.

The effects of the standards on domestic fuel prices are not expected to be significant. The price of gasoline is based on the price of oil, which is set in world markets, not domestic markets. Though the volume reduction in fuel consumption is significant in the context of the U.S. economy, in the world context its effect on price is expected to be small due to inelastic demand; see the discussion of rebound in RIA Chapter 3.1 for discussion of consumer response to changes in fuel prices. We agree that, if the effect is measurable, EPA will have underestimated the net benefits of the rule.

Commenter: Consumer Federation of America

Our economic analysis shows, and the agency seems to agree that this can all be done with a net positive benefit-cost ratio. The total cost of driving will go down, measured by the pocketbook saving consumers. Public health and environmental benefits increase an already positive benefit-cost ratio. Given that finding and the already demonstrated commitment to infrastructure, all Americans of all income levels will be better off at the end of the transition. [EPA-HQ-OAR-2021-0208-0297-A1, p. 24]

EPA Response

EPA agrees that as a result of our final standards, net benefits are positive, the per-mile cost of driving will go down, and environmental benefits will accrue. See Preamble Sections VII.I. and J., and RIA Chapters 6, 7, and 10.

Commenter: Environmental Defense Fund (EDF)

Standards that eliminate tailpipe pollution from new passenger cars and light trucks by 2035 could. . .

• Save consumers over $5,000 over the life of the average vehicle. [EPA-HQ-OAR-2021-0208-0688-A1, p. 2]

Some of the benefits include:• Saving buyers of a new 2027 battery electric vehicle (BEV) more than $5,300 over the life of the vehicle. In 2035, buyers of new BEVs will save more than $8,200 compared to a gasoline vehicle; [EPA-HQ-OAR-2021-0208-0688-A1, p. 37]

EPA Response

EPA agrees that, as the up-front costs of BEVs falls, their net lifetime savings will increase.

Commenter: Environmental Protection Network (EPN)

Given the lower fuel and maintenance costs associated with EVs, a consumer who buys an EV today and drives it for many years will frequently realize a lower overall cost of ownership, but the upfront EV cost premium is still often cited as a major reason why many consumers do not seriously consider an EV purchase. [EPA-HQ-OAR-2021-0208-0213-A1, p.5]

EDF projects that consumers would benefit from new EVs being slightly less expensive to purchase and maintain beginning in 2027, and from large fuel savings due to the much lower cost of electricity per mile relative to gasoline. Owners who buy and retain a typical new model year 2035 vehicle for its full useful life would realize lifetime savings of about $8,200 relative to a comparable gasoline vehicle. [EPA-HQ-OAR-2021-0208-0213-A1, p. 7]

<u>EPA Response</u>

EPA agrees that, as the up-front costs of BEVs falls, their net lifetime savings will increase.

Commenter: Holmgreen, Jack

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 40-41.]

My '06 Sienna travels about 500 miles on 30 gallons of gasoline while my Hybrid Sienna will go that far with 12 gallons. That comes out to about a 55 percent increase in efficiency. A fully electric vehicle, however, such as the Tesla plug-in models, while having zero gasoline emissions, is actually less efficient due to the shorter range, reliance on charging from the grid, which in Texas is overwhelmingly powered by natural gas and some coal with very little wind or solar.

<u>EPA Response</u>

The range of BEVs has increased substantially in recent years. The GHG intensity of BEVs compared to ICE vehicles is also changing over time, as electricity production becomes less GHG-intensive. For instance, whereas Holland et al. (2016)[92] found that BEVs produce fewer environmental benefits than ICE vehicles in much of the country, Holland et al. (2020)[93] find the reverse when they updated their information on electricity generation. Thus, while EPA agrees that local circumstances affect the relative environmental intensity of EVs compared to ICE vehicles, the ongoing reductions in emissions from electricity generation are improving the environmental impacts of EVs.

Commenter: Kuntz, Laurie

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 209-210.]

Setting strong federal clean car standards through 2026 can put us back on track to save consumers up to $80 billion in reduced gas, maintenance, and price costs over the lifetime of new vehicles purchased during the next five years while restoring clean air in our communities.

EPA Response

EPA's comparison of fuel costs to vehicle ownership costs is in Preamble Section VII.J. EPA agrees that vehicle operating costs will be lower as a result of these standards.

Commenter: National Coalition for Advanced Transportation (NCAT)

Lower Lifetime Costs: Electric vehicle use results in significant cost savings for consumers.79 Consumer Reports finds that the total cost of ownership for the nine most popular electric vehicles—considering purchase price, fueling costs, maintenance, and more—is less on average than their conventional fuel counterparts.80 The benefits of electric vehicles add up to "many thousands of dollars" in savings, "with most EVs offering savings of between $6,000 and $10,000."81 Electric vehicle drivers save around 60% on fuel costs,82 which varies across states, but in no state is electric vehicle fueling more expensive than conventional fueling.83 And electric vehicles have lower maintenance costs than conventional fuel vehicles. Total cost of ownership for electric vehicles is expected to decline by at least a third by 2035, while the total cost for conventional fuel vehicles remains the same,84 with one report estimating that electric vehicles will be $12,800 less expensive than conventional fuel vehicles on average by 2030.85 [EPA-HQ-OAR-2021-0208-0239-A1][EPA-HQ-OAR-2021-0208-0239-A1, p. 13]

EPA Response

EPA agrees that operating and maintenance costs for EVs are lower than for ICE vehicles, and that, as up-front costs of EV technology decreases, total cost of ownership will also decline.

Commenter: Securing America's Future Energy

In 2011 there were only two electric vehicle models available in the United States. Today, however, there are now nearly 20 electric vehicles available to U.S. consumers.13 Still, electric vehicles represent just one out of every 58 new vehicles sold in the United States.[14] While this sales penetration ratio is an improvement over the rates of just a decade ago, electric vehicles remain a niche product within a car market that sold more than 14.46 million units last year.[15]

Greatly expanded model availability of EVs over the last several years has helped to interest new consumers in electric vehicles. By the end of 2020, electric vehicles were available in nearly every vehicle segment—compact cars, sedans, and SUVs, with more new vehicles, including full size pickup trucks on the near horizon. Current reports show that as many as 18 new models of electric vehicles will be available for sale by 2022.[16]

Despite the progress in bringing electric vehicles to market, the transition to electrification remains in its early stages. National sales remain heavily skewed, as approximately 37 percent of the nation's electric vehicle sales have been concentrated in California,[17] a state that in 2020 represented only 11 percent of the total new vehicle market.[18] Moreover, it can be more difficult to find a selection of electric vehicles or inventory at dealers outside California or the other states that have chosen to adopt California's strict vehicle emission standards.[19] [EPA-HQ-OAR-2021-0208-0527-A1 p. 7]

EPA Response

EPA agrees that EV adoption is in its early stages, and that increased availability of different models and styles will contribute to increasing adoption.

Commenter: Southern Environmental Law Center

[31] The national average gasoline cost burden is 7 percent of total income. Shruti Vaidyanathan, Peter Huether, & Ben Jennings, Understanding Transportation Energy Burdens, AM. COUNCIL FOR AN ENERGY-EFFICIENT ECON., iii (May 2021), https://www.aceee.org/sites/default/files/pdfs/transportation_energy_burdens_final_5-13-21.pdf. When accounting for race, in the Southeast the gasoline burden is 6.9 percent for white households, 9.5 percent for Black households, 9 percent for Hispanic households, and 4.3 percent for Asian households. Id. at 14. The gasoline burdens for low-income households are even greater: 13.8 to 14.1 percent on average nationwide. Id. at 8.

EPA Response

EPA agrees that fuel savings are important for households, including lower-income households; see Preamble Section VII.M. and RIA Chapter 8.4.1 for further discussion of these issues.

Commenter: Witt, Anthony

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 167.]

My seven-year-old hybrid vehicle gets 40 miles to the gallon. The relatively high fuel economy of my hybrid saves money at the gas pump and I know that I'm doing a small part to limit use of non-renewable resources and reduce carbon emissions.

EPA Response

EPA appreciates that the commenter is happy with his fuel-efficient vehicle.

17.2. Affordability and equity

17.2.1. Tradeoffs between Up-Front Costs and Operating and Maintenance Costs

Commenter: Allen, Martin

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 24-25.]

Upfront costs. Yes, purchasing an EV is more expensive than purchasing a petroleum-fueled car. However, the cost savings for ownership of an all-wheel drive SUV to an all-wheel drive EV have been remarkable. I went from spending over $200 per month in gasoline alone as compared with a nominal additional cost to my home electricity of maybe $30 a month, a difference in cost that more than offset my higher monthly lease payments for my EV.

After that, I have zero maintenance charges on the new car, no oil changes, no fuel changes, no filter changes, no periodic scheduled maintenance costs, and I'm saving more than the upfront costs on my 'more expensive electric vehicle.'

Commenter: American Council for an Energy-Efficient Economy (ACEEE)

Greater efficiency can also provide significant cost savings for drivers when they refuel their vehicles. Low-income households are especially burdened by fueling costs, paying three times more than their higher-income counterparts on gasoline, as a percent of their total income (Vaidyanathan, Huether, and Jennings 2021). [EPA-HQ-OAR-2021-0208-0251-A1, p.2]

Commenter: Americans for Prosperity

This proposed rule is the most expensive to date of the Biden administration; EPA estimates $150 billion through 2050.1 These new burdensome vehicle regulations will raise the price of a new vehicle by $1,044, constraining choice and replacing consumer preferences with politically preferred technology and fuels that hurt the most vulnerable citizens. [EPA-HQ-OAR-2021-0208-0226-A1, p. 1]

Commenter: Bednar, Valencia

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 210.]

I need cars to become cheaper so my family can get one.

Commenter: Center for Climate and Energy Solutions (C2ES)

The greatest barrier to purchasing an electric vehicle for many households is the up-front cost of the vehicle; although lifetime operating and maintenance costs of electric vehicles are significantly lower than those of internal combustion engine vehicles, purchase prices for both new and used models currently remain significantly higher. Performance standards and policies should support rapid cost reductions and access to more affordable vehicles. [EPA-HQ-OAR-2021-0208-0287-A1, p.4]

Commenter: Durrer, Ely

On one hand I feel like I agree with this concept. But, on the stronger hand I do not agree with this. Whether light duty vehicles or heavy duty vehicles, each one is going to cause green house gasses. I do not think that you can make cars more environmentally friendly without making the cost go up. I do think that the environment needs our help but on the flip side, it is very costly to make vehicles that are better for the environment. A good majority of the population cannot afford vehicles like that [EPA-HQ-OAR-2021-0208-0375, p. 1]

Commenter: Environmental Protection Network (EPN)

This economic calculus is also changing. With battery prices continuing to drop due to innovation and scale and gasoline vehicles getting more expensive, there is a consensus that EVs will become cost competitive with gasoline cars in the next few years. Subsequently, EVs are expected to become lower in cost than their gasoline counterparts, due to simpler designs and fewer moving parts. Then the economic proposition becomes incredibly appealing to consumers—an EV will have both a lower purchase price and be cheaper to fuel and maintain. [EPA-HQ-OAR-2021-0208-0213-A1, p.5]

Commenter: Haines, Meredith

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 114.]

To keep this in very human scale terms, driveway issues, if you will, with Alternative 2 consumers will have more dollars in their pockets, in their budgets, and Consumer Reports tells me it would be $2,100 per vehicle.

Commenter: Mass Comment Campaign sponsoring organization unknown-5 (71)

As an American consumer, I stand against the proposed rule change that would make finding affordable vehicles even more difficult because of Price Tag of Cars & Bat. Longevity etc. [EPA-HQ-OAR-2021-0208-0549,p.1]

Commenter: National Automobile Dealers Association (NADA)

Assuming the requisite desire, prospective purchasers of new light-duty vehicles must also be able to purchase or lease. Critical factors impacting ability include financial wherewithal (for most consumers, this means creditworthiness), and for alternative and new technology vehicles, the availability of convenient, cost-effective refueling. Importantly, most light-duty vehicle operators cannot afford to make a new vehicle purchase. The chart below, which is based on data from an average new vehicle purchase and on reasonable assumptions about how a U.S. household budgets for a new vehicle purchase, just under 41% of U.S. households can afford to buy a new vehicle purchase in the current market. [Chart # can be found on p. 5 of Docket number EPA-HQ-OAR-2021-0208-0290-A1]

A light-duty car or truck purchase is the most expensive consumer transaction made by most households. Unlike for most other consumer goods, more than 90 percent of consumers finance the new light-duty vehicles they acquire by means of a credit sale or lease, with less than ten percent involved in all-cash transactions. When prospective purchasers lack sufficient creditworthiness to enable a lender or lessor to finance the new light-duty vehicles they desire, they may be compelled to consider other options, including less expensive new vehicle choices. At some point, no new vehicle options are available, leaving consumers with three principal transportation choices: the used vehicle marketplace, maintaining their current personal transportation (vehicle service and repair), or foregoing personal transportation altogether in favor of potentially less practical and convenient (if available) transportation options like public transportation, or ride-hailing (e.g., Uber, Lyft, or taxis).

Importantly, with respect to the new vehicles subject to EPA's proposal, whether prospective purchasers can get financed (and on what terms) will not at all depend on whether those vehicles offer prospective purchasers improved GHG emission reduction performance or better fuel economy. When underwriting loans or leases, lenders and lessors do not consider whether new vehicles offer more torque or horsepower, improved fuel economy, reduced GHG emissions, ubiquitous cup holders, or prettier paint. All that matters is whether prospective purchasers are creditworthy; that is, whether they will comply with their payment obligations as spelled out in their loan or lease. Regarding new vehicles themselves, lenders and lessors use objective criteria and focus on one key factor: the total amount financed.

EPA's proposal keys on the increased fuel economy performance resulting from enhanced GHG emission reductions (i.e., operating cost reductions) as potentially mitigating or offsetting the higher up-front costs needed to buy such performance, particularly for lower-income households.18 Admittedly, certain business and "fleet" buyers may use total cost of ownership (TCO) analyses that balances higher up-front costs against lower operating costs. But for the vast majority of prospective purchasers, TCO "payback" cost/benefit analyses are flawed and problematic for several reasons.

Consumers shopping for vehicles with better fuel economy19 cannot obtain that improved fuel economy unless they are able to pay for it. As noted above, over 90 percent of new vehicle customers finance or lease, typically at or near the maximum terms for which they qualify. Thus, when vehicle prices increase due to higher costs, consumers may no longer qualify for the same loan or lease amount. Moreover, increased per vehicle costs constrain the ability of retail consumers to obtain loans with affordable monthly payments. Simply, it is commercially unreasonable to expect vehicle lenders and lessors to know and account for potential reductions in vehicle operating costs, such as those that may result from lower fuel costs, because they cannot predict actuarially whether any such cost reductions will be saved, let alone applied to a loan or lease. And while EPA asserts in its proposal that some lenders give discounts on loans to purchase more fuel-efficient vehicles,20 the reality is that lenders and lessors do not consider vehicle operating costs when they offer loan or lease terms, which, as noted, usually reflect the maximum for which a consumer qualifies.21 [EPA-HQ-OAR-2021-0208-0290-A1, p. 4-6]

Commenter: National Coalition for Advanced Transportation (NCAT)

Declining Battery Costs: Electric vehicle battery costs have continued to decline, reducing the cost of electric vehicles relative to other vehicles.71 Bloomberg New Energy Finance finds that the cost of lithium-ion batteries fell 89% from 2010 to 2020—with a 13% drop in just 2020 alone.72 This trend is expected to continue due to advances in battery chemistry and the opportunities presented by economies of scale as the battery market grows.73

Declining Purchase Price: Electric vehicles are rapidly moving toward purchase price parity, in part because of declining battery costs. Between 25% and 40% of a battery electric vehicle's total price is typically attributable to the battery. 74 UBS75 and BNEF76 both predict that by 2025, battery prices will have dropped so much that battery electric vehicles will no longer cost more to manufacture than conventional fuel vehicles. The Goldman School of Public Policy predicts this price parity in the mid to late 2020s.77 By 2022, there will be at least six electric vehicles models priced below $30,000. 78 [EPA-HQ-OAR-2021-0208-0239-A1, p. 12-13]

Commenter: Osbourn, Paul

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 186-187.]

While I believe the EPA plan has a noble intent, I am concerned about the economic impact and it potentially having a counterproductive result.

We have seen trucks go from 2012 selling around $25,000 to today at over $45,000 and this current plan looks to drive things well north of 50. With the addition of precious metals that will have to go into the catalyst calibration time, we expect that.

We're already seeing fleets in dealers around the country placing record orders for Model Year '22. Some manufacturers have already shut off the order window as early as November, which normally would have stayed open well into March or April of next year.

The reason they're doing it is to avoid what they believe to be higher prices of the Model '23 and newer vehicles.

Commenter: Peavler, Jean

As an American consumer, I stand against the proposed rule change that would make finding affordable vehicles even more difficult because electric vehicles are more expensive, used gasoline vehicles would become obsolete and have no resale or trade-in value, and any still-existing gasoline vehicles would be small, lightweight, and unsafe because of the increased fuel economy standards they would need to meet. [EPA-HQ-OAR-2021-0208-0395, p. 1]

Commenter: Southern Environmental Law Center

Drivers are estimated to save between $150 billion and $290 billion through 2050 under Alternative 2 (as compared to between $120 billion and $250 billion under the proposed standards over that same period) .[30] These savings make a real difference for drivers, especially for low-income households and households of color that generally spend a greater proportion of their income on transportation costs .[31] [EPA-HQ-OAR-2021-0208-0244-A1, p. 5]

[31] The national average gasoline cost burden is 7 percent of total income. Shruti Vaidyanathan, Peter Huether, & Ben Jennings, Understanding Transportation Energy Burdens, AM. COUNCIL FOR AN ENERGY-EFFICIENT ECON., iii (May 2021). When accounting for race, in the

Southeast the gasoline burden is 6.9 percent for white households, 9.5 percent for Black households, 9 percent for Hispanic households, and 4.3 percent for Asian households. Id. at 14. The gasoline burdens for low-income households are even greater: 13.8 to 14.1 percent on average nationwide. Id. at 8.

Commenter: Tesla

Electric Vehicle Technology Costs Compare Favorably with ICE Vehicles and Are Rapidly Declining.

Tesla cannot achieve its mission without increasing consumer access to EVs, especially to those most negatively impacted by the effects of climate change. Therefore, Tesla is hard at work on battery cell innovations that it expects will lower kWh battery costs by over 50%.119 The Tesla Model 3 is the first EV in history priced on-par with its gas-powered equivalents, even before taking into consideration any regional subsidies and lower total costs of ownership from fuel and maintenance.120

As of June 2021, the Model 3 currently retails for less than the average cost of a light-duty vehicle in the U.S., estimated at over $42,258, the average price of a full-size pickup truck ($57,267) and the average price of a full size SUV ($68,173).121 Over five years of average driving, the ownership costs of a Tesla Model 3 are roughly the same as a Toyota Camry. 122 Notably, running costs such as fuel (electricity or gasoline), maintenance, tires and repairs for Model 3 should cost just over half of a mass-market ICE vehicle such as a Toyota Camry.123 [EPA-HQ-OAR-2021-0208-0278-A1][pp.14-15]

Commenter: Trevino, Erandi

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 194.]

As the previous speakers have noted, there is a big leap financial struggle that communities face in buying an electric vehicle. So that the only way that we can reach a point where electric vehicles are such a big part of our transportation system is if the people get help in order to make that initial payment.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 195.]

So, please, I urge you to be as effective and as aggressive in terms of funding for making it so that people are even able to make that purchase because the way that it is right now, people are struggling even to buy cars at the lower end. They're becoming more expensive every day.

I'm sure you have heard about the chip shortage that has caused vehicle shortages all over the country. So vehicles are already becoming more and more expensive and electric vehicles are even more expensive than that.

So in order for it to be a reality for people who are not earning any additional money now that prices are going up, it would be really great to see a program that makes this a possibility for the communities that are impacted the most, the ones that are already at the fenceline with these refineries and these other sources of carbon emissions.

Commenter: Valero Energy Corporation (Valero)

Regarding consumer protection, although EPA concludes that the prohibitive up-front costs of electric vehicles will eventually be offset by fuel savings from improved efficiency, this conclusion is inconsistent with the findings of comprehensive assessments by Arthur D. Little Consulting and an April 2021 Report by Argonne National Laboratory.15 Further, the preamble acknowledges that consumers will be impacted by higher vehicle purchase costs and that this may particularly impact consumers' ability to obtain credit. Although EPA projects that the proposed rule will result in doubling the current electric vehicle fleet in a four-year period, the preamble omits any consideration of harm to consumers resulting from increased costs and diminished reliability resulting from increased electricity demand. It does not appear that EPA has considered the findings of a recent IEA report noting that there are insufficient mineral resources or processing capability to supply the need for electrification of the transportation sector. 16 EPA should evaluate whether such scarcities have the potential to result in significant price increases to consumers as well as shortages of batteries and vehicles. [EPA-HQ-OAR-2021-0208-0601-A2, p.7]

EPA Response

Many of these comments address the tradeoff between the increased up-front vehicles costs and the lower operating and maintenance costs due the to these standards or associated with EVs in particular. As discussed in Preamble Section VII.J., the estimated fuel savings for vehicles subject to the standards are expected to outweigh the up-front technology costs over the vehicle’s lifetime. The net purchase cost to an owner will depend on the vehicle age when bought, and, if sold, the length of time that the vehicle was owned. In general, the purchasers of older vehicles will see a greater portion of their depreciation costs offset by fuel savings. EPA agrees that, as the up-front costs of EVs decrease over time, the net lifetime savings and total cost of ownership of these vehicles will continue to fall. For more information from EPA’s updated analysis for the final rule, see Preamble section VII.J.

Some comments express concerns over the increase in up-front costs because the higher costs may limit purchases due to inability to access credit for the higher amount. As EPA discusses in Preamble Section VII.M. and RIA Chapter 8.4.3, while we recognize this concern, the evidence we have collected suggests that there is no clear criterion for determining how or whether people will have trouble gaining access to credit. Debt-to-income ratio, for instance, does not appear to be a rigid criterion: even if lenders use “objective criteria” to measure this ratio, there appears to be some discretion in how the ratio is used. In addition, some lending institutions offer a reduced loan rate for “green” vehicles, even though, as NADA points out, many lenders do not take into account reduced fuel consumption when deciding how much to lend.

NADA expresses concern that “At some point, no new options are available,” due to lack of access to credit. A recent EPA report analyzes the interconnectedness of the new and used vehicle markets.[94] If used vehicles become a more desirable option than new vehicles, then sellers of used vehicles will get a higher price. Because the initial sellers of used vehicles are those who bought new vehicles, the new vehicle buyers are recovering a greater proportion of the new vehicle costs. This higher resale price provides feedback to new vehicle buyers that they will not bear the full costs of the higher prices, and they are thus more willing to buy the higher-priced vehicles. The higher number of new vehicles then reduces the higher prices to used-vehicle buyers. This effect leads to lower impacts on new vehicle sales than if the feedback between the new and used vehicle markets is not considered. NADA’s extreme case thus is unlikely to materialize. This finding is discussed in RIA Chapter 8.1.2 and Section 18 of this Response to Comments in the form of the inelastic response of new vehicle sales to higher new vehicle prices. RIA Chapters 8.1.2 and 8.1.3 discuss our calculation of vehicle sales impacts, which we estimate to reduce sales by up to 1 percent, though the effects may be less negative or even positive.

Several commenters discuss the high average price of new vehicles and concerns over the standards increasing that price. A couple commenters point specifically to increased vehicle costs due to shortages of microchips. It is difficult to separate, in this average, the effect of higher vehicle costs from the effect of changes in the mix of vehicles purchased: when people buy a higher share of more expensive vehicles (for example, more SUVs instead of sedans), the average price increases even if the prices of all vehicles stay the same. The recent EPA Automotive Trends report shows the increase in production share of truck SUVs in recent years, with sedans and wagons decreasing their shares;[95] this trend is expected to contribute to the increase in average vehicle prices. The increase in microchips is expected to be due to pandemic supply chain issues and thus temporary. As discussed in Preamble Section VII.M. and RIA Chapter 8.4.4, a wide range of vehicle models and price points are available in the new vehicle market. See Preamble Section VII.A. and RIA Chapter 8.1 for further discussion of the role of reduced fuel consumption in vehicle purchase decisions.

With regard to the comments suggesting that financial support is needed for EVs to become a “big part of our transportation system,” the comments are outside the scope of this rulemaking and EPA does not have the authority to provide subsidies for vehicle purchases.

Even while EVs become a larger share of new vehicle purchases, used gasoline vehicles are expected to stay in use for several decades, due to their reliability. They will become obsolete or

---

have no resale value only if EVs become very widespread in the used vehicle fleet as well as the new vehicle fleet.

See Section 21 for discussion of the safety impacts of the standards.

The performance-based, footprint-based standards are intended to maintain the diversity of vehicle sizes and utilities, while providing multiple paths for compliance. See Section 17.2.2 for further discussion of the impacts of the standards on choices of vehicles available.

See Section 12.1 for discussion of the effects of EVs on the reliability of electricity production.

See Section 12.1 for discussion of the costs specifically associated with EVs, and Section 19 of this document for discussion of access to minerals needed for EVs.

17.2.2. Effects on Lower-Income Households

Commenter: Americans for Prosperity

The Proposed Rule Will Raise the Cost of New Vehicles and Hurt the Most Vulnerable. In 2021 the average price of a new vehicle is over $40,000, nearly $2,300 above the average cost in 2020. 11 EPA's proposed rule is the most expensive rule to date from the Biden administration costing $150 billion through 2050.12 These new burdensome vehicle regulations will raise the price of new vehicles yet again with a low estimate from EPA of an additional $1,044 in cost per vehicle by 2026. The proposal constrains choice and replaces consumer preferences with politically preferred technology and fuels that hurt the most vulnerable Americans.

Affordable mobility for individuals, especially low-income individuals is essential to earn success, provide for their families, and ultimately realize their potential. In the Regulatory Impact Analysis (RIA) EPA claims, '[t]hese standards might affect affordability of vehicles and their impacts on low-income households in particular.'13 The Agency suggests 'online working and shopping may provide alternative ways to accomplish some goals, for those with stable access to internet services.'14 This out of touch response is one of many throughout the regulatory analysis, this does not present a solution to the problem for many working individuals or students that rely on a vehicle to get places.

EPA and the administration's focus on helping disadvantaged communities is lost in this proposed rule, many of these low-income individuals live in these communities. In the RIA the Agency states '[i]t is not clear how to identify the socially acceptable minimum level of transportation service. It seems reasonable to assume that such a socially acceptable minimum level should allow access to employment, education, and basic services like buying food, but it is not clear where consumption of transportation moves from necessity to optional.'15 When push comes to shove the Agency does not recognize affordable mobility or freedom of mobility as a means of allowing people to prosper in society. The Agency views this as a current 'necessity' that can change to an 'option'. Any supposed benefits from the proposed standard would not be going to these disadvantaged communities and would instead hurt them. What you can expect is, you will be priced out of new vehicles and used vehicles could increase in price too. This sentiment from EPA should concern consumers and environmental justice advocates. [EPA-HQ-OAR-2021-0208-0226-A1, pp. 3-4]

Commenter: Attorney General of Missouri et al.

Negative Impact on Working-Class Americans. The EPA claims to have considered the negative impact of this rule on lower-income families by analyzing 'The increase in the up-front costs of new vehicles subject to more stringent standards, and the decrease in operating costs from reduced fuel consumption over time.' FR 43737. Not surprisingly, the EPA concludes that in spite of the 'increase in up-front new vehicle costs ... the potential to increase the prices of used vehicles, to make credit more difficult to obtain, and to make the least expensive new vehicles less desirable compared to used vehicles,' all-in-all, this policy will benefit the poor. FR 43737. After all, reasons the EPA, at some point in the future, when upfront costs of this new technology and/or higher fuel efficiency standards has somehow been absorbed, the poor (who naturally buy less expensive traditional cars) will reap the benefits of a lower per-mile fuel cost. Or, with luck, there will be an 'increase access to transportation services, such as ridehailing and ride-sharing, where the lower per mile costs may play a larger role than up-front costs in pricing.' FR 43737. This gives the impression that the American public should not worry about making vehicles more expensive because minimum wage workers can always just call a cab or an Uber. Though the bureaucrats at the EPA seem oblivious to the real-world impact of their proposed regulation, as elected officials from our respective states we are concerned that costs will be shifted to those who can least afford them. [EPA-HQ-OAR-2021-0208-0288-A1, p.17]

Commenter: California Air Resources Board (CARB)

The proposed standards will also deliver greater economic benefits to those that need the most assistance. California agrees that for most of the population, operating and fueling costs are lower for electric vehicles, although it may not be the case for all individuals. In assessing standards and how they affect equity, California also agrees that it is important to consider the used car market since 70 percent of car purchases are used.74 More stringent standards benefit aftermarket buyers as well as new car buyers.

California appreciates EPA's actions to acknowledge past and current policies that result in environmental, health, and other social burdens and future actions to assess and minimize further harms, meet equity goals, and distribute community benefits intentionally and equitably. Looking at the affordability and equity impacts of the proposed standards is critical to ensuring that all communities benefit and are not negatively impacted. [EPA-HQ-OAR-2021-0208-0643-A6, pp. 27-28]

In sum, stricter emission standards that pay for themselves through reduced fuel costs would deliver greater benefits to the people that need them most – those with lower incomes who spend a greater percentage of their household budget on transportation. U.S. EPA fails to quantify these benefits. [EPA-HQ-OAR-2021-0208-0643-A6, p. 40]

Commenter: Center for Biological Diversity, et al.

To help address upfront affordability impacts for low income consumers, the Biden administration should develop targeted incentives for environmental justice communities.

Though upfront affordability impacts for lower income households are a concern, the Proposed Standards would reduce the total cost of vehicle ownership over its lifetime. DRIA at 8-20. The Proposal would benefit lower-income used-vehicle purchasers more than new vehicle purchasers (by offsetting the used vehicle cost with fuel cost savings much more quickly than for new vehicle purchases), Proposal, 86 Fed. Reg. at 43,798; see consumer impact section supra, and lower-income households may benefit more from operating cost reduction than the upfront cost increase because "they own fewer vehicles per household, spend more on fuel than on vehicles on an annual basis, and those fuel expenditures represent a higher fraction of their household income." Proposal, 86 Fed. Reg. at 43,804.175 Increasing stringency by adopting Alternative 2 plus would help bring more electric vehicles to the market faster, lowering upfront vehicle costs sooner, and increasing affordability for potential low-income purchasers as more electric vehicles are moved to the used car market.176 Nevertheless to help prepare for an electric vehicle future, this Administration should develop a suite of programs to address the barriers to electric vehicle adoption in environmental justice communities.

President Biden's E.O. 14008 directs federal agencies to develop programs to address disproportionate adverse impacts as well as accompanying economic challenges.177 This administration should address affordability implications of this Proposal and future increased vehicle electrification through targeted policy mechanisms that direct dollars to the consumers who most need it.

Studies have shown that low-income EV buyers are more responsive to incentives,178 and have suggested gradually increasing eligibility requirements by income.179 State policies offer examples of income-qualified policies that could be considered.180 California provides grants and affordable financing to help income-qualified Californians purchase or lease hybrid or electric vehicles.181 Pennsylvania offers an additional rebate for purchase of hydrogen fueled, battery and plug-in vehicles for low-income residents.182

For policy recommendations, we encourage review of the Greenlining Institute's "Electric Vehicles for All: An Equity Toolkit."183 Greenlining recommends that up-front vouchers or "instant cash rebates" like Connecticut's program184 are the most effective purchase incentive tool because they reduce the price of the vehicle at the time of purchase. Although tax credits can lower annual income taxes, because a purchaser has to wait until tax season for the benefit, and because low-income individuals usually have low tax liability, these mechanisms are less equitable. Financing assistance like loan loss guarantees for financial institutions or programs that buy down interest rates for consumers can improve loan options for potential low-income EV purchasers.

Policymakers can also ensure targeted deployment of public charging stations to support affordability and access for environmental justice communities. One California pilot program has a 15 percent minimum commitment with a goal of 20 percent in disadvantaged communities.185 [EPA-HQ-OAR-2021-0208-0651-A1, p. 73-76]

Commenter: Center for Climate and Energy Solutions (C2ES)

In addition to up-front costs, many households cite lack of access to charging infrastructure as a barrier.11 These households are overwhelmingly residents of lower-income communities or communities of color, and often historically marginalized communities who have disproportionately borne the largest costs of climate change and pollution, while contributing the least to global emissions.12 An equitable and just climate future should prioritize increased access to cleaner, quieter, safer, and lower emitting vehicles for these communities. [EPA-HQ-OAR-2021-0208-0287-A1, p.4]

In 2021 alone, states including Louisiana, Maryland, Indiana, and North Carolina announced millions of dollars in grants to local utilities and municipalities to install charging stations, many emphasizing expanding access for rural or low income communities.17 [EPA-HQ-OAR-2021-0208-0287-A1, p. 5]

Commenter: Connecticut Department of Energy and Environmental Protection

Additionally, EPA and the federal government need to adopt policies to improve access to clean forms of transportation in underserved and highly impacted environmental justice communities. [EPA-HQ-OAR-2021-0208-0264-A1, p.2]

Commenter: Consumer Reports (CR)

New car buyers on average are older, whiter, and wealthier than average,18 and the decisions they make determine the vehicles available for purchase on the used market. That means that the preferences of a smaller, less diverse subset of Americans largely drives the market for new cars, even if those vehicles do not match the needs and wants of the 70% of Americans who can’t afford, or chose not to enter, the new car market.19 Strong federal standards are necessary to ensure the needs of all Americans are met by the new car market, even those who cannot afford to participate in it. In setting these standards EPA should explicitly consider the needs of lower income Americans, who participate mainly in the used car market, and spend a larger portion of their income on fuel. [EPA-HQ-OAR-2021-0208-0602-A1, p.9]

Commenter: Dream Corps Green for All et al.

Strong GHG emission standards for passenger vehicles are essential to meet climate and racial equity goals. Racial inequalities in wealth, health, and risks from a changing climate based on where we live mean that every improvement to addressing climate change is especially beneficial to people and communities of color.[2] We may be beyond the point of being able to truly 'fix' the climate disaster that burning fossil fuels has wreaked, but every fraction of a degree matters. The big impact of a marginal difference in emission abatement is especially felt by the most vulnerable--people who live in floodplains or heat islands (often redlined neighborhoods), low-income households who may be uninsured or underinsured for health or property coverage, people who don't have the means to move or improve the resiliency of their homes, and people exposed to air pollution or who have pre-existing health conditions are all more vulnerable to the effects of climate change.[3] [EPA-HQ-OAR-2021-0208-0285-A1, pp.1-2]

In addition, the losses of low-wealth households are inherently underestimated in cost-benefit analyses from climate change because their assets are statistically undervalued compared to those of high-wealth households.[7] For example, the loss of a home due to flooding is calculated by the market value, which would assess a home in a high-wealth neighborhood as a greater loss than a home in a lower-wealth neighborhood, but it is still the loss of a family's home. This inherent bias in cost-benefit analysis that undervalues the quality of life and public health impacts for low-wealth- (disproportionately BIPOC) held assets is beyond the scope of this one rulemaking, but the presence and direction of this bias further supports adopting the strongest feasible emission standard that shows positive net benefits. [EPA-HQ-OAR-2021-0208-0285-A1, p.3]

Strong GHG emission standards for passenger vehicles help lower transportation costs for low-income drivers and advance long standing environmental justice goals. Cleaner vehicles save money. [EPA-HQ-OAR-2021-0208-0285-A1,p. 3]

In addition to the health, economic, and innovation benefits of stronger standards, cleaner vehicles actually have lower costs for both maintenance and fueling than dirtier vehicles. While in the short-term, adding low or zero-emission technology to vehicles does increase the upfront costs for new vehicles, the total cost of ownership for many cleaner vehicles is already lower,[9] and price parity on upfront costs of cleaner technology for new vehicles will occur for most passenger vehicles within five years.[10]

Low-income households spend a disproportionately higher share of their income on gasoline and purchase primarily used vehicles.[11] As EPA itself and Consumer Reports have pointed out, owners of used vehicles get the savings from cleaner vehicles at a lower upfront price because vehicles depreciate while their fuel economy remains steady.[12] Most vehicle owners, especially low-income vehicle owners, purchase used vehicles, and so the net benefits are progressive with the largest benefits going to lower-income households.[EPA-HQ-OAR-2021-0208-0285-A1, p.4]

Cleaner vehicles reduce health burdens. Low-wealth and BIPOC (Black, Indigenous, People of Color) communities experience disproportionate harm from vehicle pollution, which compounds exposure with other sources of pollution and disproportionate stressors, leading to increased rates of illness and premature death.[13] In addition, localized pollution hotspots are often overlooked in EPA's air quality monitoring,[14[so the benefits of reducing emissions from passenger vehicles in heavily polluted areas or highly trafficked corridors may be underestimated. [EPA-HQ-OAR-2021-0208-0285-A1, p.4]

Neglecting the most vulnerable among us has exacerbated the current pandemic and propped up a fossil-fuel based economy, which as we know, puts everyone at risk. We can build prosperity for all Americans by adopting pollution standards that are strong enough to protect the health of the most vulnerable and to encourage innovation and deployment of clean transportation solutions.[EPA-HQ-OAR-2021-0208-0285-A1, p.5]

Stronger standards improve access to electric vehicles. Stronger standards also improve equitable outcomes because they stimulate deployment and manufacturing of electric vehicles. As electric vehicle adoption becomes more widespread and EVs are readily available at different price points and in the used market, this will reduce the potential of “eco-apartheid” where people with high-wealth have access to efficient, electric vehicles and homes and people with low-wealth are stuck with high energy and fuel bills and health burdens while still being reliant on fossil fuels.15 [EPA-HQ-OAR-2021-0208-0285-A1, pp. 4-5]

Commenter: Institute for Policy Integrity

EPA should consider the economic effects to lower-income households as well as the environmental justice effects from changes to criteria and toxic pollution, and the environmental justice gains associated with the increased climate benefits from more stringent alternatives.15 If Alternative 2 plus the 5–10 g/mile increase for MY 2026 is consistent with equity goals as well as with EPA’s statutory mandates and with maximizing net benefits, that would further strengthen the case for selecting that combination of policy options. [EPA-HQ-OAR-2021-0208-0299-A1, p. 3]

Commenter: Kreucher, Walter

According to the NPRM, ‘the majority of both costs and benefits that occur under the proposed standards accrue to buyers of new cars and trucks, rather than society in general.’ Since only the wealthy can afford to purchase new vehicles, minority communities will be harmed by this rulemaking action. More specifically, only the ultra-wealthy can afford the price premium for costly electric vehicles (even with the tax credits which only the wealthy can use) advocated in the rulemaking.

The CAFE Model estimates that between $800 million and $1 billion will be spent on tax credits given to the wealthy for the purchase of electric vehicles. [EPA-HQ-OAR-2021-0208-0199-A1, p. 11]

Commenter: Osbourn, Paul

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 186-187.]

The reason they're doing it is to avoid what they believe to be higher prices of the Model '23 and newer vehicles.

This also has a significant impact to the used truck market. The people that fix your roof and paint your house and deliver your Amazon packages and trim your trees, these folks typically drive used vehicles and those folks are also seeing particularly with the chip shortage incredible rises in prices. What they typically end up doing is extending the life of their vehicle. They will often just buy a new engine or rebuild the transmission and we get stuck with the same emissions that we had that we're trying to replace.

Commenter: Platt, Keari

Increased stringency standards work in tandem with state-run programs that enable low-income individuals to purchase fuel efficient vehicles. Often, low-income individuals and members of environmental justice communities are unable to obtain more energy efficient technologies. To address this issue, California operates the Clean Vehicle Assistance program, so that low-income individuals can purchase more efficient vehicles4. If automakers are required to put more of these vehicles on the market, qualified low-income individuals will likely have wider variety of affordable purchase options. With that, expanding the number of full electric vehicles sold will prompt automakers to provide more public charging stations, further increasing access to these vehicles.5 Overall, setting more stringent standards for automakers will ensure that there is variety of zero emissions cars on the market, benefitting all income groups. [EPA-HQ-OAR-2021-0208-0201-A1, p. 2]

Commenter: Poore, Michael

Additionally, while it does consider environmental justice issues, I believe more research needs to be conducted regarding short term affordability and equity. [EPA-HQ-OAR-2021-0208-0371, p. 1]

Commenter: Stellantis

Unfortunately, the current federal incentive structure does not go far enough to reach the necessary consumers for the future of electrification. The current structure phases out the credit for a manufacturer’s vehicles after 200,000 units are sold, which could help increase the diversity of vehicles in the short term, but is not expansive enough to capture market needs. Additionally, the current incentive is non-refundable and requires consumers to wait until their annual tax filings to benefit from any funds they are eligible for given their individual tax liability. This has been shown to leave out many consumers, particularly those in low- to moderate-income ranges. Figure 5, below, from the Center for Sustainable Energy shows how much of the incentive was received by consumers broken down by percentage of the Federal Poverty Level.35 [Figure 5 can be found on p. 23 at docket number EPA-HQ-OAR-2021-0208-0532-A1]

Commenter: Taxpayers Protection Alliance

Despite stated goals of reducing the likelihood and severity of significant climate change, proposed changes to current standards would do little to reverse current climate trends at a significant cost. The increased expenses that would result from tighter regulatory requirements would be disproportionately borne by low-income Americans, who have already had to face rising prices and dire job prospects over the past year. The Environmental Protection Agency

(EPA) can strive toward a better, cleaner future without imposing large runaway costs on consumers and taxpayers across the country. [EPA-HQ-OAR-2021-0208-0202-A1, p.1]

In recent years, emissions requirements have become a bipartisan endeavor. Politicians and political appointees across the aisle tend to agree on the need for some emission control, even if they disagree on the magnitude of required changes over time. For example, the current 'Safer Affordable Fuel-Efficient Vehicles Rule for Model Years 2021-2026 Passenger Cars and Light Trucks' (SAFE Rule) put into place by the Trump administration requires emissions to be reduced by 1.5 percent each year over the next five years.

In contrast, the current rule proposed by the EPA calls for approximately 5 percent annual reductions in light-duty vehicle emissions. This policy would essentially replicate the Obama administration's approach, continuing the unfortunate status-quo of administrations steering the regulatory state to reflect partisan preferences. The shift back to the Obama era would result in significant costs for a country already gripped by rising inflation. The EPA estimates $150 billion in increased costs through 2050. Given that there are roughly 17 million light-duty vehicles sold each year, the proposed changes would result in an indirect tax of approximately $300 for buyers. And like most lump-sum taxes on products, the impact would disproportionately be felt by low-income consumers. [EPA-HQ-OAR-2021-0208-0202-A1, p.1]

Commenter: Trombetta, Nick

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 217.]

Furthermore, clean cars standards are a win for everyone, consumers, car manufacturers, and the environment. It will allow customers to more easily afford fuel efficient vehicles which are frequently more expensive than gas-guzzling alternatives.

<u>EPA Response</u>

Commenters differ on whether the standards will benefit or harm lower-income households. EPA discusses the impacts of the standards on lower-income households in Preamble Section VII.M. and RIA Chapter 8.4.1. As discussed there, lower-income households disproportionately buy used rather than new vehicles, and, as some commenters note, they spend a higher share of their income on fuel than higher-income households. Attorney General of Missouri and Taxpayers Protection Alliance put more emphasis on the up-front costs of new vehicles than on the reduced operating and maintenance costs. As discussed in Preamble Section VII.J., buyers of used vehicles subject to these standards are expected to benefit more than buyers of new vehicles, because of the lower up-front costs of used vehicles that will also have reduced operating costs.

Americans for Prosperity (AFP) asserts that "the Agency does not recognize affordable mobility or freedom of mobility as a means of allowing people to prosper in society." RIA Chapter 8.4 discusses defining and measuring affordable mobility, in order to assess these effects. Among the challenges associated with defining affordable mobility is that transportation needs vary with individual circumstances, such as the nature of a person's employment, health, and where they live relative to work and shopping. Nevertheless, as discussed in RIA Chapter 8.4.1 and in the previous paragraph, we examine effects on lower-income households, who are expected to see benefits from lower vehicle operating costs. We note that AFP does not provide suggestions for defining or measuring affordable transportation. AFP considers EPA's mention of online working and shopping as possible adaptations "out of touch. . . for many working individuals or students that rely on a vehicle to get places." EPA's statement was in the context that many people in the U.S. currently do not own vehicles and already seek out alternatives to driving; other people who do have access to vehicles seek alternatives to using them, or to adding vehicles to their households. Reducing the operating costs of transportation alternatives may provide greater mobility through lower per-mile costs.

EPA disagrees with AFP, Attorney General of Missouri, Kreucher, and Taxpayers Protection Alliance that disadvantaged communities would not get benefits from these standards. As noted by Blue Green Alliance, CARB, CBD, Consumer Reports, Dream Corps Green for All, and discussed in RIA Chapter 8.3, many low-income communities are disproportionately affected by environmental damages associated with climate change and local air pollution, and will benefit from reduced emissions associated with these standards. In addition, as discussed in RIA Chapter 8.4.1, lower-income households disproportionately buy used vehicles; Preamble Section VII.J. provides calculations supporting the conclusion that used-vehicle buyers will get most of the benefits of more efficient vehicles meeting the final standards, because up-front costs are depreciated while fuel savings persist. As Consumer Reports notes, new vehicle purchasers are wealthier than average, and are therefore more likely to bear higher up-front costs than lower-income households.

EPA disagrees with the Attorney General of Missouri and the Taxpayers Protection Alliance that the standards will have minimal or negative impacts on the environment (see Preamble Sections IV. and V. and RIA Chapter 5.1), or the economy (see Preamble Section VII.I. and RIA Chapter 10) because we in fact project significant emission reductions and net societal benefits from the final standards. Energy security impacts are discussed in RIA Chapter 3.2, and impacts on lower-income households in RIA Chapter 8.4.1.

While EPA considers its assessment of affordability and equity implications of the standards to provide insights on these issues, we agree with Poore that further research would further clarify these effects.

AFP asserts that the standards will constrain choice and require "politically preferred technology." The standards are performance-based; they do not require any specific technology to be in compliance. In addition, the use of footprint-based standards is intended to support the diversity of vehicle sizes. Further, EPA's cost estimates are based on the diversity of vehicles in the fleet. As Helfand and Dorsey-Palmateer (2015) and Whitefoot et al. (2017) discuss, basing cost estimates on maintaining constant performance and other vehicle attributes is likely to overstate the costs of the standards, because automakers and vehicle buyers will decide for themselves whether to maintain attributes and increase costs, as modeled here, or reduce attributes and reduce costs.[96] They will choose the latter option only if they prefer it to the option modeled here. If they do, the chosen option must be preferable and thus have lower costs or higher benefits.

Complementary policies to assist lower-income (or other) households with EV purchases are generally beyond the authority of EPA or the scope of this rulemaking, though we agree such measures would facilitate EV adoption in those communities.

Commenter: California Air Resources Board (CARB)

CARB appreciates U.S. EPA's recognition that consumers value savings differently than presumed in the SAFE Final Rule. However, CARB continues to disagree that a sales elasticity of -1 is a valid estimate of consumer response to price changes. Even U.S. EPA's Science Advisory Board has criticized a sales elasticity estimate of -1. As Professor Gillingham explains in his enclosed expert comment, it is not much more than an assumption. The best evidence supports an elasticity of -0.34. U.S. EPA should adopt this estimate as its base case, which is close to its sensitivity case of -0.4, and explore sensitivity cases using a sales elasticity closer to zero.114 Underscoring the point, as Gary Rogers of Roush Engineering explains in his accompanying expert report, consumers are responding positively to the features and performance of the vehicles that pollute less. [EPA-HQ-OAR-2021-0208-0643-A6, p. 38]

U.S. EPA should apply more reliable estimates of the rebound and sales effects of more stringent standards to provide more reliable estimates of the costs and benefits of the proposal. In both instances, it happens that the net benefits are greater than otherwise estimated. [EPA-HQ-OAR-2021-0208-0643-A6, p. 38]

Commenter: California Attorney General Office, et al.

Notably, sales of these vehicles have outpaced EPA's projections.132 And there are good reasons to expect these trends to continue.133 [EPA-HQ-OAR-2021-0208-0245-A1, p.28]

Commenter: Center for Biological Diversity, et al.

EPA overstates the impact of stronger GHG standards on vehicle sales, increasing the costs and decreasing the benefits of more stringent standards.

EPA's use of a -1.0 price elasticity of demand for new vehicles is arbitrarily high and EPA should correct it to a price elasticity value that is lower in magnitude.

EPA's Proposal offers no support for its use of a -1.0 price elasticity of demand for new vehicles, merely stating that the value comes from the 2020 Final Rule and that the agency is working to review more recent estimates. 86 Fed. Reg. at 43,788. EPA is correct to reconsider using -1.0 as the price elasticity of demand applicable to this regulatory context, as this value is inaccurate, unsupported by both historical and recent research, and leads to an artificially high decline in new vehicle sales under the Proposal. Recent research supports a value closer to EPA's sensitivity analysis of -0.4, or even lower.

Using a more accurate value for the price elasticity of demand—one that is lower in absolute value, such as the -0.4 estimate used in EPA's sensitivity analyses—would provide a more realistic picture of the sales impacts of the LDV GHG regulations. Proposal, 86 Fed. Reg. at 43,788 (noting use of -0.4 in sensitivity analysis). The price elasticity of demand for new vehicles is a critical factor to consider in setting light-duty vehicle regulations because without this input EPA could not quantify the rule's effect on vehicle purchases. Changes in demand for new vehicles can have an impact on jobs, emissions, safety, and other factors relevant to the net benefits of revised standards.

Vehicles have different price elasticities depending on the timeframe considered, and sales of automobiles tend to be less sensitive to price fluctuations, especially in the long run.115 This is because in most areas of the United States vehicles are essential goods.116 EPA's Science Advisory Board explained that while "a consumer can easily hold on to their existing vehicle a bit longer[,] . . . an old vehicle will not be functional forever, and thus the long-run price elasticity for new vehicles is likely to be smaller [in magnitude] than the short-run elasticity."117 Therefore, it is common to distinguish between short-run elasticity values (sales effects that take place within one year of a price change)118 and long-run elasticity values (sales effects beginning approximately five years into the future).119 In the 2012 Final Rule, EPA acknowledged that -1.0 is "generally considered to be a short-run elasticity," 77 Fed. Reg. at 63,102 n.1300, and explained that price elasticity for vehicles is "smaller in the long run" because "though people may be able to change the timing of their purchase when price changes in the short term, they must eventually make the investment" in a new vehicle. Id. Thus, the 2012 Final Rule explained, while short-run elasticity may apply very briefly at the start of a program, "over time, a long-run elasticity may better reflect behavior." Id. Similarly, in the 2016 Midterm Evaluation Proposed Determination, EPA explained that "short run elasticity estimate[s] . . . may not be appropriate for standards that apply several years into the future."120

Because analyses of LDV GHG emissions standards project sales many years into the future, the long-run price elasticity is the relevant value to apply to the analysis. And because vehicle sales are less elastic in the long run, the price elasticity of demand for vehicles is substantively lower in magnitude in the long run than in the short run.

The -1.0 price elasticity value used in the Proposal is wholly unsupported and should not be used here. Because EPA draws the -1.0 price elasticity from the 2020 Final Rule, it is important to look at how that rule justified this value. In the NPRM, EPA states that the 2020 Final Rule estimated -1.0 "based on literature more than 25 years old." Proposal, 86 Fed. Reg. at 43,788; DRIA at 8-7. This value, however, was not even "based on literature more than 25 years old," but rather arbitrarily chosen by EPA during the 2020 rulemaking with minimal explanation and no real support from the relevant body of literature.

Based on the available research, the 2020 Rule NPRM conducted a data analysis and projected an elasticity in the range of -0.2 to -0.3. 83 Fed. Reg. at 43,075.121 In the 2020 Final Rule, however, EPA raised the elasticity estimate more than threefold. EPA's entire discussion about this massive change in price elasticity was only two sentences, and the agency included only a few mostly outdated citations. Authors of some of the key papers on price elasticity have called -1.0 a price elasticity number "far outside of any reasonable range that could be supported by the relevant literature."122

Experts have advised EPA numerous times that -1.0 is not an appropriate number for price elasticity for vehicle sales. During the 2020 rulemaking, one of EPA and NHTSA's peer reviewers, Dr. John Graham, explained that the relevant literature "with a proper focus on long-term price elasticity of demand, provides support for a price elasticity of demand that is well below -1.0 (in absolute value)," and that "the -1.0 elasticity figure does not have a solid grounding in economic evidence."123 Furthermore, EPA's Science Advisory Board advised the agencies that -1.0 was unjustified as a price elasticity of demand for new vehicles, explaining that the value was not based on the relevant body of academic literature (even the "literature more than 25 years old" that EPA mentions in the Proposal).124 The Science Advisory Board advised EPA to consider alternatives "both larger and smaller than -0.2 to -0.3," but EPA disregarded this advice.125 The small body of old literature relied on by EPA in the 2020 Final Rule does not actually support a -1.0 price elasticity of demand for vehicle sales because the studies were primarily short-run estimates of price elasticity, but the long run is the proper time frame to consider. In fact, the papers cited do not support even a short-run elasticity of -1.0.126

Specifically, the 2020 Final Rule, 85 Fed. Reg. at 24,617 n. 1641-42, relied on the following studies:

- McCarthy (1996): Estimated short-run elasticity of -0.87.127

- Bordley (1994): Assumed a short-run elasticity of -1.0, but did not estimate this value itself, nor provide justification for this assumption.128

- Kleit (1990): Assumed a long-run elasticity of -1.0, but cited another study, Irvine (1983), as the source of this value. Irvine (1983) was a partial literature review of papers published between 1967 and 1978, most of which reported short-run elasticity estimates.129 In fact, the few long-run estimates reported in Irvine support a long-run elasticity of -0.5 to -0.6 when using the median estimate or taking the mean without the outlier estimate.130 Kleit (1990) did not estimate an elasticity value itself.131

- CAR Report (2016): Estimated a mean long-run price elasticity of -0.61 and a short-run price elasticity of -0.79. EPA's 2020 Final Rule, however, improperly cited -0.72 as the CAR Report's long-run elasticity estimate. This latter value, according to the CAR Report, was influenced by an "extreme outlier" (published in 1957 using pre-World War II data), which the authors stated should be "excluded from consideration," making the -0.72 value cited in the 2020 Final Rule inaccurately large. Moreover, economists James Stock and Benjamin Leard have explained that even -0.61 "based on this literature is still too large," explaining that the CAR Report misreports the elasticity values from the one post-1970 paper that it cites and that “[u]sing the correct value” from the paper “would make the CAR Report’s estimated long-run price elasticity even smaller.” Specifically, the CAR Report separately reported elasticities for cars and light trucks from Fischer et al. (2007), ignoring substitution between the two, deriving a long-run elasticity based on this paper of -0.82. Because more stringent standards apply to all new light-duty vehicles, the correct elasticity is the combined market affected by a price increase, not one supposing that only cars are affected or, alternatively, only light trucks, which Fischer et al. (2007) estimates to be -0.36.132 The only long-run estimate from these studies considered in the 2020 Final Rule is the CAR Report’s -0.61. The other four estimates of between -0.8 and -1.0 are all short-run estimates. Moreover, they are the product of wildly outdated evidence, as EPA has acknowledged.133 Three of the studies are between 25-31 years old, but they mostly rely on data from the 1960s and 1970s, with some data even dating back to the 1920s.134 Thus, at most, the literature relied on in the 2020 Final Rule could support a short-run estimate of a magnitude close to but less than -1.0. A price elasticity of -1.0 based on this research is “a high-end estimate,”135 even for the short-run, and it is well-established that price elasticity of demand for vehicles decreases in magnitude in the long-run and should be substantially lower in magnitude. 2. The most recent literature supports a price elasticity value well below -1.0 in magnitude. The chart below ["Sales Elasticity Estimates" can be found on p. 56-59 of Docket number EPA-HQ-OAR-2021-0208-0651-A1] provides a comprehensive review of current and historical long-run and short-run elasticity estimates.136 The median elasticity of the studies published since 2000 (including an outlier estimate) is approximately -0.35, with a mean of -0.4, and those numbers decrease when looking only at studies published since 2010. 137 There is no basis for a price elasticity estimate of -1.0. EPA should revise this input to a more accurate value, such as the -0.4 estimate that is used in the Proposal’s sensitivity analyses and that is consistent with recent studies. The most recent reliable studies, such as Leard (2021) and Stock et al. (2018), would support values even lower in magnitude than -0.4. [EPA-HQ-OAR-2021-0208-0651-A1, p. 52-56]

121 This number was actually incorrectly calculated and too high due to a spreadsheet error identified in a Comment to the 2018 NPRM. It should be -0.07. See Stock, J.H. et al., Comment on Proposed Model Year 2021- 2026 Standards, EPA-HQ-OAR-2018-0283-6220 (Oct. 26, 2018). Attached as Exhibit 84.

129 Of the sixteen elasticities cited in Irvine (1983), thirteen are short-run elasticities. Irvine, F.O., Demand Equations for Individual New Car Models Estimated Using Transaction Prices with Implications for Regulatory Issues, 49 S. Econ. J. 764, 766 tbl. 1 (1983). Attached as Exhibit 87.

137 These values are consistent with a review done by several economists and detailed in an amicus brief filed in the litigation over the 2020 Final Rule. That review considered what the economists viewed as the four most relevant, distinct estimates of long-run elasticity based on original data analysis since 2000, and found a long-run price elasticity of demand for vehicles subject to the Proposal of between -0.03 and -0.61. See Amicus Brief of Economists at 25-26.

Commenter: Institute for Policy Integrity

EPA Should Use Long-Run (Not Just Short-Run) Estimates for Sales Elasticity in the Final Rule

As in the final SAFE 2 Rule, EPA has used a value of -1 to estimate the elasticity of demand.154 EPA admits that this estimate is ‘based on literature more than 25 years old’ and therefore the agency is reviewing more recent estimates and has run a sensitivity analysis at -0.4.155 Based on the best available evidence, EPA should in fact focus its main analysis on a lower demand elasticity based on long-run estimates.

Price elasticity measures the sensitivity of the sales of a particular product to fluctuations in that product’s price. While sales will typically increase when prices drop and decrease when prices rise, the strength of that relationship will depend on buyers’ need for the product and the availability of substitutes. Sales of necessity products with few comparable substitutes are likely more insensitive to price fluctuations. In economic terms, such products are inelastic. By contrast, products that are less essential or that can be easily substituted by other products are typically elastic, meaning that their sales are more sensitive to price fluctuations.156

Automobiles currently fall into the former category. Because automobiles are typically considered to be essential goods in most areas of the United States today, due to the current lack of adequate comparable substitutes, both economic theory and observed behavior finds that vehicle sales are relatively inelastic—meaning that price fluctuations produce just modest changes in vehicle sales.157 Indeed, EPA and NHTSA’s model even assumes that all consumers will remain in the automotive market, with used vehicles being the only reasonable substitute for new vehicles.158 Though this is an appropriately simplifying assumption for now, going forward the agencies should work toward a more realistic sales model if public transportation, ride sharing, and other alternatives become more available, and EPA should consider modeling changes in elasticity over time.

As shown in Table 1 (see appendix), the economic literature generally finds a relatively higher elasticity for short-run estimates of vehicle sales (effects within one year)159 but much lower elasticity for longer run estimates (especially for effects beginning five to ten years in the future).160 This reflects that vehicle sales are more elastic in the very short term because a consumer may delay a car purchase for a year or so when faced with higher prices, but most consumers facing modest prices changes are not willing to delay their car purchase more than that, given the general necessity of vehicle ownership and relative inability of current alternative modes of transportation to provide a complete substitute. Given that tailpipe emissions standards apply several model years in the future, and that the analytical model used by EPA and NHTSA projects sales impacts 30 years in the future, EPA has previously indicated that shortrun estimates of elasticity are not appropriate.161 [EPA-HQ-OAR-2021-0208-0299-A1, pp. 21-22] [Table 1 can be found at docket number EPA-HQ-OAR-2021-0208-0299, p. 25]

In the regulatory proposal underlying the SAFE 2 Rule, EPA and NHTSA projected that the price elasticity for new car and light truck sales ‘ranged from -0.2 to -0.3’—meaning, in other words, that a 1 percent increase in sticker price would decrease sales by only 0.2–0.3 percent.162 Yet in the final Safe 2 Rule, the agencies abruptly rejected their earlier elasticity estimate and drastically increased the price elasticity more than three-fold. The agencies claimed that the price elasticity for new vehicles was -1—meaning that new car sales would decline by 1 percent for every 1 percent increase in sticker price.163 But the agencies offered minimal justification for this substantial revision. And by making this change in the final rule, the agencies did not provide an opportunity for comment.164

Policy Integrity provides these comments now to urge EPA not to rely on the overly conservative estimate of demand elasticity from the SAFE 2 Rule. The agency should instead conduct a full review of the relevant economic literature, which confirms that vehicles are currently an inelastic good in the long run—with a price elasticity far below -1 in absolute terms.

After EPA and NHTSA abruptly changed the demand elasticity in the final SAFE 2 Rule, Policy Integrity issued a report reviewing the relevant literature.165 As further explained in this report, the SAFE 2 Rule erroneously relied on short-run estimates of demand elasticity even though long-run estimates are more appropriate for standards that apply several years into the future,166 and even though the agencies used long-run estimates of other inputs elsewhere in their rule analysis.167 Table 1 (see appendix) [Tabe 1 can be found at docket number EPA-HQ-OAR-2021-0208-0299, p. 25] demonstrates that EPA's continued use of -1 is overly conservative compared to the most current literature.

The estimate chosen for sales elasticity has a significant impact on EPA's analysis, as it directly influences the dynamic fleet share model's projection of sales and scrappage impacts and fleet size, thus affecting key projections such as criteria pollutant and greenhouse gas emissions.168 By continuing to use the conservative demand elasticity from the SAFE 2 Rule, EPA may be undervaluing the net benefits of its new proposed standards by as much as $10 billion.169 [EPA-HQ-OAR-2021-0208-0299-A1, p. 22.]

In its main analysis of its final rule, EPA should base its analysis on the best available estimates of long run sales elasticity. An estimate around -0.4 would be appropriate for a long-run estimate based on the most recent literature. EPA could consider higher estimates as sensitivity analysis, but a value as high as -1.0 is not supported by the literature to estimate the long-run elasticity. If EPA uses a value of -1.0, it should be as a sensitivity analysis that makes clear it is very conservatively focusing on a short-run estimate. [EPA-HQ-OAR-2021-0208-0299-A1, p. 23]

Commenter: National Automobile Dealers Association (NADA)

EPA acknowledges that its proposed mandates will likely depress new vehicle sales by approximately two percent compared to the sales rate it forecasted in the SAFE rule.12 At best, NADA believes this to be a significant underestimation. Regardless, EPA excuses the lower sales impact of its proposed mandates by suggesting that it no longer supports "the weight placed in the SAFE rulemaking on promoting fleet turnover as a standalone factor," stating that it is now looking at fleet turnover in the context of the full range effects of its proposed standards.13 EPA concludes that "the emissions reductions from more stringent standards far outweigh any temporary effect from delayed purchases."14 EPA also concludes that, after assessing the benefits of its proposed mandates over a vehicle's entire lifetime, lower operating costs resulting from fuel savings, including those that may accrue to later owners, will offset the increased upfront vehicle costs.15 [EPA-HQ-OAR-2021-0208-0290-A1, p. 2-3]

EPA Response

As discussed in Preamble Section VII.B. and RIA Chapter 8.1.2, EPA has re-evaluated the demand elasticity it is using in its analysis. For the final rule we use a less elastic value of -0.4 for our central case, based on the latest available data and considering public comments, with sensitivity analyses of -0.15 and -1. This revision, along with other changes in model inputs discussed in Preamble Section III. and RIA Chapter 4, results in estimates of vehicle sales impacts of up to -1 percent (compared to our NPRM estimate using a -1 sales elasticity of up to -2 percent); see RIA Table 8-2. EPA thus estimates that the sales impacts will be less negative than calculated in the NPRM. EPA notes that NADA did not provide data or other information to support its claim that vehicle sales impacts were underestimated. In addition, as discussed in Preamble Section VII.B. and RIA Chapter 8.1.2, EPA considers the maintained assumption that both producers and vehicle buyers consider 2.5 years of fuel consumption in the purchase decision to be conservative; adjusting this assumption would lead to more positive sales impacts. EPA agrees that it considers effects on fleet turnover in the context of considering other effects of the standards (see Preamble Section VI. and Section 16 of this document), and that EPA finds the reduced operating costs exceed the increase in up-front costs; see Preamble Section VII.J.

In its use of the GREET model to estimate PM2.5 benefits from reduced upstream petroleum-sector sources, both Agencies appear to be assuming that a decrease in gasoline consumption in the U.S. will lead to a proportional decrease in the amount of upstream emissions during oil production, transportation and refining in the U.S. Without those decreases, there is no basis for assuming a reduction in PM2.5 emissions throughout the U.S. petroleum supply chain. However, in the energy-security benefits analysis (discussed below), the Agencies assume that over 90% of the petroleum impact of the proposed rules will occur in the form of reduced oil imports rather than reduced production of oil in the U.S. Moreover, the energy-security analyses in the RIAs and in the NHTSA TSD argue that the U.S. refinery sector will not be impacted significantly by a modest decline in U.S. gasoline consumption, since the U.S. refinery sector has opportunities to expand the export of refined products around the world. If the agencies maintain these energy security assumptions for the final rule, they cannot logically assume upstream PM 2.5 control benefits in the U.S. If the Agencies forecast PM2.5 health benefits outside the U.S. (e.g., from reduced production, transport and refining of petroleum elsewhere in the world), those health benefits should be based on applicable dose- response and valuation data and be reported separately as suggested in OMB Circular A-4.

Policies to support development of EV and battery manufacturing and domestic supply chains, including critical minerals. At present, most critical minerals necessary for the production of advanced EV motors and batteries are mined and processed outside of the United States, primarily in China. Additional domestic sources and processing capacity are needed to supply EV production and encourage domestic manufacturing and jobs. [EPA-HQ-OAR-2021-0208-0571-A1, p. 5]

Commenter: American Enterprise Institute (AEI)

The asserted 'energy security' externality of petroleum consumption and imports is fundamentally incorrect, in that there can be only one price in the international petroleum market, confronted equally by economies importing all or none of their oil. Nor are the defense costs of defending sea lanes or intersectoral economic effects relevant analytically. [EPA-HQ-OAR-2021-0208-0254-A1, p. 2]

Other purported benefits of the Proposed Rule are defined as climate-related benefits, 'energy security externalities caused by U.S. petroleum consumption and imports,' the health benefits of reductions in emissions of particulates, and the value of reduced refueling time needed for a vehicle fleet characterized by an increase in fuel economy. The Proposed Rule includes a 'rebound' parameter for increased vehicle use attendant upon a purported reduction in fuel costs, but that effect is highly speculative, and will not be addressed here.14 Each of these components of the purported benefit stream is incorrect analytically. [EPA-HQ-OAR-2021-0208-0254-A1, p. 5]

Energy security externalities caused by U.S. petroleum consumption and imports. The 'energy security' argument for reductions in petroleum consumption and imports is fundamentally flawed, however commonly asserted. The magnitude or percentage importance of imported oil is irrelevant to the availability of petroleum to the U.S. economy or the price that the U.S. would have to pay for imported oil.

Many observers argue that it was the 1973 OPEC oil embargo that created the gasoline queues and other market distortions observed in the U.S. during the 1973-4 time period, but that historical interpretation is not correct. Since there was and remains only one world market for crude oil, an embargo — a refusal to sell to a given buyer (i.e., impose a higher price on that buyer only) —cannot work, as market forces will reallocate oil so that prices are equal everywhere (adjusting for such minor complications as differential transport costs). The 1973 embargo aimed at the U.S., the Netherlands, and a few others had no effect at all: All the targeted nations obtained oil on the same terms as all other buyers, although the transport directions of oil trade changed because of the reallocation process. It was the production cutback by Arab OPEC that raised international prices; and it was the U.S. system of price and allocation controls that created the queues and other market distortions. Note that there was no embargo in 1979, but there was a production cutback in the wake of the Iranian revolution, and the U.S. again imposed price and allocation regulations. And, once again, there were queues and market distortions.36

Accordingly, there is no 'energy security externality caused by U.S. petroleum consumption and imports,' notwithstanding the assertions offered in the Proposed Rule. Nations that import none of their oil face the same prices, and price changes, as nations that import all of their oil; and the effects of supply disruptions are the same, except for exchange rate impacts and other such second-order effects. This part of the economic benefit of the Proposed Rule is illusory, and thus illegitimate analytically.

Some argue that the defense cost of policing sea lanes and other such budget cost parameters facilitating the oil trade is a source of an oil-import ‘externality.’ This is not correct: The effect of the Proposed Rule and other GHG regulations on the defense budget and force structure would be imperceptible, and in any event an attempt to allocate the costs of specific parts of that force structure among the various defense missions would be arbitrary. Another argument often made is the economic effect of changing oil prices across economic sectors, including indirect effects. This also is incorrect, as such effects, whether direct or indirect, are risks that can be evaluated and hedged by market participants. There is no ‘externality’ not reflected in market prices. [EPA-HQ-OAR-2021-0208-0254-A1, pp. 9-10]

14 In Table 3-3 of the RIA, the range of estimated ‘rebound’ effects is 0-87 percent.

36 See Benjamin Zycher, ‘Emergency Management,’ in S. Fred Singer, ed., Free Market Energy: The Way to Benefit Consumers, New York: Universe Books, 1984, pp. 74-98.

Commenter: Attorney General of Missouri et al.

Building on the IWG's flawed analysis, the EPA's rush to carbon-zero vehicles compounds the risk to the American economy with ever more stringent mandates. Although promising, such technology also comes with substantial negative impacts to the environment, the economy, the poor, and to national security. For these reasons, we urge the EPA with withdraw this proposed rule and leave in place the rule promulgated by the previous administration. [EPA-HQ-OAR-2021-0208-0288-A1, p.17]

In addition, human exploitation and ecological damage, international and diplomatic concerns abound. China is a major player in the emerging realm of high tech batteries and is heavily vested in controlling related raw natural resources around the globe. 'China's leading battery maker, CATL, is already exporting and has opened up production facilities abroad. Chinese firms have also become the largest investors in cobalt mining and processing facilities in the Democratic Republic of Congo, home to a large proportion of the world's cobalt, a critical element used in many NEV batteries. These investments have raised significant concerns about the availability and price of cobalt as well as the treatment of workers.' [15] The EPA's rush to mandate a massive societal and industrial shift away from gasoline engines in favor of a technology that is at substantial risk of geopolitical manipulation and supply chain vulnerabilities and which at present seems to be in no small part controlled by one of America's chief global adversaries, and a notorious human-rights abuser is extremely concerning. [EPA-HQ-OAR-2021-0208-0288-A1, p.16]

Commenter: California Air Resources Board (CARB)

Stringent Standards Increase Domestic Energy Security. As Dr. Stanton discusses in her enclosed expert report, An Analysis of EPA's Proposed Revised 2023 and Later Model Year Light-Duty Greenhouse Gas Emission Standards, U.S. EPA has improved its analysis of the benefits of more stringent greenhouse gas emission standards, but still likely understates their benefits.115 Stricter standards will benefit the United States through decreased exposure to volatile oil prices, reduced prices from reduced demand, and potential savings to the federal budget from reduced dependency on imported oil.

The proposed standards will reduce U.S. oil demand. They are thus likely to reduce the global price of oil, known as a monopsony effect. This is true regardless of the position of the U.S. as a net exporter and in any event the net effect is not definitive; the U.S. is importing heavier crude oils to satisfy the needs of refineries.116 U.S. EPA's Draft Regulatory Impact Analysis disregards the monopsony impacts that come from decreased domestic demand. Instead, U.S. EPA treats this effect as a neutral transfer payment. It is not neutral in its effects. The shift of costs to oil producers and away from U.S. consumers would likely have wider societal benefits than the other way around.

Stricter standards that reduce consumption is also likely to reduce exposure to volatile prices. Dr. Stanton recognized that U.S. EPA 'appears to conservatively understate the costs of global oil market instabilities, omitting costs of managing oil market volatility and likely underestimating U.S. exposure to global oil markets.'117 CARB recommends that U.S. EPA consider a broader range of sectors that can be impacted by oil imports and prices. This is expected to more accurately show the benefits from stricter emission standards, including on the budgets of the federal government and consumers. [EPA-HQ-OAR-2021-0208-0643-A6, p.39]

Although U.S. EPA asserts it is not able to quantify the potential for stringent standards to reduce U.S. military expenditures, the available information suggests it could be significant. The U.S. military helps secure international oil production and imports.118 Studies cited in U.S. EPA's Draft Regulatory Impact Analysis of the proposal estimate the implicit subsidy of crude oil for this security ranges from $11.25 to more than $30 a barrel.119 If decreased demand for oil meant that the U.S. no longer needed to defend oil supplies and sea lines in the Persian Gulf, the savings to the U.S. defense budget could be significant. The RAND study cited by U.S. EPA stated that the U.S. defense budget could be reduced by 12-15%.120 The defense budget in 2019 was $704 billion. If this was reduced 12%, it would save U.S. taxpayers more than $84 billion a year.

Moreover, the U.S. military is the largest single consumer of oil in the world, using about 100 million barrels (despite also heavily investing in clean technology).121 Separate from expenditures for securing oil supply lines, a decrease in the price of oil from decreased demand would directly benefit the U.S. military budget. This effect can be quantified based on the estimated effects of the proposal on oil prices. [EPA-HQ-OAR-2021-0208-0643-A6, p. 40]

Commenter: Center for Biological Diversity, et al.

Energy security remains an important consideration with respect to U.S. oil consumption. Reducing U.S. reliance on oil enhances U.S. energy security, and—with energy security in mind—Congress has specifically directed the U.S. to conserve energy. Energy Policy and Conservation Act of 1975, 42 U.S.C. § 32902(f). Energy security impacts remain an important benefit of reduced domestic oil consumption, as will occur under more stringent standards. Even in the 2020 Final Rule, EPA acknowledged that energy security externalities were "paramount" (along with climate change externalities) among the various externalities "in their extent, magnitude, and economic importance." EPA & NHTSA, Final Regulatory Impact Analysis, The Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Year 2021-2026 Passenger Cars and Light Trucks, EPA-HQ-OAR-2018-0283-7671, at 116 (Mar. 2020; updated July 1, 2020).

Despite the increases in domestic oil production that have made the United States an energy exporter, EPA must continue to consider the energy security impacts of standards for two key reasons, as EPA explains in the NPRM. First, U.S. refineries continue to import heavy crude oil from potentially unstable regions of the world, and sudden disruptions of supply pose a threat to U.S. financial and strategic interests. For example, EPA's Proposal assumes that for every gallon change in oil demand as a result of the new standards, oil imports will be reduced by approximately 0.91 gallons, DRIA at 3-24, meaning that most of the decline in demand would be applied to decreased oil imports. Second, as EPA notes in the Proposal, oil exporters that have a large share of global production have the ability to raise or lower the price of oil by exerting the monopoly power associated with OPEC to restrict oil supply relative to demand, which could cause oil price shocks that have greater impacts when nations are heavily reliant on oil. DRIA at 3-16. For these reasons, it remains important to consider the costs of oil imports beyond simply the market price paid for the oil.

EPA's oil import and refining assumptions that underlie the energy security benefits more accurately reflect current realities. In the 2010, 2012, and 2020 Final Rules, EPA assumed that 50% of the change in domestic fuel consumption as a result of the regulations would lead to a change in imports of refined fuel, and of the remaining 50% refined domestically, 90% would come from imported crude.

These assumptions are misguided. In particular, the assumption that 50% of a change in gasoline demand would come from a change in imports of refined oil (rather than a reduction in domestic refining) is unjustified given the already small proportion of U.S. gasoline demand that is supplied by foreign-refined oil. Because the United States already has negligible gasoline imports, the realistic result of a domestic decline in gasoline demand is that the majority of the decrease in demand will be represented in a decrease in domestic refining. EPA recognizes this, assuming in the NPRM that 93% of the decline in gasoline demand under the Proposal would lead to a decrease in domestic refining, with 7% of the decline in demand leading to a decrease in imports of refined fuel. Proposal, 86 Fed. Reg. at 43,769. The Energy Information Administration's models have found a strong positive correlation between domestic demand and domestic refining. For example, AEO 2018 data indicated that the vast majority (92%) of a change in domestic gasoline demand would be satisfied by domestic refining.99 AEO 2021 had the opportunity to observe what actually results from a decrease in demand for transportation fuels, as gasoline demand in 2020 dropped to 90% of its 2019 levels, largely due to the pandemic. AEO 2021 explained that this lower demand for transportation fuels resulted in a decrease in the amount of crude oil processed at U.S. refineries—giving a timely example of the effects of a decrease in domestic demand.100 As global oil demand "is unlikely to catch up with its pre-Covid trajectory," and "[g]asoline demand is unlikely to return to 2019 levels, as efficiency gains and the shift to electric vehicles eclipse robust mobility growth in the developing world,"101 there will not be global capacity to absorb substantial additional exports of refined gasoline. EPA's assumption that 93% of the decrease in domestic gasoline fuel consumption under the Proposal will lead to a decrease in domestic fuel refining therefore brings more accuracy to the oil import and refining assumptions. For the Final Rule, EPA should clearly explain the data underlying its new oil import and refining assumptions and values.

EPA appropriately updated the oil import reduction factor and oil security premiums from those used in the 2020 Final Rule. EPA's Proposal updates two key inputs used to calculate the energy security benefits of a decline in U.S. demand for oil: (1) the oil import reduction factor, and (2) the macroeconomic oil security premiums. DRIA at 3-18 to 3-25. In updating these inputs, EPA is able to more accurately estimate the energy security benefits of new standards.

The oil import factor appears reasonable, but EPA should make its calculation methods more transparent. The oil import reduction factor, an important input for calculating the energy security benefits of a regulation, explains what percentage of a decrease in oil demand will decrease imports of foreign oil. In the 2010, 2012, and 2020 Final Rules, EPA calculated this value to be 95%, based on its underlying assumptions regarding oil imports and refining.102

EPA explains that its new oil import reduction factor is calculated "[b]ased on a detailed analysis of differences in U.S. fuel consumption, crude oil imports/exports of petroleum products for the time frame 2023-2050, and using the AEO 2021 (Reference Case) and two alternative sensitivity cases, i.e., (Low Economic Growth) and (High Economic Growth)." DRIA at 3-23 to 3-24. Taking the ratio of the changes in U.S. net crude oil and product imports divided by the change in U.S. oil consumption in the different AEO cases, EPA concluded that the oil import factor is 91%, meaning that each gallon of petroleum reduced as a result of the Proposal would also reduce total U.S. imports of petroleum by 0.91 gallons. Id. at 3-24. EPA's method for calculating this value appears in line with EPA's underlying assumptions regarding oil imports and refining—using the same simple calculation method used in previous rulemakings results in a very similar oil import reduction factor to EPA's estimates, of 91.63%.103 For the Final Rule, EPA should clearly explain its methodology and the data that supports its calculation.

EPA's estimated oil security premiums are based on more accurate and comprehensive data than the values used in the 2020 Final Rule. Oil security premiums measure the extra cost of importing oil beyond the price paid for the oil itself (or, in the case of a reduction in demand, the extra benefit of reducing oil imports beyond the actual expenditures saved). The main input to calculating the oil security premium is the macroeconomic benefit, which measures the potential macroeconomic disruptions and increased oil import costs to the economy resulting from oil price spikes or "shocks," or the value of avoiding these costs due to less domestic reliance on oil.

In estimating the macroeconomic benefit used to calculate oil security premiums, EPA has historically relied on research conducted by Oak Ridge National Laboratory (ORNL), and EPA again takes this approach in the Proposal. EPA has estimated macroeconomic oil security premiums based on ORNL's methodology developed in 1997 and updated in 2008 for a series of past rulemakings including the 2010 and 2012 Final Rules and the heavy-duty vehicle GHG and fuel economy Phase I and Phase II standards.104 The 2020 Proposal also relies on the ORNL literature and methodologies for estimating the oil security premiums.

It was only in the 2020 Final Rule that EPA abandoned this research and methodology, relying instead on a single paper, Stephen A. Brown, New estimates of the security costs of U.S. oil consumption, 105 to drastically reduce oil security premiums. The 2020 Final Rule's reliance on Brown (2018) was inappropriate for two reasons.

First, EPA failed to provide adequate justification for departing from the established ORNL methodologies and research that had been used and updated for over 20 years to instead rely on a single study. By contrast, EPA's reliance on ORNL in the Proposal is a return to historical methods used for calculating oil security premiums and included working with ORNL "to revise the oil security premiums based upon recent energy security literature." Specifically, EPA updated the inputs for price elasticity of demand for oil and elasticity of GDP to oil price shocks. DRIA at 3-25. These updates looked at historical and recent data, and properly incorporated AEO 2018 (and will incorporate AEO 2021), making them more current and accurate than those used in the Brown paper, which relied on world oil market conditions that prevailed in 2014 and on AEO 2012 and AEO 2016, for its estimates.

The second reason that the 2020 Final Rule's sole reliance on Brown (2018) rather than the historical ORNL methodology is improper is that the 2020 Final Rule does not actually appear to have used Brown's best or most accurate estimates in setting its oil security premiums. Instead, the much lower macroeconomic oil security premiums used in the 2020 Final Rule appear to be in line with estimates that Brown (2018) suspects are inaccurate.

Brown (2018) acknowledges that while "individuals may prefer newer research to older," with respect to oil security premiums there remain many questions with regard to whether the newer research can adequately "represent how world oil markets and the U.S. economy would respond to a sizable oil supply disruption."106 In contrast to other factors for which the most recent research may be the most reliable, there are several reasons why this is not true of oil security premiums.

Specifically, Brown (2018) discusses the "lack of big oil supply disruptions in the modern era," explaining that "the differences between the current U.S. economy and that of the 1970s" means that "the effects of any oil price shocks are likely smaller than was estimated with data from the era in which the big oil price shocks occurred."107 Brown (2018) makes clear, however, that "[b]ecause we have not observed a modern economy with large oil supply disruption, we have no reliable methods to quantify the effects of these disruptions,"108 citing research "that the world has not seen a major oil supply disruption since 2003, which raises the concern that newer research, which relies on recent data, may not capture the effects of major oil supply disruptions."109 Thus, Brown (2018) estimated three different oil security premiums—one relying on the old literature, one on the new literature, and a "combined" value that integrated both bodies of data and estimations. Brown (2018) made clear which value was most appropriate for setting policy—the combined value—explaining that this "combined" value "might best reflect the uncertainty in what we know about the oil security premiums."110

The oil security premiums in Brown (2018) derived from the combined values—the estimates that study considered most reflective of reality—are in the range of $3.67 per barrel (in 2015) to $6.08 per barrel (in 2040).111 These values are very similar to the NPRM's estimates, which range from $3.63 (in 2023) to $5.57 (in 2050). Proposal, 86 Fed. Reg. at 43,792, Tbl. 49. The 2020 Final Rule, however, citing Brown (2018), estimated the macroeconomic oil security premium to range from $1.43 in 2023 to $2.61 in 2050. 85 Fed. Reg. at 24,728-29, Tbl. VI-200. These values appear closest to the estimates Brown (2018) derives from only the recent research, which the paper explains may not be the most reliable. Brown (2018)'s recent-literature-only estimations for price elasticity of demand for oil of -0.0175 and elasticity of GDP of -0.018 are significantly lower values than those indicated by any other comprehensive studies.112 In fact, Brown (2018)'s combined values relied on a price elasticity of demand for oil of -0.055, and an elasticity of GDP of -0.028, values very close to the -0.07 and -0.023 estimations arrived at through EPA's latest estimation. A thorough reading of Brown (2018), then, actually supports EPA's latest oil security premiums, as the paper's most accurate estimates are very close to EPA's values, and Brown (2018) appears to advise against using oil security premiums as low as those applied in the 2020 Final Rule.

EPA's exclusion of the military and monopsony benefits in the calculation of oil security premiums means that the energy security benefit estimates in the Proposal are conservative, and reductions in oil use as a result of more stringent GHG standards are likely to have an even greater benefit than those quantified in the NPRM.

In addition to the macroeconomic oil security premium, military and monopsony benefits are considered energy security benefits of reduced U.S. oil demand. While EPA has historically refrained from applying these values in any quantified way, it is important to recognize that energy security benefits that take into account only the macroeconomic oil security premiums could be low estimates.

EPA's Proposal correctly explains that one cost of oil use is "maintaining a military presence to help secure a stable oil supply from potentially vulnerable regions of the world," DRIA at 3-21, and therefore, reducing domestic reliance on oil has the potential to result in some form of military benefit. EPA states that the agency does not include these benefits because they are hard to quantify. Id. at 3-21 to 3-23. EPA is encouraged to consider methodologies for quantifying these benefits in the future, and to acknowledge that their existence makes EPA's current estimations of energy security benefits conservative. [EPA-HQ-OAR-2021-0208-0651-A1, p. 40-45]

Finally, EPA's failure to calculate the fuel price reductions attributable to stronger GHG standards causes EPA to further understate consumer benefits. [EPA-HQ-OAR-2021-0208-0651-A1, p. 48]

103 If calculated as in the 2020 Final Rule, the Proposal's oil import factor would be calculated as 7% (the share of reduction in refined imports) plus 91% of 93% (the share of reduction in domestically-refined oil refined from imported crude), or 7% plus 84.63%, which equals 91.63%. See DRIA 3-24 and EPA's parameters file for the underlying values.

112 Compare Brown (2018) at 174 Tbl. 5 with R. Uria-Martinez (2018) (cited in DRIA at 3-19) (finding a short-run price elasticity of demand for world oil of -0.07); Oladosu, G. et al., Impacts of Oil Price Shocks on the U.S. Economy: A Meta-Analysis of Oil Price Elasticity of GDP for Net Oil Importing Economies, 115 Energy Pol'y 523-544 (2018) (cited in DRIA at 3-20) (finding an elasticity of GDP of -0.021), attached as Exhibit 77; Krupnick, A., Oil Supply Shocks, U.S. Gross Domestic Product, and the Oil Security Problem, Resources for the Future Report (2017) (cited in DRIA at 3-18) (finding a "blended" price elasticity of demand for oil "to better capture the uncertainty involved in calculating the oil security premiums" because "the older literature has not been wholly overtaken by the new" of -0.05 and a "blended" elasticity of GDP of -0.028), attached as Exhibit 78.

Commenter: CERES

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 84.]

Additionally, strong standards insulate the auto industry from oil price spikes. The Standards Act is insurance against loss of U.S. auto industry market share if fuel prices spike as happened in the 2000s, particularly as they move towards larger, less fuel-efficient vehicles which now make up 51 percent of new vehicle sales.

Commenter: Clean Fuels Development Coalition (CFDC)

A nationwide E30 'Clean Octane' Gasoline Standard would reduce U.S demand for imported oil by one billion barrels a year, which at $100 oil would free up an additional $100 billion/year for investment in the creation of quality jobs, improved infrastructure, and better health and education for our children.15 Increased supplies of unconventional oil and gas (fracking) should not be eligible contenders for displacing oil imports because of their extremely high carbon intensity and toxicity which poses substantial risk to the climate and human health.16 E30 HOLC fuels utilize 100% domestic inputs, so there is zero risk of critical material supply chain interference from foreign actors, unlike the energy transition minerals required by electric vehicle manufacturers. DOE’s Energy Information Administration (EIA) has warned of a worsening octane shortage in the U.S. as automobile manufacturers adopt advanced internal combustion engine designs such as direct injection and turbocharging in response to tighter fuel efficiency and carbon emission requirements. [EPA-HQ-OAR-2021-0208-0564-A2, p. 14]

Commenter: E2 - Environmental Entrepreneurs

Other Non-emissions Benefits: EPA has also quantified the non-emission benefits from the rebound effect (the increase in driving resulting from reduced operating costs), changes in refueling time, and energy security benefits from reduced dependence on foreign petroleum. EPA projected non-emission benefits for the Proposal to be $35 billion through 2050, while Alternative 2 would generate $53 billion—a difference of $18 billion. DRIA, Tables 6-8, 6-10. [EPA-HQ-OAR-2021-0208-0604-A1, p. 3]

Commenter: Merlotti, J.

This proposal states that EVs, powered by renewable energy, will increase the energy dependence security of the US. The actual facts oppose this position and are twofold.

First, the US was very close to a net petroleum exporter for the first time in its history. This is a remarkable achievement led by advances in hydraulic fracking. In fact, the restrictions that have been places on the US oil industry by the current Executive administration have already led to energy security issues in a very short time – highlighting the need for a more balanced energy approach. [EPA-HQ-OAR-2021-0208-0189-A1, pp. 2-3]

Second, renewable energy is complementary to fossil fuels, not a replacement. The only feasible way for the US to produce enough non-fossil fuel or 'green' electrical energy for EVs would be to develop more nuclear energy plants (which has no current momentum). Solar and wind simply cannot supply he needed energy for the current electrical demand and mass scaling of EVs. Besides electrical charging, EV batteries require significant mining of rare earth minerals Lithium and Cobalt - that create harmful environmental issues of their own.

'There is no way there’s enough raw materials being produced right now to start replacing millions of gasoline-powered motor vehicles with EVs,' said Lewis Black, CEO of Almonty Industries Inc, which mines the hardening metal tungsten in Portugal and South Korea. 3/1/21 A shift to green energy will create energy dependence for the US on foreign states – many of which are not allies of the US.

[EPA-HQ-OAR-2021-0208-0189-A1, p. 3]

Commenter: Ohio Attorney General Office, et al.

The proposed rule considers as a benefit 'reductions in energy security externalities caused by U.S. petroleum consumption and imports.'[68] On one hand, that is a concern of the Administration's own choosing, as the United States produced more energy than it consumed in 2019 for the first time in [62] years, [69] and remained a net exporter in 2020.[70]

Regardless, the proposed rule entirely fails to mention the additional risks to the transportation sector, even if certain risks are alleviated in the energy sector. China dominates the lithium-ion battery market, and is poised to capture a greater share with time.[71] China is home to three-quarters of the global manufacturing capacity for lithium-ion batteries, while the United States has only 12 percent.72 Not only does China own the final manufacturing process, but China also 'controls 80 percent of the world's raw material refining in the lithium-ion battery supply chain, 77 percent of the world's cell capacity, and [60] percent of the world's component manufacturing.'[73] This is not merely a problem of manufacturing, which through various incentives could theoretically be on-shored. China controls [90] percent of the supply of rare-earth magnets, which work to power electric vehicles.[74] Dependence on China for our transportation is a national security threat—one that cannot be overcome overnight. The EPA failed to consider whether the proposed timeframe to change our vehicle fleet will create an overreliance on China, given the current lack of manufacturing and raw materials in United States control. Such failure renders any final rule arbitrary, but more importantly, dangerous. [EPA-HQ-OAR-2021-0208-0258-A1, p.10]

Commenter: Peavler, Jean

This would also make us even more dependent on China, as around 80% of the manufacturing capacity for electric vehicle batteries is in China. A vast majority of the chemical processing and refining for the raw materials (cobalt and lithium) used in these batteries is also performed in China. We are already too dependent on China and need to decrease this, not increase it! We would also be even more dependent on the electric power grid, which is vulnerable to cyber attacks as well as power plant failures. [EPA-HQ-OAR-2021-0208-0395, p. 1]

Commenter: Securing America's Future Energy

Oil dependence is a unique strategic challenge that has undermined the nation's economic sovereignty and national security for over a century. For 17 years, SAFE has advocated for policies to address the risk posed by the United States' dependence on the global oil market. We applaud the Biden Administration for revisiting the greenhouse gas emission standards for light-duty vehicles that the Environmental Protection Agency relaxed in April 2020.

Oil is the lifeblood of the U.S. economy. The nation's transportation sector is 90 percent powered by oil, and although the transition away from oil is happening slowly, volatile crude oil and petroleum product prices still represent a continuing threat to the U.S. economy. At the same time, there is a growing global consensus that the future of transportation will be electric. In addition to being cleaner than internal combustion fueled vehicles, electrified transportation is powered by a diverse portfolio of clean domestic fuels, the sine qua non of a clean and secure energy future. Moreover, electric vehicles also are destined to become cheaper than petroleum-fueled transportation.

The shift away from internal combustion engines has provided provides countries like China with an opportunity to recalibrate its engagement in the global auto manufacturing sector in which it has not participated for much of the industry's history. Recognizing that opportunity, Beijing is investing heavily in the production of electric vehicles (EVs), and more specifically battery technology. China has adopted a whole-of-nation approach to achieve a first-mover advantage and secure a permanent lead in what will be a critical sector of the future global economy. Therefore, despite the opportunity that electrification presents for automakers to follow a path to a cleaner and more secure transportation future, it presents China and other nations an opportunity to surpass the United States' position of global leadership in the automotive sector. [EPA-HQ-OAR-2021-0208-0527-A1, p. 1]

The Importance of Fuel Economy

Oil dependence threatens U.S. national security and long-term economic vitality, and it remains a core energy security challenge facing the country today. Although robust domestic liquid fuels production has reduced some of the negative consequences of oil dependence, energy security is primarily a function of consumption, not production. U.S. energy security is determined by oil's role in the economy and the transportation sector. Mobility—the movement of people, goods, and services throughout the country— is a central component of U.S. economic competitiveness and a cornerstone of the American way of life. Today, this mobility is almost entirely powered by petroleum-based fuels, which accounted for 90 percent of the transportation energy consumed in 2020.[1]

Since oil is a globally traded commodity, prices are affected by events in all oil-producing and oil-consuming countries. The key consequence of this dynamic is that changes in oil supply or demand anywhere generally affect prices everywhere. Because there are limited substitutes to oil in the U.S. transportation sector, and the transition away from oil is happening slowly, volatile crude oil and petroleum product prices still represent a continuing threat to the U.S. economy. As we all know, the United States has faced serious challenges as a nation over the past several decades as a result of its dependence on oil. In nearly every instance, these challenges would have been more serious without the progress made in improving the fuel efficiency of light-duty vehicles.

A perception has developed that the risks posed by dependence on a global oil market are waning, as we see growing domestic production of crude oil and meaningful steps towards the electrification of the transportation system. Yet, despite the growth in domestic oil production, we remain reliant on crude oil prices set on a global market. And despite the growing consumer interest in electric vehicles, the transition to electrification remains in its infancy, with electric vehicles comprising less than 2 percent of all new car sales in 2020,[2] and forecast to remain below 8 percent by 2026 in EPA's analysis supporting this very rulemaking.[3]

Because electric powered transportation system is increasingly recognized as the technology of the future, a global competition has developed to stake a claim in the future of the auto industry, with countries around the world taking measures to encourage local investment to develop domestic electric vehicle (EV) supply chains. As reflected in pages 1 to 3 of Attachment 1 to these comments, which present analysis of the automotive sector prepared for SAFE, China and Europe are forecast to lead this race over the coming decade. Beijing, in particular, has worked to consolidate control of the important EV supply chains for more than a decade. Of the 200 lithium-ion battery gigafactories planned across the globe as of early 2021, for example, 148 are located in China and 21 are in Europe, while only 11 are in North America.4 The United States, clearly, is playing from behind. As a result, EVs are projected to account for roughly 30 percent of vehicles manufactured in China by 2030, more than three times as large a share as EPA forecasts in the United States. [EPA-HQ-OAR-2021-0208-0527-A1, pp.4-5] [Please refer to Attachment 1 at Docket number [EPA-HQ-OAR-2021-0208-0527-A1 pp. 18-26.]

As we navigate the transition to electrification, we must ensure that we do not swap our current dependence on an unstable oil market for reliance on China for our future transportation needs. Beijing has been working for over a decade to take commanding leadership on industries of emerging economic and strategic reliance, including electric vehicles. This has provided China with a tremendous comparative advantage, while threatening the U.S. automotive industry. How the EV supply chain develops over the coming years will have profound long-term implications for U.S. jobs, investment, technology leadership, and security of a major sector of the economy. As reflected in page 4 of the Attachment 1, if the entire EV supply chain is developed in the United States, for example, the number of jobs created in the EV industry can replace all jobs lost in parts related to internal combustion engine (ICE) vehicles.[5] If the United States remains complacent, we risk undermining the vibrancy and health of the domestic automobile industry. Although we are late to the competition, the nascency of the technology, still in the early stages of deployment, offers a chance for the United States to regain its leadership. An update to the fuel efficiency and GHG emissions standards can strengthen the case for private sector investment across the EV supply chain, and enable the EV market in the United States to grow more quickly. [Please refer to Attachment 1 at Docket number [EPA-HQ-OAR-2021-0208-0527-A1 pp. 18-26]]

SAFE believes that the standards being considered today can reinforce, and build on, the foundation that was laid by the Obama Administration to reduce the United States' dependence on oil, thereby enhancing our nation's economic and national security. The Environmental Protection Agency (EPA) has a momentous opportunity to place the transportation sector on a trajectory for long-term oil savings and greenhouse gas (GHG) emission reductions driven by electrification that will have clear, positive implications for U.S. energy security in the coming years. In fact, the opportunity to modernize the GHG emission standards, spur innovation in the industry, and advance the administration's manufacturing supply chain agenda has never been greater.

The federal government has provided assistance to automakers to support the transition to electrification. Yet we cannot expect them to make cars for which there is not a promising market. The government has a limited number of tools to incentivize that market, including consumer incentives and government purchasing commitments. But neither of those tools match the power of the government's regulatory authority which can be used to shape the market. This rulemaking is the singular opportunity for the federal government to exercise its regulatory authority to accelerate the growth of that market. SAFE encourages EPA to take full advantage of this opportunity and finalize standards that continue to increase the stringency of the standards in a manner that accelerates the transition from a fleet powered predominately by petroleum to one powered predominantly by electricity. [EPA-HQ-OAR-2021-0208-0527-A1 pp. 5-6]

EV Sales in the United States and Their Importance to U.S. Economic and National Security

In 2011 there were only two electric vehicle models available in the United States. Today, however, there are now nearly 20 electric vehicles available to U.S. consumers.13 Still, electric vehicles represent just one out of every 58 new vehicles sold in the United States.[14] While this sales penetration ratio is an improvement over the rates of just a decade ago, electric vehicles remain a niche product within a car market that sold more than 14.46 million units last year.[15]

Greatly expanded model availability of EVs over the last several years has helped to interest new consumers in electric vehicles. By the end of 2020, electric vehicles were available in nearly every vehicle segment—compact cars, sedans, and SUVs, with more new vehicles, including full size pickup trucks on the near horizon. Current reports show that as many as 18 new models of electric vehicles will be available for sale by 2022.[16]

Despite the progress in bringing electric vehicles to market, the transition to electrification remains in its early stages. National sales remain heavily skewed, as approximately 37 percent of the nation's electric vehicle sales have been concentrated in California,[17] a state that in 2020 represented only 11 percent of the total new vehicle market.[18] Moreover, it can be more difficult to find a selection of electric vehicles or inventory at dealers outside California or the other states that have chosen to adopt California's strict vehicle emission standards.[19]

Further, U.S. electric vehicle sales remain far behind those in China and Europe. In China and Europe, electric vehicles represent 7 and 7.6 percent of new vehicle sales respectively.[20] These rates represent far greater progress in these two giant auto markets towards electrification than we have achieved here in the United States. These sales are spurred by generous incentives for the purchase of electric vehicles, robust financial and policy support for their manufacture, and a better cost-effectiveness calculus as gasoline prices in Europe and China are greater than gasoline prices in the United States, making electric vehicles more cost competitive abroad.[21]

SAFE believes that it is important to accelerate the transition to electrification of transportation to protect our economy. Today, the transition to electrification appears inevitable. The primary questions are how fast or slowly it will occur, and which nations will secure positions of global leadership and power in the new transportation landscape. Central to China's efforts to secure its global position is consolidating control of the important supply chains for the future global transportation industry, from mineral extraction and processing, to electric vehicle battery and motor production, development of autonomous vehicles and 5G technology on which cars will communicate, the design and assembly of electric vehicles, and the deployment of charging infrastructure and battery storage. The United States is capable of competing against China and Europe in this competition and winning, but we are late to the game. As explained above, the sales of electric vehicles in the United States lags far behind China and Europe, and U.S. automakers cannot be expected to make the required investments to accelerate the transition if the market does not develop for electric vehicles.

This global competition for leadership in electric vehicles matters because the automobile industry is the manufacturing backbone of the U.S. economy. It not only supports 10 million direct and indirect jobs, but accounts for more than three percent of GDP.22 Moreover, the industry has a highly skilled workforce that our nation has turned to in times of crisis. If such manufacturing capacity is lost, or severely degraded, it would not only threaten our economy and millions of jobs, but it could also undermine our capacity to innovate, with implications extending to the military and defense industry. As the United States awakens to these risks, we must adopt a long-term comprehensive strategy—from minerals to markets—that overcomes political discord in Washington. Using the regulatory powers of the federal government is an important tool in creating the demand for electric vehicles that are the engine of that transition, and SAFE believes that the GHG emission rule should be developed in a manner to accelerate this critical transition. [EPA-HQ-OAR-2021-0208-0527-A1, pp. 7-8]

Military Costs of Oil Dependence

EPA declined to consider the military cost to protect global oil supplies in undertaking the benefit cost analysis of this proposed rule.34 In SAFE's view, this is a significant omission. In a 2018 report, SAFE found that an average of $81 billion, or approximately 16 percent of the (roughly $500 billion) U.S. base defense budget, is spent every year on protecting the worldwide free flow of oil.[35] If one distributes this cost across the 19.8 million barrels of oil consumed daily in the United States in 2017, the implicit subsidy for all petroleum consumers is approximately $11.25 per barrel of crude oil. If the Overseas Contingency Operations (OCO) funds are included, this cost rises to over $13 per barrel.[36] '$82 billion is fairly conservative and does not include the additional cost for defense of the oil and that freedom of the seas,' says General McNabb in an interview with SAFE. 'The benefit to the United States is the stability that allows for prosperity,' he said.[37]

According to SAFE's Energy Security Leadership Council (ESLC) member and former Secretary of the Navy John F. Lehman, 'more than half the Defense budget is for the security of Persian Gulf oil.' And 'defending Persian Gulf oil is a major distraction from existential defense issues. Oil dependency complicates the military equation beyond our comprehension.' Moreover, if the long term, full economic costs of fighting wars in the Middle East are included, the true costs '…may well be in the range of $4 to $6 trillion, or even higher, once the long-term budgetary and economic costs are factored in.'[38] This equates to more than $30 per barrel of crude oil.

Reducing oil use in the transportation sector can shift U.S. military priorities toward other critical strategic threats. 'If we reduced our oil consumption by half, [the United States military] would act differently,' says ESLC member Admiral Dennis C. Blair, the former Director of National

Intelligence and Commander in Chief of the U.S. Pacific Command. ‘These are not small incremental gains. You would generate huge savings.’[39] SAFE appreciates the difficulty in estimating the savings if our dependence on oil was not eliminated, but only reduced. Given the evidence presented by SAFE and other parties that the savings would be substantial, SAFE believes that they should be given some consideration in the analysis, which would enhance the cost-effectiveness of the standards, and support a more stringent standard. [EPA-HQ-OAR-2021-0208-0527-A1 p.10]

Commenter: Schrier, Paul

And to top it all off, the United States doesn’t currently have the resources or processing capability to make EV batteries -- meaning Bidens push for EVs will primarily benefit China, which is leading the race as one of the largest and fastest-growing EV markets in the world. [EPA-HQ-OAR-2021-0208-0466, p. 1]

Commenter: Valero Energy Corporation (Valero)

In addition to providing for increased production of renewable fuels and improvements in vehicle efficiency, EISA's statutory purposes include enhancing energy independence and security, consumer protection, and promotion of research and deployment of GHG capture and storage options. The proposed rule undermines each of these objectives:

By subsidizing accelerated electric vehicle adoption through the extension of multipliers and ignoring the upstream GHG emissions associated with generation of electricity and production of batteries, the rule fails to address the energy security consequences of encouraging greater dependence on electric vehicles that rely on batteries requiring rare earth and other metals sourced substantially outside of the United States and its sphere of influence.14 [EPA-HQ-OAR-2021-0208-0601-A2, pp.6-7]

EPA Response

One commenter (American Enterprise Institute) suggests that there are no energy security benefits from this rule. The absence of energy security benefits, according to the commenter, is a result of the fact that there is only one price in the international petroleum market, confronted equally by economies importing all or none of their oil. EPA disagrees with the commenter’s suggestion that there are no energy security benefits resulting from this final rule. In EPA’s energy security analysis, a reduction in U.S. oil consumption from this final rule results in a 91 percent reduction in U.S. oil imports. Thus, there is a close relationship between reductions in U.S. oil consumption and U.S. oil imports resulting from this rule. EPA’s analysis assumes that future disruptions in world oil supply over the time frame of this analysis, 2023-2050, will cause spikes in world oil prices. To the extent that the U.S. sees a reduction in both its oil consumption and imports from this rule, the effects of spikes in world oil prices will have a less significant impact on the overall U.S. economy, measured in terms of a loss in U.S. gross domestic product (i.e., GDP). The Oak Ridge National Laboratory (ORNL) model estimates the avoided losses in GDP from future world oil supply disruptions, using a GDP elasticity with respect to a change in the short-term world oil price. See the paper by Oladosu et al., Impacts of oil price shocks on the U.S. economy: a meta-analysis of oil price elasticity of GDP for net oil-importing economies, Energy Policy (2018), which provides the basis for the GDP elasticity. This elasticity has been reduced compared to analyses undertaken for previous EPA LDV GHG rules, since it is generally thought that the U.S. economy is more resilient (i.e., less sensitive) to changes in the short-term world oil price than EPA previously assumed. The avoided losses in GDP from oil supply disruption are then converted into benefits on a per barrel of reduced U.S. oil import reductions basis, which is referred to as the macroeconomic oil security premiums and are reported in Table 3-6 in Section 3.2.5, Oil Security Premiums Used for this Final Rule, in the RIA.

To summarize, even though the world oil price faced by all participants is the same regardless of how much oil they import, a reduction in U.S. oil consumption and imports is still valuable, as it helps in mitigating the macroeconomic effects resulting from exposure to that volatile world oil price where a cartel continues to play a significant role in oil price formation.

Two commenters (Center for Biological Diversity et al., California Air Resources Board) suggest that EPA is underestimating the energy security benefits of the final LDV GHG rule by not accounting for the monopsony oil security impact. EPA disagrees with the commenters' suggestion that EPA is underestimating the energy security benefits of this rule by not counting monopsony effects as a benefit. U.S. monopsony power in global oil markets means that decreases in U.S. oil consumption and U.S. oil imports cause the world price of crude oil to decline modestly. In previous LDV GHG rules when the U.S. was forecasted by the U.S. Energy Information Administration (EIA) to be a net importer of crude oil and product, monopsony impacts represented reduced payments by U.S. consumers to oil producers outside of the U.S. There is some debate in the economics literature as to whether the U.S. exercise of its monopsony power in oil markets, for example from the implementation of LDV GHG rules, was a "transfer payment" or a "benefit." Given the redistributive nature of this monopsony impact from a global perspective, and since there are no changes in resource production costs when the U.S. exercises it monopsony power, some economists argued that it is a transfer payment. Other economists argued that monopsony impacts are a benefit since they partially address, and partially offset, the market power of OPEC.

In previous EPA LDV GHG rules, after weighing both countervailing arguments, EPA concluded that the U.S.'s exercise of its monopsony power was a transfer payment, and not a benefit. In the context of this rule, the U.S.'s oil trade balance is quite a bit different than in previous LDV GHG rules. The U.S. is projected to be a net exporter of oil in the time frame of this analysis of this rule, 2023-2050. As a result, reductions in U.S. oil consumption and, in turn, U.S. oil imports, still lowers the world oil price modestly. But the net effect of the lower world oil price is now a decrease in revenue for U.S. exporters of crude oil and products, instead of a decrease in payments to foreign oil producers. The argument that monopsony impacts address the market power of OPEC is no longer appropriate. Thus, EPA continues to consider the U.S. exercise of monopsony power to be transfer payments. Therefore, EPA does not believe that excluding monopsony effects stemming from this rule results in an underestimate of the energy security benefits of this rule.

Three commenters (Center for Biological Diversity et al., Securing America's Future Energy, California Air Resources Board) suggest that EPA should include a military cost savings from this rule, since reductions in U.S. oil imports from this rule will result in military cost savings. One commenter, the American Enterprise Institute, suggests that military cost savings from this rule would be imperceptible. The ramifications of reduced U.S. oil consumption and, in turn, U.S. oil imports on U.S. military costs to protect the U.S.'s access to foreign oil supplies is an important issue. The U.S. spends significant resources to protect its access to foreign oil supplies, mainly in the Middle East. The question that arises in the context of this rule is the magnitude of military cost savings resulting from reductions in U.S. oil imports from this rule.

The twin issues of attribution and incremental analysis pose significant challenges to providing a robust estimate of the military cost component of the U.S.'s energy security. The attribution analysis challenge is to determine which military programs and expenditures can properly be attributed to oil supply protection, rather than to some other military or foreign policy objective. The Securing America's Future Energy comments quoting statements by the former Secretary of the Navy that roughly half of the U.S. defense budget is devoted to the security of Persian Gulf oil presents an interesting perspective on the attributional issue. On the other hand, the American Enterprise Institute suggests that applying estimates of the mission of specific parts of the U.S.'s military force structure would be inherently arbitrary.

The incremental analysis challenge is to estimate how much the petroleum supply protection costs might vary if U.S. oil use were to be reduced, but not eliminated. Two commenters (California Air Resources Board, Securing America's Future Energy) suggest that military cost savings from reduced U.S. oil imports from this rule would be significant. Another commenter, (American Enterprise Institute) suggests that military costs savings stemming from this rule would be imperceptible. Better methods of addressing both attribution and incremental analysis challenges are necessary in order to better estimate military cost savings attributable to this final rule. Therefore, EPA continues to believe that the military cost savings from this rule cannot be accurately quantified for this rulemaking.

Several commenters (Securing America's Future Energy, Attorney General of Missouri et al., Alliance for Automotive Innovation, an energy company, private citizens) express concern that this rule will increase the U.S. reliance on non-U.S. producers, including China, of materials and components used in electric vehicles. Since the 1970s, the topic of energy security has focused on imported oil from unstable supply sources and OPEC's ability to exert market power in oil markets. These commenters express concern that transitioning from internal combustion engine (ICE)-powered vehicles to battery electric vehicles (BEVs) will have other implications beyond decreased U.S. reliance on imported oil; in particular, commenters identified the sourcing of materials and components used in BEVs, including batteries. We note that the scope of EPA's discussion of "energy security," which is defined in RIA section 3.2 as "the continued availability of energy sources at an acceptable price," was not intended to include security risks associated with the manufacture and importation of different types of vehicles and vehicle components.

The topic of the security implications of an emerging electric vehicle global supply chain is an important issue. To help address this issue, Executive Order 14017, signed by President Biden on February 24, 2021, directed a government-wide review of U.S. supply chains and vulnerabilities.[97] As directed within the Executive Order, a report on advanced batteries, led by the Department of Energy, was submitted to the President in June 2021, and the Biden Administration subsequently announced a set of immediate actions to make the U.S. more competitive in automotive Li-ion battery manufacturing. "With the global lithium battery market expected to grow by a factor of five to ten by 2030, it is imperative that the United States invests immediately in scaling up a secure, diversified supply chain for high-capacity batteries here at home. That means seizing a critical opportunity to increase domestic battery manufacturing while investing to scale the full lithium battery supply chain, including the sustainable sourcing and processing of the critical minerals used in battery production all the way through to end-of-life battery collection and recycling."[98] The Administration has committed millions of dollars toward R&D, loan programs and a 10-year government-wide plan to "urgently develop a domestic lithium battery supply chain that creates equitable clean energy economy jobs in America."[99] The Administration also recommended that Congress make "critical investments to grow America's ability to produce high-capacity batteries and products that use batteries, like electric vehicles and stationary storage,"[100] and noted that the battery supply chain should employ sustainable and environmentally protective methods, including "sustainable sourcing and processing of the critical minerals used in battery production all the way through to end-of-life battery collection and recycling."[101]

Auto manufacturers in the U.S. are already addressing demand for domestic and European mineral and battery supply. In addition to seeking to reduce cobalt and rare earth magnet content in batteries and electric machines (see RTC 12.1), manufacturers are increasingly adopting an approach in which new manufacturing plants are to be constructed as part of joint ventures, by which the OEM may secure a supply of batteries for its products and develop a supply chain that will support their production

appropriate action to address this business need. EPA also believes that this activity as well as the abovementioned federal investments and initiatives indicate that the federal government is taking appropriate actions to support its development. See 12.1 of the RTC for more discussion of comments related to supply chain development and critical minerals.

One commenter (Center for Biological Diversity et al.) asked for a more detailed explanation of how the oil import reduction factor was estimated. As described in RIA section 3.2, EPA estimates a reduction in refined oil consumption (i.e., mainly gasoline) resulting from this rule will be reflected in a 91 percent reduction in net imports of oil and refined products. To calculate the 91 percent value, EPA uses Table 11: Petroleum and Other Liquids Supply and Disposition, for two different case studies, the Reference Case and the Low Economic Growth Case from the U.S. Energy Information Administration's (EIA) latest Annual Energy Outlook (AEO) 2021. While EPA reviewed EIA's High Economic Growth Case, the Low Economic Growth Case better matches the projected impact of this rulemaking on fuel demand, since it shows reduced petroleum demand. The Low Economic Growth Case is compared with the Reference Case to calculate the average difference in net oil and refined product imports as a percentage of the reduction in U.S. refined product (i.e., mainly gasoline) consumption. Comparing the AEO 2021 Reference Case and the Low Economic Growth scenario yields an import reduction factor of 91 percent when averaging over the years 2021 through 2050, roughly the time frame of analysis of this rule. The calculations used to estimate the oil import reduction factor in this rule are in the docket to this rule in a spreadsheet entitled, "AEO 2021 Change in product demand on imports".

This commenter also stated that because U.S. gasoline imports are near zero, it would not be possible for reduced domestic U.S. gasoline demand to cause reductions in U.S. gasoline imports. This comment is somewhat unclear, but we believe the commenter is referring to net U.S. gasoline imports and is not considering the gross U.S. gasoline imports into the U.S. For example, in 2019, over 12 billion gallons of gasoline were imported into the U.S. (https://www.eia.gov/dnav/pet/pet_move_imp_dc_NUS-Z00_mbbl_a.htm), but these gasoline imports were offset by about a roughly equal volume of U.S. gasoline exports (https://www.eia.gov/dnav/pet/pet_move_exp_dc_NUS-Z00_mbbl_a.htm). Considering the volume of gasoline that the U.S. imports currently, reductions in U.S. imports of gasoline would not be constrained as the commenter suggests.

In developing oil security premium estimates for this rule, one commenter (Center for Biological Diversity et al.) supports EPA's updated inputs for the short-run price elasticity of demand for oil and the elasticity of GDP to oil price shocks based upon the ORNL meta-analyses. We agree with the commenter that the ORNL meta-analyses provide the most well supported inputs for estimating oil security premiums for this rule, since both of the ORNL studies have broad

coverage of the economics literature on the topics of the price responsiveness of short-run oil demand and the sensitivity of the U.S. economy to oil shocks

One commenter (Alliance for Automotive Innovation) suggests that oil use declines from this rule will result in greater impacts on U.S. oil producers and refineries than EPA's analysis estimates. This commenter suggests that EPA undertake a rigorous analysis of which oil producers/refiners in the world will be adversely impacted by an incremental decline in U.S. demand for oil. EPA disagrees with the commenter that there will be greater impacts on U.S. oil producers and refineries than estimated in this rulemaking. The import reduction and energy security analyses in this rule are based on AEO 2021, which uses Department of Energy's Energy Information Administration (EIA) modeling. This modeling balances worldwide oil supply and demand with regional detail. The AEO 2021 projects that over 93 percent of the reduced fuel demand resulting from this rule will be met by reduced production by U.S. refineries. The continued volume of U.S. gasoline imports is more than large enough for reductions to occur from U.S. gasoline imports as well.

EPA continues to believe that the use of the AEO 2021 methodology employed in this rule is appropriate to estimate aggregate oil and product import reductions as a result of this rule. We note that Oak Ridge National Lab's (ORNL) oil security premium estimation methodology represents the U.S., OPEC, and non-OPEC states, but is not disaggregated to individual countries. EPA believes it is not necessary to have country-specific changes in oil production and refinery use as a result of this rule when using the ORNL oil security premium model to estimate energy security benefits. We continue to believe that combining the oil import reduction factor modeled by EIA in its AEO 2021, along with the oil security premiums estimated using the ORNL oil security premium model, provide a reasonable estimate of the energy security impacts of this rule.

One commenter (Alliance for Automotive Innovation) expresses concern about the alignment of U.S. oil market outcomes in the development of the GREET PM2.5 benefits estimates in EPA/NHTSA's criteria air emissions analyses and EPA's energy security analysis. Comparing EPA's PM2.5 analysis and EPA's energy security analysis, both analyses are estimated from oil industry modeling output conducted by the Energy Information Administration (EIA) for its Annual Energy Outlook (AEO 2021) by taking the ratio of the changes in crude oil and product imports and domestic crude oil divided by the change in U.S. refined product consumption over roughly the analytical time frame of the LDV rule, 2021-2050. These modeling results project that of the decrease in U.S. refined product demand, 93% of that decline will be due to lower U.S. domestic refined product output and 7% will be due to lower imported petroleum product. For estimating impacts on criteria emissions, criteria air emissions factors (including PM2.5) from GREET are used.

Based on the same EIA modeling output, EPA's energy security analysis calculates changes in oil imports. Of the reduction in domestic refined product demand, approximately 85 percent is attributed to a reduction in imported crude oil, 9 percent is attributed to a reduction in domestic crude oil, and 7 percent is attributed to a reduction in U.S. net imported product. When the 85 percent reduction in imported crude is summed with the 7 percent reduction in U.S. net imported product, the value of reduced crude oil and product imports is the 91 percent oil import reduction factor value, which is identical to the 91 percent value used in EPA's criteria air emissions analyses. Thus, the results of the impacts of the LDV rule on domestic versus imported oil are identical between the two analyses.

20. Impacts of Additional Driving (i.e., rebound effect)

U.S. EPA Improved its Analysis of the Rebound Effect and Should Revisit the Sales Elasticity Effects. CARB appreciates the work U.S. EPA has taken to reconsider its treatment of the rebound effect from the SAFE Vehicles Rule.112 As U.S. EPA recognizes, and as Professor Gillingham, a recognized authority on energy and environmental economics whose research on transportation, energy efficiency, and the adoption of new technologies has been widely-published, further explains in his enclosed expert analysis, the Final SAFE Rule rebound effect of 20% is not defensible.113 To the contrary, a national rebound effect of 10% is defensible, although it, too, may be an overestimate. U.S. EPA should apply a rebound effect of not more than 10% to estimate the impacts of the final rule. [EPA-HQ-OAR-2021-0208-0643-A6, p. 38]

U.S. EPA should apply more reliable estimates of the rebound and sales effects of more stringent standards to provide more reliable estimates of the costs and benefits of the proposal. In both instances, it happens that the net benefits are greater than otherwise estimated. [EPA-HQ-OAR-2021-0208-0643-A6, p. 38]

Commenter: Center for Biological Diversity, et al.

EPA’s use of a 10% rebound effect, while reasonable, is clearly at the high end of estimates - leading to higher costs and lower benefits for more stringent standards. EPA has provided a thorough justification for a 10% rebound effect in several prior rulemakings.

EPA’s Proposal estimates the VMT rebound effect to be 10%. 86 Fed. Reg. at 43,769-70. The quantitative estimate of the rebound effect—which indicates the amount of additional driving that will occur as the cost of driving decreases due to fuel economy improvements—significantly influences multiple factors considered in promulgating new GHG regulations for light-duty vehicles. Additional driving leads to more accidents, road congestion, and noise, while also reducing the fuel savings and emission reductions associated with more stringent standards. Therefore, without a reasonable estimate of the rebound effect, the magnitude of a new rule’s costs and benefits cannot be properly understood.

The use of a 10% rebound effect is not new. EPA also estimated the rebound effect to be 10% in both the 2010 and 2012 Final Rules. See 75 Fed. Reg. at 25,517; 77 Fed. Reg. at 62,716. During both of these previous rulemakings, EPA considered a large body of both historical and recent literature that reported a very broad range of rebound estimates arrived at through a variety of research methods. EPA understood that simply averaging all of the rebound estimates from all of the studies was an unreasonable and inadequate method for reaching an accurate estimate of rebound for the vehicles subject to the relevant standards.76 For example, many of the studies considered old research, data from other countries with vastly different driving habits, or estimates that were not forward-looking to the years when the covered vehicles would be driven. 77 Fed. Reg. at 62,924. Historically, EPA has correctly acknowledged that rebound research should be weighted based on its relevance to GHG emissions regulations in the United States.77 In the 2010 Final Rule, EPA concluded that while the historical research dating back to the 1950s suggested higher rebound values, the most recent literature supported a 10% "or lower" rebound effect. 75 Fed. Reg. at 25,517.

In the 2012 Final Rule, EPA again valued the rebound effect at 10%, and in 2016, EPA confirmed three times that a 10% rebound effect was appropriate. In both the 2016 Draft TAR and the 2016 Final TSD, EPA cited multiple studies demonstrating that the rebound effect shrinks as incomes rise, and again explained that older studies were likely to be less reliable than more recent research.78 Also in 2016, EPA used a 10% rebound effect in adopting standards for heavy-duty pickups and vans.79

EPA's Proposal properly conducts a rigorous review of the literature in order to prioritize rebound studies, and recent research provides further support for a rebound effect estimate of 10% or less. In the NPRM, EPA builds on this well-established precedent and again uses a 10% rebound effect to calculate the relevant impacts of the proposed LDV GHG emissions standards, citing much of the same support provided in the previous rulemakings. In the Proposal, EPA provides even more clarity into the agency's approach to the broad body of rebound literature spanning many decades. EPA is correct in its belief that "it is important to critically evaluate which studies are most likely to be reflective of the rebound effect that is relevant to the Proposed Standards (2023-2026)," and that "one cannot just take the 'average' rebound estimates from literature to use for the VMT rebound effect for this proposed rule." DRIA at 3- 12. When agencies consider a range of studies, they should focus on those that are similar to the relevant policy context.80

Specifically, EPA appropriately identifies factors for weighting rebound studies that reflect their relevance to the proposed rulemaking: (1) geography/timespan relevance (priority given to U.S. studies as opposed to international estimates); (2) time period of study (priority given to recent studies, including recent studies that were excluded from the 2020 Final Rule); (3) reliability/replicability of studies (priority given to studies using odometer readings vs. household surveys such as the 2009 National Household Travel Survey); and (4) statistical/methodological basis (priority given to studies employing a strong statistical/methodological basis). DRIA at 3-12.

EPA further explains why these factors are important and why they lead to more accurate estimates of the rebound effect for the rulemaking. As a result, the agency provides a clear and well-reasoned basis for its decision to give more weight to studies based on these four key criteria, and thus to conclude that the seven papers listed in Table 3-4 of the Draft RIA should be given the most significant weight in developing the rebound estimate used in the Proposal. See DRIA at 3-13 to 3-14.

EPA should make its rebound effect estimate even more accurate by considering the best estimates provided by the authors of some of the agency's preferred studies. For some of these seven studies that report a range of estimates, EPA correctly reports and relies on what the authors identify as their best rebound estimates, when those are available. For example, EPA properly includes a rebound effect of 10% for Gillingham et al. (2015), because, while that study produced a range of estimates from 8% to 22%, the authors stated that they considered their best estimate to be 10%.[81] EPA should update the rebound effect values for two of the agency's preferred studies, however, to reflect their authors' best estimates. First, EPA should report the "best estimate" for Hymel and Small (2015) because, although the study reports a range of estimates of 4% to 18% as shown in Table 3-4 of the Draft RIA, the authors have explained that their most realistic estimate is either 4% or 4.2%.[82] Accurately considering the most relevant estimate is especially important because Hymel and Small (2015) noted that their data indicated that fuel economy rebound could be lower than fuel price rebound, meaning that even the 4.0% and 4.2% values could be too high.[83] Properly considering the most relevant best estimate from Hymel and Small (2015) would mean that the two most reliable rebound estimates based on U.S. national data are 10% and around 4%, offering even clearer support for a rebound effect of 10% at maximum.

Second, EPA should cite the most relevant estimate from Wenzel and Fujita (2018). EPA's Proposal cites a range of values for Wenzel and Fujita (2018), from 9% to 16%. DRIA at 3- 14, Tbl. 3-4. Wenzel and Fujita also found, however, that as a vehicle's fuel economy increases, the rebound effect declines. By their estimation, vehicles with "high" fuel economy[84] would have a rebound effect of only 5.2%. The vehicles subject to the Proposal would be within this "high" fuel economy category, and therefore the 5.2% rebound effect would be most applicable to this rulemaking context.

A third paper in the list of EPA's seven preferred studies, Gillingham et al. (2015), estimates the rebound effect at 10%. But the study also found that "a high percentage of vehicles are almost entirely inelastic in response to gasoline price changes" and that "the lowest fuel economy vehicles in the fleet drive the responsiveness, with higher fuel economy vehicles highly inelastic with respect to gasoline price changes."[85] While Gillingham et al. (2015) does not offer an alternative best rebound estimate for higher fuel economy vehicles (which would include all those subject to the rulemaking), it is fair to assume that the 10% estimate is at the high end of reasonable estimates for the purposes of this rulemaking.

The 2020 Final Rule's rebound effect of 20% arbitrarily doubled EPA's prior reasonable estimates and was unjustified and unsupported. When promulgating the 2020 Final Rule, EPA arbitrarily doubled the prior reasonable 10% estimate of the rebound effect to 20%, without offering any real support for the massive increase in magnitude. Moreover, despite acknowledging that the criteria used for weighting literature based on the quality of the underlying analysis could make a large difference in the rebound effect, the 2020 Final Rule made no clear effort to lay out such criteria, in contrast to the new rule proposed by EPA.

The 2020 Final Rule purported to rely on "the totality of empirical evidence, rather than restricting the available evidence," 85 Fed. Reg. at 24,674, but as EPA's Proposed Rule, along with the 2010 and 2012 Final Rules and the 2016 Midterm Evaluation make clear, not all "available" evidence is equally relevant to achieving an accurate rebound estimate. Even in the 2020 rulemaking, EPA explained that if the agency considered only studies using recent U.S. data, and if higher weight were assigned to studies that meet certain quality criteria suggested in the comments they received, the resulting set of studies would make a "reasonable case . . . to support values of the rebound effect falling in the 5-15 percent range" and in fact "more likely to lie toward the lower end of that range." Id. at 24,676. During its interagency review process for the 2020 Rule, EPA also explained that "[g]iven the broad range of values, EPA believes it is important to critically evaluate which studies are most likely to be reflective of the rebound effect" of future GHG standards, and that "[i]n other words, we can't just take the 'average' rebound estimates from literature."86 Only by ignoring their own guidance regarding the importance of properly weighting studies based on relevance and reliability could EPA increase the rebound effect to an arbitrary and unsupported 20%. In fact, the 2020 Final Rule's 20% rebound effect has been called "outside reasonable professional judgment" by leading experts in the field—many of whom authored the studies on which EPA has relied historically, in the 2020 rulemaking, and for the Proposed Rule.87

EPA is therefore correct to abandon the poorly considered and wholly unsupported 20% rebound effect used in the 2020 Final Rule and return to the more accurate and supportable estimate used in its earlier rulemakings. EPA has added value to its historical rebound analysis by defining the relevant factors for weighting studies and clearly articulating which studies satisfy these parameters and are thus given extra weight, in contrast to its vague and conclusory approach during the 2020 rulemaking.

Even the 10% rebound effect is too high, and EPA should consider using a rebound effect of a lesser magnitude. EPA has requested comment regarding alternative rebound values of 5% or 15%. EPA's weighted criteria, explained above, provide ample support that 10% is at the maximum end of appropriate rebound values, and using a 15% rebound effect would be unsupportable. EPA's set of the seven most relevant studies makes this clear. If using the preferred rebound estimates from Hymel and Small (2015) of around 4% to 4.2%, and from Wenzel and Fujita (2018) of 5.2%, as explained above, the un-weighted average of the most relevant studies would be well below 10%, as shown below: [Table # can be found on p. 35 of Docket number EPA-HQ-OAR-2021-0208-0651-A1] [EPA-HQ-OAR-2021-0208-0651-A1, p. 30-35]

A number of other factors would suggest that even these best and most relevant studies could lead to a rebound estimate that is too large. First, a substantial body of research indicates that fuel price or fuel cost rebound effects are higher than fuel economy rebound effects, meaning that rebound may be more responsive to fuel prices than fuel efficiency. Both Greene (2012) and Hymel and Small (2015)—two of EPA's seven most preferred studies—came to this conclusion. Other studies cited by EPA—Gillingham (2012), Small and Van Dender (2007), West et al. (2015), and Wang and Chen (2014)—also concluded the same. Kenneth A. Small has explained that his studies indicate that the fuel economy rebound effect "is statistically indistinguishable from zero," and that "[t]his is also true of the vast majority of other studies that have tried to measure separately these two responses."90 He further explained that "the most defensible result empirically is that people do respond to fuel prices as expected, but that they do not respond to fuel economy at all," and that "Small and Van Dender (2007) make this point explicitly, and point out that we are therefore assuming a positive [fuel economy] rebound effect when actually we cannot prove that it's greater than zero."91 Greene (2012) also found that the impact of fuel efficiency on VMT was not statistically significant, a point EPA referred to in the 2016 Draft TAR to suggest that the relevant rebound effect for policymaking purposes "could be zero." 2016 Draft TAR at 10-14. Because some of EPA's seven most preferred studies consider fuel prices rather than fuel efficiency, the most accurate rebound estimate would be no higher than—and likely lower than—the average of those studies' best estimates.

Another fact that indicates that a 10% rebound effect—and even the lower unweighted average of the preferred studies' best estimates—is too high is that the rebound effect's magnitude diminishes over time, largely due to increasing income and decreasing driving costs, a fact that EPA has historically understood.92 As incomes rise over time, any fuel efficiency improvement will have less of an effect on the total vehicle miles traveled, and thus the rebound effect will decline. In both 2010 and 2012, EPA chose to use a 10% rebound effect as "a reasonable compromise between historical estimates and projected future estimates."93 The 2012 Final Rule noted, however, that several high-quality studies indicated that the rebound effect's magnitude was significantly diminishing over time as incomes rise.94 This income effect on rebound makes clear that the projected future estimates are in fact much more accurate than historical estimates. Moreover, more than 10 years have passed since the 2010 Final Rule found a 10% rebound effect to be a good compromise, and income has continued to grow since that time, supporting a substantially diminished rebound effect.

EPA should give more weight to the fact that the rebound effect varies with income over time. The agency cites Gillingham (2014) to assert that the evidence is "mixed," but then also correctly excludes that study from its list of preferred studies. This paper specifically considers the response to the 2008 gasoline price shock in California. EPA is correct to conclude that this was "an unusual period when gasoline prices were particularly salient to consumers." DRIA at 3- 6. As EPA's Proposal notes, Gillingham explained in a follow-up paper in 2020 that the Gillingham (2014) results should not be used for developing an estimate of the VMT rebound effect for fuel economy or GHG standards. The Gillingham (2014) paper is equally irrelevant to the question of the income effect on rebound. Various papers have confirmed that the rebound effect is declining over time and one study certainly should not be used as the basis for giving this factor "less weight," especially a study whose own author acknowledges its irrelevance to this rulemaking context and to which EPA gives little to no weight otherwise. Because of this, EPA should more fully consider the impacts of the income effect on rebound, and in doing so, could support a rebound effect of a magnitude lower than 10%.

In fact, the income effect on rebound is particularly important in the context of setting LDV GHG emissions regulations for two reasons. First, even the most recent relevant studies on which rebound estimates are based consider data only from 2013 and earlier. The historical growth rate of per capita personal income was 1.4% between 2001 and 2019, and thus income growth since 2013 would indicate a declining rebound effect even in the time since the most recent data utilized were collected. Second, EPA's final standards will affect the fuel efficiency—and therefore the rebound effect—for vehicles for the next 30 years or more. Private forecasts estimate approximately 1.6% growth in real personal income per year over the next 30 years, meaning that when most vehicles subject to the regulations are retired, incomes will be 61% higher than they are today. AEO 2021 projected incomes to rise an average of 1.9% per year through 2050.95 This income growth would be expected to cause a large reduction in the magnitude of the rebound effect, supporting a rebound effect for the vehicles subject to EPA's final standards of a magnitude well below 10%. [EPA-HQ-OAR-2021-0208-0651-A1, p. 35-37]

Commenter: Consumer Federation of America

Above, we identified an unsupported and unsupportable assumption about the rebound effect as having an impact on the pocketbook benefits of a higher standard. Rebound is part and parcel, the tip of the iceberg, for a much larger issue–unrealistic assumptions about driving, and new vehicle safety (see Figure 5.1). By claiming to avoid a slew of fatalities due to consumers driving less because of increased annual fuel costs and driving in safer vehicles, the Trump rule claimed to avoid a significant negative impact on congestion, noise, and safety.

Correcting the significant flaws in the NHTSA/EPA framework, including the rebound effect and the failure to recognize technological flexibility for automakers, dramatically reduces the assumed safety benefits of the Trump SAFE 2 rule. As shown in Figure 3, these adjustments eliminate over 80 percent of the claimed reduction in accidents. We believe other technological improvements, introduced along with higher fuel economy, further reduce the impact of increased accidents. [EPA-HQ-OAR-2021-0208-0297-A1, p.15]

Commenter: Consumer Reports (CR)

Consumer Reports supports EPA's shift to a 10% rebound effect which is consistent with the existing literature when applied to increases in efficiency from conventional vehicles. However, we would ask that EPA consider doing more research prior to future rulemakings on the potential applicability of rebound effects for conventional vehicles being applied to battery electric vehicles. [EPA-HQ-OAR-2021-0208-0602-A1, p.22]

Commenter: E2 - Environmental Entrepreneurs

Other Non-emissions Benefits: EPA has also quantified the non-emission benefits from the rebound effect (the increase in driving resulting from reduced operating costs), changes in refueling time, and energy security benefits from reduced dependence on foreign petroleum. EPA projected non-emission benefits for the Proposal to be $35 billion through 2050, while

Alternative 2 would generate $53 billion—a difference of $18 billion. DRIA, Tables 6-8, 6-10. [EPA-HQ-OAR-2021-0208-0604-A1, p. 3]

Commenter: Gillingham, Kenneth

This comment focuses on the choice of the “rebound effect” parameter in the proposed U.S. Environmental Protection Agency (EPA) rulemaking “Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards” (86 Fed. Reg. 43,726 Aug 10, 2021). In the context of the rule, the rebound effect is defined as the increase in driving (and associated impacts) when improved vehicle energy efficiency lowers the cost per mile of driving, making driving cheaper. This commenter has performed research on the rebound effect for many years and has an extensive comment included in the SAFE rule docket (Gillingham 2018).
This commenter believes that EPA has done a thoughtful job in supporting the choice of a 10% rebound effect. As was discussed in detail in Gillingham (2020), as well as in the attached recent Amicus Brief by expert economists (the present author was not included), the best evidence available—from the United States, using odometer reading data from emissions or safety inspections, and from recent years—tends to fall in the ballpark of 10%. There have been no more recent additions to the literature since the Gillingham (2020) review article and the amicus brief, which quite fully characterize the body of work available on the subject. Most importantly, the 20% rebound effect estimate cannot be justified based on the best work available on the subject. This assessment accords with the assessment of EPA’s own Science Advisory Board. This commenter will also note that there is evidence supporting a lower rebound effect for projections into the future. Specifically, in a well-known and well-regarded series of papers, Ken Small and coauthors provide a strong case that the rebound effect converges towards zero with higher incomes, and most projections suggest that incomes will continue rising in the United States (Hymel and Small 2015, Small and van Dender 2007). Please see also Ken Small’s letter in the SAFE rule docket (Small 2018), which describes his logic for a “dynamic rebound effect” that changes over time due to improved incomes. In Ken Small’s letter, the rebound effect is 5.3% using his base model and 0.2% using his asymmetric model, and he deems his asymmetric model to likely be more valid. This evidence can be used to support a nationwide rebound effect closer to zero in the regulatory analysis projecting the rebound effect into the future.

Commenter: Institute for Policy Integrity

Notably, EPA’s return to an assumed 10% rebound effect is appropriate. [EPA-HQ-OAR-2021-0208-0299-A1, pp. 1-2]

While EPA and NHTSA previous relied on a 10% rebound estimate in the Clean Car Standards issued in 2012, the agencies used a 20% rebound estimate in the final SAFE 2 Rule in 2020.132 The agencies’ departure from prior practice in the SAFE rulemaking was arbitrary and capricious, and EPA’s return to 10% in the proposal here is more consistent with the best available evidence.

To arrive at the new estimate in the SAFE 2 Rule, the agencies in 2020 made significant changes to their assumptions about the magnitude of the rebound effect. These changes resulted in a significant increase in the costs and fatalities that the agencies attributed to the baseline standards.133 Those fatalities and costs helped serve as the agencies' justification for the misguided 2020 rollback of those standards.134 But the agencies' methodological changes in the 2018 SAFE proposal and 2020 final SAFE 2 Rule were inconsistent with the best available evidence regarding rebound.

Policy Integrity provided comments during the SAFE rulemaking demonstrating that EPA and NHTSA's selection of a 20% value for rebound effect was arbitrary and capricious.135 By restoring the value of rebound effect to 10%, consistent with the agency's practice prior to the SAFE rulemaking, EPA has improved the accuracy of the CCEMS model for this rulemaking by using a value supported by an appropriate meta-analysis of the academic literature.136

As Policy Integrity noted in comments on the SAFE proposal, EPA and NHTSA failed to adequately explain their departure from a 10% rebound effect. The agencies ignored studies that supported a lower rebound value, including studies relied upon by the agencies in the past and new studies published since the prior rulemaking.137 Overall, the agencies failed to present sufficient evidence in 2020 to support abandoning its prior use of a 10% rebound effect.138

In contrast, EPA has now conducted an updated and rigorous literature review that more fully presents the large body of academic literature on the rebound effect.139 This literature review includes studies that were previously considered by the agencies but ignored in the SAFE rulemaking, including Greene (2012),140 Wang and Chen (2014),141 and Gillingham (2016);142 studies that Policy Integrity recommended the agencies consider in the SAFE rulemaking, including Gillingham (2015)143 and Wenzel and Fujita (2018);144 and studies published after the SAFE rule was finalized, including Knittel and Sandler (2018),145 Gillingham and Munk-Nielsen (2019),146 and Gillingham (2020).147

Most importantly, EPA has now evaluated the available economic literature to determine which studies were most relevant to the proposed standards, weighting the analysis based on geographic/timespan relevance, time period of study, reliability/replicability, and strong statistical/methodological basis.148 In the SAFE rulemaking, the agencies calculated a simple average from the arbitrarily incomplete set of studies they considered—a flawed methodology, inconsistent with EPA's own guidelines for reaching conclusions using multiple studies, that led to an improperly inflated rebound effect.149 As Policy Integrity noted in previous comments, a meta-analysis focusing on closely matched studies—as EPA has done in the Proposed Rule—is a much more rigorous approach to evaluate results based on multiple studies.150

In addition, EPA has now offered several specific reasons why the agencies' prior rebound estimate of 20% are likely overstated. First, consumers' total VMT (vehicle miles traveled) may be more responsive to sharp increases in fuel prices as compared to the gradual decrease in fuel costs-per-mile that will result from these proposed standards, and therefore any rebound effect resulting from the standards may be smaller than some historical estimates of rebound based on price fluctuations.151 Second, consumers are likely to respond less to small changes in their costs per mile traveled as they become wealthier, and total U.S. GDP is projected to increase over time based on the latest projections.152 Together, these two considerations further suggest that an estimate of 10% or lower is appropriate, whereas the 20% estimate was much too high. And while EPA could not quantify the possible indirect and economy-wide rebound effects due to limited data,153 such effects are likely small and, to the extent they exist, they may be offset by the two consumer response factors discussed above. [EPA-HQ-OAR-2021-0208-0299-A1, pp. 19-20.]

Commenter: National Association of Clean Air Agencies (NACAA)

EPA also flags this issue in the NPRM: 'For on-road light duty vehicles, the proposed standards would reduce total non-GHG emissions, though we expect small increases in some non-GHG emissions in the years immediately following implementation of the proposal, followed by growing decreases in emissions in later years. This is due to our assumptions about increased 'rebound' driving' (see 86 Fed. Reg. 43,802). Among the pollutants for which these short-term tailpipe emission increases are expected are NOx and VOCs, both of which are ozone precursors (see 86 Fed. Reg. 43,780). Currently, more than 120 million people live in areas around the country that do not meet the federal, health-based standards for ozone. Millions more live in areas that are on the cusp of exceeding the ozone NAAQS and tipping into nonattainment.

While the effects from 'rebound driving' and sales responses to price changes (referred to as elasticity) are uncertain and the available evidence suggests they may be overstated by EPA, the initial NOx and VOC emission increases estimated by EPA under its assumptions are relatively small and would be outweighed by reductions within a few years. States and local areas with ozone attainment and maintenance obligations cannot afford increases in NOx and VOC emissions, particularly from a sector over which they have no regulatory authority. This is true in general and, in particular, for communities along highways and freeways, which are likely to bear a disproportionate share of adverse environmental and public health impacts. While NACAA strongly supports EPA's efforts to enact LDV GHG emission standards that are far more rigorous than the existing standards, such action should not impede public health imperatives underlying the NAAQS.

EPA Response

Several commenters (Consumer Federation of America, Consumer Reports, New York University-Institute for Policy Integrity, Center for Biological Diversity et al., California Air Resources Board/Gillingham) support a 10 percent VMT rebound value, or a lower value, for use in this LDV GHG rule. The commenters are generally highly supportive of the proposed 10 percent VMT rebound estimate and methodology used to develop the VMT rebound estimate for use in this rulemaking for a variety of reasons, including: the use of a critical factors methodology, as opposed to "averaging", in assessing various VMT rebound studies; the use of a comprehensive set of recent U.S. studies estimating the VMT rebound effect; and the relative weights given to various critical factors in developing the 10 percent VMT rebound estimate.

Two commenters (New York University-Institute for Policy Integrity, Center for Biological Diversity et al.) disagree with using an "averaging" approach used in a previous LDV GHG rulemaking, and instead support an approach that identifies critical factors for weighting rebound studies that reflect their relevance to this LDV GHG rulemaking context. One commenter (New York University-Institute for Policy Integrity) suggests that EPA has “conducted an updated and rigorous literature review that more fully presents the large body of academic literature on the rebound effect…” Another commenter (Gillingham) states “EPA has done a thoughtful job in supporting the choice of a 10% rebound effect…There have been no more recent additions to the literature since the Gillingham (2020) review article and the amicus brief…This assessment accords with the assessment of EPA’s own Science Advisory Board.”[i] In addition, one commenter (Center for Biological Diversity et al.) suggests that EPA “provides a clear and well-reasoned basis for its decision to give more weight to studies based on these four key criteria…” EPA acknowledges the general support from many commenters in its approach to developing the basis for a 10 percent VMT rebound estimate in this LDV GHG rule.

Three commenters (New York University-Institute for Policy Integrity, Center for Biological Diversity et al., Gillingham) suggest that the 10 percent VMT rebound estimates may be too high because: (1) VMT may be more responsive to increases in fuel prices as compared to the gradual decrease in fuel costs per mile that will result from the LDV GHG standards and (2) drivers are likely to respond less to small changes in their costs per mile traveled as their income rises. EPA agrees that motorists may respond more to a change in fuel prices during times of high gasoline prices and when fuel prices are “salient”, in comparison to a long-term gradual change in fuel costs from improvements in vehicle fuel economy stemming from LDV GHG standards. With respect to the use of fuel price responses to estimate the VMT response to GHG standards, it is not clear how significant the extent of overestimate of the VMT rebound effect may be due to this factor. As a result, EPA is not adjusting the VMT rebound value of 10 percent for use in this rule based upon a qualitative assessment of this factor.

Based upon economic theory, the VMT rebound effect will likely decline with income since the time costs of travel become larger with increases in income. As a result, the fuel costs of travel will become a smaller fraction of the total travel costs. Thus, drivers will likely become less responsive to changes in the fuel costs of travel. Some key aggregate, national U.S. studies, Greene (2012) and Hymel and Small (2015), find that the VMT rebound effect declines with income. Alternatively, Gillingham (2015) using cross-sectional, odometer-based data using California data finds that VMT rebound effects increase with income. Gillingham speculates that high income households have more vehicles, which could increase the VMT rebound effect, or there could switching from flying to driving. Even though the Gillingham (2015) VMT rebound study involves a “salient” price increase (as Gillingham notes), the study still suggests that other factors related to income may be influencing the VMT rebound effect. Also, De Borger (2016) using cross-sectional data from Denmark did not find that the VMT rebound declines with income. EPA is not adjusting the VMT rebound effect for income because research is not conclusive on this effect.

One commenter (Center for Biological Diversity et al.) notes that EPA cites a range of VMT rebound values of 9 to 16 percent from the Wenzel and Fujita VMT rebound study (2018) in developing a VMT rebound estimate. However, the commenter also notes that the Wenzel and Fujita study finds that vehicles with “high” fuel economy would have a rebound effect of only 5.2 percent. According to the commenter, since vehicles subject to the LDV GHG rule would be within this “high” fuel economy category, the 5.2 percent VMT rebound effect would be most applicable in developing an overall VMT estimate in this LDV GHG rulemaking context. In addition, the commenter also notes that while the Gillingham et al. (2015) study estimates an overall VMT rebound effect of 10 percent, the Gillingham et al. study also finds that “a high percentage of vehicles are almost entirely inelastic in response to gasoline price changes” and that “the lowest fuel economy vehicles in the fleet drive the responsiveness, with higher fuel economy vehicles highly inelastic with respect to gasoline price changes.”

Both the studies, Wenzel and Fujita & Gillingham et al., examine the relationship between VMT rebound & fuel economy of vehicles using odometer-based data. Though they characterize low, medium, and high fuel economy vehicles differently, they both find that drivers with high fuel economy vehicles have a lower VMT rebound effect than vehicles with low efficiency. EPA notes that in Gillingham’s comments on the SAFE rule, he recommends using a 10 percent VMT rebound from the Gillingham et al. study, instead of the high fuel economy VMT rebound estimate.[116] These results are interesting and further raise the possibility that VMT rebound effects may be lower than the 10 percent value being used in this rule. More research is needed on this topic to provide a robust conclusion about the relationship between the VMT rebound effect and high mileage vehicles using odometer-based studies.

One commenter (Center for Biological Diversity et al.) suggests that while EPA’s proposed rule reports a range of VMT rebound estimates from the Hymel and Small (2015) study of 4 to 18 percent, that only the lower value of the range, 4 percent, should be used in developing an estimate of the VMT rebound effect for use in this rule. The basis for this commenters’ suggestion is a statement by Small in the context of the SAFE rule that: “A better characterization of the most recent study would be that it finds a long-run rebound effect of 4.0 percent or 4.2 percent under two more realistic models that are supported by the data”.[117] Since Hymel and Small find asymmetric responses to fuel price and fuel cost changes, we agree with the commenter that the 4 percent VMT rebound value is more applicable than other estimates from this study for estimating a VMT rebound effect for this rule. This is because this rule results in a decline in the costs of driving by increasing vehicle fuel economy. Updating the VMT rebound estimate in the Hymel and Small study from a range, 4 to 18 percent, to a single value of 4 percent, does not change the overall VMT rebound effect estimate used in this rule. In the proposal for this rule, seven studies are used to provide a basis for the VMT rebound estimate. For this final rule, the same seven studies are being utilized. EPA believes that when considering the range of values from the seven studies including only the 4 percent value for the Hymel and Small (2015) study, a reliable estimate of the overall VMT rebound effect for use in this rule is still a 10 percent value.

[116] Gillingham, Kenneth, The Rebound Effect of Fuel Economy Standards: Comment on the Safer Affordable Fuel-Efficient Vehicle Proposed Rule for Model Years 2021-2026 Passenger Vehicles and Light Trucks. 2018.

[117] See Small, Kenneth, Comment Letter on Proposed MY 2021-2026 Standards, 2018.

One commenter (Alliance for Automotive Innovation) supports EPA's approach to undertaking sensitivity analyses as to the magnitude of this VMT rebound effect, since rebound effects are difficult to estimate with a high degree of precision. EPA agrees with the commenter that sensitivity analyses of the VMT rebound effect are important to include in an analysis of the impacts of this rule. As discussed in the proposal and for this final rule, EPA is using 5 and 15 percent VMT rebound estimates as sensitivities to bound the uncertainty of the VMT rebound effect.

One commenter (Consumer Reports) requests that EPA consider doing more research prior to future rulemakings on the potential applicability of rebound effects for conventional vehicles being applied to battery electric vehicles (BEVs). Given the limited penetration of BEVs in the U.S. passenger fleet currently, EPA has not found any available, peer reviewed studies on the VMT rebound effect of BEVs. EPA will continue to monitor the economics and transportation literature for studies on the VMT rebound effect associated with BEVs.

One commenter (National Association of Clean Air Agencies) suggests that EPA used a VMT rebound estimate in the SAFE rule, 20 percent, that was too high. The higher VMT rebound estimate resulted in too larger of a predicted increase in criteria pollutants (i.e., NOx/VOC emissions) from this rule. For this final rule, EPA is using a lower value for the VMT rebound effect, 10 percent, than in the previous SAFE rule.

Commenter: Alliance For Automotive Innovation

Attribute substitution can also occur when households make decisions about which vehicle to use for specific trips.193 The Agencies' RIAs make the implicit assumption that VMT by new gasoline-powered cars will be replaced, one to one, by VMT in new electric vehicles.

In Norway, however, some households supplemented – rather than replaced – their ICE vehicles with electric vehicles. Both vehicles were used with intensity, and some uses of public transit declined.194 Thus, attribute substitution for specific trips is a complex process that the Agencies should model to supply accurate estimates of how much GHG control is accomplished during the transition to an EV-dominated fleet. Insofar as the EV transition contributes to more congested traffic in urban areas (e.g., as BEV trips substitute for public-transit trips, biking and walking), the RIAs should acknowledge this effect and quantify the ramifications for commuter travel times and other adverse effects of congestion.195

One of the rationales for comprehensive modeling of rebound effects is that such modeling underscores the importance of complementary and supporting policies during thetransition to BEVs. [EPA-HQ-OAR-2021-0208-0116]

Commenter: Aluminum Association

The conclusions reached in the NPRM regarding the ability of vehicles manufactured in compliance with the proposed standards to ensure continued passenger and societal safety are accurate. In the case of aluminum's use, nearly every aluminum-bodied vehicle ever tested has earned the highest 5-Star safety rating from NHTSA (Audi A8, Tesla Model S and Ford F-150). Other 5-star safety rated, aluminum-intensive vehicles include Ford's Navigator and Expedition, and Audi's A6. And while not crash-tested by NHTSA, the Jaguar XJ, XF, XE, F-Type, F-Pace and Range Rover aluminum-bodied vehicles have 5-Star Euro New Car Assessment Program (NCAP) ratings and are rated highly by insurance companies. Aluminum's use is particularly valuable to automakers in lightweighting heavier pickup trucks and SUVs and this use has resulted in the parallel benefit of reducing the mass differential between vehicles when vehicles collide, resulting in overall societal safety benefits [EPA-HQ-OAR-2021-0208-0233-A1, p.3]

Commenter: California Air Resources Board (CARB)

The Standards Do Not Significantly Affect Highway Fatalities. CARB agrees that the impact on highway fatalities of the Final SAFE Rule and the proposed standards are similar and the model does not provide statistically significant results irrespective of the varying stringency. The emissions standards do not significantly lead to fatalities, where the analysis does not provide statistically significant effects, and any fatalities attributed to the standards are, unfortunately, overwhelmed by total highway fatalities. Moreover, CARB supports considering risk on a per-mile traveled basis when assessing fatalities. [EPA-HQ-OAR-2021-0208-0643-A6, p.39]

Commenter: Center for Biological Diversity, et al.

EPA's safety analysis reveals that more stringent standards do not have a material impact on safety, and EPA's analysis likely overstates any safety impacts. EPA correctly focuses on fatality rate rather than total fatalities, and should not consider fatalities that occur as a result of increased driving in its safety analysis.

A new regulation's impact on fatalities can be evaluated in two ways: (1) by calculating the total change in fatalities, or (2) by calculating the change in the fatality rate, or the number of fatalities per mile. A change in the total number of fatalities can have many causes, which could be imposed by new standards or other external factors not compelled by the standards. For example, if more driving occurs over a period of time, fatalities over that period of time may also increase, but this is not necessarily imposed by the technological or other changes that are made to fulfill the requirements of new standards. Historically, therefore, EPA has taken the fatalities-per-mile approach, correctly defining vehicle safety as "societal fatality rates per vehicle miles traveled." 77 Fed. Reg. at 62,740 n.313; 2016 Draft TAR at 8-1 n.A.

Only in the 2020 Final Rule did EPA move away from this fatalities-per-mile estimate, in order to make that rule appear to have greater safety implications than it actually did. But the vast majority of the fatalities projected by both the 2020 Final Rule and the NPRM are due not to changes in the fatality rate, but to projected increased driving under the standards (i.e., "rebound" driving due to the cost of driving decreasing). In fact, approximately 85% of the estimated change in total fatalities under the Proposal would be due to the projected increases in VMT, DRIA at 5-10, and these rebound fatalities should not be the focus of the safety analysis for the rule.96 An increase in traffic accidents resulting from individuals choosing to drive more cannot be viewed as actually imposed by new standards, and these decisions to drive more are choices made by individual consumers. See also State and Local Government Petitioners' Brief at 58-61.

In addition, Congress has spoken regarding how EPA should consider the safety impacts of vehicle emission standards. Section 202(a)(4)(A) of the Clean Air Act provides that "no emission control device, system, or element of design shall be used in a new motor vehicle or new motor vehicle engine for purposes of complying with requirements prescribed under this subchapter if such device, system, or element of design will cause or contribute to an unreasonable risk to public health, welfare, or safety in its operation or function." 42 U.S.C. § 7521(a)(2). Because additional fatalities that occur due to individual voluntary choices to drive more do not stem from the “operation or function” of the technologies at issue, they should not be attributed to the standards. Consistent with Section 202(a)(4), it would be unreasonable for EPA to use a projection that individuals may drive more—and therefore might get into more traffic accidents—to undermine its statutory obligations to reduce GHG emissions. Even in the NPRM for the 2020 Rule, EPA recognized that nothing in more stringent standards “compels consumers to drive additional miles. If consumers choose to do so, they are making a decision that the utility of more driving exceeds the marginal operating costs as well as the added crash risk it entails.” 83 Fed. Reg. at 43,107.

In fact, considering the impacts of increased driving in the analysis of safety could be used to undermine many different standards. There are many government actions that lead to increases in driving, but the government does not decline to take these steps because of the increased accidents that might occur from increased driving` example, highway funding could be a government action that would increase driving, and personal income tax cuts might also put additional money in people’s pockets which could lead to increased driving. Governments do not consider the fatalities due to this increased driving in making these policies, and EPA should not do so here. In fact, increased driving is generally seen as a societal good. Had Congress intended for fatalities solely due to a possible increase in miles traveled to be a determinative factor, it would have said so. Whitman v. Am. Trucking Associations, 531 U.S. 457, 469 (2001) (stating that when a “factor is both so indirectly related to” a criterion of consideration “and so full of potential for canceling the conclusions drawn from” that consideration, “it would surely have been expressly mentioned”).

In the Proposal, therefore, EPA properly returns to the use of fatality rate rather than total fatalities as the relevant safety measure for understanding the impacts of a new regulation. Analyzing safety implications in terms of fatality rate helps focus the analysis on whether new regulations actually make driving less safe. This approach is consistent with EPA’s statutory obligations to mitigate the dangerous air pollution from vehicles.

EPA’s Proposal does not have a material impact on vehicle safety and any safety impacts of more stringent standards are likely overstated. In the NPRM, EPA shows virtually no change in the fatality rate with the Proposed Standards versus the fatality rate absent those standards. Proposal, 86 Fed. Reg. at 43,793. Specifically, EPA shows that vehicle safety “will remain almost unchanged” at 4.624 fatalities per billion miles under the Proposal, versus 4.640 fatalities per billion miles for the no-action case. DRIA at 5-10. These estimates make clear that the overwhelming majority of fatalities estimated in the Proposal are not caused by the standards, but by changes in individual driving habits.

Moreover, the bases for all of the agencies’ fatality estimates are overly conservative. As discussed elsewhere, the rebound estimate used by EPA—which is the foundation for 85% of the fatalities projected by EPA—is at the high end of relevant estimates, leading to greater projected fatalities in EPA’s modeling. In addition, the agency’s estimate of fleet turnover— another source of estimated fatalities in the model—is premised on an estimate of the impact of more stringent standards on new vehicle sales that is too high, using a price elasticity of -1 instead of something more reasonable like -0.4, as is also discussed elsewhere in these Comments. See also

State and Local Government Petitioners' Brief at 55-57. Finally, EPA acknowledges that its analysis of the fatalities from mass reduction in vehicles—the third and final source of estimated fatalities in EPA's modeling—is based on mass reduction coefficients that EPA has acknowledged are not statistically significant. Proposal, 86 Fed. Reg. at 43,793 ("the empirical analysis . . . did not produce any mass safety coefficients with a statistically significant difference from zero"); see also 83 Fed. Reg. at 43,111. In addition, recent technological developments in vehicle safety engineering and design make clear that reducing vehicle mass does not necessarily make vehicles less safe. See, e.g., State and Local Government Petitioners' Brief at 57-58. Automakers can and do use improved methods of mass reduction to minimize safety impacts, such as by replacing steel with new materials that are stronger and lighter,97 or applying mass reduction technologies to larger and heavier vehicles but not to smaller vehicles, which would actually have safety benefits rather than costs.98

The Proposal's impact on the actual safety of vehicles or driving is minimal, as reflected in the "almost unchanged" fatality rate of the fleet, and the agency's estimates of all fatalities resulting from more stringent standards (including from rebound driving) are very likely inflated. [EPA-HQ-OAR-2021-0208-0651-A1, p. 38-40]

96 As in the 2020 Final Rule, EPA has inexplicably decided to offset only 90% of rebound-driving costs, despite the substantial mobility benefits of any rebound driving, making it more appropriate to offset all rebound costs with equal benefits.

Commenter: Competitive Enterprise Institute (CEI)

EPA has also downplayed the safety risks inherent in the mass and size reductions that its regulations will cause. EPA incorrectly claims manufacturers will only consider the costs of such downsizing rather than other non-cost criteria, such as customer satisfaction. EPA claims benefits of downsizing larger vehicles that are no longer accurate. [EPA-HQ-OAR-2021-0208-0652-A1, p. 2]

EPA Is Arbitrarily Downplaying the Safety risks of Mass and Size Reductions in Vehicles. Greenhouse gas emission standards put pressure on automakers to limit average vehicle weight. Tailpipe carbon dioxide emissions comprise 94 percent of such emissions, and an automobile's carbon dioxide emissions per mile are directly proportional to its fuel consumption per mile. Reducing vehicle weight tends to reduce fuel consumption and, thus, CO_2 emissions as well. See EPA and NHTSA, Final Rule, 75 FR 25326-25327, 25332 (2010). In short, there is a clear tradeoff between vehicle weight and reduced emissions.

EPA claims that this tradeoff is not inevitable. It states that 'manufacturers can achieve the MY 2023-2026 standards while using modest levels of mass reduction as one technology option among many ….' 86 FR 43793. But even if manufacturers can use only modest downsizing, this does not mean that they necessarily will. EPA has used a least-cost approach in estimating the extent to which manufacturers may employ downsizing as one means among many of reducing emissions. But individual manufacturers may well employ non-cost criteria in some cases, such as customer satisfaction. To the extent that runs counter to EPA's approach and results in more downsizing than EPA anticipates, the adverse safety impacts will be greater.

For the downsizing that EPA admits may occur, EPA gives a 'central estimate of a 0.07 percent increase in fatalities'. Id. This appears to be questionably low, especially since a large component of that estimate rests on some alleged safety benefit from downsizing. But the size-safety relationship is too strong to be undercut by such unspecified benefits. According to the Insurance Institute for Highway Safety, 'A bigger, heavier vehicle provides better crash protection than a smaller, lighter one, assuming no other differences.' https://www.iihs.org/topics/vehicle-size-and-weight. As for the possibility that larger vehicles pose a significant danger to the occupants of smaller vehicles, the Insurance Institute finds that 'large vehicles aren't as big a threat to people in small vehicles as they used to be.' Id. [EPA-HQ-OAR-2021-0208-0652-A1, pp. 8-9]

The SAFE rulemaking indicated that the less stringent alternatives considered by the agencies had greater traffic safety benefits than the more stringent alternatives. In the agencies' words, 'Less-stringent standards remain better for safety and are projected to save thousands of lives and prevent tens of thousands of hospitalizations ….' 85 FR 25185. Similarly, '[a]nother factor weighing toward reduced stringency is safety. Reduced stringency results in less pressure on manufacturers to reduce mass in vehicles, which, for smaller passenger cars has negative safety implications when involved in accidents with heavier vehicles.' 85 FR 25119; see also 85 FR 24256 ('avoiding standards that unduly encourage safety-eroding downsizing').

But in setting the California Framework as the floor for lenient standards, EPA has arbitrarily ruled out any consideration of less stringent but safer alternatives. For example, in the SAFE rulemaking, CEI pointed out that a freeze at the 2018 level would save 2,900 more lives than the SAFE Rule, using the agencies' own modeling software. And an even more lenient rollback to 2017 would save 4,300 additional lives over the agencies' rule. CEI SAFE Comments, p. 4, see attached. In the SAFE rulemaking, EPA inappropriately dismissed these safety concerns based on an unrelated minimal increase in average car costs. SAFE Rule, 85 FR 24259 (2020). EPA continues in this rulemaking to ignore the lives saved by these reasonable alternatives.[EPA-HQ-OAR-2021-0208-0652-A1, pp. 7-8]

Commenter: Competitive Enterprise Institute et al.

Such policies (3) make the average vehicle less crashworthy than it otherwise could be.5 [EPA-HQ-OAR-2021-0208-0292-A1, p. 1]

5 GHG standards put pressure on automakers to limit average vehicle weight. Tailpipe carbon dioxide (CO2) emissions comprise 94 percent of motor vehicle GHG emissions, an automobile's CO2 emissions per mile are directly proportional to its fuel consumption per mile, and reducing vehicle weight is a common method of reducing fuel consumption and, thus, CO2 emissions as well. See EPA and National Highway Traffic Safety Administration (NHTSA), Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards; Final Rule, 75 FR 25326-25327, 25332, May 7, 2010, https://www.govinfo.gov/content/pkg/FR-

2010-05-07/pdf/2010-8159.pdf. Lighter vehicles have less mass to absorb collision forces, so they tend to provide less protection in crashes. Under the SAFE Rule, automakers are already projected to reduce average vehicle weight by 4.2-4.7 percent during model years 2023-2026. EPA 2021, DRIA, p. 4-19. GHG standards can also divert automaker R&D spending from safety to fuel efficiency, for the simple reason that automakers do not have unlimited budgets. See SAFE Rule, 85 FR 24174, 25136, April 30, 2020, https://www.govinfo.gov/content/pkg/FR-2020-04-30/pdf/2020-06967.pdf.

Commenter: Consumer Federation of America

One of the largest changes from the current SAFE 2 rule involves vehicle safety. By irrationally doubling the rebound rate, the Trump administration projected increased fatalities by 75 lives. The Administration also underestimated the increasing crashworthiness of vehicles. While the proposed SAFE 2 rule revisions do correctly establish that vehicles are becoming lighter to meet the standards, the rule rightly points out that vehicles are more crashworthy compared to just a decade ago when the standards went into effect. [EPA-HQ-OAR-2021-0208-0297-A1, p. 2]

Rebound Rate: Above, we identified an unsupported and unsupportable assumption about the rebound effect as having an impact on the pocketbook benefits of a higher standard. Rebound is part and parcel, the tip of the iceberg, for a much larger issue–unrealistic assumptions about driving, and new vehicle safety (see Figure 5.1). By claiming to avoid a slew of fatalities due to consumers driving less because of increased annual fuel costs and driving in safer vehicles, the Trump rule claimed to avoid a significant negative impact on congestion, noise, and safety.

Correcting the significant flaws in the NHTSA/EPA framework, including the rebound effect and the failure to recognize technological flexibility for automakers, dramatically reduces the assumed safety benefits of the Trump SAFE 2 rule. As shown in Figure 3, these adjustments eliminate over 80 percent of the claimed reduction in accidents. We believe other technological improvements, introduced along with higher fuel economy, further reduce the impact of increased accidents. [EPA-HQ-OAR-2021-0208-0297-A1, p.15]

Vehicle Safety By far, the largest change from previous analyses in connection with safety is the change in the rebound rate. By irrationally doubling the rebound rate, the agencies projected increased fatalities by 75. The agencies also underestimate the increasing crashworthiness of vehicles. While the agencies correctly point out that vehicles are becoming lighter to meet the standards, vehicles are also more crashworthy compared to just seven years ago when the standards went into effect. An analysis15 of all 2018 crash tests showed that 71 percent of vehicles weigh less and had better fuel economy than its previously crash-tested version. Of these vehicles, 47 percent had a better crash test rating, while the other 53 percent had the same rating. Not a single vehicle in the analysis had a worse crash test rating than its previous version. Outside of the passive nature of crashworthiness, the amount of added safety features that actively help to prevent a crash16 have increased by 60 percent since 2011. These facts can be proven by real-world driving experiences as well. The percentage of crashes that result in a fatality has steadily been decreasing with a full tenth of a percentage decline from 0.61 percent to

0.51 percent from 2011, when the standards were enacted, to 2016.17 [EPA-HQ-OAR-2021-0208-0297-A1, p. 17]

Another argument the Trump administration put forward to roll back the standards is that due to the increased cost of vehicles, the turnover rate would decrease, meaning there would be more, older, less safe vehicles on the road. The Administration ignored the fact that each year from 2014 to 2018, an average of 16.9 million new, safer and more fuel-efficient vehicles were added to the fleet, while an average of 13 million older, less safe, and less fuel-efficient vehicles were retired18.

And our national survey conducted in August 2018 revealed that over three quarters (76 percent) of Americans reject the assertion that increasing fuel economy standards would lead to more accidents.19 This rejection is widely bipartisan, with 60 percent of Republicans, 80 percent of independents, and a plurality of 90 percent among Democrats rejecting the argument. [EPA-HQ-OAR-2021-0208-0297-A1, p. 16]

Commenter: Consumer Reports (CR)

In terms of the safety impacts of the proposed rule, EPA found: "This proposal would have no adverse impact on driving safety. EPA estimates that the risk of fatal and non-fatal injuries will remain virtually unchanged by this program" [EPA-HQ-OAR-2021-0208-0602-A1, p.18]

This conclusion is consistent with the results of analysis CR performed in originally analyzing the SAFE rule proposal.50 In this analysis CR found that weakening standards resulted in a small, but negligible decrease in safety, and that strengthening standards resulted in a similarly small but negligible increase in safety. [EPA-HQ-OAR-2021-0208-0602-A1, p.18]

However, while the overall conclusion is sound, there remain significant problems with many of the assumptions used to calculate the safety impact, and the inclusion of financial costs associated with these small and uncertain risks within the cost-benefit analysis. EPA's analysis shows that the uncertainty in the analysis at the 95% confidence interval spans zero,51 indicating that strengthening standards may have no effect on, slightly increase, or slightly decrease safety. Given this fact, the scientifically appropriate conclusions to draw would be that the impact is indistinguishable from zero. [EPA-HQ-OAR-2021-0208-0602-A1, p.18]

Furthermore, EPA continues to attribute fatalities caused by rebound driving to the rule. Nothing in this rule compels anyone to drive more. Driving more is a consumer choice, and the fatalities associated with that driving should not be attributed to the rule. It is true that there are risks associated with driving, but those are risks that everyone understands and assumes when they get into a vehicle, and when they pay their monthly insurance premium. Any policy that puts more money in consumers' pockets may allow them to drive more, yet we don't attempt to estimate the traffic fatality impact of any additional driving that might be stimulated by tax cuts, and we shouldn't for consumer savings from increasing vehicle efficiency either. [EPA-HQ-OAR-2021-0208-0602-A1, p.18]

EPA Response

Several commenters (CARB, CBD, CR) supported EPA's use of societal fatality risk per mile driven as an appropriate metric for considering crash safety effects resulting from the standards. We continue to use this metric for the final rule, and have concluded that this rule will not have any adverse effect on crash safety (RIA 5.3 and Preamble VII.H.)

We disagree with CEI's assertions that our analysis underestimates the safety risk of downsizing ('downsizing' and "mass reduction" appear to be used interchangeably in the comment.) Specifically, our analysis does not conclude that the standards will result in smaller vehicles overall. On the contrary, our analysis shows a very slight increase in average vehicle footprint (from 50.55 sq. ft. in the no-action case to 50.65 sq. ft. under the final standards in MY 2026) due to a small sales shift from cars towards light trucks. Since the commenter did not provide any further detail or supporting information for their assertion of vehicle size reductions, for our responses here we are interpreting the commenter's use of the term 'downsizing' to mean mass reduction, and not a reduction in vehicle size.

CEI asserted that manufacturers have the option to use more mass reduction than the modest levels we projected in our analysis (under the final standards, 6.3% compared to 5.4% in no-action case, as shown in RIA 4.1.4), and that there are 'inherent safety risks' which arise from greater levels of mass reduction. We agree that manufacturers have many compliance pathways to meet the final standards, and that some pathways may involve higher levels of mass reduction. However, we do not agree that these choices will result in a measurable change in safety risk. As noted in the comments from the Aluminum Associations, manufacturers have achieved the highest crash safety rating while using vehicle light weighting strategies such as material substitution. Further, in addition to our central analysis in which we found no notable impacts on societal safety (RIA 5.3 and Preamble VII.H), we also conducted several sensitivity analyses (RIA 4.1.5) with manufacturers projected to apply different types of technologies under each sensitivity case, including different mass reduction levels. Among these sensitivity analyses, we projected the highest levels of additional mass reduction in the high battery cost case, increasing from 5.9% in the no-action case to 7.4% under the final standards. Yet even in this bounding case with higher levels of mass reduction, the fatality rate remains virtually unchanged at 4.920 fatalities per billion miles, compared to 4.916 under the central case.

CEI also commented that less-stringent alternatives would be preferable because the reductions in overall VMT would correspond to lower overall fatalities. EPA explains its views on safety-related impacts of the final standards in the preamble. In short, EPA finds that it would not be appropriate to give significant weight in selecting standards to traffic fatalities that are the result of voluntary choices to drive more because more stringent standards make driving less expensive. EPA does not believe the changes in vehicle attributes that may result from the standards will result in materially increased fatalities, and that it is not appropriate to attribute fatalities from increased vehicles miles traveled (but a constant rate of injury per million vehicles miles traveled) to these standards.

Some commenters observed that our estimates of fatality risk are based on mass-safety coefficients which are not statistically significant (CARB, CBD) and that because manufacturers can apply more mass reduction on larger vehicles, there may be a safety benefit in multi-vehicle crashes that arises from a reduction in mass disparity between vehicles. Our final rulemaking analysis is based on currently available statistical data which does not account for changes in mass disparity between vehicles as penetration of mass reduction technology expands more broadly across the fleet. Our decision to include mass-safety coefficients at levels below the 95^{th} percentile confidence interval in this rulemaking analysis is a conservative assumption (i.e. it tends to increase any projected safety effects of the standards.) Therefore, the exclusion of non-statistically significant findings would not change our conclusion that this rule does not adversely affect safety.

Policies to support development of EV and battery manufacturing and domestic supply chains, including critical minerals

At present, most critical minerals necessary for the production of advanced EV motors and batteries are mined and processed outside of the United States, primarily in China. Additional domestic sources and processing capacity are needed to supply EV production and encourage domestic manufacturing and jobs. [EPA-HQ-OAR-2021-0208-0571-A1, p. 5]

EPA and NHTSA project that battery costs will learn down quickly compared to other fuel saving technologies, and the employment module uses total technology costs to help forecast job-years. Given the Agencies' assumptions, it is notable that the projected jobs related to the production of batteries will shrink (on a per unit shipped basis) in proportion to the learning rate of batteries. Employment related to the production of engine and transmission technologies (on a per unit shipped basis), are stable over time in comparison. [EPA-HQ-OAR-2021-0208-0116]

Employment Impacts of the EV Transition

The proposed GHG and CAFE standards, insofar as they boost the EV transition, will have complex impacts on employment in different sectors and different regions of the country. Auto Innovators recommends that the agencies go beyond their current rudimentary analysis (which considers only new vehicle sales and stimulus of battery manufacturing) and consider employment analysis of each of the following issues.

1. The impacts of EVs on employment at U.S. plants that produce gasoline engines and transmissions, and their supply chains.

2. The impacts of EVs on employment in the U.S. petroleum and biofuels sectors, including their supply chains.

3. The employment impacts of EV production in the U.S. and elsewhere, including effects on U.S. content, accounting for the global geographic distribution of the mining and processing of raw materials, the manufacture of cathodes, anodes, electrolytes and separators, the production of battery cells and the assembly of battery packs, and the production of electric motors and other systems/components (*e.g.*, charging networks) that are critical to EVs.

It would be useful for the agencies to present geographical maps of where in the US employment is likely to be lost, where employment gains are likely to occur, and what the net distribution of employment changes will be in different regions. The offsetting effects are challenging to model but are important to appreciate.316 Such information could be useful in guiding retraining and community assistance programs. A think tank in Germany has produced a related study on how the BEV transition might impact employment in towns throughout Germany.317 [EPA-HQ-OAR-2021-0208-0116]

Commenter: Blue Green Alliance

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 92.]

We know that climate change and economic injustice are the most fundamental challenges we face today—and we know they're inextricably intertwined. . . . It's visible in the disparities in access to cleaner vehicles and other mobility options across income levels and it's visible in the impact (audio glitch) that auto manufacturing communities which have seen good jobs offshored and anchor facilities shuttered due to ill-conceived industrial policies that gutted the middle-class.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 93-94.]

Research from the BlueGreen Alliance and the Natural Resources Defense Council shows that strong vehicle standards represent a critical foundation of domestic certainty for jobs supporting manufacturing investment across the United States. Over the past decade, auto parts and materials manufacturing workers rose to the challenge of building the technologies needed to meet the 2010 and 2012 vehicle standards. Those strong standards, coupled with reinvestment in domestic manufacturing, helped bring back good jobs after the last recession. They have spurred rapid investment in assembly facilities and in the supply chains building fuel economy and enhancing technology. The weakening of these standards under the past Administration put jobs at risk and threatened the health of the industry as a whole. We can't afford to fall behind, particularly as our global competitors are proactively moving to capture the gains from the shift to EVs already underway. Coupling ambitious standards with auto sector investment is key to capturing opportunities for workers and communities to partake in the equitable transition to the next generation of clean vehicles. The EPA can leverage its clean vehicle standards to drive innovation and deliver fuel savings and pollution reduction for all types of vehicles that meet all communities' needs. Vehicle standards and manufacturing investment will achieve deep GHG reductions, protect and create good auto manufacturing jobs for workers of all backgrounds, and ensure that those workers are the center of building and deploying the EV fleet of the future here in the United States.

Commenter: Center for Biological Diversity, et al.

EPA’s employment analysis of stronger GHG standards shows positive growth, but is likely an underestimate. EPA’s own modeling projects long-term employment increases due to the Proposal.

EPA’s Proposal projected two models of long-term employment impacts from the Proposal that both showed overall increases in employment when compared to the 2020 Final Rule. DRIA at 8-9 – 8-13. Under the first model assuming a -1 elasticity of demand value, EPA projected an initial decrease in employment of only 0.2%, or roughly 2,000 jobs, by 2024 when compared to the 2020 Final Rule. DRIA at 8-12, tab. 8-3. That change would soon become positive by 2026, a 0.2% increase, and reach a 1% increase in employment, or roughly 11,000 jobs, by 2035. DRIA at 8-12, tab. 8-3. EPA’s model assuming a -0.4 demand elasticity projects an even greater increase in employment. Under that model, the Proposal would increase employment immediately, 0.1% in 2022 and 1.8% by 2035, or roughly 21,000 additional jobs. DRIA at 8-12, tab. 8-4. Thus, under both of EPA’s models, the Proposal would increase employment over the 2020 Final Rule’s status quo. Moreover, as discussed below, a demand elasticity of -1 is arbitrarily high. A lower magnitude elasticity of demand such as -0.4, which projects consistent employment increases, is a more realistic projection (see infra Section 7.g).

Higher EV production will further increase employment. The Proposal undercounts increases in employment by focusing on a narrow range of the economy and by underestimating the likely increase in EV penetration and manufacturing. While EPA acknowledges that vehicle electrification “is likely to affect both the number and the nature of employment in the auto and parts sectors and related sectors, such as providers of charging infrastructure,” DRIA at 8-13, the agency focuses solely on automotive dealers, final assembly labor and parts production, and fuel saving or emissions reducing technology labor. DRIA at 8-11. However, the expansion of the EV market will involve not just EV manufacturers and charging providers, but also growth in mining materials for batteries, battery manufacturers, new technicians (or retrained existing technicians) to properly install and eventually replace battery cells, computer programmers and engineers, semiconductor technology, electricity generation, battery disposal and recycling, and other sectors more relevant to EV manufacturing than ICEVs.114 Thus, EPA's employment projections would show even larger increases if the agency had modelled impacts on a wider range of automotive and EV-related industries.

This undercounting of the Proposal's increases in employment is compounded by EPA's assumption that there will be only a modest increase in EV market penetration over the next several years. The agency assumes that EV penetration will more than double from 3.6% in MY 2023 to 7.8% in MY 2026 despite its belief that "it is likely that an even higher percentage of the industry-wide … fleet could be electrified" based on statements from numerous parties "including but not limited to the automotive manufacturers and the automotive suppliers." DRIA at xx, 2-7, Tbl. 4,12; Proposal, 86 Fed. Reg. at 43,766. Indeed the agency referenced statements by GM, Volvo, Volkswagen, Honda, and Fiat of their goals for electric vehicles to make up half or more of their sales by 2035 or sooner. DRIA at 2-14. Furthermore, the agency noted that upcoming ZEV targets from more than 3 states and 12 countries would help spur development and drive EV penetration in the global market. DRIA at 2-15. These developments are supported by recent modeling indicating higher EV penetration is likely. Thus, actual employment increases would likely be even greater than EPA estimates. [EPA-HQ-OAR-2021-0208-0651-A1, p. 51-52]

Commenter: Center for Climate and Energy Solutions (C2ES)

For manufacturers, the global electric vehicle market represented about $120 billion in 2020 and demand is projected to grow as much as 30 percent per year through 2030.8 As countries including the UK and China continue to expand commitments to phase out internal combustion engine vehicles, economic opportunities to supply zero-emission vehicles globally will grow accordingly. [EPA-HQ-OAR-2021-0208-0287-A1, p.3]

Commenter: CERES

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 82-83.]

Ceres analyses consistently show that weak standards generate fewer jobs while stronger standards support growth in the auto industry and throughout the U.S. economy. Auto parts suppliers especially stand to lose under weakened standards. They employ 2.6 times more Americans than automakers and Ceres analyses found that the suppliers sector would have stood to lose $20 billion in sales of clean vehicle technologies from 2021 to 2025 under the Trump Administration's rule.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 83-84.]

Weak standards also undermine global competitiveness. U.S. auto industry offerings will not be aligned with global market demand without strong standards that drive investment in more efficient vehicles and electrification.

Commenter: District of Columbia Department of Energy and Environment

A multi-pollutant strategy will also allow the environmental justice issues associated with air toxics from all light- and medium-duty vehicles and fine particulate pollution from light and medium-duty diesel vehicles to be approached with more precision. This will also give EPA the opportunity to ensure a level playing field between auto makers that have committed to phasing out fossil fuel engines and those that are lagging. [EPA-HQ-OAR-2021-0208-0240-A1, p.2]

Commenter: E2 - Environmental Entrepreneurs

More than 273,600 Americans worked in the electric vehicle (EV) and plug-in vehicle sector at the beginning of 2021. These jobs are in every state. Thousands more work across electric vehicle charging companies. With bold federal standards we can protect these jobs and create more of them in the face of foreign competition. [EPA-HQ-OAR-2021-0208-0604-A1, p. 1]

Global competitiveness is another important consideration. The number of EVs on the road globally is expected to increase dramatically in the coming decades, with already more than 20 countries committed to limiting all new auto sales to Zero Emissioin Vehicles by 2035 or 2040. The competition to supply this growing market is on, but the U.S. is lagging. Europe and China have backed bold national targets and incentives to drive innovation, demand, and growth in their own EV auto sectors. Without similar bold federal initiatives in the U.S., our auto industry is in danger of falling further behind. In fact, from 2017 to 2020, the U.S. market share of global EV production dropped from 20% to 18%. [EPA-HQ-OAR-2021-0208-0604-A1, pp. 1-2]

We also recognize the tremendous economic opportunity that strong regulations will provide. A federal standard that advances clean vehicles, will ensure US auto industry is more globally competitive, it will also save money for businesses and consumers and drive private investment in not only vehicles but clean vehicle infrastructure as well all of which is a boom for the economy. [EPA-HQ-OAR-2021-0208-0604-A1, p. 3]

Commenter: Environmental Defense Fund (EDF)

Standards that eliminate tailpipe pollution from new passenger cars and light trucks by 2035 could reduce more than 11 billion tons of climate pollution by 2050, prevent nearly 100,000 premature deaths, and save consumers over $5,000 over the life of the average vehicle, and all while growing domestic, well-paying jobs.4 [EPA-HQ-OAR-2021-0208-0688-A1, p. 2]

Commenter: Environmental Law & Policy Center (ELPC), et al.

Stronger emissions standards will support clean car innovation and manufacturing.

Strong emission standards from EPA will support the auto manufacturing that is critical to the economies and well-being of Midwest states—from Michigan, Ohio, Indiana, Minnesota, and Wisconsin, to the Dakotas.

Past analysis by the Blue Green Alliance and Natural Resources Defense Council concluded that there were nearly 290,000 jobs in the advanced technology vehicle sector. These are workers making more efficient cars and trucks possible. Across the Midwest, according to that report, there were a total of 151,714 jobs in 480 facilities associated with making cleaner vehicles. Three states—Michigan, Indiana, and Ohio—topped the list.[24] [EPA-HQ-OAR-2021-0208-0567-A1, pp. 4-5]

Commenter: Environmental Law and Policy Center (ELPC)

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 290.]

Third, a strong auto manufacturing base is critical to the economies and well-being of Great Lakes Midwest states where ELPC works. Past analysis by BGA and NRDC concluded that there were nearly 300,000 jobs in the advanced technology vehicle sector. Three states, Michigan, Indiana, and Ohio, top the list.

Commenter: EOS at Federated Hermes (on behalf of its stewardship clients)

We see climate change as a significant economic risk, and reducing GHG emissions by transitioning to cleaner vehicles as a major economic opportunity. Ceres analyses consistently show that stronger standards support growth both in the auto industry and throughout the U.S. economy. For example, our 2018 analysis found that auto parts suppliers, who at the time employed 2.6 times more Americans than automakers, would especially stand to lose under weakened standards; the supplier sector could have lost $20 billion in sales of clean vehicle technologies from 2021-2025 under the current rule. [EPA-HQ-OAR-2021-0208-0568-A1, p. 1]

Commenter: International Union, United Automobile, Aerospace & Agricultural Implement Workers of America (UAW)

We have learned from experience that strong standards based on broad input from key stakeholders can be good for the environment and autoworkers. Well-constructed regulations promote investment, establish certainty, create new jobs in vehicle production and advanced technology, and allow manufacturers the flexibility necessary to meet the standards. [EPA-HQ-OAR-2021-0208-0749-A1]

The auto industry is dynamic and complex, which requires flexible regulations and continual input from stakeholders. Over time, automakers have faced increasing challenges in adhering to emissions standards. And in recent years, we have seen how the auto industry can be impacted by a variety of factors, including consumer preference, fuel prices, global supply chains, and even public health. This is why the UAW has long held that emissions regulations must be responsive to conditions on the ground to ensure a robust domestic auto industry. [EPA-HQ-OAR-2021-0208-0749-A1, pp. 1-2]

The long-term health of the industry is critically important to both workers and the economy at large. A strong and vibrant industry is important for active UAW members who work in the auto industry and retirees who worked in the auto industry. Their ability to make a good living and retire in dignity is directly impacted by greenhouse gas standards. By extension, standards also impact their families and communities. UAW members continue to work on cutting-edge technology. We are proud to already be building the vehicles of the future, including hybrids, plugin hybrids, battery electric vehicles, autonomous vehicles, and increasingly efficient gasoline vehicles. The UAW represents workers at 26 final assembly plants in eight states building vehicles for a wide variety of applications – from sports cars to work-oriented pickups. Additionally, the UAW represents auto parts workers throughout the country making engines, transmissions, stampings, axles, drivelines, seats, interiors, and various other components. The domestic vehicle assembly and parts industries are vital to the nation's manufacturing base, and it is imperative that we stay strong and competitive now and into the future. [EPA-HQ-OAR-2021-0208-0749-A1, p. 2]

Commenter: Mass Comment Campaign sponsored by Center for Biological Diversity (77,692)

I urge you to write new long-term rules that: Promote justice and good electric-vehicle jobs. [EPA-HQ-OAR-2021-0208-0560-A1, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-1 (7,010)

Stronger tailpipe emissions standards will improve the American economy along with our environment. Clean car manufacturing has the potential to bring high-quality automotive manufacturing back to the United States and provide well-paying jobs for workers. As President Biden has said many times, we have an historic opportunity to Build Back Better by putting our communities to work in the clean energy economy. [EPA-HQ-OAR-2021-0208-0545, p.1]

Commenter: National Coalition for Advanced Transportation (NCAT)

The growth in the electric vehicle industry has created jobs and will continue to do so. About 10% of the employees in the motor vehicles and component parts sector (including manufacturing, repair and maintenance, and professional services) work on alternative fuel vehicles.121 Component parts manufacturing employs nearly half a million people in jobs that work on increasing fuel economy in the United States.122 The domestic manufacturing of alternative fuels vehicles and hybrids grew from 2018 to 2019 in most technologies, with electric vehicles adding 6,200 manufacturing jobs. 123 The jump was even greater in 2020: electric and hybrid electric vehicle employment grew more than 6% from 2019, adding over 12,000 new jobs.124 This was the largest jobs increase of any clean energy category.125 One study found that the electric vehicle industry (defined broadly to include professional services, management, personal services, etc.) in California employed 275,600 people in 2018, and these jobs grew an average of 2.9% per year (2010-2018). 126 Securing America's Future Energy estimates that updating fuel economy standards and sustaining emission reductions over five years will lead to the creation of 60,378 new jobs nationwide.127 [EPA-HQ-OAR-2021-0208-0239-A1, p. 18-19]

Commenter: New Mexico Environment Department

In New Mexico, new jobs will be created to build the network to fuel the zero-emission vehicles. [EPA-HQ-OAR-2021-0208-0205-A1][p.2]

Commenter: New York State Department of Environmental Conservation

create jobs in the burgeoning clean vehicle sector. [EPA-HQ-OAR-2021-0208-0238-A1, p.3]

Commenter: Pien, Natalie

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 44.]

Additionally, Alternative 2 will complement President Biden's American Jobs Plan by creating distributed jobs installing charging stations nationwide.

Commenter: Securing America's Future Energy

The transition to EVs has significant economic implications. Part of the goal of established automakers, Tier 1 suppliers, and their host nations, is to retain the industry's contribution to their economy. Oftentimes, national income and employment, including in working-class communities, depend significantly on the auto industry. The manufacture of engines, transmissions, fuel systems, and exhaust systems in conventional vehicles, representing substantial value-added manufacturing and employment, will be replaced with the manufacture of batteries, electric motors, and power electronics. We must proactively work to retain these types of manufacturing jobs. The alternative would risk losing jobs to economies that are supporting a quicker and more thoughtful transition. [EPA-HQ-OAR-2021-0208-0527-A1, p. 2]

The Importance of Fuel Economy

Because electric powered transportation system is increasingly recognized as the technology of the future, a global competition has developed to stake a claim in the future of the auto industry, with countries around the world taking measures to encourage local investment to develop domestic electric vehicle (EV) supply chains. As reflected in pages 1 to 3 of Attachment 1 to these comments, which present analysis of the automotive sector prepared for SAFE, China and Europe are forecast to lead this race over the coming decade. Beijing, in particular, has worked to consolidate control of the important EV supply chains for more than a decade. Of the 200 lithium-ion battery gigafactories planned across the globe as of early 2021, for example, 148 are located in China and 21 are in Europe, while only 11 are in North America.4 The United States, clearly, is playing from behind. As a result, EVs are projected to account for roughly 30 percent of vehicles manufactured in China by 2030, more than three times as large a share as EPA forecasts in the United States. [EPA-HQ-OAR-2021-0208-0527-A1, pp.4-5] [Please refer to Attachment 1 at Docket number [EPA-HQ-OAR-2021-0208-0527-A1 pp. 18-26]]

As we navigate the transition to electrification, we must ensure that we do not swap our current dependence on an unstable oil market for reliance on China for our future transportation needs. Beijing has been working for over a decade to take commanding leadership on industries of emerging economic and strategic reliance, including electric vehicles. This has provided China with a tremendous comparative advantage, while threatening the U.S. automotive industry. How the EV supply chain develops over the coming years will have profound long-term implications for U.S. jobs, investment, technology leadership, and security of a major sector of the economy. As reflected in page 4 of the Attachment 1, if the entire EV supply chain is developed in the United States, for example, the number of jobs created in the EV industry can replace all jobs lost in parts related to internal combustion engine (ICE) vehicles.[5] If the United States remains complacent, we risk undermining the vibrancy and health of the domestic automobile industry. Although we are late to the competition, the nascency of the technology, still in the early stages of deployment, offers a chance for the United States to regain its leadership. An update to the fuel efficiency and GHG emissions standards can strengthen the case for private sector investment across the EV supply chain, and enable the EV market in the United States to grow more quickly. [Please refer to Attachment 1 at Docket number [EPA-HQ-OAR-2021-0208-0527-A1 pp. 18-26]]

EV Sales in the United States and Their Importance to U.S. Economic and National Security

Further, U.S. electric vehicle sales remain far behind those in China and Europe. In China and Europe, electric vehicles represent 7 and 7.6 percent of new vehicle sales respectively.[20] These rates represent far greater progress in these two giant auto markets towards electrification than we have achieved here in the United States. These sales are spurred by generous incentives for the purchase of electric vehicles, robust financial and policy support for their manufacture, and a better cost-effectiveness calculus as gasoline prices in Europe and China are greater than gasoline prices in the United States, making electric vehicles more cost competitive abroad.[21]

SAFE believes that it is important to accelerate the transition to electrification of transportation to protect our economy. Today, the transition to electrification appears inevitable. The primary questions are how fast or slowly it will occur, and which nations will secure positions of global leadership and power in the new transportation landscape. Central to China's efforts to secure its global position is consolidating control of the important supply chains for the future global transportation industry, from mineral extraction and processing, to electric vehicle battery and motor production, development of autonomous vehicles and 5G technology on which cars will communicate, the design and assembly of electric vehicles, and the deployment of charging infrastructure and battery storage. The United States is capable of competing against China and Europe in this competition and winning, but we are late to the game. As explained above, the sales of electric vehicles in the United States lags far behind China and Europe, and U.S.

automakers cannot be expected to make the required investments to accelerate the transition if the market does not develop for electric vehicles.

This global competition for leadership in electric vehicles matters because the automobile industry is the manufacturing backbone of the U.S. economy. It not only supports 10 million direct and indirect jobs, but accounts for more than three percent of GDP.22 Moreover, the industry has a highly skilled workforce that our nation has turned to in times of crisis. If such manufacturing capacity is lost, or severely degraded, it would not only threaten our economy and millions of jobs, but it could also undermine our capacity to innovate, with implications extending to the military and defense industry. As the United States awakens to these risks, we must adopt a long-term comprehensive strategy—from minerals to markets—that overcomes political discord in Washington. Using the regulatory powers of the federal government is an important tool in creating the demand for electric vehicles that are the engine of that transition, and SAFE believes that the GHG emission rule should be developed in a manner to accelerate this critical transition. [EPA-HQ-OAR-2021-0208-0527-A1, pp. 7-8]

Commenter: Trombetta, Nick

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 217.]

Furthermore, clean cars standards are a win for everyone, consumers, car manufacturers, and the environment. It will allow customers to more easily afford fuel efficient vehicles which are frequently more expensive than gas-guzzling alternatives. This will also spur greater innovation and guide car manufacturers in the correct direction, making it most profitable to invest in electric and hybrid vehicles instead of archaic cars and SUVs with poor gas mileage.

Essentially, we will be saving the car manufacturers from themselves and promoting their best interests down the line.

Commenter: Volkswagen Group of America, Inc. (Volkswagen)

Our greatest asset in helping to execute our electrification strategy is our people. The success of future electrification will be dependent on having an advanced workforce capable of developing, building and servicing the exciting new electrified vehicles Volkswagen will be bringing to the US market. Volkswagen has adopted proactive strategies in the US to help create the next generation of diverse and talented American autoworkers. We are investing in our people to ensure a sustainable future business and to help strengthen the communities in which our employees and customers live.

Electric vehicle technologies, along with other advanced connectivity and digitalization, will require an increasingly skilled and flexible future workforce. Programs like the Volkswagen Academy in Chattanooga, which is partnered with the Chattanooga State Community College, has established an apprenticeship program, which is aimed at developing next generation high-tech skills and career opportunities in the automotive sector. Apprentices in the program learn about mechatronics, robotics, electric vehicles, digitalization and other high-tech, high-demand job skills. As a testament to the success of the VW Academy apprenticeship program, Volkswagen won the inaugural Presidential Award for Workforce Development in 2020. Future production and servicing of electric vehicles in the US will need these jobs in order to be successful.

Furthermore, at our headquarters in Virginia, Volkswagen has collaborated with the Washington DC Urban League to start the Future Leaders in Mobility Program. This program introduces local high school students from minority school systems to the auto industry. In discussions led by our local leadership, the students get a behind the scenes look into the daily operations of a global auto manufacturer. Volkswagen uses this as an opportunity to encourage students to further their education and to excite them about future career prospects in the auto industry. America's automotive market is continuing to diversify with minority customers bringing more purchasing power to the market. Volkswagen recognizes and appreciates the power of diversity in our employees and the benefits this can bring in understanding and meeting the needs of our increasingly diverse customer base, and programs like the Future Leaders in Mobility helps build our talent pipeline. [EPA-HQ-OAR-2021-0208-0237-A1, p.5]

EPA Response

As discussed in Preamble Section VII.K. and RIA Chapter 8.2, EPA examines employment impacts specifically in the auto manufacturing and dealer sectors and estimates roughly a 2 percent increase in employment in those sectors. This approach is based on the costs of technologies, because labor is a part of those technology costs. The proportion of labor in technology costs is likely to change over time. EPA agrees that, by focusing on employment in the regulated sector, we may underestimate the employment impacts associated with the standards by not addressing increased employment associated with growing production of EVs, such as development of charging infrastructure or materials supply chains specific to EV components. We have also not fully examined shifts in employment associated with the transition from gasoline vehicles to EVs, nor have we conducted a geographic analysis of these impacts. As discussed in those sections, EPA has focused on the regulated sector because wider economic impacts depend on the state of the macroeconomy, which are difficult to predict. In addition, it is difficult to predict changes in where production may locate, and how much current automotive employees will transition into EV production. EPA agrees that developing supply chains within the U.S. would both provide additional employment in those sectors and improve the U.S. position to compete in world markets. Further, EPA agrees that developing EVs domestically will help the domestic auto industry to maintain and improve its competitive position in world markets, and thus to continue employment opportunities in the automotive sector.

Commenter: Alliance of Nurses for Health Environments

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 22.]

The Administration has also expressed its priority of promoting environmental justice. Communities of color and low-income communities are disproportionately exposed and harmed by exposure to air pollution, including pollution from the transportation sector. Clean air pollution from this sector is a critical step in achieving that priority.

Commenter: American Council for an Energy-Efficient Economy (ACEEE)

These impacts are particularly bad in low-income communities and communities of color, which bear a disproportionate air pollution burden (American Lung Association 2020). [EPA-HQ-OAR-2021-0208-0251-A1, p.2]

Commenter: American Lung Association

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp.17-18]

Air pollution is a major threat to public health and air pollution discriminates against black and brown communities and low-income communities.

Our report also found that people of color are much more likely to live in counties with failing grades for air pollution than white Americans.

We know that people who live near roadways and oil and gas operations, including refineries, bear a disproportionate burden of air pollution and that climate change is making that pollution worse.

Commenter: Asthma and Allergy Foundation of America (AAFA)

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 216-217.]

Measures to reduce vehicle emissions will address the burden of air pollution on two fronts. First, the populations near highways will benefit from reduced pollution in their immediate outdoor environments and, second, other communities will benefit from the upstream pollution reductions associated with the extraction, transportation, and refinement of petroleum products.

As we know, the communities most impacted on both fronts are disproportionately low-income, largely racial and ethnic minority populations, making this proposal an environmental justice imperative.

We support clean and safe air for everyone bur especially for vulnerable populations, like those with asthma and other chronic respiratory diseases. EPA's proposal is a good start to addressing the previous Administration's rollbacks but that's just it. It's a start.

Commenter: Bay Area Air Quality Management District

Moreover, innovation-inducing regulations are also an important tool to help better protect communities that suffer from climate change and localized air pollution more than others. A recent report by EPA found that socially vulnerable populations, already disproportionately burdened, may also be more exposed to the highest impacts of climate change.[1] Without strong greenhouse gas standards, it is inevitable that these community-level challenges will worsen, further jeopardizing public health. [EPA-HQ-OAR-2021-0208-0283-A1, p.3]

As the Bay Area Air District strives to make progress to address disparate air pollution impacts that can harm local communities, particularly low income and communities of color in the San Francisco Bay Area, it is essential that efforts to control pollution and foster clean technologies proceed. [EPA-HQ-OAR-2021-0208-0283-A1, p.3]

Commenter: Begley, Amanda

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 248.]

The environmental justice concerns of this are immense. Our communities of color suffer from higher rates of asthma and respiratory disease.

Commenter: Blue Green Alliance

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 91-92.]

In the transportation sector, which accounts for nearly 30 percent of U.S. greenhouse gas emissions, this intersection is visible in the disproportionate impact of vehicle emissions on low-income and non-white communities.

Commenter: California Air Resources Board (CARB)

America's most vulnerable communities, especially in California, face very serious public health and economic threats without swift action. [EPA-HQ-OAR-2021-0208-0643-A6, p.6]

Reducing this pollution will deliver a range of important public health benefits, especially for communities that have been disproportionately impacted by pollution. [EPA-HQ-OAR-2021-0208-0643-A6, pp. 8-9]

Stringent Standards Will Reduce Disparate Pollution Impacts.

U.S. EPA's proposal acknowledges the pollution disparities faced by communities with EJ concerns generally.24 CARB appreciates U.S. EPA's review of disproportionate emission impacts faced by minority and low-income communities. While comprehensive air quality and health risk modeling is critical to fully understanding the impacts of the proposal on impacted populations, proximity to emissions sources is a useful indicator of potential exposure and a reasonable screening metric to emphasize and evaluate the disproportionate impacts faced by communities near roadways and the property lines of stationary sources whose operations may be affected by the proposal, like petroleum refineries. In many over-burdened communities, the pollution and public health impacts from on-road vehicle emissions are especially significant and greater than in other communities. These impacts are often compounded by the congregation of nearby industrial sources, including upstream, mid-stream, and downstream fuel production sources. Recognizing and underscoring the cumulative effects of socio-economic and environmental burdens in these communities is a critical first step. [EPA-HQ-OAR-2021-0208-0643-A6, pp. 14-15]

The Los Angeles Area Illustrates the Importance of Stringent Standards

The community of Wilmington, Carson, and West Long Beach in the greater Los Angeles region is an example of an overburdened community. It is impacted by a variety of sources including freight, freeway traffic, port and rail operations, oil and gas production, and five petroleum refineries – petroleum refining and related activities are one of the major sources of emissions in this region. Major freeways bisecting the community include California Highways 1, 47, 91, and 60, and Interstates 110, 405, and 710, resulting in six major freeway junctions and increased pollution exposures for the populations living and working in this community as compared to Los Angeles County as a whole. With more than 40 miles of freeways within its approximately 48 square mile community boundary area and an aggregation of major industrial sources25 (Figure 1), on-road vehicle and industrial emissions are a significant contributor to the community's air pollution exposure, and its population shows a greater degree of health impacts from air pollution than other California communities. The community has a high cumulative air pollution exposure burden, a significant number of sensitive receptors, and includes census tracts that have been designated as disadvantaged communities by California law.26 [EPA-HQ-OAR-2021-0208-0643-A6, p.15] [Figure 1 can be found at docket number EPA-HQ-OAR-2021-0208-0643-A6, p. 16]

Based on the 2018 American Community Survey (ACS) data from the Census Bureau,27 more than 310,600 people live within the Wilmington, Carson, West Long Beach community boundary. Approximately 67 percent of the population in this community is Latino and African American compared to a statewide average of 44 percent (Figure 2), nearly 13 percent are children under the age of 10 years, and 13 percent of the population is elderly (over the age of 65 years) (Figure 3). These population characteristics are important indicators of disparities in existing pollution burden, exposure to air pollution, and health vulnerabilities - especially for children and the elderly. [EPA-HQ-OAR-2021-0208-0643-A6, p.16] [Figure 2 and 3 can be found at docket number EPA-HQ-OAR-2021-0208-0643-A6, p. 17]

Certain groups of the general population are more vulnerable to air pollution by virtue of their age and health, including children, elderly, pregnant women, and health compromised individuals. Places where these sensitive populations gather, called sensitive receptor locations, can include schools, day-care providers, hospitals, nursing homes, and senior care facilities. There are numerous sensitive receptor locations in the Wilmington, Carson, West Long Beach community, including 83 schools, 110 licensed daycare facilities, and 53 healthcare facilities including hospitals, nursing homes and dialysis and community clinics and they are concentrated along the major freeway routes. (Figure 4). [EPA-HQ-OAR-2021-0208-0643-A6, p.17] [Figure 4 can be found at docket number EPA-HQ-OAR-2021-0208-0643-A6, p. 18]

Most of the census tracts in this community are considered disadvantaged under California law.29 Approximately 80 percent of the census tracts in this community are in the top 25 percent (75-100th percentile) of the Draft CalEnviroScreen 4.030 (CES) scores within the State (Figure 5). The California Office of Environmental Health Hazard Assessment's (OEHHA) CES is a screening method that can be used to help identify California communities that are disproportionately burdened by multiple sources of pollution. [EPA-HQ-OAR-2021-0208-0643-A6, pp. 18-19] [Figure 5, which can be found at docket number EPA-HQ-OAR-2021-0208-0643-A6, p. 19]

Figure 6 compares the average scores for exposure (e.g., ozone, PM2.5, diesel PM, traffic impacts), health status (asthma, cardiovascular disease, low birth weight), and socio-economic (education, linguistic isolation, poverty, unemployment, and housing burden) indicators in the community against statewide averages - the community scores for these key indicators are generally higher compared to the statewide averages. [EPA-HQ-OAR-2021-0208-0643-A6, p.19] [Figure 6 can be found at docket number EPA-HQ-OAR-2021-0208-0643-A6, p. 20]

The indicators discussed above explain the disparate effects of air pollution faced by many communities in California, which extends to numerous other communities across the nation. Figure 7 presents the average scores for PM2.5 concentrations and diesel PM emissions relative to statewide averages for a few communities across the State; vehicle emissions contribute predominantly to the particulate matter and diesel PM impacts in these communities. The chart includes asthma related emergency room visits and linguistic isolation (i.e., limited English speaking) as proxies for demographic and socio-economic disadvantages faced by these communities. [EPA-HQ-OAR-2021-0208-0643-A6, p.20] [Figure 7 can be found at docket number EPA-HQ-OAR-2021-0208-0643-A6, p. 21]

Existing scientific literature conclusively links air pollution to adverse health outcomes, including pre-mature mortality, and the disproportionate pollution and health burden on poor and socially disadvantaged communities. OEHHA's draft CES 4.0 report provides an exhaustive review of existing literature connecting each of the indicators used in the CES method to pollution burden and population sensitivities.32 A 2019 CARB research study revealed on-road vehicles and industrial activity to be the top two sources of exposure in California, each contributing to 24 percent of the total PM2.5 exposure, and disproportionately impacting non-white and low-income populations.33

Additionally, several occupational studies of refineries, petroleum storage, and distribution facilities have found that benzene exposure can increase the risk of hematological malignancies (i.e., cancers affecting the blood, bone marrow, lymph, and lymphatic system) among workers, even at low daily concentrations below 0.1 ppm. Hazardous releases from these facilities are also believed to increase the risk of cancer incidences in fence line communities.34 The research report 'A systematic review and meta-analysis of hematological malignancies in residents living near petrochemical facilities' referenced 16 studies that recorded the incidences of hematological malignancies across 187,585 residents living within five kilometers of petrochemical sites (upstream, midstream and downstream), across varied geographical locations, between 1960 and 2011. Findings showed that those living within five kilometers of a petrochemical facility have a 30% higher risk of developing leukemia than residents from communities with no petrochemical activity.

The 2019 report 'Chemical exposures, health and environmental justice in communities living on the fenceline of industry' compared emergency department visits and hospital admissions 4 weeks after and 4 weeks prior to the 2012 major chemical release event at the Chevron refinery in Richmond, California. Results showed a 3.7-fold increase in the number of people seeking care at emergency departments within the zip codes closest to the refinery. The visits were for treatment of sensory/nervous system conditions (migraine headaches, eye conditions, and dizziness), asthma, upper and lower respiratory conditions, and chest pain.35

Research has also shown that refineries are more likely to be located in low-income communities of color who likely experience greater social stressors that may make them more vulnerable than others to the health impacts of such exposure. This is presented in the 2017 report, 'Fumes Across the Fence-Line the Health Impacts of Air Pollution from Oil & Gas Facilities on African American Communities.' The report discussed a case study based out of the City of Richmond, which houses five petroleum refineries within a condensed region. The case study presents the fact that residents of color disproportionately live near the refineries and chemical plants and acknowledges that while there have been many strides to clean up these major sources of air pollution, health impacts in the region, including cancer rates, are still disproportionately high.36

In conclusion, many overburdened communities experience significantly higher levels of both regional and near-source air pollution; and the demographic and socio-economic characteristics of these communities exacerbate their susceptibility and vulnerability to the adverse effects of air pollution. The Wilmington, Carson, Long Beach community is just one example of many such communities across the nation that bear the consequences of multiple sources of air pollution. For these fence-line communities, reducing emissions from concentrated mobile and stationary sources is a priority. [EPA-HQ-OAR-2021-0208-0643-A6, pp. 21-23]

Stringent Standards Redress Disparate Impacts of Pollution.

Environmental equity means that no group or community bears a larger, unfair share of harmful effects from pollution or environmental hazards, or the equitable distribution of environmental benefits and burdens. The people suffering the impacts of social, economic, and environmental burdens are also often those closest to the solutions. Continual, meaningful engagement and capacity building within priority communities is key to ensuring that regulatory measures provide direct and assured benefits to those most impacted by poor air quality and lack of access to clean mobility and high-road jobs.

Achieving environmental justice is about recognizing past injustices and taking steps to address them and avoid their proliferation. Historic policies, like redlining, forced certain communities to be nearer highways, trains, factories, and other major pollutant-emitting sources. To remedy the continuing impacts, environmental equity considerations and specific principles, such as community inclusion and collaborative decision making, must be embedded in governmental decision-making from the inception.

Federal authorities and both longstanding and recent Presidential Executive Orders (E.O.) underscore the necessity of environmental justice and increasing environmental equity through federal actions. Title VI of the Civil Rights Act of 1964 prohibits discrimination based on race, color, or national origin by programs and activities that receive federal assistance.38 E.O. 12898, 'Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations,' directs 'each Federal agency [to] make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations[.]

President Biden has issued several E.O.s that underscore the need to remedy environmental inequity and direct the federal government to prioritize environmental justice. E.O. 14008, 'Tackling the Climate Crisis at Home and Abroad,' provides, 'Agencies shall make achieving environmental justice part of their missions by developing programs, policies, and activities to address the disproportionately high and adverse human health, environmental, climate-related and other cumulative impacts on disadvantaged communities[.]' It establishes a White House Environmental Justice Interagency Council and directs EPA to 'strengthen enforcement of environmental violations with disproportionate impact on underserved communities' and create a community notification program. Perhaps most significantly, it creates a government-wide 'Justice40 Initiative,' establishing a goal that 40 percent of the overall benefits of relevant federal funding flow to disadvantaged communities.

E.O. 14030 directs the federal government to take action on climate-related financial risk 'while accounting for and addressing disparate impacts on disadvantaged communities and communities of color' and using climate finance to advance 'environmental mitigation, especially in disadvantaged communities and communities of color[.]'43 E.O. 13985, 'Advancing Racial Equity and Support for Underserved Communities Through the Federal Government,' acknowledges, 'Our country faces converging economic, health, and climate crises that have exposed and exacerbated inequities,' and directs the federal government to 'pursue a comprehensive approach to advancing equity for all, including people of color and others who have been historically underserved, marginalized, and adversely affected by persistent poverty and inequality.' U.S. EPA should act within its statutory authority consistent with these further obligations, which it plainly has discretion to do. Indeed, it would be improper for it to overlook these considerations, given the clear evidence of public health needs in many communities these authorities require it to serve. The Clean Air Act's core public health mandates are entirely consistent with setting standards stringently enough to ameliorate public health concerns in these communities.

Such action would also help California meet its own public health obligations – an important consideration in light of the Act's direction to U.S. EPA to partner with states to improve public health. Similar to the EPA definition of environmental justice, 45 California state law defines environmental justice as ‘the fair treatment and meaningful involvement of people of all races, cultures, and incomes with respect to the development, adoption, implementation, and enforcement of environmental laws, regulations, and policies.’46 Equity is one of CARB’s core values and fundamental to achieving its mission.47 CARB offers the following comments about its efforts in this regard for U.S. EPA to consider in meeting its obligations and demonstrate the importance of these efforts.

The Board approved its Environmental Justice Policies and Actions in 2001 to establish a framework for incorporating environmental justice into CARB's programs consistent with state law. These policies and actions apply to all communities in California but are intended to address the disproportionate environmental exposure burden borne by low-income communities and communities of color. Most recently, on October 22, 2020, the California Air Resources Board adopted Resolution 20-33 'A Commitment to Racial Equity and Social Justice.’

As defined in California’s Zero-Emission Vehicle Market Development Strategy, priority communities include neighborhoods of California that disproportionately suffer from historic environmental, health, and other social burdens.48 These burdens include, but are not limited to, air and water pollution, presence of hazardous wastes, poverty, high unemployment, inadequate access to educational resources and training opportunities to secure high-road jobs, and high incidence of asthma, heart disease, and other chronic illnesses. Priority communities include disadvantaged communities, low-income communities, and underserved communities, which are terms defined in many of California’s statutes and regulations.49 Due to historic discrimination, these communities often include households with people of color, low-wealth status, working families, immigrants, seniors, people with disabilities, California Native American Tribes, and others who have limited awareness of or access to clean mobility options and who are more likely to bear disproportionate impacts of climate change. 56

As EPA has noted, environmental justice populations of concern are especially vulnerable to the economic impacts and health burdens associated with climate change effects.57 58 59 60 61 62 63 64 65 Racial and ethnic minority communities are particularly vulnerable to the greatest impacts of climate change. 66 67 Climate change increasingly impacts places, foods, and lifestyles of American Indians. In Alaska—home to 40 percent of federally recognized tribes—reduced sea ice and warming temperatures threaten traditional livelihoods and critical infrastructure. 68 69 70 71 72 Furthermore, a new US EPA analysis, Climate Change and Social Vulnerability in the United States: A Focus on Six Impact Sectors, also indicates that the most severe harms from climate change fall disproportionately upon underserved communities who are least able to prepare for and recover from associated impacts.

Reducing transportation emissions is critical in meeting health-based air quality standards and reducing the risk of dangerous climate change, especially in areas that most vulnerable and have been disproportionately impacted. As discussed above, more stringent pollution control standards are likely to deliver greater health benefits to the communities that suffer the most from pollution from motor vehicles and the fossil fuels that power them. [EPA-HQ-OAR-2021-0208-0643-A6, pp. 23-27]

38 § 601, 42 U.S.C. § 2000d et seq. (‘No person in the United States shall, on the ground of race, color, or national origin, be excluded from participation in, be denied the benefits of, or be subjected to discrimination under any program or activity receiving Federal financial assistance.’). But see Alexander v. Sandoval, 532 U.S. 275 (2001) (private right of action to enforce § 601 is limited to intentional discrimination).

56 Rural communities are highly dependent upon natural resources that are affected by climate change. These communities also face obstacles in responding to climate change that increase their vulnerability to its impacts. See IPCC, Third National Climate Assessment, https://nca2014.globalchange.gov/highlights/regions/rural-communities

Commenter: California Attorney General Office, et al.

Socially-vulnerable populations—including children, the elderly, low income, and minority populations—experience greater impacts from higher temperatures.15 For instance, ‘the average person of color lives in a census tract with higher summer daytime surface urban heat island (SUHI) intensity than non-Hispanic whites in all but 6 of the 175 largest urbanized areas in the continental United States.’16 [EPA-HQ-OAR-2021-0208-0245-A1, p,4]

And, as with rising average temperatures, the effects of extreme heat are not evenly distributed: ‘Black and African American individuals are 40% more likely than non- Black and non-African American individuals to live in areas with the highest projected increases in extreme temperature related mortality with 2°C of global warming.’68 ‘With 4°C of global warming, this estimate increases to 59%.’69 [EPA-HQ-OAR-2021-0208-0245-A1, p.10]

In Philadelphia, for example, some of the most polluted areas are along major highways or zones with heavy traffic, and the most polluted zip codes also have the largest number of lung cancer patients.87 [EPA-HQ-OAR-2021-0208-0245-A1, p.12]

The projected short- and long-term impacts of EPA’s proposed standards are likely to be magnified in communities with higher percentages of Black, Asian American, and Latinx residents because refineries and other upstream sources of emissions, as well as major roadways, are often located in those communities.90 In the Northeast and Mid-Atlantic Region, average concentrations of exposures to PM2.5 are 75%, 73%, and 61% higher for Latinx residents, Asian-American residents, and African American residents, respectively, than they are for white residents.91 PM2.5 and NO2 concentrations are also highest for Black and Latinx communities in Massachusetts, in part because of their proximity to industrial facilities and highways, and these concentrations have increased over time even though overall exposure to those pollutants has decreased in the Commonwealth.92 [EPA-HQ-OAR-2021-0208-0245-A1, p.13]

More stringent standards will reduce the air pollution dangers faced by communities near refineries and roadways

Decreasing the criteria pollution and benzene and other hazardous air emissions associated with refining—as more stringent standards will do, 86 Fed. Reg. at 43,779, 43,790-91, 43,802—will benefit communities proximate to refineries. Nearly 700,000 people live within three miles of the seventeen refineries that reported actual annual benzene fenceline concentrations in 2020 above the level set by EPA that requires the refinery to take action to clean up emissions. Of these 700,000 people, 62% are African-American, Hispanic, Asian/Pacific Islander, or American Indian residents, and nearly 45% have incomes below the poverty level.119 The City of Richmond, California, with five petroleum refineries nearby and residents facing disproportionately high rates of cancer and other health impacts from air pollution, serves as a localized example of these national trends. See CARB Comments at 22-23.

Communities near major roadways will also benefit greatly from even slight improvements in air quality. EPA has long acknowledged that people living, working, and attending school near major roadways face greater air pollution exposure. 77 Fed. Reg. 62,624, 62,907 (Oct. 15, 2012); 75 Fed. Reg. 25,324, 25,504 (May 7, 2010). The pollution and public health impacts from on-road vehicle emissions are especially significant and greater in disadvantaged communities.120 For example, the community of Wilmington, Carson, and West Long Beach in Los Angeles, California is affected by six major freeway junctions, as well as freight, port, and rail operations, oil and gas production, and five petroleum refineries. CARB Comments at 15. A majority of this community is considered disadvantaged under California law, scoring higher than the state average on key indicators of vulnerability, including criteria pollutant exposure, health status, and socio-economic criteria. [EPA-HQ-OAR-2021-0208-0245-A1, pp.23-24]

5 See U.S. Environmental Protection Agency, Climate Change and Social Vulnerability in the United States: A Focus on Six Impacts 32-36 (2021), available at www.epa.gov/cira/social-vulnerability-report; U.S. Global Change Research Program, supra note 14, at 45; Angel Hsu et al., Disproportionate exposure to urban heat island intensity across major U.S. cities, Nature Communications 8 (2021), available at https://doi.org/10.1038/s41467-021-22799-5 ('Currently disadvantaged groups suffer more from greater heat exposure that can further exacerbate existing inequities in health outcomes and associated economic burdens, leaving them with fewer resources to adapt to increasing temperature.').

Commenter: Caudill, Gregory

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 312.]

Additionally, we are failing our low-wealth and people of color communities by not achieving environmental justice to mitigate the impact that climate change is causing.

Commenter: Center for Biological Diversity, et al.

Stronger GHG Standards Promote Environmental Justice and Equity.

EPA's Proposal will provide benefits to environmental justice communities by reducing harm from climate change and pollution exposure, and Alternative 2 plus would bring even greater benefits to vulnerable populations that suffer the brunt of pollution and climate change harms.

EPA appropriately recognizes that environmental justice communities are disproportionately affected by climate change and pollution impacts related to light duty vehicles and upstream emissions, and addressing these harms by providing these communities relief more quickly—a priority for this Administration—is another compelling reason that EPA should adopt Alternative 2 plus.

More Stringent Standards Would Bring Greater Benefits to Environmental Justice Communities.

Reduction in greenhouse gas emissions would bring climate change benefits to environmental justice communities.

Reducing greenhouse gas emissions from light duty vehicles will help reduce the significant harm that climate change inflicts on environmental justice communities. By 2050 the Proposed Standards would reduce CO2 by 1.2 billion metric tons compared to the status quo, Proposal, 86 Fed. Reg. at 43,778, and EPA's calculations show the Proposal would produce climate benefits of $91 billion in 2018 dollars by 2050. DRIA at 3-39, Tbl. 3-14 (using a 3 % discount rate). Adopting Alternative 2, increasing the stringency by 10 g/mile in MY2025, and/or eliminating some credits would bring even more climate change benefits to environmental justice communities. See supra section 1.b (EPA must adopt stronger standards than its preferred alternative). As compared to the Proposal, by 2050 Alternative 2 will achieve an additional 293 MMT of CO2 savings (110 MMT of upstream CO2 and 183 MMT of tailpipe CO2) and increasing climate benefits by $9 billion. See Section 1.b, supra.

These reductions are significant on a national and global scale because greenhouse gas emissions from cars are a consequential portion of national and also international greenhouse gas emissions. Emissions from the transportation sector are the largest source (29%) of greenhouse gas in the country, and light duty vehicles are the largest portion of that, contributing 17 percent of all United States' greenhouse gas emissions. Proposal, 86 Fed. Reg. at 43,779. The United States is responsible for a large portion - approximately 15% - of global CO2 emissions, and is the second largest emitter in the world.156 Reducing greenhouse gas emissions from light duty vehicles is therefore one of the most consequential steps, EPA - or the United States - can take to mitigate climate change harm. And, as the Supreme Court found in Massachusetts v. EPA, "A reduction in domestic emissions would slow the pace of global emissions increases, no matter what happens elsewhere." 549 U.S. 497, 500 (2007).

Reducing climate harm will benefit environmental justice communities because, as EPA has aptly described, climate change disproportionately affects these communities. Proposal, 86 Fed. Reg. at 43,800. EPA recognized in the 2009 Endangerment Finding that vulnerable populations including economically and socially disadvantaged communities and Indigenous or minority populations are especially vulnerable to climate change. Id. Reports from the U.S. and international climate bodies over the last decade add evidence to the conclusion that climate change disproportionately impacts environmental justice communities including by "altering exposures to heat waves, floods, droughts, and other extreme events; vector-, food- and waterborne infectious diseases; changes in the quality and safety of air, food, and water; and stresses to mental health and well-being.'' Id. Notably the 2016 scientific assessment on the

Impacts of Climate Change on Human Health predicts people of color will suffer a disproportionate impact of climate exacerbations of air pollution. Id. at 43,801. It also describes unique vulnerabilities of Native American communities because of expected impacts to their cultural resources, customs and to traditional subsistence lifestyles, including expected decrease in food security for Alaskan Indigenous Peoples. Id.

Since the publication of EPA's Proposal, EPA published an important new analysis of the disproportionate climate impacts on vulnerable populations. The study quantifies the increased risks of climate change on socially vulnerable populations in six categories: Air Quality and Health; Extreme Temperature and Health; Extreme Temperature and Labor; Coastal Flooding and Traffic; Coastal Flooding and Property; and Inland Flooding and Property, using data on where people live as an indicator of exposure.157 The report concludes that Black and African American individuals will likely face higher impacts of climate change for all six impacts analyzed compared to all other demographic groups. Black and African Americans are 40% more likely to live in communities with the highest increase in premature mortality from extreme temperatures, and 34% are more likely to live in areas with the highest increases in asthma diagnoses with 2°C (3.6°F) of global warming.158 Hispanic and Latinos are also significantly more likely to live in areas where impacts are projected to be highest.159 Lowincome individuals and those without a high school diploma have 25-26% greater risk of living in areas with the highest extreme temperature labor hours lost.160

And as we witness time and again with each unfolding disaster, the most vulnerable populations suffer from climate change fueled extreme events. Taking recent events in this country as illustrative examples, it is economically disadvantaged, low-wage outdoor workers, homeless and elderly people who died from heat stroke in the Northwest heat wave,161 an event that researchers found would have been "virtually impossible without human-caused climate change."162 In New Orleans, the people who could not evacuate before disastrous Hurricanes Katrina or Ida struck land are those who do not have the means or ability to.163 In New York City, people who could only afford to live in illegal basement apartments died as a result of the flooding.164 During the western wildfire season, those without homes or means do not have the luxury of filtered air to protect their lungs.165 To help address the urgency of the climate crisis on vulnerable populations, EPA must adopt the more stringent Alternative 2 plus.

Significant decreases in vehicle and upstream non-GHG emissions over time will provide benefits to environmental justice communities.

In addition to GHG reductions, the Proposal will reduce tailpipe emissions over time as well as upstream emissions from refineries, Proposal, 86 Fed. Reg. at 43,779, both of which will benefit environmental justice communities. Id. at 43,802. Alternative 2 would result in increased health benefits from reduced emissions and exposure to pollutants of at least $7.2 billion,166 and adding 10 g/mile to Alternative 2 would bring even greater benefits.167 Importantly, the new standards will be a necessary stepping stone for the next phase of standards where EPA "expects that [air] impacts may be considerably larger." Proposal, 86 Fed. Reg. at 43,781. EPA should adopt Alternative 2 plus to bring more relief more quickly to environmental justice communities.

Notably, the immediate benefits more stringent standards will provide from reductions in upstream refining and over time from tailpipes vastly outweigh any potentially small nonGHG emissions increases from rebound driving and upstream electric generation. See Proposal, 86 Fed. Reg. at 43,802. By one measure, reducing refinery emissions may be more beneficial to environmental justice communities as a whole than reducing emissions from electric generation. EPA has concluded that refineries have far higher health benefits per ton of emission reductions than do electric generating units due in part to greater proximity to population.168

EPA correctly concludes that environmental justice communities are disproportionately harmed by the non-GHG emissions associated with this Proposal. Proposal, 86 Fed. Reg. at 43,802. As EPA recognizes, PM2.5 disproportionately harms people of color. Id. And the agency recognizes that higher percentages of communities of color and low-income communities live near electric generating units and refineries, and live or attend school near major roadways, suffering the largest share of their emissions and adverse health impacts. Id. EPA should, however, strengthen its statement that "Vulnerable populations near upstream refineries may experience potential disparities in pollution-related health risk from that source." Id. (emphasis added). The study of socioeconomic factors near refineries cited by EPA itself concludes that "Minority and African American percentages are approximately twice as high as nationwide percentages" for cancer risk as a result of petroleum refineries emissions.169 That study alone is enough evidence to warrant a conclusion that such populations do experience disparities in health risk. For further evidence, please see NGO coalition comments on Proposed SAFE Vehicles Rule for Model Years 2021-2026.170 [EPA-HQ-OAR-2021-0208-0651-A1, p. 69-73]

Upstream electric generation emissions will continue to decrease as clean energy generation continues to increase and fossil fuel sources shut down.

As EPA recognizes, although increasing stringency of the standards may result in small increases in upstream emissions from electric generating units that disproportionately harm environmental justice communities in the near term, these impacts will decrease over time as clean energy generation continues to increase. Proposal, 86 Fed. Reg. at 43,802. We encourage EPA to consider the expected impacts of its clean energy and power plant policies and rulemakings as it evaluates the environmental justice implications of non-GHG emissions in future rulemaking. See Proposal, 86 Fed. Reg. at 43,803.

President Biden's Climate Executive Order 14008 commits to achieve a carbon-free electricity sector no later than 2035, and to "deploy the full capacity of its agencies to combat the climate crisis to implement a Government-wide approach that reduces climate pollution in every sector of the economy; . . . and spurs well-paying union jobs and economic growth, especially through innovation, commercialization, and deployment of clean energy technologies and infrastructure."171

Relatedly, EPA is or soon will be reconsidering at least two major rules regarding electric generating units that may further increase the already-comparatively expensive operating costs of coal plants. EPA is reconsidering revised CO2 standards for existing fossil fuel-fired power plants under Clean Air Act section 111(d) after the Court of Appeals for the D.C. Circuit's remand in Am. Lung Ass'n v. EPA. 985 F.3d 914, 995 (D.C. Cir. 2021) (holding that "the ACE Rule must be vacated and remanded to the EPA so that the Agency may 'consider the question afresh in light of the ambiguity we see.'"). Continued operation of coal-fired power plants may also be affected by EPA's review of the Mercury and Air Toxics Standards hazardous air pollutant rules172 and possibly the national ambient air quality standards for PM2.5.

Even without new policies and rules requiring coal plants to internalize pollution costs, clean energy generation continues to increase while fossil fuel use is declining. The cost of clean energy generation technologies has fallen dramatically over the previous decade and is increasingly below the cost of conventional fossil fuel generation.173 The U.S. Energy Information Administration has predicted that electricity generation from renewable sources will soon surpass coal and will continue to rapidly increase in share of U.S. electricity generation.174

Commenter: Chicago Metropolitan Agency for Planning

Enacting the proposed rule would also lower emissions of other pollutants, resulting in better public health, especially among our environmental justice and vulnerable communities. [EPA-HQ-OAR-2021-0208-0219-A1, p.2]

Commenter: City of Albuquerque, NM

Low-income communities of color suffer increased exposure to air pollution, especially along roadways,[6] and asthma disproportionally impacts these communities.[7] For these reasons, the City supports EPA's Proposed Emission Standards to help protect our local vulnerable communities which experience disparate health outcomes.

Commenter: City of San Antonio, Texas

While climate change is addressed through the mention of impacts on vulnerable populations such as children as stated in the Fourth National Climate Assessment (2018) and The Impacts of Climate Change on Human Health in the United States (2016), there is a need for additional impact analysis on these populations within this proposed revision. Therefore, the City of San Antonio also recommends a comprehensive study into health equity and environmental justice impacts on marginalized populations. [EPA-HQ-OAR-2021-0208-0236-A1, p.1]

Commenter: Climate Group EV100

Removing complex credit schemes and loopholes will drive automakers to accelerate vehicle emission improvements and significantly boost the EV market beyond existing automaker plans. By implementing the strongest possible clean car standards, President Biden would follow through on his commitment to environmental justice and address key health impacts in low-income and BIPOC (Black, Indigenous, People of Color) communities that experience disproportionate harm from dirty vehicle pollution. [EPA-HQ-OAR-2021-0208-0200-A1, p. 1]

Commenter: Collins, Molly

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 231-232.]

It's past time we take action and start to meaningfully work towards environmental justice.

Commenter: Connecticut Department of Energy and Environmental Protection

Additionally, EPA and the federal government need to adopt policies to improve access to clean forms of transportation in underserved and highly impacted environmental justice communities. [EPA-HQ-OAR-2021-0208-0264-A1, p.2]

Commenter: Cooper, Almeta

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 76.]

As a mom, as an African American woman, and a member of my community, I care deeply about environmental justice, especially the connection between climate change and health equity for our nation's most vulnerable populations.

I encourage the EPA to frequently consult with front line communities and environmental justice leaders to provide their input into decisions related to the design and implementation of EPA rules.

As a Georgian, I am witnessing my own state government trying to suppress the voice and vote of many Georgians by imposing rules that will have disparate adverse impact on communities of color.

Commenter: Dang, Vinh

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 220.]

Homeless individuals are on the front lines of ongoing climate crisis and are repeatedly exposed to toxic air pollution.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 221.]

The homeless community members that we work with in Philadelphia have been diagnosed with pollution-induced asthma from panhandling along busy roads and intersections where toxic pollution is spewing into their communities.

While they panhandle for hours outside, they're slowly being killed from the vehicle pollutants from vehicles owned by the very individuals they're trying to earn a dollar or two from to feed themselves. The homeless individuals that I've met with and supported on the ground have mentioned how they're suffering not just from pollution-induced respiratory diseases but how rising temperatures have caused them heat exhaustion, heat strokes, and immense fatigue to the point of delirium. We need to take strong action to help everyone in this country, including the homeless

Commenter: Davis, Darien

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 161.]

In addition to fighting climate change, robust regulations would protect communities from vehicle pollution and save drivers money at the pump.

This is especially critical because black and brown communities and low-wealth communities experience disproportionate harm from dirty vehicle pollution. This environmental injustice leads to increased rates of asthma and other respiratory illnesses.

Commenter: District of Columbia Department of Energy and Environment

A multi-pollutant strategy will also allow the environmental justice issues associated with air toxics from all light- and medium-duty vehicles and fine particulate pollution from light and medium-duty diesel vehicles to be approached with more precision. This will also give EPA the opportunity to ensure a level playing field between auto makers that have committed to phasing out fossil fuel engines and those that are lagging. [EPA-HQ-OAR-2021-0208-0240-A1, p.2]

Commenter: Dream Corp Green for All

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 305.]

In a short time I'd like to focus on two main points. First, strong greenhouse gas emissions standards for passenger vehicles are essential to meet climate and racial equity goals,

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 306.]

Racial inequalities and wealth, health, and risks from a changing climate means that every improvement to addressing climate change is especially beneficial to people in communities of color.

The big impact and a marginal difference in emission abatement is especially true for the most vulnerable. People who live in floodplains or red-line neighborhoods, low-income households who may be uninsured or underinsured for health or property coverage, people who don't have the means to move or improve the resiliency of their homes, and people exposed to air pollution or have pre-existing health conditions are all more vulnerable to the effects of climate change.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 308-309.]

In conclusion, the status quo even before the COVID-19 pandemic made far too many people of color sick and died too early from issues directly related to inequity in economic and environmental injustice. We can build prosperity for all Americans by adopting pollution standards that are strong enough to protect the health of the most vulnerable and to encourage innovation and deployment of clean transportation solutions.

Commenter: Dream Corps Green for All et al.

Strong GHG emission standards for passenger vehicles are essential to meet climate and racial equity goals.

Racial inequalities in wealth, health, and risks from a changing climate based on where we live mean that every improvement to addressing climate change is especially beneficial to people and communities of color.[2] We may be beyond the point of being able to truly 'fix' the climate disaster that burning fossil fuels has wreaked, but every fraction of a degree matters. The big impact of a marginal difference in emission abatement is especially felt by the most vulnerable--people who live in floodplains or heat islands (often redlined neighborhoods), low-income households who may be uninsured or underinsured for health or property coverage, people who don't have the means to move or improve the resiliency of their homes, and people exposed to air pollution or who have pre-existing health conditions are all more vulnerable to the effects of climate change.[3] [EPA-HQ-OAR-2021-0208-0285-A1, pp.1-2]

In addition, the losses of low-wealth households are inherently underestimated in cost-benefit analyses from climate change because their assets are statistically undervalued compared to those of high-wealth households.[7] For example, the loss of a home due to flooding is calculated by the market value, which would assess a home in a high-wealth neighborhood as a greater loss than a home in a lower-wealth neighborhood, but it is still the loss of a family's home. This inherent bias in cost-benefit analysis that undervalues the quality of life and public health impacts for low-wealth- (disproportionately BIPOC) held assets is beyond the scope of this one rulemaking, but the presence and direction of this bias further supports adopting the strongest feasible emission standard that shows positive net benefits. [EPA-HQ-OAR-2021-0208-0285-A1, p.3]

Cleaner vehicles reduce health burdens.

Low-wealth and BIPOC (Black, Indigenous, People of Color) communities experience disproportionate harm from vehicle pollution, which compounds exposure with other sources of pollution and disproportionate stressors, leading to increased rates of illness and premature death.[13] In addition, localized pollution hotspots are often overlooked in EPA's air quality monitoring,[14[so the benefits of reducing emissions from passenger vehicles in heavily polluted areas or highly trafficked corridors may be underestimated. [EPA-HQ-OAR-2021-0208-0285-A1, p.4]

Neglecting the most vulnerable among us has exacerbated the current pandemic and propped up a fossil-fuel based economy, which as we know, puts everyone at risk. We can build prosperity for all Americans by adopting pollution standards that are strong enough to protect the health of the most vulnerable and to encourage innovation and deployment of clean transportation solutions. [EPA-HQ-OAR-2021-0208-0285-A1, p.5]

Commenter: Elders Climate Action (ECA)

The CDC reports that 'About 1 in 10 of all children have asthma, and about 1 in 6 (17%) of non-Hispanic black children had asthma in 2009.' Given the greater presence of BIPOC populations in most urban counties compared to the nation as a whole, urban smog is likely a major contributor to the elevated incidence of childhood asthma among Black children and children in other communities of color. [EPA-HQ-OAR-2021-0208-0521-A1, p. 14]

Commenter: Energy Innovation Policy and Technology LLC

Finally, we concur with the EPA's assertion that 'mitigating the impacts of climate change by achieving significant GHG emission reductions…would benefit populations that may be especially vulnerable to various forms of damages associated with climate change' [vii] and reducing pollution will similarly address disproportionate impacts on BIPOC populations and people of low socioeconomic status. [viii] [EPA-HQ-OAR-2021-0208-0605-A1, pp. 2]

Commenter: Environmental Defense Fund (EDF)

those that live closest to our nation's roads and highways face the greatest harms. 9 [EPA-HQ-OAR-2021-0208-0688-A1, p. 5]

Rapidly ensuring all light, medium- and heavy-duty vehicles are zero-emitting is one of the most important actions that the United States can take to reduce climate pollution and provide healthier and longer lives for millions of Americans, especially communities of color and low-income communities that are more likely to be harmed by pollution from the transportation sector. It is critical that EPA consider the beneficial equity impacts of robust standards, listening to and working closely with impacted communities to help ensure the standards are designed in a manner that reduces inequities.

As a result of housing discrimination and other unjust policies, communities of color suffer disproportionately from harmful vehicle pollution. 14 And these communities already face health disparities, including higher rates of chronic disease and premature death.15 A recent report by Moving Forward Network found that, on average, Asian and Black Americans bear a PM2.5 pollution burden from cars, trucks and buses that is 56 and 44 percent higher, respectively, than white Americans.16 According to the American Lung Association's 2021 State of the Air report, people of color are more than three times more likely to breathe the most polluted air when compared to white people.17 Another recent study found that Black Americans are exposed to 21 percent more fine particle pollution compared to average concentrations, while white Americans, by contrast, have 8 percent less pollution exposure than the average.18 The study concludes that highway vehicles are often among the largest sources of this disparity and that the disparity is systemic, holding for nearly all major sectors, as well as across states and urban and rural areas, income levels, and exposure levels. The study also found that because of a legacy of racist housing policy and other factors, racial-ethnic exposure disparities have persisted even as overall pollution exposure has decreased.

An EDF analysis of the Bay Area study data referenced above found that neighborhoods with higher percentages of residents of color experienced double the rate of asthma from NO2 – a pollutant often used as a marker for transportation-related pollution.19 Another study found satellite-observed levels of NO2 in the least white census tracts of the United States were double the levels in the most white tracts prior to the COVID-19 lockdown in 2020. And even though COVID-19 lockdowns led to sharp reductions in NO2 across all areas, the racial disparities were so large before the pandemic that the least white tracts continued to face even higher NO2 levels during the lockdown than the most white tracts experienced before the lockdowns.20 Similarly, another study tracking NO2 levels in cities across the nation during the COVID lockdown found that Levels of NO2 and VMT reduction in March and April compared to January 2020 ranged between 11–65% and 11–89%, consistent with a sharp drop in vehicular traffic from shutdown related travel restrictions.21 [EPA-HQ-OAR-2021-0208-0688-A1, p. 5-6]

Eliminating harmful pollution from the transportation sector is a critical measure that can help to protect public health, particularly for the communities that disproportionately bear the burdens of this pollution. [EPA-HQ-OAR-2021-0208-0688-A1, p. 7]

Commenter: Environmental Protection Network (EPN)

The burden of living with unhealthy air is not shared equally, of course. Of the 20.7 million people who lived in counties with unhealthy levels of ozone, short-term particle pollution,and year-round particle pollution, 14 million are people of color. People of color were 61% more likely than white people to live in a county with a failing grade for at least one pollutant, and over three times as likely to live in a county with a failing grade for all three pollutants.

Cars and light trucks (and heavy-duty trucks and buses) are major emitters of ozone precursors (volatile organic compounds and NOx) and fine PM (carbon soot and NOx that form particles in the atmosphere). Transportation-related emissions often disproportionately affect vulnerable communities that are in close proximity to urban freeways and oil refineries. [EPA-HQ-OAR-2021-0208-0213-A1, pp.3-4]

These emissions benefits would be especially valuable to vulnerable communities who are the most at risk to high pollution levels from urban freeways and oil refineries, as well as to climate-related extreme weather events. [EPA-HQ-OAR-2021-0208-0213-A1, p. 8]

Commenter: Filippelli, Garbirel

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 42.]

Now air pollution from transportation has severe impacts on urban populations and as stated earlier, it really does disproportionately impact our lower-income brown and black communities and we have research ongoing that shows just that.

Commenter: Gersten, Dana

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 281.]

Many of the people most at risk for lung conditions are already the most vulnerable: the working poor and people of color. The failure to have the strongest possible clean air standards entrench the cycle of poverty that is profound and increasingly difficult to escape.

Commenter: Gillet, Victoria

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 287-288.] I had patients start to come in as vehicles got back on the road with asthma exacerbations. Those patients who are coming in more frequently for those exacerbations were those who lived in those areas next to the vehicles, and it probably comes as no surprise that those patients were also more likely to be people of color and low-income. We know that these people are more likely to be located in areas and cities where they're exposed to more air pollution. We also know that they are more likely to suffer the negative consequences of rising greenhouse gas emissions as well as that particle pollution that decreases their health outcomes and will be more susceptible to increasing heat and other negative consequences.

Commenter: GreenLatinos

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 46-47.]

I'm here today because I'm very concerned on behalf of my organization about the urgent need to create and support the implementation of stringent clean vehicle standards in order to mitigate the impacts of tailpipe emissions for Latino communities.

As you may know, a recent nationwide study found that Latino children are three times more likely than non-Hispanic white children to live in counties where air quality standards are poor and nearly one-third of Latino children live in counties where hazardous air pollutant concentrations exceed the one-in-10,000 cancer risk level. Emissions from cars are literally killing children.

A year-long study of 756 asthmatic Latino children from inner city urban areas showed that participants who live near a freeway were significantly more likely to have asthma that was not well controlled and it is well known that Latinos are twice as likely to visit the emergency room for asthma than whites, and Latino children are twice as likely to die from asthma as their white counterparts.

Commenter: High Octane-Low Carbon Fuel Alliance (HOLC)

Low-Income Communities and Communities of Color Face a Disproportionate Burden from Gasoline Emissions

Indeed, EPA notes in the Proposed Rule scientific reports by the U.S. Global Change Research Program (USGCRP), the Intergovernmental Panel on Climate Change (IPCC), and the National Academies of Science, Engineering, and Medicine that have provided evidence of environmental justice concerns. Importantly, these reports have concluded that 'poorer or predominantly non-White communities can be especially vulnerable to climate change impacts because they tend to have limited adaptive capacities and are more dependent on climate-sensitive resources such as local water and food supplies, or have less access to social and information resources.'98 Further, '[s]ome communities of color, specifically populations defined jointly by ethnic/racial characteristics and geographic location, may be uniquely vulnerable to climate change health impacts in the [U.S.]'99

In addition to these reports highlighted in the Proposed Rule, a recent study found that Black people are exposed to higher concentrations of PM2.5 emissions, the most significant environmental cause of death.100 PM2.5 is responsible for an estimated 85,000 to 200,000 excess deaths each year in the U.S. Meanwhile people of color generally are exposed more to almost every source of pollution as compared to white people. Equally concerning was an April 2021 Environmental Integrity Project report, which found that thirteen oil refineries across the country released elevated and reportable levels of benzene into predominantly minority and low-income communities in 2020.101

Given the direction of Executive Order 12898 to make achieving environmental justice part of each agency's mission, it's imperative that EPA do more than recognize the historical impact of GHG emissions on low-income and minority communities. [EPA-HQ-OAR-2021-0208-0262-A1, pp. 18-19]

Commenter: Institute for Policy Integrity

EPA should consider the economic effects to lower-income households as well as the environmental justice effects from changes to criteria and toxic pollution, and the environmental justice gains associated with the increased climate benefits from more stringent alternatives.15 If Alternative 2 plus the 5–10 g/mile increase for MY 2026 is consistent with equity goals as well as with EPA's statutory mandates and with maximizing net benefits, that would further strengthen the case for selecting that combination of policy options. [EPA-HQ-OAR-2021-0208-0299-A1, p. 3]

Commenter: Klein, Stephanie

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 280.]

One in 10 kids in D.C. suffers from asthma which is exacerbated by ground level ozone pollution, and in some parts of the city, particularly our low-wealth and BIPOC communities, the childhood asthma rate is as high as one in three.

Commenter: Manufacturers of Emission Controls Association (MECA)

In closing, MECA believes that EPA should continue to set performance-based standards that assess technology pathways based on delivering the intended emission reductions in all neighborhoods and communities. [EPA-HQ-OAR-2021-0208-0261-A1, p.5]

Commenter: Marcot, Nicole

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 157-158.]

My community in Detroit is a low-wealth community near a major highway system and my parents, who live in the same neighborhood as us, suffer from asthma as do many other people in my neighborhood. As many as 15 percent of adults and 11 percent of children in Detroit suffer from asthma.

As an educator, I've frequently witnessed children missing school because of asthma. In addition to asthma, heart disease is also a major health concern. In the past year and a half, three of my neighbors have passed away from health issues related to heart disease.

According to Yale University, vehicles are the leading cause of air pollution and this pollution causes a variety of health issues in humans, including asthma and heart disease. Residents of my community are predominantly people of color and studies have shown that low-wealth and black and Indigenous, people of color communities experience disproportionate harm from dirty vehicle pollution, leading to racial disparities in rates of asthma and heart disease.

Aside from the direct impacts of air pollution, here in Detroit we've been hit with drastically increasing amounts of extreme weather. Just last week we were without electricity for six days due to a storm that swept through Southeast Michigan and left close to a million customers without power. Please note that once again it is low-income communities that suffer the most from extreme weather. Wealthy communities and the suburbs had their electricity restored much sooner than we did.

Commenter: Mass Comment Campaign sponsored by Center for Biological Diversity (77,692)

I urge you to write new long-term rules that:

Promote justice and good electric-vehicle jobs. [EPA-HQ-OAR-2021-0208-0560-A1, p.1]

Commenter: Mass Comment Campaign sponsored by Interfaith Power and Light et al. (1,599)

The climate crisis is a challenge of racial, economic, and generational justice, and we call on the Biden administration to meet it with an eye towards the most vulnerable in our communities. Choosing to make less efficient vehicles isn't just wasteful—it is a moral travesty. Children, our elders, low wealth and Black and Brown communities are all suffering disproportionately due to increased pollution and climate-fueled disasters. [EPA-HQ-OAR-2021-0208-0192-A1,p.2]

Commenter: Mass Comment Campaign sponsored by National Religious Partnership for the Environment-GA (563)

As a Christian I am called to protect God's creation and care for God's people. This means stopping pollution that is harming our communities and families and fighting climate change that is creating an unequal burden on communities of color. [EPA-HQ-OAR-2021-0208-0554-A1, p.1]

Black communities are disproportionally harmed from vehicle pollution since our neighborhoods are often located closest to highways and other sources of vehicle pollution. This has resulted tragically in higher rates of asthma and other respiratory illnesses. In order for attend to this injustice, we need stronger vehicle emission standards. [EPA-HQ-OAR-2021-0208-0554-A1, p.1]

I urge the EPA to make clean car standards as strong as possible in order to protect Black communities and all communities from vehicle pollution. [EPA-HQ-OAR-2021-0208-0554-A1, p.1]

Commenter: Mass Comment Campaign sponsored by National Religious Partnership for the Environment-MN (92)

As a Christian I am called to protect God's creation and care for God's people. This means stopping pollution that is harming our communities and families and fighting climate change that is creating an unequal burden on communities of color. [EPA-HQ-OAR-2021-0208-0556-A1, p.1]

Black communities are disproportionally harmed from vehicle pollution since our neighborhoods are often located closest to highways and other sources of vehicle pollution. This has resulted tragically in higher rates of asthma and other respiratory illnesses. In order for attend to this injustice, we need stronger vehicle emission standards. [EPA-HQ-OAR-2021-0208-0556-A1, p.1]

I urge the EPA to make clean car standards as strong as possible in order to protect Black communities and all communities from vehicle pollution. [EPA-HQ-OAR-2021-0208-0556-A1, p.1]

Commenter: Mass Comment Campaign sponsored by National Religious Partnership for the Environment-PA (142)

As a Christian I am called to protect God's creation and care for God's people. This means stopping pollution that is harming our communities and families and fighting climate change that is creating an unequal burden on communities of color. [EPA-HQ-OAR-2021-0208-0555-A1, p.1]

Black communities are disproportionally harmed from vehicle pollution since our neighborhoods are often located closest to highways and other sources of vehicle pollution. This has resulted tragically in higher rates of asthma and other respiratory illnesses. In order for attend to this injustice, we need stronger vehicle emission standards. [EPA-HQ-OAR-2021-0208-0555-A1, p.1]

I urge the EPA to make clean car standards as strong as possible in order to protect Black communities and all communities from vehicle pollution. [EPA-HQ-OAR-2021-0208-0555-A1, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-1 (7,010)

Curbing tailpipe emissions will also help to combat racial injustice in the United States. Communities of color and low-wealth communities currently experience disproportionate harm from vehicle pollution, leading to higher rates of asthma and other respiratory illnesses. During the COVID-19 pandemic, these communities have experienced higher rates of severe illness as a result of exposure to these harmful pollutants. Strong federal clean cars standards will create improved health outcomes for communities currently at disproportionate risk from vehicle emissions. [EPA-HQ-OAR-2021-0208-0545, p.1]

Commenter: Metropolitan Washington Air Quality Committee (MWAQC)

As noted in the Metropolitan Washington 2030 Climate and Energy Action Plan, underserved communities have been disproportionately affected by environmental exposures, such as ambient air pollution and climate-change-related health impacts; therefore, more stringent universal GHG emissions standards and subsequent emissions reductions have the potential to help the most vulnerable populations. [EPA-HQ-OAR-2021-0208-0208-A1][p.2]

Commenter: Mid-America Regional Council (MARC)

The benefits of this proposed rule support the Air Quality Forum’s mission to maintain the health-based National Ambient Air Quality Standards for the Kansas City region and make progress in decreasing criteria pollutants from passenger cars and trucks that disproportionately impact people of color and low-income communities in the Kansas City region. The Air Quality Forum encourages EPA to address equity in the accessibility of low- and zero-emissions vehicles ensuring that environmental justice communities with a greater burden of pollution can participate in solutions that will meaningfully impact health outcomes [EPA-HQ-OAR-2021-0208-0265-A1, p.1]

Commenter: Minnesota Pollution Control Agency (MPCA) and Minnesota Department of Transportation (MnDOT)

We know, too, that communities of color, lower-income communities, and Tribal communities are disproportionately feeling the effects of climate change and that climate change exacerbates existing disparities.5 [EPA-HQ-OAR-2021-0208-0211-A1, p.2]

Environmental justice

Transportation is the largest source of GHG emissions in Minnesota and light-duty vehicles are the largest source of emissions within that sector. Communities of color and lower income communities are disproportionately impacted by climate change and have fewer resources to adapt to our changing climate. Vehicle emissions also account for almost a quarter of Minnesota's overall emissions and are one of the primary sources of risk from outdoor air pollution. Further, we know that air pollution from vehicles disproportionately harms communities of color and individuals with lower incomes in Minnesota.9 For these reasons, it is critical that EPA act quickly and aggressively to reduce pollution from vehicles.

The MPCA and MnDOT also challenge EPA to pursue more robust environmental justice analysis in future rulemakings, including the quantification of damages and benefits. As part of the Clean Car Minnesota rulemaking, the MPCA began an effort to quantify emissions impacts on communities of concern for environmental justice.10 The MPCA sees the methodology we used for this analysis as a starting point for future equity analyses. We look forward to opportunities to learn from and collaborate with EPA on the topic of equity analysis into the future. [EPA-HQ-OAR-2021-0208-0211-A1, p.4]

Commenter: Moore, Cinthia

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 117.]

Improving our air quality is important for vulnerable 22 groups, like older Nevadans, and for children who lungs are still developing, and for Latino families who are more likely to be exposed to air pollution.

Latino children are 60 percent more at risk of having asthma attacks exacerbated by air pollution and 40 percent more likely to die from an asthma attack.

Efforts to improve our air quality are particularly important to me as the mother of a four-year-old who has breathing problems and the parents of over 40,000 children who have asthma in Clark County.

President Biden has promised to address climate change and fight for environmental justice. By acting swiftly on clean cars, the Administration has taken an important first step in tackling climate pollution for our transportation.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 118.]

This proposal is a step in the right direction to address the climate emergency. Improving our air quality is an environmental justice issue. Everyone has a right to breathe clean air.

Commenter: Moore, Kenneth

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 323.]

I'm thankful for the EPA's commitment to environmental justice because pollution has had its greatest impacts on the most vulnerable in our communities.

Commenter: Muller, Melinda

Air pollution from cars and trucks harms people's health — especially in low-income communities and communities of color that border major roads and freeways. Vehicle emissions cause thousands of premature deaths and billions in health care costs every year. In my city of Seattle, the city's geography magnifies this issue, with two major freeways east/west and north/south running through the heart of the city and its lowest-income and most densely populated neighborhoods. [EPA-HQ-OAR-2021-0208-0500, p. 1]

Commenter: National Association of Clean Air Agencies (NACAA)

Impact of This Rule on Environmental Justice

NACAA also challenges EPA to more fully embrace its charge on environmental justice. Across many jurisdictions, air pollution from vehicles disproportionately harms communities of color and lower income communities. For SIP planning, states need the support of strong federal standards to reduce emissions associated with light-duty vehicles. This final rule should deliver stringent federal standards needed to reduce emissions, including in environmental justice communities that have been disproportionately impacted for far too long. Emission standards for LDVs consistent with the recommendations NACAA makes in these comments will also support state and local work towards achieving just environmental outcomes. EPA should provide more specific information about, if not an actual quantification of, the emissions impacts on disadvantaged communities. [EPA-HQ-OAR-2021-0208-0255-A1, pp. 8-9]

Commenter: National Coalition for Advanced Transportation (NCAT)

Further, PM2.5 and other transportation emissions are not evenly distributed and raise environmental justice concerns. Studies have shown that low-income and historically marginalized communities live disproportionately close high-traffic roads and highways, exposing these communities to greater levels of transportation emissions and associated impacts. [EPA-HQ-OAR-2021-0208-0239-A1, p. 15-16]

Commenter: National Parks Conservation Association (NPCA)

Beyond our parks and environment, we need a bold clean cars strategy that strongly considers the outsized role that environmental justice and public health play in this crisis. Communities of color and low-income individuals far too often bear disproportionate levels of economic and health consequences from air pollution and climate instability. [EPA-HQ-OAR-2021-0208-0291-A1, p. 2]

Commenter: Nebraska Ethanol Board (NEB)

This serves EPA's important interest in protecting health; and, as EPA has separately stated in its September 2021 'Social Vulnerability Report,' the negative effects of climate change are going to be felt most by the poor and racial minorities.8 [EPA-HQ-OAR-2021-0208-0248-A1, p. 4]

Commenter: Oliver, Shaina

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 71.]

Most importantly, I'm an Indigenous mother of four and we are the descendants of the genocide known as the Indian Removal Act and known as the Long Walk of the Navajo. These types of policy violations have had a historic impact on Indigenous People's communities, health, wealth, and environmental well-being. Its impacts continue to be felt today in the form of lack of Indigenous representation and extractive capitalism, decisions made about resource extraction continue to hurt our communities of color, often as low-income community members.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 72-73.]

It is the Indigenous, black, Latino, and low-income communities who bear the disproportionate burden of air pollution and segregation has led to our communities being located by highways and industrial zones that impact our health.

Many people like myself bear the health burdens of pollution, such as asthma, diabetes, heart disease, respiratory illness, cancer, adverse birth outcomes, and COVID-19 has become one more health burden our communities disproportionately bear.

Commenter: Pien, Natalie

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 44]

Zero emission vehicles would eliminate this experience and restore clean air and improved health to our communities, especially communities of color disproportionately exposed to air pollution.

Commenter: Richards, Claire

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 269.]

Given structural inequity and the history of redlining in the United States, this disproportionately affects low-income communities and black, indigenous, and people of color. This means that to achieve the environmental justice agenda of the Biden Administration, a rapid transition to clean transportation is necessary.

Commenter: Sabetta, Tracy

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 100.]

We see racial disparities in these asthma rates as low-wealth and BIPOC communities experience disproportionate harm from vehicle pollution.

Adopting strong clean car standards that will limit pollution from dirty vehicles would subsequently help advance environmental justice, addressing inequitable transportation-related health impacts and protecting our most vulnerable.

Commenter: Sainz, Columba

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 226.]

It is a step in the right direction to address the climate emergency. Pollution from cars not only causes climate change, it harms my family's health and my community's. It threatens our health without mentioning families with no insurance, undocumented immigrants with no health access, low-wealth, and BIPOC communities experience disproportionate harm from dirty vehicle pollution, living through racial disparities in rates of asthma and other respiratory illnesses.

Commenter: San Joaquin Valley Air Pollution Control District

As such, emissions reductions from mobile sources are considered critical to attain the federal air quality standards and associated benefits to public health, particularly given that the San Joaquin Valley is home to many of the most disadvantaged communities in the state and nation.[EPA-HQ-OAR-2021-0208-0566-A1, p.1]

Commenter: Scholar, Reverend

Beyond this, the transportation sector contributes significantly to health-harming particulates and smog-forming nitrogen oxides, exacerbating respiratory illnesses like asthma and resulting in premature deaths. These health impacts are felt disproportionately by low-income communities and communities of color. [EPA-HQ-OAR-2021-0208-0724-A1, p. 1]

Commenter: Smith, Rita L.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 104.]

The health of low-income families and communities of color disproportionately damaged by tailpipe pollution and rolling back fuel economy standards means denying them the promise of cleaner air and a healthy community.

Compared to non-Hispanic white children, Latino children are twice as likely to die from asthma. African American (audio glitch.)

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 105.]

With cleaner transportation vehicles, African American children like my granddaughter would not miss school due to respiratory problems.

Commenter: South Coast Air Quality Management District

Regarding non-GHG emissions under the proposal, EPA can recognize environmental justice benefits will accrue and materialize faster in areas with greater prevalence of electric vehicles in local vehicle fleets. EPA states it expects the proposed rule 'would result in both small reductions and small increases of non-GHG emissions.' 86 FR at 43737 and 43803. The District agrees with EPA that caution is needed in 'interpreting these broad, qualitative observations.' Id [EPA-HQ-OAR-2021-0208-0215-A1, p.4]

EPA further states it is seeking comment on how to conduct an environmental justice (EJ) analysis on the non-GHG impacts associated with mobile source rulemakings, including how EV penetration in the future fleet would affect these impacts. The current proposal, which scarcely mentions near-roadway pollution, does not give occasion for any such EJ analysis, but EPA can still refine its own qualitative observations. Whatever might be said of unknowns in differential distribution of effects or differential exposure to pollutants, it is at least knowable that a major intersection or a school parking lot with 50% zero emission vehicle traffic should have roughly 50% less emissions from the area's light duty vehicles. This would not be any kind of farfetched scenario for the Los Angeles area, where year-to-date sales of electric vehicles are nearly 11% (and likely higher since 11% is a statewide figure) and growing. In the South Coast Air Basin that is designated nonattainment for fine particulates and extreme nonattainment for multiple ozone standards, these trends point to meaningful reductions in pollution exposure; moreover, this area has relatively clean sources of electrical generation as compared to the national generation mix. In other words, here, the benefits of increased stringency are not such a mixed picture as the proposal suggests. Instead, the realistic EJ benefits of greater zero emissions vehicle prevalence are tangible, and the projected or potential benefits should far exceed anything envisioned by the proposed rule's aggregated, nationwide calculations for an 8 percent market share for plug-in vehicles by MY2026. The District agrees that increased granularity of study for EJ impacts as affected by EV penetration in the future fleet will be warranted. Moreover, some of EPA's existing analytical approaches, e.g., reliance on FHA noise costs that are likely based on internal combustion engine vehicles, may warrant revisiting. [EPA-HQ-OAR-2021-0208-0215-A1, pp.4-5]

Commenter: Southern Environmental Law Center

Poor air quality can lead to or exacerbate asthma and other serious health conditions, and has been shown to disproportionately impact low-income communities and communities of color.[15] [EPA-HQ-OAR-2021-0208-0244-A1, p. 3]

Stronger standards that hasten the transition to cleaner and zero-emissions vehicles will also help reduce health impacts and costs associated with transportation pollution, which often disproportionately impact low-income communities and communities of color.[37]

[28] EPA's current proposal is projected to result in about a 2,205 MMT reduction in CO_2 emissions as compared to the no-action scenario through 2050. Id. at 43783; U.S. ENV'T PROT. AGENCY, supra note 23, at 5-1. In comparison, Alternative 2 would result in in approximately a 2,498 MMT reduction in CO_2 emissions over that same period. Id. at 5-3.

Commenter: Spencer, Sam

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 150-151.]

Low-income, black, and immigrant communities experience disproportionate harm from dirty vehicle pollution leading to increased rates of asthma and other respiratory illnesses.

It's one of the main reasons I'm testifying today because it is so important to our growing city for the EPA to implement the strongest possible vehicle pollution standards.

Issuing stronger clean car standards will not only address these transportation-related impacts but also help the EPA follow through on its commitment to environmental justice.

Commenter: Spirit of the Sun

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 135-136.]

We helped define last year what is disproportionately-impacted communities starting with Indigenous communities and that means if there has been any degradation to our quality of life, our health and safety, and ultimately endangerment when there is no regulations and true forceful and enforceable protections for our future generations.

We need to strengthen proposals from the EPA and we need clean car standards now. In all honesty, President Biden has promised to address climate change and fight for environmental justice, but that needs to have radical and revolutionary actions now.

EV is a technology that we can help in disproportionately-impacted communities now. We need to have some form of reparations from the harm done by corporations, especially extractive industries, but ultimately we need to build true transformative transition for disproportionately-impacted communities and future generations first. That does have to start with some support of convertible energy and this proposal to honestly safeguard standards and forcible protections.

What is the use of having regulations if we do not have corporations able to be regulated when they cause harm and, most of all, have protections to communities that we know are already harmed by disproportionate disparities of respiratory? This is asthma, anemia, heart disease, and death by COVID for Indigenous communities which has wreaked havoc in our communities, urban and rural.

Commenter: Sturza, Taisia

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 169-170.]

In my experience working as an EMT in the Houston 22 region, we would serve lower-income communities that overwhelmingly suffered from chronic conditions that are exacerbated by environmental factors like poor air quality due to the vehicle emissions.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 170.]

By implementing the strongest possible fuel economy standards, the EPA would also be following through on its stated commitment to environmental justice because issuing stronger clean car standards will help address key transportation-related impacts, like social determinants of health, which impact low-wealth and black, Indigenous, people of color communities that experience disproportionate harm from dirty vehicle pollution, leading to increased rates of asthma and other respiratory illnesses and cancer.

Commenter: Terwilliger, Phyllis

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 34.]

The American Lung Association states, ‘An estimated 30 to 45 percent of the people in North American cities live or work near enough to a busy road to experience significantly higher levels of pollution.’ This, of course, leads to increased rates of asthma and other respiratory illnesses.

Low-income people and communities of color are often closest to highways and bear the greatest burden from vehicle pollution.

Commenter: Tesla

Similarly, EPA Administrator Regan said in a speech in Michigan, 'Today, COVID-19 has magnified the daily injustices facing our communities of color – the same communities who suffer disproportionately from the impacts of climate change, who face higher rates of heart and lung disease, and whose children are more likely to develop asthma.' The Administrator is absolutely right that our nation must accelerate its efforts on behalf of communities most impacted by a changing climate. We remain optimistic that the agency, upon further review of the scientific literature and updated industry cost/deployment modeling, will strengthen the GHG standards in line with Administrator Regan and President Biden’s call to accelerate climate action for all communities. [EPA-HQ-OAR-2021-0208-0278-A1][p.2]

Commenter: Trombetta, Nick

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 217-218.]

Cleaner car standards are a true win for all parties. It will be a positive for long-term profits of car manufacturers, a strong step towards addressing climate change, importantly protect vulnerable communities. This will be important in terms of environmental justice of low-income and minority communities who suffer the most from excess air pollution who are generally positioned closest to highways leading to increased rates of asthma and respiratory disease.

This is an important issue in North Carolina, particularly where I live in Chapel Hill. The University of North Carolina where I went to school operates a coal-powered plant right by Northside, a predominantly African American community.

The other day, an activist was telling me about a factory that operated near the HBCU she went to for college and how the foul smell reached her every time the wind blew in her direction.

Environmental racism is persistent in North Carolina and clean cars standards can at the very least serve as a step towards righting these historic wrongs.

Commenter: UGA Climate and Society Club

Air pollution from cars negatively impacts all communities living near major roads and highways. These populations tend to be minorities making a lack of EPA regulation unacceptable for everyone's health and especially for a disproportionately large number of minority persons. [EPA-HQ-OAR-2021-0208-0412, p. 1]

Commenter: Union of Concerned Scientists (UCS)

Improved benefits for increasing stringency Importantly, not only does our modeling show that compliance with more stringent standards is possible, but it shows that the public is better off with stronger standards (Tables 1 and 2). [Table 1 can be found at docket number EPA-HQ-OAR-2021-0208-0277-A1, p. 21 and Table 2 can be found at docket number EPA-HQ-OAR-2021-0208-0277-A1, p. 22]

In addition to the consumer and climate benefits, there are clear public health outcomes from EPA strengthening the standards for MY2023-2026 (Tables 3 and 4). As the agency notes, the tailpipe and upstream emissions affected by this rule have the potential to disproportionately affect vulnerable communities, as communities who live in close proximity to roads and refineries are more likely to be of a racial minority, Hispanic ethnicity, and/or low socioeconomic status.40 [Tables 3 and 4 can be found at docket number EPA-HQ-OAR-2021-0208-0277-A1, p. 22]

The spatial extent of these pollution impacts are a critical component of understanding the environmental justice element of this rule, particularly if the agency moves forward with finalizing a rule much stronger than the one it proposed, which will inevitably drive greater EV adoption and could yield even more complex variations between local pollution from tailpipe and upstream sources. At the same time, previous air quality analysis of the MY2017-2025 rules found only a handful of areas that would experience a negative shift in PM or ozone levels,41 and coal-fired power plants continue to be retired,42 helping to clean up some of the dirtiest local sources of upstream emissions. Moreover, as EPA also notes, the public health impacts of these rules extend well beyond immediate proximity as a result of the complex atmospheric chemistry involving these pollutants, and the estimated public health impacts based on average emissions shows in general a small but positive trend (Tables 3 and 4). While we support EPA's effort to better assess local exposure impacts, we concur that it is more appropriate for a future rule and not a critical component of assessing the benefits of the proposal. [EPA-HQ-OAR-2021-0208-0277-A1, pp. 21-22]

Commenter: United Methodist Women

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 131-132.]

Women, children, and youth are already being disproportionately affected. The UN reports that 80 percent of people being displaced by climate change are women and when natural disasters hit, women and children have been 14 times more likely than men to die, more vulnerable to gender-based violence, and afterwards there has been as much as 20 to 30 percent increase in trafficking.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 132.]

It was unsurprising when I read that the 2019 Union of Concerned Scientists Report found that Asian American residents are exposed to twice as much PM 2.5 pollution as were white residents in New York. Our roads are heavily trafficked by cars and buses and our air is heavily polluted from tailpipe emissions.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 133.]

Implementing the strongest fuel economy standards that exceeds Obama's standards will address the climate crisis, protect women, protect communities of color, and protect the health of all our families.

Commenter: Valero Energy Corporation (Valero)

Further, while EPA's assessment of environmental justice impacts recognizes that increased electrical generation is likely to result in higher criteria pollutant emissions near EJ communities, the proposal does not address the impacts on disadvantaged communities of increased exposure to heavy metals and other toxins as a result of increased battery disposal and recycling,4 nor does it acknowledge the energy independence or mineral extraction concerns associated with large-scale electric vehicle battery production. A lifecycle analysis by Arthur D. Little concluded that "...the ultimate environmental and economic reality of electric vehicles is far more complicated than their promise...Combined with the greater financial burden [battery electric vehicles] place on the consumer, the complex environmental reality of BEVs will continue to present challenges for the sustainability-minded consumer."5 [EPA-HQ-OAR-2021-0208-0601-A2, p.2]

Commenter: Verdin, Langston

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 265.]

I was analyzing asthma data from the Department of Health Services, I found that asthma-related health care utilization wasn't equally distributed across Milwaukee. Instead, it's heavily concentrated among high-traffic corridors in the city's black and Latinx communities.

Commenter: Zero Emission Transportation Association (ZETA) and EVHybridNoire (EVHN)

Strong emissions standards can help move the industry toward a more equitable and just transportation system. Socioeconomic status is intimately linked to a neighborhood's air quality. Studies show that in the United States, approximately 80% of marginalized and socioeconomically disadvantaged communities experience higher levels of air pollution.9 Fine particulate matter pollution, mainly from the transportation sector, has been found to disproportionately and systemically negatively impact the health of people of color.10 Therefore, we must ensure that the EPA deters the further deployment of combustion-engine vehicles and instead promotes EV development. These policies would improve air quality in the communities facing the worst impacts from pollution. [EPA-HQ-OAR-2021-0208-0275-A1, p.4]

Commenter: Zewadski-Bricker, Edith

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 227-228.]

We are in a moment where our policy choices will impact the present and the future, harming those that are poor the most.

EPA Response

As discussed in Preamble Section VII.L, EPA acknowledges and agrees with comments in this RTC section stating that communities of color and low wealth communities may be disproportionately impacted by climate change and by air pollutants and that communities with EJ concerns could be affected by the emissions associated with this rule, onroad transportation emissions and refinery and EGU emissions.

The commenters supported the projected emissions reductions from this rulemaking and noted that this is a step towards meeting the Administrator's goal of prioritizing environmental justice but there is more to be done. For example, commenters stated that a comprehensive study into health equity and environmental justice impacts on marginalized populations would be useful, there are potential methods for quantifying emissions impacts on EJ communities, and additional impacts could be included in future analyses such as environmental impacts of battery production, disposal and recycling.

As discussed in Section III.C of this preamble, future EPA regulatory actions that would result in increased zero-emission vehicles and cleaner energy generation may have greater non-GHG impacts for transportation and electricity generation, and those impacts will be analyzed in more detail in those future actions.

Commenter: Alliance For Automotive Innovation

The comment period on the GHG NPRM is abnormally short.

Executive Order 12866 states in part, "…each agency should afford the public a meaningful opportunity to comment on any proposed regulation, which in most cases should include a comment period of not less than 60 days."167

As a "significant regulatory action" as defined in EO 12866, Auto Innovators anticipated at least a 60-day comment period. In contrast, EPA only provided a 53-day comment period based on the public release of the proposed rule (August 5, 2021), and only 48 days based on the proposed rule's publication in the Federal Register (August 10, 2021), the official means of publishing such notices.

Historically, EPA has provided more than 60 days for public comment on proposed light-duty vehicle GHG rules. For the SAFE Vehicles proposal, 86 days were provided from its public release and 63 days from its publication in the Federal Register.168,169 For the 2012 Rule, 74 days were provided from the proposed rule's publication in the Federal Register. 170,171 EPA provided 60 days for public comment on its first proposed light-duty vehicle GHG rulemaking from its publication in the Federal Register, plus the additional time between its public release and formal publication.172

The shorter comment period is particularly constraining when one considers that past EPA and NHTSA rulemakings were done as a single set of coordinated documents with joint hearings, And a single comment deadline. In the case of the present EPA rulemaking, the regulated stakeholders (and other interested parties) must respond to two related regulatory proposals from EPA and NHTSA with separate, uncoordinated technical inputs and analysis, non-harmonized standards, and separate hearings, all on significantly overlapping, but separate timelines. In addition, a third related rulemaking to revise CAFE civil penalties was also on a concurrent timeline, further consuming the same engineering and human resources to evaluate and respond to GHG and CAFE proposals.

Although we recognize that EPA is on an accelerated rulemaking timeline to finalize MY 2023 standards prior to its start on January 2, 2022, it is more important to get the standards done right than it is to get them done fast.

EPA should consider supplemental comments to the extent possible for this rulemaking, and in the context of future rulemaking actions for later model years.

Auto Innovators anticipates submitting additional comments following the official closure of the comment period on the GHG NPRM. To the extent possible, such comments should be considered as informative to the present rulemaking. EPA should also consider such supplemental comments as it prepares to undertake a post-model year 2026 rulemaking. [EPA-HQ-OAR-2021-0208-0571-A1, p. 62-64]

EPA Response

EPA appreciates the comments of the Alliance and believes that the time for public comment allowed a meaningful opportunity for comment, as illustrated by the numerous and detailed comments submitted by the Alliance and hundreds of thousands of members of the public. EPA believes the schedule allowed for commenters to adequately consider the proposal and for EPA to properly consider public comments in selecting standards for the final rule. As suggested by the Alliance, EPA considered comments received after the close of the comment period to the extent practicable, including supplemental comments submitted by the Alliance.

Commenter: Americans for Prosperity

The Proposed Rule Violates the Environmental Research, Development, and Demonstration Authorization Act of 1978 (ERDDAA) for Science Advisory Board Advice

Despite intense and repeated interest from EPA's Congressionally mandated Science Advisory Board in the scientific and technical underpinnings of previous Clean Air Act standards for greenhouse gases from light-duty vehicles over the last decade, EPA has clearly violated peer review and scientific advice requirements under ERDDAA. ERDDAA directs the EPA Administrator to establish a standing Science Advisory Board. Congress further required that '[t]he Administrator, at the time any proposed criteria document, standard, limitation, or regulation under the Clean Air Act…, or under any other authority of the Administrator, is provided to any other federal agency for formal review and comment, shall make available to the Board such proposed criteria document, standard, limitation, or regulation, together with relevant scientific and technical information in the possession of the Environmental Protection Agency on which the proposed action is based.' Providing this information at the stage of interagency review and comment facilitates the Board providing 'its advice and comments on the adequacy of the scientific and technical basis of the… regulation, together with any pertinent information in the Board's possession.'25

EPA violated this requirement with the Proposed Rule. On June 24, 2021, the Proposed Rule began formal review and comment by other federal agencies through the Office of Information and Regulatory Affairs Executive Order 12866 process. It completed the interagency process on July 29, 2021.26 There is no evidence in the docket, the Science Advisory Board's website, or elsewhere that EPA provided the Proposed Rule or any relevant scientific and technical information to the Board at any time.27 Any claim by EPA that the interagency process under

Executive Order 12866 does not constitute 'formal review and comment' ignores the context of ERDDAA and CAA Section 307 and would eviscerate this clear direction from Congress. In addition, the failure to provide the Proposed Rule to the Board even after interagency review had been completed, including through the full public comment period, is a compounding violation that eliminates the Board's role under ERDDAA as well as its potential role as an interested stakeholder in the notice-and-comment process. These violations are particularly egregious for three reasons:

First, on March 31, 2021, three months before the Proposed Rule had been provided to other agencies for review and comment, EPA announced it was 'resetting' the entire membership of its Science Advisory Board, removing the several dozen sitting members before the end of their membership terms for the first time in the Board's history.28 On August 2, EPA announced the new members, including appointments to several new or relevant subpanels focused on climate science, economic analysis, and environmental justice analysis.29 The Board was disbanded for the duration of the interagency review period and, for the six weeks that the charter SAB has been reconstituted, EPA has not provided the proposed rule to the Board for review and comment underscores the harm of this violation of ERDDAA, actions that undermine the dual goals of independent scientific advice and transparency. 25

Second, the Science Advisory Board has been extremely interested in prior rulemaking in this area, offering individual and/or Board advice and comment on rulemaking activities over the last decade. More recently, this has included a variety of methodological, modeling, economic, scientific, and technical feedback in mid-2019,30 October 2019,31 January 2020,32 and February 2020.33 In the background for the January 2020 meeting, the full SAB considered a workgroup's recommendation and 'decided that the SAB should provide advice and comment on the science supporting the proposed rule.' In its October 201934 and January 202035 comments, which numbered dozens of pages, the Board highlighted 'significant weaknesses that should be addressed in the regulatory analysis,' as well as 'analytic concerns' with 'strong policy ramifications.' EPA's proposed rule has not included a request, let alone meaningful feedback, for the statutorily required role of the independent Science Advisory Board.

Third, inconsistencies and a lack of meaningful engagement with peer review bodies like the Science Advisory Board have resulted in litigation36 and significant reports from EPA's Office of the Inspector General37 when EPA has previously sidestepped these procedural requirements related to the scientific determinations underpinning this rule, including the so-called 'endangerment finding.' [EPA-HQ-OAR-2021-0208-0226-A1, pp. 6-7]

EPA Response

EPA notes, as the commenter points out, that the Science Advisory Board (SAB) was in the process of being reconstituted when the proposed rule was submitted to OIRA, and thus there was not a quorum of the SAB available to consider the proposed rule at that time. The decision to reconstitute the SAB was made to correct deficiencies and procedural irregularities, including not following the standard process for appointing committee members, as noted in a July 2019 Government Accountability Office report on EPA Advisory Committees. The proposed rule, and all the data and information underlying the proposed rule, was available to the SAB through the public docket when it regained a quorum in October 2021.

Furthermore, in preparing the proposal, EPA considered SAB's February 27, 2020 Report entitled, "Science Advisory Board (SAB) Consideration of the Scientific and Technical Basis of the EPA's Proposed Rule titled The Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021–2026 Passenger Cars and Light Trucks," as well as reports from the National Academies of Sciences, and made changes consistent with many of the recommendations of the SAB and the National Academies to the modeling used for the SAFE rulemaking. For example, EPA modified the VMT rebound estimate and updated the new vehicle demand elasticity in CCEMS based in part on a peer-reviewed study of new and used vehicle market demand. Thus, EPA benefited from prior SAB engagement on light duty greenhouse gas standards, but does not believe that prior engagement supports the conclusion that the SAB would recommend further changes to EPA's use of modeling.

Finally, in November 2021, after the SAB reached a quorum, the Principal Deputy Assistant Administrator of the Office of Air and Radiation wrote to the Director of the Science Advisory Board Staff Office to ensure that the newly constituted SAB had sufficient information about the rulemaking and the use of science and modeling for the rulemaking. For all of these reasons, EPA strongly disagrees that it has not meaningfully engaged with peer review bodies, including the SAB.

Commenter: Consumer Federation of America

The Trump administration unjustly rolled back the previous 2011 standard, which was in good compliance with both the Administrative Procedures Act principles and required by Congressional statute. In fact, the continuous advancement of standards, which the Trump administration rejected, was mandated by the statutes. [EPA-HQ-OAR-2021-0208-0297-A1, p. 2]

Commenter: Alliance For Automotive Innovation

Additionally, it is essential for EPA and NHTSA (collectively "the Agencies") to coordinate with each other in preparing their respective rules through MY 2026 and to set harmonized standards. The Agencies should make every effort to reduce and avoid unnecessary burdens associated with multiple regulations set under the authority of differing statutes that ultimately affect light-duty vehicle design in the same ways. Therefore, we also refer these comments to NHTSA for their consideration in revising CAFE standards. We anticipate submitting additional comments to NHTSA specific to the CAFE NPRM. [EPA-HQ-OAR-2021-0208-0571-A1, p. 2]

Coordination between EPA and NHTSA, and harmonization of the stringency of their respective GHG and CAFE standards, is critical to reducing unnecessary burdens that distract from the common goals of reduced GHG emissions and fuel consumption. [EPA-HQ-OAR-2021-0208-0571-A1, p. 7]

Comments on Coordination and Harmonization Between the EPA and NHTSA Proposals

In 2010, EPA, NHTSA, and CARB created the first "National Program" for regulation of fuel economy and GHG emissions. For their part, EPA and NHTSA issued a joint final rule with separate standards that generally accounted for statutory differences, resulting in roughly equivalent required fuel economy improvements under both programs. CARB, for its part, adopted a "deemed-to-comply" provision in its GHG regulation that allowed manufacturers to demonstrate compliance by meeting the EPA's GHG regulation. In the words of the Agencies, the National Program allowed "automakers to produce and sell a single fleet nationally, mitigating the additional costs the manufacturers would otherwise face in having to comply with multiple sets of Federal and State standards."

Coordination among the regulatory agencies can create public and private benefits. Harmonized regulations allow manufacturers to focus their planning and investments to achieve fuel economy and GHG improvements while reducing the added challenge of meeting three differing federal and state regulations. The same environmental and energy-saving benefits can be achieved at a lower cost to consumers while supporting jobs in automobile manufacturing. Lower costs also result in faster fleet turnover by encouraging more new vehicle sales, replacing older vehicles with more efficient, cleaner, and safer new vehicles.

In 2007, the Supreme Court noted that although EPA's obligation to protect the public health and welfare may overlap with NHTSA's obligation to promote energy efficiency, "there is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency." It is our belief that, for the subject GHG and CAFE rulemakings, such inconsistency is best avoided by coordination between the agencies and harmonization of stringency to the fullest extent possible.

Coordination and harmonization between EPA and NHTSA should result in GHG and CAFE regulations that allow manufacturers to build a single fleet of vehicles that complies with both regulations, and that does not interfere with the other agency's policy goals and statutory obligations. Developing such harmonized regulations requires the Agencies to assess their policies in the context of the other's proposal. [EPA-HQ-OAR-2021-0208-0571-A1, p. 14]

Coordination

Coordination between the Agencies should be improved in the development of final GHG and CAFE rules for model years 2023-2026.

It is clear from the Agencies' proposals and supporting analyses that coordination in preparing the proposals was minimal. The Agencies use different versions of the CAFE Compliance and Effects Modeling System ("CCEMS"), begin their analysis with different model year vehicles, and even use different assumptions for what the future mix of vehicles will look like. More importantly, the Agencies both fail to analyze how automakers would comply with the other's proposal, increasing the risk that one agency's proposal may be inconsistent with the other's.

This topic is explored more thoroughly in our assessment of the Agencies' technical modeling, below.

Harmonization

Key differences between the Agencies' regulations and governing statutes should be considered when developing harmonized regulations.

Auto Innovators previously identified regulatory and statutory differences between the Agencies that affect harmonization of the stringency of their respective standards. The Agencies should consider these differences and finalize regulations that are harmonized by MY 2026. Of particular concern is the treatment of EVs given the larger role they are expected to play through MY 2026 and beyond. Also, constraints on credit transfers (between compliance fleets) and trades (between manufacturers) have played a significant and growing role in the challenges manufacturers face in planning a single fleet that complies with CAFE, GHG, and other regulations such as the California zero emission vehicle mandate. [EPA-HQ-OAR-2021-0208-0571-A1, p. 15]

Auto Innovators also noticed that there are large variations in the ratio of climate-related benefits to air-quality benefits in the two RIAs and in the peer-reviewed scientific literature. As a quality-control check, Auto Innovators recommends that the Agencies compare the four different studies below (Table VII-1) and isolate the major factors that explain the huge variation in the ratio of climate benefits to local air-quality benefits. In the process of performing this comparison, the Agencies may learn about analytic inputs or procedures that can be updated or harmonized to reduce the huge variation. The Agencies should certainly explain the eight-fold difference in their own estimates of the ratio. Moreover, the Agencies might present some additional sensitivity analyses to reveal how the ratio of climate benefits to air-quality benefits might vary under alternative yet plausible assumptions. Each entry in the table below is based on a 3% discount rate, so differences in the discount rate should not be contributing to the huge variation. Factors to investigate are the tailpipe emissions rates of PM2.5 and its precursors for the relevant model years, rebound rates, upstream emissions from electric power plants due to the charging of BEVs, emissions during the manufacturing of BEVs and batteries, PM2.5 dose-response assumptions, the Social Cost of Carbon and value of a statistical life ("VSL") values.

Table VII-1: Ratio of Climate Benefits to Air Quality Benefits in the RIAs and in Selected Studies in the PeerReviewed Scientific Literature

Study	Ratio of Climate to Air Quality Benefits
NHTSA RIA (2021)	80 [185]
EPA RIA (2021)	10.3 [186]
Choma, et al. (2020)	0.2 [187]
Tong and Azevedo (2020)	Climate Benefits > 0; Air Quality Benefits < 0 [188]

Neither the two RIAs nor the two cited scientific papers include some important reasons for giving less weight to local air quality as a rationale for the revised standards. We summarize those reasons below and encourage the Agencies to address them.

Commenter: Alliance for Vehicle Efficiency (AVE)

Following EPA's issuance of emission standards over a decade ago, automotive suppliers invested billions of dollars in innovative technologies needed to meet the vehicle standards promulgated in 2010 and 2012. Those standards, drafted in conjunction with the National Highway Transportation Safety Administration (NHTSA) and the State of California, set out to provide industry with over a decade of regulatory certainty with the objective of creating One National Program. This decade-long regulatory certainty spurred an unprecedented reinvestment in domestic manufacturing by creating tens of thousands of new manufacturing jobs, investment in new facilities, and the ability for manufacturers to develop and expand new supply chains for the advanced technologies needed to meet the new standards.2 As EPA and NHTSA look to enact standards for vehicles produced after model year 2027, AVE strongly urges the agencies to proceed with a joint rulemaking that provides industry with a unified approach to test cycles and compliance targets and timelines. [EPA-HQ-OAR-2021-0208-0256-A1, pp. 1-2]

Commenter: Aluminum Association

The Association favors a single national standard for light duty GHG emission targets based on EPA's regulation rather than a patchwork of shifting state standards overlaid on top of EPA's standards. Regulatory certainty across a long-time horizon is critical for industries, including the aluminum industry, in making capital allocation and investment decisions and the lack of a single national standard hinders that certainty. Toward that end, the Association believes that the stringency of the national standards as proposed is sufficient to pre-empt the need for any state specific standards [EPA-HQ-OAR-2021-0208-0233-A1, p.4]

For the first time, with this proposal EPA has delinked its rulemaking process from that of NHTSA's – which will now put GHG emissions and fuel economy regulations in separate rulemakings. The Association encourages the two agencies to work together to ensure alignment of their standards in such a way to minimize automaker burden and ensure vehicles remain affordable and provide consumers with value [EPA-HQ-OAR-2021-0208-0233-A1, p.4]

Commenter: BorgWarner Inc.

Coordinated Standards

We encourage EPA, National Highway Transportation Safety Administration (NHTSA), and the California Air Resources Board (CARB) to coordinate standards. Vehicle efficiencies and CO_2 emissions are determined by fundamental vehicle architectures that do not change from state to state. Decisions regarding long-term investment in R&D, capital and tooling are challenging for suppliers like BorgWarner, who support all major automakers, and therefore need to invest in multiple technology solutions to meet our customers' needs. Synchronization of the CO_2 and

Corporate Average Fuel Economy (CAFE) standards are necessary to provide industry with certainty for investments and efficiencies in product development and manufacturing. [EPA-HQ-OAR-2021-0208-0260-A1, p. 2]

Commenter: Center for Biological Diversity, et al.

EPA Need Not and Should Not Await NHTSA's Revised Fuel-economy Standards before Finalizing Revised GHG Emission Standards.

As explained in Part II, supra, automakers' compliance with EPA's preferred alternative and Alternative 2 for MY2023-2026 is achievable considering costs. Commenters urge EPA to finalize its revised standards promptly, without awaiting NHTSA's consideration of revising corporate average fuel economy (CAFE) standards under the Energy Policy and Conservation Act of 1975 (EPCA) for MY2024-2026. EPA need not, and ought not, delay finalizing revised emission standards until NHTSA is prepared to finalize its own rulemaking in early 2022.

First, no statute or regulation mandates that EPA and NHTSA conduct joint rulemakings. In particular, Section 202(a) of the Clean Air Act has no such mandate. NHTSA, like other federal agencies, may comment on EPA's Proposal along with the public, see 42 U.S.C. § 7607(d)(4)(B)(i), and also during the interagency review process for EPA's rule, see id. § 7607(d)(4)(B)(ii). And EPA must consider any "significant comments, criticisms, and new data" NHTSA offers in comments. Id. § 7607(d)(6)(B). But EPA has no special obligation to consult, much less proceed in lockstep, with NHTSA.

As the Supreme Court has observed, EPA's duty to prescribe and revise greenhouse gas standards is "wholly independent" of NHTSA's duty to impose CAFE standards. Massachusetts v. EPA, 549 U.S. 497, 532 (2007). Whatever NHTSA's standards might be or become, EPA must not "shirk its environmental responsibilities" and must act to "protect[ ] the public's 'health' and 'welfare.'" Id. (quoting 42 U.S.C. § 7521(a)); see also Coal. for Responsible Regulation v. EPA, 684 F.3d 102, 127 (D.C. Cir. 2012) (rejecting argument that EPA could defer GHG regulation due to NHTSA's authority or treat NHTSA's proposed regulations as a baseline), rev'd in part on other grounds sub nom. Util. Air Regulatory Grp. v. EPA, 573 U.S. 302 (2014). EPA therefore retains "significant latitude as to the … coordination of its regulations with those of other agencies," NHTSA included. Massachusetts, 549 U.S. at 533.

EPA previously has conducted joint rulemakings with NHTSA at the President's urging, see Presidential Memorandum, Improving Energy Security, American Competitiveness and Job Creation, and Environmental Protection Through a Transformation of Our Nation's Fleet of Cars and Trucks, 75 Fed. Reg. 29,399, 29,399 (May 26, 2010); Exec. Order 13,432 § 3(a), reprinted at 72 Fed. Reg. 27,717, 27,717 (May 16, 2007), or as an exercise of discretion. But neither agency has suggested that joint rulemaking is required by statute or regulation, and past practice is not binding.

Second, whereas EPCA bars NHTSA from strengthening CAFE standards fewer than 18 months before a model year begins, 49 U.S.C. § 32902(g)(2), the CAA contains no such explicit lead-time requirement. Rather, the CAA vests EPA with discretion to strengthen emission standards with whatever lead-time is appropriate under the statutory test. See Section 5, supra; 42 U.S.C. § 7521(a)(2). If EPA finalizes its (correct) finding that automakers require “relatively limited lead time” to comply with stronger GHG emission standards for MY2023, Proposal, 86 Fed. Reg. at 43,753, the prudent course is for EPA to finalize its new standards promptly rather than erode that lead time solely to await NHTSA’s possible revision to its CAFE standards, which is unlikely to conclude until April 2022, see Corporate Average Fuel Economy Standards for Model Years 2024-2026 Passenger Cars and Light Trucks, 86 Fed. Reg. 49,602, 49,610 (Sept. 3, 2021) (NHTSA 2021 NPRM).

Third, there is no possibility that EPA will finalize stronger GHG standards that are “inconsisten[t],” Massachusetts, 549 U.S. at 532, with NHTSA’s CAFE standards. The latter standards “specify[ ] the minimum level of average fuel economy applicable to a manufacturer in a model year,” 49 U.S.C. § 32901(a)(6) (emphasis added), and no GHG standard in the range EPA is considering in this rulemaking would render it infeasible for any automaker to attain that statutory minimum. Further, any subsequent NHTSA rulemaking must account for EPA’s emission standards as “other motor vehicle standards of the Government.” 49 U.S.C. § 32902(f); see NHTSA 2021 NPRM, 86 Fed. Reg. at 49,793 (noting that, since EPA first set standards for vehicular GHG emissions, “NHTSA has considered [them]" under this provision); 2020 Final Rule, 85 Fed. Reg. at 25,137 (NHTSA considering fuel-economy effects of EPA’s GHG standards before prescribing MY2021-2026 CAFE standards). Put differently, Congress put EPA’s emission standards in pole position and assigned NHTSA chief responsibility for “avoid[ing] inconsistency” between the two agencies’ respective standards. Massachusetts, 549 U.S. at 532; see also Cent. Valley Chrysler-Jeep v. Goldstene, 529 F. Supp. 2d 1151, 1168 (E.D. Cal. 2007). NHTSA will be no less able (in fact, it will be better able) to consider EPA’s revised “other motor vehicle standards of the Government,” 49 U.S.C. § 32902(f), if those standards have already taken effect than if EPA pauses its own rulemaking to await NHTSA’s.

Fourth, given the present and projected state of emissions-reduction technologies, EPA’s GHG standards will increasingly diverge from NHTSA’s CAFE standards, making joint rulemaking increasingly the wrong choice. As Commenters have detailed elsewhere, see Br. of State & Local Gov’t Pet’rs & Pub. Interest Pet’rs 96–101, No. 19-1230 (D.C. Cir. Oct. 27, 2020), EPCA artificially constrains NHTSA from considering fuel economy of vehicles powered by “alternative fuel” like electricity, 49 U.S.C. §§ 32901(a), 32902(h), 32904(a)(2)(B), which make up an increasing portion of the new-vehicle fleet. EPA, unshackled by those statutory constraints, is far better positioned than NHTSA to set standards responsive to the vehicle fleets of MY2023 and beyond. Thus, not only is it not “necessary,” 42 U.S.C. § 7521(a)(2), for EPA to await NHTSA’s rulemaking process, it is not prudent for EPA to do so. [EPA-HQ-OAR-2021-0208-0651-A1, p. 28-29]

Commenter: Environmental Protection Network (EPN)

Separate EPA Rulemaking

EPA and the National Highway Traffic Safety Administration (NHTSA) have separate and differing responsibilities under the Clean Air Act and the Energy Policy and Conservation Act. The agencies have previously exercised their authorities through a joint GHG and Corporate Average Fuel Economy (CAFE) standard-setting rulemaking, and in general this has been an appropriate and effective approach to rulemaking. However, the Safer Affordable Fuel-Efficient (SAFE) 2 rulemaking inappropriately used this approach to limit and push to the side EPA's long experience and expertise in motor vehicle emissions control.

There is no legal requirement that the agencies use a joint rulemaking process. EPA can pursue a separate rulemaking and appropriately consult and coordinate with NHTSA, and vice versa. EPA can use its deep technical and policy expertise to achieve well-coordinated federal GHG and CAFE programs. In addition, separate EPA and NHTSA rulemakings make increasing sense as EVs become a greater share of the market, given the various limitations on NHTSA's authority when it sets CAFE standards. These limitations include the number of model years NHTSA can address, its inability to consider credits and credit transfers, and its statutory prohibition on considering EVs when setting CAFE standards. It is imperative that future EPA rulemakings not be constrained by NHTSA's statutory limitations. [EPA-HQ-OAR-2021-0208-0213-A1, p. 14]

Commenter: General Motors LLC (GM)

GM supports one national program for all 50 states that will reduce regulatory uncertainty and enable all stakeholders to focus cooperatively on reducing greenhouse gas emissions, conserving energy, and growing the economy. The ability to sell the same fleet in all 50 states will also reduce manufacturer burden and consumer price, enabling quicker fleet turnover with sales of newer, more efficient vehicles. [EPA-HQ-OAR-2021-0208-0234-A1] [p.2]

Harmonization between EPA and CARB's GHG Programs and NHTSA's CAFE Program

In 2012, when the Obama Administration developed the initial 2017-2025 model year standards, attempts were made to harmonize the various programs as fully as possible. In fact, the Administration said in its regulatory announcement that 'Continuing the National Program ensures that auto manufacturers can build a single fleet of U.S. vehicles that satisfy requirements of both federal programs as well as California's program.' However, the 'One National Program' still amounts to three separate regulatory programs, created under three separate regulations, managed by three separate regulatory agencies. As a result, the mechanics of the three programs and the regulatory incentives permitted in each are different. Resulting from an extensive list of differences2 and acknowledged by NHTSA in its recent CAFE NPRM,3 compliance with one program does not guarantee compliance with all.

EPA's proposed GHG program is historically stringent. It is aligned with GM's and the nation's Paris Agreement commitments, and it achieves greater overall emission reductions than the Settlement Agreements entered into by California and several OEMs. Accordingly, GM believes that the Federal government should take all appropriate action to ensure that compliance with EPA's program for the 2021-2026 model years is deemed compliant with both the NHTSA and CARB programs for those years. GM further stresses that if an OEM complies with the EPA program, it should not be subject to civil penalties in the NHTSA program that may arise from the geographic location of its supply chain, or from the distinct requirements in California's program.

The certainty that EPA's proposed standards will serve as harmonized 50-state standards will enable industry to focus on innovation and investment in tailpipe-free solutions, and enable all three regulatory agencies and other stakeholders to put the nation's precious resources toward the complementary policies that are critical to achieving the low-carbon transportation future that we all desire. It will also help ensure that investments are focused on tailpipe-free solutions rather than marginal internal combustion engine improvements that divert resources from innovations needed to achieve the goals of the Paris Agreement. [EPA-HQ-OAR-2021-0208-0234-A1][pp.5-6]

Commenter: Hyundai America Technical Center, Inc. (Hyundai)

Harmonization is key

GHG emissions and fuel economy are highly correlated and we appreciate EPA's statement that 'it remains committed to ensuring that GHG emissions standards for light duty vehicles are coordinated with fuel economy standards'.8 Hyundai believes this coordination is critical to avoid unnecessary inefficiencies and reduce reporting redundancies from conflicting requirements, and we support the Alliance for Automotive Innovation's comments on this topic. [EPA-HQ-OAR-2021-0208-0603-A1 p.7]

Commenter: International Union, United Automobile, Aerospace & Agricultural Implement Workers of America (UAW)

In the next phase of finalizing the regulations, it will be important to harmonize standards between the Environmental Protection Agency (EPA), the National Highway Traffic Safety Administration (NHTSA), and the California Air Resources Board (CARB) as much as possible to avoid unnecessary regulatory burdens. We support a national standard. Additional flexibilities should be explored within this process. [EPA-HQ-OAR-2021-0208-0749-A1, p. 2]

In the next phase of finalizing the regulations, it will be important to harmonize standards between the Environmental Protection Agency (EPA), the National Highway Traffic Safety Administration (NHTSA), and the California Air Resources Board (CARB) as much as possible to avoid unnecessary regulatory burdens. We support a national standard. Additional flexibilities should be explored within this process.

Commenter: Jaguar Land Rover North America, LLC (JLRNA)

Finally, we would like EPA to consider long-term harmonization between its GHG standards and NHTSA's CAFE standards due to the complications for a manufacturer having to comply with two differing sets of targets. We propose that any targets should be designed to be of equal measure when considering the differences between the regulations. This allows us as a manufacturer to design our US fleet to one set of targets. [EPA-HQ-OAR-2021-0208-0269-A1, p.8]

Organization: Kreucher, Walter

49 U.S.C. 32902 prohibits consideration of the fuel economy of dedicated and dual fueled alternative fuel vehicle (AFV) models when NHTSA determines what levels of CAFE standards are maximum feasible. Once these vehicles are excluded from consideration, the Agencies own CAFE Model and assumptions demonstrates that the proposed standards ARE NOT technologically feasible. [EPA-HQ-OAR-2021-0208-0199-A1, p. 5]

Commenter: Lucid USA, Inc. (Lucid)

Due to the flexibility afforded under the Clean Air Act, EPA is the appropriate agency to take the lead on regulating EVs. Allowing EPA to pursue a National ZEV program while NHTSA focuses on pursuing the maximum feasible improvements in fuel economy of internal combustion engines is consistent with each agency's statutory authority and will bolster the legitimacy and defensibility of each program. [EPA-HQ-OAR-2021-0208-0528-A1, p. 6]

Commenter: Motor & Equipment Manufacturers Association (MEMA)

MEMA Supports Coordinated Programs - MEMA continues to support the long-standing goal of a One National Program where EPA, NHTSA, and the California Air Resources Board (CARB) work together to coordinate regulations, strive to align stringency, and reduce burden. Closely coordinated programs will provide the stability and predictability that vehicle suppliers need for controlling capital costs and driving significant domestic technological investments. This stability is critical as technology investments become more diversified. [EPA-HQ-OAR-2021-0208-0249-A1, p. 3]

MEMA Continues to Support Coordinated Programs

MEMA continues to support the goal of a One National Program as much as possible between EPA's GHG program, NHTSA's CAFE program and CARB's program. Since 2009, the industry has worked under a principle of a One National Program that NHTSA, EPA and CARB will work together to coordinate these regulations, striving to align stringency and reducing unnecessary compliance burden where possible. MEMA urges the agencies to focus on providing a clear, streamlined compliance pathway for the industry. Harmonization and consistency are even more critical as technology investments become more diversified into a broader spectrum of propulsion technologies.

A coordinated program between the agencies is of the utmost importance to suppliers because the industry needs an aligned set of unified test cycles, targets, and timelines. Suppliers plan technology deployments according to production cycles and emissions standards to avoid stranded investments. A consistent approach is important for suppliers as the industry makes important long-term business decisions and the necessary investments to drive toward meeting the nation's goals.

Closely coordinated programs will provide the stability and predictability that vehicle suppliers need for controlling capital costs and driving significant domestic technological investments. This stability will provide vehicle manufacturers with improved market availability and optimal economies of scale for technologies, which will ensure the lowest possible compliance cost is achieved. This certainty will sustain U.S. innovation, enhance global competitiveness, and support jobs in the vehicle parts supplier sector. [EPA-HQ-OAR-2021-0208-0249-A1, p. 6]

Commenter: National Automobile Dealers Association (NADA)

EPA and NHTSA Should Harmonize Their Programs and Establish a Single National Program.

Although EPA and the National Highway Traffic Safety Administration (NHTSA) have adopted fuel economy and GHG standards in joint rulemakings since 2010, EPA states that it is unnecessary to do so in this instance and proposes to revise its GHG standards in a rulemaking separate from that NHTSA has initiated.39

NADA disputes EPA's assertion and contends, as it has in response to prior EPA GHG regulatory actions, that a single national light-duty vehicle fuel-economy/GHG program administered principally by one federal regulator is not only needed, but consistent with the structure designed by Congress in EISA. The regulation of both light-duty motor vehicle fuel economy and tailpipe GHG emissions is largely duplicative.

The physics and chemistry involved establish a direct relationship; controlling fuel economy controls GHG emissions and vice versa. Two Federal agencies regulating essentially the same thing raises government inefficiency and waste concerns, and results in unnecessary regulatory burdens and complexities, which inevitably increase vehicle costs for dealers and their customers.

Moreover, EPA's proposal only appears to adopt the standards equivalent to those established in the "framework" agreements for MY 2023, proposing much stricter standards for MYs 2024-2026. As articulated above and in prior submissions, NADA supports a harmonized set of federal light-duty vehicle GHG/fuel economy standards that are technologically feasible, economically practicable, and thus will result in vehicles that will be attractive and affordable to prospective new light duty motor vehicle for consumers. Again, regulatory benefits will not be achieved unless and until vehicles subject to new mandates are sold or leased to end-users. [EPA-HQ-OAR-2021-0208-0290-A1, p. 10-11]

Commenter: Nissan North America, Inc.

Moreover, Nissan encourages EPA and NHTSA to continue their efforts to coordinate the federal GHG emission and CAFE standards with the GHG and ZEV standards set by the California Air Resources Board ("CARB"), to develop a harmonized national program for automotive certification. In particular, Nissan believes it is important for EPA to work with CARB to clarify the relationship between the federal GHG standards, the California GHG standards, and the Framework Agreements between CARB and several automakers. Close coordination between these three regulatory entities would ensure that manufacturers can focus on developing the cleanest, most fuel efficient, and most affordable vehicles rather than on compliance with uncertain and unnecessarily fragmented regulatory programs. [EPA-HQ-OAR-2021-0208-0529-A1, p. 2]

Continued Support for a Unified National Approach

Nissan strongly encourages EPA, NHTSA, and CARB to develop a unified national approach to automotive regulation. In particular, Nissan echoes the points made in the letter submitted by the Alliance for Automotive Innovation ("Alliance") to Secretary Buttigieg and Administrator Regan on June 28, 2021, regarding harmonization of CAFE and GHG light-duty vehicle standards.

A patchwork of different federal and state GHG and CAFE programs is neither effective nor efficient. In contrast, a harmonized national program maximizes both GHG and CAFE benefits on a nationwide basis while also providing regulatory certainty and minimizing unnecessary compliance burdens for the industry. Such an approach allows automakers to develop a single, unified fleet that meets all federal and state requirements while maintaining a full range of vehicle options for consumers. More importantly, a harmonized approach allows manufacturers to focus their planning and investments on achieving fuel economy improvements and emissions reductions rather than on compliance with unnecessarily fragmented regulatory standards and programs. Under a harmonized approach, environmental benefits can be achieved at a lower cost to manufacturers and consumers. Lower costs help address social equity concerns related to EV accessibility and also encourage faster fleet turnover, replacing older vehicles with more efficient, cleaner, and safer vehicles.

As EPA and NHTSA consider potential changes to the federal GHG and CAFE programs, Nissan believes it is essential that the agencies work together to maximize compatibility and coordination of the programs. Nissan understands that, due to statutory limitations, certain programmatic elements of the GHG and CAFE programs may not be identical. Nissan encourages EPA and NHTSA to make the standards as equivalent and complementary as possible, however, by adopting appropriate regulatory adjustments where available.

Nissan also urges the Administration to work with California regulators to harmonize the federal and CARB programs to the fullest extent possible. This could be accomplished by reinstating California's "deemed-to-comply" measures, under which vehicles that meet federal standards are "deemed-to-comply" with CARB standards. Nissan is also open to new alternative approaches for harmonizing federal and California standards, as well. Nissan encourages EPA to work proactively with CARB to clarify the relationship between federal and California standards, including between OEMs that signed on to California's Framework Agreements and those that did not. In particular, harmonization amongst all three agencies (EPA, NHTSA, and CARB) will be critical if EPA restores California's Clean Air Act Waiver covering model years 2021 through 2025 California GHG standards and ZEV requirements.

For its part, EPA has self-characterized the Proposed GHG Rule as: “equivalent to the stringency of the California Framework Agreements emission reduction targets in MY 2023 and increasingly more stringent than the Framework Agreements from MY 2024 through 2026.” It is critical for the industry to have a clear understanding of how EPA’s Proposed GHG Rule and California’s enforcement of its standards will be implemented going forward (e.g., whether a “deemed-to-comply” option will be available for compliance with California GHG requirements). [EPA-HQ-OAR-2021-0208-0529-A1, p. 5-6]

Commenter: Stellantis

Stellantis Supports One National Program

Stellantis supports One National Program for regulating automotive greenhouse gases and fuel economy. As part of his Build Back Better platform, then-Candidate Biden pledged to ‘negotiate fuel economy standards with all stakeholders, workers and their unions, environmentalists, industry and states that achieve new ambition by integrating… [and] accelerate the adoption of zero-emissions light- and medium duty vehicles, provide long-term certainty for workers and the industry and save consumers money through avoided fuel costs.’ Stellantis has stated our public support for the President’s electrification targets, and we also support the inclusive approach to setting standards in the U.S.

The U.S. is the only major market with multiple regulatory programs for light-duty vehicles. Navigating three sets of standards introduces significant complexity to compliance and adds unnecessary costs to a resource-intensive transition to electric vehicles. Manufacturers will be looking for every possible efficiency and cost containment strategy to deliver affordable, electrified vehicles to our customers. We urge EPA, NHTSA and CARB to do the same. [EPA-HQ-OAR-2021-0208-0532-A1, p. 5]

Commenter: Toyota Motor North America, Inc. (Toyota)

Finally, we remain concerned that EPA and NHTSA appear to be moving further away from a coordinated One National Program (ONP) rather than closer to unified approach that could reduce consumer costs and provide optimal environmental and fuel saving benefits. While we will comment separately on NHTSA’s proposed CAFE regulations, these comments include an overview of key areas of concern regarding regulatory harmonization. [EPA-HQ-OAR-2021-0208-0531-A1, p. 2]

Success Can be Aided by Harmonized GHG and CAFE Requirements

One National Program More Important Now Than Ever T

he purpose of the National Program for GHG and CAFE standards has always been “establishing consistent, harmonized, and streamlined requirements that would reduce GHG emissions and improve fuel economy for all new cars and light-duty trucks sold in the United States.”22 The preamble of the 2012 Final Rule states the “National Program will deliver additional environmental and energy benefits, cost savings, and administrative efficiencies on a nationwide basis that would likely not be available under a less coordinated approach and that it will "allow automakers to produce and sell a single fleet nationally, mitigating the additional costs that manufacturers would otherwise face in having to comply with multiple sets of federal and state standards."23 These core principles become paramount as the automotive industry embarks on significant investments toward the most significant technology transition in the past 100 years.

While we are still reviewing both the GHG and CAFE proposals given the short comment period, we remain concerned that the proposals were issued as two separate regulations and seem to be moving further away from a unified federal approach. Our early analysis finds an erosion of harmonization between the proposed GHG and CAFE programs that breaks from recent regulatory history.

Our preliminary analysis shows several reasons for this, but a significant one appears to be that the GHG proposal overestimates the performance contribution of gasoline-only powertrains and the CAFE proposal underestimates the cost of electrification required to comply.

Toyota's upcoming comments on the proposed CAFE standards will address concerns specific to that program in greater depth. For now, we highlight several areas of disharmony, primarily involving compliance modeling and assumptions, that cause the agencies to draw different conclusions on fundamental issues such as the level of electrification needed for compliance. Toyota can provide further information to EPA and NHTSA if requested.

Adjustments for Equivalent GHG-CAFE Stringency

NHSTA has not adequately adjusted the CAFE standards to account for the flexibility and fleet credit transfer restrictions relative to the GHG program. The result is the proposed CAFE standards become more stringent than the proposed GHG standards. Greater detail is forthcoming in Toyota comments on the CAFE standards proposal.

CA/177 State ZEV Compliance

In determining the feasibility of the proposed standards, NHTSA has incorporated assumed manufacturer compliance with the CA/177 State ZEV program as input to the CAFE Model without considering ZEV compliance costs. Including ZEV compliance as a given ignores ZEV compliance uncertainties, double counts regulatory benefits while ignoring all costs, and discards NHTSA's long-standing compliance modeling process where the least expensive improvement technologies are assumed to be deployed into the fleet first. This dubious approach masks the cost of electrification to consumers as well as the overall cost of the regulation. Toyota will address this concern in the upcoming CAFE comments.

Advanced Gasoline Technologies

For compliance modeling of gasoline powertrains, EPA is extensively relying on the HCR2 classification of Atkinson engine technology for which the assumed efficacy remains unproven and highly unlikely as previously explained. NHTSA effectively deploys only to the HCR1 level of Atkinson engines which better reflects the state of technology in the fleet today and identifies HCR1D24 as a more advanced future pathway that while not cost-effective has a considerably more reasonable assumed technology effectiveness than HCR2.

CAFE Model Versions

EPA and NHTSA are using different versions of the CAFE Model. We appreciate EPA using Autonomie simulation to determine technology effectiveness and the CAFE Model to determine compliance pathways for the proposed standards. However, EPA is relying on an outdated version of the CAFE model and several input assumptions “for the purpose of enabling direct comparison to the SAFE FRM analysis”. NHTSA is using the latest version of the CAFE model that incorporates many recommendations highlighted in the peer review of modeling tools for GHG/CAFE policy analysis. Toyota believes it is important for both agencies to use the same version of the most recent model with the same and most recent input assumptions where possible.

Baseline Fleets

The baseline fleet represent a snapshot of performance and the starting point from which technologies are “added” to the fleet to demonstrate compliance pathways using the CAFE Model. EPA is starting with a 2017 baseline fleet whereas NHTSA uses a more appropriate 2020 baseline fleet. EPA’s older baseline fleet is missing the latest, cleanest, and most efficient technologies in vehicles on the road today. Instead, EPA must rely on more assumed or simulated technology effectiveness for these very same technologies where errors propagate through the fleet over a longer period (2017 to 2026 model year) as explained previously. The 2017 fleet excludes important recent market trends that have real impact on overall fleet performance such as the ongoing shift in vehicle mix.

Deployment of Off-Cycle Technologies

EPA is adding off-cycle technologies to the fleet more rapidly than being deployed by manufacturers. Compliance modeling assumes many manufacturers have earned upwards of 10 g/mi to 15 g/mi of credits by the 2020 model year while manufacturer compliance data over the same period shows significantly fewer credits being earned. Further, the pool of available credits over the 2023 through 2026 model years will be reduced by the proposed revised definitions for passive cabin ventilation, engine warm-up, and transmission warm-up technologies. NHTSA more realistically assumes manufacturers will not reach maximum credit values until the 2026 model year and that some companies will not attain the maximum. EPA’s inflated off-cycle credit assumptions factor into the artificially low the reliance on electrification for compliance. [EPA-HQ-OAR-2021-0208-0531-A1, p. 12-14]

Commenter: U.S. Chamber of Commerce ('the Chamber')

Durable standards are needed to provide stability for long-term business planning and investment

The automobile industry is an enormously important economic sector, historically contributing 3.0 – 3.5 percent of overall U.S. gross domestic product (GDP) and directly employing an estimated 1.5 million people in the design, manufacturing, sales, and service of motor vehicles.12 Additionally, the industry is a very large consumer of materials and services from other sectors, from machinery and computing to advertising, finance, and more. Together, these direct and indirect activities amount to a net employment contribution in the U.S. economy of more than 7 million jobs, and state and federal tax revenue generation of $206 billion.13

According to the Alliance for Automotive Innovation, the industry is investing $330 billion on electrification through 2025 alone, with additional significant investment anticipated beyond this timeline. Concomitant with this level of investment is the need for regulatory agencies to work with the industry and other stakeholders to ensure the full and adequate consideration of relevant factors and objectives that is needed to achieve sound and effective regulatory policy.

Maximizing alignment of EPA's greenhouse gas (GHG) and NHTSA's Corporate Average Fuel Economy (CAFE) programs will allow for a more efficient compliance process and reduced costs under which automobile manufacturers can sell new vehicles across every state in U.S. that meets the state and federal standards. This significantly reduces vehicle design, supply chain, and distribution costs.

It is imperative that all sides work together to identify a flexible, achievable path to continued fuel economy gains. As a practical matter, any scenario that results in two sets of standards—whether via continuation of California's waiver authority while NHTSA and EPA modify federal standards, or via some other mechanism—is sure to result in added costs to the industry that will inevitably be passed along to consumers. It also has the potential for increased litigation risk, injecting even more uncertainty into markets and disrupting efforts to plan, invest, and deliver continued fuel economy and emissions gains. [EPA-HQ-OAR-2021-0208-0524-A1, p. 7]

Commenter: Volkswagen Group of America, Inc. (Volkswagen)

Aligning Federal Standards and Coordinating into the Future

Volkswagen will comment separately on the parallel rulemaking being conducted by the National Highway Traffic Safety Administration (NHTSA) to update the 2024-2026 model year Corporate Average Fuel Economy (CAFE) standards. Volkswagen supports the national policies of energy security and greenhouse gas reductions and the decade long history of the two agencies coordinating on standards. Volkswagen urges EPA and NHTSA to continue their engagement to ensure that their final rules provide aligned pathways that will continue to ensure that compliance with both regulatory programs can be achieved with one single National fleet of vehicles. [EPA-HQ-OAR-2021-0208-0237-A1, p.2]

We are encouraged by the cooperation between EPA and NHTSA in working to ensure that through 2026 manufacturers should have a pathway for equal compliance under both regulations. Furthermore, as outlined in the Presidents Executive Order on Strengthening American Leadership in Clean Cars and Trucks, we are supportive of the direction for EPA and NHTSA to coordinate with the State of California in consideration of longer-term standards through 2030MY. Volkswagen continues to support the idea of future standards that are aligned between Federal and State authorities. We believe that harmonized standards can help reduce complexity and costs and efficiently achieve long-term environmental, climate, and energy objectives. [EPA-HQ-OAR-2021-0208-0237-A1, p.7]

Commenter: Volvo Car Corporation

Volvo Cars has consistently stated that the goal of achieving one single national harmonized program (California, EPA and NHTSA) is the preferred path forward to increase fuel economy and lower emissions year over year. However, in 2020 a harmonized national program consistent with Volvo Cars global electrification strategy and climate neutrality goal was not in place. In 2020, Volvo Cars signed onto the California Voluntary Agreement and Volvo Cars is pleased that this framework has now served as a national path forward for the current federal proposed rule.

However, Volvo Cars believes regulatory consistency, and a clear federal framework are necessary to effectively and efficiently enable the auto industry to develop more efficient vehicles and to advance the market for advanced technology vehicles. Multiple vehicle regulatory programs at the Federal and State level that require separate and duplicative reporting, accounting, and testing are inefficient and increase uncertainty in the market. [EPA-HQ-OAR-2021-0208-0253-A1, p.2]

The US should work to minimize disparities between EPA (GHG) and NHTSA (CAFE) regulations and California regulations. The program should reduce reporting requirements by allowing manufacturers to demonstrate compliance at the end of the year for all programs. The current multi-agency credit programs ends up rewarding automakers moving slowly to electrify their fleet verses automakers that are moving more rapidly to electrify. There seems to be a disparity in the agency programs and this maybe an unintended consequence of multiple programs, but we urge EPA to look into this further. Compliance reporting should be consolidated so that it is one report for one agency and that agency determines compliance (so reciprocal recognition). Currently, there are separate assessments for each program, and this is unnecessary and especially burdensome for smaller manufacturers like Volvo Cars. [EPA-HQ-OAR-2021-0208-0253-A1, p.2]

Organization: Wisconsin DNR

In a departure from the 2012 and 2020 light-duty vehicle rulemakings, EPA and NHTSA are not undertaking a joint rulemaking, but are instead proposing separate regulations under each agency's individual legal authority. While the two proposals generally align in their requirements by MY 2026, they contain differences significant enough that assessing the combined impact of the rules on GHGs and criteria pollutants is challenging.9 As such, WDNR strongly recommends that, in the future, the agencies return to the joint rulemaking model. [EPA-HQ-OAR-2021-0208-0223-A1, p.4]

9 For example, EPA and NHTSA employ different methods to estimate the GHG and criteria pollutant impacts of their rules resulting in directionally consistent, yet quantitatively different, results.

EPA Response

We discuss in Section II.A.8 of the preamble comments relating to consultation and alignment between the EPA and NHTSA programs and the decision to issue separate and not joint rulemakings and the relationship between the EPA and California programs.

Regarding comments requesting that testing and reporting be consolidated across the EPA and NHTSA programs, we note that since the beginning of the LD GHG program the agencies have worked to harmonize testing and reporting requirements where appropriate (e.g., emissions and fuel economy testing) We also note there have been differences between certain features of the two programs, stemming from different statutory authorities for the two agencies. For example, EPA's program allows credits for air conditioning leakage which impacts GHGs but not fuel economy.,. As discussed in the preamble, we will continue to coordinate with NHTSA going forward.

GM requested that EPA and NHTSA "take all appropriate action to ensure that compliance with EPA's program for the 2021-2026 model years is deemed compliant with both the NHTSA and CARB programs for those years." As discussed in Sections II.A.8.i and II.A.8.ii, EPA   will continue to coordinate with NHTSA and CARB, subject to limitations due to different statutory authorities, as EPA implements the GHG final standards.

Toyota points to several areas of our proposed rulemaking that are different from NHTSA's proposed rulemaking that they believe will "cause the agencies to draw different conclusions on fundamental issues such as level of electrification needed for compliance." Although NHTSA has not yet completed its fuel economy rulemaking, we believe that any ultimate differences in in the agencies' respective modeling platforms, approaches and estimated impacts will not interfere with each agency's ability to meet our separate statutory requirements.

EPA's responses to the items that Toyota listed that apply to EPA's rulemaking follow:

- Regarding Toyota's comment about how EPA applies "HCR2" engine technology in our modeling, we do not use that technology in our primary modeling for the final rule. See Chapters 2.3.2 and 4.1.1.3 of the RIA for an analysis of the sensitivity of our modeling results to this parameter.
- Regarding Toyota's comment about the base fleet EPA uses in our modeling, we have updated our analysis for this final rule to use a 2020 base fleet, as described in Section III of the preamble and Chapter 4 of the RIA.
- Regarding Toyota's comment about EPA and NHTSA using different versions of the CAFE model, we describe in Section III of the preamble and Chapter 4 of the RIA our rationale for why and how we have used a specific version of the CAFE model

(CCEMS). We note that EPA and NHTSA have in the past used different models in support of our respective GHG and fuel economy rules.

- Regarding Toyota's comment about EPA's modeling of off-cycle technologies, we have updated our modeling approach for this final rule, as we discuss in Chapter 4.1.1.1 of the RIA.

Comments about EPA's statutory authority to issue greenhouse gas standards are addressed in section 16 of this RTC. Comments about NHTSA's statutory authority are beyond the scope of this action.

Commenter: 25x '25 Alliance

While we recognize that increasing emissions standards is an important pathway to addressing climate change, so too is increasing the stringency of standards for fuel quality. Unfortunately, while the proposal includes incentives for the production of vehicles with zero or near-zero emissions technology, it does not include any provisions that could significantly reduce GHG emissions from gasoline powered vehicles. Matching increased octane with improved engines could nearly double the emissions reduction claimed for the SAFE rule proposal – an enormous, missed opportunity.

While the transition to electric mobility is steadily advancing, we are decades away from the disappearance of the internal combustion engine, so the rationale for lowering emissions from new and legacy vehicles is paramount. The situation created by the inventory shortages also means that fewer new vehicles will be hitting the road during the current and probably next couple model years, therefore older, fuel inefficient vehicles stay in use. Fuel with lower emissions addresses this challenge. Research by Steffen Mueller, principal economist at the University of Illinois at Chicago's Energy Resources Center, shows that greenhouse gas cuts that could be achieved by using higher-octane midlevel blends with ethanol equal those that EPA thinks are available from electrification. EPA is thus ignoring a very cost-effective way of achieving its desired improvements to the detriment of environmental quality, consumers, farmers, and industry.1

While the research shows that the GHG cuts achieved by using higher-octane, midlevel ethanol blends are equal to the emission reductions that the EPA thinks are available from electrification, the agency is ignoring a duty to consider a very cost-effective way of achieving desired improvements, to the detriment of environmental quality, public health, consumers, farmers and industry.

We recommend that EPA take action to increase the minimum octane standard of gasoline and phasing out today's low-octane blends, as new vehicles are available to take advantage of the efficiency benefits of midlevel ethanol blends. EPA should also correct its inaccurate fuel economy formula to allow the use of midlevel ethanol blends. The agency has admitted that the formula is erroneous and that it unfairly penalizes fuel containing ethanol but has yet to fix the problem. The erroneous formula discourages automakers from proposing use of higher-octane gasoline that uses ethanol as the octane enhancer.

High-octane midlevel ethanol blends would offer cost effective GHG reduction for gasoline powered vehicles for several decades. The current option for high octane gasoline is to use 'premium' gasoline. Only about 10 percent of the market chooses to buy this more expensive product. Considering the historical cost of ethanol, using ethanol to increase octane would encourage adoption of more efficient engines by the whole ICE market because the high-octane product would cost about the same as current 'regular.' This companion program would add to the GHG reductions considered as portions of the vehicle fleet gradually shifts to electric.

In closing, the EPA needs to take this opportunity to open the door for the use of high-octane, low-carbon fuels made with ethanol. It is clear that the blends would enable more efficient vehicles, reduce greenhouse gas emissions and reduce pollution. The EPA's duty under the

Clean Air Act is to protect the health of all Americans by use of commercially available methods. The agency would be irresponsible to ignore this option in regulating greenhouse gas emissions from cars and trucks. An improved gasoline blended with 25-30-percent ethanol is an immediate, low-cost pathway that offers substantial carbon and health risk reductions that will have the greatest impact in poor, urban areas. We urge you to include this important option in those considered for adoption in the new rule, with an immediate effective point of no later than 2025. [EPA-HQ-OAR-2021-0208-0228-A1, pp. 1-2]

An improved gasoline blended with 25-30-percent ethanol is an immediate, low-cost pathway that offers substantial carbon and health risk reductions that will have the greatest impact in poor, urban areas [EPA-HQ-OAR-2021-0208-0228-A1, p. 2]

Commenter: Alliance For Automotive Innovation

A nationwide low carbon fuel standard program Low carbon fuel standards are a market-based approach to decarbonizing transportation fuel and driving funds toward incentivizing EVs. [EPA-HQ-OAR-2021-0208-0571-A1, p. 6]

Comments on Fuels

Action on Liquid Fuels Will Help During the Transition to Vehicle Electrification

Given the timespan over which ICE technology will continue to be available to new vehicle purchasers, and the years that those vehicles will remain in the field, improved liquid fuels are a critically important technology pathway. The largely ignored improved liquid fuels pathway will facilitate increased fuel efficiency, and reduced GHG and non-GHG emissions while the EV market continues to grow.

EPA Should Undertake a Comprehensive Fuels Rulemaking

EPA should consider actions to:

• Transition to a higher minimum-octane gasoline (i.e., minimum 95–98 research octane number) to facilitate higher engine efficiency;

• Implement a nationwide low carbon fuel standard to lower GHG emissions;

• Immediately eliminate sub-87 anti-knock index (“AKI”) octane fuels from the market to increase fuel efficiency and reduce GHG emissions;

• Lower the sulfur cap of gasoline from 80 ppm to 20 ppm at the refinery gate to further reduce non-GHG emissions from ICE-equipped vehicles and engines to improve air quality;

• Cap summer vapor pressure of gasoline at 9.0 psi or less, regardless of ethanol content, to further reduce evaporative emissions as E10 fuel is ubiquitous in the market;

• Regulate the particulate forming tendency of market gasoline by eliminating the heavy aromatic fraction of gasoline, thereby reducing PM emissions from all ICE vehicles, equipment, and engines to improve air quality for all; and

• Limit air toxics, e.g., olefins and aromatics, and their precursors from the fuel to improve air quality for all.

Legacy and New ICE-Equipped Vehicles Will Continue in the Fleet for a Significant Time

There are nearly 290 million light-duty cars and trucks in the United States,113 and nearly 99 percent of those vehicles operate on gasoline or diesel fuel.114 Looking forward, after meeting the Administration’s goal of 50% EV new vehicle market share by 2030,115 it is clear that substantial numbers of liquid-fueled vehicles will be produced well through this decade and into the next. In addition, the average age of a vehicle in the U.S. has grown to over 12 years.116 The car parc will continue to rely on liquid fuels for years to come, and gasoline will continue to play a significant role in transportation. If EPA does not undertake a comprehensive fuels rulemaking, it is missing an opportunity to implement a low-cost approach to improving fuel economy and reducing GHG and criteria pollutant emissions.

EPA Should Adopt a High-Octane Fuel Standard for the ICE Vehicle Market

Automobile and engine manufacturers from around the world publish the Worldwide Fuel Charter (“WWFC”). The WWFC outlines the fuel properties needed for vehicles and engines to achieve a desired level of fuel efficiency and exhaust emissions. In 2019, the Sixth Edition of the WWFC outlined the use of a minimum 95 and higher Research Octane Number (“RON”) for markets with advanced requirements for emission control and fuel efficiency.117 Many developed markets including Europe already have mandatory 95 RON minimum.

Higher-octane gasoline enables opportunities for the use of key energy-efficient technologies, including higher compression-ratio engines, lighter and smaller engines, improved turbocharging, and optimized engine combustion phasing and timing. All of these technologies, when paired with higheroctane gasoline, permit smaller engines to meet the demands of the consumer while at the same time providing higher efficiencies and thus reducing GHG emissions during vehicle use. Furthermore, depending on its composition, high-octane fuel is safe to use in many existing vehicles.

The relative efficiency gain enabled by higher octane rated gasoline is well documented. A literature review published by Leone et al. shows that increasing fuel octane rating from 91 RON to 95 RON facilitates an increase in efficiency by three to five percent.118 Figure 3 [Figure 3 can be found on p. 39 of Docket number EPA-HQ-OAR-2021-0208-0571-A1] shows the correlation of efficiency gain enabled by higher octane rated fuels with higher compression ratio engines. [EPA-HQ-OAR-2021-0208-0571-A1, p. 37-38]

Auto Innovators and its predecessor associations have long advocated that EPA should require a transition to a higher minimum-octane gasoline (minimum 95–98 RON). There are several ways to produce higher octane-grade gasoline. Increasing the ethanol content of gasoline is one approach. Hydrocarbon composition changes are another. Reducing the proportion of low octane naphtha or increasing the proportion of higher-octane streams such as alkylate or reformate will result in higher octane fuels. Ethanol blends higher than E10, with misfuelling mitigation measures in place, have been suggested by some to provide better value to consumers to achieve higher octane numbers and reduce carbon emissions. Auto Innovators does not promote any sole or particular pathway.

Producing higher octane fuel for the future ICE fleet will not impose any significant burdens on the refining and retail sectors. Hirshfeld et al. analyzed the refining economics of raising the average octane rating of the U.S. gasoline pool by increasing the octane rating of refinery produced blendstocks for oxygenated blending and/or the ethanol content of the finished gasoline.119,120 These studies found a transition to higher-octane (95 RON, E10) gasoline was technically feasible and could be made without considerable increases in cost or CO2 emissions for refineries.121 The implementation of higher octane-rated gasoline in the marketplace would be a cost-effective means of improving fuel economy and therefore should be encouraged as soon as possible to maximize environmental benefits across the new car fleet.

EPA has the ability to enable the ICE to achieve increased fuel efficiency by requiring higher minimum octane rated gasoline in the marketplace. Research, data, and evidence confirms the ability to increase ICE efficiencies as the octane rating of gasoline increases. EPA, in the past, has recognized its authority to alter fuel quality to increase efficiencies. Specifically, as the criteria emission standards have increased in stringency, the allowable sulfur concentration decreased in recognition of sulfur’s deleterious effects on emission control systems. Today, the GHG regulation has achieved such levels that the minimum market gasoline octane rating is limiting the ability to advance ICE technology. It is now necessary to adjust the gasoline octane rating (higher) commensurate with required decreases in GHG emissions. The new minimum octane rating needs to be set immediately to 95 RON and then increased to 98 RON as new GHG standards are implemented. The new gasoline octane levels are backwards compatible, and a subset of the vehicles in the legacy fleet have the ability to also increase efficiency in response to higher octane. Being able to leverage the legacy fleet in assisting in the reduction in transportation carbon emissions can significantly benefit the portfolio of technology solutions in achieving the collective goals associated with the climate.

The implementation of higher octane-rated gasoline in new vehicles would be a cost-effective means of improving fuel economy and reducing GHG emissions for the light-duty vehicle fleet.

EPA Has the Authority to Regulate Fuels to Improve GHG Emissions

The Clean Air Act provides statutory authority for the EPA to regulate GHG emissions, which can “cause, or contribute to, air pollution which may reasonably be anticipated to endanger the public health or welfare” (Massachusetts v. EPA, 549 U.S. 497 (2007)). Section 211 of the Clean Air Act provides EPA with the authority to regulate motor vehicle fuels in furtherance of the Act’s goals. Specifically, Section 211(c) of the Act grants EPA the authority to set new national fuel standards, including octane rating, under the following circumstances:

• (1)(A) "if in the judgment of the Administrator, any fuel or fuel additive or any emission product of such fuel or fuel additive causes or contributes to air pollution or water pollution… that may reasonably be anticipated to endanger the public health or welfare," or

• (1)(B) "if emission products of such fuel or fuel additive will impair to a significant degree the performance of any emission control device or system which is in general use, or has been developed to a point where in a reasonable time it would be in general use were such regulations to be promulgated."

It is important to note that the addition of GHGs to the list of Clean Air Act "pollutants" is changing how one thinks of emissions control. For purposes of considering EPA's authority under 211(c)(1)(B), it is important to realize that the term "any emission control device or system" must be understood more broadly than it once was. With this realization, it is easy to see that engine efficiency improvements offer emission control benefits. However, low-octane fuel acts as a barrier to these efficiency benefits. EPA has the authority and must stand firmly on the side of removing these barriers and providing manufacturers with a full menu of options for striving to meet the future GHG standards.

In light of increasing GHG and CAFE requirements, it continues to be essential for vehicles and the fuels they operate on to be treated as a system and developed in tandem. Prospective fuels should enable greater vehicle efficiency and lower emissions, optimize the consumer experience, and fulfill societal values. Technology is in place to produce advanced engines. However, without a promulgated higher-octane fuel standard, the advanced engines cannot optimize their potential operational efficiency. It is now timely for EPA to undertake an accelerated process to implement and synchronize the market introduction of higher-octane gasoline that will enable the benefits of advanced technologies and support manufacturer investments. EPA has the authority to regulate national commercial gasoline octane specifications under the Clean Air Act. EPA should initiate a fast-track process to assure higher octane gasoline that meets the market and timing needs of new vehicle technologies for the U.S. commercial supply.

EPA Should Implement a Nationwide Low Carbon Fuel Standard ("LCFS")

EPA should take actions to support lower or net-zero carbon liquid fuels. Although automobile manufacturers are focused on electrification, actions on liquid fuels can provide benefits to legacy vehicles, would support even lower GHG emissions from PHEVs, and could provide much-needed GHG reduction pathways. EPA should leverage a new national LCFS and/or modified renewable fuel standard (RFS) to incentivize low carbon fuel use in legacy and future ICE vehicles and engines. A properly structured nationwide LCFS, while providing GHG reductions, can also create new revenue sources to incentivize market adoption of EVs.

EPA Should Take Further Action on Fuels to Reduce Emissions and Improve Air Quality

Use of improved liquid fuels supports ongoing efforts to improve air quality and can provide an important bridge in reducing emissions in low-income communities during the transition to expanded vehicle electrification. While today's vehicles emit near-zero levels of tailpipe and evaporative emissions, more can be done to support lower emissions and air toxics exposure, especially in disadvantaged communities.

EPA states:

EPA recognizes that in addition to substantially reducing GHG emissions, a longer-term rulemaking could also address criteria pollutant and air toxics emissions from the new light-duty vehicle fleet—especially important considerations during the transition to zero-emission vehicles. EPA expects that a future longer-term rulemaking will take critical steps to continue the trajectory of transportation emission reductions needed to protect public health and welfare.122

Auto Innovators agrees that "… a longer-term rulemaking could also address criteria pollutant and air toxics emissions from the new light-duty vehicle fleet…" Auto Innovators would add that in many cases gasoline improvements would improve emissions from virtually all of the 290 million vehicles on the road today in addition to other liquid-fueled equipment. Given that these vehicles are on the road today and that benefits would accrue immediately upon introduction, we see no reason for EPA to delay in implementing a rulemaking. Auto Innovators has commented extensively in the past on the fuel improvements needed to address criteria pollutant and air toxics emissions.

Several improvements to market fuels can be made:

1. Reduce sulfur

When EPA finalized the Tier 3 rules governing gasoline, it lowered the maximum average sulfur level from 30 ppm to 10 ppm. This change was essential to facilitating the lower tailpipe emissions standards that are part of the Tier 3 standards because, as EPA points out, "any amount of gasoline sulfur will deteriorate catalyst efficiency."123 However, EPA continues to allow 80 ppm sulfur at the refinery gate and has a 95 ppm downstream cap. Auto Innovators continues to stand behind previous industry comments on sulfur as detailed in the Auto Alliance Tier 3 comments.124 Refiners and the distribution system have had many years to adjust to lower sulfur standards. We urge EPA to reduce the refinery gate and downstream caps to 20 and 25 ppm, respectively, perhaps with a phase-in period, and at the same time to develop a pathway toward a retail cap of 10 ppm per gallon. EPA can then provide ad hoc relief, with a notice and comment process, for refiners and downstream distributors that can show evidence of reasons they actually need it.

2. Cap vapor pressure

The EPA must cap summer gasoline vapor pressure at 9.0 psi or less regardless of ethanol level. From a vehicle operability perspective, there is no need for fuel vapor pressure to be even as high as 9.0 psi. California summer fuel is capped at 7 psi, and in Japan (JIS K 2202), the summer maximum is 6.4 psi. No operability issues with on-specification fuel are experienced in either place. Lower vapor pressure will reduce evaporative emissions across the fleet, particularly in older vehicles and off-road and handheld equipment. Since the beneficial effects of lower vapor pressure are enhanced by progressively lowering it and applying it to all gasoline fueled equipment from day one, there is no reason for EPA not to follow the California or Japanese examples for summer fuels and cap other seasons at ASTM D4814 maxima.

3. Eliminate sub-87 AKI market fuels

Vehicles sold in the U.S. require fuel octane of 87 AKI or higher. Tier 3 regular grade certification fuel has closely controlled octane and is specified at 87-88.4 AKI. In the majority of the U.S., the minimum market octane is 87 AKI by regulation or custom. However, in the Rocky Mountain states sub-octane fuel continues to be marketed. This was justified in the past by high altitude effects on engine knock. However, as ASTM D4814 section X1.6 points out:

New vehicles have sensors to measure [sic] and engine management computers, which take into account such conditions as air charge temperature and barometric pressure. These vehicles are designed to have the same antiknock requirement at all altitudes and a reduced sensitivity to changes in ambient temperature. This more sophisticated control technology began to be used extensively in 1984. This technology, while constantly evolving and improving, is used on almost all new vehicles. This means that many vehicles in today's fleet require fuel having the same antiknock index regardless of changes in altitude or ambient temperatures.

This text implies that the vehicles produced in the last 37 years require the same fuel as the rest of the country. More recently, automakers have produced increasing proportions of vehicles with turbocharged engines. These engines boost manifold pressure using turbochargers and are insensitive to altitude.

The result of misfuelling these vehicles, whether they have sensors and engine management computers dating from 1984 or more advanced technologies, is that the vehicle will knock on the suboctane fuel resulting in spark retard and enrichment to protect the engine from damage. Spark retard will reduce fuel economy and increase GHG emissions, while fuel enrichment will increase CO and HC emissions. The solution to these issues is easy: EPA must mandate that all market fuels meet or exceed the octane of Tier 3 certification fuel.

4. Remove heavy aromatic compounds

Both EPA and CARB recognize the deleterious effects of vehicle particulate emissions. This is demonstrated by their regulations limiting tailpipe emissions of particulate matter (“PM”). The European Union (“EU”) and China also regulate particulate emissions.125,126 While establishing and tightening particulate emissions standards for prospective vehicles may lower emissions in future, there is a way to lower emissions today from all gasoline-powered equipment. Many studies have linked fuel properties, especially heavy aromatics, to tailpipe PM; some of particular importance were published by Honda and include the development of a PM index for fuels.127,128 While the Honda-developed PM index correlates well with tailpipe PM, other methods of measuring PM forming tendency beyond the detailed hydrocarbon analysis method used may be more effective.129,130,131,132 The hard-to-identify heaviest fraction of the fuel harbors the molecules with the highest contribution to PM.133

There have been several Coordinating Research Council ("CRC") projects to investigate the impacts of ethanol, PM index and octane.134,135 The data showed that there is a direct correlation between increased fuel PM index to increased tailpipe PM. Detailed hydrocarbon analysis of the fuels showed that the high molecular weight aromatics fractions of the fuel, C10+ hydrocarbons, are the main contributors to increased tailpipe PM. The more C10+ hydrocarbons there are, the greater the increase in PM formation.

Therefore, EPA should proceed with controlling the particulate forming tendency of market gasoline by requiring the removal of the heavy aromatic components to lower PM emissions throughout the fleet and improve air quality for all, especially those who live and work in close proximity to major highways.

5. Limit air toxics

The emissions from an average light duty vehicle have been reduced by over 99% since the introduction of emissions control technology. The reduction has been such that, according to CARB, in the California south coast air basin, lawn and garden equipment is a greater contributor to poor air quality than light-duty vehicles.136 Nonetheless, toxic emissions continue, especially from older vehicles and off-road equipment. The best approach to limiting toxic emissions is to remove toxics from the fuel prior to distribution. EPA recognized and applied this approach to limiting benzene emissions. Going forward, EPA must broaden its approach and limit air toxics, e.g., olefins and aromatics, and their precursors from the fuel prior to distribution.

E10 Test Procedure Adjustment

In May 2020, EPA proposed an adjustment to laboratory-measured CO2 when tested on Tier 3 certification fuel.137 This proposed adjustment effectively revises the stringency of GHG standards and sets a policy precedent that is not supportive of the potential of future low carbon fuels to contribute to reductions in transportation carbon emissions. If an adjustment is necessary, we continue to encourage EPA to account for such adjustment in a full GHG standard-setting rulemaking under Section 202(a) of the Clean Air Act.138

As was stated in comments submitted on the E10 Test Procedure Adjustment NPRM, "the goal of Auto Innovators is to ensure that this rulemaking helps set a positive policy foundation that values the potential of low carbon fuels in contributing toward our shared climate goals. Auto Innovators proposes that making adjustments to laboratory results is not the optimal path forward and that the effect of E10, and other future low carbon fuels, is best handled within the context of future iterations of fleet average GHG standards."139 [EPA-HQ-OAR-2021-0208-0571-A1, p. 39-45]

Commenter: Alliance for Vehicle Efficiency (AVE)

AVE recommends that EPA's regulatory programs link the GHG reduction of vehicles to the cleaner fuels that now power them. [EPA-HQ-OAR-2021-0208-0256-A1, p. 2]

A Pathway to Cleaner Fuels:

To further help the U.S. reach our carbon reduction goals, AVE recommends EPA's regulatory programs link the GHG reduction of vehicles with the cleaner fuels that now power them.

Applying LCA to the vehicle certification process could lead to more investments in, and the expanded use of, renewable fuels and low carbon fuels (eFuels). Unlike with EVs, the EPA's GHG emissions analysis for certification/compliance of ICE vehicles is not representative of the actual emissions from the country's in-use fuels pool. Using LCA, EPA's GHG rules (and NHTSA's CAFE rules) could be modified to enable automakers to certify gasoline/diesel vehicles with compliance values reflective of the projected in-use carbon intensity of national fuels.

For example, the national fuel pool currently contains approximately 10% ethanol. California's published estimates for carbon intensities of ethanol pathways average 35.1%, and the average carbon intensity of the ethanol pool is 57-61%.18 The national average E10 carbon intensity has a factor of 96 and is approximately 4% below the compliance value used by automakers toward their fleet average GHG and fuel economy.

Another example is the significant growth and development of renewable natural gas (RNG). According to data from the California Air Resources Board (CARB), the annual average carbon intensity score of RNG was -5.845 gCO2e/MJ,19 with 92% of all on-road fuels used in natural gas vehicles in 2020 being RNG.20 While the majority of this RNG is currently used in heavy-duty fleets, the current GHG regulations restrict development of innovative technologies for light-duty vehicles to be fueled by RNG.

The EPA's current and proposed GHG regulations include no mechanism to account for the lower carbon intensity of fuels to stimulate OEM investment in technologies that could utilize these fuels. There is also no incentive to further reduce the carbon intensity of fuels irrespective of any investments made by producers. AVE recommends EPA adjust compliance values for the actual carbon intensity of in-use fuels. Doing so will positively impact the annual certification compliance values of the OEMs' ICE vehicles and would likely incentivize fuel producers and OEMs to monetize future carbon reductions.

Applying upstream energy-based GHG accounting measures that consider the projected in-use carbon intensity to all vehicles could have several benefits:

• Create a market-based incentive for investment to expand the use of renewable fuels and to lower the carbon intensity of manufacturing petroleum-based fuels.

• When coupled with a national Low Carbon Fuel Standard, would provide certainty that GHG reductions would be met in-use and provide significant environmental benefits. [EPA-HQ-OAR-2021-0208-0256-A1, p. 8]

Commenter: American Coalition for Ethanol (ACE)

We stand ready to support the fulfilment of these goals but need to make it clear the U.S. will not succeed in this endeavor unless steps are taken to reward farmers and biofuel producers for their ability to be part of the solution to mitigate climate change.

While it may be an inconvenient truth for some to accept, corn ethanol is a proven and cost-effective low carbon fuel playing an important role in reducing GHG emissions and air pollution from the transportation sector, evidenced by the fact the Renewable Fuel Standard (RFS) has cut GHG emissions by nearly 600 million metric tons since 2007, exceeding EPA's original expectation of 444 million metric tons.1

ACE members believe ethanol can and should be an even bigger part of the solution to climate change, but this depends upon the Administration's willingness to engage us on ethanol's role as a low carbon fuel through policies such as the RFS and the topic of this request for comments; how to reduce GHG emissions from future vehicles.

A recent study published by Harvard University, Tufts University and Environmental Health & Engineering Inc. scientists reinforces the fact that the GHG reduction benefits of corn ethanol have been significantly undervalued because some regulatory bodies refuse to apply or use the latest lifecycle science. The Harvard/Tufts study found that average corn ethanol reduces GHGs by 46 percent compared to gasoline and given improvements occurring in corn farming and within ethanol facilities, corn ethanol's carbon footprint will continue to decline over time.2

Nevertheless, there is a disconnect between this reality and the proposal by EPA to reduce GHGs from 2023 and later model year vehicles. Since nearly all the 270 million light-duty vehicles on U.S. roads today run on liquid fuel, it would seem reasonable that to significantly cut CO2 emissions from their tailpipes, consideration must be given to the fuel powering the engines, including steps to replace fossil fuel with a lower carbon and higher octane fuel, such as ethanol. Unfortunately, and unbelievably, EPA's proposal fails to adequately address these important issues.

Instead, EPA impractically suggests vehicle GHG emissions can be reduced merely by plugging more cars into the grid, without much attention to how the electricity powering those cars is generated. When electric vehicles (EVs) are actually charged by low carbon power sources, they will play a role in reducing GHG emissions, but EVs comprise just 2 percent of all light-duty vehicles on the road today, and most of them are hybrid models that also operate on liquid fuels. In other words, even as EV sales increase, Americans will continue to rely on billions upon billions of gallons of liquid fuels for decades to come. Therefore, this proposal must place much greater emphasis on improving the quality of liquid fuel and the role low carbon, high octane ethanol can play in making significant GHG reductions in the near-term. [EPA-HQ-OAR-2021-0208-0221-A1, p. 1-2]

In January, the Rhodium Group released a compelling report indicating even under the most aggressive sales projections, EVs alone will not achieve net-zero transportation emissions by 2050.3 Rhodium explained meeting this goal also depends upon decarbonizing liquid fuels and more stringent CAFE-GHG standards. [EPA-HQ-OAR-2021-0208-0221-A1, p. 2]

Many leading ethanol producers are on a trajectory to both net-zero and net-negative lifecycle emissions in the not-too-distant future. If the overarching goal is net-zero emissions by mid-century, let's start making progress right now by taking full advantage of the 15 billion gallons of domestically-produced ethanol available today as an affordable way to boost octane and meaningfully reduce GHG emissions from gasoline powered engines.

While it is regrettable EPA's proposal does not invite comments on the role high octane and low carbon fuels such as ethanol can play in helping automakers comply with GHG standards, it does invite comments on what should be done to promote more fuel efficient vehicles.

We have already discussed the incredible lifecycle GHG benefits of corn ethanol, but ethanol also delivers the highest octane rating for fuel at the lowest cost, allowing automakers to benefit by continuing to develop high-compression and fuel efficient engine technologies to reduce vehicle GHG emissions. We believe high octane, low carbon blends comprised of 25 to 30 percent ethanol would enable more fuel efficient vehicles, reduce GHG emissions, and reduce other pollutants.

It is in that spirit we urge EPA to use this rulemaking to establish a minimum Research Octane Number (RON) rating for fuel in the range of 98 to 100 RON with 25 to 30 percent ethanol and provide automakers with a corresponding certification fuel for engine testing purposes. As part of this action, the Agency should finally phase-out the use of sub-octane blends (85 AKI) because automakers indicate this inferior low octane fuel can harm the engines in their vehicles. EPA has acknowledged that Section 211 of the Clean Air Act provides authority to control gasoline octane levels. EPA can set a minimum octane rating for fuel because low octane gasoline impairs engine manufacturer's ability to further increase compression ratios to reduce CO_2 emissions to meet the GHG standards and increases CO_2 emissions in legacy vehicles.

If the final rule does not establish minimum octane standard for fuel, EPA should immediately proceed to initiate a separate rulemaking on this issue.

Automakers have wanted EPA to increase the octane rating of gasoline for several years. Consider the following statements from automaker representatives and research findings from fuel and engine experts:

• In an October 6, 2011, letter to EPA from Mitch Bainwol, the President and CEO of the Alliance of Automobile Manufacturers at the time: "Furthermore, to help achieve future requirements for the reduction of greenhouse gas emissions, we also recommend increasing the minimum market gasoline octane rating, commensurate with increased use of ethanol. Adding ethanol to gasoline increases its octane rating. To attain necessary octane levels, it is important that refiners not be permitted to reduce base gasoline octane ratings in light of the additional octane contribution from higher ethanol."4

• Dan Nicholson, Vice President of Global Propulsion Systems for General Motors (GM), said the following about high octane fuel at the 2016 CAR Management Briefing Seminars. "Higher octane fuels are the cheapest CO_2 reduction on a well-to-wheels analysis…Fuels and engines must be designed as a total system. It makes absolutely no sense to have fuel out of the mix of engine technology discussions."5

• Oak Ridge National Laboratory (ORNL) has found the use of 100 RON E25 and E40 in high-compression engines reduce well-to-wheel GHG emissions by 4 and 8 percent per mile, respectively, compared to E10. Total GHG emissions per mile were 8 percent lower for E25 and 17 percent lower for E40 when ethanol's upstream lifecycle GHG benefits were added.6

• According to a study by Jim Anderson of Ford Motor Company, "It appears that substantial benefits may be associated with capitalizing on the high octane rating of ethanol. We estimate large increases (4 to 7 points) in the RON of U.S. gasoline are possible by blending 10 to 20 percent by volume ethanol above the E10 already present."7

• Ford and General Motors experts indicate 98 to 100 RON fuel would result in a 7 to 8 percent efficiency gain in turbocharged port-fuel injected engines, a 5 to 6 percent efficiency gain in turbocharged direct injection engines, a 4 to 5 percent gain in naturally-aspirated port-fuel injected engines, and 3 to 4 percent gain in naturally-aspirated direct-injection engines. The same study found the maximum efficiency gain from 95 RON is merely 4 percent and limited strictly to turbocharged port-fuel injected engines.8 [EPA-HQ-OAR-2021-0208-0221-A1, p. 2-4]

In addition to establishing a minimum octane rating for fuel, ACE encourages EPA to take a technology-neutral approach to the incentives and multipliers offered by the Agency with respect to low carbon fuel use in various vehicle technology. Unfortunately, EPA's proposal is considerably biased in favor of EVs over other vehicle/engine technologies. For example, under existing GHG standards the value of the multiplier used by the Agency to encourage the production of EVs falls from 2 (for model years 2017 through 2019) to 1.5 for model year 2021 and thereafter. But EPA's proposal would increase the EV multiplier to 2 again for model years 2022 through 2024. Instead of putting its thumb on the scale to favor EVs through multipliers and compliance credits, EPA should establish a technology-neutral approach that also provides automakers with incentives to produce flexible fuel vehicles (FFVs) and vehicles designed to achieve optimal efficiency and reduced emissions on high octane ethanol blends. [EPA-HQ-OAR-2021-0208-0221-A1, p. 4]

There are approximately 25 million FFVs in the U.S. today. The ideal way to transition from today's legacy fleet of internal combustion engines to new vehicles with advanced engine technologies designed to run optimally on a high octane fuel is to utilize FFVs as bridge vehicles that can provide immediate demand for midlevel ethanol blends. As a matter of fact, ORNL has investigated the use of high octane ethanol blends such as E25 and E30 in FFVs that are designed and compatible with ethanol blend levels from 0 to 85 percent and can therefore seamlessly and with OEM approval utilize midlevel ethanol blends.9 Key findings from Oak Ridge include: "Experiments were performed with four FFVs using an E10 (92 RON) and E30 (100 RON) fuel. The two direct-injection FFVs demonstrated performance improvements for E30 compared to E10 of 2.5 to 3 percent, based on the 15-80 wide-open throttle acceleration time. Three of the four FFVs showed performance improvement with high-octane E30 compared to regular E10. (…) Marketing E25 or E30 to FFV owners as a performance fuel may enable greater utilization of ethanol in the near term and could help establish the refueling infrastructure to enable manufacturers to build dedicated vehicles designed for a high-octane midlevel ethanol blend."

FFVs using E85 significantly reduce lifecycle GHG emissions because the carbon emissions produced during the combustion of ethanol are largely recycled back in the growing of corn and other biofuel crops. Until 2015, EPA allowed automakers to use a 0.15 multiplier to account for this carbon regeneration and comply with CAFE-GHG standards. We encourage EPA to reinstate this FFV multiplier or establish an incentive that is on equal footing with the EV credits in its proposal and establish a similar credit for vehicles designed to run optimally on midlevel blends of ethanol such as E25/30.

Vehicle incentives/credits are not the only area in which EPA seems to penalize technologies designed to operate efficiently on ethanol-blended fuel, indeed another inequity exists with the Agency's outdated fuel economy formula. In previous statements, EPA has acknowledged part of the fuel economy formula (the R-factor) unfairly penalizes fuel containing ethanol. Consequently, EPA is discouraging automakers from developing efficient engines that require higher octane ratings and higher ethanol content. EPA has previously said the 0.6 R-factor is erroneous and fails to achieve the statutory purpose of evaluating the fuel economy of fuels containing ethanol The auto industry has asked EPA for an R-factor of 1.0. In response, EPA has suggested the correct value may lie "between 0.8 and 0.9." While ACE supports an R-factor of 1.0, an increase to 0.8 or 0.9 would represent an improvement.

In the spirit of helping inform future EPA decision-making regarding the RFS and the lifecycle GHG emissions of corn ethanol generally, we feel compelled to once again point out that the approach the Agency takes regarding corn ethanol's lifecycle analysis is wildly outdated and fails to include the continuing advancements in this science documented by the Department of Energy's Greenhouse gas and Regulated Emissions and Energy use in Transportation (GREET) model. One of the most glaring discrepancies between EPA's outdated approach to lifecycle modeling and more recent versions of the GREET model is assumptions about the impact of land use change from ethanol production.[EPA-HQ-OAR-2021-0208-0221-A1, pp.4-5] [Figure 1 can be found on p. 5 of Docket number EPA-HQ-OAR-2021-0208-0221-A1]

EPA's outdated modeling included in the final RFS (in 2010) assigns a 29-gram penalty to the overall carbon intensity (CI) of corn ethanol. Subsequent research on this topic, in addition to the fact that the U.S. has produced more than 15 billion gallons of corn ethanol (so actual land use changes can be observed), indicates a more accurate land use factor of between 4 and 8 grams. Even the California Air Resources Board (CARB), in its implementation of the Low Carbon Fuel Standard, has reduced the corn ethanol land use change assumption from the 30-gram penalty it originally applied in 2011 to a 19.8-gram factor today. While that is still inexplicably higher than what most research suggests should be the case, the fact remains CARB has at least tried to update their lifecycle analysis of corn ethanol while EPA has not. [EPA-HQ-OAR-2021-0208-0221-A1, p.5]

Nearly three decades ago, Dr. Michael Wang at the Department of Energy's Argonne National Laboratory developed the GREET model. It is considered the gold-standard for calculating energy use, GHGs, and other regulated emissions that occur during the full lifecycle production and combustion of all transportation fuels. The assumptions used by Argonne scientists in GREET are under constant review and updates to the model occur frequently. GREET is used by the California Low Carbon Fuel Standard program and the Oregon Clean Fuels program and has more than 40,000 registered users worldwide. Like the results found in the recent Harvard/Tufts study, the latest (2020) version of the GREET model indicates that average dry mill corn ethanol production reduces lifecycle GHG emissions by 45 percent compared to gasoline.10 ACE has repeatedly asked EPA to adopt the latest GREET model to make all GHG determinations for the RFS and we echo that recommendation in these comments. [EPA-HQ-OAR-2021-0208-0221-A1,pp.5-6]

Emerging scientific research indicates the GHG carbon intensity for corn ethanol will continue to improve through advancements on-the-farm and in ethanol facilities. We would strongly encourage EPA to engage us on this topic. [EPA-HQ-OAR-2021-0208-0221-A1, p. 6]

In the near-term, a properly implemented RFS and year-round availability of E15 will meaningfully reduce the carbon intensity of the U.S. transportation sector by capitalizing on the existing vehicle fleet's ability to use lower-carbon biofuels. [EPA-HQ-OAR-2021-0208-0221-A1, p. 6]

Commenter: American Petroleum Institute (API)

Systems Approach to Evaluating Transportation Emissions

Liquid fuels can provide near-term and ongoing GHG reductions from the on-road vehicle fleet when evaluated within an analytical systems-based framework that comprehends technology neutral, performance-based standards for fuels, vehicles, and infrastructure. To achieve this goal, it is critical that EPA link fuel and vehicle standards to ensure consistent CO2 accounting across all fuel/vehicle technology options. Current vehicle greenhouse gas emissions standards consider only tailpipe emissions. A well-to-wheels approach provides a systems-based analytical framework for evaluating the GHG impacts of various fuel-vehicle pathways, including internal combustion engines (i.e., gasoline, diesel, or natural gas), battery electric, hydrogen, and hybrid technologies.

API also supports federal policy that improves fuel carbon intensity to drive CO2 reductions from transportation. Liquid fuels can provide GHG emissions improvements using feedstock and process technologies that reduce fuel carbon intensity. Existing federal programs, including the current Renewable Fuel Standard, do not adequately incentivize the deployment of available technologies to produce lower carbon fuels.

There are significant benefits to developing a holistic, systems approach to regulating greenhouse gas emissions from transportation. Establishing a carbon intensity standard for the motor fuel pool that declines over time and is reflected in the evolution of the EPA test fuel properties used for emissions standard certification purposes would not only benefit new vehicles, but also could achieve emissions reductions across the entire existing vehicle fleet. A well-to-wheels approach would allow the market to drive carbon reductions at the lowest abatement cost, while preserving consumer choice. Vehicle manufacturers benefit with the ability to demonstrate the overall emissions reductions that are achieved as the carbon intensities of the fuel pool, electric grid and vehicle fleet improve over time. And consumers will benefit through market competition that results in a variety of innovative technologies that help to reduce the cost of carbon abatement for each fuel/vehicle technology pathway. Adopting a well-to-wheels approach, combined with fuel carbon intensity reductions, provides a broad spectrum of industries that power the transportation system (e.g., automakers, engine and equipment makers, petroleum refiners, power generators, and biofuels manufacturers) with incentives to reduce GHGs. [EPA-HQ-OAR-2021-0208-0247-A1, pp. 1-2]

Commenter: City of Albuquerque, NM

Furthermore, AQP is in the process of updating our gasoline vehicle emissions inspection program and creating a diesel vehicle emissions inspection program. [EPA-HQ-OAR-2021-0208-0535-A1, p.2]

Commenter: Clean Fuels Development Coalition (CFDC)

Over the past 15 years the CFDC has made dozens of submissions and comments to the U.S. Environmental Protection Agency (EPA) concerning the value of HOLC fuels as replacements for carbon-intensive, carcinogenic, and costly gasoline aromatics. Without exception, the EPA has rejected these comments as ‘outside the scope’ despite having requested comments on how ethanol’s superior octane properties can be used to meet the objectives of various EPA rulemakings such as the Tier 3 Rule and more recently, the SAFE Rule that is currently being revised. In addition to providing information on how HOLC Fuels can increase vehicle efficiency, we showed how high octane ethanol can protect public health by cost effectively replacing gasoline aromatics. Frequently, it seemed to us that two different sets of authors had been involved in the NPRMs and final rules.

CFDC had hoped this rule would turn out differently. Immediately upon taking office, President Biden singled out the SAFE-2 Rule as one of his Administration’s top priorities in the fight against climate change and promotion of environmental justice. The U.S. gasoline market is the world’s largest. Americans consume more than half of all the gasoline burned on earth. Gasoline is the primary source of U.S. carbon emissions and the most harmful urban toxics emissions. Consequently, CFDC assumed that President Biden’s EPA would recognize the opportunity the fuel economy rule presented and pay special attention to decarbonizing U.S. gasoline by substantially reducing its most carbon-intensive components: the carcinogenic aromatics petroleum refiners use to increase gasoline octane ratings. In fact, EPA is legally required to take such action by a mandatory provision first enacted in Section 202(l) of the 1990 Clean Air Act Amendments (CAAA).

CFDC was greatly disappointed when EPA in its proposed rule did not even request comments on how the US light-duty fleet's fuel efficiency could be improved and its carbon emissions could be reduced. We met with EPA staff, provided preliminary information, and requested that at a minimum EPA solicit comments on octane, just as the agency did in formulating the 2018 Final SAFE Rule. While EPA took no action on octane in that rule, as we testified in the August 2021 public hearing, we do not understand how the agency could acknowledge a potential role for high octane fuels then, but not now.

EPA Invokes Section 202(a) and 'Places Greater Weight on Reducing Emissions that Endanger Public Health and Welfare.' After years of disappointment, CFDC had feared the flawed analyses and anti-ethanol biases displayed by EPA's Office of Transportation and Air Quality (OTAQ) would once again prevent EPA's acknowledgment that HOLC fuels are a superior substitute for gasoline aromatics. However, the NPRM contained an obscure statement on p. 43729 in the Federal Register that rekindled CFDC's hope that Administrator Regan will honor his pledge to 'be driven by science and the rule of law' and direct OTAQ to comply with mandatory language in section 202(l) of the Clean Air Act that requires EPA to reduce gasoline aromatics to the 'greatest achievable extent'.

Specifically, the NPRM announced that EPA is 'revising decisions made in the SAFE final rule in accordance with Supreme Court decisions' based upon 'statutory purposes…in particular of section 202(a)'. EPA further explained that 'it is more appropriate to place greater weight on the magnitude and benefits of reducing emissions that endanger public health and welfare…'.

Section 202(a)(1) of the CAA states that 'The Administrator shall by regulation prescribe (and from time to time revise) * * * standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in the Administrator's judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare.'

Before the Administrator may issue standards addressing emissions of greenhouse gases from new motor vehicles or engines under section 202(a), the Administrator must satisfy a two-step test. First, the Administrator must decide whether the air pollution under consideration may reasonably be anticipated to endanger public health or welfare. Second, the Administrator must decide whether emissions of an air pollutant from new motor vehicles or engines cause or contribute to this air pollution. If the Administrator answers both questions in the affirmative, he/she must issue standards under section 202(a). Massachusetts v. EPA, 549 U.S. at 533.

However, Congress Made Its Own Endangerment Finding for Gasoline Aromatics When It Enacted Section 202(l).

Section 202(l) is a unique provision of the Clean Air Act in that it constitutes a Congressional endangerment finding—there is no need to wait for EPA to make one under section 202(a) because the MSAT provisions of CAA section 202 are not like most EPA provisions. including the climate endangerment sections, which ask for or authorize studies of possible harm as a necessary predicate to action.

According to C. Boyden Gray, Counsel to President George H.W. Bush during the CAAA deliberations, 'The MSAT provisions by contrast constitute a legislative finding of harm and command a correction--- an elimination of air toxics to the extent technology permits with attention to cost factors. There is no need to find harm---that having already been established by Congress.'

9th Circuit Ruled EPA Can't Selectively Choose Which Parts of a Statute to Enforce.

In the United States National Bank of Oregon v. Independent Insurance Agents of America, Inc. [508 U.S. 439---] decided in 1993, the DC Circuit found that the 'court must not be guided by a single sentence of a statute but must look to the provisions of the whole law and to its object and policy.' The court ruled that EPA could not uncouple one sentence of a section from the rest of the section in order to expand its authority beyond the aims and limits of the section as a whole.

Consequently, CFDC believes if EPA is going to justify its proposed revisions to the 2020 ruling upon the statutory objectives of section 202(a), it is also bound by the statutory requirements of section 202(l). As we noted above, this requires EPA/OTAQ to recognize that Congress has made a legislative endangerment finding as technologies present themselves.

U.S.C. 7545 Guidelines Support CFDC Position on 'Substantially Similar' and Legacy Vehicles. In the 1995 API v. EPA ROR ruling, the DC Circuit Court cited 42 U.S.C. section 7545, which authorizes EPA to control or prohibit the manufacture or sale of fuels or fuel additives if the agency finds that such fuels or fuel additives cause or contribute to air pollution or impair the performance of emission Control devices. However, before it can prohibit a fuel or fuel additive, EPA must do several things, including publish a finding that such prohibition will not cause the use of any other fuel or fuel additive which will produce emissions to endanger the public health to the same or greater degree than use of the fuel or additive to be prohibited.

CFDC believes that EPA is in violation of this legal principle because it has unlawfully blocked the use of higher ethanol blends as octane substitutes for highly toxic gasoline aromatics in defiance of the aforementioned Congressional endangerment finding. EPA's prohibition against the use of HOLC fuels such as E30 has led to the continued or expanded use of aromatics which Congress has directed EPA to reduce to the greatest achievable extent in section 202(l). EPA has known for many years that gasoline aromatics are the predominant source of highly toxic SOA-bound PAHs that its defective MOVES Model is unable to predict. Furthermore, PAHs formed in the presence of SOAs have a synergetic effect in which PN (particle number) concentrations are amplified by a factor of 100 or greater, and the particles are insulated and preserved, enabling long-range transport. EPA's failure to come clean on its models' deficiencies—and the grave consequences that has for public health—borders on professional malpractice.

Fuel Additive 'Already in Commerce'. In American Methyl Corp. v. EPA [749 F.2d at 943-836], the court determined that EPA must comply with this section to ban or control a fuel additive that is already in commerce. The Court wrote: 'This suggests that EPA's power to control a…fuel additive already in commerce is controlled by section 7545(c) and that EPA does not have an independent source of authority to control or prohibit nonrenewable oxygenates springing from the considerations enumerated in section 7545(k)(1).'

EPA Has Signaled its Intention to Avoid 202(l) Compliance by Claiming Excessive 'Lead Times' for E30 and HOLC Fuels to be used in Standard Vehicles.

In the NPRM [p. 43279], EPA states the following:

'We are revising decisions made in the SAFE final rule in accordance with Supreme Court decisions affirming that agencies are free to reconsider and revise their prior decisions where they provide a reasonable explanation for their revised decisions. In this rulemaking, the agency is changing its 2020 position and restoring its previous approach by proposing to find, in light of the statutory purposes of the Clean Air Act and in particular of section 202(a), that it is more appropriate to place greater weight on the magnitude and benefits of reducing emissions that endanger public health and welfare, while continuing to consider compliance costs, lead time and other relevant factors.'

CFDC challenges EPA's historical position as set forth in its 2018 Preliminary Regulatory Impact Analysis, where it gravely distorted the facts at pp. 256, 257:

' 6.3.2.2.17.3 Potential of higher octane fuels. Automakers and advocacy groups have expressed support for increases to fuel octane levels for the US market and are actively participating in Department of Energy research programs on the potential of higher octane fuel usage. Some positions for potential future octane levels include advocacy for today's premium grade becoming the base grade of fuel available, which could enable low cost design changes that would improve fuel economy and CO2. Challenges associated with this approach include the increased fuel cost to consumers who drive vehicles designed for current regular octane grade fuel that would not benefit from the use of the higher cost higher octane fuel. The net costs for a shift to higher octane fuel would persist well into the future. Net benefits for the transition would not be achieved until current regular octane fuel is not available in the North American market, and manufacturers then redesign all engines to operate the higher octane fuel, and then after those vehicles have been in production a sufficient number of model years to largely replace the current on-road vehicle fleet. The transition to net positive benefits could take many years.' (Emphasis supplied)

EPA's Assertion on High Octane Fuels, and specifically the use of E30 Clean Octane Fuels in Legacy Vehicles Is Insupportable on Technical, Commercial, and Legal Grounds.

Over the years, CFDC provided detailed information on the benefits from transitioning to a nationwide E30 Clean Octane standard. We rebutted EPA's assertions in its 2018 Preliminary RIA, which misstated the facts as noted above. EPA did not respond to CFDC's arguments, once again claiming them to be 'outside the scope' even though it had requested comment on that very issue.

In fact, the opposite is true. E30 can be safely used in, and benefit, standard (non-flex fuel) vehicles on the road today.1 Light-duty vehicles (LDVs) would operate more efficiently and with more power, the most dangerous tailpipe emissions would be substantially reduced, and consumers would save billions of dollars by paying less for a higher quality fuel. For example, between 2008 and 2014 U.S. gasoline prices remained well above the $3 per gallon mark. Without ethanol's contribution to the finished gasoline pool, Merrill Lynch estimated gasoline prices could have been 50¢ per gallon higher. The Department of Energy also concluded that ethanol reduces retail gasoline prices and reduces crude oil demand, which makes crude oil cheaper for the entire world.2 Other studies show using E30 would save consumers 20 cents per gallon. Consequently, this language should be deleted from the final SAFE Rule RIA.3

Ethanol Blends' Unique 'Time to Market' Strengths Are Critical to Success of the Biden Carbon Reduction Plan and its Role in Environmental Justice.

Even in a best-case scenario for transport sector electrification, literally TRILLIONS of gasoline-powered miles will be driven by Americans over the next several decades. In 2021, approximately 270 million light-duty vehicles (LDVs) will consume 120 billion gallons of gasoline containing 25% aromatics. U.S. LDVs are typically in service for 12 or more years. Every year, billions of gallons of aromatics will be emitted in the form of millions of tons of ultrafine particles (UFPs), secondary organic aerosol (SOA)-bound PAHs and other potent toxics, and black carbon (BC). Americans—especially infants, children, and other vulnerable citizens—will be exposed to billions of invisible nanoparticles on a 24/7 basis with no means of escape.

Unfortunately, unless EPA acts quickly, things will get worse. As gasoline direct injection (GDI) engines dominate the US fleet, the most dangerous emissions will get increase exponentially. GDI engines increase particle number (PN) and UFP-bound toxic emissions by a factor of 100 or more. Their associated, highly potent PAH toxics cause harm in the parts-per-trillion according to experts like Dr. Frederica Perera (Columbia University) and former NIEHS Director Linda Birnbaum.

Again, in the context of information that has already been submitted to EPA, a recent letter from the Alliance of Automotive Innovation (AAI) to former Senate Majority Leader Tom Daschle, chair of the High Octane Low Carbon (HOLC) Alliance, provides new information that we believe has been ignored. AAI's membership includes the manufacturers of 99% of all new LDVs sold in the U.S. There can be no more credible source of information about vehicle performance, the importance of fuel quality and octane, and the connection between emissions and human health. AAI stated high octane low carbon fuels can provide benefits 'in new and existing internal combustion engines and therefore should be encouraged … as soon as possible'.

This is not a new position for automakers—they have always recognized the importance of linking fuel quality to vehicle performance and emissions. In October 2011, the automakers' alliance wrote then-EPA Administrator Lisa Jackson: 'EPA has long recognized that vehicle technology and the fuel employed with that technology need to work in concert as an integrated 'system' so that vehicles can operate efficiently and achieve the lowest technologically and economically feasible emissions targets.'

They concluded the letter by saying: 'Furthermore, to help achieve future requirements for the reduction of greenhouse gas emissions, we also recommend increasing the minimum market gasoline octane rating, commensurate with increased use of ethanol. Adding ethanol to gasoline increases its octane rating. To attain necessary octane levels, it is important that refiners not be permitted to reduce base gasoline octane ratings in light of the additional octane contribution from higher ethanol.' This again is further justification for our rejection of any suggestion by EPA that octane is a 'new issue', or that octane is beyond the jurisdiction of EPA regulation.

Ten years ago, the AAM letter was written as EPA was considering its Tier 3 sulfur reduction rules. Despite requesting comment on how it could encourage widespread use of E30 (30% ethanol) high octane blends in the Tier 3 NPRM, EPA ultimately rejected CFDC's comments as being 'outside the scope'. Instead of complying with Congressional directives, for the past ten years EPA has covertly encouraged refiners to increase their use of aromatics and unlawfully blocked the use of HOLC Fuels.

Please see Attachment B for Relevant Automaker Documentation [Attachment B can be found in at docket number EPA-HQ-OAR-2021-0208-0564-A2, pp 16-17]

Background on the Potential and Appropriateness of High Octane Low Carbon Fuels.

On the first day of his new Administration, President Biden identified correction of the Trump SAFE rule as a top priority for new EPA Administrator Regan. President Biden announced that the EPA would expeditiously release a new fuel efficiency rule, the primary goal of which would be to reduce transportation sector carbon emissions 50% by the year 2030. President Biden also emphasized that environmental justice issues would receive paramount attention as his agencies develop plans to reduce transportation sector carbon emissions.

In its NPRM EPA stated that 'in addition to substantially reducing GHG emissions, a longer-term rulemaking could also address criteria pollutant and air toxics emissions from the new light-duty vehicle fleet'.

CFDC and others worked in good faith with EPA officials in recent months to develop a near term carbon mitigation plan that would be consistent with the President's 2030 goals as well as his emphasis on promoting environmental justice. CFDC pointed out to EPA that trillions of miles will be driven on gasoline in the United States for the next several decades as the transition to an electrified transportation sector occurs. This means that the 25% aromatics fraction of US gasoline which petroleum refiners use to boost gasoline octane levels will emit literally billions of highly toxic nanoparticles that will seriously damage Americans' health for years to come.

Oil interests prefer to use crude oil-derived, benzene-based aromatics even though Congress has required EPA to replace them with HOLC Fuel blends. And even though gasoline aromatics are the primary source of urban carbon emissions (especially potent Short-Lived Climate Pollutants such as black carbon) and highly pathogenic toxics such as SOA-bound PAHs, the career bureaucrats at OTAQ inexplicably block the use of HOLC Fuels to displace gasoline aromatics.

Congress knew that gasoline aromatics were a predominant source of both carbon and toxics emissions when it banned leaded gasoline in the 1990 Clean Air Act amendments. At that time Congress was determined to avoid the horrendous social and economic costs imposed on America and the world by the poisonous leaded gasoline. After months of exhaustive debates, Congress overwhelmingly approved mandatory language that requires EPA to reduce gasoline aromatics to the greatest achievable extent as technologies present themselves. Despite repeated directives over the years OTAQ continues to stonewall and erect unlawful barriers to aromatics' Congressionally-preferred replacement—HOLC Fuel blends made with ethanol.

Critical to Understand Importance of Legal Authorities Created by the 1990 Clean Air Act Amendments. CFDC was actively involved in the 1990 CAAA floor debates and the passage of the Daschle – Dole 'clean octane' provision. which catalyzed the Title II provisions including sections 202(a) and 202(l). Many view this as 'miraculous' because the Senate passed that controversial—and hugely consequential—amendment by the lopsided margin of 69-30, unimaginable in today's gridlocked Congress. A primary catalyst of the Senate floor vote was EPA's 1987 proposal to approve a new certification fuel with 45% aromatics, which the agency said was necessary to compensate for the ban on leaded gasoline. Oil interests pulled out all the stops to defeat the amendment (which would impose a 25% aromatics cap and require periodic reductions as 'technologies presented themselves'). The debate raged for months, with the oil industry spending millions of dollars in national media.

Ambassador C. Boyden Gray—who was White House Counsel to President George H. W. Bush during the 1990 CAAA debates—has noted that the Section 202(l) Mobile Source Air Toxics (MSAT) provision is unique in that it represents a 'Congressional endangerment finding' which 'pinpointed gasoline aromatics as a major human health threat that demands correction.

The Congressional Record debates prove beyond a shadow of a doubt that Congress was determined to prevent a repeat of the tragic human and economic costs the nation suffered under decades of lead poisoning (which Henry Ford had warned against in 1921 when he pushed for E30 high octane fuels). The Environmental and Energy Study Institute has since stated 'Aromatics Are the New Lead.'

Behind the scenes, OTAQ officials opposed the 1990 MSAT provision—we believe they resented having Congress tell them what to do about gasoline composition. Once it passed, they refused to enforce it and years went by with little or no action. When Senators Daschle and Lugar introduced the first Renewable Fuel Standard (RFS) bill, OTAQ also covertly opposed it. When RFS1 finally became law, some within OTAQ supported oil industry efforts to have Section 202(l) repealed during the 2005 EPACT conference negotiations. However, Congress did not forget the enormous threat aromatics posed to public health, and it doubled down, requiring EPA to promulgate the 2007 MSAT Rule eighteen months later.

In a slide deck presented on January 28, 2013, OTAQ's director of fuels policy contended that 'octane' has 'historically had no effect' on air toxics. 'CAA 211(c)(1)(A) – Cause or Contribute • EPA endangerment finding and regulation of GHG emissions from motor vehicles raises the issue of considering fuel controls that might reduce GHG emissions – Octane historically has had little or no effect on criteria pollutants or air toxics but could affect GHG emissions.' [Slide 13]

CFDC and others asked EPA how a veteran OTAQ fuels expert could make such an outrageous statement, but received no satisfaction until two years later, when in May 2015 a revised version deleted this erroneous assertion:

May 2015: 'CAA 211(c)(1)(A) – Cause or Contribute • First requires an EPA finding that emissions from a F/FA causes or contributes to air pollution that endangers public health and welfare – To date we have not done so for GHG under 211(c) - fuels – Only for motor vehicles under 202(a).'

We wonder why this statement was stricken from OTAQ presentations. Apparently, someone realized that it was indefensible yet took no affirmative action to correct the record.

One likely answer can be found in Senator Daschle's letter to Acting Office of Air and Radiation Director Joe Goffman, footnote #5, which referenced the Baldauf et al. 'Ultrafine Particle Metrics and Research Considerations: Review of the 2015 UFP Workshop' peer-reviewed report published in the International Journal of Environmental Research and Public Health. Here EPA's own scientists were finally forced to admit that their atmospheric models were hopelessly defective and that an entirely new paradigm must be developed for the synergetic relationship between PAHs and SOAs generated by the combustion of gasoline aromatics.

This OTAQ 'smoking gun' was clearly explained by Reid Detchon, Senior Advisor for Climate Solutions at the U.N. Foundation, at the February 2020 Clean Fuels Forum in Washington, DC.

As noted in a July 9, 2021, Inside EPA article, featuring an interview with former Senator Daschle, Stuart Parker wrote 'The agency has long studied octane issues in relation to the vehicle rules. For example, EPA fuel programs chief Paul Machiele told a 2015 event that the agency likely has authority to require higher octane levels but that the issue is 'complicated' and that it would not occur until after MY25, the original end date of the Obama rules.'

It is time EPA answered a serious question that lies at the heart of this rulemaking: Why is OTAQ so insistent that the gasoline aromatics issue cannot be taken up until 2025 and cannot be resolved until 2035 at the earliest—45 years after Congress directed EPA to urgently address the problem and five years after President Biden wants to see 50% reductions in transport sector carbon emissions?

CFDC's confusion is further compounded by the fact former OTAQ Director Chris Grundler has confirmed EPA's ongoing legal obligations under Section 202(l). Extensive correspondence between then-OTAQ Director Grundler (who was shortly thereafter transferred to EPA's Climate Office without explanation after 30+ years at OTAQ) and Doug Sombke, South Dakota Farmers

Union president, reinforces CFDC's concerns about OTAQ's failure to comply with Congressional directives.

Notably, in his March 15, 2018, letter to Sombke, Grundler acknowledged the importance of light-duty vehicle fine particle and associated emissions:

'We agree that ambient levels of PM are a result of secondarily formed particles in addition to direct PM emissions, and that light-duty gasoline vehicles are important sources of the precursors to PM formation.'4

As noted previously, EPA has asked for comment on 'if and how EPA could support the production and use of higher octane gasoline consistent with Title II of the Clean Air Act.' In the same letter, Grundler responded to Sombke's question about why EPA has not enforced the MSAT provision in Title II:

'With respect to Clean Air Act section 202(l), the EPA has acted twice under this specific authority, including the February 2007 rule that addresses the aromatic content of gasoline through required limits on benzene (72 FR 8428, February 26, 2007). … While the EPA continues to look for opportunities to further reduce air toxics, as required by Clean Air Act section 202(l), we must also consider technological feasibility and costs, among other factors.'5

In his April 9, 2018, response, Sombke pointed out to Grundler that EPA used obsolete and fallacious factual predicates in its 2007 MSAT CBA to conclude that it would not be cost effective to substitute E30 'clean octane' fuels for BTEX/aromatic hydrocarbons to replace lost octane.

EPA's 2007 MSAT Final Rule was an uninspired distortion of science and market rationale. However, there was one very important positive aspect directly germane to this rule in that EPA admitted '…there may be compelling reasons to consider aromatics control in the future, especially regarding reduction in secondary PM2.5 emissions, to the extent that evidence supports a role for secondary PM2.5 formation'. [Federal Register/Vol. 72, No. 27/Monday, Feb. 26, 2007/Rules and Regulations, p. 8479.]

EPA Has Failed Time and Again to Control Gasoline Aromatics with 'Clean Octane'.

Over the past ten years CFDC and its affiliated organizations have communicated with OTAQ and EPA dozens of times about to clean octane issues. In every case EPA has refused to recognize the best available science and the rule of law as it pertains to the displacement of gasoline aromatics by high octane ethanol. Below is a partial list of the EPA rulemakings and other official communications between it and CFDC that clearly prove that the 'clean octane' issue is not 'new' and should be squarely addressed in this final rulemaking.

- 2005 EPACT and 2007 Final MSAT Rule.
- 2011 EPA report to Congress.
- 2011 GHG rule.

• 2013 PM rule.
• 2013 CARB Short-Lived Climate Pollutant Rule (critical importance of black carbon).
• EFC/UAI letter to EPA Administrator Gina McCarthy regarding defective MOVES Model.
• 2014 Tier 3 Rule and EPA's discredited factual predicates.
• 2014 EFC and NIEHS toxics workshop.
• 2015 EPA UFP workshop.
• 2016 greenhouse gas rule mid-term evaluation review.
• 2017 REGS rule and E15 RVP waiver.
• 2018 Trump SAFE Rule.
• 2020 UN Foundation clean fuels forum.
• 2021 HOLCA SAFE-2 rule interactions (US LDV fuel efficiency declines prove 87 AKI gasoline insufficient, contrary to EPA assertions). [EPA-HQ-OAR-2021-0208-0564-A2, pp. 1-9]

Comments Specific to NPRM Section 8.3 on Environmental Justice Concerns

In Section 8.3 of the NPRM, EPA noted the importance of environmental justice considerations, including President Biden's February 1, 2021, Executive Order 14008 (86 FR 7619), which directed federal agencies to 'develop programs, policies, and activities to address the disproportionately high and adverse human health, environmental, climate-related, and other cumulative impacts on disadvantaged communities, as well as the accompanying economic challenges of such impacts'.

There are few environmental justice challenges that demand immediate attention more than the adverse impact pre-term births (PTBs) have on communities of color. CFDC believes that EPA's models' failure to account for gasoline aromatics' substantial contribution to the United States' terrible PTB performance demands attention in this final rule as part of EPA's revised section 202(a) emphasis on the public health and welfare.

http://www.nytimes.com/2012/05/03/health/us-lags-in-global-measure-of-preterm-births.html

Best Available Science Directly Connects Gasoline Aromatics' PAH Emissions to PTBs and IQ Loss.

The 2018 Perera et al. study on PM and PAHs established a causal link to numerous adverse health endpoints for children, including preterm births. That study reviewed 205 peer reviewed studies over a course of 15 years and concluded that significant economic benefits could be achieved by reducing fossil fuel related pollutants including gasoline exhaust emissions. A recent EPA study estimates economic benefits that can be achieved by reducing fine particle matter by 10% in urban areas with an estimated benefits range of $339 million to $1 billion.

The World Health Organization has given the United States a very bad report card with regard to global comparisons of premature births. A New York Times article noted that the rate of preterm births in the United States has risen 30% since 1981. The US preterm birth rate of 12% is in the same range as Kenya, Turkey, Thailand, East Timor, and Honduras and means that one in 9 births in the U.S. is early PTB increases the risk of both mortalities and long-term morbidities in infants.

In a study of immigrants from Mexico experts found that the longer a woman lived in the U.S. the greater her chances of giving birth prematurely. Even after controlling for risk factors like age, poverty, smoking, obesity and diabetes experts really don't have an explanation. However, experts were quoted as saying that ‘whatever it is it's not genetic. It is something they acquire here.’

Policy Implications

EPA economists recently published a report that attempted to do a preliminary benefit – cost analysis of reducing PTBs of a 10% reduction in PM and related toxics emissions. It concluded that such a reduction could yield annual savings of $1 billion.

To date, EPA has not included PTB in any BCA. However, at some point EPA is expected to update its most recent integrated science assessment (ISA) for PM which was last published in 2009. Experts believe that because of emerging new science this ISA will be changed to causal or likely causal meaning that EPA will be required to conduct a BCA for PBT economic costs imposed by PM and its associated toxics.

In October of 2001, the California Office of Health and Environmental Assessment (OEHHA) explained why the state had passed the Children's Environmental Health Protection Act in October 2001: ‘…this evaluation of POM as a toxic air contaminant causing health effects in infants and children was primarily based on the known health effects of PAHs. Prenatal exposure to PAHs results in serious or irreversible effects in the fetus. PAH are transplacental carcinogens, and the effect of fetal exposure is irreversible. There is greater exposure of children to environmental PAH compared to adults. Children's daily doses of PAH were generally higher from all routes of exposure than those of adults in the same household.’

The OEHHA concluded: ‘In view of this range of evidence for differential sensitivity of the fetus, infants and children to health effects induced to POM, OEHHA has placed PAH in Tier One of the priority list.’

Consequently, it is extremely significant that EPA has recently admitted that its models fail to predict substantial quantities of SOA-bound PAHs in the urban environment (see 2015 EPA UFP Workshop). This means that the benefit cost estimates presented here are significantly understated because the models upon which they rely are vastly underestimating the amount of PM and associated toxics that urban children and pregnant women cannot escape. If EPA were to update and correct its modeling, the benefit cost of reducing gasoline aromatics for not only PTB but other childhood adverse health conditions would be far greater than the billion dollars per year estimated here.

The authors note that the seriousness of the relationship between these toxic pollutants and PTB is especially concerning because by nature of the common presence of these pollutants, exposure is effectively unavoidable. Similarly, a disproportionate burden of exposure may be placed on individuals and disadvantaged communities, who are already subjected to multiple social economic and health iniquities.

Clean Air Act regulations promulgated to limit or reduce exposure to criteria pollutants including mobile source air toxics typically require benefit cost analyses. Economically significant regulations—those with an annual effect on the economy of $100 million or more—are required by a series of executive orders dating back to 1981. Consequently, this novel methodology, which was developed by EPA policy staffers at the National Center for Environmental Economics, may offer guidance for EPA as it considers reduction of gasoline aromatics under section 202(l). [EPA-HQ-OAR-2021-0208-0564-A2, pp. 9-10]

This Rule Demands an Accurate Cost Benefit Analysis on Reducing High Carbon, Toxic Octane Additives

EPA Has Relied on Five Major Flaws in its Policies to Improve Gasoline Quality

1: EPA claims its regulatory policies have been successful at reducing U.S. transportation sector's most prevalent and harmful source of carbon and toxics emissions. Fact: The opposite is true, as the agency has focused on diesel while gasoline direct injection (GDI) engines increase particulates and their toxics by orders of magnitude unless gasoline aromatics are reduced.

2: EPA has stated decarbonizing gasoline's 'octane' is a 'new issue' that must be addressed 'outside the scope' of this rule. Fact: Ethanol's 'clean octane' has been central to every major EPA transportation sector-related rulemaking since Congress banned the use of leaded gasoline in the 1990 CAAA.

3: EPA has stated high octane low carbon (HOLC) ethanol blends such as E30 are unsuitable substitutes for carcinogenic aromatics that petroleum refiners synthesize from crude oil and use to increase market gasoline octane ratings. Fact: HOLC fuel blends are superior in terms of octane and vehicle performance, substantially reduce carbon and the most dangerous toxics emissions, and cost less than the gasoline aromatics they would replace.

4: OTAQ's regulatory schemes as they relate to gasoline emissions seem to assume that ground level ozone poses a greater threat to human health than fine/ultrafine particulate matter (PM) and its associated toxics. Fact: Fine/Ultrafine PM accounts for 90% of the human health threat, ozone less than 10% (2011 EPA Report to Congress).

5: EPA's defective atmospheric models underestimate the degree to which gasoline aromatics produce fine/ultrafine PM, and incorrectly assume that their associated toxics dissipate after 300 meters. Fact: Gasoline aromatics are the predominant source of urban fine/ultrafine PM, and their potent toxics are transported long distances, where they penetrate into the lungs, brains, and organs of infants, children, and other vulnerable Americans.

CFDC has previously noted that in its 2016 TAR, EPA conceded that:

'It is important to quantify the co-pollutant-related health and environmental impacts associated with the GHG standards because a failure to adequately consider these ancillary impacts could lead to an incorrect assessment of the standards' cost and benefits. Moreover, the health and other impacts of exposure to criteria air pollutant and airborne toxics tend to occur in the near term, while most effects from reduced climate change are likely to occur only over a time frame of several decades or longer.'6

Unfortunately, when it comes to transportation fuels-related policy, EPA does not follow its own advice—it consistently fails to conduct the necessary cost-benefit analyses as required by law.

'However, there are several health benefit categories that EPA was unable to quantify due to limitations associated with using benefits-per-ton estimates, several of which could be substantial. For example, we have not quantified a number of known or suspected health benefits linked to reduction in ozone and other criteria pollutants, as well as health benefits linked to reductions in air toxics.'7

Now that EPA/OTAQ have admitted that their atmospheric models are defective and that gasoline aromatics are a predominant contributor to SOA-bound toxics and secondary PM2.5 emissions, it must act expeditiously to comply with Congressional directives by substantially reducing gasoline aromatics content.

EPA's Office of Transportation and Air Quality (OTAQ) used obsolete and faulty data for its 2007 MSAT CBA comparative economics model. The underlying economics and technologies have undergone radical changes during that period, all of which inure to the benefit of ethanol's cleaner octane. Consequently, as emphasized earlier, we respectfully urge EPA to use the pending rule to encourage a thorough but timely update to its 2007 MSAT CBA which includes current and accurate pricing, octane values, and ethanol production rate data. Most importantly, EPA needs to ensure the use of updated and accurate octane equivalency factors by the U.S. Department of Energy national laboratory data (e.g., Oak Ridge National Laboratory, Argonne National Laboratory, etc.), and incorporate the dramatic progress that has been made in the nation's ethanol blending infrastructure, including terminals, wholesale price differentials, and legacy fleet compatibility.8

Federal law requires agencies to justify major rules like the SAFE proposal with thorough cost–benefit analyses (CBAs). CBAs include assessments of societal costs associated with harmful emissions. Recent media reports have cited economists' criticism of EPA's attempt to redefine PM2.5 health effects to justify its proposed changes to the previous administrations carbon rule.

One prominent reporter noted 'The authors of the rule had counted the health benefits from reducing particles in their justification for why the benefits of regulating greenhouse gases outweighed the costs of implementing it. The health benefits of cutting CO2 become even more evident when paired with the 'co-benefits' of cutting fine particles.'

Recognition of E30's ability to substantially reduce gasoline exhaust PM and SOA-bound toxics is especially appropriate, because failure to reduce gasoline BTEX content will substantially

INCREASE such emissions as advanced engine technologies dominate the fleet.9 As Ambassador Gray pointed out, EPA should not be allowed to ignore the Title II section 202(l) mandates to control MSAT emissions in the same rule they are relying on section 202(a) statutory authorities to improve fuel efficiency and reduce carbon emissions.

In other words, the MSAT emission reductions from a nationwide E30 HOLC Fuels ‘clean octane’ standard will not be merely ‘co-benefits’. They will be primary, direct, and mandated benefits that address national climate and health priorities, while also providing enormous energy security/trade balance, farm sector, and economic benefits.

If EPA does a proper job in conducting such an updated Cost Benefit Analysis as part of this proposed rule it will confirm the following:

Climate, Health, Economic, and Environmental Justice Benefits

• The benefits of moving to High Octane Low Carbon E30 fuels are clear and substantial with regard to their impact on greenhouse gas emissions – potentially reducing U.S. emissions by more than 100 million tons a year before 2030, accounting for a significant share of the Biden Administration’s goal of 50% carbon reduction by 2030.

• E30 HOLC fuels have important ‘time to market’ advantages over competing carbon reduction strategies. Specifically, E30 HOLC fuels dramatically reduce black carbon (BC) emissions, a short-lived climate pollutant (SLCP) with a GWP (global warming potential) 3,200 more potent than CO2.10

• Effective January 1, 2017, EPA adopted E10 (10% ethanol/90% gasoline) blends as the nation’s ‘certification fuel’. This means that ethanol is ‘substantially similar’ under Section 211(f) of the Clean Air Act. EPA should correct its misinterpretation of that provision and remove its regulatory barriers so that E30 high-octane fuels may be legally used in non-flex fuel (standard) vehicles.

• In addition to its carbon benefits and central to EPA’s primary mission, E30 HOLC fuels offer substantial public health benefits, with the strongest impact being seen in urban communities, a priority of the administration’s environmental justice concerns. A 2021 assessment in the journal Environmental Research11 concluded that the fossil-fuel component of PM2.5 alone is responsible for more than 8 million premature deaths annually, amounting to nearly one-fifth of all global deaths. In other words, it is the leading cause of premature death from environmental pollution.

• The smallest particles are the most dangerous to human health. A 2019 report from the International Council on Clean Transportation, ‘Recommendations for Post-Euro 6 Standards for Light-Duty Vehicles in the European Union,’12 noted that the ability of inhaled particles to be captured within the human body, called the deposition efficiency, is a function of particle size. Vehicle exhaust, in particular that of gasoline direct injection (GDI) engines, contains copious amounts of particles in the size ranges with high deposition efficiency.’ ICCT experts have noted that ‘Compared to other octane-boosting alternatives, ethanol has unique octane properties. Properly blended E30-E40 HOFs used in optimized engines could double GDI particulate-borne toxics emission reductions (John German, ICCT, Health Effects Institute PM Workshop, www.healtheffects.org/meeting/workshop-effects-fuel-composition-pm).

• A research team which included the late Nobel Prize winner, Mario Molina, reported last year that ‘Photooxidation of vehicular exhaust yields abundant [UFP] precursors, and organics, rather than sulfuric acid or base species, dominate formation of UFPs under urban conditions. Recognition of this source of UFPs is essential to assessing their impacts and developing mitigation policies. Our results imply that reduction of primary particles or removal of existing particles without simultaneously limiting organics from automobile emissions is ineffective and can even exacerbate this problem.’13 Thus, given the role of aromatic hydrocarbons in PM formation, and given the propensity of GDI engines to increase emissions of UFPs, EPA’s strategies for regulating fine particle pollution in urban areas are doomed to failure unless they significantly reduce gasoline aromatics.

• ‘…almost 96% of contribution to the PMI is from aromatics.’14

• Oak Ridge National Laboratories (ORNL) singled out E30 HOLC fuels for their unique ability to facilitate EPA compliance with the Renewable Fuel Standard, the GHG – CAFE Rule, the Tier 3 Rule, and the MSAT provision (Section 202(l) of the Clean Air Act). [EPA-HQ-OAR-2021-0208-0564-A2, pp. 11-14]

Trade Deficit, Energy Security, & Critical Material Supply Chain Benefits

• A nationwide E30 'Clean Octane' Gasoline Standard would reduce U.S demand for imported oil by one billion barrels a year, which at $100 oil would free up an additional $100 billion/year for investment in the creation of quality jobs, improved infrastructure, and better health and education for our children.15

• Increased supplies of unconventional oil and gas (fracking) should not be eligible contenders for displacing oil imports because of their extremely high carbon intensity and toxicity which poses substantial risk to the climate and human health.16

• E30 HOLC fuels utilize 100% domestic inputs, so there is zero risk of critical material supply chain interference from foreign actors, unlike the energy transition minerals required by electric vehicle manufacturers.

• DOE’s Energy Information Administration (EIA) has warned of a worsening octane shortage in the U.S. as automobile manufacturers adopt advanced internal combustion engine designs such as direct injection and turbocharging in response to tighter fuel efficiency and carbon emission requirements. [EPA-HQ-OAR-2021-0208-0564-A2, p. 14]

Farm Sector Benefits

• A nationwide E30 'Clean Octane' Gasoline Standard would re-energize the U.S. farm economy without need for taxpayer subsidies.

• Nationwide E30 would increase U.S. Gross Domestic Product (GDP) by more than $100 billion/year and save motorists billions more at the pump for a cleaner-burning, higher octane, better performing fuel.

• Ethanol's high-quality concentrated protein co-products would benefit the nation's livestock producers and enable significant reductions in ruminant animal methane emissions. [EPA-HQ-OAR-2021-0208-0564-A2, p. 14]

Conclusion:

In the NPRM, EPA states the following:

We are revising decisions made in the SAFE final rule in accordance with Supreme Court decisions affirming that agencies are free to reconsider and revise their prior decisions where they provide a reasonable explanation for their revised decisions.5 In this rulemaking, the agency is changing its 2020 position and restoring its previous approach by proposing to find, in light of the statutory purposes of the Clean Air Act and in particular of section 202(a), that it is more appropriate to place greater weight on the magnitude and benefits of reducing emissions that endanger public health and welfare, while continuing to consider compliance costs, lead time and other relevant factors.

CFDC respectfully urges EPA to in fact 'revise its position'. It is EPA's duty to account for the health impacts, the legal obligations, and all the other factors identified in these comments as the agency finalizes this rulemaking.

Ambassador C. Boyden Gray, former White House Counsel to President George H.W. Bush during enactment of the 1990 CAAA, identified the fatal flaw in EPA's 2011 GHG – CAFE rule when he said:

'If EPA is going to rely on the CAAA to reduce mobile CO2, it cannot ignore the same statute's requirements to reduce mobile source air toxics, especially if that reduction also reduces CO2… EPA cannot under the CAA cause an increase of one form of regulated pollution that causes serious health problems by reducing another that does not.'17

Increasing gasoline octane now, while enforcing toxic controls, would provide significant efficiency gains and pollution reduction. As stated by the automakers themselves, the existing LDV fleet—and the environment and public health—would see immediate benefits from an orderly transition to 'clean octane' HOLC fuels such as E30. And the benefits would increase exponentially as optimized, higher compression vehicles dominate the LDV fleet.

At a minimum we ask, in the strongest terms, for a commitment in writing in this final rule to acknowledge the factual data we have provided and work with all stakeholders to recognize the need to focus on improving gasoline octane quality as a near-term priority to protect the public health and welfare, promote environmental justice, substantially reduce transport sector carbon and toxics emissions, advance the nation's energy security, and stimulate the agricultural economy without need for taxpayer outlays. [EPA-HQ-OAR-2021-0208-0564-A2, p. 15]

Appendix A

A Regulatory Roadmap to Ensure EPA Compliance with SAFE Rule Objectives: Enforce CAA Section 202(a) and Section 202(l) Requirements, Protect Public Health and Welfare, Reduce Transportation Sector Carbon Emissions, Strengthen the Nation's Energy Security, and Stimulate the Agricultural Economy

EPA/OTAQ have all the legal and scientific tools necessary to justify each of the action steps proposed below. EPA's implementation of this roadmap will stimulate and protect free market competition; dismantle unlawful regulatory barriers that have enabled the continued use of the most carbon intensive, costly, and carcinogenic gasoline components; and restore integrity to the oversight of programs designed to protect the nation's public health and welfare, consistent with the Administration's environmental justice priorities.

Encourage an Orderly Transition to a Nationwide 100 RON Higher Octane Gasoline Standard: Consistent with Title II of the Clean Air Act, transitioning to a nationwide 100 RON market gasoline octane standard using High Octane Low Carbon (HOLC) Fuels such as E30 would achieve multiple national priorities simultaneously with no need for taxpayer outlays. EPA should emulate the successful transitions from leaded to unleaded gasoline and the Reformulated Gasoline with Minimum Oxygen programs.

Comply with the Mandatory Mobile Source Air Toxics (MSAT) Reduction Provisions in Section 202(l) of the CAAA: Similar to the transition from leaded to unleaded gasoline and then RFG, Congressional intent was clear -- the CAAA was designed to spur technological innovation and force the development and advancement of both fuels and automotive technologies. Proper enforcement of Section 202(l) will ensure compliance with the Biden Administration's transportation sector carbon and air toxics reduction goals, consistent with environmental justice priorities and existing law.

Correct the Agency's Misinterpretation of 211(f) Substantially Similar Rule: As of January 1, 2017, E10 became the nation's certification fuel. At that time, ethanol became an additive used in certification of new vehicles and is therefore not subject to control under section 211(f). If EPA wishes to control the use of HOLC Fuels such as E30 in standard (non-FFV) vehicles, the legal burden of proof is on EPA under section 211c to prove that such fuels damage emissions control systems and/or contribute to harmful tailpipe emissions.

Update The Agency's Corn Ethanol Life Cycle Analysis (LCA): Bringing EPA's woefully outdated corn ethanol carbon footprint lifecycle assessment into line with the updated and more widely accepted Argonne National Laboratory GREET model is necessary to ensure EPA's reliance on best available science. Among other changes, EPA's LCA model should recognize the ability of high-yield corn to restore soil organic matter, which transforms corn acres into substantial carbon sinks. As precision agriculture advances are adopted, the corn ethanol carbon footprint should approach ‘net zero’.

Update the Agency’s 2007 Mobile Source Air Toxics (MSAT) Cost-Benefit Analysis (CBA): EPA’s obsolete and wildly inaccurate factual predicates used in its 2007 MSAT rule (e.g., $19/barrel crude oil, $.85 gasoline, and a 2:1 ethanol’s octane replacement value for toluene/BTEX/aromatics) were used to support EPA’s conclusion that replacing toxic aromatic hydrocarbons with higher octane lower cost ethanol could not be economically justified. A properly done CBA will confirm that HOLC Fuel blends would cost effectively reduce the most harmful mobile source air toxics and ultrafine particulates.

Approve a Mid-Level Ethanol Blend Certification Fuel: EPA should expeditiously approve the use of a mid-level ethanol certification fuel (e.g., E30) to provide automakers with a clear pathway to design optimized, higher compression vehicles optimized to use 98–100 RON gasoline.

Update and Reform the Agency’s MOVES2014 Model: EPA has admitted that its atmospheric models—especially and including MOVES2014—are defective and in need of significant repair. OTAQ should immediately suspend the use of its defective and outdated MOVES2014 model which was built upon manipulated fuel samples provided by oil interests. Samples provided for the model contained the deliberate addition of ‘high boiler’ aromatics ‘to match blend’ and designed to produce negative results for ethanol blends. The results unfairly and inaccurately attribute higher emissions to ethanol rather than added aromatics.

Accelerate and Ensure Completion of the HOLC Fuel Infrastructure Buildout. Most of the nation’s terminals, underground storage tanks, and retail dispensers have been approved and readied to accept HOLC Fuels such as E30. EPA should encourage rapid completion of the infrastructure buildout, similar to the expeditious and effective transition to E10 blends as a result of the first Renewable Fuels Standard.

Reinstate Credits for Automakers Producing Engines Optimized for HOLC Fuels Such as E30: EPA should provide the regulatory roadmap and supporting data to help stakeholders interested in establishing meaningful CAFE/GHG credits, financial incentives to cover the cost of certification, or other ideas that would incentivize automakers to produce engines that utilize high octane low carbon fuels (e.g. E30).

Extend the 1 psi RVP Waiver for E10 to E15 and all Higher Blends: EPA’s longstanding misinterpretation of the Reid Vapor Pressure (RVP) prevents a timely transition to higher octane fuels. It must be rectified without delay. [EPA-HQ-OAR-2021-0208-0564-A2, pp. 16-17]

10 Black carbon is considered the second most important human emission in terms of its climate forcing; only carbon dioxide (CO2) has a greater overall effect. Because black carbon is rapidly removed from the atmosphere by deposition, its atmospheric concentrations respond quickly to reductions in emissions. Such reductions are thus an attractive near-term mitigation strategy to

slow the rate of climate change – especially as the short-term (20-year) global warming potential per ton of black carbon is 3200 times that of CO2.

Commenter: Defour Group (Defour)

Recognizing the increased urgency of reversing the trend of ever-increasing CO2 emissions, Executive Order 13990 was issued that instructed all Federal agencies including EPA to ‘immediately review all existing regulations, orders, guidance documents, policies, and any other similar agency actions promulgated, issued, or adopted between January 20, 2017, and January 20, 2021,that are or may be inconsistent with, or present obstacles to,, the policy set forth in section 1 of this order [to mitigate climate change]. For any such actions identified by the agencies, the heads of agencies shall, as appropriate and consistent with applicable law, consider suspending, revising, or rescinding the agency actions.’

Under various pieces of legislation, EPA regulates both vehicles and the fuels that power these vehicles. Yet in response to Executive Order 13990, EPA considered only area under their purview to review: vehicle tailpipe CO2 standards. We urge that the agency consider the fuel-related regulations under its authority in this rulemaking or a timely future one.

Various agencies including EPA have tried to reduce greenhouse gas emissions from gasoline use through rate-based regulatory mechanisms. Yet in the 40 years such standards have been employed1, gasoline use has increased 32%. Since 2005, when ethanol began to be mixed into gasoline, the total gasoline use remained constant but the amount of fossil fuels in that gasoline declined as fossil fuels were replaced by ethanol: a replacement that went largely unnoticed by the motoring public.

If EPA, in addition to the standards being proposed in this rulemaking, were to adopt regulations under the Clean Air Act and the Renewable Fuel Standard (RFS) to facilitate the introduction of high octane low carbon fuels like E30 and the vehicles optimized for those fuels, substantial reductions could be made in reducing fossil fuel use between now and 2050. This would provide substantial CO2 reductions while the national effort to electrify the transportation sector expands and further brings down greenhouse gas emissions. [EPA-HQ-OAR-2021-0208-0257-A1, pp. 1-2]

On August 10, 2021, the U.S. Environmental Protection Agency (EPA) published ‘Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards’ in the Federal Register. This rulemaking was being undertaken by EPA in response to President Biden’s Executive Order 13990, ‘‘Protecting Public Health and the Environment and Restoring Science To Tackle the Climate Crisis’’ to, according to EPA, ‘consider whether to propose suspending, revising, or rescinding the standards previously revised under the ‘The Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021– 2026 Passenger Cars and Light Trucks,’’ promulgated in April 2020.’

This, however, is a very limited interpretation of what the Executive Order asked agencies within the Federal Government, including EPA, to do. This Executive Order clearly framed the purpose of this order by stating: ‘the policy of my Administration to listen to the science; … to reduce greenhouse gas emissions; [and] to bolster resilience to the impacts of climate change. … To that end, this order directs all executive departments and agencies to immediately review and, as appropriate and consistent with applicable law, take action to address the promulgation of Federal regulations and other actions during the last 4 years that conflict with these important national objectives, and to immediately commence work to confront the climate crisis. ‘

What the agencies were being tasked with was also clearly stated. ‘The heads of all agencies shall immediately review all existing regulations, orders, guidance documents, policies, and any other similar agency actions promulgated, issued, or adopted between January 20, 2017, and January 20, 2021, that are or may be inconsistent with, or present obstacles to, the policy set forth in section 1 of this order [to mitigate climate change]. For any such actions identified by the agencies, the heads of agencies shall, as appropriate and consistent with applicable law, consider suspending, revising, or rescinding the agency actions.’

In other words, the Executive Order calls for a review of all agency actions taken in the last four years that could have adversely impacted this nation’s efforts to reduce greenhouse gas emissions and, once identified, consider revising or reversing these actions. In some specific areas, however, the Executive Order required agencies to complete this inquiry by certain dates.

EPA is responsible for a number of regulations relating to the impact of motor vehicles on climate change. Based on a common sense reading of Executive Order 13990, it should be expected that some discussion of all of the regulations, including fuel-related regulations, should have been reviewed and discussed in this rulemaking. This, however, did not happen.

One of the most obvious omissions was the failure of EPA to acknowledge or address regulations under the agencies’ control that impact the content of motor fuel, and more specifically, the role of biofuels in reducing greenhouse gas emissions. [EPA-HQ-OAR-2021-0208-0257-A1, pp. 2-3]

Biofuels and Electrification

By EPA’s own admission, the proposed CO2 standards in this rulemaking are only modest steps to achieve the meaningful reductions in fossil fuel use required to stabilize atmospheric CO2 levels5. Rather, to achieve that goal in some distant future time, the agency believes that extensive electrification of the transportation sector will be required. EPA states in their Regulatory Impact Analysis:

‘While we anticipate that the proposed standards will be met primarily through the continued penetration of conventional powertrain (e.g., internal combustion engine, transmission) improvements … we anticipate … long-term GHG reduction goals will require a far greater penetration of ZEVs than this proposal would require through MY2026. The need for substantial increases in fleet penetration of ZEVs over the long term is supported by the recommendations of the National Academy of Sciences, which states in its 2021 Light-duty Vehicle Technology Assessment: ‘The agencies should use all their delegated authority to drive the development and deployment of ZEVs, because they represent the long term future of energy efficiency, petroleum reduction, and greenhouse gas emissions reduction in the light-duty fleet'.'6

This proposal represents a modest reduction in fossil fuel use while electric vehicles are the plan for eventual elimination of gasoline as a transportation fuel. What if anything is being done to decarbonize the transportation sector in the meantime?

The Limits to Electrification of the Transportation Sector. As early as the late 1980s, electricity was identified as one of the obvious replacements for petroleum in the transportation sector. For instance:

• Electric vehicles are much more efficient that internal combustion engines. The average gasoline powertrain converts about 20% of the energy in the gasoline into useful energy at the wheels while electric drivetrains convert about 75% of the energy in the battery into useful energy.

• Electricity can be made from a variety of low and non-carbon sources. Of the ten electric generating plants with the highest capacity in the US, only two use fossil fuels while the others – seven nuclear and one hydroelectric – produce electricity with little or no carbon emissions. In addition, the use of solar and wind to generate electricity is increasing and other forms of low carbon energy, such as geothermal and tidal are being explored.

• Electric vehicles have low local emissions. Electric vehicles produce minimal local pollution and noise which make them ideal for crowded urban areas.

In spite of these advantages, there are significant limits to how much of the fleet can be electrified in the next half century. These include vehicle, infrastructure and material limitations.

• Vehicle Limitations. Electric vehicles also have some serious limitations that have over the last century limited their usefulness. Nearly all of these limitations – such as low range (especially in extremely hot or cold temperatures), high cost, high weight, limited towing capacity and slow recharge time are a function of battery itself. While great advancements have been made in battery technology since the first modern EV was introduced in 1996 (the GM EV-1), electric vehicles still cannot match the overall utility of liquid fueled vehicles in many applications. Vehicle not amenable to electrification will still require some form of liquid fuel well into the 21st century.

While some of these limits can be overcome by adding more batteries to increase range and power, this strategy is limited by the carrying capacity of the nation's roads and bridges. One example of this is the Hummer electric pickup, which has one model with a gross vehicle weight of 9,500 lbs. – nearly 5 tons. This exceeds the load capacity on some smaller local bridges.

• Infrastructure. The first most obvious infrastructure issue is the requirement for more electric generating capacity. Using EIA data, replacing the energy in BTU provided by gasoline in 2050 with electricity would require the construction of over 80 nuclear power plants or their equivalent in other low carbon sources. Even the much more conservative estimate of EPA in their Regulatory Impact Assessment suggests electric vehicles in 2050 would use the equivalent of one additional nuclear power plant for power.

Getting the power from the source to the vehicle is another issue. The nation has over 6 million miles of power lines, many of which are antiquated and in need of replacement. At the vehicle level, home rechargers would require extensive upgrades in wiring and the installation of home chargers. Public chargers would be needed for those without garages and people in transit. Finally, much of the vehicle manufacturing infrastructure would need to be replaced.

• Materials. Vehicle manufacturing is one of the most material intensive businesses in the world. Each vehicle weights at least 1½ ton; each year about 70 million are produced. This is possible because vehicles are made from materials that are readily recyclable. The average gasoline tank weights about 20 pounds and is made of steel or plastic. Its counterpart in an electric vehicle – the battery – can weigh over 1,000 pounds and in made up of rare materials like lithium and rare earth compounds that will largely have to be extracted from the earth rather than recycled. How fast the supply of these raw materials can be expanded may determine the growth rate of electric vehicles.

Some of these limitations, such as range and power may never be totally overcome. Others like infrastructure may be overcome with enough time and money. But it is clear that the likely scenario is that liquid fuels and electricity will coexist throughout the remainder of the 21st century. This then leaves a gap between what EPA is doing to reduce petroleum use in the transportation sector now and what can be accomplished with electrification in the long term. [EPA-HQ-OAR-2021-0208-0257-A1, pp. 11-13]

Biofuel as an Additional Mid-Term Option

The proposed tailpipe CO2 emission standards proposed by EPA beginning in 2023 will in effect be a midterm solution, not becoming fully effective until the middle of the century. Even then, the proposed standards would only reduce petroleum use to the levels when fuel economy standards were first in effect.

The ever rising levels of CO2 in the atmosphere, however, demands that more be done than just compensate for the historical shortcoming of rate-based standards. Fortunately, tailpipe emissions are not the only tool at EPA’s disposal: the agency also has considerable power under both the Clean Air Act and the Renewable Fuel Standards to regulate the fuels used in those vehicles as well.

Biofuels such as ethanol have been used to power motor vehicles since the invention of the internal combustion engine. Gasoline – ethanol blends have been on the market since the early 20th century, and expanded with the enactment of the RFS. Today, virtually all gasoline sold in the U.S. contains at least 10% ethanol.

When ethanol is added to gasoline, it directly substitutes for fossil fuel and boosts the octane rating of the fuel. When ethanol was first added to regular gasoline to comply with the RFS, the octane of the resulting fuel was that of a mid-grade fuel (89 AKI octane). Retailers often marketed it as such, thereby creating a mid-grade gasoline that cost the same or less than ethanol-free regular. Rather than allow consumers to benefit from the additional octane that ethanol provides, refiners created a cheaper special sub-octane gasoline7 to be used only as a blend stock for mixing with ethanol, and the resulting blend became a 87 AKI octane regular grade gasoline.

Over the last decade, the U.S. Department of Energy (DOE) has been investigating the potential of biofuels to significantly both improve the efficiency of internal combustion engines and displace the use of fossil fuels as an energy source. As stated in a recent DOE report,

'New engine architectures and combustion strategies can provide higher thermodynamic efficiencies than those that are currently delivered by commercially available internal combustion engines, but new fuels are required to maximize efficiency and operability across a wide range of speeds and loads.8'

One of the most promising of these potential fuels is a mixture of 30% ethanol and 70% gasoline blend stock, or E30.

Using the same blend stock as today's regular grade fuel, an E30 fuel could be made that had higher octane than today's premium grade fuel (thus allowing automakers to build higher efficiency internal combustion engines). In addition, this fuel would cost consumers about the same as regular grade gasoline.

Using this fuel's higher octane, automakers could build liquid fueled vehicles with more efficient engines that would compensate for the lower energy content of ethanol. Most importantly for reducing atmospheric levels of CO2, the additional ethanol would displace a significant amount of petroleum. Mid-level ethanol blend fuel like E30, when fully phased in, would reduce petroleum use to a level not seen since 1969 as illustrated in Figure 8 [Figure 8 can be found at docket number EPA-HQ-OAR-2021-0208-0257-A1, pp. 13-14].

As a complement to the rate-based standards established by this proposal, EPA should use its regulatory authority to facilitate the rollout of a new fuel and the vehicles optimized to use them. At the very minimum, EPA should:

• Mandate a minimum fuel octane standard. EPA has the authority under existing to establish fuel specifications such as octane. Just as lead in gasoline made it impossible to use catalytic converters on vehicles, the low octane of today's regular grade gasoline impairs the ability of automakers' to increase an engine's compression ratio to make the engine more efficient, As explained above, such a standard would help pave the way for significant reductions in petroleum use.

• Revise existing regulations to allow the advantages of this new fuel to be reflected in regulatory compliance. Some of EPA's regulations related to fuel economy testing, such as the formula for calculating fuel economy do not reflect the environmental advantages of ethanol. Another regulation that calculated the R-factor, which EPA acknowledges needs changed, has yet to be updated.

• Use their authority under the RFS to gradually raise ethanol blending requirements beyond 2022 to reach the congressionally mandated level for 2022 in 2050. Obviously, to phase-in a new fuel like E30 that would eventually replace today's gasoline would require more ethanol. The total amount required, however, is not excessive. It appears that the ethanol required would, peak at 33 billion gallons in 2050 – slightly less than Congress mandated to be blended into vehicle fuel for 2022. Enabling this gradual conversion in liquid fuels, when compared to the cost of electrification, is modest and could result in a significant reduction of fossil fuel in the mid-term period as electric vehicles enter the fleet. The Clean Air Act give EPA the regulatory power to establish high octane low carbon fuel standards and other related vehicle standards to facilitate the transition. The Renewable Fuel program gives EPA the power to ensure that this new fuel will actually replace fossil fuels. Done correctly, this transition could be largely transparent to the motoring public. [EPA-HQ-OAR-2021-0208-0257-A1, p. 14]

1 For analytical purposes, the years 1979 through 2019 were used except where noted. Although passenger car standards were in effect for the 1978 model year, 1979 was the first year both passenger cars and trucks were subject to standards. Similarly, the analysis ended at 2019, the last full year in which the COVID 19 pandemic was not a factor.

5 According the EPA in their Regulatory Impact Analysis, this proposal would not have its maximum impact until 2050, and then would reduce gasoline consumption by only 9.9%.

Commenter: Exxon Mobil

ExxonMobil believes that existing transportation sector-based federal policies (fuel and vehicle standards) could be improved to achieve meaningful GHG emissions reductions through complementary standards that transition the vehicle fleet to a lower GHG emissions mix of vehicles and incentivize lower carbon intensity fuels (liquid, compressed/liquefied gas, electricity, hydrogen) used to power the vehicles.

For the policies to be clear and quantifiable, we list the following framework:

1. A well-designed, technology neutral, lifecycle, carbon intensity fuel standard measured in gCO2e per MJ of fuel energy (gCO2e/MJ) will establish reasonable and achievable targets and provide a long-term market signal for the production and use of lower carbon fuels. The standard will help reduce carbon across the entire vehicle fleet (currently comprising mainly of internal combustion engines) and can be expanded beyond road transportation to the marine and aviation sectors in the future.

2. A GHG emissions standard for new vehicles based on well-to-wheels (WTW) lifecycle emissions accounting methodology will drive lower CO2e emissions per mile driven (gCO2e/mile) complementing the above mentioned carbon-intensity based standards for the energy used by the vehicles.

3. Power grid carbon intensity measured in gCO2e per unit of energy (gCO2e/MJ) for electricity available for use in electric vehicles.

A WTW approach for new vehicle certification will incentivize both more efficient vehicles and those which use lower carbon intensity fuels.

The performance metric for new vehicles will be gCO2e/mile, similar to today. Vehicle manufacturers will continue to drive improvements in vehicle efficiency (mile/MJ), but vehicle certification will recognize the lifecycle GHG emissions reductions using up-to date fuel pool and electricity carbon intensities:

gCO2e/mile = Certification Fuel CI (gCO2e/MJ) / Vehicle Efficiency (mile/MJ)

In the case of liquid fuels,

gCO2e/mile = Cert. Fuel CI (gCO2e/MJ) x Energy Density (MJ/gallon) / Vehicle Efficiency (mile/gallon)

For example, as the electricity grid and liquid fuels reduce carbon, the policy recognizes lower GHG emissions for both an electric and an internal combustion vehicle.

Current vehicle GHG standards account for fuel combustion or tank-to-wheels (TTW) emissions vs. a WTW approach which accounts for lifecycle emissions. The graph below provides an illustrative example comparing four vehicle types (internal combustion engine, hybrid, plug-in-electric, and battery-electric). The analysis uses data from the most recent EPA Automotive Trends report4 and for PHEV and BEV vehicles compares EPA-reported carbon intensities of U.S., Rockies and California electricity grids. [EPA-HQ-OAR-2021-0208-0734-A1, pp. 1-2] [The table can be found on p.3 of Docket number [EPA-HQ-OAR-2021-0208-0734-A1]]

Comparing all vehicles on a WTW methodology enables consistent GHG accounting. This provides the greatest degree of advancement of all technologies that can reduce GHG emissions and results in policy which is more effective at transportation carbon reductions.

As EPA finalizes the rulemaking on 'Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards', ExxonMobil respectfully recommends that the Agency includes description of the WTW methodology in the preamble of the final rule and considers this approach in future vehicle GHG standards rulemakings. [EPA-HQ-OAR-2021-0208-0734-A1, p. 3]

Commenter: Fuels Freedom Foundation

To maximize GHG reductions from light-duty transportation, the EPA must look upstream. Recognizing that a more holistic approach is outside the scope of the GHG standards that will be established by this rulemaking, the comments below recommend that in the Final Rule, the EPA commit to concrete actions to incorporate a full fuel cycle perspective to support and facilitate aggressive GHG reductions for the period under review and the longer term. [EPA-HQ-OAR-2021-0208-0231-A1, p. 1]

Benefits and Costs of High Octane Fuels

Higher-octane fuel was proffered by the EPA in Tier 3 to help automakers meet light-duty GHG standards,6 and recommended as a low-cost option in Phase II of the NHTSA-commissioned National Research Council study.7 The EPA acknowledged OEM and stakeholder support for high octane and requested comment on high-octane in the SAFE proposal. 8 The Department of Energy’s (DOE) CoOptimization of Fuel and Engines (Co-Optima) Phase 1 provided a valuable guide to the synergistic GHG benefits of spark-ignition vehicle technologies powered by fuels with the optimal properties to power them. An additional trove of peer-reviewed research from universities, automakers, petroleum companies, national labs and others bolsters the case. Appendix A to these comments provides a summary of research evaluating the impacts of high-octane fuel on fuel efficiency, GHG and criteria emissions, and costs.

Despite being a premium offering today, high-octane fuels need not increase driving costs. A study found that high compression engines coupled with high-octane fuels could reduce costs compared to other vehicle technologies.9 The National Renewable Energy Lab (NREL) found that high-octane fuels made with increasing levels of ethanol “are sufficiently competitive” with the current fuel to achieve “substantial market share.”10 Oakridge National Lab (ORNL) found “significant benefits for the United States” in that “automotive OEMs, consumers, fuel retailers, and ethanol producers all stand to benefit to varying degrees as HOF [high-octane fuels] increases its market share.”11 Even the petroleum industry has recognized the benefits of high octane in general, and ethanol in particular.12,13 From an economic perspective, studies differ on the ideal octane number, but have found ethanol to be the most cost-effective source of octane. 14,15,16 From an auto engineering perspective, there is consensus for 98-100 RON to maximize efficiency and/or performance gains regardless of the fuel formulation, but with additional marginal benefit if ethanol is the octane source.17 Consequently, Fuel Freedom joins automakers and other stakeholders18,19 and others in urging EPA to consider fuels and vehicles as an interconnected system, and to formally recognize that the system is currently limited in GHG reduction potential by 85-87 AKI gasoline.

Potential Role of Octane in MY2023-2026

The MY2023-2026 timeframe is critical not only as a gateway to greater GHG emissions reductions beyond MY 2026, but to fully capitalize on the recent increase in support for E15 and significant investments in fueling infrastructure to support higher ethanol blends. The E10 experience clearly indicates that, in the absence of an octane requirement, the social benefit (consumer, economic, environmental) will be lost if refiners again lower the octane level of the base gasoline product. Raising the national minimum octane will ensure the value of additional octane provided by E15 and higher blends up to E85 accrues to American consumers and U.S. national interests.

Even without optimization or new engine technology, premium fuel can provide a 1-2% efficiency benefit for existing ICE vehicles.20 However, to maximize cost effectiveness, higher-octane fuels must be the base offering, rather than a premium-priced niche product.

Much of the current gasoline infrastructure could be modified to deliver either petroleum-derived high-octane fuels or higher ethanol blends such as a mid-level E25-E40 and in many cases, up to E85.21 High-octane fuels with a maximum of 15% ethanol have been approved for vehicles MY2001 or newer. Market adoption of high-octane ethanol blends can also be expedited by 20+ million Flex-Fuel Vehicles (FFVs) on the road today22, as well as optimized future FFVs that may be produced in response to a commitment from EPA to ensure that high-octane fuels are generally available.

As designated by Congress, FFVs were intended to interchangeably use either gasoline or ethanol blends up to 85%, explicitly to assist a transition from petroleum-based to renewable fuels. 23 If lowcarbon midlevel blends of 20-40% ethanol are introduced, FFVs provide a ready source of demand for the fuels, in advance of the introduction of new models of compatible or dedicated high-octane vehicles. Critically, greater use of ethanol or other low-carbon octane sources can decrease not only tailpipe CO_2, but full fuel cycle GHG emissions relative to gasoline. Consequently, Fuel Freedom believes that FFVs should receive full credit for their GHG reductions. The same is true for future vehicles dedicated for use with midlevel ethanol blends.

A new minimum octane number is necessary to enable and advance low-cost GHG reductions; however, the new minimum must not preclude higher-octane formulations. The EPA should commit to exercising its recognized authority to reduce GHG emissions in light-duty transportation in order to facilitate a national transition to a higher minimum octane, and ensure that no regulatory barriers bar the market from determining the blend levels and/or source of octane. 24,25,26

Fuel Freedom recognizes that this recommendation is outside the scope of the GHG standards that will be established by this rulemaking. However, a more holistic perspective ultimately will be necessary for the EPA to maximize lifecycle GHG emissions in light-duty transportation. The EPA should commit to initiating the full technical, environmental and economic analyses for regulatory approval of highoctane ethanol blends in the Final Rule, to maximize the potential lifecycle GHG reduction potential for advanced ICE engine technologies produced in MY2023-2026, and provide a strong market signal for additional improvements into MY2027 and beyond.

Long-term GHG Reductions in Light-duty Transportation

Regardless of the octane source, high-octane fuels can enable significant reductions in fuel cycle CO_2 emissions. Argonne National Lab's comprehensive study on the well-to-wheels GHG emissions of various high-octane fuels found a 6% reduction using high-octane RON 100 E10 compared to RON 92 E10. When using higher ethanol blends of E20 and E40 to achieve a RON 100, the GHG emissions decreased by 17% and 27%, respectively.27

The relationship between vehicle energy efficiency and fuel carbon intensity, and the necessity to consider fuels and vehicles as a holistic system, are described in detail in an NREL paper. 28 In evaluating ICE, hybrid electric vehicles (HEV), battery electric vehicles (BEV) and fuel-cell electric vehicles (FCEV), the study found that, without a decrease in the carbon intensity of the fuel, all fall short of reducing GHG emissions by 80% by 2050, as needed to limit global temperature rises to 2°C or less per the United Nations Framework Convention on Climate Change (Paris Agreement).

Fuel Freedom funded a study to evaluate possible scenarios for achieving an 80% fuel cycle reduction in light-duty vehicle GHG emissions for the U.S. and for California by 2050.29 The analysis used government estimates30 of fuel carbon intensity, vehicle efficiency improvements (including those contained in the SAFE proposal), and incremental costs for each fuel-vehicle combination, to develop feasible market penetrations for various pathways. Pathways include gasoline technologies (including high-octane fuels with high-compression-ratio ICEs coupled with electrification), biofuels used in ICEs with and without hybridization, HEVs, plug-in hybrid electric vehicles (PHEVs), FCEVs, and BEVs in order to compare both feasibility and relative cost effectiveness for carbon reductions.31 Long-term results to 2050 indicate that it is critical to provide market flexibility in the near term. Regulations should therefore encourage or facilitate all feasible vehicle-fuel pathways that can maximize GHG reductions for the long term by a transition to renewable sources, including electricity, hydrogen, and biofuels.

Another key finding of this analysis is that policies that accelerate a decrease in the carbon intensity of fuels could reduce total GHGs sooner. As EPA has noted, “future [GHG] emissions are expected to produce larger incremental damages as physical and economic systems become more stressed in response to greater climatic change.”32 Given the uncertainties in measuring the long-term impacts of GHG emissions, 33 and the accumulated impacts of carbon emissions,34 EPA should not discount the benefits of pathways with significant promise to reduce emissions faster in the near-term.

Therefore, Fuel Freedom recommends that EPA investigate measures to ensure that all potential pathways to reduce GHG emissions in the light-duty transportation sector, including those that foster demand for low carbon intensity fuels, are considered on equal footing with other technologies in the Final Rule.

Summary and Recommendations

As noted in the Proposed Rule, the MY2023-2026 period is a vital gateway to the future of light-duty transportation. This Rule comes at a critical juncture for not only the future of light-duty transportation, but for the U.S. contribution to global efforts to reduce the possibility of catastrophic effects due to climate change.

Real world experience shows that consumer response cannot be either forced or taken for granted. Even optimistic estimates project that spark-ignition ICEs will dominate U.S. light-duty sales for many years, not to mention the total on-road fleet of hundreds of millions of legacy vehicles. Consequently, it is vital that EPA initiate actions to maximize GHG reductions from these vehicles. This means looking not just to vehicle technologies as in the past, but to the liquid fuels that enable them. EPA actions in conjunction with the Final Rule have the potential to ensure that no feasible pathway to dramatically and cost-effectively reduce GHG emissions and carbon intensity of the sector is foreclosed.

In this context, Fuel Freedom respectfully submits the following recommendations:

• Commit to initiating approval of higher-octane fuel(s) including midlevel ethanol blends and prepare for an expedient and minimally disruptive nationwide transition to raise the minimum octane in the marketplace.

• Commit to initiating as soon as possible, a full technical, economic and environmental analysis in preparation to raise the national minimum octane level in the U.S. fuel supply.

• Commit to incorporating a full fuel-cycle perspective to thoroughly analyze and compare the GHG emissions and total costs and benefits of fuel-vehicle systems, and develop policies and regulations according to this holistic approach.

• Fully credit vehicle technologies for the GHG reductions, including those vehicles that are designed to use low-carbon liquid fuels [EPA-HQ-OAR-2021-0208-0231-A1, p. 2-6]

21 Market forces are already moving toward higher ethanol blends. All underground fuel storage tanks manufactured since 2005 are compatible with 100% ethanol. The ethanol industry continues its Prime and Pump initiative to install blending pumps at retail fueling stations. And major fuel pump manufacturers have incorporated higher ethanol compatibility into their standard offerings.

23 Congress provided a statutory goal of encouraging “the development of widespread use of…ethanol…as transportation fuel by consumers” and “the production of…ethanol…powered motor vehicles.” Alternative Motor Fuels Act of 1988, Pub. L. 100-494 § 2, 102 Stat. 2441, 2442 (1988)

26 Legal experts assert that the EPA could rely on the CAA 211(c)(1) authority given the findings in CRC Final Report for CRC Project No. E108 that “consistent with the loss of FE, the fleet CO2 results correspondingly increased for the 85 AKI test fuel

31 Each pathway centered on a dominant vehicle technology, constrained by practical limitations and the attributes of cars versus trucks or SUVs. Vehicles not suitable for battery electric propulsion were assumed to be ICEs.

Commenter: Growth Energy

it is imperative to consider the vital role that environmentally sustainable fuel options such as ethanol will play in further reducing greenhouse gas emissions from the current and future vehicle fleet. It is also imperative to consider the full lifecycle emissions of all vehicle and fuel technologies to accurately evaluate the profiles and benefits of vehicles using different fuels and energy sources.

Ethanol is the most available and affordable means to immediately clean up our liquid fuel supply. Recent data from Environment Health and Engineering show today's corn ethanol reduces greenhouse gas emissions by an average of 46% compared to gasoline and can provide reductions of up to 70% with the use of readily available technologies.1 Ethanol's other environmental benefits are also noteworthy. As has been researched, the use of more ethanol and ethanol-blended fuel reduces air toxics such as carbon monoxide, benzene, and other harmful particulates.2

With a stable policy and access to drivers, our industry can deliver low-carbon, low-cost, high-performing, sustainable vehicle fuel solutions that reduce greenhouse gas emissions now and well into the future.

EPA must recognize the full lifecycle net greenhouse gas emission reduction benefits of vehicles that use ethanol and other low-carbon fuel alternatives to gasoline.

The proposal overlooks ethanol's benefits as a key means to reduce greenhouse gas emissions. Notably, the notice of proposed rulemaking (NPRM) doesn't contain any discussion of ethanol, other than passing reference (without discussion) such as to "Ethanol-E85" in a table. The NPRM's failure to fully evaluate the greenhouse gas emissions reduction benefits of ethanol use in vehicles is a critical error, and undermines the rule's analytical foundation, for two reasons. First, ethanol fuels the vast majority of vehicles addressed by the rule, which have internal combustion engines (ICE) that run on at least 10% ethanol.3 In fact, more than 95% of vehicles on the road today can run on up to 15% ethanol.4 Second, the entire purpose of this rulemaking is to reduce greenhouse gas emissions, yet this rulemaking overlooks the key role of ethanol in reducing vehicle greenhouse gas emissions. Ethanol can reduce vehicle greenhouse gas emissions on average 46% compared to gasoline with further reductions using readily available technologies.5 [EPA-HQ-OAR-2021-0208-0279-A1, pp. 1-2]

The proposal ignores ethanol as a key greenhouse gas emissions reduction strategy for the vast majority of the vehicle fleet. The NPRM concedes that over 92% of new light-duty vehicles will continue to use internal combustion engines through model year 2026. Specifically, EPA finds that electric vehicles (EV) and plug-in hybrid electric vehicles (PHEV) represent only 2% of the model year 2019 market, growing to 7.8% by model year 2026. (NPRM at 43,775). This means that the vast majority of vehicles addressed by the rulemaking will rely on varying blends of ethanol and gasoline. All gasoline light duty vehicles on the road today are approved for use with a 10% ethanol blend and 98% of the gasoline used in the US is blended with at least 10% ethanol.6 Furthermore, almost all gasoline light duty vehicles on the road today can run on up to 15% ethanol.7 EPA also ignores the key greenhouse gas-reducing role of flex-fuel vehicles (FFVs), which can run on up to 85% ethanol and were 20% of all vehicles produced for the U.S.

market as recently as 2014.8 Moreover, various next generation engines, including downsized and turbo-charged engines, may be particularly well suited to run on mid-level ethanol blends, which provide a clean, renewable source of octane.9 [EPA-HQ-OAR-2021-0208-0279-A1, p. 2-3]

Regarding EPA's extensive knowledge of and experience with life cycle greenhouse gas emissions analysis, the Renewable Fuel Standard (RFS) program administered by EPA is predicated on biofuels reaching certain thresholds of lifecycle greenhouse gas reductions to qualify for programmatic benefits. In its past 2012 rulemaking on EPA vehicle GHG standards, EPA asserted the existence of the RFS as an excuse not to consider life cycle emissions in its vehicle greenhouse gas program.19 However, the RFS only addresses fuel incentives, and alternative fuel vehicle incentives in this current 2021 NPRM are critical to ensure that both low carbon fuels and vehicles are available to work synergistically to reduce greenhouse gas emissions. Furthermore, the RFS just establishes a floor for biofuels use. Incentives for vehicles that can use high levels of biofuels (such as FFVs) are necessary to promote the higher use of biofuels and the corollary greenhouse gas emission reductions of doing so. Incentives for FFVs under EPA's vehicle greenhouse program can facilitate compliance with both the vehicle greenhouse gas program and the RFS, enabling far greater greenhouse gas emissions reductions than the floors established by those programs. [EPA-HQ-OAR-2021-0208-0279-A1, p. 5]

EPA should take action to encourage the use of higher biofuel blends such as E15 and E85 in today's vehicle fleet including providing year-round access with vapor pressure parity.

Today, E15 is approved for all 2001 and newer vehicles, more than 95% of today's vehicle fleet and more than 97% of the vehicle miles traveled. Two recent studies found that by moving to E15 nationwide, we can immediately reduce greenhouse gas emissions by more than 17 million tons, the equivalent of taking nearly 4 million cars off the road while also creating an additional 183,000 U.S. jobs.20 21 In order to facilitate the use of E15 nationwide and gain these important GHG and economic benefits, EPA must provide US consumers with greater access to the fuel. Given the oil refiners' recent court victory to deny American consumers year-round access to E15, it is imperative that EPA take all actions to restore RVP parity for E15. E15 remains available for year-round sale in reformulated gasoline markets as well as other lowvapor pressure areas that also give parity between E10 and E15. EPA should embark immediately under its existing authority to regulate vapor pressure to extend this parity in other conventional fuel markets as well. Not only will the sale of E15 deliver greenhouse gas and economic benefits, providing parity by lowering the vapor pressure of fuel in the conventional markets will result in considerable emission benefits as has been noted and seen in RFG and other vapor control markets. Additionally, EPA should finalize the pending regulation that would broaden the use of existing fueling infrastructure for use with E15 as well as to simplify the label for American consumers.22 By broadening availability and use of existing infrastructure, EPA will provide consumers access to these higher biofuel blends that deliver meaningful GHG and other emissions benefits.

In addition to E15, it is also important to consider the use of E85 in the sizeable flex-fuel vehicle fleet. Today, there are more than 20 million FFVs on the road and more than 5,000 fueling locations across the country. In California alone, the use of E85 has more than tripled since 2014 (see table below, “Annual E85 Volumes”).23 Given the considerable GHG benefits, EPA should take additional actions to ensure the continued production of FFVs in conjunction with the growing use of E85. Further below, we will provide additional considerations to encourage and promote the continued production of flex-fuel vehicles. [EPA-HQ-OAR-2021-0208-0279-A1, p. 5-6] [Prime the Pump Figure can be found on p. 6 of Docket number EPA-HQ-OAR-2021-0208-0279-A1] [Annual E85 Volumes Table can be found on p. 7 of Docket number EPA-HQ-OAR-2021-0208-0279-A1]

EPA should require a minimum octane standard and approve a high-octane, low-carbon mid-level ethanol blend.

It is imperative to consider the benefits of using high-octane, low carbon fuels to make engines more efficient. Growth Energy has been a leader on the need for higher octane, mid-level ethanol blends, first submitting a proposal for a 100 RON, E30 fuel nearly a decade ago. The science supporting the benefits of a high-octane, low carbon midlevel blend in conjunction with a high compression ratio engine is not new, and has been well-explored by the national labs, automobile manufacturers, and other scientific institutions.24 Ethanol has a very high-octane number, has a lower carbon content than the gasoline components it replaces, and has myriad other benefits that assist in combustion to increase engine efficiency and reduce both greenhouse gas and tailpipe criteria pollutant emissions. We are attaching our previous submission and related comments for your review. We urge EPA to move quickly to require a minimum octane standard as well as to approve a high-octane, mid-level ethanol blend such as that first proposed by Growth Energy for vehicle certification as well as for consumer use. By moving towards higher octane, lower carbon mid-level blend, automakers can optimize engines to further improve efficiency and further reduce both greenhouse gas and tailpipe emissions.

EPA should establish strong renewable volume obligations (RVO) for 2021, 2022, and well into the future to encourage the production and use of lower carbon biofuels.

The RFS has been one of our nation’s most effective climate programs. In fact, Argonne National Laboratory recently found that with the advent of the RFS, the carbon intensity of corn ethanol has fallen by 23 percent.25 ecause of ethanol’s use in fuel, EPA must continue to advance the goals of the RFS and provide access to and a foundation for these lower carbon biofuels. To that end, the agency must establish clear and strong RVOs for 2021, 2022, and set strong volumes under the RFS “Set” well into the future. EPA must also move expeditiously to approve pending pathways and pathway registrations including those for cellulosic biofuels from kernel fiber and other technologies that have languished at the agency for years. In many cases, these fuels are already certified to cellulosic carbon intensities under California’s LCFS but have yet to receive approval as such by EPA for the RFS.26 EPA must move quickly to approve these pathways and give certainty to the renewable fuel market by establishing strong volumes so that the vehicles of today and tomorrow can reduce their climate footprint through the increased use of lower carbon biofuels. [EPA-HQ-OAR-2021-0208-0279-A1, p. 7-8]

EPA must make technical adjustments to further incentivize production and use of flex-fuel vehicles (FFVs).

EPA must re-instate the volumetric conversion factor (VCF) for FFVs. Doing so provides incentives for all the main types of alternative fuel, low-carbon vehicles, not just a subset of preferred technologies.

By way of background, a statutorily derived volumetric conversion factor (VCF) of .15 is specified for calculating CAFE compliance for ethanol FFVs. The statutory provisions at 49 U.S.C. 32905(a) establishing the .15 VCF are incorporated into EPA regulations at 40 CFR 600.510-12(j)(2)(iv)(B) for FFV greenhouse gas calculations through model year 2015. FFV fuel ("E85") nominally contains up to 85% ethanol and only 15% gasoline, parallel to the .15 factor.27 Under EPA regulations, the .15 VCF is still used to increase the fuel economy compliance value of FFVs, to reflect the CAFE program's goal to reduce petroleum consumption.28 [EPA-HQ-OAR-2021-0208-0279-A1, p. 8]

EPA must re-instate the VCF for FFVs based on the significant greenhouse gas emission reductions benefits of these FFVs.

EPA has emphasized the desire to move to "near-zero emissions" technology, and FFVs can be a "near-zero emission technology."29 RFS calculations have generally found no tailpipe CO2 emissions for ethanol when calculating lifecycle emissions.30 This is because tailpipe CO2 is regenerated by crops used as fuel feedstock. This biogenic carbon uptake and EPA approach merit use of the VCF for the ethanol component of E85. This "zero emissions" ethanol (as found by EPA) can be matched with renewable naphtha for a 100% renewable, "zero carbon" fuel. Additional innovations at biorefineries and on the farm, along with cellulosic biofuels can also get to zero greenhouse gas emissions on a lifecycle basis. [EPA-HQ-OAR-2021-0208-0279-A1, p. 9]

Cost considerations also dictate EPA fully considering incentivizing FFVs. The NPRM states standards under Clean Air Act section 202(a), which provides the statutory authority for this rulemaking take effect "after such period … necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period." (NPRM at 43,728). Importantly, FFVs are a lower-cost compliance option compared to other more expensive technologies. It is imperative that EPA consider these lower-cost, highly effective solutions in its rulemaking analysis.

The VCF is also justified under EPA criteria in the NPRM to "to accelerate the introduction of zero and near-zero emissions vehicles and maintaining momentum for that market transition." (NPRM at 43,757). The NPRM references these criteria regarding the need for EV/PHEV/FCV incentives, but these criteria also apply to FFVs. Notably, the same needs of "maintaining momentum" apply to FFVs. Without reestablishing the VCF, automakers will stop making FFVs, eliminating a key compliance option for the vehicle greenhouse gas and CAFE programs. After EPA stopped allowing the VCF for vehicle greenhouse gas program compliance calculations, FFV production dropped from almost 20% of all 2014 light-duty vehicles to only about 8% of 2016 vehicles.31 FFV production for 2019 was down by almost 75% relative to 2014.32 Clearly, this is a loss in "momentum," and the VCF is needed to accelerate use of FFVs as a critical greenhouse gas reduction technology. [EPA-HQ-OAR-2021-0208-0279-A1, p. 9]

FFVs meet other EPA criteria for vehicle incentives under EPA's vehicle greenhouse gas program. For instance, EPA identifies the need for "significant" greenhouse gas emission reductions from incentivized technologies.34 Still elsewhere, EPA emphasizes the need for lowemissions technologies that create "opportunities for achieving the more stringent later year standards."35 FFVs can achieve "significant" greenhouse gas emission reductions and create "opportunities for achieving the more stringent later year standards." nder various aspects of the NPRM's stated logic, FFVs should receive the VCF incentives to fully reflect the greenhouse gas benefits of FFVs. [EPA-HQ-OAR-2021-0208-0279-A1, p. 10]

The VCF avoids the adverse programmatic consequences of multipliers.

Once FFVs are also appropriately incentivized, based on their significant lifecycle greenhouse gas emissions benefits, all the main kinds of alternative fuel vehicles (FFVs, EVs, PHEVs, and fuel cell vehicles) would be covered by at least some vehicle greenhouse gas program incentive. This would avoid EPA focusing on any one or subset of alternative fuel technologies. Technology-neutral, performance-based standards are broadly preferred. For instance, the NPRM interagency review raised questions about the "necessity of multiplier credits" which "are not technologically neutral" and could be "counterproductive."36 EPA should follow this technology-neutral approach by providing appropriate incentives for all the major types of alternative fuel vehicles, based on their ability to reduce lifecycle greenhouse gas emissions.

The VCF avoids the adverse programmatic consequences of multipliers. EPA recognizes multipliers "reduce the effective stringency of the standards" by counting more than once (multiplying) benefits from a single vehicle. (See e.g., NPRM at 43,733). Also problematic regarding EPA's use of multipliers, EVs and PHEVs are not truly a near-zero emission technology because, regarding their fuel, EVs and PHEVs rely on electric generation which broadly is not "near zero" emissions. The NPRM finds the electric generating sector will rely on fossil fuels through 2050.37 Because EVs and PHEVs rely on fossil fuel electricity well into the future, these EVs and PHEVs are not "near zero" greenhouse gas emissions vehicles. y contrast, a VCF for FFVs based on lifecycle greenhouse gas emission reductions does not have the detrimental effect of "reducing the effective stringency of the standards" because all these FFV emissions reductions are (a) "real-world" and (b) not counted more than once. It is arbitrary and capricious for EPA to fail to incentivize FFVs with a VCF that can meet the metrics that EPA uses for other vehicle incentive technologies without the detrimental impacts of the EV/PHEV multipliers. [EPA-HQ-OAR-2021-0208-0279-A1, p. 10]

The VCF must be reinstated in the GHG program for FFVs in a manner similar to how it currently appears in the regulations for FFVs through model year 2015, which is a relatively straightforward regulatory fix.

The VCF must be reinstated for FFVs in EPA's vehicle greenhouse gas program (in a manner similar to how it currently appears in 40 CFR 600.510-12(j)(2)(iv)(B) for FFVs through model year 2015), to reflect the lifecycle greenhouse benefits of ethanol. Under these existing EPA regulations as currently stated in the CFR applicable through model year 2015, the tailpipe carbon emissions of FFVs are multiplied by the VCF to reflect the lifecycle greenhouse gas benefits of ethanol use. The desired, restored formula would be as follows, when assessing FFV carbon emissions (formally referred to as Carbon Related Exhaust Emissions or "CREE"):

CREE = (F × CREEE85 x VCF) + ((1 − F) × CREEgas).38

Through model year 2015, the VCF was established at .15. This is appropriate where, under certain EPA approaches to calculating greenhouse gas emissions, the ethanol portion of E85 (nominally 85% of the fuel) can be considered "zero carbon." As noted above, RFS calculations have generally found no tailpipe CO2 emissions for ethanol when calculating lifecycle emissions.39 EPA should use a VCF of .15 (based on the Congressional level set under the CAFE standards) or such other level as EPA considers reflects the lifecycle greenhouse gas benefits of ethanol. For EPA's greenhouse gas vehicle program, a VCF of at least is .5 (perhaps also multiplied by .85 to reflect the nominal ethanol content of E85) is appropriate based on ethanol averaging approximately 50% lower greenhouse gas emissions than gasoline on a full lifecycle basis.40

To put the VCF in the CREE formula into perspective, for a selected FFV based on a popular model type (a Ford F-150), E85 has had about a 10% lower CREE based on the FFV's tailpipe emissions alone. This improves that FFV's overall CREE around 1.4% without the VCF.41 Applying the VCF to account for ethanol's lifecycle carbon benefits improves that FFV's CREE about 10% to 6% (if a VCF of .15 or .5, respectively, is used in the above CREE formula). [EPA-HQ-OAR-2021-0208-0279-A1, p. 11]

In summary, for all the reasons stated above, EPA must provide the VCF for FFVs, established at a level of .15 or some other figure that accurately reflects the lifecycle greenhouse gas emissions reduction benefits of E85 used in FFVs. If the VCF is reinstated, the rule would be appropriately technology neutral with the EV/PHEV/FCV multipliers continuing on at the levels and limits proposed in the NPRM. EPA's best option is simply to restore the VCF for FFVs which should be re-instated under any circumstances. [EPA-HQ-OAR-2021-0208-0279-A1, p. 12]

Reestablishing the VCF is appropriate under the EPA vehicle greenhouse gas program's statutory authority, as the VCF has previously been in place under the regulations through model year 2015.42 The NPRM's own goals for reducing greenhouse gas emissions from light duty vehicles, for all the reasons stated above, dictate that EPA should reestablish the VCF for FFVs within the EPA vehicle GHG program. [EPA-HQ-OAR-2021-0208-0279-A1, p. 12]

3 The NPRM finds that electric vehicles will have limited market deployment (less than 8%) over the time period covered by this rulemaking. (NPRM at 43,775).

33 Potential EPA concerns regarding less-than-optimal E85 use by FFVs during this time period are misplaced, because EPA failed to enforce the Renewable Fuel Standards during this time frame, which undercut an important source of improved E85 pricing during this timeframe. Now, with increasing desires by EPA to reduce greenhouse gas emissions, and the use of a real-world F factor in EPA regulations reflecting E85 use, FFVs are primed to be an important compliance option based on real-world greenhouse gas emission reductions.

34 See e.g., NPRM at 43,760, noting the NPRM's proposed elimination of multiplier incentives for natural gas vehicles because "EPA does not view NGVs as a pathway for significant vehicle GHG emissions reductions" (emphasis added).

39 See RFS final rule at 75 FR 14,788 (2010) and accompanying regulatory impact analysis, supra. As mentioned above, the RFS provides only a "floor" of demand for fuels that meet minimum lifecycle reduction thresholds; using a VCF in EPA's vehicle GHG program is essential to maintaining FFV production to promote vehicles that can use those lower carbon fuels and achieve higher levels of biofuel use.

41 These figures are based on a Ford 150 FFV that has CREE of 468 grams/mile using E85 and 522 grams/mile using gasoline. This calculation is based on using E85 instead of gasoline for 14% of fueling per the above "F" factor. The real-world greenhouse gas reductions of this and other FFVs would increase significantly as E85 fueling is used more often, including under strong Renewable Fuel Standards, which would increase the F factor.

Commenter: High Octane-Low Carbon Fuel Alliance (HOLC)

As stakeholders with considerable experience and expertise in areas relating to the interaction of fuel properties and vehicle performance, fuel cycle carbon intensity, and light-duty transportation policy, we are deeply disappointed by the EPA's failure to at least reference high octane, low carbon fuels as one tool for advancing the reduction of GHG emissions and improving the fuel efficiency of light-duty passenger vehicles. For as long as internal combustion engines remain on the road during the next 30 years, high octane, low carbon fuels will be needed, delivering significant reductions in carbon emissions today and providing a critical bridge to an electrified future. [EPA-HQ-OAR-2021-0208-0262-A1, p. 1]

Our comments highlight the mounting body of evidence confirming that higher octane, lower carbon fuels have the ability to contribute significantly to achieving the Biden-Harris Administration's goals of reducing carbon emissions by half by 2030 and reaching a net zero economy by 2050. Indeed, such fuels would achieve greater emissions reduction at less cost than the standards in the Proposed Rule. [EPA-HQ-OAR-2021-0208-0262-A1, p. 2]

As noted by the EPA in the Proposed Rule, the transportation sector is the largest contributor to U.S. GHG emissions. For that reason, the EPA has focused its attention on the growing shift to electric vehicles (EVs) to achieve the administration's goal of cutting carbon emissions in half by 2030 and reaching a net zero economy by 2050. Both the administration and automakers have committed to significant investments to transition from widely available internal combustion engines to electrification. However, automakers also acknowledge that 'the average age of a vehicle in the U.S. is now roughly 12 years',2 and, therefore, a large portion of vehicles will rely on liquid fuels in the coming decades. In 2021 alone, approximately 270 million light-duty vehicles will consume 120 billion gallons of gasoline containing 25 percent aromatics. Therefore, automakers are 'continuing to invest in vehicle improvements that increase fuel economy and reduce [GHG] in internal combustion engine vehicles' – many of which 'can be enhanced or complemented with the use of high octane, low carbon liquid fuels.'3 Liquid fuel will continue to be the predominant source of transportation energy, along with its GHG emissions and toxic byproducts, for years to come.

Reducing GHG emissions and improving the fuel efficiency of vehicles, therefore, requires a more immediate clean fuel solution, such as higher octane, lower carbon fuels. While EVs offer tremendous potential for helping reach net zero emissions, decarbonizing liquid fuels would deliver immediate emissions reductions in the meantime. Making today's engines and fuels as efficient, low carbon, and clean as possible now will have significant near-term benefits.

Increasing the use of biofuels such as ethanol with a lower carbon footprint than gasoline would unlock direct and indirect benefits for the climate. Specifically, increasing the ethanol fraction in our transportation fuel would reduce GHG emissions from light-duty vehicles by more than 12 percent, roughly 123 million metric tons annually, principally by enabling vehicles to operate more efficiently – a greater reduction than would be achieved by the new vehicle standards in the Proposed Rule. Enabling the wider use of mid-level ethanol blends would also support the more stringent vehicle standards for MY 2026 contemplated in the Proposed Rule and enable automakers more easily to comply.

Higher Ethanol Blends are Critical to Reducing GHG Emissions in Half by 2030

A 2017 assessment by the consulting firm ICF concluded that life-cycle GHG emissions associated with producing corn-based ethanol in the U.S., using today's practices in a typical natural gaspowered refinery, are almost 43 percent lower than those of gasoline on an energy-equivalent basis.4,5 This estimate is consistent with more than 15 years of life-cycle analysis at Argonne National Laboratory, recently reaffirmed in a retrospective analysis.6,7 It is also more than twice as large as the 21 percent reduction predicted by the EPA for an average natural gas-fired plant in 2022 in the agency's 2010 life-cycle analysis for ethanol.8 Argonne senior scientist Michael Wang estimates that the use of corn ethanol resulted in a total GHG reduction in the U.S. of more than 500 million metric tons between 2005 and 2019.9

In contrast, for electric and plug-in hybrid vehicles EPA has used 'tailpipe-only values to determine vehicle GHG emissions, without accounting for upstream emissions' in the Proposed Rule.10 This is misleading: EPA notes on its website that the power used to charge EVs may create carbon pollution. Further, EPA and the U.S. Department of Energy's (DOE's) 'Beyond Tailpipe Emissions Calculator' is offered to help individuals 'estimate the greenhouse gas emissions associated with charging and driving an EV or a plug-in hybrid electric vehicle.'11

The benefits of increased ethanol use can be achieved quickly. The proven technology used by today's ethanol industry enables rapid scale-up. The industry tripled its production capacity in just four years – from 4.4 billion gallons a year in 2005 to 14.5 billion in 2009.12 U.S. ethanol production capacity today is 17.4 billion gallons.13 The transportation fuel infrastructure has also adapted to the increased use of ethanol in cars and light trucks. New gas pumps are now certified for mid-level ethanol blends.14

The Energy Information Administration projects that demand for gasoline will decline from 137.5 billion gallons per year in 2021 to 127 billion gallons in 2050, due to increased vehicle efficiency and greater use of electric vehicles.15 Fueling the 2050 fleet with higher-level blends such as 30 percent ethanol blends (E30) would, therefore, require little more than a doubling of today's ethanol capacity. Demand will fall further if EVs are adopted more rapidly than currently envisioned.

Additionally, increased use of ethanol would bring a national security benefit. U.S. ethanol production in recent years has averaged more than 1 million barrels per day. Increasing that level to support an E30 market would displace more oil than the standards in the EPA and U.S. National Highway Transportation Safety Administration (NHTSA) Proposed Rules would save – producing an oil security premium valued at more than $1 billion per year.16,17

Higher Ethanol Blends Provide Clean, Affordable Octane to Improve Fuel Efficiency of Light-Duty Vehicles

Octane is needed in gasoline to prevent premature combustion of the fuel mixture ('knock'), which can damage engines.18 Higher octane enables greater engine efficiency and improved vehicle performance through higher compression ratios and/or more aggressive turbocharging and downsizing – also facilitated by ethanol's cylinder 'charge cooling' effect due to its high heat of vaporization.19 Raising the engine's compression ratio from 10:1 to 12:1 could increase vehicle efficiency by 5 to 7 percent.20,21

To increase octane enough to achieve these efficiency gains (i.e., to a 'premium' rating of 94 AKI (anti-knock index) at the gas pump), there are two principal options – aromatics or alcohols.22 Both have much higher octane ratings than base refinery gasoline.

Since 2016, researchers at nine National Laboratories participating in the DOE's Co-Optimization of Fuels & Engines initiative (known as Co-Optima) have explored how simultaneous innovations in fuels and engines can boost fuel economy and vehicle performance, while reducing emissions.23 The initiative identified 10 candidate fuels from four chemical families – alcohols, olefins, furans, and ketones – with the greatest potential to increase vehicle efficiency. Seven of them were alcohols.24

A team at Oak Ridge National Laboratory found that intermediate alcohol-gasoline blends, particularly E30, 'exhibit exceptional antiknock properties and performance beyond that indicated by the octane number tests,'25 and that engine and vehicle optimization could offset the reduced fuel energy content of such blends and likely reduce vehicle fuel consumption and tailpipe carbon dioxide (CO2) emissions.26,27 The use of E30 in one test vehicle enabled a 13:1 compression ratio, reducing CO2 emissions by 6 to 9 percent.28

Enabling use of high octane, mid-level ethanol blends would significantly reduce the cost of stronger fuel economy standards, a 2016 analysis by AIR, Inc., found.29 In a recent letter, the Alliance for Automotive Innovation, a group of automakers that produce nearly 99 percent of the new light-duty vehicles sold in the U.S., said:

[A]s automakers invest significantly in the transition to expanded vehicle electrification, the auto industry is also continuing to invest in vehicle improvements that increase fuel economy and reduce greenhouse gases in internal combustion engine vehicles. Many of the technologies being used to make these improvements can be enhanced or complemented with the use of high octane, low carbon liquid fuels. These fuels would simultaneously support vehicle performance, including fuel economy, and further reduce greenhouse gas emissions during vehicle use. Such benefits would be realized by new and existing internal combustion engines and therefore should be encouraged as additional solutions as soon as possible to maximize environmental benefits across the fleet. Given the timespan over which combustion technology will continue to be sought by new car shoppers, and the timespan that those vehicles will remain in the field, low carbon liquid fuels are an increasingly important technology pathway to help achieve carbon reductions while the electric vehicle market continues to grow.30 (emphasis added)

U.S. consumption of gasoline adds roughly 1 billion metric tons of CO2 to the atmosphere each year.31 Based on current consumption rates of gasoline, increasing vehicle fuel economy by 7 percent with the higher octane of an E30 blend would reduce annual U.S. emissions by 70 million metric tons per year.32 Reducing the share of aromatics in gasoline by 40 percent – with E30 fuel that is 40 percent less emitting – would reduce U.S. emissions by another 32 million metric tons per year.33 GHG emissions from oil refineries would also fall, due to reduced demand for their most intensively refined products. Lower throughput and intensity would reduce refinery CO2 emissions and crude oil consumption, at a modest additional cost of 1-2 cents per gallon.34 One assessment found that refinery GHG emissions would decline by 12 percent to 27 percent for various E30 cases, due to both lower crude oil throughput and differences in the severity of refining operations.35 Since the refinery sector emits 180 million metric tons per year,36 that would mean a further reduction in U.S. GHG emissions of at least 21 million metric tons per year.

Thus, the total reduction in U.S. GHG emissions from adoption of E30 blends – combining fuel economy gains, the replacement of aromatics with a lower-carbon substitute, and the change in refinery operations – would total 123 million metric tons per year. That would be a cut of more than 12 percent in emissions from light-duty vehicles, which comprise 58 percent of the emissions from the transportation sector.37 It would also exceed the GHG reductions from the Proposed Rule for new cars, which reach only 117 million tons in 2050.38

Valuing the social cost of those avoided emissions at $25 per ton would imply a benefit of more than $3 billion per year. Using the ‘interim’ rate of $51 per ton put forward by the administration in 2021, the benefits would come to more than $6 billion per year.39 At the rate of $76 per ton used in the NHTSA Proposed Rule, the benefits would exceed $9 billion per year.40

California is in the vanguard of the transition to electric vehicles in the U.S., with a goal of limiting new-car sales in 2035 to zero-emission vehicles.41 But under the state's Low Carbon Fuel Standard (LCFS) program to date (since 2011), ethanol has reduced GHG emissions nearly three times more than electricity. As more electric vehicles enter the market, that ratio is dropping sharply, but even last year, ethanol reduced GHG emissions by one third more than electricity – despite being limited mostly to E10 blends.42

Higher Ethanol Blends Can Replace the Toxic Aromatics in Gasoline to Improve Public Health and its Impact on Communities of Color

Toxic Aromatics in Gasoline are Harming Our Environment and Health

A shift from the standard formulation of gasoline today (E10) to a higher-level blend (E30) would displace an estimated 40 percent of the toxic aromatics in the fuel43 – also the most carbonintensive fraction of gasoline.44 Aromatics are hydrocarbons built around one or more benzene rings. Often referred to by the acronym BTEX, they include not just benzene itself, a known carcinogen, but also toluene, ethylbenzene, xylenes, and other compounds similar to benzene in their behavior in the environment.45 Aromatics are derived from petroleum during the refining process and blended into gasoline to increase octane. The use of aromatics increased dramatically during the 1980s when the previously used additive, tetraethyl lead, was phased out due to health concerns.46,47

The level of aromatics in gasoline is capped at 25 percent in regions required to use reformulated gasoline (areas that have high levels of ozone pollution, roughly 30 percent of the U.S. market).48 From 1997 to 2006, aromatics made up roughly 25 percent of the U.S. gasoline pool. That level fell to 20 percent over the next 10 years49 as ethanol's share of the market rose from 3 percent to nearly 10 percent. This 20 percent level equates to 25.3 billion gallons of aromatics used in cars and light-duty vehicles per year.50

The BTEX chemicals are characterized as hazardous air pollutants 'known or suspected to cause cancer or other serious health or environmental effects.'51 They are identified as mobile source air toxics and formed in four ways, of which the first two are most pertinent. According to the EPA:

'First, some air toxics are present in fuel and are emitted to the air when it evaporates or passes through the engine as unburned fuel. Benzene, for example, is a component of gasoline. Cars emit small quantities of benzene in unburned fuel, or as vapor when gasoline evaporates.

'Second, mobile source air toxics are formed through engine combustion processes. A significant amount of automotive benzene comes from the incomplete combustion of compounds in gasoline such as toluene and xylene that are chemically very similar to benzene.'52 (emphasis added)

According to a review of the literature by the Health Effects Institute: 'It is estimated that about 50 [percent] of the benzene produced in the exhaust is the result of decomposition of aromatic hydrocarbons in the fuel. … [Two] studies showed that lowering aromatic levels in gasoline significantly reduces toxic benzene emissions from vehicle exhausts.'53

A recent General Motors study found that nearly 96 percent of the PM emissions from gasoline are caused by the aromatics in the fuel. Due to an increase in heavy aromatics in the U.S. gasoline pool in the last three years, the gasoline particulate index has increased by more than 30 [percent] since 2016 and now is worse than in the EU and China. The authors observed: 'Fuel quality improvements are not only important for new vehicles, which are designed for it, but also will benefit the whole fleet of legacy vehicles in the market and off-highway engines.'54

Aromatics contribute about 10 percent of global anthropogenic emissions of non-methane organic gases (NMOG), the major source being car exhaust from gasoline-powered vehicles.55 Aromatics are also responsible for an estimated 30-40 percent of the ozone and other photooxidants in urban atmospheres, making them the most important class of hydrocarbons with regard to photochemical ozone formation.56

Toxic Emissions from Gasoline are Causing Premature Deaths and Long-Lasting Health Effects

Organic aerosol is a major component of fine particle pollution. Primary organic aerosol (POA) is directly emitted from fossil fuel combustion and other sources, while secondary organic aerosol (SOA) is formed from the oxidation of these emissions in the air.57 Tailpipe emissions from onroad gasoline vehicles are an important source of SOA in urban environments, where SOA concentrations often exceed POA levels. For most vehicles, SOA formation exceeds POA emissions after a few hours of atmospheric oxidation. Controlling SOA precursor emissions is necessary to reduce human exposure to fine particulate matter.58 A study of SOA formation during a severe photochemical smog event in Los Angeles found that exhaust from gasoline engines represented the single-largest anthropogenic source of SOA, and SOA in turn has been shown to be a large fraction, if not the largest, of gasoline vehicular PM.59

According to EPA's 2011 National Air Toxics Assessment, secondary formation is the largest contributor to cancer risks nationwide, accounting for 47 percent of the risk. On-road mobile sources contribute the most cancer risk from directly emitted pollutants (about 18 percent) and the most to non-cancer risks (34 percent).60 A recent study found higher toxicity in combustion aerosols than non-combustion aerosols, with emissions from vehicle engine exhaust scoring higher on overall toxicity than even those from coal combustion.61

In 2005, EPA said that '[a]romatic compounds … are considered to be the most significant anthropogenic SOA precursors and have been estimated to be responsible for 50 to 70 [percent] of total SOA in some airsheds. … The experimental work of Odum and others showed that the secondary organic aerosol formation potential of gasoline could be accounted for solely in terms of its aromatic fraction.'62 (emphasis added). One study estimated that SOA from aromatics in gasoline is responsible for 3,800 annual premature deaths and annual social costs of $28.2 billion in 2006 dollars.63

Additionally, the effect of aromatics on SOA is not linear. Increasing the level of aromatics in test fuels by less than 30 percent (from 28.5 percent to 36.7 percent) was shown to cause a 3- to 6-fold increase in SOA formation.64 Reducing aromatics would have a similarly disproportionate effect.

Further, there is a growing concern in the public health community about the contribution of ultrafine particles (UFPs) to human health. Despite their modest mass and size, they dominate in terms of the number of particles in the ambient air. UFPs contain large amounts of toxic components, and their adverse health effects potential would not be predicted from their mass alone. Particle number, surface area, and chemical composition are more important than mass as a health-relevant metric.65

A particular concern about UFPs is their ability to reach the most distal lung regions (alveoli) and circumvent primary airway defenses. Moreover, UFPs have a high surface area and a capacity to adsorb a substantial amount of toxic organic compounds. Harmful systemic health effects of PM10 or PM2.5 are often due to the UFP fraction.66 High levels of aromatic components in fuel have been conclusively shown to increase PM emissions measured by particle number, an aromatic ring being an early stage of the fundamental particulate formation process.67 The ability of inhaled particles to be captured within the human body, called the deposition efficiency, is a function of particle size, with the particle deposition efficiency rapidly increasing as the particles become smaller and smaller.68 UFPs can cross biological membranes, and their mobility within the body is thought to be high. There is considerable evidence to show that inhaled UFPs can gain access to the bloodstream and are then distributed to other organs in the body. They can even cross the placental barrier.69

An important recent study co-authored by Nobel Prize winner Mario Molina found ‘remarkable formation of UFPs from urban traffic emissions’70 – which have a disproportionate effect on communities of color: ‘Photooxidation of vehicular exhaust yields abundant UFP precursors, and organics dominate formation of UFPs under urban conditions.’ Chamber studies showed high levels of aromatics, including toluene and C8 and C9 aromatics.71 The authors concluded: ‘Recognition of this source of UFPs is essential to assessing their impacts and developing mitigation policies. Our results imply that reduction of primary particles or removal of existing particles without simultaneously limiting organics from automobile emissions is ineffective and can even exacerbate this problem.’72 (emphasis added)

Polycyclic aromatic hydrocarbons (PAHs) are among the worst of the UFPs. The EPA has classified seven PAHs as probable human carcinogens.73 A subset of polycyclic organic matter (POM), PAHs consist of three to seven benzene rings. Among all sources, vehicular exhaust is the major source for PAH air pollution in most urban areas, the product of incomplete combustion of aromatic hydrocarbons in gasoline.74,75 More than 95 percent of the lung deposition of PAHs is due to fine particles, and ultrafine particles are responsible for 10 times more PAH deposition in the alveolar region than their share of PM mass.76

PAHs are commonly divided into two categories based on their size. PAHs with two to three fused aromatic rings are considered low molecular weight PAHs, while those with four and more fused rings are high molecular weight PAHs, including the most carcinogenic PAH, benzo[a]pyrene (BaP).77 The larger PAHs are of greatest concern for human health due to their recalcitrance to degradation, persistence, bioaccumulation, carcinogenicity, genotoxicity and mutagenicity.78 Since these high molecular weight PAHs exist almost exclusively on fine particles, they travel deep into the human respiratory system and pose a serious health risk.79 Combustion of vehicle fuels appears to be the principal source of inhalation exposure for the larger PAHs, such as BaP, that are associated with particulate matter.80 Motor vehicles account for as much as 90 percent of the particle-bound PAH mass in the urban air of major metropolitan areas.81

Fetal exposure to PAHs, as measured by prenatal air monitoring for the marker PAH benzo[a]pyrene during the third trimester of pregnancy, was assessed in a long-term observational epidemiological study in New York. Exposure levels were characterized relative to a median of 2.66 nanograms per cubic meter (ng/m3) – 100,000 times less than the OSHA air standard of 0.2 mg/m3.82 Fetal exposure above the median was associated with developmental delay at age 3 years and reduced IQ at age 5 years, as well as increased anxiety and depression, possibly by interfering with knowledge acquisition or slowing cognitive processing.83 The observed decrease in full-scale IQ is similar to that reported for children with elevated concentrations of lead in their blood.84

DNA adducts are a form of DNA damage caused by attachment of a chemical entity to DNA. Adducts that are not removed by the cell can cause mutations that may give rise to cancer.85 The formation of PAH-DNA adducts has been widely studied in experimental models and has been documented in human tissues.86 Higher levels of PAH-DNA adducts found in umbilical cord blood were associated with reduced scores on neurocognitive tests.87

A long-term study in California also found an association between exposure to airborne PAHs during the last 6 weeks of pregnancy and early preterm birth – with median exposure at the extremely low level of 3.6 ng/m3.88 Preterm birth is a predictor of infant mortality and later-life morbidity. Despite recent declines, the rate of preterm birth remains high in the U.S. Research increasingly suggests a possible relationship between a mother's exposure to common air pollutants, including PM2.5 and preterm birth of her baby. 89

Based on numerous experimental studies, PAHs are also widely accepted to be precursors for soot, or black carbon – a major contributor to climate change.90,91 Products of toluene combustion (one of the BTEX aromatics) are known precursors of PAHs that are involved in soot formation.92 Black carbon is considered the second most important human emission in terms of climate forcing; only CO2 has a greater overall effect. The short-term (20-year) global warming potential per ton of black carbon is 3200 times that of CO2.

Unfortunately, new engine technology is not coming to the rescue: Most of the light-duty vehicles sold today have switched to gasoline direct injection technology (GDI) – for the laudable reason of increased engine efficiency and thus fuel economy – but with the unintended side effect of increasing the volume of UFPs, including PAHs, coming out of the exhaust pipe.93 GDI was used in fewer than 3 percent of vehicles as recently as model year 2008 but was projected to be used in more than 55 percent of vehicles in model year 2020.94 GDI engines emit UFPs and PM at levels comparable to diesel engines that do not use diesel particulate filters.95,96 Uncontrolled GDI engines have been found to emit 10 times more particles (by mass) than previous engines and more than 100 times the number of particles.97 [EPA-HQ-OAR-2021-0208-0262-A1, pp. 3-18]

Low-Income Communities and Communities of Color Face a Disproportionate Burden from Gasoline Emissions

Beyond the overall impact of gasoline emissions on the public's health, it is also worth noting the disproportionate effect on urban and low-income communities. Higher octane, lower carbon fuels have the ability to substantially increase fuel efficiency, while substantially reducing carbon emissions and the particulate-borne toxics plaguing these communities. The harm to these communities, particularly communities of color, is increasingly being brought to light in both published studies and mainstream media.

Indeed, EPA notes in the Proposed Rule scientific reports by the U.S. Global Change Research Program (USGCRP), the Intergovernmental Panel on Climate Change (IPCC), and the National Academies of Science, Engineering, and Medicine that have provided evidence of environmental justice concerns. Importantly, these reports have concluded that 'poorer or predominantly non-White communities can be especially vulnerable to climate change impacts because they tend to have limited adaptive capacities and are more dependent on climate-sensitive resources such as local water and food supplies, or have less access to social and information resources.'98 Further, '[s]ome communities of color, specifically populations defined jointly by ethnic/racial characteristics and geographic location, may be uniquely vulnerable to climate change health impacts in the [U.S.]'99

In addition to these reports highlighted in the Proposed Rule, a recent study found that Black people are exposed to higher concentrations of PM2.5 emissions, the most significant environmental cause of death.100 PM2.5 is responsible for an estimated 85,000 to 200,000 excess deaths each year in the U.S. Meanwhile people of color generally are exposed more to almost every source of pollution as compared to white people. Equally concerning was an April 2021 Environmental Integrity Project report, which found that thirteen oil refineries across the country released elevated and reportable levels of benzene into predominantly minority and low-income communities in 2020.101

Given the direction of Executive Order 12898 to make achieving environmental justice part of each agency's mission, it's imperative that EPA do more than recognize the historical impact of GHG emissions on low-income and minority communities. By opening the door to higher ethanol blends, such as E30, EPA can work toward its stated goal of increasing its focus on environmental justice and equity.102 Displacing the aromatics in gasoline with higher octane, lower carbon fuel such as ethanol enables more efficient vehicles, reduces GHG emissions, and reduces the toxic pollutants in the air. [EPA-HQ-OAR-2021-0208-0262-A1, pp. 18-19]

EPA has the Statutory Authority to Promote Higher Ethanol Blends to Control the Hazardous Emissions from Transportation Fuel

In the Proposed Rule, EPA notes its authority to regulate the emission of air pollutants from all mobile sources under section 202(a) of the Clean Air Act (CAA).103 EPA highlights the multiple factors the agency must take into consideration to revise the forthcoming GHG emission standards for light-duty vehicles, including technological feasibility, compliance cost, and lead time. EPA may also consider factors, such as the impact on the auto industry, fuel savings by consumers, oil conservation, energy security and other energy impacts, and safety.

Despite the weight given to these factors in past rulemaking, we applaud EPA for recognizing the statutory intent of section 202(a) – reducing air pollution to protect the public's health and welfare. Notably, EPA makes clear that given the statutory purpose of this section, 'the Administrator finds it is appropriate to place greater weight on reducing emissions and to adopt standards that, when implemented, would result in significant reductions of light duty vehicle emissions both the near term and over the longer term.'104 (emphasis added). In doing so, EPA is requiring that the Proposed Rule's primary goal should be to address GHG emissions by reducing the threat posed to our health and environment from hazardous emissions. However, the Proposed Rule fails to accomplish this goal.

To effectively improve our public health and welfare, EPA should use its authority under section 211(c)(1) of the CAA to regulate gasoline octane levels. Under the CAA, EPA can set a national minimum octane level of 98-100 RON to enable more efficient high-compression engines and reduce GHG emissions. As a cleaner, lower cost, and more fuel-efficient alternative to our fossil fuel supply, a national minimum octane level of 98-100 RON would open the door to increased ethanol blended fuels such as E30 fuel. Internal combustion engines and the fuels they use comprise a single system, requiring the availability of higher ethanol blends to enable the optimization of more fuel-efficient vehicles.

Importantly, ethanol is readily available based on our domestic supply without increased land use or competing with our food supply. Ethanol producers have the capacity to supply any needed supply for years to come. And our existing infrastructure is capable of supplying higher ethanol blends to the market without substantial investment, unlike the case with the eventual transition to electrification. [EPA-HQ-OAR-2021-0208-0262-A1, pp. 19-20]B. EPA Must Remove the Regulatory Barriers to Higher Ethanol Blends

In addition to setting a national minimum octane standard, there are other steps EPA can take to level the playing field and enable ethanol to compete in the market. Specifically, we urge the EPA to take the following actions:

• Comply with the Mandatory Toxic Reduction Provisions in Section 202(l) of the CAA: EPA action is required under Section 202(l) of the CAA Amendments of 1990 to control aromatic/BTEX content in order to reduce mobile source air toxics (MSAT) emissions 'to the greatest degree … achievable.'105 Action on this requirement is mandatory;106 it was enacted concurrently and was explicitly based on the same provision of Section 202(a) under which EPA has justified the Proposed Rule, based on 'the magnitude and benefits of reducing emissions that endanger public health and welfare.'107 Without a minimum toxic reduction baseline enforced, refiners will find loopholes to allow them to backslide on the aromatic content in gasoline in reformulated gasoline (RFG) areas and/or be forced to dump gasoline with higher priced and higher volumes of aromatic-laced gasoline into non-RFG areas. The debilitating health impacts of these carcinogens has been ignored by EPA and must be addressed.

• Correct the Agency's Interpretation of 211(f) Substantially Similar Rule: As of January 1, 2017, E10 became the nation's certification fuel. When that happened, ethanol became an additive used in certification; therefore, it should not be controlled under section 211(f). In addition, in light of EPA not finalizing the Renewables Enhancement and Growth Support (REGS) Rule, its 'sub-sim' position on ethanol has not been codified. Correcting this interpretation will reduce unnecessary regulations, time to market, and reduce MSATs. If EPA wishes to control the use of higher blends in standard (non-FFV) vehicles, the legal burden of proof is on the agency to prove that higher than 15 percent ethanol blends damage emissions control systems or exacerbate tailpipe emissions. EPA cannot do so factually.

• Extend the 1 psi Reid Vaper Pressure (RVP) Waiver for E10 and E15 to Higher Blends: EPA should extend the RVP waiver of ethanol blends because the RVP decreases as the level of ethanol increases, supporting the transition to higher octane fuels by opening market access to such fuels in the summer months. Overall emission reduction gains from adding ethanol to gasoline far outweigh concerns that focus only on reducing gasoline volatility, would lower MSATs and help meet the requirements of CAA Section 202(l) requirements.

• Approve a Mid-Level Ethanol Blend Certification Fuel: EPA should expeditiously approve the use of a mid-level ethanol certification fuel (e.g., E30) to provide automakers with the added justification to design optimized, high compression vehicles that can make use of 98–100 RON gasoline. The certification of E30 fuel will help automakers cost effectively meet Corporate Average Fuel Economy (CAFE) and GHG requirements by improving engine efficiency, reducing CO2, and reducing MSATs.

• Update and Reform the Agency's MOVES2014 Model: EPA should suspend the use of the MOVES2014 model because the research literature shows that the model relied on an analysis that unfairly and inaccurately attributes higher emissions to ethanol rather than added aromatics. The MOVES model analysis has been proven to be contrary to what happens in real-world retail gasoline/ethanol blending, which is 'splash blending.' By updating the model, states currently using the MOVES2014 Model for State Implementation Plan (SIP) compliance will no longer be deterred from using higher blends of ethanol to reduce MSATs and meet ozone attainment goals that restrict the development of new business and roads.

• Update the 2007 MSAT Cost-Benefit Analysis (CBA): The assumptions used in EPA's 2007 MSAT rule (e.g., $19/barrel crude oil, $0.85 gasoline, and a 2:1 ethanol octane replacement value for toluene/BTEX/aromatics) inaccurately create the impression that replacing toxic aromatic hydrocarbons with higher octane, lower cost ethanol would not be cost effective. An updated CBA will show that ethanol provides positive MSAT reduction at a lower cost.

• Update and Reform the Agency's Life Cycle Assessment (LCA): Updating EPA's outdated 2010 LCA of ethanol's carbon emissions would align the agency's data with the continually updated and widely accepted Argonne National Laboratory GREET model, which shows double the GHG benefit identified by EPA. EPA's LCA model also should recognize the ability of high-yield corn to restore soil organic matter, which transforms corn acres into substantial carbon sinks, and therefore adjust its carbon intensity (CI) factors for corn ethanol downward. This adjustment would accelerate the penetration of higher ethanol blends in states and countries that do or will adopt high-octane low-carbon fuel standards. This will support EPA's responsibility to successfully implement the Renewable Fuel Standard (RFS) and help automobile manufacturers meet the requirements of CAFE and GHG standards.

• Reinstate Flexible-Fuel Vehicle (FFV) Type Credits: EPA should provide the regulatory roadmap and supporting data to help stakeholders interested in reinstating meaningful vehicle credits to incentivize automakers to design engines to utilize highoctane low-carbon fuels (e.g., E30). Similar to the transition to unleaded gasoline, this regulatory action would send a clear investment signal to automakers that have expressed interest in being able to pro-rate FFV-type credits (previously established and based on E85 ethanol volumes) and recalculate them for the use of high octane, low carbon midlevel ethanol blends (e.g., E30). These credits will help justify and offset the cost of investing in retooling and testing to meet CAFE and GHG requirements and will also leverage the DOE's investment into E85 refueling infrastructure by increasing the renewable/alternative fuel throughput to meet the objectives of that program. [EPA-HQ-OAR-2021-0208-0262-A1, pp. 20-22]

Commenter: Hyundai America Technical Center, Inc. (Hyundai)

Hyundai also expects FCEVs to play an important role in the full suite of diversified electric solutions. Diversification is important for serving differing use cases, preferences, resiliency, and energy security. As such the government should be committed to ensuring the expansion of hydrogen stations and establish a metric that helps ensure infrastructure growth for these vehicles. [EPA-HQ-OAR-2021-0208-0603-A1, p.5]

Low-Carbon Fuels

As shown in Figure 1 [Figure 1 can be found at docket number EPA-HQ-OAR-2021-0208-0603-A1, p. 5], above, even with aggressive introduction of electric vehicles the on-road fleet in 2030 is still expected to be comprised of more than 80% internal combustion engine vehicles. As such, we support EPA's plans to build upon their Renewable Fuels Standard12 by promoting the addition of more low-carbon fuels. A low carbon fuel standard would be another tool that would incentivize both auto manufacturers and utilities to sell electric vehicles and develop smart charging strategies, respectively. These fuels will reduce emissions from new gasoline vehicles but also, more importantly, from the existing fleet of gasoline vehicles on the road today. [EPA-HQ-OAR-2021-0208-0603-A1, p.10]

Commenter: Illinois et al. Corn Growers Associations

Currently, the regulatory barriers to low-carbon, high-octane fuels prevent automakers from taking advantage of octane's anti-knock properties to improve the efficiency of internal combustion engines—and thereby reduce carbon-dioxide emissions. Removing these barriers will allow EPA to achieve its emissions goals at much lower cost and with greater real-world benefit. The proposal acknowledges that liquid fuel-related issues will be "especially important considerations during the transition to zero-emission vehicles."1 But its suggestion that these issues should wait for a future rulemaking is fundamentally misguided and, in fact, arbitrary and capricious. Fuels and engines constitute a single system; EPA cannot rationally regulate the one without taking into account the other.2 Thus, as explained below, EPA should use the final rule to require a minimum octane standard pursuant to its authority under Title II of the Clean Air Act and should correct its inaccurate fuel economy formula to allow for the use of midlevel ethanol blends. [EPA-HQ-OAR-2021-0208-0563-A2,pp.2-3]

THE SOLUTION

Fortunately, there is a readily available solution that both lowers costs and that actually works in the real world. That solution is to unleash the potential of low-carbon, high-octane fuels made with ethanol. While we respectfully submit that this should take the place of multipliers in the final rule, the two approaches are independent. Regardless of whether EPA changes or eliminates the multipliers in the final rule, it should implement the fuel-related fixes described below. [EPA-HQ-OAR-2021-0208-0563-A2, p.5]

The Potential of Octane. Internal combustion engines are "heat engines": the hotter the burned gas in the cylinder, the more useful "work" can be extracted from the fuel's chemical energy to move the piston. Thus, the hotter the gas, the greater the potential energy efficiency. Burnt gas gets hotter as the "compression ratio" of the engine increases, boosting efficiency and thereby reducing the carbondioxide emission rate. Unfortunately, one cannot increase the compression ratio indefinitely. When a piston travels up the cylinder, the increase in pressure also increases the heat of the fuel-air mixture. If the pressure increases too much and too fast, the flammable mixture ignites by itself—a phenomenon known as "knock." When an automobile engine knocks, the gasoline burns before the engine is ready to extract work from it and much of the energy is wasted, decreasing efficiency and increasing wear and tear on the engine. [EPA-HQ-OAR-2021-0208-0563-A2, p.5]

The key benefit of octane is that it has anti-knock properties. Thus, high-octane fuels can be compressed to a higher rate than low-octane fuels without spontaneously combusting. This makes octane "the single most important property of gasoline when determining engine design."10 Despite this, octane's potential to increase fuel efficiency and decrease carbon-dioxide emissions is largely untapped. For example, as EPA has previously explained, a change opening the door to high-octane fuels such as E30 (gasoline blended with 30% ethanol) would enable automakers "to raise compression ratios to improve vehicle efficiency as a step toward complying with . . . light-duty greenhouse gas and CAFE standards."11 [EPA-HQ-OAR-2021-0208-0563-A2, pp.5-6]

In previous rulemakings before EPA, auto industry commenters have repeatedly pointed out that higher octane fuel's anti-knock properties make it "a key enabler for the next phase of advanced engines expected to occupy a large fraction of the vehicle fleet."12 This is because the use of high-octane fuel blends would "immediately improv[e] fuel economy across a substantial portion of the existing light-duty vehicle fleet."13 This is also supported by a large body of empirical research.14 In particular, recent research by Professor Mueller at the University of Illinois at Chicago has shown that the greenhouse gas reductions available from midlevel ethanol blends approximately equals those that EPA believes could be achieved through electrification.15 [EPA-HQ-OAR-2021-0208-0563-A2,pp.6-7]

Ethanol is the Best Source of Octane. Widespread use of high-octane fuel will not be achieved without more ethanol. As the Urban Air Initiative has pointed out in previous comments before EPA, "[t]oday's premium gasoline costs substantially more to produce than regular gasoline or midlevel ethanol blends, and premium will only become more expensive as the need for octane increases and as refiners increase their reliance on domestic, low-octane, light tight oil. By contrast, ethanol is readily available."16 [EPA-HQ-OAR-2021-0208-0563-A2, p.7]

Our members are willing and able to supply the corn as soon as it is needed. In addition, refiners can produce high-octane midlevel ethanol blends at low cost.17 And, unlike electrification, the existing fueling infrastructure is capable of supplying mid-level blends to the market without substantial investment—for example, the law has required underground storage tanks have to be compatible with E100 since roughly 1993, and above-ground systems are trending strongly towards E25 compatibility as a result of the rapid phase-in of chip-reader pumps. [EPA-HQ-OAR-2021-0208-0563-A2, p.7]

In addition, ethanol is a low-carbon source of octane, and midlevel ethanol blends also have the added benefit of reducing particulate matter pollution from GDI engines.18 [EPA-HQ-OAR-2021-0208-0563-A2, pp.7-8]

The benefits of ethanol-based midlevel blends can be realized in the near- to mid-term and without significant cost or disruption. All that stands in the way are regulatory barriers, most of which can be removed in short order by EPA. [EPA-HQ-OAR-2021-0208-0563-A2, p.8]

THREE WAYS EPA MUST ACT NOW TO REMOVE REGULATORY BARRIERS TO MIDLEVEL ETHANOL BLENDS

While there are many regulatory barriers that improperly limit the adoption of midlevel ethanol blends, we believe that the following three are the most important and that EPA should not delay acting on these issues. [EPA-HQ-OAR-2021-0208-0563-A2, p.8]

EPA Should Require a Minimum Octane Standard. Fuels and internal combustion engines are a single system. Despite this, EPA has often not considered fuels when regulating vehicle emissions. What this has meant in practice is that automakers are still having to build engines compatible with the lowest octane fuels available nationwide.19 This includes not only regular fuel, but also even lower "suboctane" blends used in some high-altitude states. As EPA has noted, "[i]f the minimum octane level available in the market were higher (especially the current suboctane regular grade in the mountain states), vehicle manufacturers might not feel compelled to design vehicles suboptimally to accommodate such blends."20 [EPA-HQ-OAR-2021-0208-0563-A2,p.8]

Section 211(c)(1) of the Clean Air Act gives EPA broad authority to address this issue by "control[ing]" gasoline octane levels.21 [EPA-HQ-OAR-2021-0208-0563-A2, p.9]

The Administrator may . . . by regulation, control or prohibit the manufacture, introduction into commerce, offering for sale, or sale of any fuel or fuel additive for use in a motor vehicle, motor vehicle engine, or nonroad engine or nonroad vehicle if, in the judgment of the Administrator, any fuel or fuel additive or any emission product of such fuel or fuel additive causes, or contributes, to air pollution or water pollution (including any degradation in the quality of groundwater) that may reasonably be anticipated to endanger the public health or welfare.22 [EPA-HQ-OAR-2021-0208-0563-A2, p.9]

As explained above, low-octane gasoline impairs manufacturers' ability to further increase compression ratios to reduce carbon-dioxide emissions to meet its greenhouse gas standards. This easily satisfies the "endangerment" requirement. In addition, EPA may use its § 211(c) authority because the low-octane fuel currently sold also increases the carbon dioxide emissions from existing legacy vehicles. [EPA-HQ-OAR-2021-0208-0563-A2, p.9]

In the final rule, EPA should use this authority to phase out today's low-octane blends. Indeed, it would be arbitrary and capricious not to. Not addressing this issue here and now will result in higher emissions and greater costs, which in turn will harm both "public health" and "welfare" by increasing health risks associated with both traditional criteria pollutants and greenhouse gas emissions as well as by driving up new vehicle costs. If EPA does not act here, it should commit in its final rule to pursuing minimum octane standard through a separate rulemaking as soon as possible. [EPA-HQ-OAR-2021-0208-0563-A2, p.9]

EPA Should Correct Its Inaccurate Fuel Economy Formula to Allow for the Use of Midlevel Ethanol Blends. EPA should repeal and replace its outdated fuel economy formula. EPA has admitted that part of that formula is erroneous and that it unfairly penalizes fuel with ethanol in it; but, inexplicably, EPA has not yet fixed the problem. The problem is an important one for automakers that face increasingly stringent fuel economy standards, and it discourages them from developing high-efficiency engines that require higher octane ratings and higher ethanol content. [EPA-HQ-OAR-2021-0208-0563-A2, pp.9-10]

The fuel-economy calculation turns on the so-called "R-factor." This is intended to make fuel economy testing on today's fuel equivalent to fuel economy testing in 1975 by adjusting for the lower energy content of ethanol.23 The current R-factor of 0.6 required by EPA's rules is—as EPA itself has recognized—inaccurate.24 So far, however, the Agency has failed to act. [EPA-HQ-OAR-2021-0208-0563-A2, p.10]

More fundamentally, the current fuel economy formula is wrong because it does not account for how the addition of ethanol reduces petroleum consumption per gallon of fuel. Under the Energy Independence and Security Act of 2007, EPA has authority to promote energy independence by "decid[ing] on the quantity of other fuel that is equivalent to one gallon of gasoline."25 EPA has relied on that authority to calculate a fuel efficiency credit for electric vehicles.26 EPA should treat ethanol the same way. Thus, for example gasoline with 25% ethanol (E25) should be treated as being equivalent to 75% of a gallon of gasoline for purposes of fuel economy compliance. [EPA-HQ-OAR-2021-0208-0563-A2,p.10]

For a more detailed explanation of this point, we refer the agency to an addendum to comments made previously by the Urban Air Initiative.27 [EPA-HQ-OAR-2021-0208-0563-A2, pp.10-11]

As the nation transitions to a lower-carbon future, effective regulation of greenhouse gas emissions from light-duty vehicles requires looking at the realities of current technology and market demand. Internal-combustion engines still dominate the market and will do so for some time to come, and automakers are rapidly approaching the limits of what can be achieved with low-octane liquid fuels. They will not be able to achieve EPA's very aggressive proposed greenhouse gas emissions standards unless and until EPA uses its authority to remove regulatory barriers to high-octane, low carbon fuels made with ethanol. EPA therefore must use this rulemaking to address this issue. [EPA-HQ-OAR-2021-0208-0563-A2,p.12]

19 The availability of higher-octane premium and plus fuel grades does not change this. Automakers must design their vehicles for nationwide operation over their useful life, which has meant that they have to take into account that consumers will often fuel even premium-recommended and premium-required vehicles with lower-octane regular gasoline.

24 The error of the current R-factor, and its negative impact on ethanol due to that fuel's lower energy density, is explained in detail in comments filed by Boyden Gray & Associates. Energy Future Coalition & Urban Air Initiative, Comments on Proposed Tier 3 Rule, EPA-HQ-OAR-2011-0135-4353 (July 1, 2013), at 41-43 & Appendix I, available at http://boydengrayassociates.com/comments-of-theenergy-future-coalition-and-urban-air-initiative-on-proposed-tier-3-motor-vehicle-emission-and-fuelstandards-july-1-2013/.

Commenter: International Union, United Automobile, Aerospace & Agricultural Implement Workers of America (UAW)

We also encourage EPA to further explore alternative fuel sources such as biofuels. We have engaged with a wide variety of stakeholders with the hopes that a consensus can be reached to ensure we have standards that both reduce emissions and set the conditions for the industry to thrive in the United States. [EPA-HQ-OAR-2021-0208-0749-A1, p. 2]

Commenter: Kansas Corn Growers Association

Unfortunately, the Environmental Protection Agency (EPA) missed a vital opportunity to address climate change in the short-term while supporting American farmers and providing American consumers with a cleaner burning, more cost-effective fuel. High octane fuel containing mid-level ethanol blends can be made available today with existing infrastructure and technology, unlike alternative fuel sources such as electricity. The Biden Administration has prioritized battling climate change, protecting public health and ensuring minorities are not overlooked. If the Administration is in fact serious about these priorities, then your agency has missed a golden opportunity in leaving out octane and biofuels from this proposed rule. [EPA-HQ-OAR-2021-0208-0220-A1, p. 1]

EPA Should Mandate a Minimum Octane Standard Pursuant to Its Fuel Regulation Authority

Current low-octane blends of fuel should be phased out as new vehicles are available to take advantage of the efficiency of mid-level ethanol blends. EPA has acknowledged that CAA § 211(c) gives it authority to “control” gasoline octane levels. EPA can set a minimum octane level under the above section of the Clean Air Act because low-octane fuels impair the ability of automakers to meet GHG standards, and also increase C02 emissions. To maximize GHG reductions, if octane levels are not addressed in this rule, we implore you to move quickly to begin a separate rulemaking on this important issue. [EPA-HQ-OAR-2021-0208-0220-A1, p. 1]

EPA Should Correct Its Inaccurate Fuel Economy Formula to Allow the Use of Mid-Level Ethanol Blends

EPA should repeal and replace its outdated fuel economy formula that is erroneous and unfairly penalizes fuel with ethanol in it. EPA has previously admitted these errors but has not taken action to fix the problem. EPA has also previously admitted that the R-Factor of 0.6 is outdated and the auto industry and other groups have suggested an adjusted R-Factor of 1.0. But again, the EPA has failed to address this issue in the rule. [EPA-HQ-OAR-2021-0208-0220-A1, p. 1]

EPA Should Reinstate the 0.15 F-Factor for Flex Fuel Vehicles (FFVs)

FFVs using E85 significantly reduce lifecycle carbon emissions because much of the carbon emitted was regenerated from the atmosphere through the production of the feedstock crop (i.e. corn). This conversion factor allows automakers to utilize this credit while adjusting for E85 utilized in FFVs as to not overestimate carbon reductions. Until 2015, EPA allowed automakers to use the 0.15 conversion to improve GHG compliance. Without certainty in this credit, automakers have produced fewer FFVs, which reduces the potential GHG savings from FFVs. If the F-factor level is not addressed in this rule, we implore you to move quickly to begin a separate rulemaking on this important issue.

In closing, high octane mid-level ethanol blends would enable more efficient engines; reduce vehicle and fuel costs for consumers; and reduce conventional pollution. More importantly, these fuel blends are available now. Feedstocks such as corn are abundantly available with no increased land use, and corn production can supply all needed the ethanol for many years without any land use changes. The nation’s current fueling infrastructure can supply these mid-level blends without substantial investment, something that cannot be said about alternative fuel sources such as electricity. The increased availability mid-level ethanol blends will not only boost the rural economy, but it will also provide American consumers of all income levels a cost-effective tool to fight climate change here and now. Thank you for your time and consideration in this important matter to rural America. [EPA-HQ-OAR-2021-0208-0220-A1, p. 2]

Commenter: Minnesota Corn Growers Association (MCGA)

As stated in the proposed rule, the transportation sector is the largest source of U.S. GHG emissions, representing 29 percent of total U.S. emissions. Within the sector, light-duty vehicles are the largest contributor, comprising 17 percent of U.S. GHG emissions. Immediate progress toward decarbonizing the light duty fleet will help meet the Administration's goal of cutting emissions by 2030 and reaching net zero emissions by 2050. [EPA-HQ-OAR-2021-0208-0530-A1, p. 3]

As EPA explains in the proposal, the difference between the stringency of the SAFE rule and the revised vehicle standards proposal is due to the greater weight the Administrator puts on emissions reductions and resulting health and welfare benefits than other factors. EPA relied on similar analysis for the proposal as the agency used to develop the SAFE rule and describes the results as in agreement with prior analysis. However, despite similar analysis and results as used for the SAFE rule, the agency is changing its position from the SAFE rule because it is "more appropriate" to put greater weight on the benefit of reducing emissions, in light of the purposes of the Clean Air Act.2 Under the Clean Air Act, EPA has an obligation to protect the health and welfare of Americans. While EPA projects this proposal to increase the stringency of vehicle emissions standards for model year (MY) 2023-2026 vehicles will result in 2.2 billion tons of avoided GHG emission by 2050, EPA leaves significant GHG emission reductions on the table if the agency fails to take steps in this proposal, or in a parallel action, to also improve fuel along with vehicles. [EPA-HQ-OAR-2021-0208-0530-A1, p. 3]

We encourage EPA to focus on outcomes and opening pathways for all low carbon fuels and technologies that enable stricter standards. Allowing all solutions ensures we take advantage of not only the low carbon benefits of higher ethanol blends, but also the cuts in toxic emissions, greater fuel efficiency and consumer cost savings that come with more renewable fuel use in transportation fuel. [EPA-HQ-OAR-2021-0208-0530-A1, p. 1]

EPA missed an opportunity in this proposal to broaden the solutions that reduce transportation emissions by beginning a transition to low carbon, high octane fuels to advance climate, air quality and environmental justice goals with these and future standards. In addition, alternative fuel vehicles such as flex-fuel vehicles, which have the potential to reach zero emissions, should be equitably incentivized through vehicles standards rules. For automakers to use new technologies and enhanced engines to meet stringent standards, they need updated fuel that enables new vehicles and fuels to work as a system to enhance GHG reductions. Higher ethanol blends used with advanced engines optimized for higher octane would provide a muchneeded pathway for automakers to meet higher standards for GHG emissions and fuel economy. [EPA-HQ-OAR-2021-0208-0530-A1, p. 2]

In addition to making improvements in this proposal, we urge EPA to use the rulemaking for MY 2027 and later to open pathways to achieve more emissions reductions from sustainable, affordable low carbon ethanol through a clean, high octane standard, removing barriers to higher ethanol blends and equitably incentivizing all alternative fuel vehicles on track to reach net-zero emissions. [EPA-HQ-OAR-2021-0208-0530-A1, p. 2]

Achieving those decarbonization goals in transportation will require a mix of solutions. As recent analysis from the Rhodium Group concludes, a "portfolio of strategies is the lowest cost and most likely to succeed," including low carbon liquid fuels such as biofuels.1 [EPA-HQ-OAR-2021-0208-0530-A1, p. 3]

If the agency is truly putting greater weight on "the magnitude and benefits of reducing emissions that endanger public health and welfare" in the proposal, EPA missed a significant opportunity to include complementary fuel improvements that would enable greater GHG reductions, greater fuel efficiency and more substantial air quality improvements from further reduction of non-GHG emissions than the proposal offers.3 [EPA-HQ-OAR-2021-0208-0530-A1, p. 3]

EPA estimates that "the vast majority of vehicles produced in the time frame of the proposed standards," will be powered by liquid fuels.4 In fact, EPA projects that just eight percent of the vehicle market share by MY 2026 will be plug-in hybrid electric vehicles (PHEVs) or all-electric vehicles (EVs), meaning the vehicles in the remaining 92 percent of the market share will require liquid fuel. The proposed standards do not rely on "dramatically increased penetration of electric vehicles into the fleet during the 2023-2026 model years."5 Instead, EPA's assessment of the technology feasibility of the proposal relies on advances in engine and transmission technologies that have entered the fleet in the past 10 years and expanded use of those already in place in today's vehicles. [EPA-HQ-OAR-2021-0208-0530-A1, p. 3]

Describing use of these new technologies, EPA notes that as of MY 2020, more than half of light-duty gasoline spark ignition engines now use direct injection (GDI) engines and more than a third are turbocharged. 6 However, further advancements from these and additional engine technologies such as higher compression ratios and greater downsizing are limited by current fuel formulations in the marketplace. Improving the fuel will enable greater GHG emissions reductions from the advanced engine technologies EPA is relying on to make these proposed standards feasible. Recognizing vehicles and fuels as a complete system, increasing the octane rating of the nation's fuel supply through a clean, high octane standard would deliver greater GHG emission reductions in the 92 percent of the vehicle market share EPA projects will be powered by liquid fuel in MY 2026 and during the 15 to 20 years those vehicles remain on the road after introduction. [EPA-HQ-OAR-2021-0208-0530-A1, p. 4]

A CLEAN HIGH OCTANE STANDARD

MCGA and NCGA support EPA establishing a pathway to a higher minimum clean octane standard for fuel of at least 98 RON that enables mid-level ethanol blends to immediately and cost-effectively reduce both GHG and tailpipe emissions, supporting greater fuel efficiency and bringing lower carbon and lower cost fuels to the market.

Even with advancements in engine technology, manufacturers are nearing a point where further improvements will be difficult without a higher-octane fuel. This is because advanced downsized, down sped engines, and their associated technologies, make an engine more susceptible to knock. Because of its knock-limiting properties, a higher-octane fuel, such as a midlevel ethanol blend, enables engine designs featuring higher compression ratios, turbocharging, and down speeding and increases overall engine performance and efficiency.7 According to Department of Energy (DOE) researchers at Oak Ridge National Laboratory, "the opportunity for further downsizing and down speeding of engines to improve fuel economy is limited by the available octane rating of fuels…[which] allow higher efficiency designs of naturally aspirated and turbocharged engines dedicated to use the high octane fuel."8 Since 2016, DOE has completed extensive research through its Co-Optimization of Fuels and Engines initiative (Co-Optima) on innovating fuels and engines together and understanding the types of fuels that can improve engine performance and efficiency to reduce emissions, with alcohol fuels like ethanol identified as top contenders. 9

Numerous engine testing experiments—on different engines and vehicles, under varying test conditions, and using a spectrum of ethanol blends—have produced what's now quite a large body of evidence demonstrating ethanol's ability to increase engine efficiency and efficacy while lowering emissions.10,11,12 In 2016, DOE researchers reviewed other recent engine testing efforts to quantify the potential of E25 to E40 fuel in their Summary of High-Octane Mid-Level Ethanol Blends Study. 13 In summarizing the studies on octane, midlevel ethanol blends used in dedicated high-octane vehicles achieved efficiency gains of 5 to 10 percent, more than overcoming any energy density differences with E10.

As DOE explained in its GHG analysis of high octane fuel, determining GHG impacts of high octane fuel relative to current gasoline requires accounting for vehicle efficiency gains, refinery operation changes and GHG emissions changes from ethanol blending. DOE's results show the largest impacts on wells to wheels (WTW) emissions from high octane fuel come from efficiency gains and the level of ethanol blending.

• DOE's modeling compared 100 RON E25 and E40 fuels to baseline E10. When used in HOF vehicles, the E25 reduced WTW GHG emissions by a total of 8 to 9 percent (or 36-40 g CO_2e/mile driven) compared to baseline E10. The vehicle efficiency gains from HOF reduced GHG emissions by 4 percentage points of that total, and the additional 4 percentage points of GHG reductions with the E25 fuel were realized from ethanol offsetting petroleum. For the E40 HOF, the ethanol content provides a 9 percent reduction in WTW GHG emissions.14

Current fuels with higher octane, such as E10 blends marketed as premium grades, are not cost-effective for consumers, fall short of enabling the efficiency and emissions technology changes automakers need and fail to advance transportation decarbonization. Because ethanol results in nearly half the emissions of gasoline and is on a pathway to future net-zero emissions, producing higher-octane fuel with a midlevel ethanol blend would do more to reduce GHG emissions and support the stringency goals of the proposed rule. Optimized vehicles powered by low carbon, high octane fuel made from a midlevel ethanol blend after model year 2023 would have much lower GHG emissions than vehicles running on either current E10 blends or premium E10 blends.

A clean, low carbon, high octane fuel standard avoids increasing the use of fossil-based octane sources, which produce more carbon emissions, erasing the GHG reduction benefits from gains in engine efficiencies while releasing more toxic emissions from harmful hydrocarbon aromatics, degrading air quality and respiratory health. Due to ethanol's high octane rating, a low carbon, high octane ethanol blend results in both additional fuel efficiency and significant GHG reductions. Higher ethanol content, reached by removing regulatory barriers to higher blends, would boost GHG reductions and replace harmful aromatics, providing a cost-effective low carbon fuel solution for consumers, including low income consumers, and the environment. [EPA-HQ-OAR-2021-0208-0530-A1, p. 4-5]

LOW CARBON ETHANOL: MOVING TO NET ZERO

EPA estimates the proposal will avoid 2.2 billion tons of GHG emissions by 2050. Compared to the proposal, the Renewable Fuel Standard (RFS) has already resulted in nearly 1 billion metric tons of cumulative GHG savings from 2008-2020, exceeding projections largely due to the reduced carbon intensity of corn ethanol.15 The RFS has already delivered half the emissions reductions in 13 years that EPA projects the vehicles rule will take nearly 30 years to deliver, highlighting the importance of using biofuels like ethanol to enhance the GHG emissions reductions from transportation with the right policies.

The most recent assessment from the Department of Energy's Argonne National Laboratory concludes corn ethanol's carbon intensity decreased 23 percent from 2005 to 2019 due to increased corn yield, reduced fertilizer intensity and improved ethanol production efficiency, with corn ethanol now between 44 and 52 percent lower in carbon intensity (CI) than the gasoline it replaces.16 Argonne's conclusions are similar to analysis from Environmental Health and Engineering finding ethanol now results in 46 percent fewer GHG emissions compared to gasoline, due to improved corn production, ethanol production efficiencies and land productivity.17

Corn-based ethanol can reach net zero emissions with continued on-farm improvements and soil carbon sequestration, along with carbon capture technology and new efficiencies in ethanol production. Corn farmers are proud of our leadership in adopting conservation and best management practices. NCGA's recently released Corn Sustainability Report details corn farmers' history of improvements and our commitment to further sustainability achievements by 2030

Sustainable production means corn farmers today are producing more corn using less land and fewer resources. For example, planted corn acres in 2020, at 90.8 million acres, were less than planted acres in 2007, the year the RFS was expanded, at 93.5 million acres. USDA data also shows the area planted to principal crops in the United States is not expanding overall. Corn production has increased primarily because crop yields have increased from an average of 150 bushels per acre in 2007 to 172 bushels in 2020. With the average yield in 1980 at just 91 bushels per acre, productivity growth is a long-term trend.

Using the expertise of Argonne's scientists and the U.S. Department of Agriculture's data, we believe Argonne's Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (GREET) model is the federal government's most accurate tool for evaluating biofuel and energy lifecycle emissions. Because GREET is regularly updated, this model captures GHG emissions reductions from farmers' improved production practices and will incorporate the ongoing, voluntary climate-smart improvements in agriculture production this Administration supports, ensuring further carbon intensity reductions are accounted for in the LCA.

Corn production has improved across all measures of resource efficiency, including higher crop yields per acre, resulting in greater corn production using less land and fewer inputs, further fortifying ethanol as a sustainable, low-carbon renewable fuel. This progress is reflected in Argonne's most recent analysis, which builds on and is consistent with other recent reviews.

For example, a 2018 USDA study shows that ethanol then resulted in 39 to 43 percent fewer GHG emissions than gasoline.18 Building on this progress, additional improvements on farms and in ethanol production supported by expanding markets for low carbon fuels could result in ethanol with up to 70 percent fewer GHG emissions than gasoline, according to USDA's analysis. Furthermore, according to California Air Resources Board (CARB) data, the CI of ethanol under the state's Low Carbon Fuel Standard (LCFS) is more than 35 percent lower today than it was in 2011 and more than 40 percent lower than the CI of gasoline.19

These increasing benefits have occurred without accounting for corn's ability to sequester carbon in the soil. Corn as a crop can serve as a carbon sink. As a photo-synthetically superior C4 plant, corn has an extraordinary ability to sequester carbon and move fertilizer nutrients back to the surface for plant growth rather than polluting ground water. Corn's extensive, deep root system makes it one of the few plants with this important capability to make crop production sustainable.

High-yield corn—combined with the steady adoption of best practices such as reductions in tillage intensity—is sequestering carbon from the atmosphere into the soil. This sequestration is increasing soil carbon levels and reducing atmospheric CO2. According to the Journal of Soil and Water Conservation, the potential to sequester atmospheric carbon in soil is greatest on lands currently used for annual crops; most remarkably, there is potential to sequester carbon in the soil at an annual growth rate of 0.4 percent each year. 20 The results of tracking soil organic carbon (SOC) advancements on select USDA-specified agricultural land areas is estimated to have sequestered an estimated 309 metric tons of CO2- equivalent in less than a decade.21

Although GHG lifecycle models do not currently account for this direct GHG reduction from corn production, NCGA believes the effect of corn crops on soil carbon sequestration, among other considerations, should be incorporated into current lifecycle analysis. This increase in soil carbon from corn production, when included, could result in a 20 gram/MJ carbon credit for corn-based ethanol.22

Fully accounting for corn's carbon sequestration would further demonstrate significant low-carbon advantages of a high-octane midlevel ethanol blend. [EPA-HQ-OAR-2021-0208-0530-A1, p. 6-8]

CRITERIA POLLUTANTS AND AIR TOXICS

Bringing high octane fuel to market in the form of midlevel ethanol blends will be significantly less capital-intensive than attempting to increase blendstock octane with hydrocarbon components at refineries. It will also be incredibly cleaner. The avoided production cost and offset emissions lower end-costs to consumers, reducing both economic costs and social costs related to health and environment, key considerations in advancing environmental justice and avoiding adverse impacts from oil refineries on communities that have historically borne them.

Increased volumes of ethanol in fuel displace the most harmful compounds from gasoline.23 These aromatic hydrocarbon additives (i.e. benzene, toluene, ethylbenzene, xylene – or BTEX) have high cancer-causing potential. Increasing the ethanol volume in fuel to a midlevel blend has a positive impact on tailpipe emissions of toxins, including significant reductions in particulates and carbon monoxide. These same aromatic hydrocarbons are also precursors to the formation of secondary organic aerosols (SOA), which in turn are a major contributor to particulate matter emissions (PM 2.5).

According to EPA's review for the 2020 Anti-backsliding Study, ethanol does not form SOA directly or affect SOA formation. However, as EPA states, toluene is a large contributor to SOA. Ethanol's high octane value "greatly reduces the need for other high-octane components including aromatics such as toluene."24

As explained in EPA's Fuel Trends Report: Gasoline 2006-2016, "Ethanol's high octane value has also allowed refiners to significantly reduce the aromatic content of the gasoline, a trend borne out in the data." EPA's data shows that aromatics' share of gasoline volume dropped from nearly 25 percent to 19.3 percent, and benzene volume dropped from 0.99 percent to 0.58 percent between 2000 and 2016, the same time as ethanol blending increased from 1 percent to at least 10 percent.

EPA's data demonstrates the air quality and human health benefits of increased ethanol blending in gasoline by replacing harmful aromatics with clean octane from ethanol. Limiting the aromatics content of gasoline and using higher ethanol blends in high octane fuel would further reduce risks from SOA formation and exposure to PM 2.5, which causes serious respiratory, cardiovascular, and other health harm, including premature death, according to the American Lung Association. The same GDI engine advancements that help lower GHG emissions have the unfortunate side effect of increasing particulate emissions, which could be reduced by use of midlevel ethanol blends. [EPA-HQ-OAR-2021-0208-0530-A1, p. 8]

Petroleum-based aerosol particles represent a significant source of pollution, especially in population-dense urban areas. Health issues related to PM and other emission-based pollutants can be reduced by lowering the volume of petroleum in the domestic gasoline pool, which can be accomplished by increasing octane with higher ethanol blends and replacing more hydrocarbon aromatics with ethanol.

In the proposed rule, EPA states that based on the predicted emissions changes from the proposed standards, very small changes in ambient air quality are expected.25 EPA could greatly increase the air quality, health, and environmental justice benefits of the proposal by cleaning up the fuel going into the 92 percent vehicles by MY 2026 expected to use liquid fuels. We urge EPA to take immediate steps toward setting a clean, high octane fuel standard that blends more ethanol to replace aromatics to expand the health and environmental justice benefits of this proposal, as well as set caps or limits on air toxics in future rulemakings. [EPA-HQ-OAR-2021-0208-0530-A1, p. 9]

TRANSPORTATION COSTS

In addition to failing to decarbonize liquid fuel, simply transitioning current premium fuel to the new “regular fuel” as a higher octane E10 blend, such as a 95 RON E10, would be significantly more expensive to consumers than current regular E10 fuel.

However, a higher RON level met through increased ethanol blending, would reduce fuel costs compared to higher RON fuels with less ethanol content. Incremental refining costs to produce a 98 RON E20 or E30 fuel could be between $0.02-$0.05 per gallon, respectively, based on one analysis. Incremental refining costs are estimated to be nearly $0.20 per gallon to produce a 98 RON fuel using 10 percent ethanol.26 Because of the availability and effectiveness of ethanol as an octane enhancer, a midlevel blend 98 RON fuel is cleaner and more cost-effective.

Analysis presented to Ag-Auto-Ethanol Work Group by the Defour Group compares the economics of a 95 RON E10 fuel and a 98 RON E25 fuel.27 This analysis builds on Hirshfeld, et al.’s use of a linear programming model to estimate the refining economics of increasing fuel octane ratings and ethanol content. This additional analysis shows that the presence of a 98 RON high-octane midlevel blend in the market, along with a 95 RON E10 fuel, would change the economics of high-octane fuel and fuel pricing.

When additional ethanol is blended to reach 98 RON, it allows for a lower-octane base gasoline blendstock, which costs less to produce at the refinery and avoids refinery GHG emissions. Coupled with the low cost of ethanol added to raise octane, the finished high-octane midlevel blend is less expensive. This updated analysis concludes that a 98 RON E25 fuel would be cost comparative with the current regular fuel, accounting for a transition with both 95 RON and 98 RON fuels in the market.

Using more ethanol enables a larger increase in fuel octane, allowing for greater efficiency improvements, at a lower cost. When more refining is needed to increase fuel octane, as with current premium E10 blends, the cost will be greater. An E25 blend would support additional octane at a lower price than current premium fuel. Drivers of future model year vehicles optimized to use a higher RON fuel would not pay more for fuel over the lifetime of the vehicle with low carbon, high octane midlevel ethanol blend fuel. [EPA-HQ-OAR-2021-0208-0530-A1, p. 9-10]

NCGA believes EPA should take the following actions to support the production and use of low carbon, high octane fuel, consistent with Title II of the Clean Air Act, in conjunction with setting vehicle standards:

Implement a pathway to a minimum fuel octane level of 98 RON, phasing out lower octane fuels as new optimized vehicles enter the market.

NCGA believes EPA has ample authority to regulate fuel octane because of the impact higher fuel octane would have on reducing GHG emissions from the vehicle fleet. EPA has previously acknowledged the agency has authority to regulate fuel octane under Section 211(c). [EPA-HQ-OAR-2021-0208-0530-A1, p. 10]

Higher octane fuel, with ethanol as a clean octane source, would result in a cost-effective fuel that offers automakers an additional technologically and economically feasible means to meet more stringent emissions standards. Additionally, high-octane fuel would enable vehicle technologies that result in more GHG emissions reductions and enable greater reductions from this proposal from the new vehicles EPA expects to be sold in coming years. When automakers have the option of higher-octane fuel, the total vehicle ownership cost to consumers is less than without higher octane fuel. A higher RON level, met through greater ethanol blending, would reduce fuel costs. As discussed previously in our comments, the higher ethanol content of the midlevel blend 98 -100 RON fuel makes it much more cost effective than current E10 premium fuel. A cleaner, high-octane midlevel blend would be costcompetitive with current regular fuel.

Finally, a higher RON level met through greater ethanol blending would reduce GHG emissions. At the refinery level, production of a 98 RON E20 fuel reduces refinery CO2 emissions by nearly 5 percent, and a 98 RON E30 blend would reduce refinery emissions by more than 10 percent. Conversely, even a 95 RON E10 would result in a small increase in refinery emissions.28 On a WTW basis, based on the previously discussed DOE analysis, the greater vehicle efficiency enabled by a higher RON fuel accounts for about half of the GHG emissions reductions with a 5 percent efficiency gain, and the percentage of the ethanol blend determines the additional GHG reduction from the high octane fuel. 29

Approve a high-octane, midlevel ethanol blend vehicle certification fuel (98-100 RON, E25-E30).

EPA’s timely approval of a high-octane, midlevel ethanol blend vehicle certification fuel would enable automakers to expedite design and testing of optimized vehicles for use with this new low carbon fuel. We believe EPA should propose or invite automakers to propose submission of this certification fuel in conjunction with this or future rulemakings. [EPA-HQ-OAR-2021-0208-0530-A1, p. 10-11]

Correct the fuel economy formula by updating the R-Factor to 1.0 to reflect documented operation of modern engine technology.

Correcting the R-Factor in the fuel economy formula would support automakers developing high efficiency engines that require higher octane ratings and a higher ethanol content. EPA has acknowledged that the current EPA-mandated R-Factor of 0.6, originally established in the 1980s, is outdated and fails to achieve the statutory purpose of making fuel economy testing on today's fuel equivalent to fuel economy testing in 1975.

An update to 1 from 0.6 would reflect results of analysis by the Department of Energy and EPA using modern engines and fulfill previous observations and commitments from EPA to address this issue. Published studies have shown that R for modern vehicles should be around 0.93 to 0.96.30 As NCGA explained in 2020 comments on EPA's proposed rule on vehicle test procedure adjustments in Docket EPA–HQ–OAR–2020-0104, an R-factor of 1.0 in the fuel economy formula would support a lowercarbon fuel policy, providing automakers with greater options for choice and innovation in meeting more stringent GHG standards through vehicle technologies and lower carbon fuels. Without this overdue correction, use of lower carbon fuels will continue to be unjustifiably penalized in the fuel economy formula.

Setting the R-factor to 1.0 sets fuel economy results on an energy basis. In application, the R factor equation is a "fuel response factor," adjusting for more than just energy density. An R of 1.0 essentially converts fuel economy to mile per gallon gasoline equivalent (MPGge), which is how other alternative fuels such as propane, natural gas, and electricity have been compared to their gasoline counterparts for decades. Setting R to 1.0 provides equitable treatment to renewable ethanol that other alternative fuels already receive. This change could help speed the transition to certification with Tier 3 fuel as well as encourage vehicle manufacturers to seek certification for even higher ethanol blends, such as E15 or the high octane E30 EPA suggested in its Tier 3 proposal several years ago. Manufacturers are not incentivized to build dedicated high-octane vehicles that reduce GHG emissions when those low carbon benefits are penalized by a low R factor. [EPA-HQ-OAR-2021-0208-0530-A1, p. 11]

Lower summer vapor pressure to 9 psi or less for all fuel or provide parity in Reid Vapor Pressure (RVP) treatment for all ethanol blends with E10.

Higher ethanol blends such as E15 offer an immediate decarbonization opportunity and support a transition to low carbon, high octane fuel. However, outdated RVP rules and the oil industry's refusal to produce lower volatility blendstock prevents E15 – which is lower in evaporative, tailpipe and GHG emissions – from reaching the market on the same terms as standard E10 fuel. Addressing these outdated rules would allow lower-volatility and lower-emissions E15 full market access and support EPA's efforts to reduce emissions across the board, and it is unfortunate the oil industry took EPA to court to block the agency's 2019 action aimed at updating unnecessary fuel restrictions in order to keep cleaner E15 out of the marketplace and limit consumer choice. [EPA-HQ-OAR-2021-0208-0530-A1, p. 11-12]

By using existing authority in the Clean Air Act to require lower volatility conventional gasoline blendstock during the summer months to reduce emissions of volatile organic compounds and decrease the potential for ozone formation, EPA would simultaneously open the market to E15 year-round. NCGA urges EPA to take this action to improve air quality while simultaneously eliminating outdated barriers to cleaner, low carbon higher ethanol blends like E15 and future high octane fuel. [EPA-HQ-OAR-2021-0208-0530-A1, p. 12]

FLEX FUEL VEHICLES and CREDITING

Beyond ethanol’s utility in all gasoline engines to reduce GHG emissions, other alternative vehicle technologies can also harness the GHG reductions and air quality benefits of ethanol, such as Flex Fuel Vehicles (FFVs). FFVs utilizing higher blends of low carbon ethanol, such as E85, can provide immediate emissions reductions without tangibly altering the price of the vehicle and reducing fuel costs. In fact, E85 is typically sold at a lower price than gasoline, translating to monetary savings in addition to the significant air pollution savings.

Compared to gasoline, E85 leads to significant reductions in NOx and GHG emissions. E85 avoids use of toxic hydrocarbon aromatics in gasoline that are precursors to secondary organic aerosols that result in harmful fine particulate matter emissions that cause serious respiratory, cardiovascular, and other health harm, including premature death, according to the American Lung Association. [EPA-HQ-OAR-2021-0208-0530-A1, p. 12]

Incentivized to reduce emissions through the state’s Low Carbon Fuel Standard (LCFS), in California some FFVs are even powered by a blend of 15 percent renewable naphtha with 85 percent ethanol. These vehicles use zero fossil fuels, have improved air emissions profiles, and have an extremely low carbon intensity. As such, NCGA has recently advocated to CARB to go a step further to decrease emissions in its most recent Advanced Clean Cars and Scoping Plan proposals by requiring that all PHEVs MY 2026 and later up be a FFV.

Just as we recommended to CARB, EPA also should not constrain its vision of a zero-emission vehicle and a zero-emissions future based on today’s vehicle limitations, but rather remain focused on setting technology and feedstock neutral standards and allowing markets to innovate and respond. California’s LCFS has resulted in a reduction in ethanol CI in the state, as well as increased demand for low carbon fuel like E85 and FFVs, as low carbon ethanol has helped the state meet ambitious GHG emission reduction goals. [EPA-HQ-OAR-2021-0208-0530-A1, p. 12-13]

Despite the GHG and criteria pollution reduction benefits of FFVs, as well as the low cost to purchase and fuel these vehicles, automakers have cut back on FFV models and now offer very few choices to consumers. Well-structured vehicle credit programs remain an impactful, cost-effective means for the government to encourage the introduction and adoption of new products and technologies. However, NCGA is concerned that reinstating a credit multiplier for EVs, as the proposal would do, further incentivizes selected types of low emissions vehicles but not others. With this proposal, EPA picks technology winners and losers. To encourage introduction of a wider range of low emission vehicle choices, NCGA believes EPA must provide equitable crediting across the spectrum of low emission vehicles, including FFVs. [EPA-HQ-OAR-2021-0208-0530-A1, p. 13]

NCGA also urges EPA to take steps to update the F-factor in the fuel economy formula to a forward looking F-factor of at least 0.2, as we outlined in 2020 comments in response to Docket EPA–HQ–OAR–2020-0104. Furthermore, we urge EPA to reinstate the 0.15 volumetric conversion factor for FFVs. EPA should reharmonize the 0.15 factor for FFVs in these standards, and, if not, in future standards. This change would accurately reflect the significant carbon emissions reductions from FFVs using E85 because the carbon emissions from the fuel are the release of carbon taken up through crop growth. [EPA-HQ-OAR-2021-0208-0530-A1, p. 13]

Conversely, EPA could also level the playing field for vehicle technology by similarly treating the ethanol portion of fuel as carbon neutral, supporting greater use of low carbon renewable fuels. The carbon emitted from ethanol use is the same carbon the corn plant absorbed from the atmosphere, resulting in no net carbon. [EPA-HQ-OAR-2021-0208-0530-A1, p. 14]

Commenter: Minnesota Farmers Union (MFU)

Urge your agency to support moving toward mid-level ethanol blends. This is a priority for our members not only because it will provide significant benefit to Minnesota’s rural economy, but also because it will immediately curb greenhouse gas emissions, improving our environment and contributing to the fight against climate change. [EPA-HQ-OAR-2021-0208-0534-A1, p.1]

We see biofuels—and moving toward high-octane mid-level ethanol blends—as a near-term, cost-effective step we can take to lower the carbon intensity of our transportation fleet. We echo National Farmers Union (NFU) in requesting that you prioritize moving toward mid-level ethanol blends, including by requiring specific octane levels under the Clean Air Act; easing the ability to use mid-level ethanol blends as a certification fuel; ensuring the appropriate R-factor for increased ethanol volumes; and working with the industry to resolve Reid Vapor Pressure (RVP) restrictions, allowing the year-round use of higher ethanol blends. We also strongly support establishing polices that promote the manufacture and sale of Flex Fuel Vehicles (FFVs), including by restoring incentives. [EPA-HQ-OAR-2021-0208-0534-A1, p.1]

Commenter: Modlin, R.R. and Detchon, B. Reid

As discussed below, and then presented in carefully annotated detail, we believe EPA missed an opportunity to consider the benefits of high-octane, low-carbon fuels to contribute to the objectives of the Proposed Rule. Such fuels could deliver average annualized benefits comparable to that claimed for the Proposed Rule and could achieve them sooner. As you prepare the Final Rule, we urge you to consider that potential and to seek input from stakeholders beyond the walls of EPA as to how an improved fuel can be adopted by the market. This consideration should be seen as a companion to the electrification of the transportation sector by application of feasible, available, and affordable technological solutions to climate and health challenges.

The Proposed Rule targets reducing emissions of greenhouse gases (GHGs) from new vehicles. However, we observe that EPA has missed a substantial opportunity to reduce GHG emissions from vehicles now on the road. To achieve early wins in the climate challenge by deploying effective, available, and affordable technology packages, EPA should also consider improving the fuel used by over 250 million existing vehicles. An analysis of the potential effectiveness of an improved fuel used in internal combustion engine (ICE) vehicles now and into the next few decades shows that adoption of an improved fuel could possibly double the CO2 reductions claimed by the Proposed Rule. (See analysis conducted by Steffen Mueller, University of Illinois at Chicago, to be reported by B. West, “Benefits of Ethanol Blending and Impact on Emissions and Emissions Control,” at SAE Powertrains, Fuels and Lubricants Summit, October 2021.) This observation alone should cause EPA to give very serious consideration into how an improved fuel can be adopted and deployed. An improved fuel would also bring along substantial further benefits.

We note the comment in the Proposed Rule that “in addition to substantially reducing GHG emissions, a longer-term rulemaking could also address criteria pollutant and air toxics emissions from the new light-duty vehicle fleet – especially important considerations during the transition to zero-emission vehicles.” Most vehicles entering the market today use gasoline direct injection (GDI) to enhance performance. DOE studies have identified a notable increase in ultrafine particle emissions from GDI engines. The increased number of particles and their size include emissions of toxic polycyclic aromatic hydrocarbons (PAHs).

For mobile source air toxics, such as PAHs derived from gasoline emissions, the Clean Air Act requires “the greatest degree of emission reduction achievable through the application of technology which will be available.” In that context, just as with greenhouse gas emissions, vehicles and fuels must be seen as parts of an integrated system. The Department of Energy clearly understands the need for such an approach. Since 2016, the Co-Optimization of Fuels & Engines initiative (known as Co-Optima) has explored how simultaneous innovations in fuels and engines can boost fuel economy and vehicle performance, while reducing emissions. The Co-Optima team views fuels “not as standalone elements in the transportation system, but as dynamic design variables that can work with modern engines to optimize and revolutionize the entire on-road fleet.” Their work will be useful as EPA considers the adoption of improved fuels in current and future rulemakings.

Because of the long lead time for capital planning in both the automobile and fuels industries, it is vital for EPA to send a signal of its intent as part of the current rulemaking. By encouraging the entry and adoption of higher-level biofuel blends in the market to reduce carbon emissions now, you will begin to see the benefits immediately – in terms of greenhouse gas emissions, air quality, and public health – a critical consideration in light of the Administration’s goal of reducing U.S. greenhouse gas emissions by at least 50% by 2030.

As explained in detail below, widespread adoption of improved fuels can complement the pathway to an electric vehicle future. With a period of 30 years needed to achieve that transition, and with emissions today causing premature deaths and stunting child development in the very cities that are the focus of the environmental justice movement, this is an approach that EPA should seize and embrace. It does not require new legislation – EPA has all the authority it needs to act and the subject Proposed Rule provides a convenient vehicle. Action, or inaction, now will affect public health for decades to come.

We urge your careful consideration of adopting an improved fuel to aid in attacking the climate challenge and improving the health of all Americans through the Final Rule and subsequent rules. [EPA-HQ-OAR-2021-0208-0235-A1, p. 1-3]

Commenter: National Corn Growers Association (NCGA)

As stated in the proposed rule, the transportation sector is the largest source of U.S. GHG emissions, representing 29 percent of total U.S. emissions. Within the sector, light-duty vehicles are the largest contributor, comprising 17 percent of U.S. GHG emissions. Immediate progress toward decarbonizing the light duty fleet will help meet the Administration's goal of cutting emissions by 2030 and reaching net zero emissions by 2050 [EPA-HQ-OAR-2021-0208-0246-A1, p. 2]

As the producers of low carbon feedstock for low carbon ethanol, corn farmers are part of the solution to cut transportation emissions. We encourage EPA to focus on outcomes and opening pathways for all low carbon fuels and technologies that enable stricter standards, taking advantage of not only the low carbon benefits of higher ethanol blends, but also the cuts in toxic emissions, greater fuel efficiency and consumer cost savings that come with more renewables. For automakers to use new technologies and enhanced engines to meet stringent standards, they need updated fuel that enables new vehicles and fuels to work as a system to enhance GHG reductions.

Higher ethanol blends used with advanced engines optimized for higher octane would provide a much-needed pathway for low carbon fuels. Higher octane fuel is an essential tool for automakers to meet revised standards, but higher octane must also be clean octane to meet emission reduction goals. Clean octane from today's ethanol is 50 percent lower in GHG emissions than gasoline and replaces the most harmful hydrocarbon aromatics to improve air quality and prevent adverse health impacts. EPA missed an opportunity in this proposal to broaden the solutions that reduce transportation emissions by beginning a transition to low carbon, high octane fuels to advance climate, air quality and environmental justice goals with these and future standards. Furthermore, alternative fuel vehicles such as flex-fuel vehicles, which have the potential to reach zero emissions, should be equitably incentivized through vehicle standards rules.

In addition to improving this proposal, NCGA urges EPA to use the rulemaking for MY 2027 and later to open pathways to achieve greater emissions reductions from sustainable, affordable low carbon ethanol through a clean, high octane standard, removing barriers to higher ethanol blends and equitably incentivizing all alternative fuels and vehicles on track to reach net-zero emissions. Low carbon, high octane fuels would also support any longer-term EPA rulemaking to address vehicle criteria pollutant and air toxics emissions. [EPA-HQ-OAR-2021-0208-0246-A1, p. 1]

Achieving those decarbonization goals in transportation will require a mix of solutions. As recent analysis from the Rhodium Group concludes, a 'portfolio of strategies is the lowest cost and most likely to succeed,' including low carbon liquid fuels such as biofuels.[1] [EPA-HQ-OAR-2021-0208-0246-A1, p. 2]

If the agency is truly putting greater weight on 'the magnitude and benefits of reducing emissions that endanger public health and welfare' in the proposal, EPA missed a significant opportunity to include complementary fuel improvements that would enable greater GHG reductions, greater fuel efficiency and more substantial air quality improvements from further reduction of non-GHG emissions than the proposal offers.[3] [EPA-HQ-OAR-2021-0208-0246-A1, p. 2]

Improving the fuel will enable greater GHG emissions reductions from the advanced engine technologies EPA is relying on to make these proposed standards feasible. Recognizing vehicles and fuels as a complete system, increasing the octane rating of the nation’s fuel supply through a clean, high octane standard would deliver greater GHG emission reductions in the 92 percent of the vehicle market share EPA projects will be powered by liquid fuel in MY 2026 and during the 15 to 20 years those vehicles remain on the road after introduction. [EPA-HQ-OAR-2021-0208-0246-A1, p. 2]

EPA estimates that 'the vast majority of vehicles produced in the time frame of the proposed standards,' will be powered by liquid fuels.[4] In fact, EPA projects that just eight percent of the vehicle market share by MY 2026 will be plug-in hybrid electric vehicles (PHEVs) or all-electric vehicles (EVs), meaning the vehicles in the remaining 92 percent of the market share will require liquid fuel. The proposed standards do not rely on 'dramatically increased penetration of electric vehicles into the fleet during the 2023-2026 model years.'[5] Instead, EPA’s assessment of the technology feasibility of the proposal relies on advances in engine and transmission technologies that have entered the fleet in the past 10 years and expanded use of those already in place in today’s vehicles. [EPA-HQ-OAR-2021-0208-0246-A1, p. 2]

A CLEAN HIGH OCTANE STANDARD

NCGA supports EPA establishing a pathway to a higher minimum clean octane standard for fuel of at least 98 RON that enables mid-level ethanol blends to immediately and cost-effectively reduce both GHG and tailpipe emissions, supporting greater fuel efficiency and bringing lower carbon and lower cost fuels to the market.

Even with advancements in engine technology, manufacturers are nearing a point where further improvements will be difficult without a higher-octane fuel. This is because advanced downsized, down sped engines, and their associated technologies, make an engine more susceptible to knock. Because of its knock-limiting properties, a higher-octane fuel, such as a midlevel ethanol blend, enables engine designs featuring higher compression ratios, turbocharging, and down speeding and increases overall engine performance and efficiency.[7] According to Department of Energy (DOE) researchers at Oak Ridge National Laboratory, ‘the opportunity for further downsizing and down speeding of engines to improve fuel economy is limited by the available octane rating of fuels…[which] allow higher efficiency designs of naturally aspirated and turbocharged engines dedicated to use the high octane fuel.' [8] Since 2016, DOE has completed extensive research through its Co-Optimization of Fuels and Engines initiative (Co-Optima) on innovating fuels and engines together and understanding the types of fuels that can improve engine performance and efficiency to reduce emissions, with alcohol fuels like ethanol identified as top contenders.[9]

Numerous engine testing experiments—on different engines and vehicles, under varying test conditions, and using a spectrum of ethanol blends—have produced what's now quite a large body of evidence demonstrating ethanol's ability to increase engine efficiency and efficacy while lowering emissions.[10],[11],[12] In 2016, DOE researchers reviewed other recent engine testing efforts to quantify the potential of E25 to E40 fuel in their Summary of High-Octane Mid-Level Ethanol Blends Study.[13] In summarizing the studies on octane, midlevel ethanol blends used in dedicated high-octane vehicles achieved efficiency gains of 5 to 10 percent, more than overcoming any energy density differences with E10.

As DOE explained in its GHG analysis of high octane fuel, determining GHG impacts of high octane fuel relative to current gasoline requires accounting for vehicle efficiency gains, refinery operation changes and GHG emissions changes from ethanol blending. DOE's results show the largest impacts on wells to wheels (WTW) emissions from high octane fuel come from efficiency gains and the level of ethanol blending.

• DOE's modeling compared 100 RON E25 and E40 fuels to baseline E10. When used in HOF vehicles, the E25 reduced WTW GHG emissions by a total of 8 to 9 percent (or 36-40 g CO2e/mile driven) compared to baseline E10. The vehicle efficiency gains from HOF reduced GHG emissions by 4 percentage points of that total, and the additional 4 percentage points of GHG reductions with the E25 fuel were realized from ethanol offsetting petroleum. For the E40 HOF, the ethanol content provides a 9 percent reduction in WTW GHG emissions.14

Current fuels with higher octane, such as E10 blends marketed as premium grades, are not cost-effective for consumers, fall short of enabling the efficiency and emissions technology changes automakers need and fail to advance transportation decarbonization. Because ethanol results in nearly half the emissions of gasoline and is on a pathway to future net-zero emissions, producing higher-octane fuel with a midlevel ethanol blend would do more to reduce GHG emissions and support the stringency goals of the proposed rule. Optimized vehicles powered by low carbon, high octane fuel made from a midlevel ethanol blend after model year 2023 would have much lower GHG emissions than vehicles running on either current E10 blends or premium E10 blends.

A clean, low carbon, high octane fuel standard avoids increasing the use of fossil-based octane sources, which produce more carbon emissions, erasing the GHG reduction benefits from gains in engine efficiencies while releasing more toxic emissions from harmful hydrocarbon aromatics, degrading air quality and respiratory health. Due to ethanol's high octane rating, a low carbon, high octane ethanol blend results in both additional fuel efficiency and significant GHG reductions. Higher ethanol content, reached by removing regulatory barriers to higher blends, would boost GHG reductions and replace harmful aromatics, providing a cost-effective low carbon fuel solution for consumers, including low income consumers, and the environment.

LOW CARBON ETHANOL: MOVING TO NET ZERO

EPA estimates the proposal will avoid 2.2 billion tons of GHG emissions by 2050. Compared to the proposal, the Renewable Fuel Standard (RFS) has already resulted in nearly 1 billion metric tons of cumulative GHG savings from 2008-2020, exceeding projections largely due to the reduced carbon intensity of corn ethanol.[15] The RFS has already delivered half the emissions reductions in 13 years that EPA projects the vehicles rule will take nearly 30 years to deliver, highlighting the importance of using biofuels like ethanol to enhance the GHG emissions reductions from transportation with the right policies.

The most recent assessment from the Department of Energy’s Argonne National Laboratory concludes corn ethanol’s carbon intensity decreased 23 percent from 2005 to 2019 due to increased corn yield, reduced fertilizer intensity and improved ethanol production efficiency, with corn ethanol now between 44 and 52 percent lower in carbon intensity (CI) than the gasoline it replaces.16 Argonne’s conclusions are similar to analysis from Environmental Health and Engineering finding ethanol now results in 46 percent fewer GHG emissions compared to gasoline, due to improved corn production, ethanol production efficiencies and land productivity.[17]

Corn-based ethanol can reach net zero emissions with continued on-farm improvements and soil carbon sequestration, along with carbon capture technology and new efficiencies in ethanol production. Corn farmers are proud of our leadership in adopting conservation and best management practices. NCGA’s recently released Corn Sustainability Report details corn farmers’ history of improvements and our commitment to further sustainability achievements by 2030

Sustainable production means corn farmers today are producing more corn using less land and fewer resources. For example, planted corn acres in 2020, at 90.8 million acres, were less than planted acres in 2007, the year the RFS was expanded, at 93.5 million acres. USDA data also shows the area planted to principal crops in the United States is not expanding overall. Corn production has increased primarily because crop yields have increased from an average of 150 bushels per acre in 2007 to 172 bushels in 2020. With the average yield in 1980 at just 91 bushels per acre, productivity growth is a long-term trend.

Using the expertise of Argonne’s scientists and the U.S. Department of Agriculture’s data, we believe Argonne’s Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (GREET) model is the federal government’s most accurate tool for evaluating biofuel and energy lifecycle emissions. Because GREET is regularly updated, this model captures GHG emissions reductions from farmers’ improved production practices and will incorporate the ongoing, voluntary climate-smart improvements in agriculture production this Administration supports, ensuring further carbon intensity reductions are accounted for in the LCA.

Corn production has improved across all measures of resource efficiency, including higher crop yields per acre, resulting in greater corn production using less land and fewer inputs, further fortifying ethanol as a sustainable, low-carbon renewable fuel. This progress is reflected in Argonne's most recent analysis, which builds on and is consistent with other recent reviews.

For example, a 2018 USDA study shows that ethanol then resulted in 39 to 43 percent fewer GHG emissions than gasoline.[18] Building on this progress, additional improvements on farms and in ethanol production supported by expanding markets for low carbon fuels could result in ethanol with up to 70 percent fewer GHG emissions than gasoline, according to USDA's analysis. Furthermore, according to California Air Resources Board (CARB) data, the CI of ethanol under the state's Low Carbon Fuel Standard (LCFS) is more than 35 percent lower today than it was in 2011 and more than 40 percent lower than the CI of gasoline.[19]

These increasing benefits have occurred without accounting for corn's ability to sequester carbon in the soil. Corn as a crop can serve as a carbon sink. As a photo-synthetically superior C4 plant, corn has an extraordinary ability to sequester carbon and move fertilizer nutrients back to the surface for plant growth rather than polluting ground water. Corn's extensive, deep root system makes it one of the few plants with this important capability to make crop production sustainable.

High-yield corn—combined with the steady adoption of best practices such as reductions in tillage intensity—is sequestering carbon from the atmosphere into the soil. This sequestration is increasing soil carbon levels and reducing atmospheric CO2. According to the Journal of Soil and Water Conservation, the potential to sequester atmospheric carbon in soil is greatest on lands currently used for annual crops; most remarkably, there is potential to sequester carbon in the soil at an annual growth rate of 0.4 percent each year.[20] The results of tracking soil organic carbon (SOC) advancements on select USDA-specified agricultural land areas is estimated to have sequestered an estimated 309 metric tons of CO2-equivalent in less than a decade.[21]

Although GHG lifecycle models do not currently account for this direct GHG reduction from corn production, NCGA believes the effect of corn crops on soil carbon sequestration, among other considerations, should be incorporated into current lifecycle analysis. This increase in soil carbon from corn production, when included, could result in a 20 gram/MJ carbon credit for corn-based ethanol.[22] Fully accounting for corn's carbon sequestration would further demonstrate significant low-carbon advantages of a high-octane midlevel ethanol blend.

CRITERIA POLLUTANTS AND AIR TOXICS

Bringing high octane fuel to market in the form of midlevel ethanol blends will be significantly less capital-intensive than attempting to increase blendstock octane with hydrocarbon components at refineries. It will also be incredibly cleaner. The avoided production cost and offset emissions lower end-costs to consumers, reducing both economic costs and social costs related to health and environment, key considerations in advancing environmental justice and avoiding adverse impacts from oil refineries on communities that have historically borne them.

Increased volumes of ethanol in fuel displace the most harmful compounds from gasoline.[23] These aromatic hydrocarbon additives (i.e. benzene, toluene, ethylbenzene, xylene – or BTEX) have high cancer-causing potential. Increasing the ethanol volume in fuel to a midlevel blend has a positive impact on tailpipe emissions of toxins, including significant reductions in particulates and carbon monoxide. These same aromatic hydrocarbons are also precursors to the formation of secondary organic aerosols (SOA), which in turn are a major contributor to particulate matter emissions (PM 2.5). [23]

According to EPA’s review for the 2020 Anti-backsliding Study, ethanol does not form SOA directly or affect SOA formation. However, as EPA states, toluene is a large contributor to SOA. Ethanol’s high octane value ‘greatly reduces the need for other high-octane components including aromatics such as toluene.’ [24]

As explained in EPA’s Fuel Trends Report: Gasoline 2006-2016, ‘Ethanol’s high octane value has also allowed refiners to significantly reduce the aromatic content of the gasoline, a trend borne out in the data.’ EPA’s data shows that aromatics’ share of gasoline volume dropped from nearly 25 percent to 19.3 percent, and benzene volume dropped from 0.99 percent to 0.58 percent between 2000 and 2016, the same time as ethanol blending increased from 1 percent to at least 10 percent.

EPA’s data demonstrates the air quality and human health benefits of increased ethanol blending in gasoline by replacing harmful aromatics with clean octane from ethanol. Limiting the aromatics content of gasoline and using higher ethanol blends in high octane fuel would further reduce risks from SOA formation and exposure to PM 2.5, which causes serious respiratory, cardiovascular, and other health harm, including premature death, according to the American Lung Association. The same GDI engine advancements that help lower GHG emissions have the unfortunate side effect of increasing particulate emissions, which could be reduced by use of midlevel ethanol blends.

Petroleum-based aerosol particles represent a significant source of pollution, especially in population-dense urban areas. Health issues related to PM and other emission-based pollutants can be reduced by lowering the volume of petroleum in the domestic gasoline pool, which can be accomplished by increasing octane with higher ethanol blends and replacing more hydrocarbon aromatics with ethanol.

In the proposed rule, EPA states that based on the predicted emissions changes from the proposed standards, very small changes in ambient air quality are expected.[25] EPA could greatly increase the air quality, health, and environmental justice benefits of the proposal by cleaning up the fuel going into the 92 percent vehicles by MY 2026 expected to use liquid fuels. We urge EPA to take immediate steps toward setting a clean, high octane fuel standard that blends more ethanol to replace aromatics to expand the health and environmental justice benefits of this proposal, as well as set caps or limits on air toxics in future rulemakings. [EPA-HQ-OAR-2021-0208-0246-A1, p. 6]

TRANSPORTATION COSTS

In addition to failing to decarbonize liquid fuel, simply transitioning current premium fuel to the new ‘regular fuel’ as a higher octane E10 blend, such as a 95 RON E10, would be significantly more expensive to consumers than current regular E10 fuel.

However, a higher RON level met through increased ethanol blending, would reduce fuel costs compared to higher RON fuels with less ethanol content. Incremental refining costs to produce a 98 RON E20 or E30 fuel could be between $0.02-$0.05 per gallon, respectively, based on one analysis. Incremental refining costs are estimated to be nearly $0.20 per gallon to produce a 98 RON fuel using 10 percent ethanol.26 Because of the availability and effectiveness of ethanol as an octane enhancer, a midlevel blend 98 RON fuel is cleaner and more cost-effective.

Analysis presented to Ag-Auto-Ethanol Work Group by the Defour Group compares the economics of a 95 RON E10 fuel and a 98 RON E25 fuel.[27] This analysis builds on Hirshfeld, et al.’s use of a linear programming model to estimate the refining economics of increasing fuel octane ratings and ethanol content. This additional analysis shows that the presence of a 98 RON high-octane midlevel blend in the market, along with a 95 RON E10 fuel, would change the economics of high-octane fuel and fuel pricing.

When additional ethanol is blended to reach 98 RON, it allows for a lower-octane base gasoline blendstock, which costs less to produce at the refinery and avoids refinery GHG emissions. Coupled with the low cost of ethanol added to raise octane, the finished high-octane midlevel blend is less expensive. This updated analysis concludes that a 98 RON E25 fuel would be cost comparative with the current regular fuel, accounting for a transition with both 95 RON and 98 RON fuels in the market.

Using more ethanol enables a larger increase in fuel octane, allowing for greater efficiency improvements, at a lower cost. When more refining is needed to increase fuel octane, as with current premium E10 blends, the cost will be greater. An E25 blend would support additional octane at a lower price than current premium fuel. Drivers of future model year vehicles optimized to use a higher RON fuel would not pay more for fuel over the lifetime of the vehicle with low carbon, high octane midlevel ethanol blend fuel.[EPA-HQ-OAR-2021-0208-0246-A1, pp. 2-7]

Higher octane fuel, with ethanol as a clean octane source, would result in a cost-effective fuel that offers automakers an additional technologically and economically feasible means to meet more stringent emissions standards. Additionally, high-octane fuel would enable vehicle technologies that result in more GHG emissions reductions and enable greater [EPA-HQ-OAR-2021-0208-0246-A1, p. 7]

Correct the fuel economy formula by updating the R-Factor to 1.0 to reflect documented operation of modern engine technology.

Correcting the R-Factor in the fuel economy formula would support automakers developing high efficiency engines that require higher octane ratings and a higher ethanol content. EPA has acknowledged that the current EPA-mandated R-Factor of 0.6, originally established in the

1980s, is outdated and fails to achieve the statutory purpose of making fuel economy testing on today's fuel equivalent to fuel economy testing in 1975.

An update to 1 from 0.6 would reflect results of analysis by the Department of Energy and EPA using modern engines and fulfill previous observations and commitments from EPA to address this issue. Published studies have shown that R for modern vehicles should be around 0.93 to 0.96.[30]

As NCGA explained in 2020 comments on EPA's proposed rule on vehicle test procedure adjustments in Docket EPA–HQ–OAR–2020-0104, an R-factor of 1.0 in the fuel economy formula would support a lower-carbon fuel policy, providing automakers with greater options for choice and innovation in meeting more stringent GHG standards through vehicle technologies and lower carbon fuels. Without this overdue correction, use of lower carbon fuels will continue to be unjustifiably penalized in the fuel economy formula. Setting the R-factor to 1.0 sets fuel economy results on an energy basis. In application, the R factor equation is a 'fuel response factor,' adjusting for more than just energy density. An R of 1.0 essentially converts fuel economy to mile per gallon gasoline equivalent (MPGge), which is how other alternative fuels such as propane, natural gas, and electricity have been compared to their gasoline counterparts for decades.

Setting R to 1.0 provides equitable treatment to renewable ethanol that other alternative fuels already receive. This change could help speed the transition to certification with Tier 3 fuel as well as encourage vehicle manufacturers to seek certification for even higher ethanol blends, such as E15 or the high octane E30 EPA suggested in its Tier 3 proposal several years ago. Manufacturers are not incentivized to build dedicated high-octane vehicles that reduce GHG emissions when those low carbon benefits are penalized by a low R factor. [EPA-HQ-OAR-2021-0208-0246-A1, p. 8]

Lower summer vapor pressure to 9 psi or less for all fuel or provide parity in Reid Vapor Pressure (RVP) treatment for all ethanol blends with E10.

Higher ethanol blends such as E15 offer an immediate decarbonization opportunity and support a transition to low carbon, high octane fuel. However, outdated RVP rules and the oil industry's refusal to produce lower volatility blendstock prevents E15 – which is lower in evaporative, tailpipe and GHG emissions – from reaching the market on the same terms as standard E10 fuel. Addressing these outdated rules would allow lower-volatility and lower-emissions E15 full market access and support EPA's efforts to reduce emissions across the board, and it is unfortunate the oil industry took EPA to court to block the agency's 2019 action aimed at updating unnecessary fuel restrictions in order to keep cleaner E15 out of the marketplace and limit consumer choice.

By using existing authority in the Clean Air Act to require lower volatility conventional gasoline blendstock during the summer months to reduce emissions of volatile organic compounds and decrease the potential for ozone formation, EPA would simultaneously open the market to E15 year-round. NCGA urges EPA to take this action to improve air quality while simultaneously eliminating outdated barriers to cleaner, low carbon higher ethanol blends like E15 and future high octane fuel. [EPA-HQ-OAR-2021-0208-0246-A1, p. 9]

FLEX FUEL VEHICLES and CREDITING

Beyond ethanol's utility in all gasoline engines to reduce GHG emissions, other alternative vehicle technologies can also harness the GHG reductions and air quality benefits of ethanol, such as Flex Fuel Vehicles (FFVs). FFVs utilizing higher blends of low carbon ethanol, such as E85, can provide immediate emissions reductions without tangibly altering the price of the vehicle and reducing fuel costs. In fact, E85 is typically sold at a lower price than gasoline, translating to monetary savings in addition to the significant air pollution savings.

Compared to gasoline, E85 leads to significant reductions in NOx and GHG emissions. E85 avoids use of toxic hydrocarbon aromatics in gasoline that are precursors to secondary organic aerosols that result in harmful fine particulate matter emissions that cause serious respiratory, cardiovascular, and other health harm, including premature death, according to the American Lung Association.

Incentivized to reduce emissions through the state's Low Carbon Fuel Standard (LCFS), in California some FFVs are even powered by a blend of 15 percent renewable naphtha with 85 percent ethanol. These vehicles use zero fossil fuels, have improved air emissions profiles, and have an extremely low carbon intensity. As such, NCGA has recently advocated to CARB to go a step further to decrease emissions in its most recent Advanced Clean Cars and Scoping Plan proposals by requiring that all PHEVs MY 2026 and later up be a FFV.

Just as we recommended to CARB, EPA also should not constrain its vision of a zero-emission vehicle and a zero-emissions future based on today's vehicle limitations, but rather remain focused on setting technology and feedstock neutral standards and allowing markets to innovate and respond. California's LCFS has resulted in a reduction in ethanol CI in the state, as well as increased demand for low carbon fuel like E85 and FFVs, as low carbon ethanol has helped the state meet ambitious GHG emission reduction goals. [EPA-HQ-OAR-2021-0208-0246-A1, pp. 9-10]

Despite the GHG and criteria pollution reduction benefits of FFVs, as well as the low cost to purchase and fuel these vehicles, automakers have cut back on FFV models and now offer very few choices to consumers. Well-structured vehicle credit programs remain an impactful, cost-effective means for the government to encourage the introduction and adoption of new products and technologies. However, NCGA is concerned that reinstating a credit multiplier for EVs, as the proposal would do, further incentivizes selected types of low emissions vehicles but not others. With this proposal, EPA picks technology winners and losers. To encourage introduction of a wider range of low emission vehicle choices, NCGA believes EPA must provide equitable crediting across the spectrum of low emission vehicles, including FFVs. [EPA-HQ-OAR-2021-0208-0246-A1, p. 10]

NCGA also urges EPA to take steps to update the F-factor in the fuel economy formula to a forward looking F-factor of at least 0.2, as we outlined in 2020 comments in response to Docket EPA–HQ–OAR–2020-0104. Furthermore, we urge EPA to reinstate the 0.15 volumetric conversion factor for FFVs. EPA should reharmonize the 0.15 factor for FFVs in these standards, and, if not, in future standards. This change would accurately reflect the significant carbon emissions reductions from FFVs using E85 because the carbon emissions from the fuel are the release of carbon taken up through crop growth. [EPA-HQ-OAR-2021-0208-0246-A1, p. 10]

Conversely, EPA could also level the playing field for vehicle technology by similarly treating the ethanol portion of fuel as carbon neutral, supporting greater use of low carbon renewable fuels. The carbon emitted from ethanol use is the same carbon the corn plant absorbed from the atmosphere, resulting in no net carbon. [EPA-HQ-OAR-2021-0208-0246-A1, p. 10]

Commenter: National Farmers Union (NFU)

NFU is particularly concerned with the challenges that climate change poses to agricultural production and family farmers’ ability to pursue improvements in global food security.1 Farmers, ranchers and rural communities can contribute to climate resilience and help circumvent serious harms to the economy and human health.[EPA-HQ-OAR-2021-0208-0243-A1, p.1]

These efforts are supported by the biofuels industry that eases the burdens on farmers and provides additional markets to facilitate a move toward sustainable practices and climate mitigation actions. Toward those ends, NFU supports the use of ethanol as a fuel additive for gasoline formulations to enhance octane levels, especially moving toward use of mid-level blends of ethanol. Use of higher ethanol blends will provide significant benefits to the rural community and beyond. Disincentives to move toward higher ethanol blends by favoring other technologies limits these investments and benefits to farmers. [EPA-HQ-OAR-2021-0208-0243-A1, pp. 1-2]

NFU has called upon EPA to take immediate and concrete steps aimed at curbing greenhouse gas (GHG) emissions. Ethanol has superior octane-boosting properties and is an environmentally safer substitute for oil-derived, benzene-based octane enhancers. Mid-level ethanol blends (e.g., E20-E40) are the most economical high-octane fuels available today. In response to numerous comments suggesting various actions EPA should take to support and promote use of high octane fuels, such as mid-level ethanol blends,2 EPA stated that it ‘has given careful consideration to these comments and agrees that these commenters have identified both current and promising technologies that may be able to deliver significant improvements in reducing GHG emissions once fully deployed.’3 Recently, NFU, as part of the High Octane Low Carbon Alliance (HOLCA) led by former Senator Tom Daschle, joined with numerous organizations, calling for this Administration to address octane in the revised Light-Duty Vehicle GHG Emissions Standards.4

Despite the widespread agreement regarding the need to move this country toward high octane fuels, including by auto manufacturers, and the numerous studies that have been presented to

EPA on the benefits of mid-level ethanol blends, EPA's proposal for revising the GHG standards for light-duty vehicles fails to take these fuels into account. This ignores a key consideration. NFU also understands EPA is planning to take additional actions to address emissions from vehicles. NFU submits these comments to urge the Administration to promote high octane fuels through supporting mid-level ethanol blends in the final rule and in future rulemakings. [EPA-HQ-OAR-2021-0208-0243-A1, p.2]

EPA MUST CONSIDER THE AVAILABILITY OF HIGH-OCTANE FUELS TO REDUCE GHG EMISSIONS FROM LIGHT-DUTY VEHICLES.

Automakers have been working on developing higher compression engines to improve thermal efficiency and thereby fuel economy. Studies have been presented to EPA that show the benefits of using high octane fuels on vehicle efficiency.5 Increased volume of ethanol increases the octane level of gasoline across grades. In addition to its higher octane level, ethanol also features high sensitivity and high heat of vaporization, which increase engine efficiency.6 In short, ethanol offers engine knock resistance at a lower cost than any other octane booster in gasoline. Higher ethanol blends can increase fuel octane without expensive refinery upgrades. A report issued by Oak Ridge National Laboratory, Argonne National Laboratory and the National Renewable Energy Laboratory cites increased vehicle efficiency, increased acceleration and significant reductions in GHG emissions among the demonstrated benefits of mid-level ethanol blend fuels.7 The study found that vehicle manufacturers could benefit from high octane, low carbon fuels as a means to meet future fuel economy and GHG requirements, and serve as a way to increase torque in performance applications. That study also found that feedstock availability and costs are not expected to be obstacles to the substantial development of a high-octane fuel market, with E40 providing the greater fuel cost savings.

EPA's proposal recognizes high compression engines as advancements in internal combustion engines (ICE), noting the availability of the 'very cost-effective ICE technology that is in-use today and ready for broader application.'8 For years, auto manufacturers have supported 'bringing high octane fuels to market' that are aligned with these improved engine technologies and vehicles,9 recognizing '[h]igher-octane fuels are the cheapest CO2 [carbon dioxide] reduction.'10 Recently, the Alliance for Automotive Innovation (Alliance), which represents automakers that produce nearly 99% of the new light-duty vehicles sold in the United States, acknowledged that vehicle improvements, along with high octane fuels, 'should be encouraged as additional solutions as soon as possible to maximize environmental benefits across the fleet.'11 The Alliance stated the use of high octane low carbon liquid fuels 'would simultaneously support vehicle performance, including fuel economy, and further reduce greenhouse gas emissions'; these benefits 'would be realized by new and existing internal combustion engines.'12 These engines and high octane fuels, specifically mid-level ethanol blends, are not 'crystal ball' technologies, but are technologically feasible and economically reasonable means to achieve better fuel economy and reduced GHG emissions available today.

Yet, it appears that EPA's proposal ignores the availability of high octane fuels to utilize high-compression ratio technology and advanced ICE technologies. These engine technologies can deliver the emissions reductions necessary to meet these and future GHG standards, but high octane fuels best optimize these technologies, and thereby optimize GHG reductions. Recent reports on climate change impacts indicate the very real need to reduce GHG emissions today. It is not just a missed opportunity to incorporate use of mid-level ethanol blends as high octane fuel for reducing GHG emissions from light-duty vehicles, it is error to refuse to even consider it. [EPA-HQ-OAR-2021-0208-0243-A1, pp. 2-4]

MID-LEVEL ETHANOL BLENDS ARE COST-EFFECTIVE, HIGH OCTANE LOW CARBON FUELS THAT PROVIIDE NUMEROUS BENEFITS.

The alternatives to ethanol as an octane booster are petroleum-based. [EPA-HQ-OAR-2021-0208-0243-A1, p. 4]

Ethanol, however, is substantially cleaner than petroleum-based octane additives, and 'using ethanol as the source of octane in future high octane fuels has the potential to significantly decrease petroleum refinery GHG emissions by reducing the energy intensity of the refining process.'[EPA-HQ-OAR-2021-0208-0243-A1, p. 4]

It reduces emissions of particulate matter (PM) and air toxics such as benzene, toluene, and xylene. PM2.5 has been shown to contribute to a significant portion of premature deaths due to air pollution, and such emissions from gasoline are likely significantly underreported.14 EPA-HQ-OAR-2021-0208-0243-A1, p. 4]

Importantly, increased ethanol use provides additional GHG emissions reductions, which is increasingly important as the carbon intensity of gasoline is increasing with greater use of unconventional fossil fuels. 'Emissions from fossil fuel combustion comprise the vast majority of energy-related emissions,' with an increase in emissions from the transportation sector largely attributed to increased vehicle miles travelled and motor gasoline consumption by light-duty vehicles.15 At the same time, energy use in ethanol production and lifecycle GHG emissions have decreased with changes in farming practices and increased intensification (e.g., higher yields). EPA has found, the land use, land-use change, and forestry sector resulted in a net increase in carbon stocks (i.e., net CO2 removals). [EPA-HQ-OAR-2021-0208-0243-A1, p. 4]

The National Highway Traffic Safety Administration's (NHTSA) Draft Supplemental Environmental Impact Statement on its recent proposal to revise fuel economy standards recognizes increased GHG benefits with higher blends of ethanol, as well as the ongoing reduced carbon intensity of corn ethanol.17 [EPA-HQ-OAR-2021-0208-0243-A1, pp. 4-5]

Previously, EPA has referenced purported challenges to transitioning to high octane fuels stemming from costs to consumers who drive vehicles designed for current regular octane grade fuel, contending the 'net positive benefits could take many years.'18 But, this has been disputed by automakers. In testimony before Congress, a representative of General Motors stated: 'We believe increasing the minimum octane level in U.S. gasoline for new vehicles will be a win for all industries and, most importantly, consumers.'19 'We have an opportunity to play a large role in offering consumers the most affordable option for fuel economy improvement and greenhouse gas reduction. We believe a higher efficiency gasoline solution with a higher Research Octane

Number (RON) is very important to achieving this.'20 Although that testimony referenced a lower RON than NFU believes should be utilized, consumers would benefit from projected fuel cost savings, reduced price volatility, increased torque in performance applications, and the energy security and environmental attributes of mid-level ethanol blends. Based on information previously provided, EPA should be fully aware of the reduced costs of producing mid-level ethanol blends, where ethanol is less expensive than gasoline, decreasing costs at the pump.21 As noted, the National Renewable Energy Laboratory found costs to not be a limiting factor to increase biofuel use through requiring higher octane fuels.22 More recent information confirm the benefits to consumers as a result of increased biofuel use.23 [EPA-HQ-OAR-2021-0208-0243-A1, p. 5]

As noted above, the Alliance has recognized that high octane fuels can benefit existing vehicles. More recent analysis further supports that mid-level ethanol blends can be used in existing vehicles, which should reduce concerns about any 'transition' to use of higher octane fuels. A study conducted by North Carolina State University found that vehicles on the road today can adapt to mid-level ethanol blends.24 Researchers compared E10 (regular and premium) with E27 in one flexible fuel vehicle (FFV) and four non-FFVs and found all five vehicles adapted to each fuel. The study also found E27 can increase engine efficiency and reduce carbon monoxide (CO) and PM emissions. A study by the University of Nebraska Lincoln on use of E30 in non-FFVs used by the State of Nebraska also found the non-FFVs were able to adjust the airto- fuel ratio to adapt to the higher oxygen content of E30, and E30 had no observable negative effect on overall vehicle performance.25 Comparing E15 to E30, the Nebraska report found a 40% reduction in CO2 emissions and that E30 is cost-effective due to the increased use of ethanol. Thus, these are benefits that can be achieved today, even in existing vehicles. [EPA-HQ-OAR-2021-0208-0243-A1, pp. 5-6]

EPA CAN, AND SHOULD, UNDERTAKE REGULATORY REVISIONS TO PROMOTE MID-LEVEL BLENDS OF ETHANOL.

Mid-level ethanol blends are available today, as they are authorized for use in FFVs and provide cost savings to consumers. But regulatory barriers are preventing their wider use. While EPA should have considered the availability of high octane fuels in its revised proposal, additional regulatory actions by EPA also should be taken to promote use of mid-level ethanol blends, as previously explained by NFU, among others.

Octane Fuel Requirements: First, as again stated by many at EPA's public hearing on EPA's proposal for revised light-duty vehicle GHG standards, EPA can use its authority under the Clean Air Act to approve and require specific octane levels, like 100 RON. Several comments have been submitted to EPA previously, outlining this authority.26 While NFU expects other comments on this proposal also will further address EPA's authority to approve and require higher octane in fuels under its Clean Air Act authority in Sections 202 and 211, which NFU supports, EPA has acknowledged that 42 U.S.C. §7545(c) gives it authority to 'control' gasoline octane levels.27

Certification Fuel Requirements: Second, EPA should ease the ability to use mid-level ethanol blends as certification fuel. EPA has acknowledged that mid-level ethanol blends can be approved as certification fuel under 40 C.F.R. §1065.701.28 NFU, among others, previously explained how EPA can streamline the approval process for mid-level ethanol blends, as high octane fuels, to be certification fuels.29 As explained, EPA can make findings to facilitate use of mid-level ethanol blends as certification fuel but may need to make regulatory changes to ensure flexibility to use mid-level ethanol blends more generally. Because mid-level ethanol blends are 'accessible, obtainable'30 in commerce today, EPA should make clear that mid-level ethanol blends meet the criteria in Section 1065.701(c) that the fuel be 'commercially available.'31 EPA should also clarify that E30 is representative of mid-level ethanol blends to give retailers and automakers more flexibility in sales and engine design without imposing undue certification requirements for each blend level. Once EPA approves the certification fuel, the manufacturer should be able to make a determination that the approved fuel can be appropriately used in other model year vehicles without going through the waiver process under 42 U.S.C. §7545(f). Such flexibility may require updates to EPA's fuel registration process under 40 C.F.R. Part 79. [EPA-HQ-OAR-2021-0208-0243-A1, pp. 6-7]

Fuel Economy Formula (R-Factor): Third, with approval of alternative certification fuels, EPA should also adjust the formula in 40 C.F.R. §600.113-12 used for determining fuel economy to ensure an appropriate R-factor and a multiplier in recognition of the lower carbon content of the proposed certification fuel. The current fuel economy equation includes adjustments meant to control for changes in the test fuel from testing in 1975 that affect fuel economy.32 One adjustment is known as the R-factor, which is intended to represent the response of a typical vehicle's fuel economy to small changes in the fuel's energy content.33 The current equation in the regulations uses an R-factor of 0.6 based on data from the 1980s. This factor fails to adequately adjust for changes in the test fuel with increased ethanol volume, as required by law.34 There has been support for making this change for years, and EPA has acknowledged that changes to the R-factor may be warranted.35 While EPA did propose a change in 2020 for E10,36 that proposed R-Factor (Ra=0.81) may still be too low, as there is ample information to show that the R-Factor should be '1' or closer to 1, which several commenters supported, including automakers.37 'With [a] correct R Factor, high-octane mid-level blends can offer real CAFE as well as GHG benefits.'8 Making this adjustment would allow automakers to use the new test fuel for purposes of compliance with the fuel economy requirements without being unfairly penalized for using a test fuel with a lower energy content. [EPA-HQ-OAR-2021-0208-0243-A1, pp. 7-8]

Reid Vapor Pressure: Fourth, EPA should work with the ethanol industry to resolve Reid Vapor Pressure (RVP) restrictions on using ethanol blends above E10 year-round. Ethanol itself has a low RVP rating, and, at higher blends, such as E30, the RVP should not be an issue, as the higher volume of ethanol counteracts potential increases based on the petroleum gasoline. NFU appreciates EPA's recent efforts to address the RVP waiver for E15. While those efforts remain pending in litigation on appeal, those efforts did not adequately address mid-level ethanol blends. The ethanol and automotive manufacturing industries have also suggested an alternative approach to issuing a broader waiver; that is, imposing lower RVP limits on the petroleum gasoline blendstock to ensure available blendstock for higher blends of ethanol. While EPA referenced potential adverse impacts on fungibility of fuel, there is precedent showing the gasoline blendstock can be set at a lower RVP to protect against exceeding 9 psi to address air quality concerns.39 In either case, NFU urges EPA to continue to work with the ethanol industry to find a solution to allow year-round sales, as the potential restrictions during the summer months will create practical restrictions to expanding the use of ethanol.40 [EPA-HQ-OAR-2021-0208-0243-A1, p. 8]

Substantially Similar Finding: Finally, EPA can also use its authority to approve midlevel ethanol blends for use under Clean Air Act section 211(f), 42 U.S.C. § 7545(f). Starting in 2017, gasoline emissions certification fuel now contains 10 percent ethanol. As such, section 211(f)(1) no longer limits ethanol blending in market fuel, as any ethanol blend, including midlevel ethanol blends, are 'substantially similar' to a certification fuel. Moreover, given that the effects of gasoline/ethanol blends like E20, E25, and E30 are already well-known, it makes little to no sense for EPA to interpret the requirements of section 211 as rigidly and burdensome as it has done in the past for new fuels. EPA should issue an updated interpretation of 'substantially similar' to confirm the ability to use these fuels. [EPA-HQ-OAR-2021-0208-0243-A1, p. 8]

EPA SHOULD INSTITUTE CREDITS TO SUPPORT VEHICLES THAT PROMOTE INCREASED USE OF RENEWABLE FUELS.

Congress established policies, which were intended to work together, to promote production of U.S. biofuels and, thereby, energy independence. These policies include the Renewable Fuel Standard (RFS) program, which has worked to support growth in the use of renewable fuels, including ethanol, since 2005.41 Although EPA has pointed to the RFS to explain why it need not support renewable fuels under its GHG requirements,42 EPA's GHG emission regulations should work hand-in-hand with the RFS program, supporting biofuels. And this ignores how increased use of ethanol can support compliance with the proposed and future GHG standards. The agencies should restore or include incentives that can be provided to automakers to ensure vehicles being produced consider the increased use of renewable fuels.

One way to promote mid-level ethanol blends, and thereby higher-octane fuels, is to restore meaningful credits for FFVs and to establish a new incentive for engines optimized for efficiency on mid-level ethanol blends. FFV production has been impacted by EPA's unfair treatment compared to other alternative fuel vehicles. Incentives to stimulate the production of vehicles that produce the benefits sought, and reduce costs to consumers, are appropriate. NFU appreciates EPA's guidance that it will retain an 'F Factor' of 0.14 for E85 (rather than default to zero) until EPA revises its guidance. Information has been provided to EPA to support an increase in the F Factor to account for greater penetration of E85 in the marketplace.43 EPA should issue any guidance necessary to give automakers sufficient certainty for automakers to make appropriate investments and work to update this factor for later model years to continue to support FFVs.44 Based on EPA's current restrictions on mid-level ethanol blends, FFVs remain an important incentive to sell mid-level ethanol blends, supporting continued investment in retail and infrastructure to expand use as part of any transition to high octane fuels.

In addition, EPA has acknowledged that raising octane levels could enable 'LDGHG standards that go beyond the 2025 standards.'45 Thus, automakers that take action to move ahead of the curve should be able to obtain credits toward meeting the GHG requirements. Such incentives could be tied to use of higher ethanol blends as a certification fuel, thereby supporting those efforts to provide mid-level ethanol blends at the pump but also better ensure the benefits of these higher performing engines. Although EPA is proposing to restrict the credits under the program, it provides little incentives for these other clear solutions to address GHG emissions. EPA should not unduly restrict such incentives as it did with FFVs. Providing such incentives will create better benefits and move the country toward more efficient vehicles and higher octane, lower carbon fuels. It is also consistent with EPA's interpretation of its authority under section 202 to provide incentives to push new technologies. Introduction of these better performing fuels and engines are needed, and we believe consumers will reap the benefits and continue their use [EPA-HQ-OAR-2021-0208-0243-A1, pp. 8-10]

EPA'S EMISSIONS MODELING SHOULD BE ADJUSTED TO BETTER ACCOUNT FOR THE BENEFITS OF ETHANOL FOR AIR QUALITY.

Ethanol Provides Air Quality Benefits, Which May Not Be Accurately Reflected in EPA's Current Models.

Ethanol, a renewable fuel, changes the emissions profile of gasoline, creating a cleaner, safer motor vehicle fuel. Real-world evidence shows use of ethanol blends reduces emissions of CO, PM, air toxics, and GHGs compared to burning petroleum gasoline. With higher octane fuels, and related engines discussed above, the motor fuel can burn even more efficiently. This results in better overall air quality than when vehicles burn conventional gasoline, significantly improving public health.

Concerns have been raised regarding the models used by EPA to determine emissions from fuels. Third-party reviews have shown that MOVES2014 may be inadequate as a tool for estimating the exhaust emissions of gasoline blends containing more than 10 percent ethanol. The model's results for mid-level ethanol blends have been shown to be inconsistent with other results from the scientific literature for both exhaust emissions and evaporative emissions, including results from real-world emissions testing.46 The problems with MOVES2014 have been tied to the model's use of data that misrepresents the actual parameters and composition of mid-level ethanol blends. While EPA recently released MOVES3, it is unclear if EPA made the appropriate adjustments to adequately reflect the benefits of blends above E10,47 and EPA should ensure its models are properly updated to do so.

Recent Assessments Show Continued Improvements in GHG Lifecycle Analysis, Finding Greater Emissions Reductions for Ethanol Compared to Petroleum Gasoline Than EPA Has Estimated.

The Energy Independence and Security Act of 2007 required EPA to conduct lifecycle GHG emissions analysis to identify the renewable fuels eligible to meet the various categories under the RFS program. EPA conducted this analysis for corn-based ethanol as part of the 2010 RFS rulemaking. Since that time, published studies and more recent data have improved the understanding of corn ethanol's lifecycle GHG impacts, showing much higher reductions in GHG emissions for corn ethanol compared to petroleum gasoline.48 As noted above, corn ethanol plants have become more efficient. In addition, U.S. farmers have responded to demand and concerns by moving toward sustainable practices and intensification, not land expansion. The land use aspect of EPA's analysis has not been experienced in the real world.49

Despite these advancements in lifecycle analysis, EPA has chosen not to acknowledge the significant overall benefits of increased ethanol use with respect to GHG reductions compared to petroleum-based gasoline. While requests to update the RFS lifecycle analysis have been rejected by EPA to date, the RFS statute includes specific parameters of how that analysis must be conducted, and this should not limit EPA's analysis of GHG benefits of ethanol blends. These newer studies and data show greater emissions reductions associated with corn ethanol, which is even more pronounced where more unconventional sources and heavier crudes are being used for gasoline today than in 2005 – the baseline used under the RFS. EPA, however, has declined to consider the significant GHG impacts of burning petroleum gasoline and the benefits of increasing use of renewable fuels beyond tailpipe emissions. [EPA-HQ-OAR-2021-0208-0243-A1, pp. 10-11]

The family farm forms the backbone of this country. As discussed above, biofuels have played an important role in supporting family farms, which have faced significant pressure to stay in production from many sides and a struggling economy. NFU supports continued efforts to address GHG emissions and, thereby, climate change and the climate resilience it brings to the food system. NFU strongly encourages EPA to make appropriate regulatory changes to support increased use of mid-level ethanol blends, which are high octane, low carbon fuels. As has been shown by numerous studies, ethanol provides significant air quality benefits, in addition to providing much needed jobs and creating stability in markets providing benefits and promoting investments in the rural economy. Virtually all parties, including EPA, acknowledge the GHG and fuel economy benefits of high octane fuels in more efficient engines, and the costeffectiveness of using higher ethanol blends to meet the goals of these requirements. [EPA-HQ-OAR-2021-0208-0243-A1, pp. 11-12]

20 Id. at 2. As described further below, NFU urges EPA to make various changes to expand use of mid-level ethanol blends. These actions would provide a transition to these improved technologies and achieve the benefits of using higher octane fuels today.

30 available, https://www.merriam-webster.com/dictionary/available. For example, E25 and E30 are 'common blends' offered at blender pumps. U.S. Department of Energy (DOE), Alternative Fuels Data Center: Ethanol Blends, https://www.afdc.energy.gov/fuels/ethanol_blends.html (last visited Aug. 27, 2021). The Renewable Fuels Association has estimated over 5000 retail stations as offering flexible fuel. RFA, Essential Energy: 2021 Pocket Guide to Ethanol, at 15 (2021), https://ethanolrfa.org/wp-content/uploads/2021/02/2021-Pocket-Guide.pdf. ASTM International has also established a standard for mid-level ethanol blends (D8076).

41 EPA has fallen behind in enforcing the RFS volume mandates, negatively impacting biofuel producers. NFU appreciates EPA's efforts to get the program 'back on track,' and urges EPA to enforce the full 'implied' conventional biofuel requirement of 15 billion gallons and increase the advanced biofuel volumes.

Commenter: National Propane Gas Association (NPGA)

Propane, also known as liquefied petroleum gas (LPG) or 'autogas' when used as a vehicle fuel, is a clean alternative engine fuel for both over-the-road vehicles and industrial lift trucks. Propane is also used in more than 18 million installations nationwide for home and commercial heating and cooking, in agriculture, in industrial processing.[EPA-HQ-OAR-2021-0208-0252-A1, p.1]

EPA recognizes propane as a clean, alternative fuel within the Clean Air Act, possessing lower emissions of hydrocarbons than gasoline and significantly less GHG emissions.8 Additionally, propane is an abundant domestic energy source.9 [EPA-HQ-OAR-2021-0208-0252-A1, p.2]

NPGA urges EPA to incorporate autogas among the multiplier incentives on the basis of its present-day contribution to effective reductions in GHG emissions aligned with the principles of the Biden Administration. The increasing popularity of autogas domestically and globally is evidence of market recognition for an affordable alternative fuel capable of significant emissions reductions.10 [EPA-HQ-OAR-2021-0208-0252-A1, p.2]

We also encourage EPA to include incentives for the production of vehicles that utilize renewable fuel sources, which is surprisingly absent in the proposal. Vehicles across the U.S. – from California11 to Virginia12 – are employing renewable propane to drop carbon intensity to 19 percent.13 We ask EPA to consider these alternative fuels in reevaluating multiplier incentives and leveraging present day technology to direct vehicle production in the orientation of President Biden's environmental goals. [EPA-HQ-OAR-2021-0208-0252-A1, p.2]

Autogas Vehicles

Many public and private vehicle fleets utilize autogas, and research continues to progress on new ways to expand on the clean emissions profile and abundant production volume of autogas. Autogas offers similar power, acceleration, and cruising speed as diesel and gasoline engines, but with a significant reduction in GHG emissions as well as other pollutants.14 Today's marketplace includes many autogas vehicle options15 and thousands of autogas fueling stations across the country.16 Industry-collected data indicates more than 85.4 million gallons of autogas were sold in 2018.17 Initial estimations for total sales in 2019 exceed 90 million gallons. 18 There are more than 200,000 autogas vehicles on the road in the U.S. including passenger and light-duty vehicles manufactured by original equipment manufacturers (OEMs) like Ford, Chevrolet, Freightliner, and Bluebird.19

The adoption of autogas vehicles, incorporation of bi-fuel vehicles, and evolution of renewable propane are evidence of autogas' success as well as an indication of the success autogas can bring to the environmental goals of the Administration. For example, the Clean Cities initiative by the U.S. Department of Energy awards funding to local governments for the procurement of autogas vehicles.20 In a partnership with Clean Cities, the Department of Energy's Argonne National Laboratory evaluated the replacement of 22 diesel commercial delivery trucks with autogas vehicles.21 Research revealed that less than two dozen autogas vehicles displaced 38,000 gallons of diesel annually and reduced greenhouse gas emissions by 80 tons annually.22 Public fleets also successfully utilize aftermarket conversions to reduce vehicle maintenance and fuel costs as well as emissions footprints and improve fuel reliability.23

Renewable Propane Technology

Renewable propane has entered the U.S. and European markets, unveiling new opportunities to transition from conventional fuel and equipment to renewable fuel created by vegetable oil waste.24 In contrast to diesel filters and electric or other alternatives, the innovative options of autogas rely on simple, cost-effective infrastructure and can drop-in to conventional propane equipment without expensive modifications. Renewable propane maintains all the advantages of conventional propane, but with even greater reductions in emissions.25 In Europe, an operation in the Netherlands is distributing approximately 160,000 tons of renewable propane over the next four years.26 One domestic operation based in Louisiana produces approximately 75 million gallons/year of renewable fuels including renewable propane.27 The produced renewable propane is currently utilized in the autogas market throughout the U.S. with a carbon intensity of 45-65 gCO_2e/MJ.28 Further, renewable propane is identical in chemical composition to conventional propane, which means that engines and equipment do not require add-ons or modification to utilize renewable propane or a combination of renewable and conventional propane.29

Our industry is also developing dual-fuel engines with DME. Dual-fuel engines blend two fuels and use a single injection system. Autogas and DME are readily combined based on similar properties and characteristics as both fuels must be kept in pressurized storage.30 DME and autogas can be blended at a ratio of 20 percent DME and 80 percent autogas.31 As noted by EPA, DME is a promising alternative fuel option.32 We are continuing our partnership with DME to explore blending propane and renewable DME (rDME). Specifically, Oberon Fuels and SHV Energy are partnering to develop vehicles and fueling infrastructure needs to utilize a blend of propane autogas and rDME.33 Blending conventional propane with rDME reduces the carbon intensity to 11 gCO_2e/MJ.34 With further research and development, it will be feasible to combine renewable propane and rDME for greater emissions reductions; opening the door to an entirely new fuel concept.35 We ask that EPA incorporate the potential of renewable propane as well as renewable and convention DME as the agency evaluates the multiplier incentives that encourage technology to reach the Administration's environmental goals. [EPA-HQ-OAR-2021-0208-0252-A1, pp. 2-4]

The multiplier incentive program should include provisions for alternative fuels, including autogas, to achieve the agency's ambition for effective GHG emission reduction. [EPA-HQ-OAR-2021-0208-0252-A1, p. 5]

We request that EPA recognize autogas as an alternative fuel that provides significant contributions to the reduction of GHG emissions without sacrificing affordability, convenience, safety, or national energy security. We believe that the incentives should incorporate the advancement of alternative fuels like autogas in the current marketplace. Likewise, EPA should consider the potential market growth as well as energy and emissions achievements that could be accomplished with incentives for alternative fuel combinations like bi-fuel and dual fuel engines. Also, renewable propane is a modern alternative fuel worthy of federal support to encourage market proliferation and deployment to achieve substantial GHG emissions reduction among today's vehicle fleet and engine technology. We strongly ask EPA to review the current landscape of the autogas vehicle market and the ongoing research to advance and improve the industry's vehicle technology. [EPA-HQ-OAR-2021-0208-0252-A1, p. 5]

35 For context on the possibilities, the California Air Resources Board estimates that manure converted to DME by Oberon has a carbon intensity of -278 gCO2/MJ. California Air Resources Board, Low Carbon Fuel Standard Proposed New Temporary Fuel Pathway: Renewable Propane (May 8, 2019).

Commenter: NATSO, Representing America's Travel Centers and Truck Stops et al.

The Associations support EPA's desire to lower GHG emissions from light-duty vehicles, but believe that – to best achieve the Agency's stated objectives – any review of emissions standards should be based on science and fuel-neutral. The most expeditious and economical way to lower GHG emissions is through market-oriented, consumer-focused policies that encourage: (1) all technologies to improve their respective emissions consequences and (2) retailers (and thus consumers) to gravitate toward the most environmentally and economically attractive solutions. [EPA-HQ-OAR-2021-0208-0570-A1, p.1]

In particular, the Associations urge EPA to fully account for the environmental benefits of renewable natural gas ('RNG') and high octane fuels. These technologies have the potential to provide compliance flexibility for automakers and expanded choice for consumers while also delivering increased environmental benefits. [EPA-HQ-OAR-2021-0208-0570-A1, p.1]

Octane

The Associations urge EPA to consider the opportunities associated with high octane fuels coupled with increased use of high compression engines. This would not only improve motor fuel's emissions characteristics, but it would enhance fuel economy as well. The Associations are eager to work with the Agency to explore ways that do this in a cost-effective manner that is feasible for both retailers and consumers. In so doing, it will be important that the Agency consider and address a variety of uncertainties around what fuel octane levels would appropriately balance feasibility, cost, and environmental concerns, and how such fuel can be integrated into the existing fuel infrastructure and markets. EPA should specifically address these issues, including:

• Cost-Effectiveness for Retailers – Higher octane fuels can only achieve significant market penetration if it is cost-effective for fuel retailers to sell such fuels. Done properly, higher octane fuels and vehicles that must run on them could gain consumer acceptance over time and fuel retailers will respond accordingly.

• Retailer Liability – Retailers would need to be assured that they will not be held responsible for customers that misfuel (e.g., dispensing less expensive, lower octane fuel into vehicles that must run on higher octane fuels).

• Labeling Requirements – Federal dispenser labeling requirements would have to be streamlined and state requirements would have to be preempted.

• Vehicle Warranties – Auto manufacturers would have to warrant all new higher octane vehicles up to at least E15 depending upon vehicles' capabilities, and would have to affirmatively state which cars in the existing fleet can run on E15 and ensure that the cars are warrantied or retroactively warrantied as such. [EPA-HQ-OAR-2021-0208-0570-A1, p.3]

Commenter: Nebraska Ethanol Board (NEB)

Unfortunately, the proposed rule does not include any provisions dealing with octane specifically or biofuels more generally. This is an enormous, missed opportunity.

While a successful pro-ethanol regulatory strategy will require work beyond this specific rule, EPA's proposal does invite comments on what the agency can do to promote more fuel-efficient vehicles and mentions various fuel-related issues. And, more generally, the Biden Administration has emphasized the following three priorities that, if taken seriously, strongly support the increased use of ethanol-based fuels: addressing climate change, protecting public health, and ensuring that minorities and the poor are not overlooked. We think that EPA needs to take this opportunity to open the door for the use of high-octane, low-carbon fuels made with ethanol. In the following text of these comments, we lay out a high-level overview of what this request should focus on as well as a non-exhaustive list of supporting points and related fixes that EPA would do well to consider.

High-octane midlevel ethanol blends would enable more efficient vehicles, reduce greenhouse gas emissions, and reduce pollution.2 EPA's duty under the Clean Air Act is to protect the health of all Americans by use of commercially available methods. And it is thus irresponsible for EPA to ignore this option in regulating greenhouse gas emissions from cars and trucks. An improved gasoline blended with 25-30% Ethanol offers an immediate, low-cost program that offers substantial carbon and health risk reduction that will have the greatest impact in poor, urban areas. EPA must include this important option in those considered for adoption in the new rule with an immediate effective point of no later than 2025. [EPA-HQ-OAR-2021-0208-0248-A1, pp. 1-2]

EPA Should Mandate a Minimum Octane Standard Pursuant to Its Fuel Regulation Authority.

• EPA should phase out today's low-octane blends, as new vehicles are available to take advantage of the efficiency benefits of midlevel ethanol blends. EPA has acknowledged that CAA § 211(c) gives it authority to 'control' gasoline octane levels.3

• EPA can set a minimum octane level under CAA § 211(c)(1) because low-octane gasoline (1) impairs manufacturers' ability to further increase compression ratios to reduce CO2 emissions to meet the GHG standards and also (2) increases CO2 emissions in existing legacy vehicles.4

• The fact that EPA did not explicitly discuss this option does not mean that EPA cannot include octane in the final rule. Indeed, it would be arbitrary and capricious not to do so. EPA has flagged fuel-quality-related issues in the proposal, such as efficiency and particulate matter emissions. Internal combustion engines and the fuels they use comprise a single system, and automakers will not be able to develop engines that can take full advantage of the efficiency benefits of midlevel blends unless EPA acts promptly. If not now, when?

• If this rule does not address octane, EPA should move quickly to begin a separate rulemaking on this issue. [EPA-HQ-OAR-2021-0208-0248-A1, p. 2]

EPA Should Correct Its Inaccurate Fuel Economy Formula to Allow the Use of Midlevel Ethanol Blends.5

• EPA should repeal and replace its outdated fuel economy formula. EPA has admitted that part of that formula is erroneous and that it unfairly penalizes fuel with ethanol in it; but EPA has not yet fixed the problem. The problem is an important one because it discourages automakers from developing high-efficiency engines that require higher octane ratings and higher ethanol content.

• The fuel-economy calculation contains an 'R-factor,' which is intended to make fuel economy testing on today's certification fuel equivalent to fuel economy testing in 1975 by adjusting for varying energy content in certification fuels. The error is exacerbated with the addition of lower energy content ethanol. But as EPA has acknowledged, the current EPA-mandated R-factor of 0.6 is erroneous and fails to achieve its statutory purpose. The auto industry has asked EPA for an R-factor of 1.0. In response, EPA has acknowledged that the current R-factor is wrong and suggested that a corrected value might lie 'between 0.8 and 0.9.' This would be an improvement, but it would be even better if EPA simply abandoned the R-factor equation and simply use MPGe. [EPA-HQ-OAR-2021-0208-0248-A1, p. 3]

EPA Should Address Outstanding Tier-III Adjustment Issues.

• A closely related issue to greenhouse gas emissions regulation is the so-called 'Tier III adjustment,' a long-promised correction to that would re-align test results from greenhouse gas and CAFE fuel economy testing to account for EPA's 2014 change of laboratory test fuel to be more similar to the fuels actually used on the road. Until this change is made, EPA has acknowledged that there has been an effective change in the stringency of the greenhouse and CAFE standards.

• EPA has not acted on its May 2020 proposed rulemaking—with EPA now proposing new, more stringent greenhouse gas requirements, it is long past time that it make the necessary changes to test fuel requirements to ensure that the stringency requirements it sets will be measured in a way that corresponds to real-world engine efficiency. [EPA-HQ-OAR-2021-0208-0248-A1, p. 3]

EPA Should Reinstate the 0.15 ‘Volumetric Conversion Factor’ for FFVs.

• FFVs using E85 significantly reduce lifecycle carbon emissions because the carbon emissions produced in the combustion of ethanol are in large measure regenerated through crop-growing cycles. Under CAFE, the fuel efficiency of alternative fuel is divided by the 0.15 ‘volumetric conversion factor’ to account for this carbon regeneration.

• Until 2015, EPA allowed automakers to use the 0.15 volumetric conversion factor to improve greenhouse gas compliance. Its removal improperly decreases the greenhouse gas emissions calculations for FFVs because automakers must comply with both CAFE standards and EPA’s greenhouse gas standards. This has significantly reduced FFV production and, correspondingly, has decreased the greenhouse gas reductions that FFVs are able to contribute.

• EPA should reharmonize the 0.15 factor for FFVs as part of the new greenhouse gas rule. If it does not do so, it should tackle this issue in a separate rulemaking in the near future. [EPA-HQ-OAR-2021-0208-0248-A1, pp. 3-4]

High-Octane Midlevel Ethanol Blends Would Enable More Efficient High-Compression Engines and Would Reduce Greenhous Gas Emissions.6

• Scientific literature establishes that a 95 to 100 RON midlevel ethanol blend would enable vehicles with increased compression ratios and would reduce carbon dioxide emissions. Research also shows that 95 to 100 RON fuel with high sensitivity is ideal from an engine efficiency standpoint.

• Research by Prof. Mueller shows that greenhouse gas cuts that could be achieved by using higher-octane midlevel blends with ethanol equal those that EPA thinks are available from electrification. EPA is thus ignoring a very cost-effective way of achieving its desired improvements to the detriment of environmental quality, consumers, farmers, and industry.7 [EPA-HQ-OAR-2021-0208-0248-A1, p. 4]

This serves EPA’s important interest in protecting health; and, as EPA has separately stated in its September 2021 ‘Social Vulnerability Report,’ the negative effects of climate change are going to be felt most by the poor and racial minorities. [EPA-HQ-OAR-2021-0208-0248-A1, p. 4]

High-Octane Midlevel Ethanol Blends Would Reduce Vehicle and Fuel Costs for Consumers.9

• Including high-octane midlevel ethanol blends as a compliance option would reduce the cost of complying with the proposed standards, further reducing vehicle costs.

• Optimizing vehicles for high-octane midlevel ethanol blends would benefit consumers. Unlike today's premium gasoline, midlevel ethanol blends could be cheaper than regular gasoline, so consumers would save money at the pump.10

• EPA's proposal claims that consumers will see a benefit from having more fuel-efficient cars. However, this benefit will come at the expense of other attributes that purchasers want like higher horsepower or greater towing capacity. EPA wrongly assumes that consumers are unable to prioritize fuel economy in choosing a new vehicle. If it really wants to benefit consumers, EPA should open the door to mid-level blends, which would allow automakers to improve both fuel economy and power simultaneously and at low cost. [EPA-HQ-OAR-2021-0208-0248-A1, pp. 4-5]

High-Octane Midlevel Ethanol Blends Would Reduce Conventional Pollution.11

• Midlevel ethanol blends would reduce primary particulate matter pollution from GDI engines.

• Midlevel ethanol blends would reduce secondary particulate matter pollution caused by gasoline aromatics. This is important because lowering aromatics will reduce health risks, especially in disadvantaged communities throughout the country.12

• Midlevel ethanol blends would reduce or have no significant effect on other conventional pollutants. [EPA-HQ-OAR-2021-0208-0248-A1, p. 5]

High-Octane, Low-Carbon Midlevel Blends Are Available Now.

• Corn is abundantly available with no increased land use or challenged food supply. Production capacity is capable of supplying all needed ethanol for several years, and growing demand will encourage profitable production growth.

• Infrastructure is capable of supplying mid-level blends to the market without substantial investment. For example, underground storage tanks have been required to be compatible with E100 since about 1993.13 Above ground systems are trending strongly toward E25 compatibility at least as a result of rapid phase in of chip-reader pumps. [EPA-HQ-OAR-2021-0208-0248-A1, p. 5]

13 The only significant hurdle about underground storage tank systems concerns whether adequate documentation demonstrating compliance is available.

Commenter: NGVAmerica

All clean options must be advanced to make a collective difference beginning today. We can't afford to pick the wrong solution or leave out available solutions. It is imperative that regulatory incentives not be used as a weapon to ensure market dominance for any one technology or company. It is abundantly clear that regulatory incentives influence today's market decisions. Our industry would not be where it is without the Renewable Fuel Standard and clean fuel standard programs adopted by several states. These programs have proven extremely valuable in encouraging the development, production, and use of low-carbon fuels. It is also clear that regulatory incentives for electric vehicles have been disproportionately favorable to that technology (e.g., ignoring upstream emissions, providing sales multipliers, allowing credit trading from low-mileage vehicles to high-mileage vehicles, providing credits for fueling station capacity - not actual fuel use or emission reductions). It was revealing to hear the overwhelming opposition to regulatory incentives voiced during the August EPA hearing. Perhaps there would be less opposition to regulatory incentives if there was a much greater relationship between the performance of a technology and the level of credit it receives. [EPA-HQ-OAR-2021-0208-0214-A1, p.3]

EPA's motor vehicle standards also can and should be used to support vehicles that operate on lowcarbon fuels. If there are no vehicle incentives, there likely will be no vehicles – that is what we have seen in the U.S. market for light-duty natural gas vehicles. There is no imperative and no real incentive for OEMs to produce light-duty natural gas vehicles at this time. The limited demand for natural gas vehicles in this segment has only been sufficient to justify limited production runs (e.g., previously the Honda Civic, Chevrolet Cavalier) and conversions. Impending mandates related to zero emission vehicles and emission standards that only look at tailpipe emissions eliminate any appetite for automakers to consider other fuel options. Without significant incentives, natural gas vehicles are unlikely to return in this market segment in the U.S. Outside the U.S. in Europe, Asia, and South America there continues to be strong interest in natural gas vehicles with significant OEM offerings. [EPA-HQ-OAR-2021-0208-0214-A1, p.3]

Commenter: North Dakota Farmers Union (NDFU)

The National Highway Traffic Safety Administration's (NHTSA) Draft Supplemental Environmental Impact Statement on its recent proposal to revise fuel economy standards recognizes increased GHG benefits with higher blends of ethanol, as well as the ongoing reduced carbon intensity of corn ethanol.15 [EPA-HQ-OAR-2021-0208-0293-A1, p. 4]

EPA SHOULD INSTITUTE CREDITS TO SUPPORT VEHICLES THAT PROMOTE INCREASED USE OF RENEWABLE FUELS.

Congress established policies, which were intended to work together, to promote production of U.S. biofuels and, thereby, energy independence. These policies include the Renewable Fuel Standard (RFS) program, which has worked to support growth in the use of renewable fuels, including ethanol, since 2005.38 Although EPA has pointed to the RFS to explain why it need not support renewable fuels under its GHG requirements,39 EPA's GHG emission regulations should work hand-in-hand with the RFS program, supporting biofuels. Increased use of ethanol can support compliance with the proposed and future GHG standards. The agencies should restore or include incentives that can be provided to automakers to ensure vehicles being produced consider the increased use of renewable fuels.

One way to promote mid-level ethanol blends, and thereby higher-octane fuels, is to restore meaningful credits for FFVs and to establish a new incentive for engines optimized for efficiency on mid-level ethanol blends. FFV production has been impacted by EPA's unfair treatment compared to other alternative fuel vehicles. Incentives to stimulate the production of vehicles that produce the benefits sought, and reduce costs to consumers, are appropriate. NDFU appreciates EPA's guidance that it will retain an "F Factor" of 0.14 for E85 (rather than default to zero) until EPA revises its guidance. Information has been provided to EPA to support an increase in the F Factor to account for greater penetration of E85 in the marketplace.40 EPA should issue any guidance necessary to give automakers sufficient certainty for automakers to make appropriate investments and work to update this factor for later model years to continue to support FFVs.41 Based on EPA's current restrictions on mid-level ethanol blends, FFVs remain an important incentive to sell mid-level ethanol blends, supporting continued investment in retail and infrastructure to expand use as part of any transition to high octane fuels.

In addition, EPA has acknowledged that raising octane levels could enable "LDGHG standards that go beyond the 2025 standards."42 Thus, automakers that take action to move ahead of the curve should be able to obtain credits toward meeting the GHG requirements. Such incentives could be tied to use of higher ethanol blends as a certification fuel, thereby supporting those efforts to provide mid-level ethanol blends at the pump but also better ensure the benefits of these higher performing engines. Although EPA is proposing to restrict the credits under the program, it provides little incentives for these other clear solutions to address GHG emissions. EPA should not unduly restrict such incentives as it did with FFVs. Providing such incentives will create better benefits and move the country toward more efficient vehicles and higher octane, lower carbon fuels. It is also consistent with EPA's interpretation of its authority under section 202 to provide incentives to push new technologies. Introduction of these better performing fuels and engines are needed, and we believe consumers will reap the benefits and continue their use. [EPA-HQ-OAR-2021-0208-0293-A1, p. 8-10]

NDFU is concerned by the challenges that climate change poses to agricultural production. Farmers, ranchers and rural communities can contribute to climate resilience and help circumvent serious harms to the economy and human health. These efforts are supported by the biofuels industry that eases the burdens on farmers and provides additional markets to facilitate a move toward sustainable practices and climate mitigation actions. NDFU supports the use of ethanol as a fuel additive for gasoline formulations to enhance octane levels, especially moving toward use of mid-level blends of ethanol. Use of higher ethanol blends will provide significant benefits to the rural community and beyond.

Ethanol has superior octane-boosting properties and is an environmentally safer substitute for oil-derived, benzene-based octane enhancers. Mid-level ethanol blends (e.g., E20-E40) are the most economical high-octane fuels available today. In response to numerous comments suggesting various actions EPA should take to support and promote use of high octane fuels, such as mid-level ethanol blends,1 EPA stated that it "has given careful consideration to these comments and agrees that these commenters have identified both current and promising technologies that may be able to deliver significant improvements in reducing GHG emissions once fully deployed."2

Despite the widespread agreement regarding the need to move this country toward high octane fuels, including by auto manufacturers, and the numerous studies that have been presented to EPA on the benefits of mid-level ethanol blends, EPA's proposal for revising the GHG standards for light-duty vehicles fails to take these fuels into account. This ignores a key consideration. NDFU also understands EPA is planning to take additional actions to address emissions from vehicles. NDFU urges the Administration to promote high octane fuels through supporting mid-level ethanol blends in the final rule and in future rulemakings.

EPA MUST CONSIDER THE AVAILABILITY OF HIGH-OCTANE FUELS TO REDUCE GHG EMISSIONS FROM LIGHT-DUTY VEHICLES.

Automakers have been working on developing higher compression engines to improve thermal efficiency and thereby fuel economy. Studies have been presented to EPA that show the benefits of using high octane fuels on vehicle efficiency.3 Increased volume of ethanol increases the octane level of gasoline across grades. In addition to its higher octane level, ethanol also features high sensitivity and high heat of vaporization, which increase engine efficiency.4 In short, ethanol offers engine knock resistance at a lower cost than any other octane booster in gasoline. Higher ethanol blends can increase fuel octane without expensive refinery upgrades. A report issued by Oak Ridge National Laboratory, Argonne National Laboratory and the National Renewable Energy Laboratory cites increased vehicle efficiency, increased acceleration and significant reductions in GHG emissions among the demonstrated benefits of mid-level ethanol blend fuels.5 The study found that vehicle manufacturers could benefit from high octane, low carbon fuels as a means to meet future fuel economy and GHG requirements, and serve as a way to increase torque in performance applications. That study also found that feedstock availability and costs are not expected to be obstacles to the substantial development of a high-octane fuel market, with E40 providing the greater fuel cost savings.

EPA's proposal recognizes high compression engines as advancements in internal combustion engines (ICE), noting the availability of the "very cost-effective ICE technology that is in-use today and ready for broader application."6 For years, auto manufacturers have supported "bringing high octane fuels to market" that are aligned with these improved engine technologies and vehicles,7 recognizing "[h]igher-octane fuels are the cheapest CO2 [carbon dioxide] reduction."8 Recently, the Alliance for Automotive Innovation (Alliance), which represents automakers that produce nearly 99% of the new light-duty vehicles sold in the United States, acknowledged that vehicle improvements, along with high octane fuels, "should be encouraged as additional solutions as soon as possible to maximize environmental benefits across the fleet."9 The Alliance stated the use of high octane low carbon liquid fuels "would simultaneously support vehicle performance, including fuel economy, and further reduce greenhouse gas emissions"; these benefits "would be realized by new and existing internal combustion engines."10 These engines and high octane fuels, specifically mid-level ethanol blends, are not "crystal ball" technologies, but are technologically feasible and economically reasonable means to achieve better fuel economy and reduced GHG emissions available today.

Yet, it appears that EPA's proposal ignores the availability of high octane fuels to utilize high-compression ratio technology and advanced ICE technologies. These engine technologies can deliver the emissions reductions necessary to meet these and future GHG standards, but high octane fuels best optimize these technologies, and thereby optimize GHG reductions. Recent reports on climate change impacts indicate the very real need to reduce GHG emissions today. EPA's decision not to incorporate mid-level ethanol blends for reducing GHG emissions is a missed opportunity. We believe the refusal to even consider mid-level ethanol blends is an error. [EPA-HQ-OAR-2021-0208-0293-A1, p. 1-3]

MID-LEVEL ETHANOL BLENDS ARE COST-EFFECTIVE, HIGH OCTANE LOW CARBON FUELS THAT PROVIIDE NUMEROUS BENEFITS.

The alternatives to ethanol as an octane booster are petroleum-based.

Ethanol, however, is substantially cleaner than petroleum-based octane additives, and "using ethanol as the source of octane in future high octane fuels has the potential to significantly decrease petroleum refinery GHG emissions by reducing the energy intensity of the refining process."11 [EPA-HQ-OAR-2021-0208-0293-A1, p. 3-4]

It reduces emissions of particulate matter (PM) and air toxics such as benzene, toluene, and xylene. PM2.5 has been shown to contribute to a significant portion of premature deaths due to air pollution, and such emissions from gasoline are likely significantly underreported.12 [EPA-HQ-OAR-2021-0208-0293-A1, p. 4]

Importantly, increased ethanol use provides additional GHG emissions reductions, which is increasingly important as the carbon intensity of gasoline is increasing with greater use of unconventional fossil fuels. "Emissions from fossil fuel combustion comprise the vast majority of energy-related emissions," with an increase in emissions from the transportation sector largely attributed to increased vehicle miles travelled and motor gasoline consumption by lightduty vehicles.13 At the same time, energy use in ethanol production and lifecycle GHG emissions have decreased with changes in farming practices and increased intensification (e.g., higher yields). EPA has found, the land use, land-use change, and forestry sector resulted in a net increase in carbon stocks (i.e., net CO2 removals).14 [EPA-HQ-OAR-2021-0208-0293-A1, p. 4]

Previously, EPA has referenced purported challenges to transitioning to high octane fuels stemming from costs to consumers who drive vehicles designed for current regular octane grade fuel, contending the "net positive benefits could take many years."16 But, this has been disputed by automakers. In testimony before Congress, a representative of General Motors stated: "We believe increasing the minimum octane level in U.S. gasoline for new vehicles will be a win for all industries and, most importantly, consumers."17 "We have an opportunity to play a large role in offering consumers the most affordable option for fuel economy improvement and greenhouse gas reduction. We believe a higher efficiency gasoline solution with a higher Research Octane Number (RON) is very important to achieving this."18 Although that testimony referenced a lower RON than NDFU believes should be utilized, consumers would benefit from projected fuel cost savings, reduced price volatility, increased torque in performance applications, and the energy security and environmental attributes of mid-level ethanol blends. Based on information previously provided, EPA should be fully aware of the reduced costs of producing mid-level ethanol blends, where ethanol is less expensive than gasoline, decreasing costs at the pump.19 As noted, the National Renewable Energy Laboratory found costs to not be a limiting factor to increase biofuel use through requiring higher octane fuels.20 More recent information confirm the benefits to consumers as a result of increased biofuel use.21 [EPA-HQ-OAR-2021-0208-0293-A1, p. 4-5]

As noted above, the Alliance has recognized that high octane fuels can benefit existing vehicles. More recent analysis further supports that mid-level ethanol blends can be used in existing vehicles, alleviating concerns about any “transition” to use of higher octane fuels. A study conducted by North Carolina State University found that vehicles on the road today can adapt to mid-level ethanol blends.22 Researchers compared E10 (regular and premium) with E27 in one flexible fuel vehicle (FFV) and four non-FFVs and found all five vehicles adapted to each fuel. The study also found E27 can increase engine efficiency and reduce carbon monoxide (CO) and PM emissions. A study by the University of Nebraska Lincoln on use of E30 in non-FFVs used by the State of Nebraska also found the non-FFVs were able to adjust the air-to-fuel ratio to adapt to the higher oxygen content of E30, and E30 had no observable negative effect on overall vehicle performance.23 Comparing E15 to E30, the Nebraska report found that E30 use resulted in a 40% reduction in CO2 emissions and that E30 is cost-effective. These are benefits that can be achieved today, even in existing vehicles.

EPA CAN, AND SHOULD, UNDERTAKE REGULATORY REVISIONS TO PROMOTE MID-LEVEL BLENDS OF ETHANOL.

Mid-level ethanol blends are available today, as they are authorized for use in FFVs and provide cost savings to consumers. But regulatory barriers are preventing their wider use. While EPA should have considered the availability of high octane fuels in its revised proposal, additional regulatory actions by EPA also should be taken to promote use of mid-level ethanol blends.

Octane Fuel Requirements: First, as again stated by many at EPA’s public hearing on EPA’s proposal for revised light-duty vehicle GHG standards, EPA can use its authority under the Clean Air Act to approve and require specific octane levels, like 100 RON. Several comments have been submitted to EPA previously, outlining this authority.24 NDFU urges EPA to use its authority to approve and require higher octane in fuels under its Clean Air Act authority in Sections 202 and 211. EPA has acknowledged that 42 U.S.C. §7545(c) gives it authority to “control” gasoline octane levels.25

Certification Fuel Requirements: Second, EPA should ease the ability to use mid-level ethanol blends as certification fuel. EPA has acknowledged that mid-level ethanol blends can be approved as certification fuel under 40 C.F.R. §1065.701.26 EPA can make findings to facilitate use of mid-level ethanol blends as certification fuel but may need to make regulatory changes to ensure flexibility to use mid-level ethanol blends more generally. Because mid-level ethanol blends are “accessible, obtainable”27 in commerce today, EPA should make clear that mid-level ethanol blends meet the criteria in Section 1065.701(c) that the fuel be “commercially available.”28 EPA should also clarify that E30 is representative of mid-level ethanol blends to give retailers and automakers more flexibility in sales and engine design without imposing undue certification requirements for each blend level. Once EPA approves the certification fuel, the manufacturer should be able to make a determination that the approved fuel can be appropriately used in other model year vehicles without going through the waiver process under 42 U.S.C. §7545(f). Such flexibility may require updates to EPA's fuel registration process under 40 C.F.R. Part 79. [EPA-HQ-OAR-2021-0208-0293-A1, p. 5-7]

Fuel Economy Formula (R-Factor): Third, with approval of alternative certification fuels, EPA should also adjust the formula in 40 C.F.R. §600.113-12 used for determining fuel economy to ensure an appropriate R-factor and a multiplier in recognition of the lower carbon content of the proposed certification fuel. The current fuel economy equation includes adjustments meant to control for changes in the test fuel from testing in 1975 that affect fuel economy.29 One adjustment is known as the R-factor, which is intended to represent the response of a typical vehicle's fuel economy to small changes in the fuel's energy content.30 The current equation in the regulations uses an R-factor of 0.6 based on data from the 1980s. This factor fails to adequately adjust for changes in the test fuel with increased ethanol volume, as required by law.31 There has been support for making this change for years, and EPA has acknowledged that changes to the R-factor may be warranted.32 While EPA did propose a change in 2020 for E10,33 that proposed R-Factor (Ra=0.81) may still be too low, as there is ample information to show that the R-Factor should be "1" or closer to 1, which several commenters supported, including automakers.34 "With [a] correct R Factor, high-octane mid-level blends can offer real CAFE as well as GHG benefits."35 Making this adjustment would allow automakers to use the new test fuel for purposes of compliance with the fuel economy requirements without being unfairly penalized for using a test fuel with a lower energy content. [EPA-HQ-OAR-2021-0208-0293-A1, p. 7-8]

Reid Vapor Pressure: Fourth, EPA should work with the ethanol industry to resolve Reid Vapor Pressure (RVP) restrictions on using ethanol blends above E10 year-round. Ethanol itself has a low RVP rating, and, at higher blends, such as E30, the RVP should not be an issue, as the higher volume of ethanol counteracts potential increases based on the petroleum gasoline. NDFU appreciates EPA's recent efforts to address the RVP waiver for E15. While those efforts remain pending in litigation on appeal, those efforts did not adequately address mid-level ethanol blends. The ethanol and automotive manufacturing industries have also suggested an alternative approach to issuing a broader waiver; that is, imposing lower RVP limits on the petroleum gasoline blendstock to ensure available blendstock for higher blends of ethanol. While EPA referenced potential adverse impacts on fungibility of fuel, there is precedent showing the gasoline blendstock can be set at a lower RVP to protect against exceeding 9 psi to address air quality concerns.36 In either case, NDFU urges EPA to continue to work with the ethanol industry to find a solution to allow year-round sales, as the potential restrictions during the summer months will create practical restrictions to expanding the use of ethanol.37 [EPA-HQ-OAR-2021-0208-0293-A1, p. 8]

Substantially Similar Finding: Finally, EPA can also use its authority to approve mid-level ethanol blends for use under Clean Air Act section 211(f), 42 U.S.C. § 7545(f). Starting in 2017, gasoline emissions certification fuel now contains 10 percent ethanol. As such, section 211(f)(1) no longer limits ethanol blending in market fuel, as any ethanol blend, including mid-level ethanol blends, are “substantially similar” to a certification fuel. Moreover, given that the effects of gasoline/ethanol blends like E20, E25, and E30 are already well-known, it makes little to no sense for EPA to interpret the requirements of section 211 as rigidly and burdensome as it has done in the past for new fuels. EPA should issue an updated interpretation of “substantially similar” to confirm the ability to use these fuels. [EPA-HQ-OAR-2021-0208-0293-A1, p. 8]

EPA SHOULD INSTITUTE CREDITS TO SUPPORT VEHICLES THAT PROMOTE INCREASED USE OF RENEWABLE FUELS.

Congress established policies, which were intended to work together, to promote production of U.S. biofuels and, thereby, energy independence. These policies include the Renewable Fuel Standard (RFS) program, which has worked to support growth in the use of renewable fuels, including ethanol, since 2005.38 Although EPA has pointed to the RFS to explain why it need not support renewable fuels under its GHG requirements,39 EPA’s GHG emission regulations should work hand-in-hand with the RFS program, supporting biofuels. Increased use of ethanol can support compliance with the proposed and future GHG standards. The agencies should restore or include incentives that can be provided to automakers to ensure vehicles being produced consider the increased use of renewable fuels.

One way to promote mid-level ethanol blends, and thereby higher-octane fuels, is to restore meaningful credits for FFVs and to establish a new incentive for engines optimized for efficiency on mid-level ethanol blends. FFV production has been impacted by EPA’s unfair treatment compared to other alternative fuel vehicles. Incentives to stimulate the production of vehicles that produce the benefits sought, and reduce costs to consumers, are appropriate. NDFU appreciates EPA’s guidance that it will retain an “F Factor” of 0.14 for E85 (rather than default to zero) until EPA revises its guidance. Information has been provided to EPA to support an increase in the F Factor to account for greater penetration of E85 in the marketplace.40 EPA should issue any guidance necessary to give automakers sufficient certainty for automakers to make appropriate investments and work to update this factor for later model years to continue to support FFVs.41 Based on EPA’s current restrictions on mid-level ethanol blends, FFVs remain an important incentive to sell mid-level ethanol blends, supporting continued investment in retail and infrastructure to expand use as part of any transition to high octane fuels.

In addition, EPA has acknowledged that raising octane levels could enable “LDGHG standards that go beyond the 2025 standards.”42 Thus, automakers that take action to move ahead of the curve should be able to obtain credits toward meeting the GHG requirements. Such incentives could be tied to use of higher ethanol blends as a certification fuel, thereby supporting those efforts to provide mid-level ethanol blends at the pump but also better ensure the benefits of these higher performing engines. Although EPA is proposing to restrict the credits under the program, it provides little incentives for these other clear solutions to address GHG emissions. EPA should not unduly restrict such incentives as it did with FFVs. Providing such incentives will create better benefits and move the country toward more efficient vehicles and higher octane, lower carbon fuels. It is also consistent with EPA’s interpretation of its authority under section 202 to provide incentives to push new technologies. Introduction of these better performing fuels and engines are needed, and we believe consumers will reap the benefits and continue their use. [EPA-HQ-OAR-2021-0208-0293-A1, p. 8-10]

EPA'S EMISSIONS MODELING SHOULD BE ADJUSTED TO BETTER ACCOUNT FOR THE BENEFITS OF ETHANOL FOR AIR QUALITY.

Ethanol Provides Air Quality Benefits, Which May Not Be Accurately Reflected in EPA's Current Models.

Ethanol, a renewable fuel, changes the emissions profile of gasoline, creating a cleaner, safer motor vehicle fuel. Real-world evidence shows use of ethanol blends reduces emissions of CO, PM, air toxics, and GHGs compared to burning petroleum gasoline. With higher octane fuels, and related engines discussed above, the motor fuel can burn even more efficiently. This results in better overall air quality than when vehicles burn conventional gasoline, significantly improving public health.

Concerns have been raised regarding the models used by EPA to determine emissions from fuels. Third-party reviews have shown that MOVES2014 may be inadequate as a tool for estimating the exhaust emissions of gasoline blends containing more than 10 percent ethanol. The model's results for mid-level ethanol blends have been shown to be inconsistent with other results from the scientific literature for both exhaust emissions and evaporative emissions, including results from real-world emissions testing.43 The problems with MOVES2014 have been tied to the model's use of data that misrepresents the actual parameters and composition of mid-level ethanol blends. While EPA recently released MOVES3, it is unclear if EPA made the appropriate adjustments to adequately reflect the benefits of blends above E10,44 and EPA should ensure its models are properly updated to do so.

Recent Assessments Show Continued Improvements in GHG Lifecycle Analysis, Finding Greater Emissions Reductions for Ethanol Compared to Petroleum Gasoline Than EPA Has Estimated.

The Energy Independence and Security Act of 2007 required EPA to conduct lifecycle GHG emissions analysis to identify the renewable fuels eligible to meet the various categories under the RFS program. EPA conducted this analysis for corn-based ethanol as part of the 2010 RFS rulemaking. Since that time, published studies and more recent data have improved the understanding of corn ethanol's lifecycle GHG impacts, showing much higher reductions in GHG emissions for corn ethanol compared to petroleum gasoline.45 As noted above, corn ethanol plants have become more efficient. In addition, U.S. farmers have responded to demand and concerns by moving toward sustainable practices and intensification, not land expansion. The land use aspect of EPA's analysis has not been experienced in the real world.46

Despite these advancements in lifecycle analysis, EPA has chosen not to acknowledge the significant overall benefits of increased ethanol use with respect to GHG reductions compared to petroleum-based gasoline. While requests to update the RFS lifecycle analysis have been rejected by EPA to date, the RFS statute includes specific parameters of how that analysis must be conducted, and this should not limit EPA's analysis of GHG benefits of ethanol blends. These newer studies and data show greater emissions reductions associated with corn ethanol, which is even more pronounced where more unconventional sources and heavier crudes are being used for gasoline today than in 2005 – the baseline used under the RFS. EPA, however, has declined to consider the significant GHG impacts of burning petroleum gasoline and the benefits of increasing use of renewable fuels beyond tailpipe emissions. [EPA-HQ-OAR-2021-0208-0293-A1, p. 10-11]

Biofuels play an important role in supporting family farms, driving rural economic growth and reducing harmful emissions. NDFU supports continued efforts to address GHG emissions and, thereby, climate change and the climate resilience it brings to the food system. NDFU strongly encourages EPA to make appropriate regulatory changes to support increased use of mid-level ethanol blends, which are high octane, low carbon fuels. Virtually all parties, including EPA, acknowledge the GHG and fuel economy benefits of high octane fuels in more efficient engines, and the cost-effectiveness of using higher ethanol blends to meet the goals of these requirements. [EPA-HQ-OAR-2021-0208-0293-A1, p. 12]

38 EPA has fallen behind in enforcing the RFS volume mandates, negatively impacting biofuel producers. NFU appreciates EPA's efforts to get the program "back on track," and urges EPA to enforce the full "implied" conventional biofuel requirement of 15 billion gallons and increase the advanced biofuel volumes.

40 E85 Flexible Fuel Vehicle Weighting Factor (F-Factor) for Model Years 2021 and Later Vehicles; Notice, 85 Fed. Reg. 52,590 (Aug. 26, 2020) (noting EPA "has extended the use of the existing F-factor of 0.14 to model year 2020," which "will remain in place beyond MY2020 until such time as EPA adopts a revised F-factor based on new data and updated methodology"); see also EPA Aug. 20, 2020 Memo, E85 Flexible Fuel Vehicle Weighting Factor for Model Years 2020 and Later Vehicles, https://iaspub.epa.gov/otaqpub/display_file.jsp?docid=50843&flag=1.

Commenter: Noyes, James

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 262.]

I want to just provide the input to the agency that there are tremendous opportunities with flex fuel vehicles, with high-blend ethanol E85, with mid-level ethanol blends, and with other biofuels to provide greenhouse gas reductions that aren't currently integrated into the greenhouse gas proposed rule and are, frankly, carbon reductions left on the table. Within California, we've seen over 75 million metric tons of greenhouse gas reduction from the use of various low-carbon fuels and electricity over the last 10 years of the Low-Carbon Fuel Standard Program, and 85 percent of those reductions have been bio-based fuels, so we would very much encourage the agency to consider the value of these fuels. They can be utilized in existing internal combustion engines.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 263.]

And, therefore, we think California provides an indication that the agency should take very seriously of how important decarbonizing the internal combustion side of the picture is, and also realizing that, to the extent that there's not the encouragement of flex-fuel vehicles, or mid-level ethanol blends, or other biofuels and technologies, then the default is to fossil fuel with the increased criteria pollutant emissions and the increased greenhouse gases from those fuels.

Commenter: Ohio Corn & Wheat Growers Association (OCWGA)

In his January 27, 2021 Executive Order on Tackling the Climate Crisis at Home and Abroad, President Biden acknowledged agriculture's "important role to play in combating the climate crisis and reducing greenhouse gas emissions, by sequestering carbon in soils, grasses, trees, and other vegetation and sourcing sustainable bioproducts and fuels." I applaud the administration's recognition of the vital role fuels such as cleaner burning, more cost-effective corn-based ethanol can play in immediately addressing climate change.

Unfortunately, the EPA has missed a critical opportunity to support the administration's priorities by denying consumers greater access to mid-level blends of ethanol. These fuels are proven to offer significant greenhouse gas (GHG) emission reductions and are available through existing infrastructure, mitigating the need for massive subsidies required to expand the use of other alternative fuels. As the agency finalizes this proposed rule, OCWGA urges the EPA to address the following shortfalls:

EPA Should Mandate a Minimum Octane Standard Pursuant to Its Fuel Regulation Authority

Current low-octane blends of fuel should be phased out as new vehicles are available to take advantage of the efficiency of mid-level ethanol blends. EPA has acknowledged that CAA § 211(c) gives it authority to "control" gasoline octane levels. EPA can set a minimum octane level under the above section of the Clean Air Act because low-octane fuels impair the ability of automakers to meet GHG standards, and also increase C02 emissions. To maximize GHG reductions, if octane levels are not addressed in this rule, we implore you to move quickly to begin a separate rulemaking on this important issue.

EPA Should Correct Its Inaccurate Fuel Economy Formula to Allow the Use of Mid-Level Ethanol Blends

EPA should repeal and replace its outdated fuel economy formula that is erroneous and unfairly penalizes fuel with ethanol in it. EPA has previously admitted these errors but has not taken action to fix the problem. EPA has also previously admitted that the R-Factor of 0.6 is outdated and the auto industry and other groups have suggested an adjusted R-Factor of 1.0. But again, the EPA has failed to address this issue in the rule.

EPA Should Address Outstanding Tier-III Adjustment Issues

EPA has long promised to correct testing methods of GHG and fuel economy testing to account for fuels actually used on the road today. EPA has not acted on this rulemaking proposed in May of 2020, and it is past time that the agency acts on this to ensure testing corresponds to real-world engine efficiency and fuels that are actually used on the road today.

EPA Should Reinstate the 0.15 F-Factor for Flex Fuel Vehicles (FFVs)

FFVs using E85 significantly reduce lifecycle carbon emissions because much of the carbon emitted was regenerated from the atmosphere through the production of the feedstock crop (i.e. corn). This conversion factor allows automakers to utilize this credit while adjusting for E85 utilized in FFVs as to not overestimate carbon reductions. Until 2015, EPA allowed automakers to use the 0.15 conversion to improve GHG compliance. Without certainty in this credit, automakers have produced fewer FFVs, which reduces the potential GHG savings from FFVs. If the F-factor level is not addressed in this rule, we implore you to move quickly to begin a separate rulemaking on this important issue.

Ohio’s corn and grain producers have been on the front line of stewardship, conservation, and clean energy for decades. Technological advances and best management practices have positioned corn as a sustainable, reliable, and economically viable feedstock. Coupled with the advances in fueling infrastructure and modern engine technology, ethanol is positioned to deliver immediate environmental value today – while providing a cost-effective solution for hard working American consumers. In closing, I urge the EPA to recognize the role high octane, mid-level blends of ethanol can, and do, play in meeting the administration’s goals for immediate and long-term reduction in GHG emissions and delivering an “equitable, clean energy future.” [EPA-HQ-OAR-2021-0208-0217-A1, p. 1-2]

Commenter: Pearson Fuels

Summary

As the U.S. Environmental Protection Agency (EPA) completes the development of the Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards (the “Revised Standards”), Pearson Fuels recommends that the Agency incorporate specific compliance flexibilities that enable attainment of EPA’s carbon dioxide emissions (GHG) standards while providing real-world petroleum and GHG reductions. While Pearson Fuels is not taking a position on the stringency of the standards, we are providing comment on the importance of compliance flexibilities to enable manufacturers to cost- effectively meet the final GHG standards established in this process. In particular, we express concern that EPA is proposing to adopt Revised Standards that completely overlook the GHG reduction capabilities of a proven fuel used in the internal combustion engine that completely dominates the US market while providing extremely favorable treatment and placing complete reliance upon electric vehicles that made up less than 2% of new car sales in 2021.1

FFVs represent a key compliance flexibility that utilize a proven technology to cost-effectively achieve real-world petroleum and GHG reductions. FFVs are highly versatile in that these vehicles are approved by original equipment manufacturers (OEMs) to utilize blends of ethanol and gasoline that range from 0-85% ethanol, and are likewise federally certified to this range of fuel blends. Automakers can take advantage of FFVs to transition toward deployment of new efficient technologies requiring higher octane fuels in the range of 98 to 100 RON. E85 stations with blender pumps built to supply fuel to FFVs are uniquely capable of providing various ethanol blends to those future HOLC fueled vehicles that deploy advanced internal combustion engine technologies.

Restoring more harmonized FFV crediting between the Corporate Average Fuel Economy (CAFE) and GHG program structures would benefit automakers, consumers, and marketers by affording all a choice in the market and by establishing a diversified technology portfolio approach to decarbonization. FFVs deliver a wide array of real-world benefits when fueled with E85 or other gasoline-ethanol blends, including improved US energy security, support for the US farm economy, as well as significant reductions in GHG emissions.

Fuel marketers can take advantage of their existing FFV fueling infrastructure to service a wider range of vehicle fueling needs in the future. Consumers that purchase or currently have FFVs can have confidence that they have the flexibility to fuel with any gasoline-ethanol blend. And these same FFV consumers can respond to fuel market signals by utilizing high blend E85 ethanol when the fuel is at the greatest discount to petroleum, midlevel ethanol blends to obtain optimal engine performance, and conventional gasoline in the event that ethanol prices are relatively high as compared to gasoline.

These are all vital flexibilities to a successful evolution of the vehicle market and to achieving the goals of the GHG rulemaking – increased efficiency, improved energy security, reduced costs to consumers, and reduced GHG emissions from the transportation sector.

Policy Benefits of FFVs

Blend Level Flexibility

There are approximately 22 million FFVs registered in the U.S. today. 2 This equates to a little less than 10 percent of the US gasoline powered vehicle fleet. The flexible capabilities of these vehicles support consumer choice at the pump. FFVs can legally and without any risk of regulatory or warranty breach use a wide range of any gasoline-ethanol blends up to 85 percent ethanol. This flexibility is good for the consumer, the retail fuel marketers, and supports state and federal renewable fuel requirements and policy objectives.

GHG Reductions

FFVs that utilize E85 also provide significant GHG benefits. Regardless of the blend ratio, ethanol reduces the overall GHG emissions as compared to conventional gasoline. The higher the blend, the more the benefits. From a lifecycle basis, the amount of GHG reduction compared to conventional gasoline is based on multiple factors including the type of feedstock utilized to produce the ethanol, the nature of the production process, the process energy utilized, and the production of other co-products. The most extensive certification system for determining the GHG reductions achieved by ethanol produced from different facilities has been developed by the California Air Resources Board (CARB) pursuant to the Low Carbon Fuel Standard (LCFS). CARB has certified 552 different ethanol pathways. The average GHG reduction that CARB has certified for corn starch ethanol is approximately 30 percent. For advanced cellulosic feedstocks, CARB has certified multiple pathways in the range of providing 60-80 percent GHG reductions.3 While precise GHG emission benefits vary, it’s safe to say that the higher the ethanol blend, the better the GHG benefit.

Air Quality Benefits

There are numerous studies that demonstrate the value of ethanol blends in reducing tailpipe emission that cause or contribute to air quality problems as well as reduction in emissions that pose hazards to consumers from direct exposure to toxic tailpipe emissions. Two recent studies demonstrate how ethanol blends can significantly improve air quality and protect public health. The separate studies were conducted by the North Carolina State University (NCSU) and the University of California Riverside (UCR). The independent studies were designed to evaluate tailpipe emissions using fuels similar to what consumers can buy at the gas station, instead of laboratory created test fuels.4

Today, nearly all of gasoline in the United States contains 10% ethanol (E10). These studies provide evidence that air quality can be significantly improved with blends in excess of E10. While both studies focused on tailpipe emissions, the UCR study also evaluated the impact emissions have on air quality after leaving the tailpipe. Researchers found ethanol blends reduce toxic emissions by up to 50%, including smog and ultra-fine particulates. The study also found that petroleum based aromatic compounds benzene and toluene that are used to boost octane directly raise emissions, while higher blends of ethanol added to gasoline boost octane while decreasing emissions. The UCR study compared E10, E30 and E85 fuels and found the best results with the higher ethanol blends.5

Cost Savings to the American

Public It is now clear that customers are embracing E85 fuel with the largest state gasoline market in the country showing 30% year on year growth in E85 sales. CARB has confirmed the rigor of its oversight program and the rate of E85 growth in a letter to Pearson Fuels that is attached as an exhibit to this comment. 6 The growth in demand for E85 from FFVs in the nation’s largest market is remarkable, surging from less than 6.5 MGY in 2012 to over 40 MGY in 2019. While E85 demand was flat in volume in 2020 compared to 2019, the fuel was continuing to increase market share at a time when demand for gasoline dropped dramatically due to the impact of COVID-19 on the market. Preliminary Pearson Fuels’ sales data through August 2021 suggests the growth rate for 2021 E85 sales has accelerated to exceed 35% year-on-year growth compared to 2020 and is on pace to exceed 55 million gallons statewide.

The primary reason E85 use is on the rise in California and across the entire country is a typical and crucial driver in the fuel market, price. At the retail level, U.S. FFV owners can fill up on

E85 and routinely save 10 percent or more compared to conventional unleaded on a price per mile basis. FFV owners previously unable to fuel with E85 because of limited availability are just now being exposed to a robust network of E85 stations offering steep price discounts to gasoline, and providing a cleaner fuel that simultaneously boosts octane, the farm economy, and U.S. energy security. E85's rapidly growing market appeal is not limited to California and is part of broader US market transition toward higher ethanol blends. This rapid growth in E85 demand is occurring at the same time that diminished FFV crediting under the GHG program has undercut the incentive for the automakers to manufacture FFVs. At a time when all effective GHG reduction technologies should be fully deployed, the lack of EPA recognition for FFV technology with the GHG program is having the opposite effect.

Vehicle Bridge to Advanced IC Engine Technologies

In addition to delivering petroleum reduction, costs savings, air quality benefits and GHG reductions, FFVs provide a vehicle bridge to advanced IC engine technologies that utilize HOLC fuels. The resulting policy imperative to support FFVs is well-expressed in a study authored by the National Renewable Energy Laboratory and Argonne National Laboratory:

"Original equipment manufacturers (OEMs) of light-duty vehicles are pursuing a broad portfolio of technologies to reduce CO2 emissions and improve fuel economy. Central to this effort is higher efficiency spark ignition (SI) engines, including technologies reliant on higher compression ratios and fuels with improved anti-knock properties, such as gasoline with significantly increased octane numbers. Ethanol has an inherently high octane number and would be an ideal octane booster for lower-octane petroleum blendstocks. (…) Thus the legacy FFV fleet can serve as a bridge by providing a market for the new fuel immediately, so that future vehicles will have improved efficiency as the new fuel becomes widespread. In this way, (High Octane Fuel) can simultaneously help improve fuel economy while expanding the ethanol market in the United States via a growing market for an ethanol blend higher thanE10."7

The ideal way to facilitate the transition from today's legacy fleet to new vehicles with advanced internal combustion engine technologies designed to run optimally on high-octane fuels is to utilize FFVs as bridge vehicles that can provide immediate demand for any ethanol blend, including midlevel ethanol blends (MLEB). Oak Ridge National Laboratory (ORNL) has investigated the use of high octane ethanol blends such as E25 and E30 in FFVs that are designed and compatible with ethanol blend levels from 0 to 85% and can therefore seamlessly and with OEM approval utilize midlevel ethanol blends. Key findings from ORNL include: "Experiments were performed with four FFVs using an E10 (92 RON) and E30 (100 RON) fuel. The two direct-injection FFVs demonstrated performance improvements for E30 compared to E10 of 2.5 to 3 percent, based on the 15-80 wide-open throttle acceleration time. Three of the four FFVs showed performance improvement with high-octane E30 compared to regular E10. (…) Marketing E25 or E30 to FFV owners as a performance fuel may enable greater utilization of ethanol in the near term and could help establish the refueling infrastructure to enable manufacturers to build dedicated vehicles designed for a high-octane midlevel ethanol blend."8

Infrastructure Bridge to HOLC Fuels

E85 stations provide an infrastructure bridge to fuel HOLC-fueled vehicles because E85 stations maintain high-blend ethanol in storage on site and typically utilize blender pumps that enable fueling of MLEB as well as E85. Existing E85 stations can be leveraged to rapidly establish a nation-wide MLEB fueling station network. E85 stations should be recognized as national infrastructure assets that have been developed and continue to be developed as a result of the highly-effective and longstanding partnership between the federal and state governments, fuel distributors, and the farming community to expand fuel ethanol production and use. This partnership coupled with other state and federal renewable fuel policies has successfully more than tripled U.S. ethanol production and domestic use between 2005-2020. 9 To enable the supply of higher ethanol blends including pumps that supply FFVs, the U.S. Department of Agriculture recently awarded 100 million dollars to install 4,880 blender pumps across twenty states. 10 These federal grants were matched by state funds and successfully expanded the national network of E85 stations with blender pumps that is immediately available to deliver FFVs.

Carbon Neutrality Cannot Feasibly be Achieved without FFVs:

On April 22, 2021, President Biden announced a “nationally determined contribution” pledge under the 2015 Paris climate agreement to cut U.S. GHG emissions in half by 2030 at a virtual climate summit attended by dozens of world leaders. In his remarks about the pledge from the White House, the President stated, “These steps will set America on a path of net zero emissions economy by no later than 2050.”11 Thus the President has re-established aggressive GHG reduction as a priority policy of the federal government.

The State of California has taken a leadership role in climate policy dating back to 2006, and has developed a network of policies and strategies to enable decarbonization. Consistent with this, Governor Jerry Brown signed Executive Order No. B-55-18 in 2018. The Executive Order established a new statewide goal to achieve carbon neutrality as soon as possible, and no later than 2045, and to achieve and maintain net negative emissions thereafter. Further to that goal, the California Legislature approved the Budget Act of 2019 (AB 74) that funded two studies, administered by the California Environmental Protection Agency, to: 1) identify strategies to reduce emissions from transportation energy use, and 2) identify strategies to manage the decline in fossil fuel production and associated emissions in parallel with reductions in demand. The study to reduce emissions from transportation use was conducted by the University of California Institute of Transportation Studies (“ITS”) at four campuses, UC Davis, UC Berkeley, UC Irvine, and UCLA.

The resulting ITS report is entitled, “Driving California’s Transportation Emissions to Zero.”12 While California leads the nation in electrifying transportation, the primary strategy developed in the report still recognized the reality that forcing all internal combustion engines off the road by 2045 is impossible in a free country. As a result, the Driving California’s Transportation Emissions to Zero report concluded that to achieve carbon neutrality it was necessary for California to make a complete transition by 2045 from petroleum-based gasoline to bio-based gasoline including ethanol blends as is illustrated in the following graph. Consistent with this forecast, Pearson Fuels is already supplying almost 100% renewable E-85 fuel into the California marketplace. The 15% portion of the gallon formerly consisting of gasoline is now renewable naphtha with the only remaining petroleum being the denaturant.13 The only existing vehicles that can utilize this type of bio-based gasoline are FFVs. GHG-reducing innovations in fuels as well as vehicles are necessary to meet President Biden's pledge and should be supported by the EPA's Revised Standards. [EPA-HQ-OAR-2021-0208-0289-A1, p. 2-7] [Graph # can be found on p. 7 of Docket number EPA-HQ-OAR-2021-0208-0289-A1]

Recommendations:

We encourage the Agency to re-affirm the policy value of FFVs and American ethanol production by restoring meaningful GHG crediting for the manufacture of FFVs by making the following modifications to the Revised Standards. These requested modifications are consistent with the requests made in the comment letter submitted to this proceeding by Growth Energy. Pearson Fuels fully supports the reasoning and authority contained in the Growth Energy comment.

1. EPA must recognize the full lifecycle net greenhouse gas emission reduction benefits of vehicles that use ethanol and other low-carbon fuel alternatives to gasoline.

2. EPA must make technical adjustments to better incentivize production and use of flexfuel vehicles (FFVs). Specifically, EPA must re-instate the volumetric conversion factor (VCF) for FFVs. Doing so provides incentives for all the main types of alternative fuel, low-carbon vehicles, not just a subset of EPA preferred technologies.

a. EPA must re-instate the VCF for FFVs based on the significant greenhouse gas emission reductions benefits of these FFVs.

b. The VCF avoids the adverse programmatic consequences of multipliers.

c. The VCF must be reinstated in the GHG program for FFVs in a manner similar to how it currently appears in the regulations for FFVs through model year 2015, which is a relatively straightforward regulatory fix.

Controlling Precedent:

The United States Supreme Court has held that, agency action such as rulemaking contemplated by the Notice of Proposed Rulemaking (NPRM) should be overturned when it "entirely failed to consider an important aspect of the problem." Motor Vehicle Mfrs. Ass'n v. State Farm, 463 U.S. 29, 43 (1983). As outlined in these comments, the NPRM has "entirely failed to consider" vehicle GHG issues in several critical ways. First, EPA generally failed to consider ethanol at all – and ethanol blended with gasoline at various levels fuels the vast majority of vehicles addressed by the NPRM. Second, EPA failed to consider flex fuels vehicles at all, and flex fuel technology enables the cost-effective conversion of spark ignition engines to utilize a significantly lower carbon fuel than gasoline. Finally, EPA failed address lifecycle greenhouse gas emissions, which is the full and appropriate measure of the very problem EPA seeks to address.

EPA has considerable latitude in establishing the framework of its vehicle greenhouse gas program. EPA developed this program under general authority of Clean Air Act section 202, following the 2007 United States Supreme Court decision Massachusetts v. EPA. Citing that case, the NPRM notes that "Once EPA makes the appropriate endangerment and cause or contribute findings … then section 202(a) authorizes EPA to issue standards applicable to emissions of those pollutants." (NPRM at 43,751). The NPRM there continues "Indeed, EPA's obligation to do so is mandatory."

What EPA cannot do is exercise this authority to reduce greenhouse gas emissions in an arbitrary and capricious way. EPA is arbitrary and capricious in entirely failing to consider fuel blends used by the vast majority of vehicles addressed by the rule, overlooking the potential value of flex fuel vehicles to achieve immediate GHG reductions, and ignoring the full lifecycle measure of the GHG pollutants at issue.

Conclusion

As EPA works to finalize the Revised Standards, we encourage a view toward the future to identify compliance flexibilities that offer the greatest opportunity for the market to evolve in a cost-effective, transparent and flexible manner. This approach includes considerations of future vehicle design and deployment but also recognizes the importance of proven technologies, policy continuity, and vehicles capable of facilitating a transition to more efficient internal combustion engines. FFVs utilize proven technologies to improve efficiency, save consumers and automakers money, reduce GHG emissions, improve US energy security, strengthen the US farm economy, and build a bridge to future technologies. Restoring fair and harmonized incentives for the manufacture of FFVs should therefore be a part of the Revised Standards.

Specifically, we request that EPA re-affirm the value of the FFV manufacturing programs by restoring a meaningful credit for future FFV production under the GHG program. A harmonized CAFE and GHG crediting system for FFVs will save American citizens money at the pump, reduce automaker costs, recognize real-world GHG and petroleum reductions, and re-establish continuity in federal policy in support of the U.S. ethanol and farm industries. [EPA-HQ-OAR-2021-0208-0289-A1, p. 7-9]

Commenter: Piper, Edward

It is also more easy to transport recoverable energy through liquid hydrocarbon fuels than batteries, natural gas, or hydrogen. A 5 gallon can of gas weighs about 30 lbs of fuel and for a vehicle that gets about 25 mpg, it contains about 125 miles of range. A few gallons of gas can easily be carried by hand if a vehicle runs out of energy or the vehicle is being taken to a place where a fueling station is not available. This would be harder to do with the other forms of energy. This is possible (even more so) with vehicles that use gasoline or diesel with better fuel economy, but higher fuel economy requirements will likely result in a larger portion of vehicles using an alternate energy sources only for which this is not possible. Hybrids get around this potential difficulty. [EPA-HQ-OAR-2021-0208-0520, p. 2]

Commenter: Price, Heather

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 293-294.]

I used to think that hydrogen was going to be one of the main solutions, even gray and blue hydrogen, which I encourage you to look up if you don't understand what those are. The only solution if we're going to use hydrogen is if it is green hydrogen coming from clean electricity. In terms of biofuels, I used to run my 26 car on biodiesel, and through the work that I've been doing over the past 20 years, I've come to realize that biofuels are also a delay tactic. They are not a solution, that they produce the same air quality issues and air pollution, particularly NOx pollution, and, in some cases, more pollution.

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 295-296.]

The other thing I want to mention quickly is RNG, which is called renewable natural gas, is also not a viable solution either in our pipelines or people's homes. This is a little bit different than the clean fuel standards for autos, but I think it's an important piece of the puzzle because a lot of companies are trying to say that RNG belongs in vehicles, too, and natural gas is not clean. It is a climate wrecking ball as it leaks. The latest IPCC report shows that it's 84 times more potent than carbon dioxide, and when that leaks over time, it turns into carbon dioxide which persists for centuries, acidifying our oceans, continuing to heat our planet. So, we really need true solutions.

Commenter: Renewable Fuels Association (RFA)

As an initial matter, RFA believes well-designed fuel economy and greenhouse gas standards can work in tandem with programs like the Renewable Fuel Standard (RFS) to significantly reduce fossil fuel consumption, improve public health, and combat climate change. If our nation is to reach its goal of net-zero GHG emissions by mid-century, we'll need both cleaner, more efficient cars and cleaner, more efficient fuels.

Unfortunately, EPA's proposal fails to recognize that the fuels we put into our engines can have as much—or more—impact on fuel economy and GHG emissions as the engine technologies themselves. We believe the proposal missed a critical opportunity to expressly solicit public comment on potential regulatory pathways for adopting high-octane, low-carbon liquid fuels as a means of improving fuel economy and reducing emissions from the light-duty vehicle fleet.

Recent studies and analyses, including the Department of Energy's comprehensive Co-Optima research program, clearly show that ethanol-based high-octane, low-carbon fuels can increase fuel efficiency by 5-10 percent and reduce lifecycle GHG emissions per mile by 9 percent or more when paired with the high-compression ratio engine technologies.

RFA also notes that EPA's technical assessment of the proposed CO2 standards suggests that 'broader availability' of high-compression ratio technologies will be necessary to achieve the 2023-2026 fuel economy requirements.1 EPA's proposal notes that an engine with high-compression, natural-aspiration, and direct injection is 'a very cost-effective internal combustion engine technology that is in use today and ready for broader application.'2

However, the proposal fails to mention that engines utilizing high-compression ratio technology will require higher-octane fuels to prevent premature fuel ignition. In other words, the proposed rule counts on broad deployment of high-compression ratio engines that will require high-octane fuel, but does nothing to ensure those high-octane fuels will actually be produced and available in the marketplace.

Because EPA is relying on these engine technologies to deliver the fuel efficiency gains and emissions reductions necessary to meet future standards, we believe discussion of the high-octane fuels that enable these technologies is well within the scope of this rulemaking process. Thus, we urge EPA to treat any written comments received regarding the role of high-octane, low carbon fuels as germane to this rulemaking, including these comments and those submitted by the High Octane Low Carbon Alliance.

With the actions described below, EPA's final rule for 2023-2026 tailpipe GHG emissions standards could provide a powerful incentive to automakers and fuel suppliers to rapidly adopt the internal combustion engine and high-octane fuel technologies that would deliver significant efficiency gains and emissions reductions.

• Require a transition to a higher minimum-octane gasoline (98-100 RON) for all new internal combustion vehicles. EPA has acknowledged it has the authority under the Clean Air Act to regulate minimum octane levels as a means of increasing fuel efficiency and reducing emissions. In response to previous proposed rulemakings establishing light-duty vehicle tailpipe GHG emissions standards, RFA has filed extensive written comments and technical reports with EPA regarding the ability of high-octane fuels to boost fuel economy and reduce both GHG emissions and criteria air pollutants. RFA hereby incorporates those comments by reference.3

At minimum, EPA should express its intent to consider adoption of a high-octane fuel standard as part of a future rulemaking to establish longer-term standards. According to the proposed rule, 'EPA expects that a future longer-term rulemaking will take critical steps to continue the trajectory of transportation emission reductions needed to protect public health and welfare.'4 If EPA fails to use the current rulemaking to establish a higher minimum octane standard, RFA encourages EPA to undertake a longer-term rulemaking (presumably establishing standards for 2027 and beyond) as soon as possible. At a minimum, the final rule for the 2023-2026 standards should include a statement expressing the agency's intent to consider adoption of a high octane (98-100 RON) fuel standard as part of a future longer-term rulemaking to establish standards for 2027 and beyond. [EPA-HQ-OAR-2021-0208-0525-A1, pp.1-3]

• Establish parity and consistency in the regulation of fuel volatility for ethanol and gasoline blends. There is no longer any justification for certain ethanolgasoline blends to have differing regulatory allowances for volatility, as measured by Reid vapor pressure (RVP). Nearly 30 years ago, EPA developed a 1-pound per square inch (psi) waiver of the RVP volatility requirements for certain gasoline blends. It did so in recognition of the fact that lower volatility blendstocks were not readily available in the marketplace and to encourage the increased use of renewable fuels.

Partially as a result of EPA's establishment of the 1-psi RVP waiver, renewable fuels are blended into nearly every gallon of gasoline sold in the country today. The waiver has indeed served its purpose, and today EPA should take action to effectively eliminate the relevance of the 1-psi RVP waiver. The Agency should use its authority to mandate that refiners market lower-RVP blendstocks for conventional gasoline in the summertime (i.e., 8.0 psi in attainment areas) thereby allowing retailers to market a full spectrum of renewable fuel blends appropriate for use in a range of vehicle technologies.

The 1-psi RVP waiver—originally provided to expand the production and use of fuel ethanol—is now having the perverse effect of discouraging greater ethanol use in today's gasoline market, and it is obstructing the successful implementation of important fuel and carbon reduction policies enacted since then, including the Renewable Fuel Standard.

Under the Clean Air Act, EPA has general authority to regulate the composition of fuels, see 42 U.S.C. § 7545(c), and it also has specific authority to mitigate any adverse effects on air quality based on the 'renewable volumes' required by the Act, id. § 7545(v). These sections provide the Agency with ample authority to effectively eliminate the waiver by requiring lower-RVP gasoline blendstocks, thereby reducing volatility across the board and removing the refining industry's last excuse for achieving the renewable volume requirements mandated by Congress, while at the same time assuring even greater reductions in urban ozone formation. Compelling refiners to produce lower-RVP blendstock would also complement public-private efforts—such as the U.S. Department of Agriculture's Higher Blends Infrastructure Investment Program—to expand renewable fuel distribution infrastructure. [EPA-HQ-OAR-2021-0208-0525-A1, pp.3-4]

• Approve a Mid-Level Ethanol Blend Certification Fuel: EPA should expeditiously approve the use of a mid-level ethanol certification fuel (e.g., E25-E30) to provide automakers with the added justification to design optimized, high compression vehicles that can make use of 98–100 RON gasoline. The certification of E25-E30 fuel will help automakers cost effectively meet Corporate Average Fuel Economy (CAFE) and GHG requirements by improving engine efficiency, reducing CO2, and reducing MSATs. [EPA-HQ-OAR-2021-0208-0525-A1, p.4]

• Reject the results of the EPAct/V2/E-89 Fuel Effects Study and suspend further use or development of the MOVES2014 model until a new emissions study based on appropriate test fuels is conducted. According to a number of independent third-party reviews, EPA's current vehicle emissions modeling system (MOVES2014) is inadequate and unreliable as a tool for estimating the exhaust emissions of gasoline blends containing more than 10% ethanol. This is important because state air agencies use the MOVES modeling system to demonstrate compliance with Clean Air Act requirements. In its current condition, the model discourages states from pursuing the use of higher ethanol blends as a strategy for reducing mobile source emissions. The flaws in MOVES2014 with regard to ethanol blends stem from the model's use of data from the EPAct/V2/E-89 Fuel Effects Study. RFA strongly recommends suspending further use or development of the MOVES2014 model until a new emissions study is conducted using test fuels that more accurately represent real-world fuel blends. A detailed analysis of the MOVES2014 model conducted by scientists from Wyle Laboratories and the Volpe National Transportation Systems Center concluded that, 'Overall, it was found that the predictive emissions results generated by MOVES2014 for mid-level ethanol blends were sometimes inconsistent with other emissions results from the scientific literature for both exhaust emissions and evaporative emissions…results and trends from MOVES2014 for certain pollutants are often contrary to the findings of other studies and reports in the literature.'5

Of particular concern is that the MOVES2014 model predicts increased exhaust emissions of nitrogen components and particulate matter as the ethanol content in gasoline increases, even though real-world emissions testing based on mid-level ethanol blends has shown distinctly opposite trends. 'The results from other researchers often show ethanol-related emissions trends that are different than the MOVES2014 results obtained for this study…' the Volpe study found. 'In some cases not only were magnitudes different but different [directional] trends were presented.' The model's questionable predictions for certain emissions results from its use of data that misrepresents the actual parameters and composition of midlevel ethanol blends. Specifically, the default ethanol blend data in the MOVES2014 model is based on arcane 'match blending' methods intended to 'match' specific fuel parameters, rather than 'splash blending' methods that are used in the real world. This data comes from the EPAct/V2/E-89 Fuel Effects Study. According to Wyle and Volpe experts, '…real-world splash blends may not have the same attributes as the modeled default match blends used in MOVES, and actual emissions may be different than the emissions predictions from MOVES.' [EPA-HQ-OAR-2021-0208-0525-A1, pp.4-5]

• Update EPA's Lifecycle Analysis of Corn Ethanol Greenhouse Gas (GHG) Emissions: In the 2010 pre-amble for the RFS2 final rule, EPA acknowledged that lifecycle GHG analysis is an evolving science, and that updates to the Agency's analysis would be undertaken as better data and methodologies became available. EPA wrote that it '…recognizes that as the state of scientific knowledge continues to evolve in this area, the lifecycle GHG assessments for a variety of fuel pathways will continue to change.'6 The Agency further stated that it '…plans to continue to improve upon its [lifecycle] analyses, and will update it in the future as appropriate…' and '…the Agency is also committing to further reassess these determinations and lifecycle estimates.'7

Yet, nearly 12 years after EPA promised to update its lifecycle analysis as newer data and better methods became available, the Agency has failed to honor its commitment. A recent analysis conducted by the U.S. Department of Energy found that average 2019-era corn ethanol reduced lifecycle GHG emissions by 44-52% compared to EPA's 2005 petroleum baseline.8 In contrast, EPA's analysis suggests 2022-era average corn ethanol will reduce lifecycle GHG emissions by only 21% relative to the 2005 baseline. RFA again calls upon EPA to update its outdated analysis of corn ethanol lifecycle GHG emissions. An updated analysis by EPA is necessary to help inform regulatory decision-making and public policy debates about the climate benefits of the RFS and renewable fuels in general.

• Level the playing field for GHG emissions credit generation for all alternative fuel vehicles, including flexible fuel vehicles (FFVs). Ethanol flex fuels like E85 used in FFVs have been proven to significantly reduce both tailpipe and full lifecycle GHG emissions. EPA should restore the approach to GHG standard compliance credit generation that was available to FFV manufacturers during the 2012-2016 CAFE/GHG standards regime. [EPA-HQ-OAR-2021-0208-0525-A1, p.5]

Action by the EPA will be necessary to catalyze the development and introduction of cleaner, more efficient fuels into the marketplace, just as EPA action was required to eliminate lead, limit benzene, and reduce the sulfur content of our gasoline and diesel fuel. We respectfully ask that EPA use the current rulemaking process and future rulemakings to take the actions requested above and to establish the roadmap for increasing the required minimum octane rating of our nation’s light-duty vehicle fuel. [EPA-HQ-OAR-2021-0208-0525-A1, pp. 5-6]

Commenter: Scholar, Reverend

To date, the transportation sector has been the largest source of climate pollution in the U.S., accounting for nearly onethird of our nation’s greenhouse gas emissions. Cars and light trucks in particular, account for about 45 percent of all U.S. oil consumption and about 20 percent of all U.S. greenhouse gas emissions. There is no reason why we should even be using petrol or fossil fuel products we can run cars, trucks, on solid hydrogen as demonstrated by Stan Ovshinsky. We can run trains and fly planes on biodiesel, we can even make plastic-like products from biomass cellulose products so there is no reason why we should be using petrol products at all. By not using biofuels you are hurting American Farmers. So please stop allowing drilling for oil, fracking for gas, which pollutes the atmosphere and destabilizes the earth's crust by drilling and fracking. We need to move toward a sustainable and renewable future. In addition, there are biofuels which would help American Farmers make money that are also available to be used for fuel so there is no reason for us to be using petrol at all. Fundamentally the use of petrol is old world moronic thinking. Are you a wise person or a moron, be a wise person and oppose such horrible environmental damage. We all live on this planet and we only have one planet we have to be as the bible says good stewards of the earth. Do not give into greed or for the lust of power, greed and the lust for power leads to perdition. If we do not invest in a green infrastructure then the United States of America will fall behind in these technologies. All new cars should be biodiesel hybrids this would go far to eliminate pollution. Countries like China will gain market share in these areas of business. If we have sustainable green energy we will always eternally have sustainable green energy. This is a wise decision to switch to clean energy so we will always have energy. With the recent computer hack on the Colonial Company pipeline I think that need for biofuels are even more prevalent please support such legislation. [EPA-HQ-OAR-2021-0208-0724-A1, p. 1]

Commenter: South Dakota Farmers Union (SDFU)

As a family farm organization, SDFU is particularly concerned with the challenges that climate change poses to agricultural production and family farmers' ability to pursue improvements in global food security. Farmers, ranchers 1 and rural communities can contribute to climate resilience and help circumvent serious harms to the economy and human health. These efforts are supported by the biofuels industry that eases the burdens on farmers and provides additional markets to facilitate a move toward sustainable practices and climate mitigation actions. Toward those ends, SDFU supports the use of ethanol as a fuel additive for gasoline formulations to enhance octane levels, especially moving toward use of mid-level blends of ethanol. Use of higher ethanol blends will provide significant benefits to the rural community and beyond. Disincentives to move toward higher ethanol blends by favoring other technologies limits these investments and benefits to farmers. S

DFU has called upon EPA to take immediate and concrete steps aimed at curbing greenhouse gas (GHG) emissions. Ethanol has superior octane-boosting properties and is an environmentally safer substitute for oil-derived, benzene-based octane enhancers. Mid-level ethanol blends (e.g., E20-E40) are the most economical high-octane fuels available today. In response to numerous comments suggesting various actions EPA should take to support and promote use of high octane fuels, such as mid-level ethanol blends, 2 EPA stated that it 'has given careful consideration to these comments and agrees that these commenters have identified both current and promising technologies that may be able to deliver significant improvements in reducing GHG emissions once fully deployed.'3 Recently SDFU's national organizational affiliate, the National Farmers Union, as part of the High Octane Low Carbon Alliance (HOLCA) led by former Senator Tom Daschle, joined with numerous organizations, calling for this Administration to address octane in the revised Light-Duty Vehicle GHG Emissions Standards. 4

Despite the widespread agreement regarding the need to move this country toward high octane fuels, including by auto manufacturers, and the numerous studies that have been presented to EPA on the benefits of mid-level ethanol blends, EPA's proposal for revising the GHG standards for light-duty vehicles fails to take these fuels into account. This ignores a key consideration. SDFU also understands EPA is planning to take additional actions to address emissions from vehicles. SDFU submits these comments to urge the Administration to promote high octane fuels through supporting mid-level ethanol blends in the final rule and in future rulemakings. [EPA-HQ-OAR-2021-0208-0250-A1, pp.1-2]

EPA MUST CONSIDER THE AVAILABILITY OF HIGH-OCTANE FUELS TO REDUCE GHG EMISSIONS FROM LIGHT-DUTY VEHICLES.

Automakers have been working on developing higher compression engines to improve thermal efficiency and thereby fuel economy. Studies have been presented to EPA that show the benefits of using high octane fuels on vehicle efficiency. 5 Increased volume of ethanol increases the octane level of gasoline across grades. In addition to its higher octane level, ethanol also features high sensitivity and high heat of vaporization, which increase engine efficiency.6 In short, ethanol offers engine knock resistance at a lower cost than any other octane booster in gasoline. Higher ethanol blends can increase fuel octane without expensive refinery upgrades. A report issued by Oak Ridge National Laboratory, Argonne National Laboratory and the National

Renewable Energy Laboratory cites increased vehicle efficiency, increased acceleration and significant reductions in GHG emissions among the demonstrated benefits of mid-level ethanol blend fuels.7 The study found that vehicle manufacturers could benefit from high octane, low carbon fuels as a means to meet future fuel economy and GHG requirements, and serve as a way to increase torque in performance applications. That study also found that feedstock availability and costs are not expected to be obstacles to the substantial development of a high-octane fuel market, with E40 providing the greater fuel cost savings.

EPA's proposal recognizes high compression engines as advancements in internal combustion engines (ICE), noting the availability of the 'very cost-effective ICE technology that is in-use today and ready for broader application.'8 For years, auto manufacturers have supported 'bringing high octane fuels to market' that are aligned with these improved engine technologies and vehicles,9 recognizing '[h]igher-octane fuels are the cheapest CO2 [carbon dioxide] reduction.'10 Recently, the Alliance for Automotive Innovation (Alliance), which represents automakers that produce nearly 99% of the new light-duty vehicles sold in the United States, acknowledged that vehicle improvements, along with high octane fuels, 'should be encouraged as additional solutions as soon as possible to maximize environmental benefits across the fleet.' The Alliance stated the use 11 of high octane low carbon liquid fuels 'would simultaneously support vehicle performance, including fuel economy, and further reduce greenhouse gas emissions'; these benefits 'would be realized by new and existing internal combustion engines.'12 These engines and high octane fuels, specifically mid-level ethanol blends, are not 'crystal ball' technologies, but are technologically feasible and economically reasonable means to achieve better fuel economy and reduced GHG emissions available today.

Yet, it appears that EPA's proposal ignores the availability of high octane fuels to utilize high-compression ratio technology and advanced ICE technologies. These engine technologies can deliver the emissions reductions necessary to meet these and future GHG standards, but high octane fuels best optimize these technologies, and thereby optimize GHG reductions. Recent reports on climate change impacts indicate the very real need to reduce GHG emissions today. It is not just a missed opportunity to incorporate use of mid-level ethanol blends as high octane fuel for reducing GHG emissions from light-duty vehicles, it is error to refuse to even consider it. [EPA-HQ-OAR-2021-0208-0250-A1, pp.2-4]

MID-LEVEL ETHANOL BLENDS ARE COST-EFFECTIVE, HIGH OCTANE LOW CARBON FUELS THAT PROVIDE NUMEROUS BENEFITS.

The alternatives to ethanol as an octane booster are petroleum-based. Ethanol, however, is substantially cleaner than petroleum-based octane additives, and 'using ethanol as the source of octane in future high octane fuels has the potential to significantly decrease petroleum refinery GHG emissions by reducing the energy intensity of the refining process.'13 It reduces emissions of particulate matter (PM) and air toxics such as benzene, toluene, and xylene. PM2.5 has been shown to contribute to a significant portion of premature deaths due to air pollution, and such emissions from gasoline are likely significantly underreported. 14

Importantly, increased ethanol use provides additional GHG emissions reductions, which is increasingly important as the carbon intensity of gasoline is increasing with greater use of unconventional fossil fuels. ‘Emissions from fossil fuel combustion comprise the vast majority of energy-related emissions,’ with an increase in emissions from the transportation sector largely attributed to increased vehicle miles travelled and motor gasoline consumption by light-duty vehicles. At the same time, energy use in ethanol production and l 15 ifecycle GHG emissions have decreased with changes in farming practices and increased intensification (e.g., higher yields). EPA has found, the land use, land-use change, and forestry sector resulted in a net increase in carbon stocks (i.e., net CO2 removals).16 The National Highway Traffic Safety Administration’s (NHTSA) Draft Supplemental Environmental Impact Statement on its recent proposal to revise fuel economy standards recognizes increased GHG benefits with higher blends of ethanol, as well as the ongoing reduced carbon intensity of corn ethanol. 17

Previously, EPA has referenced purported challenges to transitioning to high octane fuels stemming from costs to consumers who drive vehicles designed for current regular octane grade fuel, contending the ‘net positive benefits could take many years.’18 But, this has been disputed by automakers. In testimony before Congress, a representative of General Motors stated: ‘We believe increasing the minimum octane level in U.S. gasoline for new vehicles will be a win for all industries and, most importantly, consumers.’19 ‘We have an opportunity to play a large role in offering consumers the most affordable option for fuel economy improvement and greenhouse gas reduction. We believe a higher efficiency gasoline solution with a higher Research Octane Number (RON) is very important to achieving this.’20 Although that testimony referenced a lower RON than SDFU believes should be utilized, consumers would benefit from projected fuel cost savings, reduced price volatility, increased torque in performance applications, and the energy security and environmental attributes of mid-level ethanol blends. Based on information previously provided, EPA should be fully aware of the reduced costs of producing mid-level ethanol blends, where ethanol is less expensive than gasoline, decreasing costs at the pump.21 As noted, the National Renewable Energy Laboratory found costs to not be a limiting factor to increase biofuel use through requiring higher octane fuels. 22 More recent information confirm the benefits to consumers as a result of increased biofuel use. 23

As noted above, the Alliance has recognized that high octane fuels can benefit existing vehicles. More recent analysis further supports that mid-level ethanol blends can be used in existing vehicles, which should reduce concerns about any ‘transition’ to use of higher octane fuels. A study conducted by North Carolina State University found that vehicles on the road today can adapt to mid-level ethanol blends.24 Researchers compared E10 (regular and premium) with E27 in one flexible fuel vehicle (FFV) and four non-FFVs and found all five vehicles adapted to each fuel. The study also found E27 can increase engine efficiency and reduce carbon monoxide (CO) and PM emissions. A study by the University of Nebraska Lincoln on use of E30 in non-FFVs used by the State of Nebraska also found the non-FFVs were able to adjust the airto- fuel ratio to adapt to the higher oxygen content of E30, and E30 had no observable negative effect on overall vehicle performance.25 Comparing E15 to E30, the Nebraska report found a 40% reduction in CO2 emissions and that E30 is cost-effective due to the increased use of ethanol. Thus, these are benefits that can be achieved today, even in existing vehicles. [EPA-HQ-OAR-2021-0208-0250-A1, pp.4-6]

EPA CAN, AND SHOULD, UNDERTAKE REGULATORY REVISIONS TO PROMOTE MID-LEVEL BLENDS OF ETHANOL.

Mid-level ethanol blends are available today, as they are authorized for use in FFVs and provide cost savings to consumers. But regulatory barriers are preventing their wider use. While EPA should have considered the availability of high octane fuels in its revised proposal, additional regulatory actions by EPA also should be taken to promote use of mid-level ethanol blends, as previously explained by SDFU, among others.

Octane Fuel Requirements: First, as again stated by many at EPA's public hearing on EPA's proposal for revised light-duty vehicle GHG standards, EPA can use its authority under the Clean Air Act to approve and require specific octane levels, like 100 RON. Several comments have been submitted to EPA previously, outlining this authority. 26 While SDFU expects other comments on this proposal also will further address EPA's authority to approve and require higher octane in fuels under its Clean Air Act authority in Sections 202 and 211, which SDFU supports, EPA has acknowledged that 42 U.S.C. §7545(c) gives it authority to 'control' gasoline octane levels. 27

Certification Fuel Requirements: Second, EPA should ease the ability to use mid-level ethanol blends as certification fuel. EPA has acknowledged that mid-level ethanol blends can be approved as certification fuel under 40 C.F.R. §1065.701.28 SDFU, among others, previously explained how EPA can streamline the approval process for mid-level ethanol blends, as high octane fuels, to be certification fuels.29 As explained, EPA can make findings to facilitate use of mid-level ethanol blends as certification fuel but may need to make regulatory changes to ensure flexibility to use mid-level ethanol blends more generally. Because mid-level ethanol blends are 'accessible, obtainable'30 in commerce today, EPA should make clear that mid-level ethanol blends meet the criteria in Section 1065.701(c) that the fuel be 'commercially available.'31 EPA should also clarify that E30 is representative of mid-level ethanol blends to give retailers and automakers more flexibility in sales and engine design without imposing undue certification requirements for each blend level. Once EPA approves the certification fuel, the manufacturer should be able to make a determination that the approved fuel can be appropriately used in other model year vehicles without going through the waiver process under 42 U.S.C. §7545(f). Such flexibility may require updates to EPA's fuel registration process under 40 C.F.R. Part 79.

Fuel Economy Formula (R-Factor): Third, with approval of alternative certification fuels, EPA should also adjust the formula in 40 C.F.R. §600.113-12 used for determining fuel economy to ensure an appropriate R-factor and a multiplier in recognition of the lower carbon content of the proposed certification fuel. The current fuel economy equation includes adjustments meant to control for changes in the test fuel from testing in 1975 that affect fuel economy. One adjustment is known as the R-factor, which i 32 s intended to represent the response of a typical vehicle's fuel economy to small changes in the fuel's energy content.33 The current equation in the regulations uses an R-factor of 0.6 based on data from the 1980s. This factor fails to adequately adjust for changes in the test fuel with increased ethanol volume, as required by law.34 There has been support for making this change for years, and EPA has acknowledged that changes to the R-factor may be warranted.35 While EPA did propose a change in 2020 for E10,36 that proposed R-Factor (Ra=0.81) may still be too low, as there is ample information to show that the R-Factor should be '1' or closer to 1, which several commenters supported, including automakers.37 'With [a] correct R Factor, high-octane mid-level blends can offer real CAFE as well as GHG benefits.'38 Making this adjustment would allow automakers to use the new test fuel for purposes of compliance with the fuel economy requirements without being unfairly penalized for using a test fuel with a lower energy content.

Reid Vapor Pressure: Fourth, EPA should work with the ethanol industry to resolve Reid Vapor Pressure (RVP) restrictions on using ethanol blends above E10 year-round. Ethanol itself has a low RVP rating, and, at higher blends, such as E30, the RVP should not be an issue, as the higher volume of ethanol counteracts potential increases based on the petroleum gasoline. SDFU appreciates EPA's recent efforts to address the RVP waiver for E15. While those efforts remain pending in litigation on appeal, those efforts did not adequately address mid-level ethanol blends. The ethanol and automotive manufacturing industries have also suggested an alternative approach to issuing a broader waiver; that is, imposing lower RVP limits on the petroleum gasoline blendstock to ensure available blendstock for higher blends of ethanol. While EPA referenced potential adverse impacts on fungibility of fuel, there is precedent showing the gasoline blendstock can be set at a lower RVP to protect against exceeding 9 psi to address air quality concerns.39 In either case, SDFU urges EPA to continue to work with the ethanol industry to find a solution to allow year-round sales, as the potential restrictions during the summer months will create practical restrictions to expanding the use of ethanol. 40

Substantially Similar Finding: Finally, EPA can also use its authority to approve midlevel ethanol blends for use under Clean Air Act section 211(f), 42 U.S.C. § 7545(f). Starting in 2017, gasoline emissions certification fuel now contains 10 percent ethanol. As such, section 211(f)(1) no longer limits ethanol blending in market fuel, as any ethanol blend, including midlevel ethanol blends, are 'substantially similar' to a certification fuel. Moreover, given that the effects of gasoline/ethanol blends like E20, E25, and E30 are already well-known, it makes little to no sense for EPA to interpret the requirements of section 211 as rigidly and burdensome as it has done in the past for new fuels. EPA should issue an updated interpretation of 'substantially similar' to confirm the ability to use these fuels. [EPA-HQ-OAR-2021-0208-0250-A1, pp.6-9]

EPA SHOULD INSTITUTE CREDITS TO SUPPORT VEHICLES THAT PROMOTE INCREASED USE OF RENEWABLE FUELS.

Congress established policies, which were intended to work together, to promote production of U.S. biofuels and, thereby, energy independence. These policies include the Renewable Fuel Standard (RFS) program, which has worked to support growth in the use of renewable fuels, including ethanol, since 2005.41 Although EPA has pointed to the RFS to explain why it need not support renewable fuels under its GHG requirements,42 EPA's GHG emission regulations should work hand-in-hand with the RFS program, supporting biofuels. And this ignores how increased use of ethanol can support compliance with the proposed and future GHG standards. The agencies should restore or include incentives that can be provided to automakers to ensure vehicles being produced consider the increased use of renewable fuels.

One way to promote mid-level ethanol blends, and thereby higher-octane fuels, is to restore meaningful credits for FFVs and to establish a new incentive for engines optimized for efficiency on mid-level ethanol blends. FFV production has been impacted by EPA's unfair treatment compared to other alternative fuel vehicles. Incentives to stimulate the production of vehicles that produce the benefits sought, and reduce costs to consumers, are appropriate. SDFU appreciates EPA's guidance that it will retain an 'F Factor' of 0.14 for E85 (rather than default to zero) until EPA revises its guidance. Information has been provided to EPA to support an increase in the F Factor to account for greater penetration of E85 in the marketplace.43 EPA should issue any guidance necessary to give automakers sufficient certainty for automakers to make appropriate investments and work to update this factor for later model years to continue to support FFVs.44 Based on EPA's current restrictions on mid-level ethanol blends, FFVs remain an important incentive to sell mid-level ethanol blends, supporting continued investment in retail and infrastructure to expand use as part of any transition to high octane fuels.

In addition, EPA has acknowledged that raising octane levels could enable 'LDGHG standards that go beyond the 2025 standards.'45 Thus, automakers that take action to move ahead of the curve should be able to obtain credits toward meeting the GHG requirements. Such incentives could be tied to use of higher ethanol blends as a certification fuel, thereby supporting those efforts to provide mid-level ethanol blends at the pump but also better ensure the benefits of these higher performing engines. Although EPA is proposing to restrict the credits under the program, it provides little incentives for these other clear solutions to address GHG emissions. EPA should not unduly restrict such incentives as it did with FFVs. Providing such incentives will create better benefits and move the country toward more efficient vehicles and higher octane, lower carbon fuels. It is also consistent with EPA's interpretation of its authority under section 202 to provide incentives to push new technologies. Introduction of these better performing fuels and engines are needed, and we believe consumers will reap the benefits and continue their use. [EPA-HQ-OAR-2021-0208-0250-A1, pp.9-10]

EPA'S EMISSIONS MODELING SHOULD BE ADJUSTED TO BETTER ACCOUNT FOR THE BENEFITS OF ETHANOL FOR AIR QUALITY.

Ethanol Provides Air Quality Benefits, Which May Not Be Accurately Reflected in EPA's Current Models.

Ethanol, a renewable fuel, changes the emissions profile of gasoline, creating a cleaner, safer motor vehicle fuel. Real-world evidence shows use of ethanol blends reduces emissions of CO, PM, air toxics, and GHGs compared to burning petroleum gasoline. With higher octane fuels, and related engines discussed above, the motor fuel can burn even more efficiently. This results in better overall air quality than when vehicles burn conventional gasoline, significantly improving public health.

Concerns have been raised regarding the models used by EPA to determine emissions from fuels. Third-party reviews have shown that MOVES2014 may be inadequate as a tool for estimating the exhaust emissions of gasoline blends containing more than 10 percent ethanol. The model's results for mid-level ethanol blends have been shown to be inconsistent with other results from the scientific literature for both exhaust emissions and evaporative emissions, including results from real-world emissions testing. 46 The problems with MOVES2014 have been tied to the model's use of data that misrepresents the actual parameters and composition of mid-level ethanol blends. While EPA recently released MOVES3, it is unclear if EPA made the appropriate adjustments to adequately reflect the benefits of blends above E10,47 and EPA should ensure its models are properly updated to do so.

Recent Assessments Show Continued Improvements in GHG Lifecycle Analysis, Finding Greater Emissions Reductions for Ethanol Compared to Petroleum Gasoline Than EPA Has Estimated.

The Energy Independence and Security Act of 2007 required EPA to conduct lifecycle GHG emissions analysis to identify the renewable fuels eligible to meet the various categories under the RFS program. EPA conducted this analysis for corn-based ethanol as part of the 2010 RFS rulemaking. Since that time, published studies and more recent data have improved the understanding of corn ethanol's lifecycle GHG impacts, showing much higher reductions in GHG emissions for corn ethanol compared to petroleum gasoline.48 As noted above, corn ethanol plants have become more efficient. In addition, U.S. farmers have responded to demand and concerns by moving toward sustainable practices and intensification, not land expansion.

Despite these advancements in lifecycle analysis, EPA has chosen not to acknowledge the significant overall benefits of increased ethanol use with respect to GHG reductions compared to petroleum-based gasoline. While requests to update the RFS lifecycle analysis have been rejected by EPA to date, the RFS statute includes specific parameters of how that analysis must be conducted, and this should not limit EPA's analysis of GHG benefits of ethanol blends. These newer studies and data show greater emissions reductions associated with corn ethanol, which is even more pronounced where more unconventional sources and heavier crudes are being used for gasoline today than in 2005 – the baseline used under the RFS. EPA, however, has declined to consider the significant GHG impacts of burning petroleum gasoline and the benefits of increasing use of renewable fuels beyond tailpipe emissions.

The family farm forms the backbone of this country. As discussed above, biofuels have played an important role in supporting family farms, which have faced significant pressure to stay in production from many sides and a struggling economy. SDFU supports continued efforts to address GHG emissions and, thereby, climate change and the climate resilience it brings to the food system. SDFU strongly encourages EPA to make appropriate regulatory changes to support increased use of mid-level ethanol blends, which are high octane, low carbon fuels. As has been shown by numerous studies, ethanol provides significant air quality benefits, in addition to providing much needed jobs and creating stability in markets providing benefits and promoting investments in the rural economy. Virtually all parties, including EPA, acknowledge the GHG and fuel economy benefits of high octane fuels in more efficient engines, and the costeffectiveness of using higher ethanol blends to meet the goals of these requirements. [EPA-HQ-OAR-2021-0208-0250-A1, pp. 10-12]

41 EPA has fallen behind in enforcing the RFS volume mandates, negatively impacting biofuel producers. NFU appreciates EPA's efforts to get the program 'back on track,' and urges EPA to enforce the full 'implied' conventional biofuel requirement of 15 billion gallons and increase the advanced biofuel volumes.

43 E85 Flexible Fuel Vehicle Weighting Factor (F-Factor) for Model Years 2021 and Later Vehicles; Notice, 85 Fed. Reg. 52,590 (Aug. 26, 2020) (noting EPA 'has extended the use of the existing F-factor of 0.14 to model year 2020,' which 'will remain in place beyond MY2020 until such time as EPA adopts a revised F-factor based on new data and updated methodology'); see also EPA Aug. 20, 2020 Memo, E85 Flexible Fuel Vehicle Weighting Factor for Model Years 2020 and Later Vehicles, https://iaspub.epa.gov/otaqpub/display_file.jsp?docid=50843&flag=1.

Commenter: Stellantis

Improve Fuels and Implement a Nationwide Low Carbon Fuel Standard - Improved liquid fuels will complement, not compete with, other technologies like electrification. Improving liquid fuels can provide significant reductions in GHG and non-GHG emissions from ICE equipped vehicles, engines and equipment while the EV market grows. In particular, octane is a critical fuel parameter for ICE vehicles, and low octane fuels remain a barrier to market introduction of more efficient ICE vehicles. EPA should take action and mandate a transition to higher minimum-octane gasoline (minimum 95- 98 RON) for all new ICE vehicles. Additionally, implementation of a national low carbon fuel standard could act as a market-based approach to decarbonizing transportation fuel and provide revenue sources to incentivize market adoption of EVs. Now is the time to treat vehicle and fuels as a system, and address the opportunities with new vehicles and the existing car parc, by undertaking a separate rulemaking that directly addresses liquid fuel opportunities. [EPA-HQ-OAR-2021-0208-0532-A1, p. 5]

Improve Fuels and Implement a Nationwide Low Carbon Fuel Standard

A wide range of fuel and vehicle technologies will be needed to achieve significant GHG reductions from the transportation sector going forward. Even with the push towards electrification, ICE vehicles are projected to represent a significant portion of industry sales in the future and persist in the car parc for decades to come. Improving liquid fuel is the largest remaining ICE 'system technology' lever. Improved liquid fuel can benefit the entire parc and need not rely on turnover or introduction of new vehicle onboard systems. Improved liquid fuel can provide significant reductions in GHG and non-GHG emissions from ICE equipped vehicles, engines and equipment that will complement (not replace) other technologies like electrification.

A broad spectrum of stakeholders recognizes the importance of improved liquid fuels. In 2020, the U. S. Department of Agriculture (USDA) announced the Higher Blends Infrastructure Incentive Program (HBIIP),47 which built upon previous USDA grants, to provide up to $100 million to expand the infrastructure and availability for higher blends of renewable fuels. Additionally, the U.S. Department of Energy's Bioenergy Technologies Office aims to advance biomass conversion and utilization technologies that can create cost effective, low-carbon biofuels and bioproducts.48 Domestically produced renewable biofuels support energy security and domestic jobs, while reducing GHG emissions.

The U.S. Congress seeks action to improve liquid fuels. On August 24, 2021 the ‘Next Generation Fuels Act of 2021’’,49 was introduced in the U.S. House of Representatives. The bill’s goal is, ‘to promote the use of low-carbon, high-octane fuels, to protect public health, and to improve vehicle efficiency and performance.’ The Next Generation Fuels Act of 2021 highlights one approach utilizing the improved liquid fuels pathway to facilitate increased fuel efficiency and reduced GHG emissions.

Stellantis and its predecessor companies have long advocated for cost effective liquid fuel improvements that enable increased fuel efficiency and reduced emissions. Stellantis supports the Alliance for Automotive Innovation (Auto Innovators) comments on improved liquid fuels and echoes Auto Innovators request for EPA to take action.50 Now is the time to treat vehicle and fuels as a system, and address the opportunities with new vehicles and the existing car parc, by undertaking a separate rulemaking that directly addresses liquid fuel opportunities.

EPA should undertake a comprehensive fuels rulemaking to;

• Transition to a higher minimum-octane gasoline (minimum 95–98 RON) for new ICE vehicles

• Implement a national low carbon fuel standard to increase use of lower carbon fuels in the car parc and to provide new revenue sources used to incentivize market adoption of zero emissions technologies

• Immediately eliminate sub-87 AKI octane fuels from the market to increase fuel efficiency and reduce GHG emissions

• Lower the sulfur cap of gasoline from 80 ppm to 20 ppm at the refinery gate to further reduce non-GHG emissions from ICE equipped vehicles and engines to improve air quality

• Cap summer vapor pressure of gasoline at 9.0 psi or less, regardless of ethanol content, to further reduce evaporative emissions from all ICE equipped vehicles, engines and equipment as E10 fuel is ubiquitous in the market

• Regulate the particulate forming tendency of market gasoline by eliminating the heavy aromatic fraction of gasoline, thereby reducing PM emissions from all ICE vehicles, equipment and engines to improve air quality for all

• Limit air toxics and their precursors from the fuel to improve air quality for all

• Preserve the future benefit of low carbon fuels by not implementing an E10 carbon adjustment factor, an action that effectively closes the door to future low carbon fuel GHG benefits

Improved liquid fuels are an important technology pathway that has been largely ignored. The improved liquid fuels pathway will facilitate increased fuel efficiency, reduced GHG and non-GHG emissions during the market transition to vehicle electrification. [EPA-HQ-OAR-2021-0208-0532-A1, pp. 30-32]

Commenter: Valero Energy Corporation (Valero)

If EPA is to fulfill its stated objective of reducing GHG emissions associated with the transportation sector consistent with its obligations under the Clean Air Act, it must fairly and transparently consider the full lifecycle emissions associated with all types of vehicles and fuel sources and provide a compliance demonstration methodology that fairly reflects all relevant factors and the true GHG emissions associated with them. [EPA-HQ-OAR-2021-0208-0601-A2, p.3]

Meanwhile, EPA completely overlooks the significant current and projected reductions in GHG emissions associated with the liquid transportation fuel pool that are occurring in response to the federal Renewable Fuel Standard ("RFS"),6 the California Low Carbon Fuel Standard ("LCFS"),7 and interest from shareholders to reduce GHG emissions associated with the production of fuels. Production of fuels with lower carbon intensity has already resulted in significant reductions in GHG emissions attributable to the domestic transportation fuel pool and, due to the continued implementation of the RFS and LCFS, we are seeing significant private investment in low-carbon fuel technologies that will further expand GHG reductions in the transportation economy. Indeed, renewable diesel reduces GHG emissions by up to 80% as compared with traditional diesel fuel, and EPA's own lifecycle analysis of renewable fuel pathways indicates a wide and ever-increasing range of fuel pathways achieving GHG reductions of 50-60% or more.8 Further, numerous companies involved in both exploration and production of crude oil as well as production of both renewable and nonrenewable liquid fuels, including Valero, have begun projects to sequester carbon, further reducing the GHG emissions associated with the transportation sector. These projects result in significant reductions in GHG emissions substantially earlier and at a lower cost than forcing the conversion of the transportation sector to electric vehicles only. Yet, the preamble to the proposed rule does not recognize the impact of these significant measures that are already in play or planned for near-term implementation. [EPA-HQ-OAR-2021-0208-0601-A2, p.3]

EPA is frank in the preamble that the standards currently proposed in this rulemaking as well as those under development for MY2027 and beyond aim to advance the policy goal articulated in President Biden's August 10, 2021 Executive Order 14037 ("EO") that 50 percent of all new passenger cars and light trucks sold in 2030 be zero-emission vehicles. However, it would be arbitrary for an agency to adhere blindly to aspirational directives in an executive order; the EO does not—and cannot—relieve EPA of the Congressionally directed duty to evaluate relevant information objectively, comprehensively, and fairly about the GHG emissions impacts of new motor vehicles and engines. To the extent the EO contravenes express Congressional mandates such as those under the RFS, as discussed further below, deference to the EO at the expense of the RFS renewable fuel volume mandates would violate separation of powers and the Administrative Procedure Act. [EPA-HQ-OAR-2021-0208-0601-A2, p.3]

Extension of multipliers for electric vehicles, coupled with absence of incentives for vehicles using lower-carbon fuels, arbitrarily subsidizes the electric vehicle industry while foregoing opportunities to incentivize equivalent or greater GHG reductions in the liquid fuel market.

This menu of alternatives is unreasonable because it considers incentives only for electric vehicle adoption while overlooking opportunities to create incentives for other GHG reduction measures that may provide greater and earlier emissions reductions. Emerging technology and fuel usage that facilitate lower GHG emissions needs promotion, and at a minimum should not be excluded from receiving equal treatment as electric vehicles. There is no justification for withholding incentives for other technology and fuels that reduce GHG emissions for internal combustion engines while ignoring the rather large GHG emission footprint associated with the production and charging of electric vehicles. [EPA-HQ-OAR-2021-0208-0601-A2, p.4]

EPA should develop a mechanism to incentivize and provide credit toward meeting the GHG emission standards based on vehicle efficiency improvements and reductions in lifecycle carbon intensity that could be applied fairly to all vehicle technologies and all fuel sources. This would be consistent with the objectives of the Energy Independence and Security Act of 2007 ("EISA") to promote GHG capture and storage options and the statutory mandate that EPA prescribe standards targeting "the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in its judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare," and would facilitate near-term advancement of affordable low-carbon fuels such as 95 RON that are likely to achieve widespread consumer adoption in a very short time frame.9 Because there is already a market for consumption of these fuels in the existing vehicle fleet, this would result in immediate reductions throughout the transportation fleet in addition to the reductions to be realized in new vehicles. [EPA-HQ-OAR-2021-0208-0601-A2, p.4]

Furthermore, the reductions in lifecycle carbon intensity associated with traditional renewable fuels can be enhanced significantly by use of carbon capture and storage ("CCS"). The Biden Administration and many state governments have recently taken an increased interest in CCS, and seek to encourage its use as a tool to decrease and offset CO2 emissions in the atmosphere. Therefore, while vehicles fueled by liquid fuels would not be zero-emissions vehicles, a multiplier encouraging their production would also encourage the further development and implementation of CCS. There are countless efforts to develop technology that can reduce or offset GHG emissions from internal combustion engines that may be abandoned if the EPA GHG standard is not structured in a way that allows those reductions to be counted. [EPA-HQ-OAR-2021-0208-0601-A2, pp.4-5]

EPA's proposed GHG standards must not compromise statutory mandates under the Energy Independence and Security Act. Clean Air Act § 202(a), cited as the basis for the current action as well as the anticipated rule for MY 2027 and beyond, provides nonspecific authority for EPA to prescribe standards applicable to the emission of pollutants from new motor vehicles or new motor vehicle engines based on a finding of endangerment. However, any action taken to implement EPA's general obligation under § CAA 202(a) must be consistent with EPA's very specific statutory mandates under the RFS, established pursuant to the Energy Independence and Security Act (EISA)." [EPA-HQ-OAR-2021-0208-0601-A2, p.5]

The RFS mandates that EPA issue regulations to provide for the applicable volumes of specific categories of renewable fuel as set forth in the statute. Numeric statutory volume mandates for each category of renewable fuel are listed only through 2022. However, the RFS directs that EPA, in coordination with the Secretaries of Energy and Agriculture, must determine applicable volumes of renewable fuel, advanced biofuel, cellulosic biofuel, and biomass-based diesel for 2023 and subsequent years, based on analysis of an extensive list of considerations detailed in CAA § 211(o)(2)(B)(ii), and subject to minimum volume mandates for certain categories of renewable fuels. Specifically, the RFS requires that the applicable volume for advanced biofuel must be at least the same percentage of the applicable volume of renewable fuel as in 2022, and the volume of biomass-based diesel must be at least one billion gallons.12 [EPA-HQ-OAR-2021-0208-0601-A2, p.5]

Additionally, the RFS mandates that the applicable fuel volumes for 2023 and subsequent years must be determined based on an analysis of:

(I) the impact of the production and use of renewable fuels on the environment, including on air quality, climate change, conversion of wetlands, ecosystems, wildlife habitat, water quality, and water supply;

(II) the impact of renewable fuels on the energy security of the United States;

(III) the expected annual rate of future commercial production of renewable fuels, including advanced biofuels in each category (cellulosic biofuel and biomass-based diesel);

(IV) the impact of renewable fuels on the infrastructure of the United States, including deliverability of materials, goods, and products other than renewable fuel, and the sufficiency of infrastructure to deliver and use renewable fuel;

(V) the impact of the use of renewable fuels on the cost to consumers of transportation fuel and on the cost to transport goods; and

(VI) the impact of the use of renewable fuels on other factors, including job creation, the price and supply of agricultural commodities, rural economic development, and food prices.13 [EPA-HQ-OAR-2021-0208-0601-A2, pp.5-6]

Because Congress has specifically directed EPA, EPA cannot promote the substantial or exclusive use of a technology that will frustrate the goals of the RFS. According to EPA's analysis, the proposed rule is projected to result in reducing gasoline consumption by nine million barrels (or 378 million gallons) in 2023, reducing gasoline consumption by 10% by 2050. However, EPA's analysis fails to recognize that most gasoline sold in the U.S. is E10. Thus, EPA's analysis of changes in fuel consumption overstates the reduction in petroleum-derived gasoline while overlooking entirely the reduction in renewable fuel consumption that would be expected to occur as a result of the proposed rule. Because it obscures the likely reduction in renewable fuel consumption that will occur as a result of the present rulemaking, EPA's analysis fails to address the impact of the proposed standard on availability of RINs needed to meet the mandates of the RFS. [EPA-HQ-OAR-2021-0208-0601-A2,p.6]

Further, while EPA projects that electric vehicles will represent only eight percent of the transportation vehicle market by 2026, EPA describes the proposed rule as a "critical building block for a comprehensive, multipollutant longer-term regulatory program implementing EPA's statutory authority under the CAA," signaling clearly that EPA plans to propose more aggressive measures to promote electric vehicles in the manner outlined by the EO. In developing the current and future standards, however, EPA must satisfy all of its statutory obligations under the Clean Air Act. Ironically, in over-incentivizing electric vehicles, EPA not only frustrates implementation of the RFS, it misses the opportunity to promote significant GHG-reducing opportunities that liquid fuels provide. [EPA-HQ-OAR-2021-0208-0601-A2, p.6]

Finally, as discussed above, the rule as currently proposed fails to create incentives for GHG capture and storage.

If it finalizes the proposed rule, EPA would also exceed its authority under the CAA by issuing a rule that will undermine performance of the RFS. The proposed rule contains more stringent emission standards than EPA has promulgated in the past. To accommodate for this increased stringency, EPA is extending and enhancing multipliers for electric vehicles, zero emissions vehicles, and other advanced technologies. EPA recognizes that meeting its more stringent standards is only possible if manufacturers make use of these multiplier incentives by producing more electric vehicles. Accordingly, this multiplier is designed to force transition of the light duty fleet to "zero emissions" technology. By not including similar incentives for renewable fuels, alternative fuel formulations, CCUS, and emerging technologies for internal combustion engines, the proposed rule arbitrarily forecloses greater and more timely GHG emission reduction opportunities in favor of electrification. [EPA-HQ-OAR-2021-0208-0601-A2,pp.7-8]

This is in clear conflict with the mandates of EISA. The expressly stated purpose of EISA and the RFS is "to increase the production of clean renewable fuels...."17 While EPA has broad authority to prescribe motor vehicle emission standards under Section 202(a)(1) of the CAA, its policy encouraging zero emissions vehicles at the expense of internal combustion engine vehicles is an overreach of its authority inconsistent with the statutory design of the CAA, and therefore unreasonable and not entitled to Chevron deference.[EPA-HQ-OAR-2021-0208-0601-A2,p.8]

EPA's authority to "prescribe... standards applicable to the emission of any air pollutant" 18 created by vehicles is not unfettered. EPA must not infringe on the goals of another section of Title II of the CAA. Courts generally "must ... interpret [a] statute 'as a symmetrical and coherent regulatory scheme,' and fit, 'if possible, all parts into an harmonious whole.'"19 Reading Title II of the CAA as a coherent regulatory scheme would lead to a different interpretation than EPA's: that the statute confers on EPA the power to issue emissions standards that address air pollutants from vehicles but only to the extent those standards do not interfere with EISA and the RFS' s goals of increasing production of renewable fuels. As such, the text and context of the CAA does not support EPA's interpretation. [EPA-HQ-OAR-2021-0208-0601-A2,p.8]

In conclusion, EPA's authorization under CAA § 202(a) to prescribe standards applicable to the emissions of air pollutants from motor vehicles and engines does not constrain the agency to a myopic focus on tailpipe emissions. In the proposed GHG emission standards for MY 2023-6, EPA has overlooked the opportunity to recognize and encourage development of liquid fuels that have inherently lower carbon intensities as well as opportunities to encourage offsets of GHG emissions. Emerging technologies involving carbon capture, efficiency, and blends of low carbon fuel components could result in substantially lower overall GHG emissions and could be ready more quickly for widespread consumer adoption. EPA's design of the GHG standard in a manner that treats only tailpipe emissions as relevant will lead to failure to properly identify the actual emissions of GHG associated with vehicles, passes up the opportunity to maximize GHG emission reductions, and will arbitrarily limit innovation and discourage investment in important developing technologies. Finally, by focusing only on tailpipe GHG emissions and by putting its thumb on the scale in favor of facilitating electric vehicle development, EPA has failed to properly consider the full costs and benefits of its rulemaking such as the environmental, social, and economic impacts associated with increased electricity demand and increased mineral mining and smelting. EPA's approach may very well lead to higher overall GHG emissions at almost certainly the highest cost for GHG reductions. [EPA-HQ-OAR-2021-0208-0601-A2,p.8]

Commenter: West, Brian

I support EPA’s commitment to regulating GHGs and feel strongly that all promising solutions should be pursued. Simply put, domestically produced biofuels provide the nation with improved energy security while also reducing GHG emissions. Adding a more substantial volume fraction of bio-derived fuels like ethanol to today’s gasoline offers a straightforward, low-cost approach to helping the automakers comply with tailpipe GHG regulations while further reducing GHGs. If the administration is serious about addressing climate change, it is imperative that this rule include an improved fuel component. EPA is obligated to protect public health by use of any and all readily available means. To not add an octane requirement at this time would be an appalling missed opportunity.

Countless research programs have shown that mid-level ethanol blends (e.g., E25 to E40) produced from today’s 87 AKI E10 will provide a low-cost, high-RON fuel that enables vehicle manufacturers to achieve improved efficiency. Establishing a minimum RON standard will give the manufacturers another tool for fuel economy/GHG compliance at lower cost to consumers. Renewable ethanol added to gasoline lowers the carbon intensity, and increased efficiency of the high-RON engines further reduces GHG emissions.

Years ago, EPA requested comment on a new high-octane ethanol blended fuel in the Tier 3 proposal:

“we allow vehicle manufacturers to request approval for … fuel such as a high-octane 30 percent ethanol … blend (E30) for vehicles … optimized for such fuel”

Despite wide ranging support for such an approach, EPA has taken limited action to improve certification fuel. While E10 certification fuel was defined under Tier 3 and began to phase-in for emissions compliance testing in model year 2017, many manufacturers are still using E0 for fuel economy certification due to the flawed “R-Factor” equation which unfairly penalizes oxygenated fuels. To put liquid-fueled vehicles on equal footing with electric vehicles and other alternatives, EPA should set the R factor to 1.0, or eliminate it altogether and use MPGge.

Recent analysis by Steffen Mueller at the University of Illinois Chicago shows that with a 95 RON minimum octane requirement for all new 2026 and newer vehicles, modest efficiency gains of 3% in millions of vehicles will save tens of millions of tonnes of GHG in the near term. This approach should be a key part of a robust “all of the above” strategy that is needed to complement BEV and other advanced technologies.

In closing, I strongly support EPA establishing a minimum octane standard for the United States as part of this rule. [EPA-HQ-OAR-2021-0208-0230-A1, p. 1-2]

Commenter: High Octane-Low Carbon Fuel Alliance (HOLC)

We strongly urge the agency to finalize the most stringent standards for model year (MY) 2026, and we urge the agency to signal in the final rule its intentions for 2027 and beyond to enable automakers to optimize the benefits of higher octane, lower carbon fuels in both new and existing internal combustion engines. [EPA-HQ-OAR-2021-0208-0262-A1, p. 1]

EPA Response

In response to questions regarding the use of E0 and the appropriate R-factor change for fuel economy and GHG emissions adjustments for Tier 3 E10 certification fuel, EPA notes that the Agency has proposed in a separate action adjustments to both the fuel economy equation and the CO2 results at 85 FR 28564, May 13, 2020; https://www.epa.gov/regulations-emissions-vehicles-and-engines/vehicle-test-procedure-adjustments-tier-3-certification.

EPA has determined that the other comments contained in this section are all out of the scope of this rulemaking.

California and Section 177 States Have Reduced Less Emissions Through Top-Down Regulations and Mandates

California has reduced less transportation-related CO2 emissions than states that have avoided top-down transportation climate policies. Based on data from the U.S. Energy Information Administration21 from 2005 to 2018 Alabama, Kentucky, and Oklahoma have each reduced transportation-related CO2 emissions five times more than California. West Virginia has reduced transportation-related CO2 emissions 16 times more than California. While Wyoming has reduced emissions 24 times more than California.

Not only do California and Section 177 States' mandates fail to benefit the environment, but they also pick technological winners and losers that hurt the most vulnerable in society. This proposed rule will force automakers to do the same to stay compliant. This does little to benefit the environment when consumer preferences lie elsewhere. California environmental lawyer Jennifer Hernandez articled this argument well:

[T]he state needs to embrace the best available technology today, even if it's not zero carbon and stop making ill-considered technology choices that continue to result in higher pollution impact in disadvantaged communities. [California Air Resources Board] CARB has rejected rules that would mandate trucks powered by compressed natural gas or biogas, technologies that are feasible today and would both substantially reduce greenhouse gas emissions and improve air quality in low-income communities that are disproportionately affected by particulate air pollutants, in favor of an all-electric trucking fleet that is at best aspirational and may not be technically feasible at all in view of many experts.22

The proposed rule places a heavy emphasis on the California Framework with a lens of 'environmental exceptionalism', coming from a state that has continually mandated top-down regulations that achieve worse environmental outcomes and hurt the most vulnerable. This should sound the alarm for Americans. California and New York's (Section 177 state) top-down transportation climate policies have benefited the wealthiest in the state. Before the pandemic, half of the electric vehicles sold in the U.S. were purchased in California and New York.23 The Pacific Research Institute found that almost 80 percent of those utilizing EV tax incentives have incomes over $100,000, making it not just a corporate handout but also a transfer from all workers to wealthier Americans.24 The California Framework and failed top-down policies leave Americans behind and should not be gold standard for EPA to set national vehicle emissions regulations. A better way is to recognize and embrace bottom-up innovations, remove barriers to voluntary efficiency and environmental progress, reorient programs away from restrictions on new market entrants, and streamline permitting and licensing requirements for all types of energy innovation. [EPA-HQ-OAR-2021-0208-0226-A1, p. 5]

Commenter: California Air Resources Board (CARB)

CARB has consistently and vigorously opposed the actions by U.S. EPA to improperly withdraw a waiver of federal preemption for its standards.10 CARB encourages U.S. EPA to quickly finalize its proposal to restore California's waiver of preemption for its standards. [EPA-HQ-OAR-2021-0208-0643-A6, p.9]

Commenter: California Attorney General Office, et al.

The Nation's motor vehicles have been and continue to be a substantial source of harmful air pollution. More than half a century ago, Congress established a regulatory regime to reduce motor vehicle emissions. See Pub. L. 89-272 § 201, 79 Stat. 992, 992-93 (1965). Under this regime, EPA must promulgate 'standards applicable to the emission of any air pollutant from' new motor vehicles that 'cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare.' 42 U.S.C. § 7521(a)(1). States are generally preempted from regulating new motor vehicle emissions. Id. § 7543(a). But because California had been regulating vehicular emissions long before Congress established and authorized federal standards, and because Congress recognized the value of California's leadership in this field, Congress directed EPA to waive preemption for California's new motor vehicle emission standards unless one of three, limited statutory bases for denying such a waiver are satisfied. Id. § 7543(b)(1). Other States may choose to adopt and enforce California's standards under certain conditions pursuant to Section 177 of the Clean Air Act. Id. § 7507.

The First GHG Standards for New Motor Vehicles and the First National Program

Consistent with this history and statutory scheme, California began regulating GHG emissions from new motor vehicles before EPA. In 2002, the California Legislature enacted a statute requiring the California Air Resources Board (CARB) to promulgate GHG standards for motor vehicles that, beginning with model year 2009, would 'achieve the maximum feasible and costeffective reduction' in these emissions. Cal. Health & Safety Code § 43018.5(a), (b). The

Legislature recognized both that light-duty vehicles (passenger cars and light-duty trucks) were responsible for 40% of the State's GHG emissions, A.B. 1493 § 1(e), and that the reduction of these (and other) GHG emissions was necessary to mitigate the extraordinary impacts of climate change in California, including threats to the State's water supply and food production, as well as increasing risks from catastrophic wildfires, id. § 1(c), (d)(1), (d)(4). In 2005, CARB finalized the first GHG standards for new motor vehicles in the United States, beginning with model year 2009. Cal. Code Regs. tit. 13, § 1961.1. CARB requested a waiver of preemption from EPA, and other States adopted California's GHG standards pursuant to Section 177.

Meanwhile, in 2003, EPA had denied a petition asking it to determine that GHG emissions from new motor vehicles endanger public health and welfare and to establish standards to reduce those emissions as required by Section 202(a). Massachusetts v. EPA, 549 U.S. 497, 511 (2007). In 2007, however, the Supreme Court invalidated EPA's denial of the petition, holding that GHGs are within the scope of air pollution covered by Section 202(a) and that EPA could not avoid regulation of those emissions by declining to determine whether they endanger public health and welfare. Id. at 528-534. Despite that decision, in 2008, EPA took the unprecedented step of denying California's request for a preemption waiver for its GHG emission standards. 73 Fed. Reg. 12,156 (March 6, 2008). California and others challenged that denial.

In response to Massachusetts, in 2009, EPA published its 'endangerment finding,' concluding 'that greenhouse gases in the atmosphere may reasonably be anticipated both to endanger public health and to endanger public welfare.' 74 Fed. Reg. 66,496, 66,497 (Dec. 15, 2009). EPA recognized public health risks, including changes in air quality, more frequent heat waves and other extreme weather events, and increases in food- and water-borne pathogens, id., as well as harms to public welfare, including threats to water supplies and water quality, id. at 66,497-98. EPA found that 'new motor vehicles and new motor vehicle engines contribute to the greenhouse gas air pollution' that gives rise to these threats. Id. at 66,496. This endangerment finding—which EPA has affirmed several times since 2009—requires EPA to regulate GHGs from new motor vehicles. 42 U.S.C. § 7521(a); see also Coal. for Responsible Regulation, Inc. v. EPA, 684 F.3d 102, 126-27 (D.C. Cir. 2012), rev'd in (unrelated) part by Util. Air Regul. Grp. v. EPA, 573 U.S. 302 (2014).

Also in 2009, EPA reversed its denial of California's preemption waiver for the State's GHG emission standards, permitting California and the Section 177 States to enforce those standards. 74 Fed. Reg. 32,744 (July 8, 2009). Thus, in 2009, some States were already regulating GHG emissions from new motor vehicles sold in their States, and nationwide federal regulation of those emissions was imminent.

The federal government then negotiated an agreement with California and major automakers that resulted in a 'National Program' of harmonized standards for vehicular GHG emissions and fuel economy. Chamber of Commerce v. EPA, 642 F.3d 192, 198 (D.C. Cir. 2011). Under this agreement, EPA and NHTSA conducted a joint rulemaking in which EPA promulgated the first federal GHG standards for new motor vehicles and NHTSA promulgated fuel-economy standards. 75 Fed. Reg. 25,324 (May 7, 2010). The standards covered model years 2012 through 2016. Id. at 25,324. California and EPA also aligned their respective GHG standards, and

California agreed to allow automakers to comply with its state standards by complying with EPA's. Id. at 25,327-28.

The Extension of the National Program

EPA, NHTSA, California, and major automakers later agreed to extend the National Program. In a 2012 joint rulemaking with NHTSA, EPA promulgated GHG standards for model years 2017-2025. 77 Fed. Reg. 62,624 (Oct. 15, 2012). Because NHTSA is limited to promulgating no more than five years of fuel economy standards at a time, 49 U.S.C. § 32902(b)(3)(B), NHTSA promulgated fuel-economy standards only for model years 2017-2021, 77 Fed. Reg. at 62,627. However, it announced 'augural' standards—harmonized with EPA's—for model years 2022-2025, finding they reflected 'NHTSA's current best estimate … of what levels of stringency might be maximum feasible in those model years.' Id. In 2013, EPA also granted California a preemption waiver for its Advanced Clean Cars program, which included, among other things GHG standards for model years 2017-2025 that were similar to EPA's. 78 Fed. Reg. 2,112 (Jan. 9, 2013).93

In the 2012 final rule, EPA explained it was responding 'to the country's critical need to address global climate change,' id. at 62,626-27, estimating the standards would prevent 'approximately 2 billion metric tons' of GHG emissions. Id. at 62,627. EPA found that 'a wide range of technologies' was already available for compliance, with further advancements and deployments anticipated. Id. at 62,631. Although the standards might add, on average, $1,800 to the cost of a new light-duty vehicle in MY2025, that cost would be dwarfed by fuel savings of $5,700 to $7,400 'for a net [vehicle] lifetime savings of $3,400 to $5,000.' Id. at 62,627. EPA and NHTSA projected 'net benefits to society … in the range of $326 billion to $451 billion.' Id.

The Mid-Term Evaluation

Automakers generally supported the standards but requested a mid-program review of the standards EPA set for model years 2022-2025. 77 Fed. Reg. at 62,636. EPA agreed, committing to conduct a 'Mid-Term Evaluation,' by April 2018, of the appropriateness of those later-year standards. Id. at 62,652. That evaluation was to be 'a collaborative, robust and transparent process, including public notice and comment' and would begin with, and be based on, a rigorous Technical Assessment Report (TAR) to be prepared jointly by EPA, NHTSA, and CARB. Id. at 62,784. EPA codified these commitments in its Mid-Term Evaluation regulation, identifying eight specific factors it would assess before determining whether the standards remained appropriate. 40 C.F.R. § 86.1818–12(h).

In July 2016, EPA, NHTSA, and CARB published their 1,217-page TAR. 81 Fed. Reg. 49,217 (July 27, 2016). They found that a 'wider range of [compliance] technologies' had become available at costs 'similar or lower, than those projected' when the standards were promulgated in 2012. California v. EPA, 940 F.3d 1342, 1347 (D.C. Cir. 2019) (cleaned up). Based in large part on the TAR and extensive public comments, EPA issued a 268-page Proposed Determination. Id. That Proposed Determination assessed the eight regulatory factors and concluded that the standards for model years 2022-2025 remained appropriate. 81 Fed. Reg.

87,927 (Dec. 6, 2016). EPA finalized that determination in January 2017. Final Determination on the Appropriateness of the Model Year 2022-2025 Light-Duty Vehicle Greenhouse Gas Emissions Standards under the Midterm Evaluation (January 2017)94; see also California, 940 F.3d at 1347.

’Following the transition in presidential administrations, EPA changed lanes.’ California, 940 F.3d at 1348. In March 2017, EPA announced that it would reconsider the final determination issued just two months earlier. 82 Fed. Reg. 14,671, 14,672 (March 22, 2017). In April 2018, EPA published an eleven-page Revised Determination concluding that the standards set in 2012 were no longer appropriate. 83 Fed. Reg. 16,077 (Apr. 13, 2018). The Administrator claimed, without support, that ‘uncertainty’ existed about the availability of compliance technologies, id. at 16,082, and asserted brand new, and unfounded, concerns about consumer costs, id. at 16,084. The Revised Determination contained only fleeting references to the TAR and failed to provide the detailed assessments of the eight factors required by 40 C.F.R. § 86.1818–12(h). E.g., 83 Fed. Reg. at 16,081-82, 16,085.

A number of parties (including many of the undersigned) challenged the Revised Determination. California, 940 F.3d at 1345. The Court held that the decision was not ‘final action,’ 42 U.S.C. § 7607(b)(1), and dismissed the petitions, California, 940 F.3d at 1353. Recognizing that EPA might revise its standards, and, in fact, had proposed to do so during the litigation, the D.C. Circuit and EPA’s counsel confirmed that EPA’s withdrawal of its 2017 Final Determination did not ‘eliminate any part of the existing administrative record’—including the TAR. California, 940 F.3d. at 1351. [EPA-HQ-OAR-2021-0208-0245-A1, pp.14-17]

93 California’s Advanced Clean Cars program also contained a provision that continued to allow automakers to comply with California’s GHG standards by complying with EPA’s, assuming EPA’s standards were ‘substantially as described’ in a July 2011 Notice of Intent EPA had issued. Letter from CARB Chair Mary Nichols (July 28, 2011) at 2; see also CARB Board Resolution 12-11 at 19, 20; CARB Board Resolution 12-21 at 8; CARB Staff Report: Initial Statement of Reasons for Rulemaking – Proposed Amendments to New Passenger Motor Vehicle Greenhouse Gas Emissions Standards for Model Years 2017-2025 (Sept. 14, 2012) at 4.

Commenter: City of Albuquerque, NM

Support New Mexico’s current efforts to adopt California’s advanced clean car standards; 6. Go into effect three years earlier – with model year 2023 – than New Mexico will be able to require compliance with the California advanced clean car standards; [EPA-HQ-OAR-2021-0208-0535-A1, p.2]

Commenter: Connecticut Department of Energy and Environmental Protection

National policies that push electrification are also important. While DEEP applauds President Biden’s executive order targeting 50% zero emission vehicle (ZEV) sales by 2030, EPA should work with California and the other 177 states to adopt standards with actual requirements for national ZEV sales targets. [EPA-HQ-OAR-2021-0208-0264-A1, p.2]

Commenter: Kreucher, Walter

MARKET PENETRATION OF EVS IS INCREASINGLY DRIVEN BY STATE ZEV MANDATES, WHICH ARE ‘RELATED TO’ FUEL ECONOMY STANDARDS AND, THUS, PREEMPTED UNDER EPCA 32919(A), AS THE SAFE RULE CORRECTLY ARGUES

EPA does not have the authority to grant a waiver to the State of California that effectively circumvents Federal statutes that preclude any Agency other than the Department of Transportation from issuing regulations related to vehicle fuel economy.

The SAFE Rulemaking3 correctly states: ‘California regulation of tailpipe CO2 emissions both through its GHG standards and ZEV program, conflicts directly and indirectly with EPCA and the CAFE program. Justice Roberts4, in his dissenting opinion in MASS v EPA rejects the California arguments that they are permitted to regulate fuel economy. EPCA expressly preempts State standards5 related to fuel economy. Tailpipe CO2 standards, whether in the form of fleet-wide CO2 limits or in the form of requirements that manufacturers selling vehicles in California sell a certain number of low- and no-tailpipe-CO2 emissions vehicles as part of their overall sales, are unquestionably related to fuel economy standards (one need look no further than the Agencies inclusion of the California ZEV mandate in the baseline for fuel economy standard setting). Standards that control tailpipe CO2 emissions are de facto fuel economy standards because CO2 is a direct and inevitable byproduct of the combustion of carbon-based fuels to make energy, and the vast majority of the energy that powers passenger cars and light trucks comes from carbon-based fuels.’

The current rulemaking attempts to erase the statute 49 U.S. Code § 32919 arguing that it did not possess the authority to issue ‘legislative’ rules. This is completely irrelevant. The plain reading of the statute precludes a state or any agency other than the Department of Transportation from issuing standards related to fuel economy. GHG standards and zero emission vehicle mandates are clearly related to regulating vehicle fuel economy.

‘Improving fuel economy means getting the vehicle to go farther on a gallon of gas; a vehicle that goes farther on a gallon of gas produces less CO2 per unit of distance; therefore, improving fuel economy necessarily reduces tailpipe CO2 emissions, and reducing CO2 emissions necessarily improves fuel economy. EPCA therefore necessarily preempts California’s Advanced Clean Cars program to the extent that it regulates or prohibits tailpipe CO2 emissions6.’

The EPCA preemption clearly applies not only to the tailpipe carbon dioxide standards but also to the ZEV mandate incorporated in California’s Advanced Clean Cars program.

California is not without policy options in its quest for reducing its carbon footprint. Notwithstanding its inability to regulate vehicle fuel economy, California 7 has an almost unlimited range of GHG policy tools at its disposal including: regulating State energy production and use, regulating the carbon content of fuel sold in the state, fiscal energy policy, regulating businesses, and upgrading its vast vehicle fleet to any number of alternative fuel powered vehicles or even to bicycles. What California cannot do is regulate fuel economy or its counterpart, tailpipe carbon dioxide. [EPA-HQ-OAR-2021-0208-0199-A1, pp. 4-5]

4 California's request for a waiver is based on a policy difference with the federal government. As ROBERTS, C. J., wrote in his dissenting opinion MASSACHUSETTS ET AL. v. ENVIRONMENTAL PROTECTION AGENCY ET AL 'Global warming may be a 'crisis,' even 'the most pressing environmental problem of our time.' Pet. for Cert. 26, 22. Indeed, it may ultimately affect nearly everyone on the planet in some potentially adverse way, and it may be that governments have done too little to address it. It is not a problem, however, that has escaped the attention of policymakers in the Executive and Legislative Branches of our Government, who continue to consider regulatory, legislative, and treaty-based means of addressing global climate change. Apparently dissatisfied with the pace of progress on this issue in the elected branches, petitioners have come to the courts claiming broad-ranging injury, and attempting to tie that injury to the Government's alleged failure to comply with a rather narrow statutory provision. I would reject these challenges as nonjusticiable.

7 The need for separate California tailpipe standards has already reached the point of diminishing returns. The EPA and CARB tailpipe standards for criteria pollutants are essentially the same. The policy objective of reducing the mobile source contribution to California's NAAQS compliance issues has reached the point where other policies (fiscal and otherwise reducing transportation demand) are far more effective.

Commenter: Lucid USA, Inc. (Lucid)

LUCID SUPPORTS A REGULATORY APPROACH THAT PROTECTS CALIFORNIA'S ROLE IN REGULATING GHG EMISSIONS AND PROMOTING ZEVS

Lucid strongly supports EPA's reinstatement of California's Clean Air Act waiver. California's ability to set GHG emissions standards that exceed the stringency of federal standards has clear benefits for the future of the Nation's climate policy.

Although California's specific air quality issues continue to require policies that are more stringent than national standards, California has also been a laboratory for emissions regulation mechanisms for the entire Nation. The federal government can learn from California's approaches, successes, and difficulties. California sets the pace for nationwide change by setting emissions standards that the Section 177 States also adopt, which will apply to approximately 40% of the nationwide light-duty sales.

Lucid encourages EPA to emphasize California's longstanding role as a pioneer in shaping air quality standards and regulating air pollution. In particular, Lucid encourages EPA to acknowledge the following in its final rulemaking:

the importance of California's GHG and ZEV regulatory programs in achieving the Administration's long-term electrification and zero emission goals;

California’s unique treatment under the Clean Air Act (and related regulatory history behind the provision), which allows California to seek a waiver of preemption; the Clean Air Act does not contemplate withdrawal or revocation of waivers granted under Section 209 (42 U.S.C. § 7543) and therefore EPA must reinstate the waiver; and the assertion that the Energy Policy and Conservation Act (EPCA) preempts regulation of GHGs by California’s ZEV and low-emission vehicle (LEV) programs is contrary to precedent, including Supreme Court precedent in Massachusetts v. EPA, 549 US 497, 532 (2007) ('The two obligations [to regulate fuel economy and greenhouse gas emissions] may overlap, but there is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency.'). [EPA-HQ-OAR-2021-0208-0528-A1, p.4]

Commenter: Maine Department of Environmental Protection

Zero emission vehicle (ZEV) and GHG emission reduction technologies have seen rapid advancements since the 1990’s, and these technologies are now widely available and competitive with conventional vehicles in terms of both performance and cost. These technological advancements have been driven by efforts such as California’s 2012 Advanced Clean Cars (ACC) program. The ACC program was the first comprehensive effort to reduce GHG emissions from the light-duty vehicle (LDV) fleet and has now been successfully adopted by a number of additional states pursuant to Section 177 of the Clean Air Act, including Maine. [EPA-HQ-OAR-2021-0208-0225-A1, p.1]

Looking to the future, EPA should consider ambitious post-model year 2026 GHG standards consistent with proposals currently under consideration for California’s ACC II program. [EPA-HQ-OAR-2021-0208-0225-A1, p.2]

In 2019, as federal requirements were being relaxed under the SAFE Vehicles rule and California’s authority to adopt GHG emission standards was under challenge, California and 13 other states signed agreements with five major automakers to voluntarily meet the California 2026 GHG emission reduction targets across their national vehicle fleets,. The 2019 Framework Agreements call for a yearly decrease in GHG emissions of about 4 percent through model year 2026 and provide strong evidence that the technologies needed to meet the proposed GHG standards are both readily available and cost-effective. [EPA-HQ-OAR-2021-0208-0225-A1, p.2]

Commenter: Minnesota Pollution Control Agency (MPCA) and Minnesota Department of Transportation (MnDOT)

To protect the health of Minnesotans against potential damages from the SAFE rule, and to take important steps towards our statutory Next Generation Energy Act GHG emission reduction goals, in 2021 the MPCA adopted the Clean Cars Minnesota rule. This rulemaking adopted the Low-Emission Vehicle and Zero-Emission Vehicle Standards developed by California, as allowed under section 177 of the Clean Air Act. Section 177 provides an important authority to states to protect the health of their population and environment, and avoid regulatory whiplash from changing federal rules. The MPCA and MnDOT encourage EPA to move towards strong national standards that align the federal backstop with the section 177 states and California; protect state authorities under section 177; achieve substantial emissions reductions; and support rapid and broad electrification of the transportation sector, as well as the use of biofuels. 4 [EPA-HQ-OAR-2021-0208-0211-A1, p.2]

The MPCA and MnDOT continue to support strong national standards as a critical backstop for emissions reductions. States have the clear authority under section 177 of the Clean Air Act to adopt more stringent vehicle emissions standards that are identical to standards adopted by the State of California. This authority under section 177 is a critical regulatory mechanism for states to achieve the National Ambient Air Quality Standards, as well as their local climate, environmental justice, and air quality goals. While these authorities under section 177 are critical for states, GHGs emitted anywhere impact climate everywhere, so stringent national standards are absolutely necessary for the health and wellbeing of residents of Minnesota. [EPA-HQ-OAR-2021-0208-0211-A1, pp.3-4]

Commenter: National Association of Clean Air Agencies (NACAA)

Further, EPA should work to ultimately return to a national program that maintains the authority preserved to California and other states under the Clean Air Act; includes light-duty vehicle emission standards that are informed by science; is protective of the climate; is developed in close collaboration with state and local air agencies, including California; protects and preserves states' rights; and delivers emission reductions essential for achieving and/or maintaining environmental and public health goals. [EPA-HQ-OAR-2021-0208-0255-A1, p.2]

Overall, EPA should ultimately return to a national program that maintains the authority preserved to California and other states under the Clean Air Act; includes light-duty vehicle emission standards that are informed by science; is protective of the climate; is developed in close collaboration with state and local air agencies, including California; protects and preserves states' rights; and delivers emission reductions essential for achieving and/or maintaining environmental and public health goals. [EPA-HQ-OAR-2021-0208-0255-A1, p.8]

Commenter: New Mexico Environment Department

EPA proposed national standards support New Mexico's current efforts to adopt California's advanced clean car standards as permitted under Section 177 of the Clean Air Act. NMED and the City of Albuquerque will petition their respective air quality boards to adopt California advanced clean car standards before the end of this year. NMED anticipates that the EPA-proposed national emission standard, together with the Corporate Average Fuel Economy proposed by the National Highway Traffic Safety Administration will send a strong signal to the boards, stakeholders, and the public in New Mexico about the importance of reducing LDV tailpipe emissions. [EPA-HQ-OAR-2021-0208-0205-A1][pp.2-3]

Commenter: Nissan North America, Inc.

Moreover, Nissan encourages EPA and NHTSA to continue their efforts to coordinate the federal GHG emission and CAFE standards with the GHG and ZEV standards set by the California Air Resources Board ("CARB"), to develop a harmonized national program for automotive certification. In particular, Nissan believes it is important for EPA to work with CARB to clarify the relationship between the federal GHG standards, the California GHG standards, and the Framework Agreements between CARB and several automakers. Close coordination between these three regulatory entities would ensure that manufacturers can focus on developing the cleanest, most fuel efficient, and most affordable vehicles rather than on compliance with uncertain and unnecessarily fragmented regulatory programs. [EPA-HQ-OAR-2021-0208-0529-A1, p. 2]

Continued Support for a Unified National Approach

Nissan strongly encourages EPA, NHTSA, and CARB to develop a unified national approach to automotive regulation. In particular, Nissan echoes the points made in the letter submitted by the Alliance for Automotive Innovation ("Alliance") to Secretary Buttigieg and Administrator Regan on June 28, 2021, regarding harmonization of CAFE and GHG light-duty vehicle standards.

A patchwork of different federal and state GHG and CAFE programs is neither effective nor efficient. In contrast, a harmonized national program maximizes both GHG and CAFE benefits on a nationwide basis while also providing regulatory certainty and minimizing unnecessary compliance burdens for the industry. Such an approach allows automakers to develop a single, unified fleet that meets all federal and state requirements while maintaining a full range of vehicle options for consumers. More importantly, a harmonized approach allows manufacturers to focus their planning and investments on achieving fuel economy improvements and emissions reductions rather than on compliance with unnecessarily fragmented regulatory standards and programs. Under a harmonized approach, environmental benefits can be achieved at a lower cost to manufacturers and consumers. Lower costs help address social equity concerns related to EV accessibility and also encourage faster fleet turnover, replacing older vehicles with more efficient, cleaner, and safer vehicles.

As EPA and NHTSA consider potential changes to the federal GHG and CAFE programs, Nissan believes it is essential that the agencies work together to maximize compatibility and coordination of the programs. Nissan understands that, due to statutory limitations, certain programmatic elements of the GHG and CAFE programs may not be identical. Nissan encourages EPA and NHTSA to make the standards as equivalent and complementary as possible, however, by adopting appropriate regulatory adjustments where available.

Nissan also urges the Administration to work with California regulators to harmonize the federal and CARB programs to the fullest extent possible. This could be accomplished by reinstating California's "deemed-to-comply" measures, under which vehicles that meet federal standards are "deemed-to-comply" with CARB standards. Nissan is also open to new alternative approaches for harmonizing federal and California standards, as well. Nissan encourages EPA to work proactively with CARB to clarify the relationship between federal and California standards, including between OEMs that signed on to California's Framework Agreements and those that did not. In particular, harmonization amongst all three agencies (EPA, NHTSA, and CARB) will be critical if EPA restores California's Clean Air Act Waiver covering model years 2021 through 2025 California GHG standards and ZEV requirements.

For its part, EPA has self-characterized the Proposed GHG Rule as: "equivalent to the stringency of the California Framework Agreements emission reduction targets in MY 2023 and increasingly more stringent than the Framework Agreements from MY 2024 through 2026." It is critical for the industry to have a clear understanding of how EPA's Proposed GHG Rule and California's enforcement of its standards will be implemented going forward (e.g., whether a "deemed-to-comply" option will be available for compliance with California GHG requirements). [EPA-HQ-OAR-2021-0208-0529-A1, p. 5-6]

Commenter: Ohio Attorney General Office, et al.

Annual household income for a family in Ohio is almost $19,000 less than the annual income for a family in California.[48] Thus, Ohioans may not be able to afford drastic changes mandated by California, leading Ohioans to drive older vehicles for longer and exacerbating the problem California believes it is solving. [EPA-HQ-OAR-2021-0208-0258-A1, p.6]

<u>EPA Response</u>

EPA received comments with a variety of perspectives on its pending decision with respect to reconsideration of the SAFE 1 final action which withdrew the waiver of preemption previously issued to California pursuant to section 209(b) of the Clean Air Act for California's certain elements of the Advanced Clean Car program.[118] The SAFE 1 reconsideration is a distinct proceeding, and these comments are beyond the scope of this rulemaking.

[118] See 86 FR 22,421 (Apr. 28, 2021); Docket ID No. EPA–HQ–OAR–2021–0257.

Commenter: Alliance For Automotive Innovation

Auto Innovators requests that EPA reduce pre-model year reporting requirements. EPA requires that the pre-model year report include information applicable to the next model year and, to the extent possible, two model years into the future. While we recognize that the extended report content required by EPA may be of interest to the agency, the requirement to report up to three future model years adds significant burden to prepare the information. We recommend that EPA modify the pre-model year report requirements to the next single model year. [EPA-HQ-OAR-2021-0208-0571-A1, p. 36]

First, any net reductions in PM2.5 emissions (primary or PM2.5 precursors) accomplished by the revised standards will not provide public health benefits that are additive to the emissions reductions accomplished by EPA’s mobile-source and stationary-source programs for criteria air pollutants. The public health benefits are not additive, as we explain below, because of the way Congress designed the Clean Air Act and the way EPA defines emissions limits and non-attainment on a community-by-community basis.

Second, reductions in vehicle emissions do not provide additive benefits to public health because of the structure of the Clean Air Act, which allow the states to include national changes in mobile source emissions in their state emissions inventories and implementation plans for attainment of the National Ambient Air Quality Standards. In nonattainment areas and areas close to nonattainment, states and localities are disinclined to impose any more limits on stationary source emissions than is necessary to meet EPA's air-quality standards. If state and local limits are unduly strict, new factories may be built in other states and localities where the state implementation plans are not as strict on new stationary sources. (In attainment areas, where PM2.5 health benefits might also be considered, there is the complication of the PSD doctrine that needs to be evaluated). Thus, the practical impact of diminished mobile source emissions, at the margin, is somewhat less pressure on stationary sources to meet the requirements described in state implementation plans. Thus, there are benefits from further reductions in mobile source emissions, but they are likely to be realized in reduced compliance costs for stationary sources rather than as public health benefits from reduced overall exposures to PM2.5. The magnitude of the compliance cost savings is likely to be a small fraction of the estimated public health benefits, given EPA estimates that the benefits of PM control vastly exceed costs in the stationary source arena.

Finally, insofar as residual emissions of criteria or toxic air pollutants are seen as a rationale for the revised standards or for the transition to BEVs, the Agencies should consider some possible alternative policies to accomplish those benefits that might be more effective and cost effective than stricter CAFE/GHG standards or BEVs. Examples of such measures include tighter tailpipe standards for PM-related pollutants, (indeed, CARB has already proposed tighter particulate limits, and EPA has announced interest in a new rulemaking in this area) and improvements to gasoline. The incremental air-quality benefits of BEVs would be diminished significantly as EPA and CARB took further steps to control PM from mobile sources.

Commenter: Aluminum Association

Studies continue in the increasingly important area of material life cycle assessment (LCA) to evaluate the full environmental impact of lightweighting internal combustion engine (ICE) and electric vehicles by using advanced lightweight materials like aluminum. [EPA-HQ-OAR-2021-0208-0233-A1, p.4]

According to a literature review by a team of EPA researchers on more than 26 LCA studies conducted by both independent researchers and relevant industries since 2010, 'most of the LCAs demonstrated that aluminum-intensive designs were able to achieve the largest reductions in life-cycle energy use and GHG impacts' (Hottle 2017).

Increasing aluminum recycling at the end of a vehicle's life also improves the life cycle sustainability of aluminum-intensive vehicles. In the vehicle manufacturing process, innovative closed-loop recycling systems ensure that manufacturing scrap aluminum is rigorously segregated by alloy type in order to maintain its highest possible material value for reuse. For instance, Ford Motor Company pioneered a closed-loop recycling process at its Dearborn, Michigan truck plant to recover and re-use manufacturing scrap aluminum. Ford recycles 20 million pounds of stamped aluminum each month – enough to build 37,000 new F-series truck bodies. This recycling reduces energy use by more than 90% as compared to the production of primary aluminum sheet for the same purpose. And recent Association research demonstrates that the metal recovery efficiency of end-of-life automotive aluminum recycling is, on average, 91 percent, and is in some cases as high as 96 percent (WPI 2016, 2018). [EPA-HQ-OAR-2021-0208-0233-A1, p. 5]

Commenter: American Coalition for Ethanol (ACE)

Finally, while it is outside the scope of this rulemaking, we encourage EPA to set the maximum statutory conventional renewable fuel volumes under the RFS in the 2021 and 2022 Renewable Volume Obligation (RVO) rulemaking and pursue every option at its disposal to ensure uninterrupted market access for E15. Further we strongly discourage EPA from retroactively reducing the RVO for 2020 as has been rumored. [EPA-HQ-OAR-2021-0208-0221-A1, p. 6]

Commenter: Baier, Mary Ann

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 62-63.]

I believe that disincentives should be applied to any internal combustion engine vehicle by applying a carbon tax and incentives should be given to those businesses who purchase an electric vehicle by not only giving a tax credit but by allowing them to take a faster depreciation on the vehicle.

Commenter: Brandt, Peter

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 212-214.]

So as a lawyer and a teacher, I've studied how powerful industries tend to react whenever enhanced public health and safety regulations are proposed. There's a lot to learn from that history.

The main lesson I take away from it is no matter what the new protection might be, the sky is always falling according to the regulated industry.

Many of the protective laws we take for granted now were foretold by the meat industry as the death knell for their entire enterprise.

The first U.S. animal welfare law had to do with animals on trains and it just required after a little over 24 hours you have to let those animals out so they can drink and rest and have some food. This is the late 19th Century/early 20th Century.

What did the railroad barons say? This was going to crush them. They just could not survive this. I think we are all pretty aware no one had more power and resources in that time frame than the railroads.

What happened? They complied and the sky didn't fall and the law was motivated to protect animals but Congress made clear it understood the threat to human health, like it is dangerous to eat the meat of an animal that's extremely sick from transport. The Humane Methods of Slaughter Act, the law that says you can't kill a cow by hitting it in the head with a sledgehammer. In 1950s, when the law was first enacted, it only applied to sales to the U.S. Government.

What did the industry say? Sky was falling. Even the Secretary of USDA told Congress not to enact it. Obviously the sky didn't fall. Things got better. Things got safer.

So it's just easy for trade groups to paint every new incremental protection as the death knell for their industry but it's almost universally overblown. I grew up with no airbags in cars. It was only required in the late 1990s and that was after decades of auto industry opposition and delay and that's fine. There are people that get paid a lot of money in Washington, D.C., to delay any new regulation

Commenter: Chicago Metropolitan Agency for Planning

As the comprehensive regional planning organization of northeastern Illinois, the Chicago Metropolitan Agency for Planning (CMAP) is well aware that the largest U.S. source of emissions comes from the transportation sector. ON TO 2050, the region's long-range plan, urges communities to proactively address climate change by both planning for climate resilience and intensifying climate mitigation efforts. The plan also sets a target for the Chicago region to reduce emissions to 80 percent below 1990 levels by 2050. In the region, surface transportation accounts for at least 29 percent of all emissions. Unfortunately, that carbon footprint has remained flat or slightly increased since 2010. If this trend continues, the region will fall far short of our regional goal. [EPA-HQ-OAR-2021-0208-0219-A1, p.1]

Commenter: Citizens Climate Lobby

As I am as co leader of Montrose CO citizens climate lobby I support carbon fee and dividend.There are many similar carbon fees bills in Congress.This would promote electric vehicles. [EPA-HQ-OAR-2021-0208-0600-A1, p. 1]

Commenter: Environmental Protection Network (EPN)

On inauguration day, the president rejoined the Paris Climate Agreement,[6] just two months after the previous administration had formally withdrawn. On January 27th, the president issued an Executive Order that, among other things, set a goal of a carbon-free electricity sector no later than 2035.[7] On April 22nd, Earth Day, President Biden hosted the Leaders Summit on Climate where he announced a new target for the U.S. to achieve a 50-52% reduction from 2005 levels in economy-wide net GHG emissions in 2030. This target will be formally submitted to the United Nations Framework Convention on Climate Change later this year as the first step toward reaching net zero economy-wide GHG emissions by no later than 2050.[8] On August 5th, the president set a goal that 50% of new cars and light trucks sold in 2030 be zero-emissions vehicles, putting the U.S. on track to reduce GHG emissions from new-car and light-truck sales by more than 60% in 2030, relative to 2020.[9] The administration's two infrastructure proposals include funding for a wide range of important climate initiatives. [EPA-HQ-OAR-2021-0208-0213-A1, p. 2-3]

Commenter: General Motors LLC (GM)

Complementary Policies are Essential to the Nation's Transition to an All-Electric Future GM supports the creation of a federally managed task force including stakeholders from the automotive industry, suppliers, and the public utilities commissions, to ensure that necessary complementary EV policies are enacted in the following areas, among others: Consumer Incentives and Education, EV Charging Infrastructure, Battery Research, and EV Raw Material Supply Chain.[EPA-HQ-OAR-2021-0208-0234-A1][p.4]

Battery Research and EV Raw Material Supply Chain

Today, there is an urgent global race to own the intellectual property and manufacturing footprint of battery electric and autonomous vehicle technologies, and to spur these global ambitions through deliberate and national industrial policies. Supply chains for sourcing and processing battery grade critical minerals in the U.S. are currently undeveloped. To compete in this global race, the U.S. government must adopt policies to promote domestic EV battery technologies, for example:

• Increasing the R&D investment in emerging battery cell technologies (cobalt lean/cobalt-free, Li-metal solid state and silicon-dominant negative electrode, etc.).

• Providing grants for public/private battery cell learning laboratories.

• Investing in U.S.-based battery cell and battery pack manufacturing capacity.

• Supporting growth of domestic EV battery supply chains, including extraction and processing of critical minerals for batteries, motors, and magnets.

• Enactment of the provisions for Battery Materials Research, EV and battery raw material processing, and battery cell manufacturing included in the Bipartisan Infrastructure Bill passed by the U.S. Senate on August 10, 2021 and presently pending in the U.S. House of Representatives. [EPA-HQ-OAR-2021-0208-0234-A1][p.5]

Commenter: Illinois et al. Corn Growers Associations

Further, in conjunction with this rulemaking, EPA should conclude the ongoing Tier-III adjustment rulemaking to ensure that the stringency requirements it sets with this rule will be measured in a way that corresponds to real-world engine efficiency. [EPA-HQ-OAR-2021-0208-0563-A2,p.3]

EPA Should Conclude the Outstanding Tier-III Adjustment Rulemaking.

A closely related issue is the so-called "Tier III adjustment," a longpromised correction to that would re-align test results from greenhouse gas and CAFE fuel economy testing to account for EPA's 2014 change of laboratory test fuel to be more similar to the fuels actually used on the road.28 Until proper changes are made, EPA has acknowledged that there has been an effective change in the stringency of the greenhouse and CAFE standards. Those stringency changes should come from rulemakings like this one under Clean Air Act § 202, not from testing procedures under § 206, which concerns the accuracy of testing, not the stringency of green-house gas emissions standards. [EPA-HQ-OAR-2021-0208-0563-A2, p.11]

EPA has not acted on its May 2020 proposed rulemaking about the Tier-III adjustment. Now, with EPA now proposing new, more stringent greenhouse gas requirements, it is long past time that it make the necessary changes to test fuel requirements to ensure that the stringency requirements it sets will be measured in a way that corresponds to real-world engine efficiency. [EPA-HQ-OAR-2021-0208-0563-A2,p.11]

For a full discussion of these issues, we refer EPA to the comments we submitted in response to the Tier-III adjustment rulemaking along with several other groups.29 As explained in those comments, the "fix" EPA has proposed has a number of critical flaws. Specifically, (1) the proposed rule's distortion of measured carbon-dioxide emissions exceeds EPA's authority under Clean Air Act § 206 to determine vehicle test procedures; and (2) the proposal's R-factor of 0.81 significantly underestimates actual fuel economy. EPA should adopt and follow a "fuel neutral" approach to setting emission standards and test procedures. This greenhouse gas emissions rule must be supported by proper testing procedures in order for it to be accurate and fair. EPA should therefore complete the Tier-III adjustment rulemaking in conjunction with this rule and in a manner that facilitates accurate, scientifically grounded testing. [EPA-HQ-OAR-2021-0208-0563-A2, pp.11-12]

Commenter: Kansas Corn Growers Association

EPA Should Address Outstanding Tier-III Adjustment Issues

EPA has long promised to correct testing methods of GHG and fuel economy testing to account for fuels actually used on the road today. EPA has not acted on this rulemaking proposed in May of 2020, and it is past time that the agency acts on this to ensure testing corresponds to real-world engine efficiency and fuels that are actually used on the road today. [EPA-HQ-OAR-2021-0208-0220-A1, p. 2]

Commenter: Keefe, Patricia

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 129-130.]

So I worked with our state senator and I found out that the EPA of Minnesota was developing rules about clean cars. So we do have that process already entered into the state register in Minnesota. So the process is going forward and I'm sure the EPA can get a copy of -- can you still hear me -- a copy of the rules that were developed by the EPA and they were entered into the Minnesota Register recently and they used some of the information from California's experience on clean cars.

So we now are in -- it's now being in the public domain and the rules will be applied in the future to new cars and light trucks in Minnesota. So if EPA here wants to get those, they can get them from the EPA of Minnesota and so can anybody else.

Commenter: Kempker, David

I am in favor of the revised standard. However, any change in standards of vehicle efficiency and emissions should include all pickup trucks, which are a major personal vehicle sector in the U.S. I also feel the EPA should heavily promote electrification of all vehicles - light and heavy [EPA-HQ-OAR-2021-0208-0333, p. 1]

Commenter: Maine Department of Environmental Protection

At the federal level, the U.S. EPA initially adopted GHG emission standards for 2017 model year LDVs in 2012, with these standards receiving widespread support from both industry and the states. [EPA-HQ-OAR-2021-0208-0225-A1, p.1]

Commenter: Minnesota Corn Growers Association (MCGA)

Use Tier 3 certification fuel, and any future certification fuel, without test procedure adjustments for CO2.

As NCGA recommended to EPA in 2020 comments on Docket EPA–HQ–OAR–2016-0604, actual tailpipe carbon emissions, regardless of the test fuel, must continue to be the only measure of vehicle emissions performance in vehicle testing. CO2 test adjustments would needlessly complicate vehicle test procedures. Relying solely on test results eliminates uncertainty, averaging and potential for inaccuracies in procedures to adjust emission test results for the fuel.

Lower GHG emissions from vehicles benefit consumers, our environment, and our energy security. Just as updating the test fuel from E0 to E10 reduced GHG emissions by blending cleaner, renewable ethanol with gasoline, E15 and future clean, high octane fuels that blend more ethanol will further reduce emissions and improve fuel economy when used with optimized engines. Vehicle test procedures for Tier 3 fuel, or any future certification fuel, must not create impediments to low carbon fuels such as E15 and higher blends and the vehicle technologies that help reach our mutual goal of lower GHG emissions. Stringency of the standards is best maintained through the Administrator's authority to adjust the standards, as EPA is using in this proposal, not by adjusting emission test results. [EPA-HQ-OAR-2021-0208-0530-A1, p. 12]

Commenter: National Association of Clean Air Agencies (NACAA)

Among other things, EPA should expeditiously pursue additional federal measures to reduce NOx and VOC emissions, including for mobile sources such as heavy-duty trucks, locomotives, aircraft and ocean-going vessels. [EPA-HQ-OAR-2021-0208-0255-A1, p.5]

Commenter: National Corn Growers Association (NCGA)

As EPA explains in the proposal, the difference between the stringency of the SAFE rule and the revised vehicle standards proposal is due to the greater weight the Administrator puts on emissions reductions and resulting health and welfare benefits than other factors. EPA relied on similar analysis for the proposal as the agency used to develop the SAFE rule and describes the results as in agreement with prior analysis. However, despite similar analysis and results as used for the SAFE rule, the agency is changing its position from the SAFE rule because it is 'more appropriate' to put greater weight on the benefit of reducing emissions, in light of the purposes of the Clean Air Act.[2]

Under the Clean Air Act, EPA has an obligation to protect the health and welfare of Americans. While EPA projects this proposal to increase the stringency of vehicle emissions standards for model year (MY) 2023-2026 vehicles will result in 2.2 billion tons of avoided GHG emission by 2050, EPA leaves significant GHG emission reductions on the table if the agency fails to take steps in this proposal, or in a parallel action, to also improve fuel along with vehicles. [EPA-HQ-OAR-2021-0208-0246-A1, p. 2]

NCGA believes EPA should take the following actions to support the production and use of low carbon, high octane fuel, consistent with Title II of the Clean Air Act, in conjunction with setting vehicle standards:

Implement a pathway to a minimum fuel octane level of 98 RON, phasing out lower octane fuels as new optimized vehicles enter the market.

NCGA believes EPA has ample authority to regulate fuel octane because of the impact higher fuel octane would have on reducing GHG emissions from the vehicle fleet. EPA has previously acknowledged the agency has authority to regulate fuel octane under Section 211(c). [EPA-HQ-OAR-2021-0208-0246-A1, p. 7]

Use Tier 3 certification fuel, and any future certification fuel, without test procedure adjustments for CO_2.

As NCGA recommended to EPA in 2020 comments on Docket EPA–HQ–OAR–2016-0604, actual tailpipe carbon emissions, regardless of the test fuel, must continue to be the only measure of vehicle emissions performance in vehicle testing. CO2 test adjustments would needlessly complicate vehicle test procedures. Relying solely on test results eliminates uncertainty, averaging and potential for inaccuracies in procedures to adjust emission test results for the fuel.

Lower GHG emissions from vehicles benefit consumers, our environment, and our energy security. Just as updating the test fuel from E0 to E10 reduced GHG emissions by blending cleaner, renewable ethanol with gasoline, E15 and future clean, high octane fuels that blend more ethanol will further reduce emissions and improve fuel economy when used with optimized engines. Vehicle test procedures for Tier 3 fuel, or any future certification fuel, must not create impediments to low carbon fuels such as E15 and higher blends and the vehicle technologies that help reach our mutual goal of lower GHG emissions. Stringency of the standards is best maintained through the Administrator's authority to adjust the standards, as EPA is using in this proposal, not by adjusting emission test results. [EPA-HQ-OAR-2021-0208-0246-A1, p. 9]

Commenter: Nissan North America, Inc.

CAFE Reporting Template. To the extent NHTSA is proposing to modify the CAFE Reporting Template, Nissan suggests the agency consider steps to streamline the template and remove unnecessary/additional detail that is not directly relevant to the applicable reporting 10 Nissan Group of the Americas 1 Nissan Way, Franklin, Tennessee 37067 requirements. The data requested in the new NHTSA Reporting Template is extensive and substantially increases the resources required in the data preparation process. Some of the data, however, is not necessary for calculating CAFE compliance values or determining CAFE compliance. For example, much of the in-depth powertrain specification data is not essential for CAFE compliance and reporting purposes and should be excluded from the Reporting Template.

CAFE Credit Trading and Transfer Rules. EPA's GHG credit trading program allows for the unrestricted and unlimited transfer of GHG credits between a manufacturer's car and light truck fleet. NHTSA's CAFE program, however, effectively prohibits the banking or carrying forward of transferred CAFE credits, treating them differently than credits initially generated as part of the relevant fleet. Nissan urges NHTSA to reconsider this restriction. Once transferred, credits should be considered part of the receiving fleet, and should be able to be carried forward or backward to the same extent as the credits originally generated by that fleet. Consistent with the goal of harmonization with the GHG program, NHTSA should: (1) ease the credit transfer limit; and (2) change the definition of "transfer" under the CAFE program at 40 C.F.R. § 536.3 to be consistent with EPA's GHG credit transfer program, as originally expressed in the 2010 preamble to the proposed rulemaking for the 2017-2025 GHG/CAFE standards. Additionally, Nissan urges NHTSA to reconsider the proposal to require a CAFE Credit Reporting Template. As currently proposed, the template is time-consuming and requests highly sensitive information, including monetary and non-monetary terms of credit trading contracts. To the extent such sensitive and confidential information relating to credit trades and transactions is collected by NHTSA, Nissan urges the agency to maintain confidentiality and limit the public disclosure of such information. [EPA-HQ-OAR-2021-0208-0529-A1, p. 9-10]

Commenter: Osbourn, Paul

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 187.]

I believe the flaw in the plan does not have a pragmatic path to cleaner emissions, and I believe that if the EPA wants this to success they must partner with Congress to offer greater tax incentives to buy these newer vehicles. In particular, those tax incentives must include all cleaner fuels, including renewable natural gas, renewable propane, as well as the hybrids and the EVs that are out there.

The new plan looks way too favorable towards one technology that is not going to address all the needs of all the fleets and that is my concern.

Commenter: Stellantis

EPA should study the feasibility of implementing an alternative compliance mechanism, such as the mitigation plans envisioned by the California Framework. The intent would be to achieve needed GHG reductions if there are any gaps in executing this multi-faceted industry/ government effort to transform the new vehicle fleet. [EPA-HQ-OAR-2021-0208-0532-A1, pp. 2-3]

Update Federal EV Incentives and Apply at Point of Purchase - EV technology continues to cost thousands more than comparable internal combustion engine (ICE) models,6 making affordability a key headwind to increased sales. For many popular vehicle segments, price parity between EVs and internal combustion engine vehicles may not be achieved until 2030 or later, a projection highly dependent on future battery costs. Financial incentives have shown to be effective in overcoming this gap, but the current federal incentive is phasing out and remains unattainable for many consumers. A refundable, point-of-sale incentive on both retail and commercial vehicles is necessary to close the cost gap between electrified technology and traditional ICEs and to grow the EV market. [EPA-HQ-OAR-2021-0208-0532-A1, p. 4]

Implement Fleet Purchase Requirements - Over 8 million cars and trucks are owned by fleet operators in the US.7 Fleet applications are generally more suitable to early electrification because of consistent routes and centralized charging points where it is easier to predict and plan for the total infrastructure needs. A national fleet purchase requirement, similar to those requirements being developed in California, should be considered to help create certainty during this relatively rapid transition to electrification. [EPA-HQ-OAR-2021-0208-0532-A1, p. 4]

Introduce Flexibility to Offset GHG Shortfalls

EPA should study the feasibility of implementing an alternative compliance mechanism, such as the one implemented in the California framework. The intent would be to achieve needed GHG reductions if there are any gaps in executing this multi-faceted industry/ government effort to transform the new vehicle fleet.

Stellantis will have the EV and PHEV products needed to delight customers and meet the regulatory requirements. We've highlighted throughout this document that development of the market involves a lot more than just having products – we are reliant on a commitment from the Biden Administration and U.S. policymakers to provide the full suite of supportive policies included in the Build Back Better Plan. If this doesn't happen, it could leave a manufacturer with fewer GHG credits than needed despite having a product plan that should achieve compliance.

Different from the CAFE program, EPA cannot collect fines as a compliance mechanism, however, EPA can and does use other compliance flexibilities such as allowing credit trading between manufacturers. The Clean Air Act gives EPA regulatory authority to employ Supplemental Environmental Projects (SEP) and emissions mitigation projects. These have been used in the past to address criteria emissions violations. We believe a mitigation plan, structured as a relief valve with limits, could be a compliance enabler while the market is transforming to an electrified fleet.

EPA should craft a credit mechanism, similar to that found in the California Framework agreement, which would allow compliance to be achieved through OEM funding of EPA or OEM identified carbon reduction projects in the auto, energy, or other sectors which offset GHG tons equivalent to or greater than the manufacturer's shortfall.

This would provide OEMs the ability to avoid drastic penalties for unanticipated sales variances. To avoid excessive dependence, a cap could be set by the administrator to limit the use of this mechanism. There should be a cost cap in the mechanism set to be generally consistent with prices for GHG credits in California's cap-and-trade program, the Regional Greenhouse Gas Initiative, or other similar GHG market programs, taking into account such other equitable factors as may be appropriate given the circumstances, and considering the social cost of CO2 using the 3% Average values as expressed in Table ES-1 of the Technical Support Document26, issued under Executive Order 13990 by the Interagency Working Group on Social Cost of Greenhouse Gases, United States Government (February 2021). [EPA-HQ-OAR-2021-0208-0532-A1, pp. 19-20]

Commenter: Taxpayers Protection Alliance

The EPA can and should promulgate rulemaking that would protect human health and the environment. The agency would be wise to carefully monitor the activities of other agencies such as the Department of Defense, which is responsible for about 80 percent of the federal government's carbon emissions. The EPA should also closely monitor publicly owned power plants, hospitals, and water utilities, which are approximately 15-20 percent more likely to violate federal air and water standards than their private counterparts. This tailored approach would be far preferable to current rules with low benefits and high costs. We urge you to promulgate sensible rulemaking in the best interests of taxpayers and consumers.[EPA-HQ-OAR-2021-0208-0202-A1, p.1]

Commenter: U.S. Chamber of Commerce ('the Chamber')

Pursue permitting reforms across the federal government to speed up investment in needed infrastructure to support any ambitious standards

It is well understood that the environmental review and permitting process has become hampered by unreasonable costs and delays that stifle investment and economic activity across a broad range of sectors. Though clean energy related projects often enjoy popular support, they too have fallen victim to bureaucratic roadblocks and political opposition that hinder investment and development. As the Bipartisan Policy Center has emphasized,11 even the most well-intended efforts to decarbonize the economy will simply not succeed without stable, well implemented permitting reforms, beginning with the environmental review process established under the National Environmental Policy Act and including the thoughtful reforms to that process that were made in 2020 at the conclusion of a robust and lengthy rulemaking process.

Mining that is necessary to support materials essential to the manufacture of high-capacity batteries and other clean energy resources is no exception. According to the National Mining Association, mine permitting in the U.S. takes on average seven to 10 years, and often longer. In other countries with similarly strong environmental standards, such as Canada and Australia, permitting is typically achieved in just two to three years.

The Chamber recommends that the Administration take steps to ensure timely review and fair consideration of battery-related mining development under NEPA. For mining, this includes supporting and utilizing the recently finalized rule making non-energy mining sector projects eligible for assistance and expedited review under Fixing America’s Surface Transportation Act (FAST-41) processes. Supporting implementation of this rule would help project sponsors to better navigate the federal permitting process for mining, consistent with the policy goals of multiple Administrations representing both political parties that have issued executive orders and presidential memoranda directing the government to increase the efficiency of federal permitting for critical infrastructure.

More broadly, we also recommend that any EPA reviews of environmental impact statements under NEPA and federal government updates to the permitting process explicitly consider and account for potential impacts to strategic minerals supply chains during the review process. [EPA-HQ-OAR-2021-0208-0524-A1, pp. 5-6]

Commenter: Venner, Marie

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, pp. 19-20.]

A date should be set when no more fossil fuel vehicles can be registered and used on public roads. Public funds for widening should be paused this decade and transportation funds should be spent on ensuring that everyone has access to universal broadband and transportation options, only investing in clean and healthy ones, many, many lives to condone it.

Commenter: Whyte, Yolanda

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 143-144.]

Last December for the first time in world history, air pollution was listed as a cause of death on a death certificate. The young girl had severe uncontrollable asthma due to ozone particulate matter and nitrogen dioxide air pollutants from living along a busy roadway in London and London has more protective standards than we do here in the U.S.

It would be great if the EPA worked with the U.S. Department of Health and Human Services to train physicians to also understand the health impacts of air pollution and also educate patients about it and ways to protect themselves from it.

Commenter: Wisconsin Department of Natural Resources

EPA should take timely action to further address emissions from mobile sources. EPA's proposal, while important, represents just incremental progress. It is critical that EPA further reduce mobile source emissions, including emissions from medium and heavy-duty diesel trucks, vehicle emission control systems tampering, commercial marine vehicles, and aircraft. [EPA-HQ-OAR-2021-0208-0223-A1, p.4]

NHTSA, in its proposed rule, offers some other potential mitigation measures EPA could implement to address any increases in NOx and VOC emissions, including offering incentives for the purchase of more fuel efficient vehicles and implementing various measures to reduce vehicle miles traveled. Since most state air agencies and NHTSA do not have the authority to regulate criteria pollutants from light duty vehicles, it is critically important that EPA explore its statutory options to 'net out' any near-term increases in NOx and VOC emissions associated with its final rule. [EPA-HQ-OAR-2021-0208-0223-A1, p.3]

EPA should offset any short-term increases in NOx and VOC emissions associated with the rule. In addition to addressing climate change, stringent yet technologically feasible and cost effective mobile source emissions standards are critically needed by states to reduce ozone-forming pollutants. Transportation-related emissions are significant contributors to ozone formation in Wisconsin, with the on-road sector responsible for 38% of all NOx emissions and 17% of VOC emissions.5 In addition, on-road NOx and VOC emissions from the upwind states of Illinois and Indiana significantly contribute to Wisconsin's ozone levels; for example, those two states were responsible for approximately 40% of the ozone measured at Wisconsin's Chiwaukee Prairie monitor in 2017, and that percentage is projected to increase.6 Given limited state authority to control mobile source emissions, Wisconsin, like many states, relies heavily on federal vehicle emissions standards to help attain and maintain the ozone National Ambient Air Quality Standards (NAAQS).

While EPA's proposal would result in long-term reductions in NOx and VOC emissions, it is also anticipated to cause a near-term increase of these pollutants. Specifically, VOC emissions would increase through 2025, while NOx emissions would increase through 2027.7 While these emissions increases are relatively small, they would occur as Wisconsin will face critical ozone

NAAQS attainment dates; specifically, the 2015 ozone NAAQS moderate area attainment date in 2024 and potentially the 2008 ozone NAAQS severe attainment date in 2027. Given the many challenges states already face to attain and maintain the ozone NAAQS, any increase in NOx or VOC emissions due to EPA's rule are counter to the already pressing need to further reduce emissions from this sector. [EPA-HQ-OAR-2021-0208-0223-A1, p.3]

In addition to maximizing GHG emissions reductions, Alternative 2 has the additional benefit of minimizing the short-term increases in NOx and VOC emissions associated with this rule (see comment #3 [p.3]). [EPA-HQ-OAR-2021-0208-0223-A1, p.2]

To address this disbenefit, EPA should mitigate the anticipated short-term increases in NOx and VOC emissions so that its final rule is at least neutral in its effects on those pollutants. As an initial matter, EPA should finalize Alternative 2, which would reduce VOC emissions every year and significantly decrease the near-term NOx increases (see Table 1). [EPA-HQ-OAR-2021-0208-0223-A1, p.3] [[Table 1 can be found on p.3 of EPA-HQ-OAR-2021-0208-0223-A1]]

EPA should offset any increases in sulfur dioxide (SO2) emissions associated with the rule. EPA's proposal estimates that SO2 emissions will increase every year over the lifetime of its rule, culminating with a net annual increase of nearly 5,000 tons per year by 2050. Given that EPA recently concluded a successful, decade-long campaign to reduce SO2 emissions from stationary sources through implementation of its 2010 SO2 NAAQS and associated Data Requirements Rule, it is important that those gains are not subsequently undermined by rules addressing the mobile sector. As with NOx and VOC emissions, EPA should use its authority to ensure that any potential increases in SO2 emissions are completely offset in the final rule. [EPA-HQ-OAR-2021-0208-0223-A1, p.4]

7 See Table 45 of the proposed rule (p. 43780). NHTSA's proposal similarly concludes NOx and VOC emissions will increase in this timeframe.

EPA Response

EPA has determined that the comments contained in this section are all out of scope of this rulemaking.

Commenter: Alliance of Nurses for Health Environments

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 21.]

This proposal is a step in the right direction. However, our organization strongly urges EPA to set the strongest possible clean car standards to protect public health and address the climate crisis.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 22.]

We are requesting EPA to move swiftly to set the next round of standards and specifically the rule must be as strong as possible for Model Year 2026 to ensure the U.S. can achieve a hundred percent zero emission vehicle sales by no later than 2035 consistent with the Biden Administration's Executive Order.

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 22-23.]

We thank EPA for taking the necessary first step by addressing the previous Administration's rollbacks of clean car standards but more is needed.

Also, we're urging EPA to set much stronger standards covering cars, SUVs, and light trucks through at least 2030. Standards should be reflective of the robust response required to reduce carbon pollution and to derive the transition to zero emission vehicles.

Commenter: Aluminum Association

Post 2026, clarity on future EPA emission targets will be critical for automakers and their suppliers as many automotive technologies take more than five years to engineer, develop, validate, and establish production capacity. The clarity in the 2012 standards was instrumental in supporting the unprecedented improvements in efficient technologies seen in the intervening years and similar long term regulatory certainty in the future will be essential to the U.S. aluminum industry, which continues to make significant investments in new products, processes and capacity to meet growing demand for automotive aluminum. [EPA-HQ-OAR-2021-0208-0233-A1, p. 4]

Commenter: American Council for an Energy-Efficient Economy (ACEEE)

Post-MY 2026 standards need to both be ambitious enough to meet our goals but also need to adapt to a new, more electrified automotive market. This includes accurately accounting for the emissions of electric vehicles and updating the off-cycle credit process. [EPA-HQ-OAR-2021-0208-0251-A1, p. 13]

Commenter: American Lung Association

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 166-167.]

Standards under this rule are a necessary step but are limited to Model Years 2023 to 2026. We need to see more health-protective standards beyond that.

In the Executive Order on Strengthening American Leadership and Clean Cars and Trucks, the President directed EPA to establish new multi-pollutant emissions standards for light- and medium-duty vehicles covering Model Years 2026 to 2030.

Setting up more protective standards now will ensure that the nation is on track to meet the President's goal of having 50 percent on passenger vehicles be zero emission in 2030.

We encourage EPA to move quickly to finalize this current rule and begin the process of future standards without delay.

Commenter: American Lung Association (Sacramento, CA)

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 255.]

U.S. EPA should also move quickly to establish even more stringent next round standards that set the path to full electrification in the light-duty sector as well as to begin the work of standards to accelerate the growing medium- and heavy-duty zero emission vehicle segments.

Commenter: Brandt, Elizabeth

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 199.]

This proposal is a step toward a safer climate for all of us. The EPA must set more ambitious clean car standards for Model Year 2027 and beyond.

Commenter: Center for Biological Diversity, Earthjustice, and Sierra Club

or future rulemakings, we recommend that the agency provide models of EV penetration rates in the coming years. As discussed above, EPA heard from a 'wide range of stakeholders . . . that significant investments [are] being made now to develop and launch new EV [models] and in the expansion of EV charging infrastructure could enable higher levels of EV penetration . . . than EPA has projected.'59 The likely higher future EV penetration rate would support more stringent alternatives both by reducing each model year's tailpipe emissions and through the production of credits that otherwise noncompliant automakers can purchase. [EPA-HQ-OAR-2021-0208-0270-A1, pp.9-10]

Commenter: Center for Climate and Energy Solutions (C2ES)

Any future rulemaking, particularly beginning in MY 2027, should adjust the trajectory of increased ambition to coincide with this goal: reaching zero or near-zero average fleet wide emissions no later than 2035. [EPA-HQ-OAR-2021-0208-0287-A1, p.4]

EPA should set the emissions standards at a stringent enough level to preserve ambition while still allowing this flexibility. Lowering the MY 2026 fleet average target levels five to 10 g/mile below the current level proposed would support increased ambition and prepare the auto industry for more ambitious targets beginning in MY 2027, while preparing the national fleet to meet the decarbonization challenge ahead. [EPA-HQ-OAR-2021-0208-0287-A1, p.4]

Commenter: CERES

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, pp. 84-85.]

We also strongly urge that the next round of standards are aligned with climate goals by ensuring at least 50 percent EV sales by 2030 while ensuring requisite reductions in conventional vehicles in the interim.

Commenter: Chemours Company (Chemours)

Finally, EPA should consider accelerating its timetable for the consideration of additional GHG standards to apply to MY 2027 and later vehicles. Given the Administration's announced goal of achieving 50% electric vehicle sales by 2030, early engagement of industry in the upcoming regulatory process is essential. [EPA-HQ-OAR-2021-0208-0232-A1, p. 3]

Executive Order 14037 indicates that EPA shall "consider beginning work on a rulemaking" that would address light- and medium duty vehicles "beginning with model year 2027 and extending through and including at least model year 2030." And as part of this work, the President has articulated a policy goal that "50% of all new passenger cars and light duty trucks sold in 2030 be zero-emission vehicles."

The proposed rule, however, only indicates that the next phase of GHG standards will be considered in a "separate, future rulemaking for model years 2027 and beyond" and does not set any precise timeframe for this action, nor indicate when EPA will begin the process necessary to propose and finalize a rule in accordance with the schedule outlined in Executive Order 14037. Therefore, EPA should clearly articulate in the final rule the Agency's intended schedule for standards that will apply beginning with MY 2027, with a goal that work begin simultaneously with the promulgation of standards for MY 2023-2026.

There are many policy reasons for EPA to begin work on MY 2027+ standards promptly. The Agency, however, must consider that vehicle manufacturers and the vendors that work closely with such manufacturers to develop new vehicles and vehicle subsystems require sufficient lead time to plan for more stringent requirements. Especially with regard to standards that seek to reduce GHGs dramatically, advance notice and planning will be essential to eventual success. Given that the 2027 MY is barely five years away, EPA must strive to give the regulated industry as much time as possible to efficiently bring new technology and products to market.[EPA-HQ-OAR-2021-0208-0232-A1, p. 17]

Finally, as noted above, EPA should promptly begin work on standards that are intended to apply in MY 2027 and later years. Given the need to develop product plans and work with vendors on new technology, EPA should begin work on "follow-on" standards concurrent with the finalization of this proposed rulemaking. [EPA-HQ-OAR-2021-0208-0232-A1, p. 18]

Commenter: Chicago Metropolitan Agency for Planning

Should this rule be implemented, CMAP encourages the continued adoption of aggressive post-Model Year 2026 emission standards to continue the acceleration of a transition to low and zero emissions fleets. [EPA-HQ-OAR-2021-0208-0219-A1, p.2]

Commenter: City of Albuquerque, NM

Set the precedent for EPA to adopt more ambitious standards for model year 2027 and beyond. [EPA-HQ-OAR-2021-0208-0535-A1, p. 2]

Commenter: Connecticut Department of Energy and Environmental Protection

Additionally, EPA should adopt longer term goals beyond 2026, to ensure continued emission reductions and turn a critical eye toward standards that can be adopted to curb criteria pollutant and GHG emissions from the heavy-duty sector, which stands to be an increasing portion of mobile source emissions. [EPA-HQ-OAR-2021-0208-0264-A1, p. 2]

Commenter: District of Columbia Department of Energy and Environment

DOEE also supports beginning work on a new rule that takes a multi-pollutant approach, to be in place for MY 2027 and beyond. [EPA-HQ-OAR-2021-0208-0240-A1, p.1]

In his August 5, 2021 Executive Order 14037, 'Strengthening American Leadership on Clean Cars and Trucks,' President Biden directs the EPA to develop an additional rule that would establish more stringent GHGs and criteria pollutant emission standards for light- and medium-duty vehicles beginning with MY 2025. Given the District's commitment to a fifty percent reduction in GHG emissions by 2032 and to being carbon neutral by 2050, as well as its need to attain and maintain the NAAQS (in particular the 2015 ozone NAAQS for which the District is still in nonattainment), a long-term multi-pollutant approach to light- and medium-duty vehicle standards is necessary. [EPA-HQ-OAR-2021-0208-0240-A1, p.2]

Begin work on stronger multi-pollutant emission standards for MY 2027 and beyond. [EPA-HQ-OAR-2021-0208-0240-A1, p.3]

Commenter: Edison Electric Institute (EEI)

EPA's Commitment to Future Rulemaking to Drive Electrification is Appropriate, and the Electrical Grid Can Meet the Challenge.

EPA includes a lengthy discussion in its preamble to this rule noting its long-term regulatory focus on driving the electrification of the transportation sector via future rulemakings. The Agency notes that:

This proposed action therefore serves as a critical building block for a comprehensive, multipollutant longer-term regulatory program implementing EPA's statutory authority under the [Clean Air Act (CAA)]. We are at a pivotal moment in the history of the light-duty transportation sector—a shift to zero-emission vehicle technologies is already underway, and it presents a strong potential for dramatic reductions in GHG and criteria pollutant emissions over the longer term. Major automakers as well as many global jurisdictions and U.S. states have announced plans to shift the light-duty fleet toward zero-emissions technology, as detailed below. EPA anticipates that the design of a future, longer-term program beyond 2026 will incorporate accelerating advances in zero-emission technologies.

86 Fed. Reg. at 43,729. EPA goes on to cite the major announcements by every major automaker regarding new EV sales goals and cites the growing prevalence of EV penetration globally. Id. This discussion provides an important market and regulatory signal to all interested stakeholders—in particular, to the electric sector. States such as California, a leader in vehicle electrification, often includes these kinds of discussions in their long-term planning documents, which have provided critical direction to California electric companies in building the infrastructure to support increased electrification of the transportation sector. These types of broad market and regulatory signals will be helpful to EEI's members as they engage with their state commissions to move quickly to build EV infrastructure. Including specific language regarding upcoming likely moves by EPA to set further regulatory standards to incentivize an 7 increase in transportation electrification can send these signals effectively and should be included in any final rule.

EEI member companies are leading the charge to ready the market for widescale EV adoption. EEI members are making investments and offering customer programs designed to help their customers overcome barriers to EV adoption, while also supporting existing EV users and yearover-year growth in the EV market. Many of these programs help to deploy and/or offset the cost of EV charging infrastructure in homes, workplaces, and public locations, as well as for fleet operators. To date, more than 30 states and the District of Columbia have approved customer programs and investments totaling nearly $3 billion.8 Furthermore, EEI members are leading by example with their own fleets by setting individual fleet electrification goals that put them on track to electrify more than a third of their fleet vehicles by 2030.

Currently, more than 33 EEI member companies have proposed or are implementing more than 52 separate programs in 24 different states, with more on the way.9 Electric company investments coupled with those of other companies and stakeholders have dramatically increased access to charging in the U.S. Electric company investments have the potential (pending regulatory approval) to support more than 300,000 new charging stations in the next several years. 10 As of September 2021, there were more than 108,000 public charging ports, not including home chargers.11 This represents a more than 2000 percent increase in the number of public charging ports since 2011.12

These investments are substantial and demonstrate that the industry—with the support of stakeholders necessary to authorize and enable these investments—are ready and willing to help facilitate America's shift towards EVs. The Agency's comments regarding future electrification both acknowledge this progress while also laying out the roadmap on how future standards will provide a clear path for increasing electrification in the transportation sector—and sends a strong signal about the need to build even greater EV infrastructure to meet an electrified future. EPA's role here is consistent with both the Administration's and broad electrification stakeholder community's objectives and will be helpful to EEI's members as they continue to propose and implement even more EV infrastructure projects across their service territories. EPA should finalize this language expeditiously. [EPA-HQ-OAR-2021-0208-0284-A1, p. 6-8]

9 These programs include efforts to increase access to charging for all customers, including lowincome customers and customers who live in multi-family housing

Commenter: Energy Innovation Policy and Technology LLC

For example, our 2035 Report 2.0 shows it is technically feasible and economically beneficial for 100 percent of new light-duty vehicle (LDV) sales to be electric by 2030, and 100 percent of medium- and heavy-duty truck (MDV/HDT) sales to be electric by 2035, while supported by a 90 percent clean electricity grid. Based on our analysis, transitioning to an electrified transportation future and a decarbonized electricity system would:

- Yield a 93 percent reduction in transportation-sector greenhouse gas emissions (GHG) by 2050, helping mitigate the harmful impacts of climate change and aligning the U.S. with broader decarbonization objectives on the path to a 1.5 degree Celsius scenario;

- Prevent 150,000 premature deaths and avoid $1.3 trillion in environmental and health costs through 2050 by reducing harmful air pollution, which disproportionately impacts frontline communities, Black, Indigenous, and People of Color (BIPOC) communities, and low-income/low-wealth populations;

- Save consumers $2.7 trillion by 2050, which translates to about $1,000 for every household per year over the next 30 years;

- Support a net increase of over 2 million jobs in 2035; and

- Maintain a reliable and affordable electricity system.

While we recognize the proposed rule does not endeavor to regulate electric vehicle (EV) sales out to 2035, the adopted standards and future tailpipe emissions standards for all vehicle classes should be as forward-looking as possible to ensure a swift transition to a clean, electrified transportation future and provide more Americans access to the above benefits. A more ambitious approach going forward would also put the U.S. on the path to achieve President Biden's Executive Order aimed at making ZEVs 50 percent of all new cars sold in 2030.[i] [EPA-HQ-OAR-2021-0208-0605-A1, pp. 2]

As noted by the EPA, '[a]ddressing the climate crisis will require substantial reductions in the GHG emissions from the transportation sector,'ix and 'GHG emissions have significant impacts on public health and welfare as evidenced by well-documented scientific record and as set forth in the EPA's Endangerment and Cause of Contribute Findings under Section 202(a) of the CAA.'x We agree with these findings, and modeling from Energy Innovation's EPS demonstrates that widespread deployment of ZEVs, powered by a clean grid, is essential to reducing GHG emissions in alignment with a 1.5°C Scenario (Figure 1).[xi] [Figure 1 can be found at Docket number [EPA-HQ-OAR-2021-0208-0605-A1, p.3]

As the EPA undertakes its subsequent analyses to inform the next iteration of tailpipe standards for both light-duty and medium- and heavy-duty vehicles, we strongly encourage it consider integrating the key findings and underlying assumptions from the 2035 Report 2.0 series (summarized below and discussed in more detail in the attached reports).

To comprehensively address the concurrent imperatives of climate change, public health, environmental justice, consumer affordability, and global competitiveness, we encourage the EPA to continue integrating the most updated assumptions in its analyses. Vehicle technology innovations, consumer adoption trends, cost declines, and other benefits should be reflected in the next iteration of the standards.

Based on our analysis, the strongest possible clean car standards can deliver multiple benefits like reducing vehicle pollution, saving consumers money, and spurring domestic economic activity and innovation in the transportation sector. In addition, strong clean car standards are key to mitigating the disproportionate impacts on the health and well-being of BIPOC and low-wealth communities.[xiv] To that end, we recommend the EPA aim for adoption of a 0g/mile by 2035 tailpipe standard by 2035, to accelerate ZEV deployment and achieve the array of benefits from a clean, electrified transportation system. The key findings from the 2035 Report 2.0 highlight the benefits and opportunities such a shift would entail.

Key Findings from the 2035 2.0 Report Series

• Given recent advances in EV battery cost and performance, range, and recharging, along with a proliferation of vehicle models and the plummeting cost of wind and solar power, the 2035 2.0 Report shows achieving a cost-effective 90 percent clean electricity grid by 2035 and ending pollution-emitting light-duty vehicles sales is technically feasible and economically beneficial within the next 10 to 15 years.

• The 2035 2.0 Report compares two scenarios:

(1) the Drive Rapid Innovation in Vehicle Electrification (DRIVE Clean) scenario, in which EVs constitute 100 percent of new U.S. LDV sales by 2030 as well as 100 percent of MDV and HDT sales by 2035. The grid reaches 90 percent clean electricity by 2035, and substantial EV charging infrastructure is deployed.

(2) the No New Policy scenario, in which EVs constitute 45 percent of new LDV sales, 38 percent of MDV sales, and 12 percent of HDT sales in 2035, and the clean electricity share reaches only 47 percent by 2035.

The study models public charging infrastructure, estimating the number and cost of the public charging ports needed to accommodate tens of millions of electric cars and trucks, the power supplies needed to meet the increased power demand from this shift, and the capital investment needed to achieve an accelerated transition in the DRIVE Clean scenario.

• The DRIVE Clean scenario yields cumulative economic savings of approximately $2.7 trillion through 2050 compared to the No New Policy scenario — an average household savings of approximately $1,000 per year over the next 30 years. The 2035 2.0 report models the total cost of ownership for gasoline and EVs, finding that electric trucks are already cheaper to own than diesel versions on a total cost-per-mile basis, and that electric cars will be cheaper than gasoline equivalents within the next five years (Figures 3 and 4). [EPA-HQ-OAR-2021-0208-0605-A1, pp. 5-6] [Figure 3 can be found on Docket number [EPA-HQ-OAR-2021-0208-0605-A1, p. 6] and figure 4 can be found on Docket number [EPA-HQ-OAR-2021-0208-0605-A1, p. 7]

• Compared with the No New Policy scenario, the total transportation sector pollutant3 and carbon dioxide emissions reductions in the DRIVE Clean scenario avoid approximately 150,000 premature deaths and equate to nearly $1.3 trillion in health and environmental savings through 2050. The DRIVE Clean scenario reduces ground transportation sector CO2 emissions by 60 percent in 2035 and by 93 percent in 2050, relative to 2020 levels (Figures 5 and 6). [Figure 5 can be found on Docket number [EPA-HQ-OAR-2021-0208-0605-A1, p. 7] and figure 6 can be found on Docket number [EPA-HQ-OAR-2021-0208-0605-A1, p. 8] [3] Namely fine particulate matter, nitrous oxides, and sulfur oxides.

• The DRIVE Clean scenario results in 2 million net new jobs in 2035 compared to the No New Policy scenario (Figure 7). Employment gradually ramps up in this timeframe as EV manufacturing expands, and the electricity grid adds new renewable energy and battery storage resources to support increased vehicle electrification. Consumer cost savings in the transition to EVs similarly creates induced jobs in the economy. [Figure 7 can be found at Docket number [EPA-HQ-OAR-2021-0208-0605-A1, p. 8]

• The DRIVE Clean scenario would require an amplified deployment of EV charging infrastructure: the U.S. must install an average of approximately 270,000 public chargepoints for LDVs and 35,000 MDV/HDT chargepoints each year for the next 30 years. The rate of installation is comparable to that achieved in other rapidly electrifying countries.[4,xv]

• The DRIVE Clean scenario's 90 percent by 2035 clean grid is dependable without coal plants or new natural gas plants, and the resulting wholesale electricity cost is lower than today's costs. Electricity demand growth from increased electrification averages about 2 percent per year, a growth rate slower than that achieved in between 1975 to 2005 (Figure 8). To meet this demand, the U.S. must install on average 105 gigawatts of new wind and solar and 30 gigawatts of new battery storage each year. [Figure 8 can be found at Docket number [EPA-HQ-OAR-2021-0208-0605-A1, p. 9]

• New investments in the distribution system are necessary to support increased load from EVs and enable more chargers. However, a complementary analysis to the 2035 Report 2.0, Distribution Grid Cost Impacts Driven by Transportation Electrification (attached), led by Energy+Environmental Economics shows that cost of public charging and estimated distribution upgrade costs associated with transportation electrification will not increase electricity rates. The analysis found that transportation electrification increases system utilization and reduces average distribution rates, even in the high-cost estimates. Managed EV charging, which was not modeled, could further improve the economics.[xvi]

Similarly, EPA's acknowledgement that a 'longer-term rulemaking could also address criteria pollutant and air toxics emissions from the new light-duty vehicle fleet' supports its stated plan to take 'critical steps to continue the trajectory of transportation emission reductions needed to protect public health and welfare.'[vi] [EPA-HQ-OAR-2021-0208-0605-A1, pp . 2]

Commenter: Environmental Defense Fund (EDF)

EDF supports EPA's and the Administration's vision that "a future, longer-term program for MYs 2027 and later will build upon these near-term standards." Moreover, as both the Proposal and President Biden's August 5, 2021 Executive Order 14037 recognize, those long-term standards must ensure substantial deployment of zero-emission vehicles ("ZEVs") to deliver urgently needed climate reductions and to protect the health of communities. To that end, it is important that this Proposal create the strongest foundation possible for future action. [EPA-HQ-OAR-2021-0208-0688-A1, p. 1]

Finally, we urge the administration to propose and finalize those next-generation standards promptly and set new multi-pollutant standards for passenger cars that eliminate tailpipe pollution from new vehicles sold by 2035. Long term standards beyond MY 2026 are crucial to achieving President Biden's goal of 50 percent sales of new zero-emitting passenger cars and light trucks by 2030, and to put the country firmly on the path to eliminating tailpipe pollution from new passenger vehicles by 2035.3 [EPA-HQ-OAR-2021-0208-0688-A1, p. 2]

The Proposed Standards are an important first step to begin the shift toward all new ZEV sales. The agencies must follow this rulemaking promptly with longer-term transformative, multipollutant light-duty standards that will fully transition the light-duty fleet. EDF modeled the impacts of multipollutant standards that ensure all new light-duty vehicles sold by model year 2035 are ZEVs. Such standards would deliver substantial benefits to all Americans by reducing harmful air and climate pollution, saving lives, saving consumers money, and delivering high-quality jobs. [EPA-HQ-OAR-2021-0208-0688-A1, p. 36-37]

Commenter: Environmental Law & Policy Center (ELPC), et al.

EPA must also act swiftly to set standards for MY 2027 and beyond that will slash climate-changing pollution and ensure the U.S. can achieve 100% zero-emission vehicle sales no later than 2035, consistent with the Biden administration's science-based goal of net-zero greenhouse gas emissions economy-wide by 2050. [EPA-HQ-OAR-2021-0208-0567-A1, p. 5]

Commenter: Environmental Law and Policy Center (ELPC)

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 291.]

EPA must act swiftly on setting standards for Model Year 2027 and beyond.

Commenter: Environmental Protection Network (EPN)

Section III discusses how this proposal fits with the longer-term goal. EPN recognizes that this proposal covers just MYs 2023 through 2026, and that most of the necessary transformation to zero-emissions technology will occur after these model years. Therefore, the most important way to judge this proposal is by asking whether it provides the most appropriate foundation for adopting and implementing the longer-term strategy discussed in Section II, and whether it takes the most appropriate steps in these four MYs to make the most progress possible towards this longer-term goal. [EPA-HQ-OAR-2021-0208-0213-A1, p. 1]

EPN is pleased that EPA framed the proposed MY 2023-2026 standards as 'a critical building block for a comprehensive, multipollutant longer-term regulatory program…[with]…a strong potential for dramatic reductions in GHG and criteria pollutant emissions over the longer term.[2] EPN strongly recommends that the agency follow through with an unequivocal commitment to make promulgation of a post-MY 2026 rulemaking requiring near-100% zero emissions vehicle sales by MY 2035 its top mobile source priority over the next two years. [EPA-HQ-OAR-2021-0208-0213-A1, p. 2]

EPA, by promulgating a post-MY 2026 rulemaking requiring near-100% zero-emissions vehicle sales by MY 2035, can play a critical role in facilitating a fast EV transition. There are several compelling justifications for such a strong rule.

One, a fast transition to EVs would yield massive societal benefits. The Environmental Defense Fund (EDF) has projected that a transformation of the new-car and light-truck market to 100% EVs by 2035 would yield net societal benefits of $88 billion in calendar year 2040 and $112 billion in calendar year 2050, with cumulative net societal benefits through 2050 of $1.6 trillion. The societal benefits are about equally split between monetary savings to consumers and health and environmental benefits. [EPA-HQ-OAR-2021-0208-0213-A1, p.7]

Three, as discussed above, it seems increasingly apparent that there are some automakers who want to be leaders in a fast EV transition. In the absence of regulation, however, those automakers may be wary of ‘getting out in front of the market’ while their competitors try to delay the transition as long as possible in order to maximize profits from past investments in existing gasoline vehicle designs and engine/transmission/assembly plants. A strong regulation can provide critical regulatory certainty and a level playing field for those automakers who want to be leaders without worrying that others may drag their feet.

Finally, the most compelling justification for a near-100% EV sales requirement in 2035 is simply that we have no more time to waste. We are facing a global climate emergency, and we must commit to a zero-emissions vehicle future over the next decade if we are to protect ourselves, the planet, and future generations from increasingly severe climate-related tragedies.

EPN stipulates that a fast transition to EVs will be a very big deal for consumers and automakers alike, and EPN understands that the agency will be criticized by many for going too fast. But EPA simply must act to protect the planet and public health, and for the first time, the agency can show that there is a practical and cost-effective technological pathway for doing so, with at least some automakers likely willing to support a regulatory requirement with sufficient lead time.

EPN strongly believes that anything short of a near-100% zero-emissions requirement in model year 2035—e.g., a rule that only goes through model year 2030—would miss the best opportunity the agency has ever had, and may ever have, to define a zero emissions future, and would allow those automakers who do not want to lead to continue to stall and make it harder for those automakers who do.

EPA has a critical decision to make—its post-2026 rule will either define a clear path to a zero-emissions car and light-truck future by 2035 or it won't. EPN implores the agency to have the courage of its convictions and do what we all know must be done to protect the planet and public health for future generations. [EPA-HQ-OAR-2021-0208-0213-A1,pp.8-9]

How This Proposal Furthers the Administration's Stated Long-Term Climate Goals

The proposal makes the minimum progress needed to lay a strong foundation for reaching the longer-term electrification goals, and EPA should consider strengthening it to make greater progress.

As discussed in Section II, EPN strongly believes it is critically important that EPA adopt longer-term standards calling for almost all new passenger cars and light trucks to be electric powered by MY 2035. President Biden's August 5, 2021, Executive Order calls for America to lead the world on clean and efficient cars and trucks and sets a goal of 50% of new cars and light trucks to be electric powered by MY 2030. To implement this the Executive Order calls for EPA to conduct a longer-term rulemaking for MY 2027 and later to be finalized by July 2024.

This proposal is limited to the four MYs preceding MY 2027, making it a relatively limited and near-term set of standards. However, this rulemaking lays the groundwork for the critically important longer-term rulemaking addressed in the Executive Order. Given the need for strong longer-term standards, the most important way to judge this proposal is by asking whether it provides the most appropriate foundation for adopting and implementing the longer-term strategy discussed above. Does this rulemaking take the most appropriate steps in these four MYs and make the most progress possible towards this longer-term goal?

As discussed in Section II, there is no time to lose given the dire need to reduce GHGs from the transportation sector as part of addressing climate change, and the compelling need for large reductions in NOx and PM. There is a relatively short time span to work with. Reaching 50% electric power by MY 2030 and near 100% by MY 2035 will require strong progress through MY 2026 and establishment of a strong foundation for progress after MY 2026.[EPA-HQ-OAR-2021-0208-0213-A1, p. 9]

The NPRM only provides a limited discussion of EPA's longer-term goals and plans. While recognizing EPA retains flexibility on many of the details of its plans, the agency needs to provide a clear signal to all stakeholders, domestic and global, that EPA is moving aggressively to achieve a goal of 50% electrification of new cars and light trucks by MY 2030 and near 100% electrification by MY 2035. Based on the Executive Order, this next rulemaking is around the corner. EPA should publicly recognize this and clearly announce its basic goals for this critical rulemaking addressing MYs after 2026. [EPA-HQ-OAR-2021-0208-0213-A1, p. 13]

Conclusion

Overall, EPN is supportive of this proposal and looks forward to swift finalization and implementation. As previously stated, we believe EPA's top priority moving forward should be a post-2026 rule to establish a clear regulatory requirement to achieve near-100% zero-emissions car and light-truck sales by 2035. If the U.S. is to reach the IPCC goal of net-zero emissions by 2050, it is imperative that the agency promulgate standards to transform the new car fleet to zero-emissions vehicles by 2035, providing critical regulatory certainty and lead time, and a level playing field for U.S. automakers to be EV leaders. [EPA-HQ-OAR-2021-0208-0213-A1, p. 14]

EPA should clearly lay out its goal for the next rulemaking and send a clear signal of what it intends for the years leading to MY 2035, recognizing the need to retain flexibility on the myriad details involved in the next rulemaking. EPN looks forward to the opportunity to work with EPA as the agency begins to develop post-2026 standards. [EPA-HQ-OAR-2021-0208-0213-A1, p. 14]

Commenter: EOS at Federated Hermes (on behalf of its stewardship clients)

Robust vehicle standards are critical to ensuring the global competitiveness of the U.S. auto industry, as well as staving off the worst impacts of climate change. In addition to adopting standards at least as stringent as Alternative 2, we urge EPA to ensure that the next round of standards is aligned with climate goals by ensuring at least 50% ZEV sales, and a 60% reduction in emissions, by 2030. [EPA-HQ-OAR-2021-0208-0568-A1, p. 1]

Commenter: Fajardo, Jane-Marie

As a parent, I am writing to oppose the electrification of all new cars by 2035. The transportation sector is the largest source of climate pollution in the US, but electrification is not the only answer. I could support a smaller percentage, but there are several issues with this aggressive goal.

1) it does not address the emissions upstream that are a result of manufacturing batteries, nor the end life of said batteries. Until there is a crib to crypt model, it would be irresponsible of the EPA to mandate electrification of all cars.

2) the infrastructure is not in place yet to handle so many electric cars.

We do not need 100% of new car sales to be zero-emissions by 2035. To reach that goal, the infrastructure should be in place first. In addition, electrification, only, ignores other renewable resources. We must view climate protection holistically, we cannot think that electrification is the only way when zero emissions at the tailpipe is not the same as zero emissions. Please finalize the strongest possible climate pollution action plan by holistically striving to lower emissions to help protect our children's health and future from the climate crisis. [EPA-HQ-OAR-2021-0208-0668-A1, p. 1]

Commenter: Fuels Freedom Foundation

As acknowledged in the Proposed Rule, internal combustion engines (ICE) vehicles are expected to dominate U.S. roadways far beyond MY2026. Vehicles purchased in any given year will be on the road for 12 years or more. Yet the continued dominance of ICEs does not mean that EPA should decrease ambitions to reduce GHG emissions. Parallel to the long-term commitment to electric vehicles (EVs) in the Proposed Rule, in the Final Rule, the agency should initiate measures to ensure the ability of automakers to both maximize GHG reductions in the vehicles of today, and produce the full range of vehicles that can dramatically reduce carbon intensity and satisfy consumer needs, budgets, and preferences into MY2027 and beyond. [EPA-HQ-OAR-2021-0208-0231-A1, p. 2]

For the long term to 2050, a holistic program is necessary for the EPA to maximize lifecycle GHG emissions in light-duty transportation. From a full fuel-cycle perspective, feedstocks and fuel production are significant contributors to GHG emissions. For electric vehicles, GHG emissions of the electric grid needs to be fully accounted for. For liquid fuels, the carbon intensity of gasoline and diesel increases as production moves further afield, incorporates more carbon-intensive sources, and easier reservoirs are drawn down. The Proposed Rule's recognition that liquid fuels will continue to power the vast majority of vehicles for decades thus demands concerted action to aggressively reverse this direction in order to dramatically reduce carbon intensity. [EPA-HQ-OAR-2021-0208-0231-A1, p. 2]

Commenter: General Motors LLC (GM)

We additionally recognize that this proposal will set the baseline for a future rulemaking by the Biden Administration for the 2027 model year and beyond. We fully expect that rulemaking to leverage and accelerate the ambitious progress by industry toward our shared – and ultimate – goal of an all electric, low-carbon transportation future. [EPA-HQ-OAR-2021-0208-0234-A1][pp.2-3]

Commenter: Hyundai America Technical Center, Inc. (Hyundai)

Hyundai supports the Administration's aspirational goal of achieving 40 to 50% zero emission vehicle sales by 2030. Meeting this electrification goal and the foundation being laid by the GHG reductions proposed in EPA's GHG NPRM will be both challenging and transformative. As such, a host of complementary measures are needed to make it a reality. Ensuring consumer demand, grid resiliency, widespread infrastructure availability, consumer incentives, and green electricity and hydrogen are just a few examples of necessary actions. Coordination between Federal agencies, automakers, and other stakeholders is paramount. [EPA-HQ-OAR-2021-0208-0603-A1, p.1]

Commenter: Interfaith Power & Light (IPL)

[E]stablish a 2030 standard for cars and light-duty trucks that achieves fleet average greenhouse gas emissions 60 percent or more below today's average; put the nation on a trajectory to make all new cars and light-duty trucks electric vehicles no later than 2035, which requires at least 60% to be electric by 2030; and ensure all new trucks and buses are zero-emission no later than 2040.[EPA-HQ-OAR-2021-0208-0224-A1, p. 2]

Commenter: Lish, Christopher

Then, to drive real progress, I urge you to write new long-term rules that:

2. Supplement this proposal with another, to be finalized before the end of 2022, that sets a ZEV mandate for model year 2026 consistent with a pathway toward requiring 100 percent of new vehicles to be ZEVs by 2030.

3. Start another rulemaking for model years 2027 to 2030 that achieves 100 percent ZEVs by 2030.

4. Require automakers to reduce heat-trapping pollution by 7% each year till then;

5. Close loopholes that allow manufacturers to avoid making real improvements;

6. Promote justice and good electric-vehicle jobs. [EPA-HQ-OAR-2021-0208-0218-A1, p. 2]

Commenter: Lucid USA, Inc. (Lucid)

The U.S. automobile market needs a transition period from its current state to a more efficient vehicle mix, and the proposed standards could facilitate that transition. After the transition period of model years 2023-2026, the federal agencies must consider the next stage: a national ZEV program. In the United States, the transportation sector is one of the largest contributors to GHG emissions and in 2019 accounted for 29% of total U.S. GHG emissions. Of those transportation sector GHG emissions, light-duty automobiles accounted for 58% of U.S. GHG emissions in 2019, by far outproducing any other mobile source. A National ZEV program is the natural next step to respond to the climate crisis. [EPA-HQ-OAR-2021-0208-0528-A1, p. 6]

As EPA moves to a final regulation in this rulemaking, Lucid urges the Agency to look ahead to the next rulemaking for Model Years 2027 and beyond. EPA can lay the groundwork now for a technology-forcing regulation in the future that will set nationwide ZEV standards. The auto industry in the United States has given clear signals this year that it is ready for the transition to electric vehicles. The Biden Administration can give the industry a push down the road to a zero emission future with these standards and the next round of standards. [EPA-HQ-OAR-2021-0208-0528-A1, p. 6]

Commenter: Manufacturers of Emission Controls Association (MECA)

While suppliers continue to innovate and introduce new technologies, the uncertainty surrounding these standards over the past five years has limited investment and job creation in the U.S. We therefore urge EPA to set standards as soon as possible for MY2027 and beyond. Our members depend on long term regulatory certainty to justify their investments that will allow the U.S. to meet its national climate objectives and ensure that U.S. technology suppliers remain internationally competitive. [EPA-HQ-OAR-2021-0208-0261-A1, p.1]

MECA supports EPA’s efforts to develop multipollutant standards, including criteria and GHG emission limits for MY 2027 and later light-duty vehicles which are vital to the attainment of long term national environmental goals. Since most economic forecasts out to 2050 include scenarios that predict millions of cars will be sold with ICEs, including some limited sales in 2050, these standards should take into consideration technologies that can feasibly reduce the environmental footprint of all vehicles. In addition, MECA suggests that EPA consider the vehicle and fuel in a systems approach when developing the MY 2027+ standards in order to encourage that all powertrains and fuels are contributing to our national air quality and climate goals.

As electric vehicles become a more significant fraction of the on-road vehicle fleet in 2027 and beyond, MECA urges EPA to consider upstream emissions through a full lifecycle assessment for all vehicle powertrains and advanced vehicle fuels in EPA, NHTSA and DOE programs and regulations. With the growing emphasis on rapid real world emission reductions, it becomes increasingly important to consider all emissions and impacts to the environment, including upstream emissions related to fuels, vehicle production supply chains and supporting fueling infrastructures in a consistent, accurate and equitable manner. Historically, EPA’s methodology has considered a balanced and equitable treatment of fuels and technologies to arrive at cost effective regulations. Numerous studies have shown that in many parts of the country, the air quality benefits of transportation strategies are not uniform with regards to lifecycle emissions. In order to make sound incentive and investment decisions, there is a vital need to consider these additional factors to ensure the most environmentally equitable near-term CO2 reductions that support the attainment of long-term national objectives. [EPA-HQ-OAR-2021-0208-0261-A1, pp.4-5]

Commenter: Maryland Department of Environment

Therefore, Maryland also agrees with NACAA and 'supports such a second rulemaking for future longer-term actions to further reduce LDV emissions – GHG, criteria pollutant and air toxics – and advance penetration of EVs into the market, beginning with MY 2027 and extending through at least MY 2030, to lead to 50 percent of all new passenger cars and light trucks sold in 2030, and 100 percent of those sold in 2035, being ZEVs.' [EPA-HQ-OAR-2021-0208-0241-A1, p.2]

Commenter: Mass Comment Campaign sponsored by American Lung Association (121)

Then, please act quickly to set stronger standards out to at least 2030 that drive the transition to zero-emission transportation nationwide. [EPA-HQ-OAR-2021-0208-0559-A1,p.1]

Commenter: Mass Comment Campaign sponsored by Center for Biological Diversity (77,692)

I urge you to write new long-term rules that:

1. Phase out sales of gas-powered cars and trucks in favor of electric vehicles by 2030; [EPA-HQ-OAR-2021-0208-0560-A1, p.1]

Require automakers to reduce heat-trapping pollution by 7% each year till then; [EPA-HQ-OAR-2021-0208-0560-A1,p.1]

Commenter: Mass Comment Campaign sponsored by Environment America (11,080)

The U.S. Environmental Protection Agency’s proposed rule to Revise Existing National GHG Emissions Standards for Passenger Cars and Light Trucks Through Model Year 2026 is a start, but must be more ambitious if we are to combat the worst effects of climate change and ensure Americans have clean air as soon as possible. Transportation is the number one source of climate change-inducing pollution in the U.S., and we cannot meet the bold climate goals set by President Biden unless we ensure all new cars are electric by no later than 2035. [EPA-HQ-OAR-2021-0208-0557-A1, p.1]

Commenter: Mass Comment Campaign sponsored by Interfaith Power and Light et al. (1,599)

As religious leaders, we urge you to enact the strongest possible standards to reduce vehicle pollution. We ask that you:

• Establish a 2030 standard for cars and light-duty trucks that achieves fleet average greenhouse gas emissions 60 percent or more below today’s average;

• Put the nation on a trajectory to make all new cars and light-duty trucks zero-emission vehicles no later than 2035;

• Ensure all new trucks and buses are zero-emission no later than 2040. [EPA-HQ-OAR-2021-0208-0192-A1, p.2]

Commenter: Mass Comment Campaign sponsoring organization unknown-2 (2,214)

Start another rulemaking for model years 2027 to 2030 that achieves 100 percent ZEVs by 2030. [EPA-HQ-OAR-2021-0208-0546,p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-4 (195)

EPA should also act quickly to set standards for model year 2027 and beyond that will slash climate-changing pollution and ensure the U.S. can achieve 100% zero-emission vehicle sales no later than 2035, as called for by President Biden. [EPA-HQ-OAR-2021-0208-0548,p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-7 (37)

In addition, I urge EPA to swiftly move forward with setting stronger emissions standards that drive a dramatic transition to zero-emission vehicles through 2030 and beyond. [EPA-HQ-OAR-2021-0208-0551, p.1]

Commenter: Mass Comment Campaign sponsoring organization unknown-9 (3,219)

I respectfully urge you to finalize them as soon as possible and move swiftly to establish the next set of standards that put us on the path to 100% sales of new zero-pollution cars and light trucks by 2035. With ambitious multi-pollutant standards, we can protect the health of our communities and achieve the President's goal of a zero-emission transportation future. [EPA-HQ-OAR-2021-0208-0640-A1, p.1]

By setting standards that put the U.S. on a pathway to eliminate all passenger vehicle tailpipe pollution by 2035, Environmental Defense Fund estimates that the U.S. could:

1. Prevent as many as 98,000 premature deaths by 2050;

2. Reduce a total of more than 11.5 billion metric tons of carbon pollution by 2050; and

3. Provide more than $1.6 trillion in benefits to Americans, including pollution reductions and economic savings. [EPA-HQ-OAR-2021-0208-0640-A1,p.1]

Commenter: Metropolitan Mayors Caucus

Act quickly to propose ambitious post-model year 2026 standards. [EPA-HQ-OAR-2021-0208-0504, p.1]

We support the most stringent GHG emission standards for light-duty vehicles feasible and will support swift and aggressive emissions standard for MY 2026 and beyond. [EPA-HQ-OAR-2021-0208-0504, p.1]

Commenter: Minnesota Corn Growers Association (MCGA)

In addition to making improvements in this proposal, we urge EPA to use the rulemaking for MY 2027 and later to open pathways to achieve more emissions reductions from sustainable, affordable low carbon ethanol through a clean, high octane standard, removing barriers to higher ethanol blends and equitably incentivizing all alternative fuel vehicles on track to reach net-zero emissions. [EPA-HQ-OAR-2021-0208-0530-A1, p. 2]

Commenter: Minnesota Pollution Control Agency (MPCA) and Minnesota Department of Transportation (MnDOT)

In his August 5, 2021, Executive Order 14037, 'Strengthening American Leadership on Clean Cars and Trucks,' President Biden directs EPA to begin work on another rule under the Clean Air Act to establish new multi-pollutant emission standards, including for GHGs, for light- and medium-duty vehicles beginning with MY 2027 and extending through at least MY 2030, with a final rule due no later than July 2024. EPA characterizes the current notice as 'a critical building block for a comprehensive, multipollutant longer-term regulatory program implementing EPA’s statutory authority under the CAA' and writes that the agency 'anticipates that the design of a future, longer-term program beyond 2026 will incorporate accelerating advances in zero-emission technologies' (86 FR 43729).

The MPCA and MnDOT support such a future, longer-term rulemaking to slash emissions from the transportation sector and advance the penetration of EV technology. We also encourage EPA to consider the role biofuels can play in reducing emissions in the near-term, and perhaps in the longer term, especially in certain use-cases where electrification is more challenging.

EPA should begin work on this second rulemaking immediately. The California Air Resources Board expects to finalize the next phase of its light-duty vehicle emission standards next year. The many states who are currently exercising their authorities under section 177 of the Clean Air Act to go farther than the backstop national standards are already having to consider whether to pursue adoption of these new standards. In order to make informed decisions about pursuing state-level rulemaking under section 177, states need to know what EPA is considering and how stringent the federal standards might be. The MPCA and MnDOT encourage EPA to pursue a national program that sets the whole country on a path to deep and rapid decarbonization of the transportation sector, while also maintaining the authority preserved to states under the Clean Air Act. We recommend that EPA issue an Advance Notice of Proposed Rulemaking by no later than mid-2022 to share its thinking and ideas, take comments and input and initiate a robust discussion to inform this subsequent regulatory effort. [EPA-HQ-OAR-2021-0208-0211-A1, pp.4-5]

Commenter: Motor & Equipment Manufacturers Association (MEMA)

Looking beyond MY2026, MEMA stands ready to work with EPA to establish a holistic long-term framework for GHG standards that are ambitious but pragmatic and provide multiple technology pathways for compliance. [EPA-HQ-OAR-2021-0208-0249-A1, p. 3]

MEMA Supports a Post-2026 Program that Utilizes a Broad Spectrum of Advanced Technologies - Beyond MY2026, we support a program that transitions the industry to a cleaner transportation future that allows multiple pathways for compliance and utilizes a broad spectrum of advanced technologies. Vehicle suppliers stand ready to help the industry meet the goal of 50 percent of passenger cars and light trucks sold in 2030 are zero emissions vehicles (ZEVs).6 The roll out of higher levels of advanced technologies, including electrification, must be partnered with cohesive complementary policies that address both supply and demand for these technologies. All these elements, along with long-term program consistency, are essential to support vehicle suppliers' commitments, avoid stranded investments, and advance industry's innovation. [EPA-HQ-OAR-2021-0208-0249-A1, p. 4]

MEMA supports EPA's proposed rule for MY2023 and beyond because the standards are achievable with currently available technologies resulting from long-term supplier resource commitments and investments and includes performance-based standards that allow multiple pathways to compliance. We emphasize that a finalization of the rule will require suppliers and the industry as a whole to continue significant capital investments and commitments.

The recent EO directs EPA to establish new emissions standards beginning with MY2027 and extending through at least MY2030. MEMA urges EPA to provide the industry with a long-term holistic framework that includes GHG target ranges and goals beyond 2030. Reaching long-term goals set by the administration, including the 50 percent ZEV target in 2030, will require significant amount of additional research and development from suppliers. As technology investments become more diversified, the supplier industry needs long-term, consistent, coordinated standards from the administration, EPA, NHTSA and California for a smooth path forward.

Vehicle suppliers look forward to working with EPA on the post-2026 program. The post-2026 program and how it is implemented, may well determine global leadership in transportation technology and how investments are made for generations to come. Similar to the pre-2026 program, MEMA strongly supports a post-2026 program that continues to be performance-based and leverages American innovation by allowing the goals to be met with a wide range of advanced propulsion technologies.

It is imperative that various pathways are utilized to meet the even more stringent targets for MY2027 and beyond. Along with higher levels of electrification, there are multiple advanced technologies for ICE and other systems that can significantly contribute to meeting the emissions targets. All these technologies have a place in meeting the nation's goals.

For supplier long-term investments, it is critical that the program allows multiple pathways for compliance, utilizing a broad spectrum of advanced technologies. This approach, partnered with a reasonable pace, will encourage competition around available cost-effective technologies, and preserve U.S. global competitiveness and innovation leadership. Allowing multiple technology pathways is also critical for suppliers to sustain previous supplier commitments, recuperate investments and development over the long-term, and avoid stranding investments.

The roll out of higher levels of electrification and other advanced technologies needs to be partnered with cohesive complementary policies. All these elements, along with long-term targets and consistency, are essential to support vehicle suppliers' investments in these technologies, advance the industry's innovation, and meet the nation's goals.

In the post-2026 program, vehicle suppliers stand ready to help the industry meet the goal set in the EO14037 establishing that ZEVs make up 50 percent of all new passenger cars and light trucks sold in 2030.43 Reaching this goal will require an enormous amount of investments from suppliers on electrification, on top of significant investments already made.

MEMA strongly supports the administration's current definition of ZEVs that includes BEVs, PHEVs, and FCEVs. MEMA strongly supports PHEVs being included in the ZEV definition. PHEVs will facilitate the transition to higher vehicle electrification and, to lower emissions, promote consumer acceptance of electrified powertrains, and reduce tensions in the supply chain, workforce, and needed U.S. charging infrastructure. Industry-based projections show PHEVs are expected to represent at least 20 percent of ZEV sales for the next five years. That percentage not expected to take a general downward trend over that period.

PHEVs offer important flexibility for consumers, including lower income consumers, who may be able to charge at work or elsewhere, but not at a consistent dedicated charging point at home. Research shows that "PHEVs may remain an important choice among lower income consumers" for the foreseeable future because there is consistent data that show a strong link to people not buying a repeat EV in lower income communities because these communities did not have a home charging option. PHEVs are a good option when a BEV or FCEV transition is not feasible. Nationwide, more than 25 percent of housing units are part of structures with at least two units and, accordingly, less likely to have a charging point at home.

While we support the current ZEV definition, MEMA strongly encourages EPA to explore broadening it to include hydrogen ICE (HICE) in the post-2026 program. Broadening the definition of ZEVs to include HICE vehicles and other potential clean technologies would encourage further technology innovation that could accelerate attaining the nation's net-zero carbon emission goals.

HICE could contribute to significant emissions reduction improvements. HICE essentially has no CO2 emissions, and the NOx emissions (comparable to normal ICEs) can be controlled with current technology such as the selective catalytic reduction (SCR). Adding HICE could provide additional flexibility in the ZEV fleet and consumer preference because HICE vehicle performance provides higher load, towing, and longer range. HICE would continue to rely on current ICE manufacturing technology and would reduce tensions in industry manufacturing capacity and retooling needs. [EPA-HQ-OAR-2021-0208-0249-A1, p. 12-14]

Commenter: National Association of Clean Air Agencies (NACAA)

In his August 5, 2021, Executive Order 14037, 'Strengthening American Leadership on Clean Cars and Trucks,' President Biden directs EPA to begin work on another rule under the Clean Air Act to establish new multi-pollutant emission standards, including for GHGs, for light- and medium-duty vehicles beginning with MY 2027 and extending through at least MY 2030, with a final rule due no later than July 2024 (see 86 Fed. Reg. 45,583-45,584). EPA characterizes the current NPRM as 'a critical building block for a comprehensive, multipollutant longer-term regulatory program implementing EPA's statutory authority under the CAA' and writes that the agency ‘anticipates that the design of a future, longer-term program beyond 2026 will incorporate accelerating advances in zero-emission technologies’ (see 86 Fed Reg 43,729).

NACAA supports such a second rulemaking for future longer-term actions to further reduce LDV emissions – GHG, criteria pollutant and air toxics – and advance penetration of EVs into the market, beginning with MY 2027 and extending through at least MY 2030, to lead to 50 percent of all new passenger cars and light trucks sold in 2030, and 100 percent of those sold in 2035, being ZEVs.

EPA should begin work on this second rule now. The California Air Resources Board expects to finalize its next phase of LDV emission standards next year. NACAA recommends that EPA issue an Advance Notice of Proposed Rulemaking by no later than mid-2022, take comments and input and initiate a robust discussion to inform this subsequent regulatory effort. [EPA-HQ-OAR-2021-0208-0255-A1, p.8]

Commenter: National Coalition for Advanced Transportation (NCAT)

Looking forward to the GHG emissions standards that EPA will promulgate in a separate rulemaking for MY 2027 and beyond, NCAT supports EPA adopting strong standards that will continue to drive very substantial reductions in GHG emissions from vehicles. EPA should adopt standards that provide a longer-term benchmark to give manufacturers, state air agencies, public utility commissions and consumers a sense of long-term clarity. EPA’s longer-term approach should be both stringent and durable. This durability is important not just for manufacturers to roll out longer-term plans, but also for state utility commissioners who are planning to meet the electricity demand and support the infrastructure necessary for the continued transition to transportation electrification.

NCAT completely agrees with EPA that “[w]e are at a pivotal moment in the history of the light-duty transportation sector—a shift to zero-emission vehicle technologies is already underway, and it presents a strong potential for dramatic reductions in GHG and criteria pollutant emissions over the longer term.” The design of the longer-term program for MY 2027 and beyond must incorporate the “accelerating advances in zero-emission technologies”, in particular given the fast-paced nature of these industry changes, and “continue the trajectory of transportation emission reductions needed to protect public health and welfare.” As EPA recognizes, the benefits from these longer-term standards achieved with increased fleet penetration of zeroemission vehicles are enormously consequential. These benefits include large reductions in GHG emissions as well as criteria pollutants and air toxics emissions on and around roadways. In addition, they would support for the future development of vehicle-to-grid services, beneficially using renewable energy sources, such as wind and solar, across the electric grid.161 [EPA-HQ-OAR-2021-0208-0239-A1, p. 23-24]

Commenter: National Corn Growers Association (NCGA)

In addition to improving this proposal, NCGA urges EPA to use the rulemaking for MY 2027 and later to open pathways to achieve greater emissions reductions from sustainable, affordable low carbon ethanol through a clean, high octane standard, removing barriers to higher ethanol blends and equitably incentivizing all alternative fuels and vehicles on track to reach net-zero emissions. Low carbon, high octane fuels would also support any longer-term EPA rulemaking to address vehicle criteria pollutant and air toxics emissions. [EPA-HQ-OAR-2021-0208-0246-A1, p. 1]

Commenter: New Mexico Environment Department

Adopting the most stringent standards now will allow the EPA to adopt more ambitious standards for Model Year 2027 and beyond. Future car standards that increase stringency of standards for GHG, criteria pollutants, and air toxins will be fundamental to meet the national and state GHGe reduction goals and improve public health. [EPA-HQ-OAR-2021-0208-0205-A1] [p.3]

In addition to the more stringent proposed rules currently proposed by the EPA, New Mexico supports EPA in proposing future, longer-term policies and regulatory actions that will address LDV criteria pollutants and air toxin emissions in addition to GHGe. These future regulations will be instrumental in defining a strong national program with a path that accelerates the transition to zero-tailpipe emission for all vehicles sold in the United States. [EPA-HQ-OAR-2021-0208-0205-A1] [p.3]

Commenter: New York State Department of Environmental Conservation

New York encourages EPA to finalize this proposed rule and immediately turn its attention to establishing new rules that effectuate President Biden's goal that 50% of all passenger vehicles sold in the United States in 2030 will be zero emission. As recommended on April 21, 2021 by the Governors of New York and eleven other states, those rules should guide the transition to the sale of only zero emission passenger vehicles by 2035, putting the nation back on track in reducing emissions from the transportation sector at a critical moment, On September 8, New York Governor Kathy Hochul signed legislation1 that establishes a 100% light-duty new vehicle. ZEV sales goal in New York State by 2035. The climate crisis is here now, and steadfast leadership from the federal government and state governments alike is necessary to protect our planet and create today the jobs of the future. [EPA-HQ-OAR-2021-0208-0238-A1, p.3]

Commenter: Nissan North America, Inc.

As an industry leader and early developer of advanced technologies, including EVs, Nissan strongly supports the Biden Administration’s long-term electrification and carbon neutrality goals. Though advancements in gasoline powered/internal combustion engine (“ICE”) vehicles are an important element of improving fuel efficiency and achieving immediate GHG goals, the development and widespread adoption of EVs is essential to more substantial, long-term reductions—and even elimination—of tailpipe emissions. [EPA-HQ-OAR-2021-0208-0529-A1, p. 3]

Nissan is committed to helping create a carbon neutral society and accelerate the global effort against climate change. Nissan appreciates the Administration's focus on and support for advancing electrification and carbon neutrality. Nissan believes that the ambitious emission and fuel economy standards embodied in the proposed rules are important steps in driving the automotive industry towards these goals. The complimentary EV market measures discussed in the next section are an essential element of those steps and reaching the long-term goals. [EPA-HQ-OAR-2021-0208-0529-A1, p. 4]

Commenter: Northeast States for Coordinated Air Use Management (NESCAUM)

For the reasons stated above, NESCAUM urges EPA to promptly adopt the most stringent GHG emission standards feasible for MYs 2023-2026, and to move swiftly thereafter to propose ambitious post-MY 2026 GHG standards, to put the nation on track to rapidly electrify the entire light-duty fleet. [EPA-HQ-OAR-2021-0208-0259-A1, p. 5.]

Commenter: Poore, Michael

A revision to the SAFE Vehicles Rule for Model Years 2021-2026 Passenger Cars and Light Trucks is both necessary to help mitigate climate change and is compliant under the Clean Air Act. However, I believe the revision should extend the SAFE rule to more align with the recent Executive Order on Strengthening American Leadership in Clean Cars and Trucks. Additionally, while it does consider environmental justice issues, I believe more research needs to be conducted regarding short term affordability and equity.

The recent executive order, as inducted by Biden, sets a goal of having "50 percent of all new passenger cars and light trucks sold in 2030 be zero-emission vehicles, including battery electric, plug-in hybrid electric, or fuel cell electric vehicles.". Additionally, the executive order calls for the establishment of "new multi-pollutant emissions standards, including for greenhouse gas emissions, for light- and medium-duty vehicles beginning with model year 2027 and extending through and including at least model year 2030.".

While this rule revision calls itself a "stepping off point" for a longer-term program, I do not believe it needs to be such. To best align and meet the standards of the previous cited executive order, the revision should extend the SAFE rule to 2030, with the likeliness of more stringent standards for the extended years. [EPA-HQ-OAR-2021-0208-0371, p. 1]

Commenter: Pruitt, Katherine

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 158.]

Additionally, EPA must also move ahead to set much stronger standards covering cars, SUVs, and light trucks through at least 2030 to drive the transition to zero emission vehicles the nation needs and that President Biden has called for in his Executive Order.

Commenter: Rauch, Molly

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p.37.]

We need 100 percent of new car sales to be zero emissions by 2035. To reach that goal the near-term standards for climate pollution must be as strong as possible as soon as possible.

Commenter: Richards, Claire

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 269.]

It is critical that we have a long-term plan. The EPA must also set stronger standards through at least 2030 to drive the transition to zero emission vehicles the Nation needs and that President Biden has called for in his executive order. We must cut emissions as quickly as possible from gasoline cars and increase the adoption of electric vehicles so that we can get to a 100-percent electric new car market by 2035.

Commenter: Sierra Club

[The following comments were submitted as testimony at the virtual public hearing on August 25, 2021. See Hearing Testimony – 25Aug2021, p. 32.]

So we must get to a hundred percent electric vehicles sales by 2035 and, unfortunately, the EPA's proposed rule doesn't go far enough to get us on that path.

Commenter: South Coast Air Quality Management District

The South Coast AQMD also supports future regulatory action to address criteria pollutant and air toxics emissions from the new light-duty vehicle fleet.

The District appreciates the proposal's recognition that the standards have an in-built 'expectation that a future, longer-term program for MYs 2027 and later will build upon these [proposed] near-term standards' 86 FR at 32287. And the District fully agrees that this is a 'pivotal moment in the history of the light-duty transportation sector,' 86 FR at 43279, where zero emission technologies hold real promise for dramatic GHG and criteria pollutant reductions over the longer term. This forward-thinking recognition contrasts starkly with the SAFE rulemaking, which stubbornly failed to take account of any of the dire, longer-term impacts of the rollback. In essentially weakening EPA standards to achieve less than would be expected even without any regulation, the SAFE rule was undermining the vehicles program for 2027 and later (not to mention indirect or attenuated impacts of the rollback for regulation of other mobile sources). As concerns the urgency of the climate crisis, where the science recognizes GHGs to be 'long-lived' pollutants, the trajectory matters. Put differently, EPA must see that it is charged to adopt standards that are directionally appropriate; in this context, weak standards, in a real sense, can be worse than doing nothing. In the concept of building on the proposed near-term standards, the District fully supports EPA's announced aspirations for a future, longer term rulemaking that 'could also address criteria pollutants and air toxics emissions from the new-light duty fleet.' 86 FR 43730. [EPA-HQ-OAR-2021-0208-0215-A1, pp.3-4]

Commenter: Toyota Motor North America, Inc. (Toyota)

Toyota embraces an electric vehicle future and shares the Administration's objective of 40% to 50% of new vehicles sales in 2030 being electrified. We believe the surest way to reduce carbon the fastest is to embrace all forms of electrified vehicles to meet the varying needs of consumers, as well as low carbon fuels to reduce carbon from Internal Combustion Engines (ICEs) as the fleet turns over to electrified vehicles. We appreciate that the proposed standards remain performance-based while providing limited regulatory incentives to promote electrification and provide manufacturers with needed regulatory flexibility.

Toyota generally supports the proposed 2023-2026 model year GHG standards. Successful implementation of, and compliance with, the proposed standards requires complementary market-development and sustainment measures, including non-discriminatory consumer tax credits, infrastructure investments on electric charging and hydrogen refueling, critical mineral supply chain development, and a robust system to recycle end-of-life vehicle batteries. Toyota stands ready to work with federal and state regulators and lawmakers to support these measures provided they maintain a level competitive playing field. [EPA-HQ-OAR-2021-0208-0531-A1, p. 3]

Conclusion

Toyota generally supports the proposed 2023-2026 model year GHG standards recognizing that compliance will involve numerous stakeholders collaborating to increase customer adoption rates for BEV, FCEV, PHEV, and conventional hybrids. The more widespread deployment of today's best-in-class conventional gasoline technologies will also play an important role. Flexibilities and regulatory harmonization between EPA's GHG regulations and NHTSA's CAFE regulations are critical to cost-effectively manage compliance. Toyota is ready to contribute the proposed program's success to achieve the desired greenhouse reductions while simultaneously meeting the needs of our customers. [EPA-HQ-OAR-2021-0208-0531-A1, p. 14-15]

Commenter: Union of Concerned Scientists (UCS)

EPA must move forward expeditiously in proposing and finalizing MY2027 and later standards which puts the U.S. on track to a full transition to zero emission light-duty vehicle sales by 2035. A proposal in 2022 followed by finalization in 2023 would provide manufacturers with regulatory certainty as they continue to invest in the transition to zero emission vehicles. [EPA-HQ-OAR-2021-0208-0277-A1, pp.3-4]

The U.S. must rapidly transition to zero-emission vehicles to address climate emissions from the transportation sector. As demonstrated by UCS modeling, achieving 100 percent sales of zero emission passenger cars and trucks by 2035 will help put the U.S. on the path to net-zero emission by 2050, the level of reductions needed to avoid the worse consequences of climate change.

EPA must move forward expeditiously to finalize the strongest standards through MY2026 and propose and finalize standards for MY2027 and beyond as soon as possible to ensure the U.S. is on track to meet 100 percent zero emission vehicle sales by 2035. As noted above, and illustrated in Figure 7, adoption of Alternative 2 with an additional 10 g/mile requirement for MY2026, would result in the greatest amount of electric vehicle sales. However, without additional action, the U.S. will not meet the zero emission vehicle goals in President Biden's August 5, 2021, Executive Order, or the recommendation of the National Academies which call for 50 percent sales of electric vehicles by 2030. [Figure 7 at docket number EPA-HQ-OAR-2021-0208-0277-A1, p. 17]

In order to send a strong signal to the automotive industry and provide regulatory certainty for manufacturers, EPA should propose standards for MY2027 and beyond in 2022 and finalize standards in 2023 consistent with reaching 100 percent sales of zero emission vehicles by 2035. Some manufacturers, including General Motors, have signaled support for a transition to 100 percent zero emission vehicle sales. However, strong standards consistent with this trajectory are necessary to drive investments across the industry, hold all manufacturers accountable, and spur the additional investments needed to make a full transition away from internal combustion vehicles.

The urgency of the moment could not be more clear. Climate change is already having catastrophic impacts on the health and well-being of millions around the globe. The latest IPCC report provides a dire warning of the consequences of failing to act quickly and aggressively to curb climate emissions. Addressing pollution from our cars and trucks is a critical, necessary step.

Fortunately, cost-effective technology is available to reduce, and even eliminate, the pollution from vehicles operating on our roads and highways. EPA must finalize the strongest standards possible to set us on a path to addressing the pollution from our nation's transportation system. [EPA-HQ-OAR-2021-0208-0277-A1, pp. 39-40]

Commenter: Volkswagen Group of America, Inc. (Volkswagen)

Volkswagen supports the intention of the Administration to begin examining similar Federal pathways for 2027 and the direction for the Federal and State agencies to coordinate on the development of future standards. Volkswagen is committed to be a constructive partner in the dialogue for those future standards and to find pathways that can further expand the market for electrification in the US. Discussions regarding post 2027 is helping Volkswagen define it's own 'New Auto' strategy. [EPA-HQ-OAR-2021-0208-0237-A1, p.3]

Commenter: Volvo Car Corporation

Volvo Cars shares the Biden administration goals to advance sustainability and electrification. Volvo Cars wants to lead the transition to zero tailpipe emission mobility and our plan is to be a fully electric car company by 2030. Our goal is to be climate neutral by 2040, in line with the Paris Agreement. Therefore, Volvo Cars supports the Administration's goals of an electric vehicle future and lower emissions year over year. [EPA-HQ-OAR-2021-0208-0253-A1, p.2]

Commenter: Wisconsin Department of Natural Resources

EPA should also proceed expediently, in conjunction with NHTSA, to further strengthen emissions standards from light-duty vehicles, starting with the 2027 model year. Given limited state authority over these sources, timely federal action is critical to help states meet their state and federal air quality requirements. [EPA-HQ-OAR-2021-0208-0223-A1, p.4]

Commenter: Wiste, Leah

[The following comments were submitted as testimony at the virtual public hearing on August 26, 2021. See Hearing Testimony – 26Aug2021, p. 87.]

We're asking for a 2030 standard for cars and light-duty trucks that reduces greenhouse gases to 60 percent below today's average and to make all new trucks and buses zero emissions by 2040.

We're calling for all cars and light-duty trucks to be zero emissions by 2035 which will require at least 60 percent to be zero emissions by 2030.

EPA Response

EPA acknowledges comments expressing views on GHG emissions standards beyond MY 2026. As explained in the proposal and this final rule, EPA is adopting this rule to revise standards for MY 2023-2026 and is not adopting standards for later model years at this time, although EPA intends to initiate a new rulemaking for later model years. EPA believes this approach is appropriate in light of the timeline and record for this rulemaking.
