Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards

Response to Comments

Assessment and Standards Division
Office of Transportation and Air Quality
U.S. Environmental Protection Agency

NOTICE

This technical report does not necessarily represent final EPA decisions or positions. It is intended to present technical analysis of issues using data that are currently available. The purpose in the release of such reports is to facilitate the exchange of technical information and to inform the public of technical developments.

EPA United States Environmental Protection Agency

EPA-420-R-22-036
December 2022

EPA's Proposed Rule and Related Materials for Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards was signed by Administrator Michael Regan on March 7, 2022. A pre-publication version of the proposal was made available on EPA's website on that date, prior to publication in the Federal Register on March 28, 2022 (87 FR 17414 et seq.).[1] The proposal indicated that the rule would be open for public comment until May 13, 2022; the comment period was subsequently extended to May 16 through a separate notice in the Federal Register (87 FR 24146, May 3, 2022).

This Response to Comments document is a compilation of public comments submitted to the public docket for this rule, Docket ID No. EPA–HQ–OAR–2019-0055, as well as EPA responses. Some aspects of our responses appear in the preamble to the final rule or other documents in this rule's docket and are incorporated by reference in this document.

This document is organized by category of comment topic. The original documents submitted by commenters, including any attachments, footnotes, tables, and figures are included in the docket.

EPA received nearly 266,250 written comments on this proposal. Of the written comments, 35 documents are mass mailer letters individually sent by, or representing through signature, 264,343 commenters. There are also an additional 1,839 documents submitted as comments to the docket for this rule, for a total of 1,874 individual posted comments. Detailed comments on various aspects of the proposed program from the mass mailers and 360 other comment documents are reproduced verbatim in this document. A list of these comments can be found in Appendix 1. Note that an individual comment or part of a comment may be reproduced in more than one section of this document if it contains observations on more than one aspect of an issue. Appendix 2 contains a list of the remaining comments submitted to the docket before the docket closed on May 16, 2022. These comments express general support for or opposition to the proposal and/or contain opinions or statements about issues but without detailed data, information, or comment relating to specific provisions of the proposal or EPA's supporting analysis. The comments listed in Appendix 2 are not reproduced verbatim in this document, as these comments did not raise issues with reasonable specificity or were outside the scope of the rulemaking. However, Appendix 2 contains a brief summary of the nature of these comments.

The public hearing transcripts are included in the docket.[2] Appendix 3 contains a list of the testifiers and a brief summary of the nature of their testimony. The public testimony that is more specific in nature and not subsequently included in written comments submitted by the testifier or the testifier's organization is included verbatim in this document.

Late comments received during the period after the comment period closed, from May 17, 2022, through October 4, 2022, were considered to the extent practicable in developing the final rule. These late comments are set out in Section 34.

---

[1] EPA notified more than 110 stakeholders of the availability of the pre-publication version through an e-mail dated March 7, 2002, from Brian J. Nelson, Director, Heavy-Duty Onroad & Nonroad Center U.S. Environmental Protection Agency.

[2] See docket ID EPA-HQ-OAR-2019-0055-2867. During the 3-day public hearing (April 12, 13, and 14, 2022), 278 individuals testified. The hearing testimony transcripts publicly available are redacted versions that were edited to remove potential Personally Identifiable Information (PII).

The responses presented in this document are intended to augment the rationale and responses to comments that appear in the preamble to the final rule and to address comments not discussed in the preamble to the final rule. To the extent there is any confusion or apparent inconsistency between this Response to Comments document and the preamble, the preamble itself remains the definitive statement of the rationale for the final rule. This document, together with the preamble to the final rule and the information contained in the Regulatory Impact Analysis, and related technical support documents, should be considered collectively as EPA's response to all of the significant comments submitted on the proposal.

Table of Contents

Table of Acronyms

Acronym	Definition
3B-MAW	3 Bin Moving Average Window
°C	Degrees Celsius
µg	Microgram
µm	Micrometers
20xx$	U.S. Dollars in calendar year 20xx
A/C	Air Conditioning
ABT	Averaging, Banking and Trading
AC	Alternating Current
ACEA	European Automobile Manufacturers Association
ACES	Advanced Collaborative Emission Study
ACF	Advanced Clean Fleet (California standards)
ACT	Advanced Clean Truck (California standards)
ADAS	Advanced Driver Assistance Systems
AECC	Association for Emission Controls by Catalyst
AECD	Auxiliary Emissions Control Device
AEO	Annual Energy Outlook
AER	All-electric range
AES	Automatic Engine Shutdown
AESS	Automatic Engine Shutdown System
AFDC	Alternative Fuels Data Center
AFTC	Alternative Fuel Tax Credit
AHS	American Housing Survey
Al	Aluminum
Al2TiO5	Aluminum Titanate
AMOC	Atlantic Meridional Overturning Circulation
AMT	Automated Manual Transmission
ANL	Argonne National Laboratory
ANPR(M)	Advanced Notice of Proposed Rulemaking
APA	Administrative Procedures Act
API	American Petroleum Institute
APU	Auxiliary Power Unit
AQ	Air Quality
AQCD	Air Quality Criteria Document
AQMD	Air Quality Management District
AR4	Fourth Assessment Report
ARB	California Air Resources Board
ARB HHDDT	California Air Resources Board Heavy Heavy-Duty Diesel Test
ASC	Ammonia Slip Catalyst
ASL	Aggressive Shift Logic
ASM	Annual Survey of Manufacturers
ASTM	ASTM International, formerly American Society for Testing and Materials
AT	Automatic Transmissions
AT	Advanced Technology
ATA	American Trucking Association
ATIS	Automated Tire Inflation System
ATRI	Alliance for Transportation Research Institute
ATS	Aftertreatment System
ATSDR	Agency for Toxic Substances and Disease Registry

Acronym	Definition
ATUS	American Time Use Survey
ATVM	Advanced Technology Vehicle Manufacturing
Avg	Average
B100	1 methyl-ester biodiesel fuel
B20	0.2 biodiesel blended with 0.8 petroleum distilate diesel fuel
BECCS	Bioenergy with Carbon Capture and Storage
BenMAP	Benefits Mapping and Analysis Program
BETP	Bleed Emissions Test Procedure
BEV	Battery Electric Vehicle
bhp	Brake Horsepower
bhp-hr	Brake Horsepower Hour
BLS	Bureau of Labor Statistics
BMEP	Brake Mean Effective Pressure
BSFC	Brake Specific Fuel Consumption
BSG	Belt-driven starter-generator
BTS	Bureau of Transportation Statistics
BTU	British Thermal Unit
C	Carbon
C	Centigrade
Ca	Calcium
CAA	Clean Air Act
CAAA	Clean Air Act Amendments
CaaS	Charge-as-a-Service
CaCO3	Calcium Carbonate
CAD/CAE	Computer Aided Design And Engineering
CAE	Computer Aided Engineering
CAFE	Corporate Average Fuel Economy
CAMx	Comprehensive Air Quality Model with Extensions
CAN	Controller Area Network
CARB	California Air Resources Board
CASAC	Clean Air Science Advisory Committee
CaSO4	Calcium Sulfate
CATF	Clean Air Task Force
CBI	Confidential Business Information
CCP	Coupled Cam Phasing
CCSCR	Close-Coupled Selective Catalytic Reduction
CCSP	Climate Change Science Program
CCV	Close Crankcase Ventilation
CD	Charge Depleting
CDA	Cylinder Deactivation
CDC	Centers for Disease Control
CDPF	Catalyzed Diesel Particulate Filter
CE-CERT	Center for Environmental Research and Technology
CEQ	Council on Environmental Quality
CF	Conformity Factor
CFD	Computational Fluid Dynamics
CFR	Code of Federal Regulations
CH4	Methane
CHEAPR	Connecticut Hydrogen and Electric Automobile Rebate Program
CI	Compression-ignition
CI	Carbon Intensity
CILCC	Combined International Local and Commuter Cycle

Acronym	Definition
CIPM	International Committee for Weights and Measures (Bureau International des Poids et Mesures)
CITT	Chemical Industry Institute of Toxicology
CM	Compliance margin
CMAQ	Community Multiscale Air Quality
CMAQ	Congestion Mitigation and Air Quality Improvement program (DoT)
CNG	Compressed Natural Gas
CO	Carbon Monoxide
CO2	Carbon Dioxide
CO2eq	CO2 Equivalent
COFC	Container-on-Flatcar
COI	Cost of Illness
COPD	Chronic Obstructive Pulmonary Disease
CoV	Coefficient of Variation
CPI	Consumer Price Index
CPO	Compressor pressure outlet
CPS	Cam Profile Switching
CPSI	Cells per Square Inch
C-R	Concentration-Response
CRC	Coordinating Research Council
CRGNSA	Columbia River Gorge National Scenic Area
CRR	Rolling Resistance Coefficient
CS	Climate Sensitivity
CS	Charge Sustaining
CSA	Combined Statistical Area
CSB	Clean School Bus Program
CSI	Cambridge Systematics Inc.
CSS	Coastal Sage Scrub
CSV	Comma-separated Values
CTP	Clean Trucks Plan
CTTP	Cold Temperature Test Procedure
Cu	Copper
CuO	Copper(II) oxide or cupric oxide
CV	Commercial Vehicle
CVD	Cardiovascular Disease
CVT	Continuously-Variable Transmission
CW	Curb Weight
CY	Calendar year
D/UAF	Downward and Upward Adjustment Factor
DAAAC	Diesel Aftertreatment Accelerated Aging Cycle
DARAP	Diesel Aftertreatment Rapid Aging Protocol
DCP	Dual Cam Phasing
DCT	Dual Clutch Transmission
DDE	Durability demonstration engine
DE	Diesel Exhaust
DEAC	Cylinder Deactivation
DEER	Diesel Engine-Efficiency and Emissions Research
DEF	Diesel Exhaust Fluid
DER	Distributed Energy Resources
DERA	Diesel Emission Reduction Act
deSOx	Removal of sulfur oxide compounds
DF	Deterioration Factor
DHHS	U.S. Department of Health and Human Services

Acronym	Definition
Diesel HAD	Diesel Health Assessment Document
DMC	Direct Manufacturing Costs
DNR	Department of Natural Resources (State-Level)
DO	Dissolved Oxygen
DOC	Diesel Oxidation Catalyst
DOD	Department of Defense
DOE	Department of Energy
DOHC	Dual Overhead Camshaft Engines
DoIP	Diagnostic over IP (???)
DOT	Department of Transportation
DPF	Diesel Particulate Filter
DPM	Diesel Particulate Matter
DQS	DEF Quality Sensor
DR	Discount Rate
DRIA	Draft Regulatory Impact Analysis
DTE	Distance to Empty
DVVL	Discrete Variable Valve Lift
EAS	Exhaust Aftertreatment System
EC	European Commission
EC	Elemental Carbon
EC	Economic Census
ECM	Electronic Control Module or Engine Control Module
ECU	Engine Control Unit
ED	Emergency Department
EERA	Energy and Environmental Research Associates
EEVO	Early exhaust valve actuation
EFR	Engine Friction Reduction
EGR	Exhaust Gas Recirculation
EGU	Electrical Generating Unit
EHC	Electrically heated catalyst
EHPS	Electrohydraulic Power Steering
EIA	Energy Information Administration (part of the U.S. Department of Energy)
EIS	Environmental Impact Statement
EISA	Energy Independence and Security Act
EIVC	Early Intake Valve Closing
EIWR	Emission Warranty Information Reporting
EJ	Environmental Justice
EMCT	Emission Measurement and Testing Committee
EMFAC	California EMission FACtors emission inventory model
EMS-HAP	Emissions Modeling System for Hazardous Air Pollution
EO	Executive Order
EPA	Environmental Protection Agency
EPCA	Energy Policy and Conservation Act
EPMA	electron probe microanalysis
EPS	Electric Power Steering
ePTO	Electric Power Take-Off System
ERC	Emision-Related Component
ERG	Eastern Research Group
ERM	Employment Requirements Matrix
ESA	Endangered Species Act
ESC	Electronic Stability Control
ETC	Electronic Throttle Control

Acronym	Definition
ETW	Estimated Test Weight
EU	European Union
EV	Electric Vehicle
EVCS	Electric Vehicle Charging Station
EVSE	Electric Vehicle Supply Equipment
F	Frequency
FAME	Fatty Acid Methyl Ester
FCAB	Federal Consortium for Advanced Batteries
FCEV	Fuel Cell Electric Vehicle
FCV	Fuel Cell Voltage
Fe	Iron
FEL	Family Emission Limit
FET	Federal Excise Tax
FEV1	Functional Expiratory Volume
FHWA	Federal Highway Administration
FIA	Forest Inventory and Analysis
FMCSA	Federal Motor Carrier Safety Administration
FOH	Fuel Operated Heater
FR	Federal Register
FRM	Final Rulemaking
FTC	Federal Trade Commission
FTE	Full Time Equivalent
FTP	Federal Test Procedure
FUL	Full Useful Life
FVC	Forced Vital Capacity
g	Gram
g/s	Gram-per-second
g/ton-mile	Grams emitted to move one ton (2000 pounds) of freight over one mile
gal	Gallon
gal/1000 ton-mile	Gallons of fuel used to move one ton of payload (2,000 pounds) over 1000 miles
GCAM	Global Change Assessment Model
GCW	Gross Combined Weight
GCWR	Rated Gross-combined Weight (vehicle + trailer)
GDI	Gasoline Direct Injection
GDP	Gross Domestic Product
GEM	Greenhouse gas Emissions Model
GEOS	Goddard Earth Observing System
GHG	Greenhouse Gas
GIFT	Geospatial Intermodal Freight Transportation
GPF	Gasoline Particulate Filter
GREET	Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation
GSA	General Services Administration
GSF1	Generic Speed Form one
GST	Generic Scan Tools
GUI	Graphical User Interface
GVWR	Gross Vehicle Weight Rating
GW	Gigawatt
GWC	Gasoline Working Capacity
GWP	Global Warming Potential
H2	Hydrogen
H2 ICE	Hydrogen Internal Combustion Engine
H2O	Water

Acronym	Definition
HABs	Harmful Algal Blooms
HAD	Diesel Health Assessment Document
HAP	Hazardous Air Pollutant
HALT	Highly Accelerated Life Testing
HC	Hydrocarbon
HD	Heavy-Duty
HDDE FTP	Heavy-Duty Diesel Engine Federal Test Procedure
HDDT	Heavy-Duty Diesel Truck
HDE	Heavy-Duty Engine
HDEV	Heavy-duty electric vehicle
HDGV	Heavy-Duty Gasoline Vehicle (GVWR <14,000 lb)
HDIUT	Heavy-Duty In-Use Testing
HDO	Heavy-Duty Otti-cycle
HDOE FTP	Heavy-Duty Otto-Cycle Engine Federal Test Procedure
HDOH	Heavy-Duty On Highway
HDT	Heavy-Duty Truck
HDUDDS	Heavy Duty Urban Dynamometer Driving Cycle
HDV	Heavy-Duty Vehicle
HEG	High Efficiency Gearbox
HEI	Health Effects Institute
HES	Health Effects Subcommittee
HEV	Hybrid Electric Vehicle
HFC	Hydrofluorocarbon
HFET	Highway Fuel Economy Dynamometer Procedure
HGTS	Hot Gas Test Stand
HHD	Heavy Heavy-Duty
HHDD	Heavy-Heavy-Duty Diesel
HHDDT	Highway Heavy-Duty Diesel Transient
HHDE	Highway Heavy-Duty Engine
HHDGV	Heavy-Heavy-Duty Gasoline Vehicle (>14,000 lb. GVWR)
HIF	Health Impact Function
HIL	Hardware-in-the-Loop
HNCO	Iso-cyanic Acid
hp	Horsepower
HrlCE	Hydrogen-Fueled Internal Combustion Engine
hrs	Hours
HRV	Heart Rate Variability
HSC	High Speed Cruise Duty Cycle
HTA	Hydrothermally aged
HTUF	Hybrid Truck User Forum
HVAC	Heating, Ventilation and Air Cooling
HWFE	Highway Fuel Economy Drive Cycle
hz	Hertz
I/M	Inspection and Maintenance
IARC	International Agency for Research on Cancer
IATC	Improved Automatic Transmission Control
IC	Indirect Costs
IC	Internal Combustion
ICCT	International Council on Clean Transport
ICD	International Classification of Diseases
ICE	Internal Combustion Engine
ICEV	Internal Combustion Engine Vehicle

Acronym	Definition
ICF	ICF International
ICI	Industrial, Commercial, Institutional
ICM	Indirect Cost Multiplier
ICP	Intake Cam Phasing
ICP-MS	Inductively coupled plasma mass spectrometry
ICR	Information Collection Request
ICV	Internal Combustion Vehicle
IIJA	Infrastructure Investment and Jobs Act
IMAC	Improved Mobile Air Conditioning
IMC	Indirect Manufacturing Costs
IMPROVE	Interagency Monitoring of Protected Visual Environments
IPCC	Intergovernmental Panel on Climate Change
IRA	Inflation Reduction Act
IRAF	infrequent regeneration adjustment factor
IRFA	Initial Regulatory Flexibility Analysis
IRIS	Integrated Risk Information System
ISA	Integrated Science Assessment
ISC	In-Service Conformity
IUL	Interim Useful Life
IUMPR	In-Use Monitor Performance Ratio
IUT	In-Use Testing
JAMA	Journal of the American Medical Association
k	Thousand
K	Potassium
kg	Kilogram
KI	kinetic intensity
km	Kilometer
km/h	Kilometers per Hour
kW	Kilowatt
L	Liter
LA92	Inventory development dynamometer driving schedule
lb	Pound
LBM	Liquified Biomethane
LCA	Life Cycle Analysis
LD	Light-Duty
LDT	Light-Duty Truck
LDV	Light-Duty Vehicle
LED	Low Emission Diesel
LHD	Light Heavy-Duty
LHDD	Light Heavy Duty Diesel
LHDGV	Light-Heavy-Duty Gasoline Vehicle
LIVC	Late Intake Valve Closing
LLC	Low Load Cycle
LLNL	Lawrence Livermore National Laboratory’s
LNG	Liquified Natural Gas
LO-SCR	Light-Off SCR (also Close-coupled SCR)
LPG	Liquified Petroleum Gas
LRR	Lower Rolling Resistance
LSC	Low Speed Cruise Duty Cycle
LT	Light Trucks
LTCCS	Large Truck Crash Causation Study
LTL	Less Than Truckload

Acronym	Definition
LUB	Low Friction Lubes
LUC	Land Use Change
m2	Square Meters
m3	Cubic Meters
MAGICC	Model for the Assessment of Greenhouse-gas Induced Climate Change
MANE-VU	Mid-Atlantic Northeast Visibility Union
MAW	Moving-Average-Windows
MCF	Mixed Conifer Forest
MCS	Megawatt Charging System
MCT	Multicycle Test
MD	Medium-Duty
MDPV	Medium-Duty Passenger Vehicle
MDV	Medium-Duty Vehicle
MECA	Manufacturers of Emissions Control Association
mg	Milligram
Mg	Magnesium
μg/m3	Micrograms per cubic meter
Mg(OH)2	Magnesium Hydroxide
mg/hp-hr	Milligrams per horsepower-hour
MHD	Medium Heavy-Duty
MHDD	Medium Heavy Duty Diesel
MHDE	Medium Heavy-Duty Engine
MHDV	Medium Heavy-Duty Vehicle (??? Evergreen Action comment)
MHEV	Mild Hybrid
mi	mile
MIL	Malfunction indicator light
min	Minute
MM	Million
MMBD	Million Barrels per Day
MMT	Million Metric Tons
Mn	Manganese
MoU	Memorandum of Understanding
MOVES	MOtor Vehicle Emissions Simulator
MP-AES	Microwave Plasma Atomic Emission Spectroscopy
mpg	Miles per Gallon
mpge	Miles per Gallon Equivalent
mph	Miles per Hour
MPO	Metropolitan Planning Organization
MRL	Minimal Risk Level
MSA	Metropolitan Statistical Area
MSAT	Mobile Source Air Toxic
MST	Manufacturer self-testing
MT	Manual Transmission
MT	Metric Tons
MTS	Maximum Test Speed
MW	Megawatt
MY	Model Year
N2	Molecular Nitrogen
N2O	Nitrous Oxide
Na	Sodium
NA	Nonattainment Area
NA	Not Applicable

Acronym	Definition
NAAQS	National Ambient Air Quality Standards
NACFE	North American Council for Clean Freight Efficiency
NAFA	National Association of Fleet Administrators
NAICS	North American Industry Classification System
NAS	National Academy of Sciences
NASTC	National Association of Small Trucking Companies
NATA	National Air Toxic Assessment
NCAR	National Center for Atmospheric Research
NCI	National Cancer Institute
NCLAN	National Crop Loss Assessment Network
NDUV	Nondispersive Ultraviolet
NEC	Net Energy Change Tolerance
NEI	National Emissions Inventory
NEMS	National Energy Modeling System
NEPA	National Environmental Policy Act
NESCAUM	Northeastern States for Coordinated Air Use Management
NESCCAF	Northeast States Center for a Clean Air Future
NESHAP	National Emissions Standards for Hazardous Air Pollutants
NH3	Ammonia
NHS	National Highway System
NHTSA	National Highway Traffic Safety Administration
NIEHS	National Institute of Environmental Health Services
NiMH	Nickel Metal-Hydride
NIOSH	National Institute of Occupational Safety and Health
NIST	National Institute for Standards and Technology
Nm	Newton-meters
NMHC	Nonmethane Hydrocarbons
NMMAPS	National Morbidity, Mortality, and Air Pollution Study
NO	Nitric Oxide
NO2	Nitrogen Dioxide
NOAA	National Oceanic and Atmospheric Administration
NOX	Oxides of Nitrogen
NPRM	Notice of Proposed Rulemaking
NPV	Net Present Value
NRC	National Research Council
NRC-CAN	National Research Council of Canada
NREL	National Renewable Energy Laboratory
NTDE	New Technology Diesel Engine
NTE	Not-to-exceed
NTEA	National Truck and Equipment Association
NTP	National Toxicology Program
NVH	Noise Vibration and Harshness
NZEV	Near-Zero Emission Vehicle
O&M	Operating and maintenance
O3	Ozone
OAQPS	Office of Air Quality Planning and Standards
OBD	Onboard diagnostics
OBDEL	On-Board Diagnostic Emissions Limit
OBM	On Board Monitoring
OC	Organic Carbon
OE	Original Equipment
OEHHA	Office of Environmental Health Hazard Assessment

Acronym	Definition
OEM	Original Equipment Manufacturer
OHV	Overhead Valve
OMB	Office of Management and Budget
OOIDA	Owner-Operator Independent Drivers Association
OOS	Out of State
OP	Opposed-Piston
OPEC	Organization of Petroleum Exporting Countries
ORD	EPA's Office of Research and Development
ORNL	Oak Ridge National Laboratory
ORVR	Onboard refueling vapor recovery
OSAR	On Board Sensor Monitoring and Reporting Consortium
OSHA	Occupational Health and Safety Administration
OTA	Over-the-Air
OTAQ	Office of Transportation and Air Quality
OTC	Ozone Transport Commission
OTR	Ozone Transport Region
P	Phosphorus
Pa	Pascal
PA	Policy Assessment
PAH	Polycyclic Aromatic Hydrocarbons
PBHPH	Per brake horsepower-hour
PCM	Powertrain Control Module
PCV	Positive Crankcase Ventilation
PEF	Peak Expiratory Flow
PEMFC	Proton-Exchange Membrane Fuel Cell
PEMS	Portable Emissions Monitoring System
PEV	Plug-in Electric Vehicle
PFI	Port Fuel Injection
PGM	Platinum Group Metal
PGM	Photochemical Grid Modeling
PHEV	Plug-in Hybrid Electric Vehicles
PLT	Production-line testing
PM	Particulate Matter
PM10	Coarse Particulate Matter (diameter of 10 µm or less)
PM2.5	Fine Particulate Matter (diameter of 2.5 µm or less)
POC	People of Color
POM	Polycyclic Organic Matter
POTW	Public Owned Treatment Works
Ppb	Parts per Billion
Ppm	Parts per Million
Psi	Pounds per Square Inch
PTO	Power Take Off
PVE	Production Engine/Vehicle Evaluation Testing
PZEV	Partial Zero Emission Vehicle
R&D	Research and Development
RBM	Resisting Bending Moment
RD	Renewable Diesel
REAL	Real Emissions Assessment Logging
REL	Reference Exposure Level
RESS	Rechargeable Energy Storage System
REV Midwest	Regional Electric Vehicle Midwest Coalition
RFA	Regulatory Flexibility Act

Acronym	Definition
RfC	Reference Concentration
RFIP	Renewable Fuels Infrastructure Program
RFS	Renewable Fuel Standard
RFSP	Renewable Fuel Standard Program
RFS2	Renewable Fuel Standard 2
RIA	Regulatory Impact Analysis
RMC	Ramped Modal Cycle
RMC-SET	Ramped Modal Cycle Supplementary Emissions Test
RNG	Renewable natural gas
RPE	Retail Price Equivalent
RPM	Revolutions per Minute
RSC	Ricardo Strategic Consulting
RSWT	Reduced-Scale Wind Tunnel
RTS	Return-to-Service
S	Second
S	Sulfur
SAB	Science Advisory Board
SAB-HES	Science Advisory Board - Health Effects Subcommittee
SAE	SAE International, formerly Society of Automotive Engineers
SAFE	Safer Affordable Fuel-Efficient
SAIPE	Small Area Income and Poverty Estimates
SAR	Second Assessment Report
SAV	Submerged Aquatic Vegetation
SBA	Small Business Administration
SBREFA	Small Business Regulatory Enforcement Fairness Act
SC-GHG	Social Cost of Greenhouse Gases
SCC	Social Cost of Carbon
SCR	Selective Catalyst Reduction
SCRF	SCR-on-DPF
SEA	Selective enforcement audit
SER	Small Entity Representation
SET	Supplemental Emission Test
SGDI	Stoichiometric Gasoline Direct Injection
SHED	Sealed Housing Evaporative Determination
SHEV	Strong Hybrid Vehicles
SI	Spark-Ignition
SiC	Silicon Carbide
SIDI	Spark Ignition Direct Injection
SIP	State Implementation Plan
SIR	Service Information Requirements (CARB)
SMAD	Supplementary Monitor Activity Data
sMCT	Short Multi-Cycle Test
sMCAT+	Short Multi-Cycle Test Plus Steady State
SO2	Sulfur Dioxide
SOA	Secondary Organic Aerosol
SOC	State of Charge
SOFC	Solid Oxide Fuel Cells
SoH	State of Health (battery or fuel cell)
SOHC	Single Overhead Cam
SOP	Start of Production
SOx	Sulfur Oxides; Oxides of Sulfur
SPR	Strategic Petroleum Reserve

Acronym	Definition
SRT	Standard repair time
SSZ-13	A Chabazite-type Aluminosilicate ABC-6 Zeolite
Stage 3 RW	Stage 3 rework
STB	Surface Transportation Board
Std.	Standard
STP	Scaled Tractive Power
SUV	Sport Utility Vehicle
SVOC	Semi-Volatile Organic Compound
SwRI	Southwest Research Institute
TaaS	Transportation-as-a-Service
TAR	Technical Assessment Report
TC	Total Costs
TCO	Total Cost of Ownership
TCp	Total Cost package
TDS	Turbocharging And Downsizing
TEU	Twenty-Foot Equivalent Units
THC	Total Hydrocarbon
TIAX	TIAX LLC
TL	Truckload
TMC	Technology & Maintenance Council
TOFC	Trailer-on-Flatcar
Ton-mile	One ton (2000 pounds) of payload over one mile
TOU	Time of Use
TP	Tailpipe
Tpd	Tons per day
TRAP	Traffic Related Air Pollution
TRBDS	Turbocharging and Downsizing
TROPOMI	Tropospheric Monitoring Instrument
TRU	Trailer Refrigeration Unit
TSD	Technical Support Document
TSS	Thermal Storage
TTW	Tank-to-Wheel
TW	Test Weight
TWC	Three-Way Catalyst
U.S.	United States
U/DAF	Upward and Downward Adjustment Factor
UBE	Useable battery energy
UCT	Urban Creep and Transient Duty Cycle
UDDS	Urban Dynamometer Driving Schedule
UF	Utility Factor
UFP	Ultra Fine Particles
UL	Useful Life
ULEDE	Ultra-Low Emissions Diesel Engines
ULSD	Ultra-low sulfur diesel
URE	Unit Risk Estimate
USDA	United States Department of Agriculture
USGCRP	United States Global Change Research Program
USPS	United States Postal Service
UTSA	Uniform Trade Secrets Act
UV	Ultraviolet
UV-b	Ultraviolet-b
V2G	Vehicle-to-Grid

Acronym	Definition
VA	Variable Allowance
VGT	Variable-geometry Turbine
VIN	Vehicle Identification Number
VIO	Vehicles in Operation
VIUS	Vehicle Inventory Use Survey
VMT	Vehicle Miles Traveled
VNT	Variable nozzle turbine
VOC	Volatile Organic Compound
VSL	Vehicle Speed Limiter
VSL	Value of Statistical Life
VTEC-E	Variable Valve Timing & Lift Electronic Control-Economy
VTG	Variable turbine geometry
VTRIS	Vehicle Travel Information System
VVA	Variable Valve Actuation
VVL	Variable Valve Lift
VVT	Variable Valve Timing
WACAP	Western Airborne Contaminants Assessment Project
WHD	Wage and Hour Division (Department of Labor)
WHO	World Health Organization
WHR	Waste Heat Recovery
WHTC	World Harmonized Transient Cycle
WHVC	World Harmonized Vehicle Cycle
WMO	World Meteorological Organization
WRF	Weather Research Forecasting
WTP	Willingness-to-Pay
WTVC	World Wide Transient Vehicle Cycle
WTW	Well to Wheels
WVU	West Virginia University
zCSF	Zone-Coated Soot Filter
ZE	Zero Emission
ZEP	Zero Emission Powertrain
ZET	Zero Emission Truck
ZETI	Zero-Emission Technology Inventory (CALSTART)
ZEV	Zero emission vehicle
ZMER	Zero-Mile Emission Rate
Zn	Zinc
ZSM-5	Zeolite Socony Mobil-5, an Aluminosilicate Pentasil Zeolite within the family of zeolites

1 Overall Reactions to EPA's Proposal

EPA categorized the content of detailed written comments received on this rule by topic area and assembled them for response in the various sections of this Response to Comment document. In addition to detailed comments on specific aspects of the proposed rule, many commenters also provided general statements that indicate their support for the proposal as written, support for the proposal while also stating that the proposal doesn't go far enough or general opposition to the proposal. Because these statements are general in nature, they were not assigned to specific sections of the document. Instead, these statements are summarized here; full excerpts are provided in Appendix 4 for completeness.

1.1 General support for the proposal as written

<u>EPA Summary and Response</u>

<u>Summary</u>:

Many individuals and organizations who commented on the proposal included general statements that supported or strongly supported the proposed action. While these commenters did not always express a preference over any of the options, many stated the need to further reduce internal combustion engine emissions while pursuing ZEV options. A few commenters noted that this may be EPA's last rulemaking setting requirements for internal combustion engines, so it is important to get it right. Several commenters generally supported specific aspects of the proposal without going into detail: the NOx limits, the GHG reduction program and improvements in PM emission levels. Some of these commenters also said that EPA should align the NOx regulations with CARB's Omnibus rule to drive a more stringent national standard. Finally, several commenters noted that the technologies to achieve the standards must be feasible and achievable over the full useful life of the engine.

<u>Response</u>:

EPA acknowledges the comments expressing general support for EPA's rulemaking. Some of these statements of general support also included additional non-specific comments that disagreed with or suggested changes in specific aspects of the proposed program; we address those comments in other sections of this Response to Comments document or in the preamble to this rule. Also, as explained in the preamble of the final rule, we are not taking final action in this rule on the GHG components of the proposal; comments on the GHG components of the proposal are contained in Section 28.

1.2 General support for the proposal while also stating that the proposal doesn't go far enough

EPA Summary and Response

Summary:

Most of the comments received, including the vast majority of mass mailer comments, generally call on EPA to do more to reduce emissions from trucks and truck engines, especially by speeding up the transition to electric vehicles. These commenters requested action that would lead to cleaner emissions from internal combustion-powered vehicles and challenged EPA to be more ambitious, more aggressive, or increase the stringency of the standards to strengthen the rule. These commenters also requested EPA to implement a program for faster and more complete implementation of zero emission vehicles. While not always providing data or detailed information, many commenters requested full ZEV sales by 2035, and a few requested EPA adopt a goal of 100% ZEV by 2050. There was also some support for fuel cell vehicles. Of the comments that generally mentioned costs, many noted that electric vehicles are becoming cost effective.

Response:

EPA acknowledges the comments that recommend EPA adopt more stringent NOx and GHG standards for heavy-duty engines and trucks. As explained elsewhere in this document as well as in the preamble and RIA for this rule, the criteria pollutant heavy-duty engine standards EPA is adopting will have a significant impact on improving air quality across the country and EPA's assessment of the relevant statutory factors in CAA section 202(a)(3)(A) justify the final emission standards (see the EPA response in section 1.3 of this document). Responses to comments that provided more detailed information and data are included in the other sections of this document. Also, as explained in the preamble of the final rule, we are not taking final action in this rule on the GHG components of the proposal; comments on the GHG components of the proposal are contained in Section 28.

1.3 General opposition to the proposal

EPA Summary and Response

Summary:

Some commenters expressed general opposition to the proposed revisions to the GHG Phase 2 program. Some comments also expressed general opposition to the proposed criteria pollutant portion of the rule due to concerns about impacts of the new standards, useful life, and warranty requirements on truck prices, transportation costs, jobs, and serviceability of hardware. Several of those who commented provided more detailed comments that are included in other sections of this document; others provided only general statements of concern.

Response:

EPA acknowledges these comments expressing general opposition to the proposed rule. As explained in the preamble of the final rule, we are not taking final action in this rule on the GHG components of the proposal; comments on the GHG components of the proposal are contained in Section 28. Preamble Section II presents the need for this final rule, which is the need for additional emissions control from heavy-duty engines and vehicles, with additional information included in RIA Chapter 4 and section 2 of this document. Preamble Sections I.D and XIII describe our statutory authority for taking this final action.

Our technical analyses that form the basis of this final rule are presented in Sections III, V, VI, VII, VIII, and X of the preamble to this rule, with additional information included in RIA Chapters 3, 5, 6, 7, 8, and 10. In setting the final emission standards, EPA appropriately assessed the statutory factors specified in CAA section 202(a)(3)(A), including giving appropriate consideration to the cost associated with the application of technology EPA determined will be available for the model year the final standards apply (i.e., cost of compliance for the manufacturer associated with the application of such technology). EPA's assessment of the relevant statutory factors in CAA section 202(a)(3)(A) justify the final emission standards. We also evaluated additional factors, including factors to comply with E.O. 12866; our assessment of these factors lends further support to the final rule. Preamble Section IV describes the basis for the final useful life and warranty periods, with comments relating to useful life and warranty in sections 3.8 and 4.0 of this document, respectively. Our analysis also shows that to the extent the final rule impacts heavy-duty vehicle sales, we expect the impacts to be small and short in duration; further, our estimates suggest a slight increase in employment in 2027 due to the final rule (see preamble Section X and RIA Chapter 10 for a description of our economic analyses). These issues are also discussed in response to more detailed comments provided by some individuals and organizations in the separate sections of this document.

2 Need for additional air quality control

2.1 Human and environmental health impacts of criteria and toxic air pollutants

Comments by Organizations

Organization: *Ali P.*

We need environment-related regulations now more than ever. Pollution is a rampant problem, and the climate crisis is only worsening, both of which are harmful to humans and the world's ecosystems. Traditional heavy-duty vehicles contribute to the formation of ozone and expel particulate matter and greenhouse gases into the atmosphere, worsening both of these issues. This proposed rule would be a step forward in reducing our global environmental impact. [EPA-HQ-OAR-2019-1032]

There is very little regulation regarding the formation of ozone in the troposphere. It has the greatest negative impact on children, teenagers, the elderly, and people with preexisting respiratory conditions. While these groups may be the most vulnerable, ozone can be detrimental to anyone's health, as it is linked to premature death and a myriad of respiratory issues, including trouble breathing, asthma, and an increased likelihood of developing a respiratory infection

(American Lung Association, 2020). Ground level ozone's dangerous and widespread nature alone warrants an increase in its regulation, but there are additional societal and environmental effects that further make ozone's regulation an urgent matter. For example, ozone significantly damages plant tissue and reduces plant productivity. This both negatively impacts wildlife that (either directly or indirectly) relies on these plants, and it can cause a decrease in crop yields (California Air Resources Board, 2020). These combined effects of ozone can thus result in a loss of biodiversity, a loss of money, and a loss of available food, all of which could be better prevented with the regulation of ozone through policies such as this proposed rule. [EPA-HQ-OAR-2019-1032]

Particulate matter (PM) released into the atmosphere also impacts people's health. PM can affect anybody, but some people experience worse effects than others. The effects of PM can range from mild eye irritation to the worsening of preexisting respiratory issues to an increased risk of lung cancer or heart attacks. The smaller the particles, the deeper they can enter the lungs, and the worse their potential damage on the respiratory system. The smallest particles can even enter the bloodstream (Centers for Disease Control and Prevention, 2019). PM is arguably the most directly harmful pollutant to humans. All particle sizes are dangerous, and their variability in size, chemical composition, and origin means the number of possible effects they can have on humans is innumerable. It also means they can have varying drastic effects on the environment if, for example, they get deposited into the soil or get dissolved into bodies of water such as lakes and ponds. PM of certain chemical makeups can cause changes in abiotic factors (such as altering the acidity of the soil or of a body of water), disrupting the ecosystems that rely on these factors (United States Environmental Protection Agency, 2021). For the sake of the public's health and the environment's health, a reduction of PM in our atmosphere is necessary. [EPA-HQ-OAR-2019-1032]

The transportation sector is responsible for over a quarter of U.S. greenhouse gas emissions, which is more than any other sector, because the vast majority of transportation methods rely on the burning of fossil fuels for power (United States Environmental Protection Agency, 2022). Heavy-duty vehicles are obviously included in this statistic, so reducing the extent of their greenhouse gas emissions is a necessary step in slowing climate change, a global crisis that has been largely ignored for too long. Immediate and effective action is crucial to becoming carbon neutral, a goal most countries have pledged to accomplish, within the next several decades. Government regulations that focus on reducing greenhouse gas emissions and promoting the health of the environment are a necessity. Implementing this proposed rule, and others like it, is the least we can do in the face of our worsening climate. [EPA-HQ-OAR-2019-1032]

Organization: *American Farm Bureau Federation (Farm Bureau)*

Since 1990, economy-wide NOx emissions from highway vehicles have declined by 75%, even as overall vehicle miles traveled have increased by nearly 50%. Continued improvements in advanced-technology diesel engines are a key driver of this success, and one of many reasons U.S. air quality is among the best in the world. [EPA-HQ-OAR-2019-0055-1163-A1, p.1]

Organization: *Anne Mellinger-Birdson*

Heavy duty vehicle engines are primarily diesel, and create fine (PM2.5) and ultrafine particles, carbondioxide (CO_2), volatile organic compounds and air toxics (VOCs), nitrogen oxides (NOx), and heavy metal air pollution. Even if the diesel exhaust is filtered to reduce particles and heavy metals such as arsenic or mercury, it does not eliminate these pollutants and all the gases are still released. In addition, VOCs and NOx are substrates for ozone formation which also causes health damage. Below, I comment on the health damage caused by all the pollutants made by heavy duty vehicle engines. [EPA-HQ-OAR-2019-0055-1244]

In addition, many vulnerable populations including children, the elderly, and communities of color are both more exposed to air pollution, and more at risk of health problems caused by air pollution. [EPA-HQ-OAR-2019-0055-1244]

1. Particles and ultrafine particles contribute major health damage in the U.S., causing heart disease, lung disease, cancer, strokes, dementia, low birth weight, premature birth, damaged lung growth in children(https://doi.org/10.1056/NEJMoa1414123), and excess deaths (https://doi.org/10.1056/NEJMoa1702747).In the U.S., PM2.5 from fossil fuels cause 13.1% of all deaths(https://doi.org/10.1016/j.envres.2021.110754), and diesel heavy duty engines are a significant percent of the PM2.5. Particulate pollution is also linked to obesity, diabetes, mental health problems, autism, and cognitive difficulties in people of all ages, from childhood to the elderly. [EPA-HQ-OAR-2019-0055-1244]

2. VOCs can cause headaches, cancer, immune system problems and are linked to other health conditions. [EPA-HQ-OAR-2019-0055-1244]

3. Nitrogen oxides cause lung disease, trigger asthma attacks, contribute to heart disease, and damage children's lung growth (https://doi.org/10.1056/NEJMoa1414123). Children who grow up with higher NOx exposure are more likely to develop asthma (https://doi.org/10.1016/S2542-5196(21)00255-2). [EPA-HQ-OAR-2019-0055-1244]

5. Heavy metals such as arsenic and mercury are carcinogenic, and cause numerous other health problems including kidney damage. [EPA-HQ-OAR-2019-0055-1244]

6. Ozone causes asthma attacks, is as bad for progression of emphysema as 29 pack-years of cigarettes(https://doi.org/10.1001/jama.2019.10255). Ozone likely contributes to children developing asthma, and contributes to heart disease in adults. Ozone causes excess deaths in Medicare recipients, this effect is more pronounced in black people (https://doi.org/10.1056/NEJMoa1702747). [EPA-HQ-OAR-2019-0055-1244; see also Section 23]

7. Air pollution (PM, NOx, and ozone) is strongly linked to increased risk of pneumonia, and to lower respiratory tract viral infections such as respiratory syncytial virus, influenza, and Covid(https://doi.org/10.1289/EHP9726). [EPA-HQ-OAR-2019-0055-1244]

8. Demetillo and colleagues found that diesel traffic is the dominant source of NO_2 disparities(https://doi.org/10.1029/2021GL094333). Lane and colleagues found that historical

redlining maps from the 1930s still cause current day disparities in PM2.5 and NOx, with the placement of highways as one of the main contributing factors (https://doi.org/10.1021/acs.estlett.1c01012). Houston and colleagues found that Black and Asian-American/Pacific Island people were more exposed to diesel truck traffic near the Port of Los Angeles (https://doi.org/10.2105/AJPH.2012.301120). [EPA-HQ-OAR-2019-0055-1244; see also Section 23]

Because air pollution from trucks and other heavy duty vehicles is so damaging to health, and especially to vulnerable populations such as children, the elderly, pregnant women, and communities of color, because of the structural inequities in our built environment placing more highways, ports, and railyards in communities of color, and because climate change is the biggest health threat we face, I support this rule. I encourage EPA to make it much stronger to fully protect the health of the most vulnerable populations. [EPA-HQ-OAR-2019-0055-1244; see also Section 23]

Organization: *American Lung Association et al.*

Cleaning up the trucking sector is a public health and health equity priority, and we urge US EPA to establish strict new standards by the end of 2022 that push the rapid cleanup of smog-forming emissions from trucks, ensure real-world pollution reductions and spur the transition to zero-emission trucking. [EPA-HQ-OAR-2019-0055-1271-A1, p.1]

Over forty percent of all Americans live in communities impacted by unhealthy levels of ozone and/or particle pollution, according to the American Lung Association's State of the Air 2022 report.1 The trucking sector is a major source of smog- and particle-forming oxides of nitrogen emissions (NOx) that threaten health across the United States and add to localized health burdens and disparities. Poor air quality is associated with a wide range of negative health outcomes, including asthma attacks, heart attacks and stroke, low birthweight, premature birth, developmental harms, lung cancer and premature death. As US EPA notes, there are significant disparities in exposures to harmful trucking pollution, and those most impacted are 'more likely to be people of color and have lower incomes.'2 [EPA-HQ-OAR-2019-0055-1271-A1, p.1]

Organization: *California Association of Sanitation Agencies (CASA)*

Last, but not least, delaying emission reductions via an electrification-only approach will negatively impact disadvantaged environmental justice (EJ) communities and trigger nonattainment penalties upon stationary sources, when mobile and federal sources are the primary cause of ozone nonattainment. [EPA-HQ-OAR-2019-0055-1301-A1, p.2]

Organization: *CALSTART*

Air pollution is the leading environmental health risk-factor worldwide and in the US and is associated with millions of premature deaths worldwide and hundreds of thousands in the US annually (Landrigan, 2018; WHO, n.d.; Thakrar, 2020). Emissions of nitrogen oxides (NOx) from vehicles and other sources are a major source of air pollution. On-road heavy-duty vehicles contribute 42 percent of NOx emissions from on-road sources in the US (EPA, 2017). While harmful to breathe on its own, NOx reacts with other chemicals to form ozone and particulate matter. In 2018, 2019 and 2020, more than 137 million people lived in US counties that received an “F” grade for either ozone or particle pollution, including 31 million children and 21 million people aged 65 or older, who face an increased risk of harm from breathing ozone or particle pollution (American Lung Association, 2022; American Lung Association, 2022a). [EPA-HQ-OAR-2019-0055-1313-A1, p.3]

Organization: *ChargePoint, Inc. (ChargePoint)*

HDVs alone are the single largest contributor to US emissions of NOx, volatile organic compounds (VOCs), and carbon dioxide (CO2). Long term exposure of NOx “can cause long term lung damage in people who live close to truck traffic.”4 ChargePoint is ready to support swift deployment of zero emission MHDVs in public and private fleets in the near future through deployment with the necessary charging infrastructure thus and proving substantial air quality benefits to roadside communities. EPA last updated the nitrogen oxides ('NOx') standards for heavy-duty vehicles in 2001.1 Since that time, a growing body of evidence has confirmed our understanding of the significant human health and environmental harm caused by air pollution from this sector. [EPA-HQ-OAR-2019-0055-1295-A1, p.1]

> 1 Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards and Highway Diesel Fuel Sulfur Control Requirements, 66 Fed. Reg. 5002 (Jan. 18, 2001).

As part of its mission, CBF is dedicated to saving the Bay—and keeping it saved—as defined by reaching a 70 on CBF’s Health Index, which uses ecological indicators to measure pollution, habitat, and fisheries.18 One indicator for pollution is nitrogen, a primary pollutant causing the excess algal blooms that block sunlight for underwater grasses and use up life-sustaining oxygen when they decompose, leading to the Bay’s dead zones.19 Since 2010, CBF has been dedicated to the success of the Chesapeake Bay Total Maximum Daily Load ('Bay TMDL'), a federal-state partnership designed to reduce the nitrogen, phosphorus, and sediment pollution contributing to dead zones in the Bay.20 The Bay TMDL sets a deadline of 2025, at which point 'all pollution control measures needed to fully restore the Bay and its tidal rivers are in place.'21 [EPA-HQ-OAR-2019-0055-1295-A1, pp.5-6]

Reg. at 3310/1 ('Environmental impacts of concern are associated with [NOx, ozone, and PM2.5] and include light extinction, decreased tree growth, foliar injury, and acidification and eutrophication of aquatic and terrestrial systems.').

20 See U.S. EPA, Chesapeake Bay Total Maximum Daily load for Nitrogen, Phosphorus, and Sediment (Dec. 2010) ('Chesapeake Bay TMDL'), available at https://www.epa.gov/chesapeake-bay-tmdl/chesapeake-bay-tmdl-document.

21 Chesapeake Bay TMDL at ES-1.

Atmospheric deposition of nitrogen, often in the form of NOx, from both mobile sources and stationary sources makes up about one-third—more than 85 million pounds—of the Bay's total yearly nitrogen load.22 The Chesapeake Bay airshed is almost nine times larger than the watershed,23 and this airborne nitrogen pollution travels from as far west as Indiana and Kentucky, and as far north as Quebec, Canada. These NOx emissions drift into the Bay watershed and fall out of the air either dry or as precipitation.24 [EPA-HQ-OAR-2019-0055-1295-A1, p.6]

22 CBF, Air Pollution, https://www.cbf.org/issues/air-pollution/; see also Chesapeake Bay TMDL, Section 4.6.2, Atmospheric Deposition, pp. 4-33 (Dec. 2010), https://www.epa.gov/sites/production/files/2014-12/documents/cbay_final_tmdl_section_4_final_0.pdf.

23 Chesapeake Bay TMDL, Appendix L, at L-4, https://www.epa.gov/sites/production/files/2015-02/documents/appendix_l_atmos_n_deposition_allocations_final.pdf.

24 Chesapeake Bay TMDL at Section 4.6.2, p. 4-33.

Fossil-fuel-powered cars and trucks are one of the principal sources of NOx pollution in the Bay region.25 Indeed, when EPA conducted air modeling for the Bay TMDL, it modeled a 2030 scenario in which 'emissions projections assume[d] continued stringent controls are in place, such as…Heavy Duty Diesel vehicle fleet fully replaced with newer heavy-duty vehicle (sic) that comply with new standards.'26 Motor vehicles emit NOx close to the ground, depositing nitrogen on plants and soils within tens of meters of the highway.27 Additional nitrogen falls on impervious surfaces, such as roads and parking lots, where much of it is washed into waterways and, ultimately, the Bay.28 A portion of motor vehicle NOx remains airborne, where it either combines with sunlight to form ozone, or remains as nitrogen in one or more forms. Many of these NOx compounds then make their way into the Bay and its tributaries. [EPA-HQ-OAR-2019-0055-1295-A1, p.6]

25 Chesapeake Bay TMDL at Section 4.6.2, p. 4-33.

Organization: *City Council District 8, Pittsburgh, PA, Erika Strassburger*

As a Member of Pittsburgh City Council, I hear from constituents on a weekly basis about the poor air quality in our region that threatens public health, especially for the most vulnerable populations, and prevents true enjoyment of our city. [EPA-HQ-OAR-2019-0055-2233, p.1]

Organization: *Clean Air Board of Central Pennsylvania*

Trucks and buses remain a dominant source of nitrogen oxide (NOx) pollution in many communities, threatening the health of millions of people. Heavy-duty trucks and buses drive American commerce and connect people across the country. Creating cleaner trucks is an economic opportunity to support jobs and make more efficient vehicles while reducing harmful pollution. Heavy-duty trucks and buses continue to contribute significantly to air pollution at the local, regional, and national level, often disproportionally affecting communities of color and low-income populations. [EPA-HQ-OAR-2019-0055-1305-A1, p.1]

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

In the sections below, Commenters detail the outsized contribution of HDVs to dangerous air pollution, public health burdens, environmental injustices, and climate change. The scale of these problems, in combination with the Agency's statutory mandates, demands a swift and protective regulatory response from EPA in this rulemaking. [EPA-HQ-OAR-2019-0055-1302-A1, p.11]

EPA must fulfill its mandate to curb emissions from HDVs, which lead to air pollution that causes significant negative health impacts. As EPA notes, 'Heavy-duty (HD) engines operating across the U.S. emit NOx and other pollutants that contribute to ambient levels of ozone, PM, and NOx. These pollutants are linked to premature death, respiratory illness (including childhood asthma), cardiovascular problems, and other adverse health impacts. Data show that heavy-duty engines are important contributors to concentrations of ozone and PM2.5 and their resulting threat to public health.'1 In particular, NOx emissions increase levels of ozone, because ground-level ozone forms when there are high concentrations of ambient NOx and VOCs and when solar radiation is high.2 NOx emissions (along with other gaseous precursors such as VOCs and SOX) also impact particulate matter by forming secondary particles through atmospheric chemical reactions.3 Reductions in NOx emitted from HDVs would therefore result in reduced ambient levels of ozone and PM and improved health and environmental outcomes. See 87 Fed. Reg. at 17,417.4 [EPA-HQ-OAR-2019-0055-1302-A1, pp.11-12]

4 See also id. at Chapter 4: Health and Environmental Impacts.

HDVs are particularly notable contributors to particulate matter (PM) and criteria air pollutants. For example, the California Air Resources Board (CARB) found that HDVs are responsible for more than 70% of NOx emissions from on-road mobile sources.5 In addition, the International Council on Clean Transportation (ICCT) found that for urban driving, the NOx emissions from one line-haul truck are equivalent to the emissions from 100 cars for each mile driven.6 Nationally, HDVs are the largest contributor to mobile-source emissions of NOx, making up about 32% of NOx emissions from on- and off-road mobile sources.7 [EPA-HQ-OAR-2019-0055-1302-A1, p.12]

5 See CARB, CARB Staff Current Assessment of the Technical Feasibility of Lower NOx Standards and Associated Test Procedures for 2022 and Subsequent Model Year 1 (2019), https://www.arb.ca.gov/msprog/hdlownox/white_paper_04182019a.pdf.

7 See EPA, EPA Announces the 'Clean Trucks Plan' 2 (2021), https://www.epa.gov/system/files/documents/2021-08/420f21057.pdf. Data is from MOVES3 for onroad and nonroad sectors and 2017 National Emissions Inventory (NEI) for all other mobile sectors.

Air pollution has become so significant that the public-health burdens attributable to air pollution are ‘now estimated to be on a par with other major global health risks such as unhealthy diet and tobacco smoking, and air pollution is now recognized as the single biggest environmental threat to human health.’8 Researchers at the University of Chicago studied the impact of air pollution on life expectancy, and found that ‘the deadly effects of PM2.5 on the heart, lungs, and other systems have a more devastating impact on life expectancy than communicable diseases like tuberculosis, behavioral killers like cigarette smoking, and even war.’9 [EPA-HQ-OAR-2019-0055-1302-A1, pp.12-13]

8 See Ken Lee & Michael Greenstone, Air Quality Life Index Annual Update, Energy Policy Institute at the University of Chicago (2021), https://aqli.epic.uchicago.edu/wp-content/uploads/2021/08/AQLI_2021-Report.EnglishGlobal.pdf.

9 See World Health Organization (WHO), WHO Global Air Quality Guidelines (2021), https://apps.who.int/iris/bitstream/handle/10665/345329/9789240034228-eng.pdf.

Particulate pollution from HDVs can cause severe health impacts even with only short-term exposures. There is consistent evidence showing the relationship between short-term exposure to PM and mortality, particularly cardiovascular and respiratory mortality. Short- and long-term exposure to PM2.5 can cause harmful health impacts such as heart attacks, strokes, worsened asthma, and early death.10 In addition, short-term PM exposure has been linked to increases in infant mortality, hospital admissions for cardiovascular disease, hospital admissions and emergency visits for chronic obstructive pulmonary disease, and severity of asthma attacks and hospitalization for asthma in children. Year-round exposure to PM is associated with elevated risks of early death, primarily from cardiovascular and respiratory problems such as heart disease, stroke, influenza, and pneumonia.11 [EPA-HQ-OAR-2019-0055-1302-A1, p.13]

10 See EPA, Integrated Science Assessment (ISA) for Particulate Matter (Dec. 2019), https://cfpub.epa.gov/ncea/isa/recordisplay.cfm?deid=347534.

11 See American Lung Association, State of the Air 2022 at 21–22 (2022), https://www.lung.org/research/sota.

Not surprisingly, air pollution from HDVs often occurs along highways and in industrial or urban hubs. A new Clean Air Task Force (CATF) map and data visualization tool, Deaths by Dirty Diesel,12 highlights the price that communities pay in negative health impacts from diesel engines (including trucks and other diesel-fueled equipment). Deaths by Dirty Diesel makes data on health impacts from diesel pollution easily accessible to community members on a state, county, and metro area basis. [EPA-HQ-OAR-2019-0055-1302-A1, p.13]

12 See CATF, Deaths by Dirty Diesel Map, https://www.catf.us/deathsbydiesel/. See also CATF, Deaths by Dirty Diesel Map: Health Impacts Methodology, https://cdn.catf.us/wp-content/uploads/2022/01/06091832/deaths-dirty-diesel-methodology.pdf.

The Deaths by Dirty Diesel tool illustrates the various impacts of PM,13 with a focus on the negative impacts from fine particulate matter, or PM2.5. The colors on the map depict diesel engines' contribution to PM2.5 air pollution in various geographic areas. The tool also contains data on the adverse health, social, and economic impacts attributable to emissions from diesel engines, including deaths, heart attacks, acute bronchitis, respiratory symptoms, asthma, emergency room visits, cancer risk, monetized health losses, and lost work and activity days.14 The tool shows the clear linkage between high levels of diesel-related air pollution and threats to public health and welfare. For example, while risk is not spread evenly across any state, the data show that California, New Jersey, and New York have the highest cancer risk from diesel pollution, and Wyoming, Montana, and Oregon have the lowest. The tool is intended to help visualize the vast impact of diesel pollution on communities and to make that information accessible to the general public. [EPA-HQ-OAR-2019-0055-1302-A1, p.14]

13 See CARB, Inhalable Particulate Matter and Health (PM2.5 and PM10), https://ww2.arb.ca.gov/resources/inhalable-particulate-matter-and-health.

14 CATF, Deaths by Dirty Diesel Map: Health Impacts Methodology, https://cdn.catf.us/wp-content/uploads/2022/01/06091832/deaths-dirty-diesel-methodology.pdf.

Not coincidentally, the negative impacts of diesel pollution are often clustered along the country's busiest interstate highways. California offers the starkest example: residents of Los Angeles cope with the country's worst diesel pollution, at 0.726 ug/m3, but the map shows that a driver heading north from Los Angeles on Interstate 5 would continue to encounter dangerously high diesel particulate matter levels in California's Central Valley (Fresno County, CA: 0.451 ug/m3), in the Bay Area (San Mateo County, CA: 0.465 ug/m3), and even at the north end of I-5 in the Puget Sound region (Kitsap County, WA: 0.221 ug/m3).15 Many of these counties, including Los Angeles and Fresno Counties in California, are in non-attainment status for their PM2.5 air quality.16 [EPA-HQ-OAR-2019-0055-1302-A1, p.14]

15 See CATF, Diesel pollution is a deadly problem in the United States (Jan. 2022), https://www.catf.us/2022/01/diesel-pollution-deadly-problem-united-states/.

16 See EPA, Current Nonattainment Counties for All Criteria Pollutants (2022), https://www3.epa.gov/airquality/greenbook/ancl.html.

According to the American Lung Association (ALA) State of the Air 2022 report, fourteen counties received failing grades on all three of the air quality indicators that ALA reviewed: daily particulate matter pollution, annual particulate matter pollution, and ozone pollution.17 Seven of those are California counties bisected by I-5, three are other California counties that sit just to the east of I-5, and another three are California counties bisected by other interstate highways (I-8, I-10, I-15, and I-40). The last is in Arizona, southeast of Phoenix and at the convergence of three highways (I-8, I-10, and I-19).18 EPA must take action to reduce the dangerous levels of pollution found across the country in this rulemaking. [EPA-HQ-OAR-2019-0055-1302-A1, p.14]

17 See ALA, State of the Air 2022 at 19.

18 See Department of Transportation, Federal Highway Administration, National Highway Freight Network Map, https://ops.fhwa.dot.gov/freight/infrastructure/nfn/maps/nhfn_map.htm (last modified Mar. 5, 2020).

These findings show the critical need for EPA to minimize the harmful emissions from the HDV sector. Doing so will not only improve a significant public-health and environmental issue but will also decrease air pollution and improve well-being in overburdened communities. [EPA-HQ-OAR-2019-0055-1302-A1, p.16]

NOx emissions from the heavy-duty sector also harm plants, wildlife, and visibility within national parks and wilderness areas, including those that have been designated as ‘Class I’ under the Clean Air Act and receive special air quality and visibility protections. 49 As EPA has noted in the past, ‘[e]nvironmental impacts of concern are associated with these pollutants and include light extinction, decreased tree growth, foliar injury, and acidification and eutrophication of aquatic and terrestrial systems.’ 85 Fed. Reg. 3,306, 3,310 (Jan. 21, 2020). These impacts are especially damaging in areas already suffering from a range of climate change impacts, such as the Rocky Mountains, Sierra Nevada Mountains, Appalachian Mountains, and Southwestern Desert ecosystems. For example, ozone phytotoxicity can lead to foliar injury and reduce the photosynthetic capacity of plants and trees, including Jeffrey and Ponderosa pines and other high-elevation coniferous species.50 Moreover, many of the tree species weakened by ozone and other air pollutants linked to NOx emissions are already facing climate change-driven stressors, such as drought, high temperatures, and native bark beetle attacks.51 As a result, NOx and GHG pollution from the heavy-duty sector directly contributes to the ongoing tree mortality and mega-wildfire crisis that has devastated the Western United States in recent years. Additionally, nitrogen deposition from NOx pollution causes widespread deleterious impacts across land and water ecosystems, including from both direct exposure (e.g., nitrogen enrichment) and biological effects (e.g., decreases in biodiversity, fish declines). See 87 Fed. Reg. at 17,454–56. Examples of nitrogen deposition impacts include expansion of algae blooms in high altitude lakes within Sequoia and Kings Canyon National Parks52 and the spread of invasive, fire-prone grasses in Joshua Tree National Park.53 These harms affect the public welfare in countless ways, damaging the ability of ecosystems to clean the air and water and to provide the basic natural resources humans rely on for food, shelter, and material goods. See generally Draft Regulatory Impact Analysis (DRIA) Chs. 4.2, 4.3. EPA must take action to mitigate these harms in this rulemaking. [EPA-HQ-OAR-2019-0055-1302-A1, pp.19-20]

Organization: *ClearFlame Engine Technologies (ClearFlame)*

By eliminating the diesel fuel from the diesel engine, ClearFlame engines will eliminate the emissions of diesel particulate matter (PM) and NOx that increase asthma emergencies and threaten health in disadvantaged communities that live with disproportionate levels of diesel pollution, while also reducing GHG emissions in the near-term from these engines. [EPA-HQ-OAR-2019-0055-1261-A1, p. 2]

Organization: *Connecticut Department of Energy and Environmental Protection (CTDEEP)*

The transportation sector is responsible for 67 percent of NOx emissions in Connecticut, a key component of ground level ozone (smog). Exposure to poor air quality exacerbates acute and chronic respiratory problems such as asthma, Chronic Obstructive Pulmonary Disease, and other lung diseases. Furthermore, the immediate health impacts of mobile source related air pollution (both direct and indirect) are felt in areas within and along transportation corridors that have borne a disproportionate impact from this pollution for decades. A recent national report, Asthma Capitals 20215, ranked New Haven (#5) and Hartford (#17) among the 100 largest U.S. cities where it is most challenging to live with asthma. Both cities sit at the intersection of major U.S. highways. CTDEEP recently conducted an analysis of on-road HD vehicle emissions and found that, in 2020, on-road HD emissions accounted for 36% of on-road NOx emissions, but emissions from HD vehicles are projected to increase to 57% of total on-road NOx emissions by

2045 without the adoption of new emissions standards.6 [EPA-HQ-OAR-2019-0055-1306-A1, p.2]

5 AAFA 2021 Asthma Capitals Report May 2021

6 MHD_Whitepaper_030822.pdf (ct.gov) p. 11

Organization: *Consumer Reports (CR)*

CR commends EPA for updating long overdue emission standards for heavy-duty vehicles. Heavy-duty vehicles transport consumer goods all across the country, delivering goods to warehouses and directly to homes. The growth of e-commerce and the promise of fast delivery times will likely increase consumer reliance on heavy-duty vehicles. The U.S. Energy Information Administration estimates a 55% growth in total medium- and heavy-duty vehicle miles traveled between 2019 and 2050.6 A recent investigative article by CR highlights the impacts of expanding e-commerce on communities living near warehouses. These impacts include increased traffic and pollution coming from heavy-duty vehicles delivering goods to the warehouses.7 The expansion of the heavy-duty industry to meet consumers' needs should not come at the expense of communities living near trucking routes, nor at the expense of the health of consumers making purchases. [EPA-HQ-OAR-2019-0055-1285-A1, p.2]

As the EPA states, heavy-duty engines will continue to be one of the largest 'contributors to mobile source NOx emissions nationwide in the future.'8 While making up only 5% of on-road vehicles, and 10% of vehicle miles traveled, EPA estimates that NOx emissions from heavy-duty vehicles will represent 32% of the mobile source NOx emissions in calendar year 2045, and that heavy-duty engines would represent 89% of the on-road NOx inventory in calendar year 2045.'9 NOx are precursors to fine particulate matter (PM2.5) and ground-level ozone. [EPA-HQ-OAR-2019-0055-1285-A1, pp.2-3]

9 Id.; Bureau of Transportation Statistics, U.S. Vehicle Miles, Available at: https://www.bts.gov/content/us-vehicle-miles

Long-term exposure to ozone and PM2.5 increases the risk of premature death from respiratory and cardiovascular diseases. Exposure to PM2.5 is also linked with increased incidences of childhood asthma.10 These health impacts more significantly affect the estimated 72 million people living within 200 meters of a truck freight route. Communities living near these routes are disproportionately people of color and those with lower incomes.11 A recent study conducted by the Union of Concerned Scientists showed that Asian-American, Black, and Latinx communities face, respectively, 34%, 24%, and 23% higher exposures to diesel pollution compared to their white counterparts.12 Stringent NOx emission standards are vital to reducing these adverse health impacts and to addressing historic environmental inequities. [EPA-HQ-OAR-2019-0055-1285-A1, p.3]

Organization: *Delaware Department of Natural Resources and Environmental Control (DNREC)*

On-Road HD vehicles are one of the largest sources of nitrogen oxide (NOx) emissions in Delaware, emitting nearly 3,945 tons/year (16%) of all NOx pollution. NOx contributes to smog and secondary particulate matter (PM), which, along with primary PM emissions, are associated with increased risk of premature deaths, hospitalization, and emergency room (ER) visits. Numerous respiratory and cardiovascular diseases are linked to these pollutants such as asthma, decreased lung function, heart attacks, and lung cancer. [EPA-HQ-OAR-2019-0055-1200-A1, p.2]

All combustion engines produce NOx and although technology has advanced in recent years, more must be done to reduce NOx emissions from mobile sources. Cutting NOx and PM emissions from the trucking industry is vital for improving public health and meeting National Ambient Air Quality Standards. [EPA-HQ-OAR-2019-0055-1200-A1, p.2]

Organization: *District of Columbia Department of Energy and the Environment (DOEE)*

The District continues to have high annual ozone. The fourth highest values above the 70 ppb 2015 8-hour Ozone National Ambient Air Quality Standard (NAAQS), except in 2020 when vehicle congestion in the Washington, DC, area was exceptionally reduced due to the Covid-19 health emergency. Oxides of Nitrogen (NOx) emissions from highway trucks are major contributors to unhealthy levels of ground-level ozone and fine particulate matter. In fact, modeling conducted by the Ozone Transport Commission (OTC) found that onroad diesel vehicles were projected to be the second largest contributor to ozone in the District, behind only onroad gasoline vehicles.1 This is detailed below in Table 1. These vehicles were modeled to contribute to 16% of anthropogenic ozone on both exceedance days and throughout ozone season in the District, which is a higher percentage than the District contributes to itself (12% on average and 10% on exceedance days). [EPA-HQ-OAR-2019-0055-1299-A1, pp. 1 - 2]

1. Ozone Transport Commission. 2011-Based Modeling Platform Support Document October 18, 2018

Urban residents in the District are exposed to higher levels of health-damaging PM2.5 and air toxic pollutants which concentrate at “hot-spots” near high-density traffic arteries. Freight transportation relies on trucks, trains, and ships operating within communities in the Northeast and Mid-Atlantic to move goods. This activity generates significant amounts of localized air pollution in communities and for frontline workers already overburdened by diesel exhaust pollution. Local emissions contribute to an ongoing health crisis in these communities. Reducing NOx from heavy-duty truck engines is of the utmost importance due to its role in local and regional ground-level ozone formation, as well as its contributions to PM2.5, and winter-time visibility impairment at Class 1 areas. There are substantial year-round benefits of implementing measures to reduce heavy-duty vehicle NOx emissions. [EPA-HQ-OAR-2019-0055-1299-A1, p. 2]

An OTC analysis, shown in Figure 1, projects that on-road diesel vehicles, including heavy-duty vehicles (HDVs), will be the third largest NOx emissions source in the Ozone Transport Region (OTR) in 2023. Emissions from highway trucks are estimated to comprise 20 percent of the OTR’s total NOx emissions. [EPA-HQ-OAR-2019-0055-1299-A1, p. 2]

2. Tan, et al., “On-Board Sensor-Based NOx Emissions from Heavy-Duty Diesel Vehicles,” Environmental Science and Technology, 53: 5504-5511 (2019).

To estimate the impact of on-road diesel the OTC modeled the contribution, in parts per billion (ppb), of on-road diesel to 8-hour maximum ozone concentrations at monitors in the District.34 Table 1, below, lists the percent contribution to total ozone from on-road diesel vehicles in the District. On-road diesel emissions are projected to contribute about 6 ppb to total ozone and the projected contribution makes up nearly 15 percent of controllable ozone contributions on these days. Also, at all monitors, on-road diesel vehicles are consistently projected to be the second largest anthropogenic contributing sector to ozone, typically only behind area/nonpoint, on-road gasoline vehicles, and in some cases, electric generating units. [EPA-HQ-OAR-2019-0055-1299-A1, p. 3]

3. Ozone Transport Commission “Technical Support Document for the 2011 Ozone Transport Commission/Mid-Atlantic Northeastern Visibility Union Modeling Platform - 2nd Revision,” December 2018.

4. The modeling evaluated the 8-hour maximum ozone on the 4th highest day, which is the metric EPA uses to evaluate compliance with the ozone NAAQS.

A national standard is necessary for a small jurisdiction such as the District because very few private heavy-duty vehicles are registered in the District. In fact, of the heavy-duty vehicles registered in the District, only about 50 vehicles are held privately, despite the thousands of heavy-duty vehicles that pass through our borders. This does not consider the numerous heavy-duty vehicles that circumnavigate the Washington Beltway which never cross the District border yet impact our air quality. Our residents require NOx reductions from diesel vehicles in order to breathe healthy air, and the only effective approach is a national solution. [EPA-HQ-OAR-2019-0055-1299-A1, p. 3]

Although as a whole the District boasts impressive health profiles, life expectancies, and quality of life indicators, many historically overburdened communities in the District do not reflect the trends found in other parts of the city. While traffic and air pollution are problems throughout the city, evidence points to motor vehicle air pollution being concentrated along the interstates and highways that serve as major commuter and goods movement routes, with the heaviest traffic channeled through Southeastern DC (Wards 6, 7, and 8). The communities in Wards 6, 7, and 8 have higher-than-average rates of asthma, which is correlated with higher NOx emissions. If the EPA does not act on the specific issues highlighted above, DOEE fears communities will not see cleaner air, and thus, will continue to suffer adverse health effects. [EPA-HQ-OAR-2019-0055-1299-A1, p. 7]

Organization: *Elders Climate Action*

ECA requests this action to –

3) to end the inequitable and unlawful disparate impact on BIPOC and low income frontline communities who are most exposed to emissions from HDVs in violation of Title VI of the Civil Rights Act and thereby suffer "disproportionately high and adverse human health or environmental effects on minority populations and low-income populations" in violation of EO 12,898. [EPA-HQ-OAR-2019-0055-1218-A1, p. 1]

Diesel trucks and buses are also major sources of other deadly air pollutants. Medium and heavy-duty diesel engines emit more than 60% percent of the deadly particle pollution from vehicles. Particle pollution cuts short tens of thousands of US lives per year and contributes to the heavy burden of asthma on our nation's children. Diesels are the primary source of particles in communities near heavily-trafficked highways where 65 million Americans are exposed to harmful concentrations. [EPA-HQ-OAR-2019-0055-1218-A1, p. 3]

Vehicle pollution inequitably harms Black and Latinex communities that are much more likely compared to whites to reside near heavy truck traffic on highways, and at truck terminals, ports and distribution centers. [EPA-HQ-OAR-2019-0055-1218-A1]

NOx from diesels combines with heat and sunlight in the atmosphere to form ground level ozone, or smog, a lung irritant and asthma trigger. Heavy duty vehicle emissions are a major contributor to urban smog in the 230 urban counties where pollution concentrations violate national air quality standards. [EPA-HQ-OAR-2019-0055-1218-A1, p. 3]

Without effective action to achieve the emission reductions needed for attainment, many at risk groups will suffer harm. EPA's review of the NAAQS for ozone and particulate matter have identified groups especially at risk from vehicle pollution, including-- Babies and children, whose bodies are rapidly developing, Pregnant women who risk increased premature birth and low weight births when exposed to vehicle pollution. Children who develop asthma. Children and adults with asthma who suffer asthma attacks. People with existing respiratory diseases including COPD, COVID-related breathing limitations, long-COVID, and people with active COVID or respiratory infections. People with lung cancer or other chronic diseases including other cancers. People with or at risk for cardiovascular disease. Elders (over age 65) who risk premature death with exposure to air pollution. [EPA-HQ-OAR-2019-0055-1218-A1, p. 4]

The proposed rule fails to achieve the public health benefits that will flow from requiring trucks and buses to emit zero particles, zero NOx and toxic pollutants that cause urban smog, childhood asthma, respiratory and cardiovascular diseases, and premature deaths. Equally objectionable is the failure of EPA to even consider zero emission standards for short-haul HDVs, and to evaluate the climate and public health benefits that would follow from the actions needed for attainment in the worst affected nonattainment areas. [EPA-HQ-OAR-2019-0055-1218-A1, p. 4]

Fire smoke and unprecedented hot temperatures are having a significant impact on human health as an example of the regional impact of heat waves, drought and wildfires. [EPA-HQ-OAR-2019-0055-1218-A1, p. 23]

The heat dome that raised temperatures above 110 F for three days in the Pacific NW in June 2021 caused over 200 heat-related deaths in Oregon and Washington. [EPA-HQ-OAR-2019-0055-1218-A1, p. 23]

Recent research demonstrates that emissions from wildfire are the largest source of fine particle pollution in large regions of the U.S. and contributed to thousands of premature deaths. Wildfire in the western U.S. now accounts for half of all fine particle pollution in some areas of the West, doubling the exposure to PM2.528 from non-fire sources including motor vehicles, power plants and industrial operations.29 [EPA-HQ-OAR-2019-0055-1218-A1, p. 23]

28. PM2.5 are particles smaller than 2.5 micrometers in diameter.

29. Burke, M. et al.,

The changing risk and burden of wildfire in the United States | PNAS (Jan 11, 2021). A warming climate is responsible for roughly half of the increase in burned area in the United States (4), and future climate change could lead to up to an additional doubling of wildfire-related particulate emissions in fireprone areas (36) or a many-fold increase in burned area (37, 38). Costs from these increases include both the downstream economic and health costs of smoke exposure, as well as the cost of suppression activities, direct loss of life and property, and other adaptive measure (e.g., power shutoffs) that have widespread economic consequences.30 [EPA-HQ-OAR-2019-0055-1218-A1, p. 23]

30. Id.

Using satellite measurements of smoke plumes integrated with ground level monitored PM2.5 (fine particle) concentration data, Burke et al. estimate that between 7,000 and 14,500 deaths per year (depending on the dose/response curve used to estimate mortality from observed exposures) are attributable to fire smoke in the contiguous U.S. [EPA-HQ-OAR-2019-0055-1218-A1, p. 24]

Mortality and other health impacts such as asthma attacks and exacerbating COPD will be experienced most severely by communities already burdened by the adverse health effects of daily exposure to fine particle pollution emitted from tailpipes, power plants and industrial sources. Exposure to fire smoke in the American West during the 2020 fire season was universal. No communities were spared. But fire smoke at least doubled the annual exposure routinely suffered by BIPOC and low income communities living near major highways and industrial sources. [EPA-HQ-OAR-2019-0055-1218-A1]

In Oregon, mortality attributed to fire includes many hundreds more deaths than the lives lost directly to fires. Statewide smoke pollution during the 2020 fires threatened lives and wellbeing with extreme hazard concentrations of particles known to cause pre-mature death and cancer, exacerbate asthma, COPD and other respiratory conditions, and cardio-vascular diseases. [EPA-HQ-OAR-2019-0055-1218-A1, p. 24]

The Oregon Health Authority (OHA) reports that "[t]he most severe recent air quality events in Oregon are due to wildfire smoke…"31 OHA cited a study finding that fire smoke in 2012 "caused hundreds of premature deaths, nearly 2,000 emergency room visits and more than $2 billion in health costs."32 OHA points to the longer fire season as increasing the harm from exposure to smoke. "Fire seasons in Oregon are roughly 100 days longer than they were in the 1970s. Longer seasons mean more smoke in Oregon communities."33 The greater density of smoke and longer duration of smoke exposure in 2020 likely at least doubled the mortality caused by smoke exposure compared to 2012. [EPA-HQ-OAR-2019-0055-1218-A1, p. 24]

31. Oregon Climate and Health Report, 40 (Oregon Health Authority, 2020).

32. Id., 33.

33. Id.,

In addition, low income families without air conditioning are much less able to escape smoke pollution by closing doors and windows during the summer heat to keep themselves safe. Workers cannot avoid exposure to smoke pollution if required to work outdoors. [EPA-HQ-OAR-2019-0055-1218-A1, p. 24]

Beyond the economic and environmental damage, social disruption, and harm to health that will result from a longer fire season and expanded fire zones, more deadly air quality will likely make parts of the American West uninhabitable during the fire season for the most vulnerable populations such as the elderly, children and those with existing respiratory and cardiovascular conditions. [EPA-HQ-OAR-2019-0055-1218-A1, p. 24]

These recent data and other sources published since 2009, including the data discussed at length in the Administrator's 2009 Endangerment Finding, 74 Fed. Reg. 66,496 (December 15, 2009), confirm the finding that EPA made 12 years ago: "The Administrator finds that the elevated atmospheric concentrations of the well-mixed greenhouse gases may reasonably be anticipated to endanger the public health and welfare of current and future generations." Id., at 66,523. [EPA-HQ-OAR-2019-0055-1218-A1, pp. 24 - 25]

Organization: *Environmental Defense Fund (EDF) (1265 and 2855)*

EDF conducted an analysis examining the climate, air pollution, health and monetized impacts that would result from electrifying 40 percent of new Class 4-8 single unit trucks, 40 percent of new Class 8 short haul (day cab) tractors, and 80 percent of all transit and school buses, in the 2027-2029 timeframe.70 [EPA-HQ-OAR-2019-0055-1265-A1, p.15]

> 70 EDF. 2022. The Opportunity for Near-Term Electrification of Medium- and Heavy-Duty Vehicles

We have attached this analysis to our comments and summarize the key results here. As stated above, numerous recent studies confirm that eliminating tailpipe emissions from these segments is both technically feasible and cost-saving.71 EDF analysis shows that advancing ZEVs at this rate would:

- Avoid 85 million metric tons of greenhouse gas (GHG) emissions every year by 2040 and more than 1.6 billion tons of GHG emissions through 2050, eliminating 46 percent of emissions from those segments by 2050.
- Significantly reduce ozone forming nitrogen oxide (NOx) pollution by nearly 45,000 tons annually in 2040 and 840,000 -2.2 million tons through 2050 – pollution that disproportionately impacts people of color and lower income neighborhoods.
- Prevent as many as 7,500 - 9,600 premature deaths through 2050.
- Provide our nation with up to $34 billion in economic benefits annually in 2040 with a cumulative savings of $650-680 billion by 2050. [EPA-HQ-OAR-2019-0055-1265-A1, p.15]

> 71 See eg. Vishnu Nair, Sawyer Stone, Gary Rogers, Sajit Pillai. 2022. Medium and Heavy-Duty Electrification Costs for MY 2027- 2030, Roush Industries for Environmental Defense Fund. http://blogs.edf.org/climate411/files/2022/02/EDF-MDHD-Electrification-v1.6_20220209.pdf; Muratori, Matteo et al. 'Decarbonizing Medium- and Heavy-Duty On-Road Vehicles: Zero-Emission Vehicles Cost Analysis.' NREL Transforming Energy. March 2022. https://www.nrel.gov/docs/fy22osti/82081.pdf.

While these segments present the most cost-effective near-term opportunity for reductions, it will be equally important for other segments, including long-haul tractors, to transition to electrification as soon as possible because of their significantly high emissions, high vehicle miles traveled and lower fuel economy. The dramatic economic and health savings shown above are the result of just a portion of the medium- and heavy-duty fleet starting to electrify over the next 7 years. The impact of 100 percent new ZEV sales across all vehicle segments would push these benefits into the trillions of dollars. (See Attachment A for the full White Paper and a more extensive justification for the near-term electrification of the truck and bus segments modeled) [EPA-HQ-OAR-2019-0055-1265-A1, p.16]

Organization: *Evangelical Environmental Network (EEN)*

We support new standards for control of air pollution from heavy-duty trucks. The transportation sector emitted pollution is a major sort of air pollution-related death and disease, and recently became the #1 source of global warming pollution in the United States. Heavy-duty trucks are a leading source of lung-damaging air pollutants—including smog-forming NOx pollution and particle pollution (soot). It's estimated that in 2020, that nationwide trucks consumed 55.3 billion gallons of fuel and emitted 561 million metric tons of greenhouse gases, 1.5 million metric tons of nitrogen oxides (NOx) and 38,000 metric tons of particulate matter (soot) (PM). The largest single source of these pollutants are heavy duty trucks (57% of vehicle generated soot comes from trucks.) [EPA-HQ-OAR-2019-0055-0993-A1, p.1]

PM2.5 alone results in at least 200,000ii deaths annually in the United States from nine (9) separate causes including: cardiovascular disease, cerebrovascular disease, chronic kidney disease, chronic obstructive pulmonary disease, dementia, type 2 diabetes, hypertension, lung cancer, and pneumonia.iii Over 15,000 preterm births are linked to PM2.5 with 1/3 of early births resulting in deaths.iv [EPA-HQ-OAR-2019-0055-0993-A1, p.2]

Ozone-forming nitrogen oxides harm the health of both children and adults – this includes asthma,1 other respiratory illnesses like COPD, and brain inflammation leading to cognitive decline. [EPA-HQ-OAR-2019-0055-1134-A1, p.1]

> 1 Rasmussen S.G., et al., "Association Between Unconventional Natural Gas Development in the Marcellus Shale and Asthma Exacerbations," JAMA Internal Medicine, 2016, 176(9), 1334–1343, https://jamanetwork.com/journals/jamainternalmedicine/fullarticle/2534153 Willis, M. D., et al., "Unconventional natural gas development and pediatric asthma hospitalizations

in Pennsylvania, Environmental Research, 166, 402-408, October 2018, https://www.ncbi.nlm.nih.gov/pubmed/29936288

Pregnant people and babies are especially vulnerable. As evangelicals, we have a special care for children – both born and unborn. Medical research shows that ozone exposure increases the likelihood of reproductive and developmental harm, including reduced fertility, preterm birth, stillbirth and low birth weight. [EPA-HQ-OAR-2019-0055-1134-A1, p.1]

Being recently pregnant, these harms hit me at a personal level. [EPA-HQ-OAR-2019-0055-1134-A1, p.1]

Medical research shows that exposure to diesel fumes like emitted from heavy duty vehicles can contribute to ADHD. [EPA-HQ-OAR-2019-0055-1134-A1, p.1]

Like every parent, I want my children to reach their full God-given potential and the truth is heavy duty vehicle pollution robs children of this. But safeguarding our children from heavy duty truck pollution is beyond the control of one person, one parent. We need the strongest standards possible to defend the health and lives of our children. [EPA-HQ-OAR-2019-0055-1134-A1, pp.1-2]

Organization: *Evergreen Action*

The transportation sector accounts for the largest share of greenhouse gas emissions in the nation, and Medium and Heavy Duty Vehicles (MHDVs) represent nearly a third of those emissions. In addition to producing greenhouse gas emissions, heavy duty vehicles are also responsible for significant soot and smog pollution. The particulate matter in soot is responsible for a range of lung and heart diseases which increases hospitalization rates and keeps people from school and work. The NOx pollution that contributes to smog formation harms millions of Americans every year by causing decreased lung function and exacerbating respiratory diseases. These health impacts most severely impact low income communities and communities of color that tend to be surrounded by and displaced by transportation routes. [EPA-HQ-OAR-2019-0055-1289-A1, p.1]

Organization: *Florida Council of Churches*

Our Sovereign God formed humanity from the dust of Earth and breathed into our nostrils the breath of life, and humanity became a living breathing creature. We all share this breath of life. In the age of the pandemic, we've masked up to limit the spread of the moisture in our breathing. But there is no break, no stop sign, no point of exchange where my breath ends and your breath begins. We breathe the same air. We are made of the same breath. Scripture says it's the breath of God. Indeed, we share this breath of the divine with all living creatures and the inanimate structures on Earth. Let us think of Earth and its biosphere as a breathing creature itself, inhaling and exhaling. Ancient rabbis say that in pronouncing the Hebrew name for God replicates this inhaling and exhaling. Breath is life. [EPA-HQ-OAR-2019-0055-1006, p.1]

Florida is home now to nearly 22 million people and is growing by 1000 new residents a day. Almost half of Floridians live in the ten counties with the highest density of population and thus traffic congestion. Density can be determined in various ways. If one excludes land area with zero population, the ten most dense counties are respectively Broward, Pinellas, Miami-Dade, Palm Beach, Orange, Seminole, Hillsborough, Duval, Sarasota, and Lee. These counties also have significant, historic populations of African descent and Latine populations who live in urban neighborhoods ringed by inner-city interstates and expressways. It has been well-documented by scholars how the road systems were intentionally designed in conjunction with redlining to box these people in. They bear the brunt of exhaust pollution in Florida. Asthma is common across the state in these hemmed in communities and life-expectancy is lower. [EPA-HQ-OAR-2019-0055-1006, p.1]

The Parramore district in Orlando has one of the highest ozone readings in the nation. It is completely hemmed in by elevated interstate highways. The City of St Petersburgh established a community garden at the Enoch Davis Center in the southcentral neighborhood but had to put it in raised beds. The ground around the center was too toxic for a garden – the toxicity was the accumulation of exhaust pollution over the decades. We must address both NOx and heavy metal pollution in these urban settings. The road runoffs create accumulated toxicities. One of our future food supplies is urban agriculture, and the soil is crying for renewal – as the New Testament says, even the stones are shouting and creation is longing for the liberation of humanity. [EPA-HQ-OAR-2019-0055-1006, pp.1-2]

Organization: *International Council on Clean Transportation (ICCT)*

Current EPA 2010 standards are inadequate to protect public health from HDV NOx emissions. Diesel vehicles are the largest contributor to health impacts from transportation-related air pollution in the U.S., responsible for more than 9 thousand premature deaths in 2015. ICCT research has shown that excess NOx emissions from diesel HDVs produce health impacts an order of magnitude greater than diesel passenger cars. Diesel HDVs are one of the top contributors to racial, ethnic, and socioeconomic disparities in PM2.5 and NO2 exposure. Previous ICCT research has shown that achieving a 90% NOx reduction for model year 2027 and later diesel engines could avoid more than $1 trillion in air pollution-related health damages cumulatively from 2027–2050. [EPA-HQ-OAR-2019-0055-1211-A1, p. 3]

RECOMMENDATION: We strongly encourage EPA to finalize stringent NOx engine standards by the end of this year. [EPA-HQ-OAR-2019-0055-1211-A1, p. 3]

On-road vehicles remain the largest source of NOx emissions in the United States,3 and the majority of these emissions are from HDVs—especially those with diesel engines.4 Current EPA 2010 standards for heavyduty vehicles have not been updated since 2010, whereas EPA's Tier 3 emissions standards will continue to reduce criteria pollutant emissions from new light- and medium-duty passenger vehicles through model year 2025.5 [EPA-HQ-OAR-2019-0055-1211-A1, p. 7]

3. EPA, “Air Pollutant Emissions Trends Data.” https://www.epa.gov/air-emissions-inventories/air-pollutantemissions-trends-data

4. https://theicct.github.io/roadmap-doc/

5. https://www.transportpolicy.net/standard/us-light-duty-emissions/ and https://www.transportpolicy.net/standard/us-heavy-duty-emissions/

EPA 2010 standards are inadequate to protect public health from HDV NOx emissions. Diesel vehicles are the largest contributor to health impacts from transportation-related air pollution in the U.S., responsible for more than 9 thousand premature deaths in 2015.6 ICCT research has shown that excess NOx emissions from diesel HDVs produce health impacts an order of magnitude greater than diesel passenger cars in the U.S.7 ICCT research also shows that a disproportionate amount of NOx emissions from heavy-duty vehicles is emitted during urban driving. Vehicle operation at speeds of less than 25 mph results in NOx emissions of more than five times the certification limit for the average HDV certified to EPA 2010 standards.8 Diesel HDVs are one of the top contributors to racial, ethnic, and socioeconomic disparities in PM2.5 and NO2 exposure in the U.S.9 [EPA-HQ-OAR-2019-0055-1211-A1, p. 7]

EPA's Option 1 will benefit communities in all states; adopting requirements similar to the scenario represented by Federal omnibus + Alternative 3 would further increase benefits by approximately 15% across U.S. states. [EPA-HQ-OAR-2019-0055-1211-A1]

The most populous states, such as California and Texas have among the highest potential health benefits in absolute terms from heavy-duty vehicle emission regulations. Yet multiple states are projected to experience outsized benefits compared to their population, such as Pennsylvania and Delaware, as well as Midwest and Southern states, including Indiana, Arkansas, Ohio, Missouri, North Carolina, and Georgia. [EPA-HQ-OAR-2019-0055-1211-A1]

Organization: *International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)*

Across the country, many of our members live in communities facing air quality issues and the concurrent health risks. [EPA-HQ-OAR-2019-0055-1138-A1, p.2]

Organization: *Lion Electric Co. USA Inc. (Lion)*

It is critical that we as a country recognize the impact that internal combustion engine (ICE) vehicles have in causing air pollution in our communities. For this reason, Lion applauds the EPA for considering updated and more stringent guidelines to curb the air quality and health-related issues associated with the on-road heavy-duty vehicle sector as it stands. [EPA-HQ-OAR-2019-0055-1151-A2, p. 1]

As the EPA noted in the rulemaking document, the health risks associated with the air pollutants from ICE vehicles are steep and costly both financially and measured in terms of human lives. Therefore, it is imperative that aggressive steps be taken to reduce this harm immediately. [EPA-HQ-OAR-2019-0055-1151-A2, p. 3]

Organization: *Maine Department of Environmental Protection (Department)*

Ozone can cause chronic obstructive pulmonary disease (COPD), and long-term exposure may result in permanent lung damage, such as abnormal lung development in children. There is also consistent evidence that short-term exposure to ozone increases risk of death from respiratory causes.1 [EPA-HQ-OAR-2019-0055-1288-A1, p.1]

> 1 U.S. EPA, "Health Effects of Ozone Pollution," https://www.epa.gov/ground-level-ozone-pollution/health-effects-ozone-pollution, last updated July 30, 2019 (accessed February 7, 2020).

NOx emissions are the major drivers of surface ozone concentrations at the regional scale in the eastern United States, and significant contributors to fine particle pollution and regional haze. Maine, because of its geographic location at the downwind terminus of the northeast corridor, is especially impacted by transported emissions from states and regions to our south.[EPA-HQ-OAR-2019-0055-1288-A1, p.2]

The primary ozone and precursor transport route is over the Gulf of Maine and along the Maine coastline. Historically, during ozone events in Maine, peak ozone levels are monitored first along the southern Maine coast, then they are monitored later in the day at downwind locations as the air mass moves along the coastline to the Northeast. As an example, Figure 1 shows the coastal track of a high-ozone air mass which occurred during the June 12, 2017, ozone event, with peak ozone levels monitored at the summit of Cadillac Mountain four (4) hours after the peak ozone level was recorded at the Kennebunkport monitoring site and seven (7) hours after the peak ozone level was recorded at a Connecticut monitoring site just outside of New York City. Figure 2 shows surface wind streams during the afternoon of June 12, 2017, where the sea breeze transport pattern matches the historical transport pattern for ozone events along the Maine coast. [EPA-HQ-OAR-2019-0055-1288-A1, p.2]

Although Maine is currently attaining all National Ambient Air Quality Standards (NAAQS)3, reducing heavy-duty vehicle NOx emissions is still important for urban and rural residents that are often exposed to higher levels of health-damaging PM2.5 and air toxic pollutants concentrated at "hot-spots" near higher-density traffic arteries. Freight transportation relies on trucks, trains, and ships operating within communities in the Northeast and mid-Atlantic to move goods. This activity generates a significant amount of localized air pollution in communities and for frontline workers already overburdened by diesel exhaust pollution. [EPA-HQ-OAR-2019-0055-1288-A1, p.3]

> 3 Maine's Limited Maintenance Plans for the Portland and Midcoast region were approved on 10/14/20202 (85 FR 64969).

Because of its role in secondary particulate formation, reducing heavy-duty vehicle NOx emissions can help improve visibility in Federal Class I areas. There are seven Class I Federal areas in the region that comprises the Mid-Atlantic Northeast Visibility Union (MANE-VU)4, with these Class I areas historically facing some of the worst visibility in the nation. Monitor analyses of the Interagency Monitoring of Protected Visual Environment (IMPROVE) network shows the increasing importance of nitrate formation on visibility impairment, especially in the winter months.5 Because of this, the MANE-VU states through the MANE-VU Regional Planning Organization process requested that EPA implement a program to reduce NOx emissions from HDVs.6 [EPA-HQ-OAR-2019-0055-1288-A1, p.3]

> 4 Maine has three Class I areas: Acadia National Park, Moosehorn Wilderness Area, and Roosevelt Campobello International Park.
>
> 5 Mid-Atlantic/Northeast Visibility Union. "Mid-Atlantic/Northeast U.S. Visibility Data 2004-2017 (2nd RH SIP Metrics)," December 18, 2018.
>
> 6 Mid-Atlantic/Northeast Visibility Union. "Statement of the MANE-VU States Concerning a Course of Action by the Environmental Protection Agency and Federal Land Managers toward Assuring Reasonable Progress for the Second Regional Haze Implementation Period (2018-2028)," August 25, 2017.

To address the region's persistent air quality problems, reducing NOx from heavy-duty truck engines is of the utmost importance due to its role in local and regional ground-level ozone formation, as well as its contributions to PM2.5, and visibility impairment at Class 1 areas. The year-round benefits of measures to reduce heavy-duty vehicle NOx emissions are substantial. [EPA-HQ-OAR-2019-0055-1288-A1, p.4]

Organization: *Mass Comment Campaign sponsored by American Lung Association (248)*

Pollution from diesel-powered trucks and buses puts the health of anyone who spends time outdoors at risk, but especially people living in communities near highways, ports, bus depots and other transportation hubs. Nitrogen oxide (NOx) emissions can cause lung damage on their own and also form ground-level ozone and particle pollution. Ozone and particle pollution can lead to asthma attacks, cardiovascular and lung disease, strokes and even premature death. [EPA-HQ-OAR-2019-0055-1609-A1, p.1]

In its 2022 “Zeroing in on Healthy Air” report, the American Lung Association found that a nationwide transition to zero-emission light, medium and heavy-duty vehicles, powered by non-combustion electricity, would save 110,000 lives and secure $1.2 trillion in public health benefits nationwide from 2020-2050. [EPA-HQ-OAR-2019-0055-1609-A1,p.1]

Organization: *Mass Comment Campaign sponsored by Climate Action Campaign (22,659)*

- Smog and soot air pollution caused by trucks and buses are among the greatest threats to public health for the more than 45 million people in the U.S. living within 300 feet of a major roadway or transportation facility. [EPA-HQ-OAR-2019-0055-1193, p.1]

Organization: *Mass Comment Campaign sponsored by Evangelical Environmental Network (EEN) (67,755)*

Pollution from transportation is a major cause of air-pollution-related death and disease, and recently transportation became the top source of global warming pollution in the United States. Heavy-Duty Trucks, like tractor-trailers, are a leading source of lung-damaging air pollutants—including smog-forming NOx pollution and particle pollution (soot). In 2020, trucks emitted an estimated 561 million metric tons of greenhouse gases, 1.5 million metric tons of nitrogen oxides (NOx) and 38,000 metric tons of particulate matter (soot) (PM), filling the air we breathe with life-threatening air pollution. The largest single source of these pollutants is heavy duty trucks. [EPA-HQ-OAR-2019-0055-1610-A1, p.1]

As pro-life Christians, we want the air that we breathe to be safe for our children. However, soot (PM2.5) from burning fossil fuels cut short the lives of 350 million Americans each year and contributes to at least 15,000 premature births of which 1/3 of those babies die. Heavy duty trucks, like tractor-trailers, emit soot and other pollutants that put God’s creation and our families - especially pregnant mothers and the unborn - in harm's way. Unborn children close to major roads are at higher risk of birth defects, and children attending school near these highways have higher rates of cancer and asthma. [EPA-HQ-OAR-2019-0055-1610-A1,pp.1-2]

That's why over 67, 755 pro-life Christians are calling on the EPA to ensure stronger standards that will cut pollution from Heavy-Duty Trucks by 2027 and move us to zero emission by 2035. Our kids deserve clean air and the right to an abundant live. [EPA-HQ-OAR-2019-0055-1610-A1, p.2]

Organization: *Mass Comment Campaign sponsored by Moms Clean Air Force and Arizona Climate Action Coalition (198)*

Trucks are also major sources of other deadly air pollution. Medium and heavy duty trucks account for more than 60% percent of the deadly particle pollution that comes from vehicles.

Particle pollution cuts short tens of thousands of US lives per year and contributes to the heavy burden of asthma on our nation's children. [EPA-HQ-OAR-2019-0055-1192-A1, pp.1-2]

Organization: *Mass Comment Campaign sponsored by Neighbors for Clean Air and Elders Climate Action (43)*

Diesel trucks and buses are also major sources of other deadly air pollutants. Medium and heavy-duty diesel engines emit more than 60% percent of the deadly particle pollution from vehicles. Diesel engines emit deadly particle pollution. NOx combines with heat and sunlight in the atmosphere to form ground level ozone, or smog, a lung irritant and asthma trigger. Particle pollution cuts short tens of thousands of US lives per year and contributes to the heavy burden of asthma on our nation's children. [EPA-HQ-OAR-2019-0055-1619-A1, p.2]

Heavy duty vehicles are major contributors to air pollution in the Portland metro area and on the I-5 and I-84 corridors. [EPA-HQ-OAR-2019-0055-1619-A1, p.2]

The Oregon Health Authority says that many groups are especially at risk from vehicle pollution, including--
Babies and children whose bodies are rapidly developing,
Pregnant women who risk premature births and low weight babies when exposed to vehicle pollution.
Children are at higher risk of developing asthma.
Children and adults with asthma suffer more frequent asthma attacks requiring urgent or emergency care.
People with existing respiratory diseases including COPD, COVID-related breathing limitations, long-COVID, and people with active COVID or other respiratory infections suffer more severe outcomes.
Non-smokers are more at risk for lung cancer or other chronic diseases including other cancers.
People with or at risk for cardiovascular disease.
Elders (over age 65) suffer higher risk of premature death with exposure to vehicle pollution. [EPA-HQ-OAR-2019-0055-1619-A1, p.2]

Organization: *Mass Comment Campaign sponsored by PennEnvironment (50)*

Smog pollution from trucks is also a threat to public health, causing childhood asthma, cancer and even premature death. To protect our health and fight climate change, EPA must strengthen the proposed heavy duty truck rule. [EPA-HQ-OAR-2019-0055-1616-A1, p.1]

Organization: *Mass Comment Campaign sponsored by Public Citizen (168)*

Diesel pollution kills. Nearly 10,000 people in the United States die each year from exposure to diesel emissions from the transportation sector, and hundreds of thousands of others face heart attacks, asthma, and respiratory conditions that damage their wellbeing and quality of life. The EPA's proposed rulemaking on diesel emissions is much needed. I appreciate the EPA for proposing these new standards to better protect the climate and the health of people. [EPA-HQ-OAR-2019-0055-1597-A2, p.1]

Organization: *Mass Comment Campaign sponsored by The Outreach Team (95)*

Smog and soot air pollution from trucks and buses are among the greatest public health threats for millions of people, which is why the EPA must create the strongest possible limits on heavy duty vehicle pollution. I support strong truck pollution regulations. [EPA-HQ-OAR-2019-0055-1618, p.1]

Organization: *Mass Comment Campaign sponsoring organization unknown - 1 (2,443)*

Every year semi-trucks, busses, and other heavy-duty vehicles emit millions of tons of nitrogen oxides (NOx) and other greenhouse gas pollutants driving climate change. [EPA-HQ-OAR-2019-0055-1594-A1, p.1]

NOx air pollution from heavy-duty vehicles contributes to ozone and fine particulate pollution, which are unsafe to breathe, especially for the young and elderly and anyone exercising outdoors. [EPA-HQ-OAR-2019-0055-1594-A1, p.1]

In our national parks it harms plants, trees, insects and other animals and it reduces the ability of visitors to see and appreciate the views of our treasured park landscapes. [EPA-HQ-OAR-2019-0055-1594-A1,p.1]

Organization: *Metropolitan Washington Air Quality Committee (MWAQC) et al.*

Poor air quality affects the residents living and working in metropolitan Washington. Some communities in metropolitan Washington face higher rates of illnesses such as asthma than the national average, and these illnesses are aggravated by these pollutants. As such, reductions in NOx emissions will provide health benefits from both reduced ozone and PM2.5 pollution. [EPA-HQ-OAR-2019-0055-0996-A1, p. 2]

Organization: *Moving Forward Network (MFN)*

It is well understood that diesel exhaust is “carcinogenic to humans,” as determined by the World Health Organization, and leads to tens of thousands of premature deaths each year.16 Diesel exhaust contains smog precursors, fine particulate matter—which can be inhaled and lodged in the lungs, and more than 40 known cancer-causing compounds.17 Exposure to pollution from diesel-powered vehicles has also been linked to low birth rate, premature birth, lower IQ, diabetes, stroke, congestive heart failure, heart disease, obesity, asthma, and allergies.18 [EPA-HQ-OAR-2019-0055-1277-A1, p. 8]

On top of this, these same communities suffer from a handful of additional harms from the freight sector: the paved areas and large, low buildings dominating freight facilities contribute to urban heat island effects, stormwater issues and other environmental impacts. Other industrial sources are often clustered near freight facilities, which means that communities impacted by diesel trucks are also impacted by other sources of air and water pollution, and toxic releases. These communities also face racism and other forms of discrimination that increase their vulnerability to environmental threats. In fact, freight-impacted communities are even more vulnerable to the impacts of air and other pollution because of socio-demographic stressors—including racial segregation, high rates of poverty, lack of access to affordable foods, and lack of access to healthcare—compared to communities that do not face these stressors.25 [EPA-HQ-OAR-2019-0055-1277-A1, p. 9 - 10]

Organization: *National Association of Clean Air Agencies (NACAA)*

Many of these areas are over-burdened communities whose citizens are exposed to a disproportionate share of harmful environmental conditions. The excessive emissions from HD trucks are a primary cause, contributing substantial emissions of NOx – the key pollutant contributing to the formation of ozone and PM2.5 – and are linked with a large number of adverse impacts on the respiratory system, as well as other ill effects associated with exposure to elevated levels of ozone and PM, including premature death. [EPA-HQ-OAR-2019-0055-1232-A1, p. 2.]

Organization: *National Association of Small Trucking Companies (NASTC)*

We appreciate the goals of the proposed rule. NASTC and our members share the aims of reduced pollution and of cleaner air. Further, we understand the health and environmental concerns cited in the proposed rule (though we do have concerns about the underlying assumptions). We also understand that heavy-duty vehicles emit a sizable amount of nitrogen oxide (NOx) and greenhouse gases (GHG) while doing their jobs. [EPA-HQ-OAR-2019-0055-1130-A1, p. 1]

Organization: *National Coalition for Advanced Transportation (NCAT)*

The transportation sector is also responsible for a significant share of criteria pollutant emissions, including over 55% of the nitrogen oxides (NOx) total emissions inventory in the U.S.,15 17.9 million tons per year of carbon monoxide, 133,000 tons per year of fine particulate matter (PM) PM2.5, 287,000 tons per year of PM10, and 1.8 million tons per year of volatile organic compounds (VOCs).16 These emissions have significant effects on communities around the country. [EPA-HQ-OAR-2019-0055-1290-A1, p. 5]

15. U.S. EPA, Smog, Soot, and Other Air Pollution from Transportation, https://www.epa.gov/transportation-air-pollution-and-climate-change/smog-soot-and-local-air-pollution (last updated Nov. 20, 2020).

16. NHTSA, The Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Year 2021 – 2026 Passenger Cars and Light Trucks Final Environmental Impact Statement (Mar. 2020) at 4-1–4-2, available at https://www.nhtsa.gov/sites/nhtsa.gov/files/documents/safe_vehicles_rule_feis.pdf.

Electric and other zero emission vehicles are a critically important, cost-effective strategy to reduce such air pollution, particularly in areas with severe air quality problems. All-electric vehicles produce zero direct emissions since these vehicles lack a tailpipe and thus have zero tailpipe emissions of GHGs or other pollutants. As a result, use of these vehicles in place of internal combustion engine vehicles can significantly improve air quality in urban areas. On average across the United States, annual life cycle emissions per vehicle are substantially lower for all electric vehicles as compared to gasoline vehicles. The emissions reductions are even greater in geographic areas that use relatively low-polluting energy sources for electricity generation.20 The share of electricity generated from renewable energy resources (e.g., wind, solar, geothermal, hydroelectric, and biomass) has dramatically increased in recent years to about 20% of total U.S. electricity generation in 2020.21 And the U.S. Energy Information Administration (EIA) predicts that this trend of significant increases in generation from renewable resources will continue.22 As the sources of electricity generation become cleaner, GHG and criteria pollutant emissions related to use of electric vehicles will further decline. Electric vehicles also emit less heat and produce less noise.23 Researchers from Harvard studied emissions from electric vehicles and conventional vehicles in large metropolitan statistical areas and concluded that in each area, air pollution mortality was significantly less from electric vehicles.24 Others have found that, regardless of the electric vehicle adoption scenario they considered, ozone and PM2.5 concentrations declined with the adoption of electric vehicles.25 [EPA-HQ-OAR-2019-0055-1290-A1, pp. 5-6]

Organization: *National Parks Conservation Association (NPCA)*

It is unquestionable that heavy-duty vehicles and engines impact the health of individuals who breathe in dirty air and the environment at large. As stated in the proposed rule, 'Heavy-duty (HD) engines operating across the U.S. emit NOx and other pollutants that contribute to ambient levels of ozone, PM, and NOx. These pollutants are linked to premature death, respiratory illness (including childhood asthma), cardiovascular problems, and other adverse health impacts. Data show that heavy-duty engines are significant contributors to concentrations of ozone and PM2.5 and their resulting threat to public health.'6 [EPA-HQ-OAR-2019-0055-1314-A1, p.2]

6 87 Fed. Reg. at 17,417.

As it relates to parks, this air pollution harms the health and wellbeing of visitors and employees within national parks and residents of the gateway communities surrounding national parks. NOx pollution also directly impacts numerous unique park ecosystems harming plants and wildlife. As EPA has noted in the past, 'Environmental impacts of concern are associated with these pollutants and include light extinction, decreased tree growth, foliar injury, and acidification and eutrophication of aquatic and terrestrial systems.'7 These impacts are especially relevant in areas already suffering from a range of climate change impacts, such as the Rocky Mountains, Sierra Nevada Mountains, Appalachian Mountains, and Southwestern Desert ecosystems. For example, ozone phytotoxicity can lead to foliar injury and reduce the photosynthetic capacity of plants and trees, including Jeffery and Ponderosa pines and other high elevation coniferous species.8 Moreover, many of the tree species weakened by ozone and other air pollutants linked to NOx emissions are already facing climate change driven stressors associated with manmade GHG emissions, such as drought, high temperatures, and native bark beetle attacks.9 Because of this, NOx and GHG pollution from heavy-duty trucks can be directly linked and the ongoing tree mortality and mega-wildfire crisis that has devastated the Western United States in recent years. Additionally, nitrogen deposition from NOx pollution causes widespread deleterious impacts across land and water ecosystems and includes both direct exposure (e.g. nitrogen enrichment) and biological effects (e.g. decreases in biodiversity; fish declines;). Examples of nitrogen deposition impacts include expansion of algae blooms in high altitude lakes within Sequoia and Kings Canyon National Parks and the spread of invasive, fire prone, grasses in Joshua Tree National Park.10 These harms affect the public welfare in countless ways, damaging the ability of ecosystems to clean our air and water and to provide us with the basic natural resources we rely on for food, shelter, and material goods. Heavy-Duty Vehicle NOx pollution also contributes to haze pollution that decreases visibility in our national parks and other Class 1 areas covered by the CAA's Regional Haze Program. Haze consists of pollutants emitted from these vehicles, engines, and other sources that causes and contributes to regional haze in the national parks resulting in views that can be distorted and impaired.11 Virtually every park in the United States is affected by haze pollution, and for 89 percent of parks, visibility impairment is either a moderate or significant concern.12 As a result of haze pollution, visitors of the national parks miss out on many miles-worth of views of the grand landscapes this country has to offer. On average, 50 miles of scenery is missed by visitors to national parks due to impaired visibility caused by regional haze, and in some parks, as many as 90 miles of scenery and landscape is lost in sight due to regional haze.13 Although air quality has improved over time, these benefits are not felt by all parks equally. In fact, 33 national parks are as polluted as this nation's 20 largest cities.14. With numerous states in the middle of their second-round regional haze planning periods additional reductions in NOx pollution from HD vehicles could go a long way towards helping achieve natural levels of visibility in national parks and other Class 1 areas as is set forth as a goal under the Clean Air Act. . Organization: *National Religious Partnership for the Environment*

For communities living near freeways, trucking corridors, and freight hubs, pollution from medium- and heavy-duty trucks and buses can be deadly. Discriminatory land use and transportation policies have resulted in the burden of diesel pollution exposure to be borne more heavily by communities of color. This exposure to diesel pollution has led to long-term respiratory and cardiovascular health issues. [EPA-HQ-OAR-2019-0055-1221-A1, p.1]

Organization: *National Tribal Air Association (NTAA)*

Tribes continue to suffer from unhealthy exposures to ozone, fine particulate matter (PM2.5) and hazardous air pollutants emitted from heavy-duty vehicles. [EPA-HQ-OAR-2019-0055-1382-A2, p.2]

Organization: *New York Farm Bureau (NYFB)*

Since 1990, economy-wide NOx emissions from highway vehicles have declined by 75%, even as overall vehicle miles traveled have increased by nearly 50%. Continued improvements in advanced-technology diesel engines are a key driver of this success, and one of many reasons U.S. air quality is among the best in the world. [EPA-HQ-OAR-2019-0055-1268-A1, p. 1]

Organization: *Northeast States for Coordinated Air Use Management (NESCAUM)*

The NESCAUM region includes the New York City (NYC) Combined Statistical Area (CSA) with over 20 million people living across portions of Connecticut, New Jersey, New York, and Pennsylvania. It is the largest CSA by population in the United States. While air pollution levels have dropped over the years across much of the United States, the NYC metropolitan area and surrounding regions continue to persistently exceed federal health-based air quality standards for ground-level ozone.[EPA-HQ-OAR-2019-0055-1249-A1, p. 2.]

The chronically persistent high ozone concentrations compromise the health and welfare of the citizens living in the NYC CSA and elsewhere in the NESCAUM region. Epidemiological studies provide strong evidence that ozone is associated with respiratory effects, including increased asthma attacks, as well as increased hospital admissions and emergency department visits for people suffering from respiratory diseases. Ozone can cause chronic obstructive pulmonary disease (COPD), and long-term exposure may result in permanent lung damage, such as abnormal lung development in children. There is also consistent evidence that short-term exposure to ozone increases risk of death from respiratory causes.5 Furthermore, more recent studies show that ozone concentrations below the current National Ambient Air Quality Standards (NAAQS) contribute to the risk of premature death in sensitive populations, such as the elderly.6 [EPA-HQ-OAR-2019-0055-1249-A1, pp. 2-3]

> 5. U.S. EPA, "Health Effects of Ozone Pollution," https://www.epa.gov/ground-level-ozone-pollution/health-effects-ozone-pollution, last updated May 5, 2021 (accessed May 12, 2022).

"Association of short-term exposure to air pollution with mortality in older adults," JAMA 318: 2446-2456 (2017). DOI: 10.1001/jama.2017.17923.

While ozone is largely a summertime issue in the Northeast, NOx emissions are a year-round problem. During colder seasons, NOx emissions play a role in producing secondary PM2.5 through the formation nitrates. PM2.5 exposure is associated with a variety of health effects, including reduced lung function, irregular heartbeat, asthma attacks, heart attacks, and premature death in people with heart or lung disease.7 Low-income communities and communities of color are often located near trucking corridors, ports, fleet garages, warehouses, and other trucking hubs. These communities are often affected by disproportionate amounts of diesel exhaust emissions and worsened health burdens due to poor air quality in US cities.8,9 Health and economic impacts include increase in asthma and other respiratory illnesses, especially in children and older adults, leading to additional trips to doctors and emergency rooms, missed days of school and work, and thousands of premature deaths each year. [EPA-HQ-OAR-2019-0055-1249-A1, p. 3.]

Available at https://agupubs.onlinelibrary.wiley.com/doi/10.1029/2021GL094333 (accessed May 12, 2022).

The public health and environmental impacts of NOx are summarized in Table 1. [EPA-HQ-OAR-2019-0055-1249-A1, p. 3]

Organization: *Our Children's Trust*

EPA continues here a long-standing practice of discounting the lives of children and unborn future generations when it analyzes and considers the formulation of proposed regulations to carry out its delegated authority to protect the air and human health and welfare. That charge, to protect air quality in order to protect human health and welfare, is a charge not to merely protect one living generation of adults' air quality, but to protect babies, children, and 'our Posterity'—for the U.S. Constitution is clear that all sovereign authority vested in our federal government, and here as delegated to EPA, cannot be used to destroy the nation and thereby its sovereignty, precluding children of today and tomorrow from inheriting the air and water and land in sound condition and having the ability to govern themselves to also protect the lifegiving air and all generations to come. [EPA-HQ-OAR-2019-0055-1317-A1, p.2]

The RIA and proposed rule analysis repeatedly reference how children are a most vulnerable class of citizens and their physical health is threatened by the pollutants being allowed by this proposed rule. However, EPA has not analyzed the extreme mental health harms to children from both the physical harms they experience from this pollution, but also from the climate anxiety they carry due to the institutional betrayal of agencies like EPA and also the acute and chronic trauma they experience from living with climate crisis. There is a mental health crisis among our young, which EPA in other contexts has acknowledged. It should be included here as well and in every analysis you conduct, particularly when so many of the physical harms you assess and monetize are respiratory in nature for children, and where the inability to breathe on bad ozone days or when fires are ripping through your community are destabilizing the mental health of so many of our children. [EPA-HQ-OAR-2019-0055-1317-A1, p.4]

Under the 5th Amendment to the U.S. Constitution, the government is restrained from engaging in conduct that infringes upon fundamental rights to life, liberty, and property, and equal protection of the law, all of which includes a climate system that sustains human life and liberty.

Under the Public Trust Doctrine, embedded in our Constitution and other founding documents, and in the very sovereignty of our Nation, U.S. residents (both present and future, i.e., Posterity) have a right to access and use crucial natural resources, like air and water. The U.S. government, and its executive agencies, have fiduciary duties as trustees to manage, protect, and prevent substantial impairment to our country's vital natural resources which the government holds in trust for present and future generations.19 [EPA-HQ-OAR-2019-0055-1317-A1, p.6]

Organization: *Retail Industry Leaders Association (RILA)*

EPA's proposed changes to its pollutant emissions standards for heavy-duty engines are a logical update that will benefit employees and customers of the nation's retailers through improved air quality.[EPA-HQ-OAR-2019-0055-1189-A2, p.2]

Organization: *Saahil Pasha*

According to the American Lung Association, approximately 3 out of every 8 people in the United States lives in a county where a grade of “F” has been assigned for the ozone pollution (American Lung Association, 2021). This means that these counties received an extremely poor rating for the ground level ozone. In 2018, 2019, and 2020, more than 122.3 million people lived in counties that received a rating of “F” (American Lung Association, 2021). According to the Environmental Protection Agency (EPA), ground level ozone forms when nitrogen oxides (NOx) and volatile organic compounds undergo a chemical reaction in the presence of sunlight and heat ("Ground-level ozone basics," 2021). Ground level ozone in high concentrations is extremely detrimental to health. Adults and children with asthma, older adults, people who work outdoors, and people that spend time outdoors are at a significant risk for lung and airway related illness ("Health effects of ozone pollution," 2021). [EPA-HQ-OAR-2019-0055-1206]

The DFW metroplex ranks 17th on the American Lung Association's list of most polluted cities in the country, due in part to both fine particulate matter (PM2.5) and ozone (American Lung Association, 2021). DFW failed to meet federally mandated air quality levels in 2019 (IQAir.com, 2021). Pollutants emitted by cars, power plants, and chemical plants react with sunlight, resulting in elevated surface ozone levels (EPA, 2021). The DFW metroplex has significant numbers of daily commuters traveling to work by private vehicle and plenty of hot, sunny days, providing the perfect environment for ozone pollution to develop. [EPA-HQ-OAR-2019-0055-1206]

Air pollution, and the resulting poor air quality leads to increased morbidity and mortality from respiratory disorders, cardiovascular diseases, cancers, and body systems dysfunctions (Manisalidis et al., 2020). Ozone and particulate matter (PM) are the most prominent air toxins, and the harmful effects are primarily related to lung function. Tissue damage associated with inhalation, affects the conducting airways (upper respiratory tract, bronchi, bronchioles) as well as the alveoli of the lungs, where air/blood oxygen exchange occurs (Steinberg, 1990). Even minute quantities of ozone negatively affect forced expiratory lung volume in healthy young people (Brown, 2008). Asthmatics and sufferers of chronic obstructive lung disease are especially affected by surface ozone. EPA regulations concerning maximum tolerable ozone levels continue to be debated, but really no amount of surface air ozone is good for humans (Levitan, 2018). [EPA-HQ-OAR-2019-0055-1206]

Air pollution directly impacts all residents of the North Texas area and is a significant public health concern. Air quality is an important consideration for all who enjoy outdoor activities, and especially those who have chronic health conditions. According to Air North Texas, 10 counties in the area fall under "non-attainment" for ozone pollution, which means that local air quality is worse than National Ambient Air Quality Standards established by amendments to the Clean Air Act of 1970 (Air North Texas, 2022). In addition, poor air quality disproportionately affects those who belong to minority groups. Black, Latinx, and low- socioeconomic populations are more likely to reside near trucking and freight routes where most of the air pollution is produced (Demetillo, 2021). These communities are excessively exposed to poor air quality, resulting in a near fifteen-year difference in life expectancy (Chaudhary, 2021). In addition, those with pre-existing conditions such as asthma, lung diseases, and heart disease have increased risk of being negatively impacted by air pollution (NSW Government, 2013). [EPA-HQ-OAR-2019-0055-1206]

Air pollution has an impact on the incidence of chronic disease and is considered a risk factor. The proposed EPA rule and improved health outcome projections will reduce the burden of chronic disease. Further, reducing the burden of chronic disease on healthcare resources can contribute towards reducing healthcare costs (Chapel et al., 2017). [EPA-HQ-OAR-2019-0055-1206]

Organization: *Sage Lincoln*

I applaud the EPA’s efforts to reduce pollution from heavy-duty trucks: truck emissions of NOx, PM, CO, and ozone are linked to premature death, respiratory illness, cardiovascular problems, and other health impacts. I support the EPA adopting the most stringent air pollution standards for three reasons:

I. Heavy-duty trucks are a leading source of harmful air pollutants.
II. Vehicle pollution is most concentrated on and near roadways, exposing bicyclists to unsafe levels of pollutants.
III. Decreasing truck emissions and ensuring safe, healthy bicycling can disproportionately benefit low-income individuals. [EPA-HQ-OAR-2019-0055-1073]

I. Heavy-duty trucks are a leading source of harmful air pollutants.

As the EPA acknowledges in its proposed comment, emissions from the transportation sector are a major source of air pollution and can lead to harmful health effects including premature death, respiratory illnesses, and cardiovascular problems. The medium- and heavy-duty vehicle and engine sector is the largest contributor to mobile source emissions of NOx, which reacts in the atmosphere to form smog and particulate matter.1 The health impacts of these pollutants are well documented. For example, PM2.5 alone results in 200,000 deaths per year in the United States.2

1 Heavy-Duty Vehicles, Air Pollution, and Climate Change, CONGRESSIONAL RES. SERVICE (Feb. 11, 2022), https://crsreports.congress.gov/product/pdf/IF/IF12043.

2 Benjamin Bowe et al., Burden of Cause-Specific Mortality Associated With PM2.5 Air Pollution in the United States, JAMA NETWORK OPEN (Nov. 20, 2019).

Currently, over 137 million people in the United States live in regions with unhealthy levels of ozone or particulate pollution.3 Many of these people live in cities: urban areas experience higher levels of truck-related air pollution than most of the country.4 Although diesel vehicles represent just 5 percent of traffic in cities, they emit up to half of urban NOx pollution.5 Furthermore, communities near truck routes exposed to the highest levels of pollution are disproportionately low-income and minority, and face a higher health burden from these pollutants.

3 2022 State of the Air, AMERICAN LUNG ASSOC. (2022), https://www.lung.org/research/sota/key-findings.

5 Kristoffer Tigue, Diesel Emissions in Major US Cities Disproportionately Harm Communities of Color, INSIDE CLIMATE NEWS (Oct. 27, 2021).

More stringent heavy-duty truck emission standards will save lives and help protect the health of the millions of Americans who live in urban areas and near truck routes. [EPA-HQ-OAR-2019-0055-1073]

II. Bicyclists Are Exposed to Dangerous Levels of Air Pollution from Exhaust.

While pollution from vehicles causes regional air quality issues, concentrations of these toxic pollutants are higher closest to traffic, particularly on and adjacent to roads.6 Individuals on or near roads, such as bicyclists, are therefore exposed to extremely high concentrations of pollution.

6 Near Roadway Air Pollution and Health: Frequently Asked Questions, EPA (Aug. 2014).

Bike lanes adjacent to traffic feature very poor air quality: bicyclists are essentially breathing in direct exhaust from vehicles before it has a chance to disperse.7 Studies have shown that this close proximity to traffic exposes bicyclists to pollution levels that greatly exceeds threshold values established as dangerous to human health.8 Just a few feet can make a huge difference for pollution concentration—bicyclists in bike lanes are exposed to 50 percent more NOx and black carbon than on bike paths adjacent to busy streets.9

7 Piers MacNaughton et. al, Impact of Bicycle Route Type on Exposure to Traffic-Related Air Pollution, 490 SCI. TOTAL ENVIRON. 37 (Aug. 15, 2014).

8 Juan F. Franco et al., Air Pollution alongside Bike-Paths in Bogota-Colombia, FRONT ENVIRON. SCI. (Nov. 25, 2016).

9 Piers MacNaughton et. al, Impact of Bicycle Route Type on Exposure to Traffic-Related Air Pollution, 490 SCI. TOTAL ENVIRON. 37 (Aug. 15, 2014).

During exercise, bikers have higher ventilation rates, exposing them to more pollution. Cyclists can breathe nine times more air while biking than resting, increasing exposure to toxic air pollution ninefold.10 This combination of proximity to traffic and higher breathing rate leads to extremely high pollution exposure. Studies are mixed on whether the harm of pollution exposure during cycling outweighs the benefit of cycling: at least some studies have found that the risk of cardiovascular disease from exposure to particulate pollution while exercising outweighed the health benefits of that exercise.11 Either way, even short-term exposure to pollutants while biking increases blood pressure,12 deaths, and cardiovascular- and respiratory-related hospitalizations.13

13 Burden of disease from environmental noise - Quantification of healthy life years lost in Europe, WORLD HEALTH ORG. (2011).

Our understanding of the health impacts of cycling adjacent to traffic is still evolving and ongoing studies are attempting to precisely determine the health impacts of breathing pollution while biking.14 However, it is clear that reductions in truck emissions will reduce the extremely high pollution exposure of bicyclists. [EPA-HQ-OAR-2019-0055-1073]

III. Safe, Healthy Bicycling Disproportionately Benefits Philadelphians and Low-Income Individuals.

The Philadelphia metro area is the 17th most polluted in the country for fine particulate pollution and the 21st most polluted for ozone.15 Philadelphia is also the poorest big city in America: 20 percent of Philadelphia families live in poverty,16 and 43 percent are unable to meet their basic needs.17 Philadelphia residents pay a higher percentage of income on transit fares than commuters in most cities, making public transit potentially cost-prohibitive.18 However, Philadelphia has higher per capita bicycle commuting rates than any of the ten largest cities in the U.S.19

18 The Cost of Commuting for Philadelphians, PEW TRUSTS (July 24, 2019), https://www.pewtrusts.org/en/research- and-analysis/reports/2019/07/24/the-cost-of-commuting-for-philadelphians.

19 Biking to Get Around, BICYCLE COALITION OF GREATER PHILADELPHIA, https://bicyclecoalition.org/resources/commuting/ (accessed May 4, 2022).

Bicycle commuting, where feasible, is an affordable method of transportation: low-income Americans commute by bike more than any other income brackets.20 Furthermore, people of color currently account for the fastest cyclist growth rate.21 Therefore, ensuring bicyclists can travel safely and healthily is an issue of equity. Additionally, as cities nationwide encourage bicycling for its climate, health, and traffic benefits, the EPA should ensure that bicyclists are not forced to breath unsafe levels of pollutants from vehicle exhaust.

20 Brian McKenzie, Modes Less Traveled—Bicycling and Walking to Work in the United States, U.S. CENSUS BUREAU (May 8, 2014), https://www.census.gov/library/publications/2014/acs/acs-25.html.

21 THE NEW MAJORITY: PEDALING TOWARDS EQUITY, BIKE LEAGUE 3 (May 2013), https://bikeleague.org/sites/default/files/equity_report.pdf.

The health effects of truck emissions are serious and well documented. Millions of Americans are exposed to unsafe levels of air pollutants each year because of our current lax standards, and communities near truck routes, urban areas, and bicyclists are disproportionately burdened. For these reasons, I urge the EPA to choose the most stringent standards possible for truck emissions and to improve emissions standards for all other vehicles. [EPA-HQ-OAR-2019-0055-1073]

Organization: *South Coast Air Quality Management District*

A strong low-NOx standard further supports the agency's mission to protect public health. The EPA's own Regulatory Impact Analysis (RIA) reaffirms much of our understanding of the health effects associated with exposure to ozone. Exposure to ambient concentrations of ozone is associated with numerous adverse health impacts including respiratory, metabolic and cardiovascular effects as a result of both short- and long-term exposure.21 The RIA also infers a causal relationship between asthma exacerbation and other respiratory effects and short term NOx exposure.22 It is also worth noting that heavy-duty emissions contribute to ambient levels of air toxics which can expose the affected population to an elevated cancer risk.23 This is significant because in addition to contributing to the formation of PM2.5 and ozone, many VOCs, including benzene, are also considered air toxics.24 [EPA-HQ-OAR-2019-0055-1201-A1, pp.6-7]

Medium- and heavy-duty vehicles generate an outsized share of harmful tailpipe pollution. Though comprising less than 10 percent of all vehicles on the road, trucks are responsible for over 60 percent of all tailpipe NOx and particulate matter (PM) emissions.4 EPA estimates these vehicles will account for 89 percent of on-road NOx emissions, and 32 percent of all mobile source NOx emissions, by calendar year 2045.5 These vehicles also contribute to ambient ozone and carbon monoxide (CO) levels. All of these pollutants are linked to serious health impacts, such as premature death, respiratory illness, and cardiovascular issues, and all have health-based National Ambient Air Quality Standards (NAAQS) developed by EPA.6 One report estimates that NOx and PM emissions from medium- and heavy-duty vehicles nationwide are 'responsible for up to 4,550 premature deaths, 4,290 hospital visits, and 2.7 million incidents of exacerbated respiratory conditions and lost or restricted workdays annually,' resulting in over $53 billion in monetized public health impacts annually.7 [EPA-HQ-OAR-2019-0055-1247-A1, p.2]

Many major metropolitan areas in the U.S., including many in the South like Washington, D.C., Atlanta, and Birmingham, already suffer from elevated concentrations of ozone, NOx, and PM.8 Medium- and heavy-duty vehicle traffic (measured in vehicle miles traveled) is expected to grow by 29 percent through 2050, with higher projected regional growth rates in the Southeast.9 As noted in the Federal Register notice, '72 million people live within 200 meters of a truck freight route,' making exposure to medium- and heavy-duty vehicle tailpipe pollution a serious public health issue nationwide.10 [EPA-HQ-OAR-2019-0055-1247-A1, p.2]

Exposure to this type of pollution is also an environmental justice issue; '[r]elative to the rest of the population, people of color and those with lower incomes are more likely to live near truck routes.'11 This is in part due to zoning practices and land use decisions, including in the South, that have consistently sited highways and commercial and industrial facilities that often rely on frequent truck deliveries in communities of color and low-income communities.12 [EPA-HQ-OAR-2019-0055-1247-A1, pp.2-3]

Heavy-duty truck engines are a significant source of air pollutants that contribute to ambient concentrations of ozone, inhalable particulate matter (PM2.5), and air toxics.6 Exposure to ozone and PM2.5 has serious health effects and is associated with increased risk of premature deaths, emergency room visits, and hospital stays.7 A range of adverse respiratory effects are linked to these pollutants such as asthma, respiratory inflammation, and decreased lung function and growth.8 [EPA-HQ-OAR-2019-0055-1255-A1, p. 4]

6. 87 Fed. Reg. at 17,444.

7. Id. at 17,444-51.

In particular, PM2.5 poses the greatest health risk among air pollutants as the fine particles can lodge deep into the lungs and possibly enter into the bloodstream, causing irregular heartbeat, heart attacks, as well as increased risk of lung cancer.9 Recent evidence also suggests a causal relationship between PM2.5 exposure and a host of other negative health impacts, including male and female reproductive and developmental effects from long-term exposure (i.e., fertility, pregnancy, and birth outcomes), metabolic effects from long-term and short-term exposure, and nervous system effects from short-term exposure.10 Heavy-duty engine emissions also contribute to ambient levels of air toxics, such as benzene, formaldehyde, acetaldehyde, and naphthalene, that are known or suspected to cause cancer and other serious health effects.11 [EPA-HQ-OAR-2019-0055-1255-A1, p. 4]

Diesel pollution from heavy duty trucks and buses is a massive public health threat. Even without considering climate change, the air pollution caused by heavy duty trucks is a environmental justice issue that causes more health issues in frontline and marginalized communities. Diesel pollution worsens asthma and is particularly dangerous to children’s developing lungs. Here in Philadelphia, 21% of children have asthma, which is more than double the national rate. Indoor and outdoor air pollution are major contributors to the high prevalence of asthma in Philadelphia. The air pollution doesn't only affect childrens' health. It increases costs for LMI families, increases absentee rates in school and days missed from work for their parents. It affects childrens ability to learn in school, affecting lifetime income levels for those children. [EPA-HQ-OAR-2019-0055-2737, p.1]

Organization: *Taxpayers Protection Alliance (TPA)*

As pointed out by other commenters such as the Lake Michigan Air Directors Consortium, pollution from diesel vehicles is a significant contributor to ground level ozone.1 In turn, ground level ozone can have an array of adverse effects including respiratory distress and damage to vegetation.2 Emissions pose a particular threat to underserved communities and can exacerbate health and wealth inequalities. Yet, heavy-handed regulations are a crude way to handle this dire threat. As the EPA rightly notes, the highway vehicles targeted play a critical economic role, including, ‘support[ing] local and regional construction, refuse collection, and delivery work to long-haul tractor-trailers that move freight cross-country.’3 [EPA-HQ-OAR-2019-0055-1102-A1, p.1]

Organization: *Tesla, Inc. (Tesla)*

Tesla fundamentally agrees with the agency that: Emissions from heavy-duty vehicles contribute to poor air quality and health across the country, especially in overburdened and underserved communities. Without further reductions, heavy duty vehicles will continue to be one of the largest contributors to mobile source emissions of NOx, which react in the atmosphere to form ozone and particulate matter.32 [EPA-HQ-OAR-2019-0055-1219-A1, p.5]

> 32 EPA, Heavy-Duty 2027 and Beyond: Clean Trucks Proposed Rulemaking (March 2022) at 2.

While comprising less than 10 percent of all vehicles on the road, medium- and heavy-duty trucks account for more than 60 percent of tailpipe NOx and particulate matter (PM) emissions from the on-road fleet; these emissions contribute to poor air quality in many urban areas, including areas with vulnerable populations.33 [EPA-HQ-OAR-2019-0055-1219-A1, p.5]

> 33 See generally, MJ Bradley, Medium- & Heavy-Duty Vehicles: Market Structure, Environmental Impact, and EV Readiness (Aug. 11, 2022) at 4; See also, Union of Concerned Scientists, Ready for Work Now Is the Time for Heavy-Duty Electric Vehicles (Dec. 11, 2019) at 2 (While heavy-duty vehicles make up only 10 percent of all vehicles on roads in the United States, they contribute 45 percent of the transportation sector’s nitrogen oxide pollution, 57 percent of its fine particulate matter pollution, and 28 percent of its global warming emissions).

Indeed, the public health, climate, and economic benefit from much more stringent NOx and GHG emission standards than the EPA proposes cannot be understated. Air pollution is estimated to cause over 200,000 premature deaths in the U.S. each year; with more than half are caused by transportation emissions.34 Recent findings indicate that the U.S. health care costs of air pollution and climate change exceed $800 billion per year.35 Air pollution impacts with pollutants like PM2.5 that are associated with the medium- and heavy-duty sector not only cause premature mortality, cardiovascular disease and respiratory disease but also can affect neurological disorders.36 Other studies suggest that exacerbation of air pollution and heat exposure related to climate change may be significantly associated with risk to pregnancy outcomes in the U.S.37 [EPA-HQ-OAR-2019-0055-1219-A1, p.6]

37 Bekkar, et al. JAMA Open Network, Association of Air Pollution and Heat Exposure with Preterm Birth, Low Birth Weight, and Stillbirth in the USA Systematic Review (June 18, 2020).

These negative effects of air pollution disproportionately harm the most vulnerable populations, including children, the elderly, and residents in low-income and disadvantaged communities.38 Indeed, two-thirds of Americans who live near high-volume roads are people of color and the median household income in these places is roughly 20% below the national average.39 Emissions from heavy-duty diesel trucks are roughly the equivalent to those of 20 to 55 light-duty vehicles on the road. Repeatedly, peer reviewed, government and inter-governmental studies point toward electrification as key to addressing criteria air pollutants, improving air quality, and lower the risk of respiratory illness.40 [EPA-HQ-OAR-2019-0055-1219-A1, p.6]

38 UN Environmental Programme, Young and old, air pollution affects the most vulnerable (Oct. 16, 2018).

40 See e.g., International Panel on Climate Change (IPCC), AR 6 Climate Change 2022: Impacts, Adaptation and Vulnerability (Feb. 28, 2022) at 7-120; USGCRP, National Climate Assessment 4, Volume II, Chapter 29 at Box 29.2 (In transportation, for example, switching away from petroleum to potentially lower GHG fuels, such as

electricity and hydrogen, is projected to reduce local air pollution. In California, drastic GHG emissions reductions have been estimated to substantially improve air quality and reduce local particulate matter emissions associated with freight transport that disproportionately impact disadvantaged communities').

By removing diesel from the heavy-duty equation altogether, BEVs represent a superior solution relative to other approaches that seek to reduce emissions by increasing the efficiency of diesel trucks or via post combustion treatment. As one recent analysis recognized, fully addressing harmful air pollution from trucks used in urban and community areas by 2035 and eliminating pollution from all new trucks and buses by 2040, can provide tremendous public health and welfare benefits, including preventing 57,000 premature deaths by 2050, reducing NOx emission by more than 10M tons, eliminating almost 200,000 tons of PM by 2050, and avoiding 4.7B tons of GHG emissions.41 [EPA-HQ-OAR-2019-0055-1219-A1, p.6]

41 EDF, Clean Trucks, Clean Air, American Jobs (Mar. 4, 2021) at 1.

Indeed, the American Lung Association (ALA) recently estimated that wide-spread transportation electrification across the United States translates into $72 billion in avoided health effects. Electrification would save approximately 6,300 lives per year and avoid more than 93,000 asthma attacks, and 416,000 lost workdays annually due to significant reductions in transportation-related pollution.42 Other studies have found dramatic localized air quality and public health benefits will result for electrifying the heavy-duty fleet.43 [EPA-HQ-OAR-2019-0055-1219-A1, pp.6-7]

42 American Lung Association, The Road to Clean Air Benefits of a Nationwide Transition to Electric Vehicles (March 31, 2022) at 5-6. See also, ZETA, Medium- and Heavy Duty Electrification: Weighing the Opportunities and Barriers to Zero Emission Fleets (Jan. 26, 2022) at 8-9.

43 See, Texas A&M, Tailpipe Emission Benefits of Medium- and Heavy-Duty Truck Electrification in Houston, TX (Apr 14, 2021) (Finding that by electrifying 40% of the predominantly diesel-fueled MHDVs in the eight-county area, Texans could avoid 21 tons per day of NOx — over a quarter of the 80 tons per day emitted by greater Houston’s on-road traffic. This could be achieved by electrifying a little over 60,000 MHDVs, about 1% of all the vehicles in greater Houston. By comparison, it would take 3.8 million light duty vehicles to achieve the same amount of NOx reductions. Electrification of MHDVs is the quickest way to take the biggest bite out of greater Houston’s NOx emissions.)

Organization: *Valeria Trujilo Aguilar*

EPA Should Support and Advance with Lower NOx Emission Standards for New HDV Engines Proposed in Option 2 of the Cleaner Trucks Initiative

As a private citizen residing in Denver, Colorado which ranks #7 among the most polluted cities in the U.S. by ozone concentration and receiving a grade of F in both ozone and particle pollution graded by the American Lung Association “State of the Air” Report2 methodology which uses quality-assured data from the EPA in accordance with current National Ambient Air Quality Standards for O3 and PM2.5. IQAir3 estimates that air quality in Denver is slightly declining from 2017-2020 at 7.4 ug/m3, 8 ug/m3, 8.2 ug/m3 and 8.7 ug/m3 respectively. Ozone pollution represents Denver's main air quality challenge with motor vehicle emissions been the single largest contributor4. Pollutants from HDV pose health risks at all stages of life accounting for significant risk of premature births and premature deaths due to the adverse effects on nearly every organ system in the body5. [EPA-HQ-OAR-2019-0055-1223]

The EPA6 recognizes that climate change and ozone pollution are highly intertwine. Ozone is formed through photochemical interactions between nitrogen oxide compounds (NOx) and volatile organic compounds (VOCs)7. Scientists suggest that there is a strong correlation between higher ozone levels and higher daylight temperatures8. Ozone levels do not always increase with higher temperatures when VOCs to NOx ratios are low, suggesting that regulating the sources of VOCs and NOx have the potential to alter the harmful health effects of ozone levels even in the presence of higher temperatures; an inedible threat of GHG contributing to climate change9. The EPA cites automobiles, trucks, and buses as significant contributing sources of VOCs and NOx emissions10. Thus, advocating for the maximum NOx stringency standards for new heavy-duty vehicles has the potential to minimize the harmful effects of ozone pollution by decreasing the sources that contribute to its formation which continue to disproportionally affect susceptive groups in ozone polluted cities like Denver. Mapping for Environmental Justice published a map for the State of Colorado in 2020 that shows communities of color breathe nearly twice as much diesel pollution than white communities11. Organization: *WE ACT for Environmental Justice*

The medium- and heavy-duty truck sector is the second largest contributor of climate change causing greenhouse gas emissions in the transportation sector and the largest source of harmful smog and soot-forming nitrogen oxides (NOx) in the United States.1 It is well known that NOx and particulate matter emitted from diesel and gasolene trucks and buses create poor air quality and severe health impacts.2 An analysis of EPA data revealed that by 2023, diesel emissions can cause nearly 9,000 premature deaths, 3,800 heart attacks, 173,067 cases of respiratory symptoms, and more than 2,963 asthma-related visits to the emergency room.3 [EPA-HQ-OAR-2019-0055-1347-A1, p.1]

Organization: *William F. Limpert*

The American people want and deserve clean air.

A recent study by Harvard University and the Universities of Birmingham and Leicester in the United Kingdom found that the fossil fuel industry causes 8,000,000 premature deaths worldwide each year, including 350,000 in the United States. In that regard it is possible that EPA's very concerning estimates of increased health costs, premature deaths, hospital emissions, asthma and allergic rhinitis symptoms, and lost days from school and work resulting from failure to act may actually underestimate the benefits these rules would bring to us, and especially to those of us with limited income. We have known for a long time that the true cost of using fossil fuels is much higher than what we are paying at this time. That true cost may very well fall to our children, grandchildren, and all those who follow us, even if they never use fossil fuels. [EPA-HQ-OAR-2019-0055-1190]

I would like to comment on the benefits of better visibility that these rules would bring to us. Good atmospheric visibility provides clearer vision, more natural colors, increased productivity, and better emotional health. My wife and I formerly owned a home and property in Bath County, in western Virginia. This is a sparsely populated area with little traffic or industrial activity. The air quality there was by far the best that we have experienced in our lifetimes. We could see fine detail far into the distance. The night sky was filled with stars. Colors were greatly enhanced by the good visibility. We were always emotionally uplifted when we were there, and I think other local residents were as well. Despite very large political differences and life experiences we all got along very well. Despite being physically separated we all felt a sense of community and togetherness. If someone had a problem, others came to help. In most cases when cars passed on the road both parties waved. Days spent there were the happiest days of our lives. I really think that the great visibility from little fossil fuel use in that area contributed heavily to all of these benefits. These benefits will convey to all of us with better outdoor visibility under the proposed rules. [EPA-HQ-OAR-2019-0055-1190]

Organization: *World Resources Institute (WRI)*

In addition to these ambient conditions, also of concern are the on-board emissions from the diesel school buses that represent more than 90 percent of the 480,000 school buses on the road today, transporting over 20 million students daily and driving 3.3 billion miles annually. Children are particularly susceptible to the negative health effects of diesel exhaust from school buses, a known carcinogen linked to reduced lung development and increased risk for asthma and pneumonia in children, among other risks. In addition, there is evidence that reducing diesel exhaust exposure can improve not only students' respiratory health, but also their academic outcomes. [EPA-HQ-OAR-2019-0055-1298-A1, p.2]

Electric school buses, which produce zero tailpipe emissions, are the healthiest solution for all students, bus drivers, and the communities they travel through. Because students from low-income communities are more likely to ride a school bus - 60% of students from low-income families ride the bus to school, compared to 45% of students from families with higher incomes - a more stringent rule will advance the transition to an electric school bus fleet and simultaneously help address this transportation inequity. [EPA-HQ-OAR-2019-0055-1298-A1, p.2]

EPA studies confirm that medium- and heavy-duty vehicles also generate 23 percent of the transportation sector's greenhouse gas emissions (GHG), contributing to the severity of climate change impacts, including heat waves, drought, sea level rise, extreme climate and weather events, coastal flooding, and wildfires. Some populations may be especially vulnerable to these and other climate change impacts, including low-income communities, people with disabilities, people of color, and Indigenous populations. Furthermore, studies (such as the recent 'Zeroing in on Healthy Air' from the American Lung Association) show that regulations and policies designed to reduce GHG emissions, such as through accelerating electric transportation, will have the added benefit of reducing other forms of pollution, such as air toxics and particular matter, that impact public health and disproportionately impact overburdened communities. [EPA-HQ-OAR-2019-0055-1298-A1, p.2]

Organization: *Yellowstone Integrated Architecture and Construction*

Dangerous nitrogen oxides and other pollution that heavy duty vehicles like trucks and buses spew into our air hurt communities of color and low wealth communities first and worst, but affect all of us, especially our children. [EPA-HQ-OAR-2019-0055-2816, p.1]

Diesel pollution from heavy duty trucks and buses is a massive public health threat. Diesel pollution worsens asthma and is particularly dangerous to children's developing lungs. [EPA-HQ-OAR-2019-0055-2816, p.1]

EPA Summary and Response

Summary:

Commenters agreed that emissions from heavy-duty trucks are a significant contributor to air pollution, including concentrations of ozone and $PM_{2.5}$, which are negatively impacting human and environmental health across the nation. Commenters noted that NOx emissions are higher in urban driving. Commenters requested a national standard for heavy-duty trucks both as soon as possible and as stringent as possible.

Many commenters noted that they need this rule to protect the health of children and future generations, and that emissions from trucks impact children's health in many ways, including asthma incidence. Commenters also mentioned other sensitive populations, e.g., pregnant women, older adults, and those with existing diseases, that are at risk from pollution by vehicles. Commenters noted that health and environmental impacts of criteria and toxic pollutants are made worse by the ongoing impacts of climate change (pollution from heavy duty trucks can have a larger impact on populations already affected by climate change).

Multiple commenters stated that visibility in Class I and other areas is negatively impacted by NOx emissions, especially in the wintertime, and that these standards will be beneficial throughout the year. A commenter emphasized that good atmospheric visibility provides clearer vision, more natural colors, increased productivity, and better emotional health. Another environmental effect noted by commenters is deposition. They stated that deposition of nitrogen and other pollutants is a problem and mobile source emissions are a significant contributor to deposition. They stated that this is demonstrated in the air quality modeling done for the Chesapeake Bay TMDL. They also stated that cleaning up air can help waterways too.

Numerous commenters mentioned that EJ communities are experiencing disproportionate health effects and being impacted by emissions of criteria and toxic pollutants from heavy duty trucks.

One commenter specifically noted that bicyclists are exposed to dangerous levels of air pollution from exhaust and that reductions in truck emissions will reduce the extremely high pollution exposure of bicyclists. They also noted that bicycle commuting, where feasible, is an affordable method of transportation: low-income Americans commute by bike more than any other income brackets and people of color currently account for the fastest cyclist growth rate. Therefore, ensuring bicyclists can travel safely and healthily is an issue of equity. Additionally, as cities nationwide encourage bicycling for its climate, health, and traffic benefits, the EPA should ensure that bicyclists are not forced to breathe unsafe levels of pollutants from vehicle exhaust.

One commenter provides an analysis of the air quality and human health benefits of electrifying 40 percent of new Class 4-8 single unit trucks, 40 percent of new Class 8 short haul (day cab) tractors, and 80 percent of all transit and school buses, in the 2027-2029 timeframe; the commenter's results show meaningful reductions in GHGs and NOx emissions through 2050, which would lead to improvements in health effects and environmental effects.

Multiple commenters mentioned or referenced the American Lung Association's State of the Air report. The State of the Air report highlights the number of Americans who continue to live in places with failing grades for unhealthy levels of particle pollution or ozone.

Response:

Section II of the preamble describes the health and environmental effects caused by emissions of NOx and other criteria and toxic pollutants from heavy-duty trucks. EPA agrees that emissions from heavy-duty trucks contribute to concentrations of ozone, NO_2, and $PM_{2.5}$, which are all associated with impacting human health. Heavy-duty trucks and buses continue to contribute significantly to air pollution at the local, regional, and national level, often disproportionally affecting communities of color and low-income populations and this final rule will achieve significant improvements in air quality, including for those disproportionately affected. EPA also agrees that protecting children's health is a high priority; we added text in preamble Section II.B describing why children can have increased vulnerability and susceptibility for adverse health effects from air pollution exposures.

Emissions from heavy-duty trucks also impact environmental health through contributing to deposition impacts and visibility decrements, as well as contributing to ozone that harms vegetation.

We are finalizing new standards for diesel engines over a new low-load duty cycle to capture operation at lower speeds and loads that would represent urban driving (see preamble section III for more information). Our responses to comments on stringency of the criteria pollutant standards can be found in Section 3. Our responses to additional, more general comments in support of the proposed rule, advocating a more stringent approach, or in opposition to the rule, can be found in Sections 1.1, 1.2., and 1.3. Finally, our responses to comments about the EJ need for this rule can be found in Section 23.

2.1.1 Emissions from Heavy-Duty Trucks are underestimated

Comments by Organizations

Organization: *District of Columbia Department of Energy and the Environment (DOEE)*

Moreover, the modeled NOx contribution from HDVs shown in Figure 2 is potentially underestimated because EPA has not yet incorporated high emitting heavy-duty trucks, such as glider vehicles and HDVs with tampered emission control systems into their mobile source emissions models. In-use testing data suggests that real-world NOx emissions are higher than modeled estimates, underscoring the need to achieve substantial NOx emission reductions from the heavy-duty diesel truck sector.2 [EPA-HQ-OAR-2019-0055-1299-A1, pp. 2 - 3]

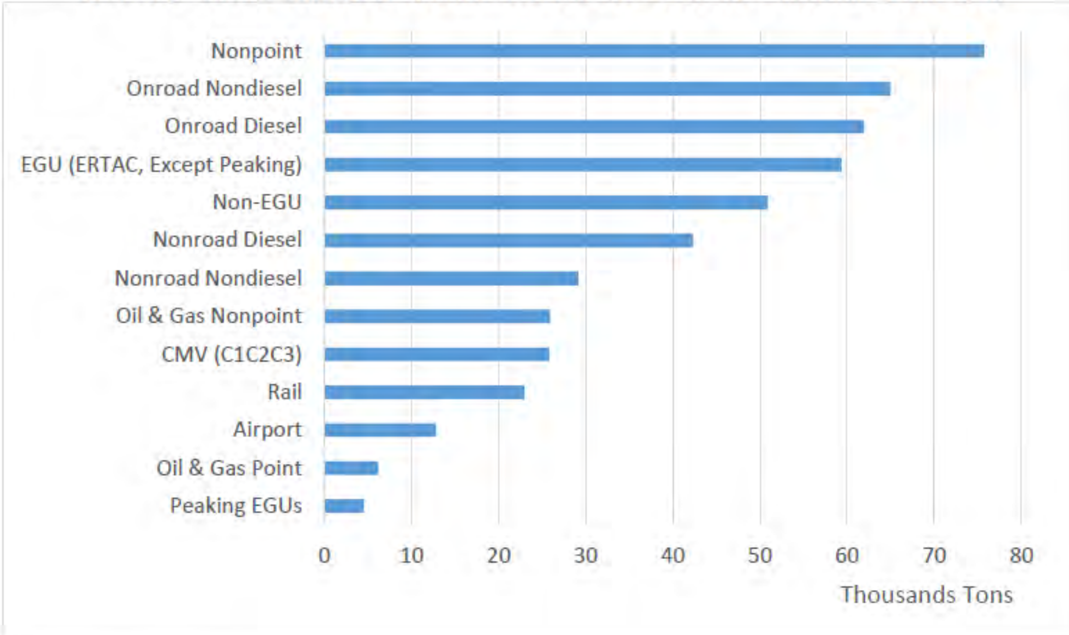
> 2. Tan, et al., "On-Board Sensor-Based NOx Emissions from Heavy-Duty Diesel Vehicles," Environmental Science and Technology, 53: 5504-5511 (2019).

Organization: *Maine Department of Environmental Protection (Department)*

Regionally, heavy-duty vehicles are the third largest source of NOx emissions as illustrated in Figure 3. Moreover, the modeled NOx contribution from HDVs shown in Figure 3 is potentially underestimated, because the mobile source model used in developing the inventory does not account for high emitting heavy-duty trucks, such as glider vehicles and HDVs with tampered emission control systems. [EPA-HQ-OAR-2019-0055-1288-A1, p.4]

> 9 Tan, Y., et al., 'On-Board Sensor-Based NOx Emissions from Heavy-Duty Diesel Vehicles,' Environmental Science and Technology, 53: 5504-5511 (2019). DOI: 10.1021/acs.est.8b07048.

Figure 3
Modeled Ozone Season NO_x Emissions in the OTR for Calendar Year 2023



Source: OTC

Organization: *Northeast States for Coordinated Air Use Management (NESCAUM)*

The modeled NOx contribution from HDVs shown in Figure 4 is potentially underestimated because the mobile source model used in developing the inventory does not account for high emitting heavy-duty trucks, such as glider vehicles and HDVs with tampered emission control systems. In-use testing data suggest that real-world NOx emissions are higher than modeled estimates, underscoring the need to achieve substantial NOx reductions from the heavy-duty diesel truck sector.16 [EPA-HQ-OAR-2019-0055-1249-A1, p. 7]

16. Tan, Y., et al., “On-Board Sensor-Based NOx Emissions from Heavy-Duty Diesel Vehicles.” Environ. Sci. Technol., 53: 5504-5511 (2019). DOI: 10.1021/acs.est.8b07048.

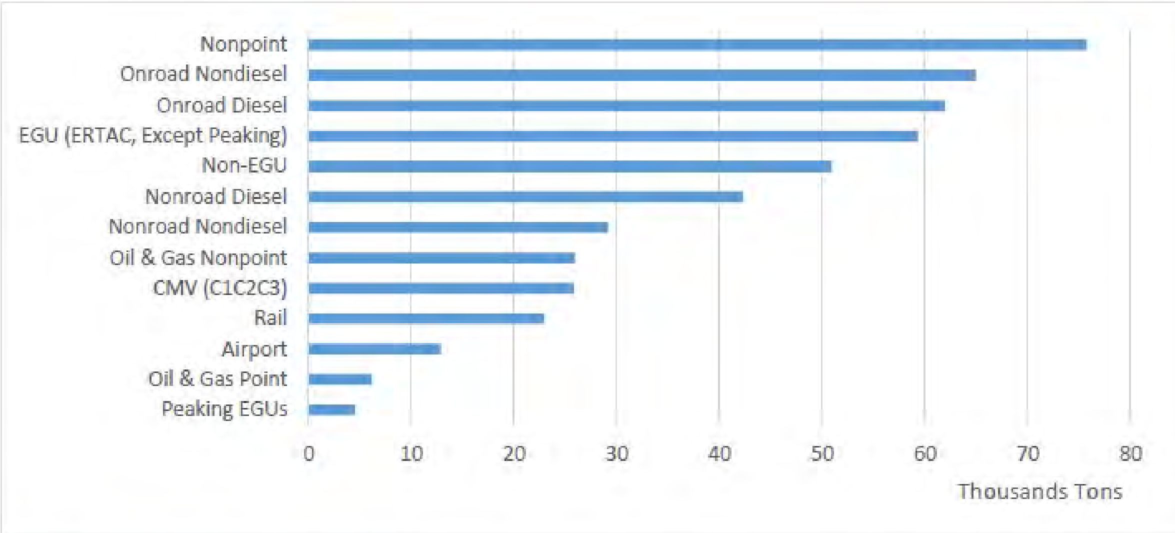


Figure 4: Modeled NOx Emissions in the Northeast (calendar year 2023).

EPA Summary and Response

Summary:

Commenters noted that modeled NOx emissions from heavy-duty trucks in the figures included as part of the comments are potentially underestimated because the modeling done to generate the NOx inventory did not account for glider kits and tampered vehicles. Commenters stated that this could mean that heavy-duty trucks are an even larger contributor of NOx emissions, compared to what's shown in the figures.

Response:

Thank you to the commenters for providing this information to support taking action on heavy-duty engines and vehicles. EPA agrees that the earlier versions of MOVES, such as the one used to generate the NOx inventory in the referenced OTC figure, did not fully account for the high-emitting heavy-duty vehicles. However, as described in Chapter 5.2.2 of the draft RIA, EPA used an updated version of MOVES (MOVES_CTI_NPRM) that accounts for glider vehicles in the analysis done for the proposal. EPA also is aware of intentional tampering of emission control systems that could increase the emissions of NOx from heavy-duty trucks. Although we account in our model for some level of tampering and mal-maintenance, such as NOx aftertreatment malfunction, we recognize the need to update the tampering and mal-maintenance effects in MOVES, particularly to incorporate recent data surveying intentional tampering in heavy-duty trucks; we are continuously working to update our inventory and inventory modeling tools.

2.1.2 Health impacts of NO_2

Comments by Organizations

Organization: *Various Academic Researchers*

Strengthening HDV NOx emissions standards is necessary to protect children's health

NOx emissions are precursors to PM2.5 and ozone, which contribute tens of thousands of premature deaths each year in the U.S. Heavy-duty trucks and buses are responsible for a substantial share of PM2.5- and ozone-attributable premature deaths. Traffic-related air pollution is responsible for an estimated 22,000 premature deaths in the U.S. each year, about 19% of all PM2.5- and ozone-attributable deaths in the U.S.1 On-road diesel vehicles contribute an estimated 43% of these traffic-related air pollution deaths. The vast majority of diesel vehicles in the U.S. are the heavy-duty vehicles that would be affected by the proposed emissions standards. [EPA-HQ-OAR-2019-0055-1220-A1, p. 1]

> 1. Anenberg, S. C.; Miller, J.; Henze, D. K.; Minjares, R.; Achakulwisut, P. The Global Burden of Transportation Tailpipe Emissions on Air Pollution-Related Mortality in 2010 and 2015. Environ. Res. Lett. 2019, 14 (9), 094012. https://doi.org/10.1088/1748-9326/ab35fc.

NOx emissions also produce NO2, which is associated with respiratory effects, and in particular the development of new cases of asthma amongst children. The 2016 EPA Integrated Science Assessment for NO2 concluded that "There is likely to be a causal relationship between long-term NO2 exposure and respiratory effects based on the evidence for development of asthma (Section 6.2.9, Table 6-5). The conclusion is strengthened from the 2008 ISA (Table ES-1) because where previous epidemiologic findings were inconsistent, recent studies consistently observe NO2-related increases in asthma development in children who are followed over time and are supported by previous experimental studies." An American Thoracic Society workshop report published in 2019 also "found that long-term exposure to air pollution, especially metrics of traffic-related air pollution such as nitrogen dioxide and black carbon, is associated with onset of childhood asthma." In 2017, a large meta-analysis of epidemiological studies found a relative risk of 1.26 (95% confidence interval, 1.10-1.37) for each 10 ppb increase in NO2.2 [EPA-HQ-OAR-2019-0055-1220-A1, p. 1]

> 2. Khreis, H.; Kelly, C.; Tate, J.; Parslow, R.; Lucas, K.; Nieuwenhuijsen, M. Exposure to Traffic-Related Air Pollution and Risk of Development of Childhood Asthma: A Systematic Review and Meta-Analysis. Environment International 2017, 100, 1–31. https://doi.org/10.1016/j.envint.2016.11.012.

Given the large burden of NO2 concentrations on children's respiratory health throughout the U.S. and the important contribution of HDV NOx emissions to those concentrations, strengthening NOx emissions limits for HDVs is necessary to protect children's health. [EPA-HQ-OAR-2019-0055-1220-A1, p. 2]

EPA Summary and Response

Section II of the preamble describes the health and environmental effects caused by emissions of NOx and other criteria and toxic pollutants from heavy duty trucks. EPA agrees that reducing NOx and other emissions from heavy-duty trucks protects children's health.

2.2 National Ambient Air Quality Standards (NAAQS)

Comments by Organizations

Organization: *California Air Pollution Control Officers Association (CAPCOA)*

As U.S. EPA is aware, California faces some of the nation's most significant air quality challenges. The state's largest facilities which include power plants and refineries, as well as our significant manufacturing industries are subject to the most stringent emissions standards nationally if not worldwide. As a result, NOx emissions have been reduced by approximately 90% through decades of implementation of strong stationary source control measures. However, much of the state remains in non-attainment of federal ambient air quality standards. [EPA-HQ-OAR-2019-0055-1253-A1,p.1]

For example, nearly 90% of California's 40 million residents live in areas that do not meet the 2015 federal ozone standards. These issues are especially acute in disadvantaged communities where residents often face additional challenges including exposure to air toxics from the transportation sector and are more vulnerable to the impacts of climate change including significantly increased risk from wildfires and wildfire smoke. [EPA-HQ-OAR-2019-0055-1253-A1, p.2]

The reason for this continued non-attainment is primarily due to emissions from the transportation sector which continues to be heavily reliant on the combustion of fossil fuels. Mobile sources are the largest contributor of criteria pollutant, toxic, and anthropogenic greenhouse gas emissions throughout the state. CARB data shows that mobile sources account for 70-80% of overall NOx emissions. To meet federal and state clean air standards and protect public health, this pollution must be cut by up to 80% by the mid-2030s. While air districts do not have authority to regulate mobile sources, we have worked diligently to implement incentive programs like the Moyer program which since its inception in 1998 has enabled the voluntary replacement, scrappage, or repower of over 68,000 engines resulting in reduction of more than 198,000 tons of NOx and Reactive Organic Gases, and reduction of over 7,300 tons of particulate matter. Additionally, CARB's Heavy-Duty Omnibus Regulation which was adopted in 2020 is expected to reduce NOx by 24 tons per day in 2031. [EPA-HQ-OAR-2019-0055-1253-A1, p.2]

Despite these significant efforts by air districts and CARB, federal action to reduce emissions is critical if we are to attain the National Ambient Air Quality Standards. For example, data shows that in the South Coast air basin, considering only emissions from ships, locomotives, and aircraft which are under federal authority, the region needs an additional 46 tons per day of NOx reductions by 2023 to attain standards in a timely manner. When also considering the emissions from on-road heavy-duty trucks that are subject to federal authority, the region needs a total of 67 – 69 tons per day of NOx reductions from federal sources. Extrapolating this example to the rest of California, it is clear that without significant progress in reducing mobile source emissions, especially at the federal level, it will be extremely difficult if not impossible to meet our air quality mandates. Absent strong federal action, extreme nonattainment areas such as the South Coast and San Joaquin Valley air basins face Clean Air Act penalties and sanctions due to mobile source emissions under federal jurisdiction. Such air districts will be forced to implement additional stationary source regulations that are much less cost-effective than federal mobile source measures and in regions that already impose the most stringent regulations in the nation. To this end, CAPCOA strongly encourage U.S. EPA to promulgate technology forcing regulations in the mobile sector that are directly and solely under U.S. EPA authority that yield as much emissions reductions as possible as quickly as possible. The health of our residents depends on it. [EPA-HQ-OAR-2019-0055-1253-A1, p.2]

Organization: *California Association of Sanitation Agencies (CASA)*

Even if all stationary sources had zero emissions, some air basins (including the South Coast Air Basin) wouldn’t be in attainment with national ambient air quality standards for ozone. Failure to comply with federal standards could result in the loss of billions of dollars in federal highway funds and a permit moratorium (as stated by the South Coast Air Quality Management District (SCAQMD)). For example, the Clean Air Act (CAA) requires the South Coast Air Basin, which is in extreme nonattainment for ozone, to come into compliance by 2023. If this deadline is not achieved, CAA Sections 179 and 185 allow the USEPA to impose the following sanctions: withhold federal highway funding and increase offsetting requirements and impose an annual penalty on major stationary sources. Some public wastewater agencies have estimated the potential penalty to exceed $1,000,000 per year. Thus, these Proposed Standards are essential to air basins for limiting ozone production prior to federal attainment deadlines, while also providing the necessary options of heavy-duty vehicles for critical operations as described in this comment letter. [EPA-HQ-OAR-2019-0055-1301-A1, p.1]

Organization: *Capital Area Council of Governments (CAPCOG) and Central Texas Clean Air Coalition (CAV)*

As of 2020, the region’s design value for ozone (O3) is at 93% of the federal limit and 80% of the annual fine particulate matter (PM2.5) limit for the National Ambient Air Quality Standards (NAAQS). While the CAC will continue to do its part to reduce emissions through voluntary programs within our region, as EPA’s proposed rule indicates, heavy-duty engines will continue to be one of the largest contributors to mobile source nitrogen oxides (NOx) emissions. [EPA-HQ-OAR-2019-0055-1274-A1, p.1]

Air quality modeling shows that NOx emissions are responsible for about 99% of the local, state, and national contribution to high O3 levels within the region. In 2028, heavy-duty vehicles will account for just 7% of the region’s weekday vehicle miles traveled (VMT) but 46% of the region’s on-road NOx emissions. [EPA-HQ-OAR-2019-0055-1274-A1, p.1]

Organization: *Clean Energy Ventures et al.*

We believe that EPA's Clean Trucks Plan, of which this Proposal is a critical component, is critical to helping states attain and maintain the National Ambient Air Quality Standard for Ozone, to providing improved health to residents of disadvantaged communities that continue to be burdened by disproportionate levels of diesel pollution, and to ensuring that the heavy-duty engine and vehicle sector will play its part in helping our nation meet our critical climate goals. [EPA-HQ-OAR-2019-0055-2339-A2, pp.1-2]

Organization: *ClearFlame Engine Technologies (ClearFlame), Remora, and SixWheel*

More than 127 million Americans live in areas that either have not attained the 8-hour National Ambient Air Quality Standard. These Americans need the emissions reductions on the fastest time frame possible. [EPA-HQ-OAR-2019-0055-1329-A2, p. 2]

Organization: *Coalition for Clean Air*

These emissions prevent most of the state from meeting national ambient air quality standards set to protect public health, with the South Coast having the worst smog – and the San Joaquin Valley the worst particulate matter -- in the entire country. That means nearly all Californians encounter unhealthful air quality days. That results in lost days at school, emergency room visits and hospitalizations, and lost days at work, not to mention human suffering. One 2008 study that remains relevant conservatively estimated that pollution in the San Joaquin Valley and the Los Angeles air basins results in a cost of about $28 billion annually. [EPA-HQ-OAR-2019-0055-1139-A1, p.1]

Organization: *Colorado Energy Office, et al.*

Environmental impacts from the transportation sector—and the resulting health and economic consequences—are a major concern. Greenhouse gas emissions from vehicles are the top source of emissions in Colorado and a significant portion of the population lives in an area of the state that is soon to be classified as a severe ozone nonattainment area by the US Environmental Protection Agency. Transportation is one of the two largest sources of ozone precursors along with oil and gas production, largely due to NOx emissions from medium and heavy duty vehicles, and reducing transportation emissions is a critical strategy to meet federal health-based air quality standards. [EPA-HQ-OAR-2019-0055-1297-A1, p.1]

Organization: *Connecticut Department of Energy and Environmental Protection (CTDEEP)*

For almost 50 years, Connecticut's citizens have suffered the public health and economic impacts from ozone nonattainment. This past year, Connecticut experienced twenty-one days with unhealthy ozone levels, and on April 13, 2022, EPA published a public notice2 proposing to reclassify Fairfield, New Haven, and Middlesex Counties as 'severe' nonattainment with respect to the 2008 national ambient air quality standard or NAAQS for ground level ozone. The importance of NOx emissions reductions to addressing ozone nonattainment is well documented and reaffirmed by EPA in 20163 in its response to Connecticut and several other states and jurisdictions reaffirming the urgent need to reduce NOx emissions that ‘significantly contribute to ozone and fine particulate problems’ noting that the parties pointed to the ‘significant contribution of heavy-duty vehicles to NOx in their areas.’ 4 [EPA-HQ-OAR-2019-0055-1306-A1, pp.1-2]

2 see, 87 Fed. Reg. 21825

3 U.S. EPA, ‘Memorandum in Response to Petition for Rulemaking to Adopt Ultra-Low NOx Standards for On-Highway Heavy-Duty Trucks and Engines,’ December 20, 2016. Available at https://www.epa.gov/sites/production/files/2016-12/documents/nox-memorandum-nox-petition-response-2016-12-20.pdf (accessed April 25, 2022).

4 81 Fed. Reg. 73478 (Oct. 25, 2016), at 73523.

Past ozone control strategies for NOx have centered around Point Source Electrical Generating Units (EGUs). EGU based strategies have been effective in reducing the long-range pollutant transport into Connecticut. However, mobile source NOx emissions dominate ozone production. Figure 1 is a graphic of contribution modeling done by the Ozone Transport Commission (OTC) which depicts sector contributions to Connecticut’s Westport monitor. On-road diesel emissions, contributing 11% of NOx emissions, constitute a major share of ozone production at this critical nonattainment monitor. States’ modeling efforts continue to yield important information about the role of widespread NOx emissions in contributing to ozone nonattainment in Connecticut. [EPA-HQ-OAR-2019-0055-1306-A1, p.2]

Figure 2 is a high-resolution gridded NOx inventory (1km). This inventory was mapped for southwest Connecticut and New York City (without EGU point sources) to show where emissions are concentrated. At this resolution, the NOx emissions along the major highways are evident. As the Westport monitor evidences, the impact of on-road mobile emissions continues to climb and account for a large percentage of the ozone produced in our state. Connecticut urges EPA to act swiftly to significantly reduce NOx emissions from HD trucks as part of this proposal. [EPA-HQ-OAR-2019-0055-1306-A1, p.3]

Actual nitrogen dioxide emissions (NO2) concentrations can also be assessed through satellite technology which has evolved to a point where NO2 can be resolved on an urban scale. The Tropospheric Monitoring Instrument (TROPOMI) satellite map in Figure 3 shows averaged monitored NO2 concentrations for the summer of 2021. Concentrated areas of NO2 emissions in urban centers occur just upwind of nearby ozone non-attainment areas. Air pollution from the transportation sector is not just a state environmental or transportation issue; it is a national issue that requires EPA to implement a federal program to achieve deep NOx reductions from HD trucks. The transportation sector in general, and the HD sector in particular, involves the shipping of freight across state lines. Effectively addressing this sector at the federal level is imperative to putting Connecticut, and many other jurisdictions across the country,7 on the path to achieving health based NAAQs and to protecting our most vulnerable communities. [EPA-HQ-OAR-2019-0055-1306-A1, p.3]

7 See NACAA_Comments-EPA_HD_Truck_NPRM-051622lh.pdf (4cleanair.org) p. 4-8

Figure 2 States have limited authority to address transportation-related emissions, nonetheless we have been active partners with EPA in reducing transportation related air pollution. In Connecticut, we continue to implement a ‘whole of government approach’ to finding innovative state air quality and transportation solutions to improve air quality, reduce climate pollution, protect public health and enhance economic competitiveness. Connecticut has been a leader in the electrification of the transportation sector, joining the seven state Zero Emission Vehicle MOU in 2013 and through the creation of clean car incentive programs like the California Low Emission and Zero Emission Programs. Connecticut is also one of fifteen states that has adopted these standards because they are more protective of public health and the environment than the federal standards. Since 2015, Connecticut has also implemented the Connecticut Hydrogen and Electric Automobile Program Rebate (CHEAPR), a first of its kind rebate program that incentivizes the purchase of electric vehicles at the point of sale. Connecticut is also a signatory the Multi-State Medium and Heavy Duty Zero-Emission Vehicle Memorandum of Understanding to advance the rapid and equitable electrification of trucks and buses. In addition, recently passed legislation, Public Act 22-25 which authorizes several programs for medium and heavy-duty vehicles and adopts aggressive procurement targets too incorporate zero-emission vehicles and transit buses into our state fleet. [EPA-HQ-OAR-2019-0055-1306-A1, p.4]

Organization: *Delaware Department of Natural Resources and Environmental Control (DNREC)*

All combustion engines produce NOx and although technology has advanced in recent years, more must be done to reduce NOx emissions from mobile sources. Cutting NOx and PM emissions from the trucking industry is vital for improving public health and meeting National Ambient Air Quality Standards. [EPA-HQ-OAR-2019-0055-1200-A1, p.2]

Delaware’s process for attaining and maintaining the NAAQS is complex, costly, and time consuming, but without more protective vehicle emission standards, Delaware will not meet air quality goals. [EPA-HQ-OAR-2019-0055-1200-A1, p.3]

Organization: *District of Columbia Department of Energy and the Environment (DOEE)*

The District has set ambitious goals for NOx emission reductions from heavy-duty vehicles through our Clean Energy Omnibus Amendment Act of 2018 (D.C. Law 22-257), which mandates that 100 percent of public buses be zero-emission by 2045. Additionally, the District has signed on to the Multi-State Medium and Heavy-Duty Zero Emission Vehicle Memorandum of Understanding (MHD ZEV MOU), committing to a phase out fossil fuel-burning medium- and heavy-duty truck and bus sales by 2050. However, both of these programs function in a longer time horizon and the District needs NOx reductions from the medium and heavy-duty vehicle sector sooner in order to attain and maintain the ozone NAAQS. [EPA-HQ-OAR-2019-0055-1299-A1, p. 3]

Organization: *Elders Climate Action*

ECA, its chapters and members have a stake in this decision both because 1) we are the elders of families whose health and well-being are personally affected by exposure to the hazardous air pollution conditions existing in 230 urban counties where the NAAQS for ozone and/or PM2.5 are violated. [EPA-HQ-OAR-2019-0055-1218-A1, p. 1]

ECA requests this action to – 2) optimize the emission reductions needed from HD on-road vehicles to ensure attainment of the ozone and PM2.5 NAAQS within the deadlines established by the CAA rather than delaying attainment until 2045 for some areas, and not attaining at all in New York City, Houston, South Coast and San Joaquin Valley; and [EPA-HQ-OAR-2019-0055-1218-A1, p. 1]

The need for national zero emission standards is greatest in the urban areas that EPA has designated “extreme” (South Coast AQMD) and “severe” (San Joaquin Valley AQMD), or recently bumped-up to “serious” for ozone. NOx emissions from HDVs are a primary contributor to their numerous elevated violations of the ozone NAAQS. These areas are not able to achieve sufficient emissions reductions to attain the NAAQS without significant reductions from HDVs. We submit modeling to show the potential emission reduction benefits of the action we request in South Coast and San Joaquin Valley where the attainment deadlines are 2035 and 2031, respectively. [EPA-HQ-OAR-2019-0055-1218-A1, pp. 3 - 4]

This statutory standard applies to emissions of four listed criteria pollutants, and subsection 202(l)(2) establishes a similar statutory directive for control of “hazardous air pollutants from motor vehicles” (including benzene and formaldehyde listed by law, 1,3 butadiene and other pollutants identified by EPA as “mobile source air toxics”). [EPA-HQ-OAR-2019-0055-1218-A1, p. 6]

These statutory mandates do not directly apply to GHG pollutants. However, they do apply to nitrogen oxides (NOx) which are governed by a NAAQS for NO2, by the NAAQS for ozone which requires the control of nitrogen oxides as precursors to the formation of ozone in the atmosphere, 1 and the NAAQS for PM2.5 which governs NOx emissions as a precursor to the formation of nitrates measured as a fine particle (PM2.5). EPA explains that this proposed HDV rule is intended to control NOx emitted from HDVs for the purpose, among others, of achieving reductions needed for attainment of both the ozone and PM2.5 NAAQS. [EPA-HQ-OAR-2019-0055-1218-A1, p. 6]

1. 40 CFR Part 50, section 50.9, 50.10.

The failure to attain the ozone NAAQS in 230 urban counties where 135 million Americans reside is a perpetual air pollution pandemic that has burdened millions of children with a lifetime of asthma and shortened millions of American lives over the last 50 years. This public health crises will continue to make our cities unhealthy places to raise our children and for elders to reside for decades to come. [EPA-HQ-OAR-2019-0055-1218-A1, p. 6]

In most nonattainment areas, the nitrogen oxides and reactive organic compounds emitted from internal combustion engines (ICEs) are the primary cause of ozone formation and a significant contributor to PM2.5 nonattainment. Replacing ICEs as quickly as possible is the solution to urban smog and soot pollution that impairs the health and quality for life for millions of urban Americans. [EPA-HQ-OAR-2019-0055-1218-A1, p. 7]

This statutory "greatest degree of emission reduction" mandate also applies to all species of PM10 and PM2.5 emitted from HDVs as particles or aerosols because both inhalable (PM10) and respirable (PM2.5) particles are governed by NAAQS issued to protect public health,2 and are included within the scope of the directive in section 202(a)(3)(A) to issue standards for "particulate matter." HDV emissions that are measured as particulate matter (PM) include metals in carbon fuels, and both particle and aerosol carbon species that are the products of incomplete carbon (C) combustion such as elemental C, black C, benzene, PAHs, aldehydes and CO2 which is the product of complete C combustion. EPA acknowledges that diesel engines emit PM that contributes to nonattainment for PM2.5 and causes significant health risks. [EPA-HQ-OAR-2019-0055-1218-A1, p. 7]

2. 40 CFR Part 50, sections 50.6, 50.7, 50.13.

The rule package identifies both ozone and PM2.5 as pollutants of concern that are the reason for proposing standards for NOx. The TSD includes a modeling analysis of the NOx reductions and the PM emission reduction benefits that will be achieved by the proposed standards for NOx, but EPA does not include any analysis of the NOx or PM emission reductions that could be achieved by adopting zero emission standards for classes or categories of HDVs. [EPA-HQ-OAR-2019-0055-1218-A1, p. 7]

The modeling analysis is performed for 2027 and 2045. 2027 is an attainment deadline year for recently bumped-up "serious" ozone nonattainment areas (NAs), but 2045 has no relation to a statutory attainment deadline. The deadlines for the San Joaquin Valley "severe" ozone nonattainment is 2031 and the deadline for South Coast AQMD is 2037. The modeling results reported in the TSD demonstrate that most NAs will attain the ozone standard by 2045, but not South Coast, San Joaquin Valley, New York City or Harris County TX. Clearly the reductions required by the proposed rule are not adequate to attain the NAAQS in these NAs by the statutory deadlines applicable to each NA. [EPA-HQ-OAR-2019-0055-1218-A1, p. 7]

Additional reductions are also needed for some PM2.5 NAs to attain by the statutory deadlines. [EPA-HQ-OAR-2019-0055-1218-A1, p. 7]

These modeling results demonstrate the need to evaluate alternative regulatory options that include standards sufficient to achieve the emission reductions needed for attainment by the applicable statutory deadlines. Zero emission standards based on the availability of zero emission power trains should be evaluated as a regulatory option for timely attainment of the NAAQS. [EPA-HQ-OAR-2019-0055-1218-A1, p. 7]

The degree of control needed for both NOx and PM2.5 emitted from HDVs should be demonstrated by modeling the impact that HDV standards will have on attainment of the

NAAQS for two reasons: 1) the statutory purpose of protecting public health, and 2) the structure of section 202 of the Act which establishes different criteria for standards for HDVs versus standards for light duty vehicles. [EPA-HQ-OAR-2019-0055-1218-A1, p. 8]

The standard setting authority granted to EPA by section 202 must be viewed in light of the statutory framework which declares the purpose of the Act is "to protect and enhance the quality of the Nation's air resources so as to promote the public health and welfare and the productive capacity of its population." 42 U.S.C. §7401(b)(1). Under the structure of the Act, the NAAQS promulgated pursuant to section 109 provide the relevant benchmarks for determining whether the primary purpose of the Act, i.e., protecting public health, is being implemented. [EPA-HQ-OAR-2019-0055-1218-A1, p. 8.]

Here EPA has investigated the impact that the proposed standards will have on attainment and found that 1) controlling emissions from HDVs are necessary for attainment in many ozone NAs because the reductions required by the proposed rules will contribute to attainment in some NAs, but 2) that the reductions are not enough to demonstrate attainment in the worst polluted air pollution control regions.3 [EPA-HQ-OAR-2019-0055-1218-A1, p. 8.]

> 3. The modeling analysis results reported in the Technical Support Document are useful for drawing these inferences, but the modeling is not adequate to determine the emission reductions needed for timely attainment by the statutory deadlines for each NA. Regional modeling for NAs that are not expected to attain before the statutory deadline should be performed, in collaboration with regional air quality planning agencies, to obtain more precise data regarding the emission reductions needed for attainment.

This statutory mandate to achieve "the greatest degree of emission reduction achievable…"for heavy duty vehicles does not apply to standards for light duty vehicles (LDVs). Section 202(i) specifically authorizes EPA to forego more stringent standards for LDVs if they are not needed for attainment, but that provision does not apply to HDVs. For HDVs, the duty to set standards that reflect "the greatest degree of emission reduction achievable…" is continuing, and is not limited by the need for reductions to attain NAAQS. These differences imply 1) that standards for both HDVs and LDVs must continue to be strengthened as necessary to support the states in developing implementation plans that can attain the NAAQS; and 2) that for HDVs the progressive emission reductions that become available from more advanced technology must continue to be reflected in more stringent standards. [EPA-HQ-OAR-2019-0055-1218-A1, p. 9.]

To estimate the emission reduction benefits of the regulatory approach that we ask EPA to adopt, we have performed modeling using the EMFAC model to quantify the emission reductions that would be achieved in the South Coast and San Joaquin Valley (SJV) Air Quality Management Districts (AQMD)s. [EPA-HQ-OAR-2019-0055-1218-A1, p. 13]

CARB has developed estimates of the NOx reductions needed for attainment in South Coast and SJV AQMDs. CARB has identified emissions from federally regulated transportation source sectors as the primary cause of nonattainment after the implementation of stationary and area source measures included in the draft ozone SIP. These source sectors include out-of-state (OOS) trucks traveling into and through California, commercial shipping and aircraft operations in CA. [EPA-HQ-OAR-2019-0055-1218-A1, p. 13]

In these comments we fault EPA for not identifying the degree of emission needed to help states achieve the emission reductions needed for ozone and PM2.5 attainment. To address that objection, we have prepared modeling analyses of two scenarios to estimate the contribution to attainment in the two most polluted ozone NAs in the U.S. where 20 million Americans are at risk from exposure to frequent (more than 100 days per year) daily violations of the ozone NAAQS, that include the most extreme daily peak concentrations measured in the U.S. [EPA-HQ-OAR-2019-0055-1218-A1, p. 13]

Organization: *Energy Innovation, LLC*

The NOx standards for HDTs should be sufficiently stringent to reduce harmful air pollution and improve public health in the near-term. The most adversely impacted communities cannot wait another decade before realizing the benefits of cleaner trucks. [EPA-HQ-OAR-2019-0055-1310-A1, p.6]

In the 20 years since EPA issued the last major rule to address NOx from HD engines, areas in the U.S. have continued to struggle with meeting National Ambient Air Quality Standards (NAAQS), with some regions increasing criteria pollutant emissions and being reclassified to 'serious' nonattainment.xxxviii [EPA-HQ-OAR-2019-0055-1310-A1, p.6]

xxxviii EPA Proposed Rule, 17418.

We know that air pollution from transportation disproportionately impacts people of color, who are three times more likely than white people to live in the most polluted counties in the U.S.xxxix [EPA-HQ-OAR-2019-0055-1310-A1, pp.6-7]

These disturbing health trends are exacerbated by the fact that the St. Louis metropolitan area has been designated as an ozone nonattainment area since 1992, with the exception of the year 2003, when the 1-hour ozone NAAQS were revoked.12 Further, EPA recently notified the Missouri Department of Natural Resources ('MDNR') that because of continued exceedances of the ozone standard, the area would likely be reclassified to higher nonattainment designation with more stringent ozone compliance requirements.13 [EPA-HQ-OAR-2019-0055-1323-A1, p.3]

12 U.S. EPA, Missouri Nonattainment/Maintenance Status for Each County by Year for All Criteria Pollutants, data current as of April 30, 2022, located at https://www3.epa.gov/airquality/greenbook/anayo_mo.html.

13 Reclassification of Areas Classified as Marginal for the 2015 Ozone National Ambient Air Quality Standards, 87 Fed. Reg. 21842, 21845 Table 1 (April 13, 2022).

It is also meaningful that very little NAAQS air monitoring measuring transportation-related pollutants is taking place in the St. Louis metro area, especially in or near the minority and other disadvantaged populations that bear the disparate impacts of this pollution. Within the entire City of St. Louis, there is only one ozone monitor, two NOx and CO monitors, and four PM monitors.20 Expanding to the entire St. Louis ozone nonattainment region, only five more ozone monitors are added to the picture.21 However, none of these additional ozone monitors are located in the areas with the highest minority populations.22 This lack of meaningful monitoring makes it very difficult for impacted communities to understand the nature of the ozone problem affecting their health. [EPA-HQ-OAR-2019-0055-1323-A1, p.5]

EPA should also include in the rule additional requirements for increased air monitoring for pollutants of concern near transportation corridors in overburdened communities so as to document whether these existing and proposed regulatory approaches are working. As EPA has admitted, current NAAQS monitoring is woefully inadequate to document the regional distribution of transportation pollutants, so increased monitoring is essential to determining the adequacy and efficiency of EPA’s final regulations.24 [EPA-HQ-OAR-2019-0055-1323-A1, p.6]

Organization: *Jessica Stevens*

I am writing in support of the Environmental Protection Agency in the proposed regulation to reduce air pollution from highway heavy duty vehicles and engines. Greenhouse gasses, ozone, and other particulate matter are primary contributors in our current climate crisis, so any recommendation to reduce these is urged. In addition, these have direct consequences in public health and environmental justice, which was put under consideration in constructing this report. I will outline why this regulation is essential in taking steps against climate change and why it is important in our quality of life, as well as providing some recommendations and other items to take under consideration. [EPA-HQ-OAR-2019-0055-1028]

Transportation is currently the greatest source of greenhouse gasses in the United States. In 2020, it accounted for 27% of the emissions produced, mostly coming from petroleum based fuel for trucks, cars, planes, etc. (Sources of Greenhouse Gas Emissions). Over half of the emissions in this industry come from cars, light, medium, and heavy duty trucks, while the other half result from other forms of transportation like planes, ships, and trains. The National Institute of Environmental Health Services (NIEHS) outlines the air pollution produced by the transportation sector and the potential health impacts this has. The NIEHS states that Traffic Related Air Pollution (TRAP) includes ground level ozone, carbon, hydrocarbons, and particulate matter (Air Pollution and Your Health). This can result in various forms of respiratory disease, like asthma or chronic obstructive pulmonary disease. Additionally, air pollution increases the risk for cardiovascular disease and certain cancers, particularly breast and lung cancer. The NIEHS also found that nine out of 10 people living in urban areas worldwide were found to be affected by air pollution (Air Pollution and Your Health). This report specifically mentions that lower income families and people of color possess higher risk for air pollution by being more likely to be located near truck routes. This is a public health and environmental justice problem that needs to be addressed. [EPA-HQ-OAR-2019-0055-1028]

Organization: *Maine Department of Environmental Protection (Department)*

Furthermore, recent studies show that ozone concentrations below the current National Ambient Air Quality Standards (NAAQS) continue to contribute to the risk of premature death in sensitive populations, such as the elderly.2 NOx emissions from trucks likewise impede the States' ability to attain and maintain federal air quality standards for particulate matter. [EPA-HQ-OAR-2019-0055-1288-A1,p.1]

"Association of short-term exposure to air pollution with mortality in older adults." JAMA 318.24 (2017): 2446-2456. DOI: 10.1001/jama.2017.17923.

Organization: *Metropolitan Washington Air Quality Committee (MWAQC) et al.*

We agree that the proposed rule has the potential to achieve significant Nitrogen Oxide (NOx) emissions reductions and will likely result in substantial public health and welfare benefits. The region is currently designated as being in non-attainment of federal National Ambient Air Quality Standards (NAAQS) for ozone. NOx is a precursor pollutant of ground-level ozone. As such, reductions in NOx emissions will help the region to attain the federal NAAQS for ozone. In addition, NOx is a precursor to secondary particulate matter, such as particulate matter measuring 2.5 micrometers in diameter and smaller (PM2.5). Exposure to PM2.5, along with ground-level ozone, is associated with premature death, increased hospitalizations, and emergency room visits due to exacerbation of chronic heart and lung diseases and other serious health impacts. [EPA-HQ-OAR-2019-0055-0996-A1, p. 1]

The National Capital region has implemented several emissions control measures in all emissions sectors, including transportation, over the years to improve its air quality and comply with NAAQS for a variety of criteria pollutants. The region also relies heavily on federal emissions control programs for a significant amount of its emissions reductions. While significant progress has been made in the Washington region to reduce emissions of criteria pollutants and GHG emissions, addressing sources of low-level NOx, including from on-road vehicles, is critical to continuing to deliver cleaner air for the residents of the region. The role of the federal government's leadership in delivering effective regulatory limits on emissions from motor vehicles is a critical component of our ability to meet our adopted and mandated environmental objectives. As such, MWAQC, TPB, and CEEPC believe the continued updates to emission standards to reduce pollutants are appropriate and necessary. [EPA-HQ-OAR-2019-0055-0996-A1, p. 2]

Organization: *Mid-America Regional Council (MARC) Air Quality Forum*

While significant reductions in NOx from industrial and electric generation sources have been achieved—helping to maintain ozone attainment in the Kansas City region—ongoing federal leadership is needed to achieve more significant emissions reductions from on-road sources. The importance of the role of the federal government in delivering effective regulatory limits on emissions from motor vehicles cannot be understated. These limits challenge manufacturers to integrate tried and tested control technology for curtailing emissions into their projects which would otherwise be adopted at a slower pace. It is a critical component to maintaining the current and future attainment for ozone and meeting GHG targets in the transportation sector in the Kansas City region. [EPA-HQ-OAR-2019-0055-1131-A1, p. 2]

Organization*: Midwest Ozone Group (MOG)*

MOG is pleased to see EPA undertake this initiative under Section 202(a)(1) of the Act. While states also have an obligation to address emissions from mobile sources as part of their nonattainment SIP planning, EPA has additional authority that is critical to the objectives of the Clean Air Act. [EPA-HQ-OAR-2019-0055-1272-A1, p.2]

It is essential that EPA's mobile source regulatory program that will impact state implementation plan development be balanced for upwind and downwind states. MOG cautions EPA to ensure the implementation of this proposed rule regulating emissions from heavy duty trucks will include direction to states relative to implementation that will target alignment encouraging all states to manage mobile emissions from heavy duty trucks in a collaborative manner. The Clean Air Act provides for the authority to regulate mobile sources within the state implementation plan strategies supporting the NAAQS as specifically noted by EPA in its proposed FIP for the 2015 ozone NAAQS.3 The Wisconsin v. EPA D.C. Circuit opinion concluded that EPA exceeded its statutory authority under the Good Neighbor Provision 'by issuing a Rule that does not call for upwind States to eliminate their substantial contributions to downwind nonattainment in concert with the attainment deadlines.' 938 F.3d 303, 318 (D.C. Cir. 2019). The Wisconsin remand directed EPA to address the downwind state 'deadline' in such a manner as to 'harmonize' the deadlines of upwind and downwind states and to apply 'parallel timeframes.' Id. at 312, 314. The D.C. Circuit repeatedly has explained the CAA directive to 'harmonize' and manage the relationship described as parallel between the Good Neighbor obligations for upwind states and statutory attainment deadlines for downwind areas. That relationship is one of ‘par,’ using the Court’s term, meaning to be judged on a common level with the other.4 With this proposed rule is opportunity to implement mobile source emissions reductions that will impact ambient air quality for upwind and downwind states. [EPA-HQ-OAR-2019-0055-1272-A1, pp.2-3]

> 3 87 Fed. Reg. 2077, ftn. 142. 'The EPA recognizes that mechanisms exist under title I of the CAA that allow for the regulation of the use and operation of mobile sources to reduce ozone-precursor emissions.'

Organization: *Moving Forward Network (MFN)*

Often, freight operations are located in communities that have poor air quality and fail to achieve federal clean air standards. As many as 40 percent of U.S. ports and many other freight facilities are in areas that are not meeting the National Ambient Air Quality Standards for ozone and PM, and freight operations have been identified as major contributors to nonattainment issues.24 [EPA-HQ-OAR-2019-0055-1277-A1, p. 9]

> 24. Clean Air Act Advisory Committee. “Ports Initiative Workgroup Report: Recommendations for the U.S. EPA.” US EPA, September 2016. https://www.epa.gov/sites/default/files/2016-09/documents/ports_workgroup_report_for_epa_9_15_16.pdf; see, e.g., South Coast Air Quality Mgmt. Dist., Proposed Rule 2304 Indirect Source Rule for Commercial Marine Ports Working Group Meeting #1, Powerpoint (Feb. 25, 2022), at p. 2, available at https://www.aqmd.gov/docs/default-source/planning/fbmsm-docs/pr-2304-wgm-no-1_2022-02-25.pdf?sfvrsn=8 (describing the ports of LA and Long Beach as the “single largest fixed source of air pollution in the South Coast Air Basin”).

Organization: *National Association of Clean Air Agencies (NACAA)*

There is a looming crisis facing many state and local clean air agencies. Currently, more than one-third of the U.S. population lives in an area that does not meet the health- and welfare-based National Ambient Air Quality Standards (NAAQS) for ozone, particulate matter (PM) or both. [EPA-HQ-OAR-2019-0055-1232-A1, p. 2.]

While state and local air agencies have made great strides in reducing emissions from stationary sources, for the most part they lack the authority to regulate mobile sources and never do they have the authority to regulate mobile sources upwind of or across their borders. The regulation of mobile sources is an authority that lies almost entirely within the purview of the federal government. Unfortunately, emission standards for this heavy-duty “federal source” have not kept pace with standards for the light-duty motor vehicle sector or stationary sources, and fall far short of what is needed to meet clean air and public health protection goals. As large swaths of the country slip deeper into nonattainment, or teeter on the cusp of it, many state and local air agencies are left with few avenues to achieve the emission reductions they sorely need. Areas that miss their attainment deadlines face the threat of "bump-up" to a more demanding classification of nonattainment – if they are not already classified as Extreme – and statutorily required economic sanctions if they fail to meet their attainment deadlines. On April 13, 2022, EPA proposed to bump up 30 areas in nonattainment of the 20082 and 20153 ozone NAAQS, meaning the citizens of these areas continue to suffer the detrimental impacts of unhealthful air. [EPA-HQ-OAR-2019-0055-1232-A1, p. 2]

3. https://www.govinfo.gov/content/pkg/FR-2022-04-13/pdf/2022-07513.pdf

Further, EPA is now in the process of reconsidering the existing PM and ozone NAAQS, adopted in 2012 and 2015, respectively, and reaffirmed in December 2020. With respect to PM, the agency's science advisors on the Clean Air Science Advisory Committee (CASAC) are recommending that EPA revise the standards to make them more protective of public health. In a letter transmitted to Administrator Michael S. Regan on March 18, 2022,4 responding to the EPA staff Draft Policy Assessment (PA) for PM, the science advisors wrote that "all CASAC members agree that the current level of the annual [PM2.5] standard [of 12 micrograms per cubic meter (µg/c3)] is not sufficiently protective of public health and should be lowered" and that a majority of CASAC members finds "that the available evidence calls into question the adequacy of the current 24-hour standard [of 35 µg/m3]" and "conditional on retaining the current form, the majority of CASAC members favor lowering the 24-hour standard." NACAA also notes that in the Draft PA EPA staff report that the risk assessment for PM2.5 revealed that Black populations experience significantly higher mortality risk when compared to other racial groups, even at the recommended lower standard.5 [EPA-HQ-OAR-2019-0055-1232-A1, pp. 2 - 3.]

4. https://www.4cleanair.org/wp-content/uploads/PM-NAAQS-CASAC-Responses-to-EPA-PM-Draft-PA-031822.pdf (see pp. 2-3)

5. https://www.epa.gov/system/files/documents/2021-12/draft-policy-assessment-for-the-reconsideration-of-the-pm-naaqs_october-2021_ed3.pdf (see pp. 3-149 – 3-150)

On April 28, 2022,6 EPA staff released for review and comment the Draft PA for ozone, in which the staff put forth their conclusion that the current evidence and information do not call into question the adequacy of the protection provided by the current standard and, instead, continue to provide support for the current standard and consideration of retaining that standard without revision. CASAC members, who have not yet weighed in, were to meet in June to conduct their peer review of the Draft PA. However, on May 13, 2022, CASAC Chair Dr. Lianne Sheppard issued a memorandum7 in which she announced that she had paused review of the Draft PA so the Committee can 1) discuss EPA's charge question about the CASAC Ozone Panel's views on "EPA's evaluation of newer studies and its conclusion that they do not materially change the findings of the 2020 ISA [Integrated Science Assessment] or warrant reopening of the air quality criteria," 2) consider several Panel members' concerns regarding some of the causal determinations made in the 2020 ISA and 3) decide if the Panel would like to have further discussion of the science prior to reviewing the draft PA. [EPA-HQ-OAR-2019-0055-1232-A1, p. 3]

7. https://www.4cleanair.org/wp-content/uploads/CASAC-Ozone-Panel-Chair-Memo-05-13-22.pdf

Regardless of whether either or both standards are strengthened, the fact is that many areas across the country are in need of NOx reductions just to meet the current standards and provide clean air to their citizens. [EPA-HQ-OAR-2019-0055-1232-A1, p. 3]

Our nation is in need of a strong, sustainable transportation strategy with top priority placed on new federal programs to continue to reduce emissions from the mobile source sector. As this strategy is developed, the need for meaningful reductions in criteria pollutant emissions, especially NOx and PM, cannot be overlooked. Regarding attainment and maintenance of the ozone NAAQS, most areas of the country are "NOx-limited," meaning that reducing NOx emissions is the key to success. In addition, research shows that in some areas of the country, such as much of the East Coast, NOx reductions are now "supercharged," meaning that one-pound of reduction in NOx emissions equals more than one pound of ozone reduction. Failure to adequately address transportation-related NOx sources will have a direct and consequential impact on state and local air agencies' abilities to fulfill their statutory obligations to attain and maintain federal air quality standards by mandated deadlines and achieve their environmental justice goals. [EPA-HQ-OAR-2019-0055-1232-A1, p. 3]

Now is the time for decisive federal action that will result in deep NOx reductions from HD trucks. Cleaning up this sector is imperative to putting our nation on a path to attaining and maintaining the health-based NAAQS and protecting our nation's most vulnerable communities. EPA must take full advantage of this opportunity to adopt a maximally stringent, technology-forcing federal rule that will take effect beginning with MY 2027 and achieve the full measure of potential emission reductions. Through a variety of actions, states are demonstrating strong leadership with respect to addressing HD truck NOx emissions, including by exercising their authority under section 177 of the CAA and through non-regulatory efforts such as collaborative Memoranda of Understanding (MOU). It is incumbent upon EPA to do its part. If EPA does not incorporate NACAA's recommendations into the final rule and does not finalize the rule this year, in time for it to take effect with MY 2027, many areas will be forced to adopt severe limits on stationary sources, for which they have authority to control, at ever-increasing costs, if reductions from such sources are even available. [EPA-HQ-OAR-2019-0055-1232-A1, pp. 3 - 4]

Americans in every part of the country urgently need improvements in NOx emissions from onroad HD vehicles; the following examples are just a few indications of this nationwide need. [EPA-HQ-OAR-2019-0055-1232-A1, p 4]

In Wisconsin, EPA action to significantly reduce NOx emissions from highway heavy-duty vehicles is critical for the state to meet its Clean Air Act (CAA) attainment obligations relative to ozone. Wisconsin's Lake Michigan shoreline experiences complex, persistent ozone issues due to a combination of emissions, meteorology and geography, as well as from transported ozone precursors originating from out of state. As a result, Wisconsin has multiple areas that remain in nonattainment of the 2015 ozone standard. Reductions in regional NOx emissions are necessary to resolve these nonattainment areas. The onroad mobile sector is the largest contributor of NOx emissions in Wisconsin. According to the 2017 National Emissions Inventory, the onroad mobile sector accounts for 38 percent of the NOx inventory in Wisconsin, with nearly half of those emissions coming from heavy-duty vehicles. Recent ozone modeling done by the Lake Michigan Air Directors Consortium indicates onroad diesel vehicles, the vast majority of which are heavy-duty vehicles, contribute up to 8 parts per billion (ppb) or 11 percent of ozone at Wisconsin's lakeshore nonattainment monitors. A comprehensive federal rule to address nationwide NOx emissions from this sector cannot be delayed any further. [EPA-HQ-OAR-2019-0055-1232-A1, p. 4]

New Jersey and its multi-state nonattainment areas need NOx reductions from HD trucks for attainment and/or maintenance reasons associated with both the 2008 and 2015 ozone NAAQS. Although the state is currently in attainment of the PM2.5 NAAQS, the NOx reductions would help the state attain any future revised PM2.5 NAAQS by reducing levels of PM2.5 precursors. In addition, New Jersey needs NOx reductions to meet its regional haze goals; given the timing of this rule – to be finalized this year – the related NOx reductions will contribute toward achievement of those goals. New Jersey is also home to several ports that are surrounded by environmental justice communities impacted by the emissions from heavy truck traffic. Mobile sources (onroad and nonroad) make up greater than 75 percent of New Jersey's annual and summer day inventory for NOx. Due to state preemption, New Jersey is limited in its capacity to address the largest sources of ozone-producing pollutants and relies on federal measures like the HD truck rule to attain. In New Jersey, electric generating units (EGU) are less than 5 percent of the inventory and non-EGU stationary sources are 14 percent. The cost per ton associated with further reductions from these source sectors would be high. [EPA-HQ-OAR-2019-0055-1232-A1, p. 4]

Over the years, Oregon has had difficulty reducing emissions from the medium- and heavy-duty mobile source sectors because of limited tools at the state level. Oregon relies on California and its federal counterparts at EPA to develop and maintain the most advanced new vehicle emission standards possible to complement bold action at the state level. In 2019, Oregon adopted the second strongest diesel regulations in the nation and will begin phasing out older model medium- and heavy-duty diesel-powered trucks in the Portland Metro Region next year. But state action alone will not be enough. The decades-long downward trend in ambient ozone concentrations has leveled off. Despite Oregon's status as a "section 177 state" and its adoption of several California rules, it remains likely that the state will see increases in ozone concentrations due to ongoing climate warming and increased interstate transportation. Further, if the ozone NAAQS is revised downward, Oregon will be at greater risk of losing its attainment status in several communities. [EPA-HQ-OAR-2019-0055-1232-A1, pp. 4 - 5]

The Puget Sound Clean Air Agency (PSCAA) in Seattle, WA seeks a technology-forcing standard to reduce NOx emission from HD trucks due to several ozone-related concerns. Reducing NOx would help reduce exposure in the near-road communities, which are disproportionately affected by air pollution, and also assist in addressing ozone-impacted areas. Finally, the PSCAA's former PM2.5 nonattainment area includes one of the largest container ports on the West Coast and strong growth in both population and goods movement are anticipated along the West Coast's main north-south interstate and the in the region served by PSCAA. Reducing PM and NOx from heavy-duty vehicles through controls that do not lose their effectiveness over time or during some duty cycles will be vital to the health of near-roadway and near-port communities and to maintaining the area's attainment status. For all these reasons, technology-forcing regulations and substantial warranties to ensure that compliant emission rates are sustained over more of the useful life of the truck and over the full set of duty cycles will provide significant benefit to the Seattle area. [EPA-HQ-OAR-2019-0055-1232-A1, p. 5]

Historically, the Louisville Metropolitan Statistical Area (MSA) has been challenged with meeting the ozone NAAQS.8 The area was designated as Marginal nonattainment for the 2015 ozone NAAQS and has recently been proposed by EPA to be bumped up to Moderate nonattainment since the area failed to meet the standard by the Marginal nonattainment deadline of August 2021. In the meantime, the MSA currently meets the standard (with a 2021 design value of 69 ppb) and a Request for Redesignation is being prepared for submittal to EPA. Even so, EPA's proposed rule provides an important opportunity to address HD truck emissions now and protect public health by reducing emissions of ozone precursors, particulate matter and toxic air pollutants. HD truck emissions are a significant contributor of ozone precursors, NOx and volatile organic compounds (VOC). The impact of this vehicle sector was apparent recently with respect to meeting transportation conformity Motor Vehicle Emission Budgets; variations in HD truck speeds were found to be critical in staying under the 2020 NOx budget (established in 2007). As with most medium- and large-size cities in the U.S., the HD trucks in the mobile emissions category are a critical source over which the Louisville Metro Air Pollution Control District (APCD) has little control, so meaningful federal controls are very important to APCD's attainment planning for ozone and subsequent maintenance of the standard. Onroad heavy-duty diesel vehicles represent the third largest overall NOx emissions sector in the area (after EGUs and onroad non-diesel light-duty vehicles).9 In addition, should EPA revise the PM NAAQS, as EPA staff and CASAC have recommended to the Administrator, reductions in NOx emissions from HD trucks will be equally important for Louisville's attainment planning for that standard. Although APCD has instituted a voluntary cooperative program, the Air Quality Action Partners Program,10 for businesses to reduce emissions, including mobile source emissions, HD trucks continue to be an ongoing concern, especially from an environmental justice standpoint. Further, a stringent HD truck rule will further reduce risk from emissions of toxic air pollutants not addressed by APCD's Strategic Toxic Air Reduction (STAR) Program. This is especially important since HD truck traffic travels through many fenceline communities and adds to the cumulative exposures of those who live nearby. The strictest version of this rule will benefit Louisville in many ways. [EPA-HQ-OAR-2019-0055-1232-A1, pp. 5 - 6]

10. https://louisvilleky.gov/government/air-pollution-control-district/air-quality-action-partners-program

Although Maryland has made significant progress over the past 30 years in improving air quality for its citizens, there is still much work needed to reduce NOx emissions and meet air quality and public health goals. Maryland has implemented aggressive NOx reduction measures such as adopting the California light-duty vehicle emission program and pursuing strong reduction measures on stationary sources via the state's Healthy Air Act. Despite these efforts, the majority of Maryland's population resides in areas designated nonattainment for the 70-ppb 2015 ozone NAAQS, and on April 13, 2022, significant portions of Maryland were proposed to be bumped up in nonattainment status. In Maryland, and the Northeast region, medium- and heavy-duty trucks are the second leading contributor of NOx emissions. To attain the federal ozone standards, emission reductions from HD trucks are needed. [EPA-HQ-OAR-2019-0055-1232-A1, p. 6]

The Yakima Regional Clean Air Agency was designated as nonattainment for PM10 and is now in its second 10-year maintenance plan. The area is now in jeopardy of becoming nonattainment for PM2.5. If EPA revises the PM2.5 NAAQS to 30 or 32 micrograms per cubic meter (μ/m3) the area will most likely be designated as nonattainment. Hence, Yakima needs reductions in NOx – a PM2.5 precursor – from HD trucks along area highway corridors to reduce its PM levels. [EPA-HQ-OAR-2019-0055-1232-A1, p. 6]

The Denver Metro/North Front Range needs reductions in emissions from heavy-duty truck traffic to aid in attainment and address environmental justice concerns. Recent source apportionment modeling for 2023 demonstrates that NOx emissions are driving ozone formation at monitors throughout the region11 and that medium- and heavy-duty truck traffic is a significant contributor to ozone formation.12 [EPA-HQ-OAR-2019-0055-1232-A1, p. 6]

Reductions in HD truck NOx emission would be a proactive measure for the Kansas City metropolitan area. While the county and Greater Kansas City metro area would obviously benefit from cleaner heavy-duty trucks, Johnson County, KS does not have data that indicate the need for NOx reductions specifically from HD trucks. That being said, the last photochemical modelling, a fairly dated data set, showed the Johnson County metro area to be a mix of VOC- and NOx-limited areas. The Kansas City metro area is in the early stages of developing a local-scale neighborhood monitoring effort, perhaps a network, that may reveal need for these reductions at a neighborhood scale. It is anticipated this monitoring will aid in confirming those suspected EJ communities in the greater metro area and within Johnson County that the regional scale monitoring does not capture. The recent trends in increased industrial warehousing across the Kansas City metro area is anticipated to increase truck traffic and bring it closer to residential neighborhoods, including environmental justice communities. Unfortunately, the area does not have targeted data to show the potential impact of this clearly beneficial program for cleaner heavy-duty trucks. However, the anticipated reductions from the proposed HD truck rule would be preventative and help keep the Kansas City metro area from needing to explore future NOx reduction strategies. Although the situation is not as dire as in other parts of the country, cleaner heavy-duty trucks would certainly help in improving and maintaining our air quality to be more protective of our residents' health. [EPA-HQ-OAR-2019-0055-1232-A1, pp. 6 - 7]

The District of Columbia continues to have annual ozone fourth highest values above the 70-ppb 2015 ozone NAAQS, except in 2020 when vehicle congestion in the Washington, DC, area was significantly reduced due to the COVID-19 health emergency. NOx emissions from highway trucks are major contributors to unhealthy levels of ground-level ozone and fine PM. In fact, modeling conducted by the Ozone Transport Commission13 found that onroad diesel vehicles are the second largest contributor to ozone in the District, behind only onroad gasoline vehicles. Onroad diesels were modeled to contribute 16 percent of anthropogenic ozone on exceedance days and throughout the ozone season in the District, which is a higher percentage than all of the District contributes to itself (12 percent on average and 10 percent on exceedance days). NOx reductions from diesel vehicles are necessary in order for residents of the District to breathe healthy air. [EPA-HQ-OAR-2019-0055-1232-A1, p. 7]

13. https://otcair.org/upload/Documents/Reports/OTC%20MANE-VU%202011%20Based%20Modeling%20Platform%20Support%20Document%20October%202018%20-%20Final.pdf

Many key environmental justice communities in Washington are located near high-traffic roadways well used by heavy-duty trucks. One such community is Seattle's Chinatown-International District, which sits next to the interchange of two major interstates (I-5 and I-90). This community is home to Seattle's near-road NOx monitoring site, which records the highest NOx concentrations in the region. Monitoring results demonstrate that ambient concentrations of NO and NO2 are highly correlated with peak traffic patterns on these interstates. As a key precursor to ozone formation, NOx also impacts air quality in communities with elevated ozone concentrations such as Washington's Tri-Cities. Previous research indicates that onroad vehicles are the dominant source of NOx in this community, which experiences some of Washington's highest ozone concentrations in the summer months. [EPA-HQ-OAR-2019-0055-1232-A1, p. 7]

For almost 50 years, Connecticut's citizens have suffered the public health and economic impacts of ozone nonattainment. This past year, Connecticut experienced 21 days with unhealthy ozone levels, and on April 13, 2022, EPA proposed to reclassify Fairfield, New Haven and Middlesex Counties as Severe nonattainment with respect to the 2008 ozone NAAQS. The importance of reducing NOx emissions to address ozone nonattainment is critical for Connecticut. A recent national report, Asthma Capitals 2021,14 ranked New Haven (#5) and Hartford (#17) among the 100 largest U.S. cities where it is most challenging to live with asthma. The Connecticut Department of Energy and Environmental Protection recently issued an assessment of onroad medium- and heavy-duty vehicle emissions,15 which included the finding that in 2020 onroad HD vehicles accounted for 36 percent of total onroad NOx emissions but are projected to increase to 57 percent of total onroad NOx emissions by 2045 without the adoption of new emission standards. Connecticut urgently needs stringent, technology-forcing federal emission standards for HD trucks now. [EPA-HQ-OAR-2019-0055-1232-A1, p. 7]

California's population closely overlaps its air quality challenges driven in large part by transportation emissions that often differentially affect the state's most vulnerable communities. Redoubled efforts to address the air quality needs of every California resident have seen focused Community Air Protection programs targeting the stationary and mobile sources impacting these communities. The communities adjacent to railyards, ports, warehouses and freight corridors experience heavy truck traffic characterized by idling, driving slowly and frequent stops – conditions under which today's HD trucks do not control NOx emissions effectively. California has spent $8 billion to date on technology advancement and early market development of cleaner and zero emission vehicles (ZEVs). New vehicles sold in California are being brought under stringent near-term tailpipe and zero emission requirements while fleet rules like the Truck and Bus regulation are driving accelerated turnover of the oldest remaining trucks by the end of this year. Despite these aggressive and sustained efforts to achieve emission reductions, a similar amount of heavy-duty truck emissions in California comes from trucks initially sold under federal jurisdiction. The necessity of dealing with "both halves" of heavy-duty truck emissions (under California's jurisdiction and under federal jurisdiction) is paramount as outlined in California's EPA-approved State Implementation Plans and underlying the state Mobile Source Strategy and local Air Quality Management Plans. It is crucial that EPA's federal HD truck standards drastically cut truck emissions, including during low load conditions, to reduce adverse health impacts and improve air quality throughout the state, especially in those areas that are already disproportionately impacted by truck emissions. [EPA-HQ-OAR-2019-0055-1232-A1, p. 8]

In 2016, state and local air agencies from around the country joined together to petition EPA to adopt "ultra-low NOx" emission standards for highway heavy-duty trucks and engines. Petitioners, who based their case on their need for the related NOx reductions, included the South Coast (CA) Air Quality Management District; Pima County (AZ) Department of Environmental Quality; Bay Area (CA) Air Quality Management District; Connecticut Department of Energy and Environmental Protection; Delaware Department of Natural Resources and Environmental Control, Division of Air Quality; Washoe County (NV) Health District, Air Quality Management; New Hampshire Department of Environmental Services; New York City (NY) Department of Environmental Protection; Akron (OH) Regional Air Quality Management District; Washington State Department of Ecology; Puget Sound (WA) Clean Air Agency; Rhode Island Department of Environmental Management; Massachusetts Department of Environmental Protection; Vermont Department of Environmental Conservation; New York State Department of Environmental Conservation; and Sacramento (CA) Metropolitan Air Quality Management District. [EPA-HQ-OAR-2019-0055-1232-A1, p. 8]

Organization: *National Coalition for Advanced Transportation (NCAT)*

In 2020, approximately 97 million people nationwide lived in counties with pollution levels above the primary National Ambient Air Quality Standards (NAAQS).17 [EPA-HQ-OAR-2019-0055-1290-A1, p. 5]

> 17. U.S. EPA, Air Quality - National Summary, https://www.epa.gov/air-trends/air-quality-nationalsummary (last updated May 26, 2021).

Organization: *National Parks Conservation Association (NPCA)*

Heavy-duty vehicles are a key contributor to ozone and PM National Ambient Air Quality Standards (NAAQS) nonattainment in air basins across the country. This is of particular concern in states like California, where NOx pollution from HD vehicles is an outsized source of ozone and PM2.5 in regions such as the San Joaquin Valley and South Coast Air Basins. When it comes to meeting the CAA's NAAQS, The San Joaquin Valley is now in extreme nonattainment with the 1997, 2008, and 2015 ozone standards, serious nonattainment with the 1997 annual and 24-hour and 2006 24-hour PM2.5 standards, and moderate nonattainment with the 2012 annual PM2.5 standard. The San Joaquin Valley is also home to the environmental justice communities of Fresno, Visalia, and Bakersfield, which are ranked by American Lung Association (ALA) as being three of the most polluted cities in the country for ozone, annual PM2.5, and short-term PM2.5 pollution.26 In terms of the economic impact, one study found that '[i]n the San Joaquin Valley overall, the cost of air pollution is more than $1,600 per person per year, which translates into a total of nearly $6 billion in savings if federal ozone and PM2.5 standards were met.'27 [EPA-HQ-OAR-2019-0055-1314-A1, pp.4-5]

> 26 ALA, 2019 State of the Air Report: Most Polluted Cities. Available at, https://www.lung.org/our-initiatives/healthy-air/sota/city-rankings/most-polluted-cities.html.
>
> 27 Jane V. Hall, et. al., The Benefits of Meeting Federal Clean Air Standards in the South Coast and San Joaquin Valley Air Basins 2008), at 5. Available at http://publichealth.lacounty.gov/mch/AsthmaCoalition/docs/BenefitsofMeetingCleanAirStandards_11_06_08.pdf.

When viewed alongside other heavily impacted areas, like West Oakland or communities in the South Coast Air Basin, the total impact to vulnerable populations in the state is enormous, both from an economic and public health standpoint. Attaining statewide standards for PM and ozone just in California would annually prevent 9,000 premature deaths—more than the total number of deaths from second-hand smoke and motor vehicle crashes combined—and avoid the annual $2.3 billion price tag in the State's economy associated with hospitalizations and treatment related to air pollution.28 The uneven distribution of health, social, and livelihood costs of the freight sector is one of California's deepest forms of environmental injustice, where freight hubs and corridors disproportionately poison the State's low-income communities and communities of color.29 In West Oakland, where CARB attributes 71% air pollution risk to truck traffic,30 residents have life expectancies as much as 24 years shorter than their neighbors in the Oakland

Hills.31 This story will sound familiar to communities in Wilmington, Roseville, Shafter, Fresno, Commerce, North Richmond, rural Riverside, and many other predominantly low-income communities and communities of color that live near freight hubs and truck corridors.32 [EPA-HQ-OAR-2019-0055-1314-A1, p.5]

EPA must quickly move forward with this rule and strengthen it to ensure California can fulfill its various NAAQS commitments already included in various state ozone and PM2.5 SIPs. For instance, California has approved a combined San Joaquin Valley SIP for the 1997, 2006, and 2012 PM2.5 standards that relies on an expected 7 tons per day (tpd) of NOx reductions through a California specific low-NOx engine standard and 8 tpd of NOx reductions through a federal low-NOx engine standard.33 [EPA-HQ-OAR-2019-0055-1314-A1, p.5]

33 CARB, San Joaquin Valley Supplement to the Revised 2016 State Strategy for the State Implementation Plan. See table 3, at 7. (plan awaiting EPA approval). Available at https://ww3.arb.ca.gov/planning/sip/sjvpm25/2018plan/20180828_sjv_supplement_sip_strategy.pdf.

Similarly, the South Coast Air Quality Management District's (SCAQMD) SIP for attainment with the 2008 8-hour ozone standard, 2006 24-hr PM2.5 standard, and the 2012 annual PM2.5 standard (approved by EPA last year), lays out an expected 5 tpd of NOx reductions through a California low-NOx engine standard and an expected 7 tpd through a federal low-NOx engine standard.34 Because heavy-duty NOx makes up such a large amount of the expected tpd emission reductions seen in state plans like these, it's clear that EPA cannot afford to waiver on moving forward with strong standards without also jeopardizing future clean air goals for millions of California's. [EPA-HQ-OAR-2019-0055-1314-A1, p.6]

> 34 South Coast Air Quality Management District, Final 2016 Air Quality Management Plan. See table 4.5, at 4-35. Available at http://www.aqmd.gov/docs/default-source/clean-air-plans/air-quality-management-plans/2016-air-quality-management-plan/final-2016-aqmp/final2016aqmp.pdf.

Organization: *North Central Texas Council of Governments (NCTCOG)*

Several counties within the Dallas-Fort Worth Metropolitan Planning Area are currently in nonattainment for the pollutant ozone under both the 2008 and 2015 8-hour ozone standards. NCTCOG supports efforts for clean air that will develop an aggressive program which takes into consideration the capabilities of Original Equipment Manufacturers (OEMs) while at the same time not disrupting commerce given the current state and future uncertainty of the economy. NCTCOG is currently implementing several programs to reduce emissions in North Texas, and these comments are informed by this experience. [EPA-HQ-OAR-2019-0055-1254-A2, p.1]

Transportation Conformity is a planning requirement carried out by a regional Metropolitan Planning Organization (MPO) to ensure long-range transportation plans are consistent with air quality goals established to bring a region into compliance with National Ambient Air Quality Standards (NAAQS). Due to increases in truck population and urban congestion, emission inventories are beginning to show increases over time. Addressing engine standards now can aid in maintaining the reduction trend of future year emission inventories which will allow for successful USDOT conformity determinations. The chart below shows this emerging future year situation. [EPA-HQ-OAR-2019-0055-1254-A2, p.4]

Organization: *Northeast States for Coordinated Air Use Management (NESCAUM)*

NESCAUM strongly supports EPA's development of new engine and vehicle emission standards and test procedures that will reduce emissions of oxides of nitrogen (NOx) from heavy-duty vehicles. NOx emissions are a primary precursor to the formation of ground-level ozone and secondary fine particulate matter (PM2.5), and contribute to acid deposition, eutrophication, and visibility impairment in the NESCAUM region. [EPA-HQ-OAR-2019-0055-1249-A1, p. 1]

In 2016, many of the NESCAUM member state agencies and the New York City Department of Environmental Protection joined with the South Coast Air Quality Management District (SCAQMD) and other agencies in petitioning EPA to undertake a rulemaking to revise the on-road heavy-duty engine exhaust emission standards for NOx from 0.2 g/bhp-hr to 0.02 g/bhp-hr.1 Also in 2016, NESCAUM requested that the Secretary of Energy incorporate research into advanced NOx reduction technologies in the Department of Energy (DOE) SuperTruck Program, given the substantial contribution heavy-duty trucks make to NOx pollution in the region.2 [EPA-HQ-OAR-2019-0055-1249-A1, pp. 1 - 2]

1. South Coast Air Quality Management District, et al. "Petition to EPA for Rulemaking to Adopt Ultra-Low NOx Exhaust Emission Standards for On-Road Heavy-Duty Trucks and Engines," June 3, 2016. Available at https://www.epa.gov/sites/production/files/2016-09/documents/petition_to_epa_ultra_low_nox_hd_trucks_and_engines.pdf. (accessed May, 12, 2022).

2. NESCAUM letter to Dr. E. Moniz, Secretary, U.S. Department of Energy, re: SuperTruck II Initiative, May 18, 2016. Available at http://www.nescaum.org/documents/nescaum-doe-supertruckii-nox-tech-lttr-20160518.pdf/.

EPA's response to the 2016 petition clearly acknowledges the importance of NOx reductions to the Northeast and other states.3 In addition, EPA's Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles—Phase 2 final regulation also detailed the importance of NOx reductions to the Northeast, stating that: EPA received compelling letters and comments from [NACAA, NESCAUM, OTC, and SCAQMD], explaining the critical and urgent need to reduce NOx emissions that significantly contribute to ozone and fine particulate air quality problems in their represented areas. The comments describe the challenges many areas face in meeting both the 2008 and recently strengthened 2015 ozone NAAQS. These organizations point to the significant contribution of heavy-duty vehicles to NOx emissions in their areas.4 [EPA-HQ-OAR-2019-0055-1249-A1, p. 2]

3. U.S. EPA, "Memorandum in Response to Petition for Rulemaking to Adopt Ultra-Low NOx Standards for On-Highway Heavy-Duty Trucks and Engines," December 20, 2016. Available at https://www.epa.gov/sites/production/files/2016-12/documents/nox-memorandum-nox-petition-response-2016-12-20.pdf (accessed April 25, 2022).

4. 81 Fed. Reg. 73478 (October 25, 2016), at 73523.

While it is now six years since EPA received the petition, NESCAUM welcomes this proposal to improve the emissions performance of on-road heavy-duty engines and vehicles. Below we describe the Northeast's need for EPA to promulgate a final rule that maximizes the pollution reductions achievable from these pollution sources. [EPA-HQ-OAR-2019-0055-1249-A1, p. 2]

The NESCAUM region includes the New York City (NYC) Combined Statistical Area (CSA) with over 20 million people living across portions of Connecticut, New Jersey, New York, and Pennsylvania. It is the largest CSA by population in the United States. While air pollution levels have dropped over the years across much of the United States, the NYC metropolitan area and surrounding regions continue to persistently exceed federal health-based air quality standards for ground-level ozone.[EPA-HQ-OAR-2019-0055-1249-A1, p. 2.]

For several decades, ozone concentrations in the Northeast trended downward due to the adoption of measures that reduce emissions of ozone precursors. In recent years, however, air quality monitoring data have shown a flattening trend. Figure 1 plots the number of days in

Connecticut where maximum 8-hour ozone was measured above the 2008 and 2015 ozone NAAQS for each year from 1976 to 2021. After significant improvements in the earlier years, the number of ozone exceedance days in Connecticut have remained level or have slightly increased since 2011. Similar patterns have been recorded in other parts of the Northeast Corridor. [EPA-HQ-OAR-2019-0055-1249-A1, pp. 3 - 4]

In addition to the stalling trend in ozone improvements, the New York-Northern New Jersey-Long Island ozone nonattainment area saw an unusually high peak 1-hour ozone average of 143 ppb in July 2018, a level not seen in the NYC region in more than 10 years. This ozone nonattainment area was classified as a serious nonattainment area for the 2008 ozone NAAQS, but failed to meet its attainment deadline of July 20, 2021. As a result, on April 13, 2022, EPA proposed reclassifying it from serious to severe nonattainment status. The NYC metro area will need additional pollution reductions to meet the 2015 NAAQS.10 [EPA-HQ-OAR-2019-0055-1249-A1, p. 4]

10. 87 Fed. Reg. 21825 (April 13, 2022).

Also on April 13, 2022, EPA proposed reclassifying the Greater Connecticut nonattainment area from marginal nonattainment for the 2015 ozone NAAQS to moderate. EPA also proposed to reclassify a number of other areas in the Northeast Corridor from marginal to moderate nonattainment status for the 2015 ozone NAAQS, including the nonattainment areas of Baltimore, MD; Philadelphia-Wilmington-Atlantic City, PA-NJ-MD-DE; and Washington, DC-MD-VA.11 These areas failed to attain the 2015 ozone NAAQS by August 3, 2021, as required for marginal classifications, and similarly to the NYC reclassification for the 2008 ozone NAAQS, these areas will need additional pollution reductions, particularly from NOx emission sources, in order to meet the 2015 ozone NAAQS. [EPA-HQ-OAR-2019-0055-1249-A1, pp. 4 - 5.]

11. 87 Fed. Reg. 21842 (April 13, 2022).

Figure 1 also includes an extensive list of requirements that have been adopted by Connecticut and other states in the NESCAUM region to reduce emissions of ozone precursors from stationary sources, area sources, fuels, mobile sources, and consumer products. Imposing further control requirements on many of these source categories can be more costly than controlling heavy-duty engine emissions and create disproportionate economic burdens for those sources. For example, estimates of the costs for additional NOx controls on industrial, commercial, and institutional boilers that are 100 million British Thermal Units per hour in size range from $2,700 to $21,000 per ton of NOx reduced as compared to a cost range of $1,000 to $5,000 per ton of NOx reduced from heavy-duty vehicles (HDVs).12,13 [EPA-HQ-OAR-2019-0055-1249-A1, p. 5]

12. OTC/Lake Michigan Air Directors Consortium (LADCO), “Evaluation of Control Options for Industrial, Commercial and Institutional (ICI) Boilers,” May 2010.

13. Manufacturers of Emission Controls Association, “Technology Feasibility for Heavy-Duty Diesel Trucks in Achieving 90% Lower NOx Standards in 2027,” February, 2020. Available at https://www.meca.org/wp-content/uploads/resources/MECA_2027_Low_NOx_White_Paper_FINAL.pdf (accessed May 12, 2022).

In 2018, NESCAUM launched the Long Island Sound Tropospheric Ozone Study (LISTOS) to investigate the evolving nature of ozone formation and transport in the NYC region and downwind. LISTOS involves a large group of researchers from state and federal agencies and academia that bring a diverse set of resources, expertise, and instrumentation skills. LISTOS has provided detailed imagery and data on ozone and its precursors in the Northeast. To illustrate the relative scale of NOx emissions during the LISTOS effort, Figure 2 readily shows enhanced nitrogen dioxide (NO2) concentrations (NO2 is a major component of NOx) observed by satellite along the Northeast Corridor during the 2018 ozone season, with the highest weekday (Mon-Fri) NO2 concentrations in the New York City area. Much of this NO2 is associated with transportation sources, and these mobile source sectors are projected to continue to be significant contributors to ozone in future years.14 [EPA-HQ-OAR-2019-0055-1249-A1, p. 5]

14. Zawacki, M., et al., “Mobile source contributions to ambient ozone and particulate matter in 2025.” Atmos. Envt. 188: 129-141 (2018).

Figure 3 shows satellite imagery of NO2 emissions in the Northeast and Mid-Atlantic on a single day in February during the 2019 winter. In addition to region-wide stagnation on this particular day, the strength of the NO2 signal also reflects the longer NO2 lifetime in winter. NO2 levels are abundant and dominant along transportation corridors and in large cities across the region, again indicating a strong mobile source NOx contribution. [EPA-HQ-OAR-2019-0055-1249-A1, p. 5]

The NO2 levels shown in Figure 3 align with the road major arteries where goods are being transported by truck from the ports of New York, Baltimore, and Philadelphia. Note also how clearly defined the area of red is along Interstate 91 in central Connecticut and Massachusetts. [EPA-HQ-OAR-2019-0055-1249-A1, p. 7]

To address the region’s persistent air quality problems, reducing NOx emissions from heavy-duty vehicles is of the utmost importance due to its role in local and regional ground-level ozone formation, as well as its contributions to PM2.5 (especially in the winter). As shown in Figure 4, on-road diesel vehicles, including HDVs, are the third largest NOx emissions source in the Northeast.15 [EPA-HQ-OAR-2019-0055-1249-A1, p. 7]

15. National Emissions Inventory Collaborative, “2016v1 Emissions Modeling Platform,” 2019. Retrieved from http://views.cira.colostate.edu/wiki/wiki/10202.

Absent adoption of stringent new engine NOx standards, emissions from HDVs will increase in the future as truck ton miles travelled is projected to increase by approximately 30 percent over the next 25 years (Figure 5). This growth in activity, if not counteracted by increased stringency of new engine and vehicle emissions standards, will result in significantly increased HDV emissions. We also note that highway trucks often travel long distances and can be registered in states far from where they operate. Therefore, a strong national program is needed to reduce highway truck emissions and maximize public health benefits in the Northeast and nationally. [EPA-HQ-OAR-2019-0055-1249-A1, pp. 7 - 8]

Due to the importance of heavy-duty vehicles to the overall NOx inventory, states in the Northeast have for decades measured, quantified, modeled, and published information on heavy-duty vehicle emissions in the region and articulated the need for further heavy-truck NOx reductions. Independently, and collaboratively with EPA and industry, states have conducted in-use emissions testing and data logging, implemented early heavy-truck periodic and roadside inspection and maintenance programs, and piloted technologies to reduce emissions from HDVs. In 2020, NESCAUM coordinated the signing of the Multi-state Medium- and Heavy-Duty Zero Emission Vehicle (MHD ZEV) Memorandum of Understanding (MOU) through the Multi-state ZEV Task Force.18 Pursuant to the MHD ZEV MOU, 17 states, the District of Columbia, and the Canadian province of Quebec are working collaboratively to accelerate electrification of MHD trucks and buses to eliminate harmful emissions from these vehicles. Their collective goal is to ensure that 100 percent of all new truck and bus sales are ZEVs by no later than 2050, with an interim target of at least 30 percent by 2030. To provide a framework for meeting these goals, the participating jurisdictions, working through the Multi-State ZEV Task Force facilitated by NESCAUM, have developed a draft MHD ZEV Action Plan. [EPA-HQ-OAR-2019-0055-1249-A1, p. 8]

> 18. Multi-state Medium- and Heavy-Duty Zero Emission Vehicle Memorandum of Understanding (announced July 14, 2020, most recent state signing on March 29, 2022). Available at https://www.nescaum.org/documents/mhdv-zev-mou-20220329.pdf.

Organization: *Ozone Transport Commission (OTC) and Mid-Atlantic/Northeast Visibility Union (MANE-VU)*

Millions of OTR residents live in areas that violate the ozone NAAQS. Many areas of the OTR are designated as in nonattainment with the 2015 8-hour average ozone NAAQS of 70 parts per billion (ppb) (Figure 1). These nonattainment areas are struggling to achieve the 2015 ozone NAAQS, and on April 13, 2022, EPA proposed reclassifying a number of them from 'marginal' to 'moderate' nonattainment status for the 2015 ozone NAAQS, including Baltimore, MD; Greater Connecticut; Philadelphia-Wilmington-Atlantic City, PA-NJ-MD-DE; and Washington, DC-MD-VA.4 These areas failed to attain the 2015 ozone NAAQS by August 3, 2021, as required for 'marginal' classifications, and will need additional pollution reductions, particularly for NOx, in order to meet the 2015 ozone NAAQS. [EPA-HQ-OAR-2019-0055-1250-A1, p.2]

> 4 87 Fed. Reg. 21842 (April 13, 2022).

The OTR also includes the New York City (NYC) Combined Statistical Area (CSA). With over 20 million people, it is the largest CSA by population in the United States. It not only violates the 2015 ozone NAAQS, but also the less stringent 2008 8-hour ozone NAAQS of 75 ppb. On April 13, 2022, EPA proposed to reclassify the New York City/Long Island-Northern New Jersey-

Southwest Connecticut area from ‘serious’ to ‘severe’ nonattainment because it failed to meet its ‘serious’ attainment deadline of July 20, 2021.5 This large metropolitan area will need additional pollution reductions to achieve both the 2008 and 2015 ozone NAAQS levels. [EPA-HQ-OAR-2019-0055-1250-A1, p.2]

5 87 Fed. Reg. 21825 (April 13, 2022).

The Clean Air Act requires ozone NAAQS attainment as ‘expeditiously as practicable,’ and EPA’s proposed Options 1 and 2 do not meet this requirement. The introduction of effective and available heavy-duty engine and vehicle pollution reduction technologies will assist jurisdictions in the OTR in reaching attainment of the ozone standards. This is the most ‘expeditiously as practicable’ path called for by the Clean Air Act and anything less than this will not be acceptable. [EPA-HQ-OAR-2019-0055-1250-A1, p.13]

Parts of the OTR continue to experience persistently high ozone levels affecting tens of millions of people. While air pollution levels have dropped over the years across much of the United States, the portions of the OTR listed in Table 2 continue to persistently exceed both past and recently revised federal health-based air quality standards for ground-level ozone. [EPA-HQ-OAR-2019-0055-1250-A1, p.4]

Organization: *Pennsylvania Chamber of Business and Industry*

The PA Chamber recognizes substantial NOx reductions may be achievable through cost-effective controls on the heavy-duty mobile source sectors, which according to EPA data is responsible for approximately 17% of nationwide NOx emissions. EPA and the Pennsylvania Department of Environmental Protection have noted the significant reductions in both direct emissions of NOx (an ozone precursor) and recorded ambient air quality readings of ozone across the state that have occurred over the past two decades. This is the product of technological innovation and efficiency measures being deployed by industry in conjunction with a predictable regulatory environment from state and federal regulators. Despite this progress, as major point sources of criteria emissions, Pennsylvania’s industrial and manufacturing facilities remain under substantial regulatory pressure. While almost the entirety of the state is in compliance with the 2015 ozone standard, a few counties remain in non-attainment. These counties are situated in close proximity to major interstate corridors. Given that mobile sources are responsible for approximately half of NOx emissions in Pennsylvania, according to EPA estimates, and that EPA has not updated heavy truck NOx standards in nearly two decades, it is certainly timely to move forward with a collaborative process to address achievable reductions. We believe a workable, cost-effective heavy-trucking rule can facilitate attainment for the few regions of the state that are above federal ozone NAAAQS goals. As a result, the operating environment for all of Pennsylvania’s industries can be improved, coinciding with an improvement in air quality. [EPA-HQ-OAR-2019-0055-1319-A1, p.2]

Organization: *San Joaquin Valley Air Pollution Control District (District)*

Despite achieving significant emissions reductions through decades of implementing the most stringent stationary and mobile regulatory control program in the nation, significant additional reductions in nitrogen oxide (NOx) emissions are needed to attain the latest health-based National Ambient Air Quality Standards (NAAQS) for ozone and PM2.5. [EPA-HQ-OAR-2019-0055-1291-A1, p.1]

NOx is the main precursor pollutant contributing to the formation of both ozone and secondary PM2.5 in the Valley. The District has jurisdiction over stationary and area sources, which now make up less than 15% of the total NOx emissions inventory. In contrast, over 85% of the Valley's NOx emissions come from mobile sources under federal jurisdiction, with heavy-duty trucks being the single largest NOx emissions source. While the District will continue to review all existing stationary source categories and regulations for additional emission reduction opportunities, attaining the federal standards is not possible without significant reductions in emissions from mobile source categories. Failure to meet the federal Clean Air Act NAAQS requirements would lead to devastating public health and economic consequences for the San Joaquin Valley. [EPA-HQ-OAR-2019-0055-1291-A1, p.2]

Federal action to reduce emissions is critical if we are to attain the NAAQS. It is clear that without significant progress in reducing mobile source emissions, especially at the federal level, it will be extremely difficult if not impossible to meet our air quality mandates. Absent strong federal action, extreme nonattainment areas such as the San Joaquin Valley face Clean Air Act penalties and sanctions due to mobile source emissions under federal jurisdiction. [EPA-HQ-OAR-2019-0055-1291-A1, p.2]

Organization: *South Coast Air Quality Management District*

The South Coast AQMD is the agency responsible for improving air quality in the South Coast Air Basin (Basin), a region in Southern California with 17 million residents that EPA has designated extreme nonattainment for ozone pollution. As a result of the Basin's historical and ongoing air quality challenges, EPA rulemaking to secure further reductions of emissions from heavy-duty truck engines is a matter of exceptional urgency for the District. In 2016, the District, allied with multiple other local air quality planning agencies, petitioned EPA for rulemaking to adopt ultra-low NOx standards for heavy-duty trucks and engines.1 [EPA-HQ-OAR-2019-0055-1201-A1, p.1]

> 1 South Coast AQMD, 2016 Petition for Rulemaking, available at https://www.epa.gov/sites/default/files/2016-09/documents/petition_to_epa_ultra_low_nox_hd_trucks_and_engines.pdf.

The South Coast Air AQMD is the regional agency responsible for control of air pollution from non-vehicular sources in the South Coast Air Basin (Basin).4 Specifically, the South Coast AQMD has jurisdiction over an area of approximately 10,743 square miles, consisting of the Basin, and the Riverside County portions of the Salton Sea Air Basin and Mojave Desert Air Basin. The Basin, which encompasses all of Orange County in addition to the non-desert portions of Los Angeles, Riverside, and San Bernardino Counties, is home to over 17 million people and approximately 11 million motor vehicles.5 The Basin has also experienced rapid growth over the course of the past century. The population of the region is expected to see continued growth through 2023 and beyond.6 The meteorology, topography, and climate of the

Southern California region combine to create a concentration of high air pollution potential in the Basin.7 Additionally, the four counties of the Basin comprise one of the largest and fastest-growing local economies in the United States, with rapid growth in the shipping, trade, service, and logistics sectors. [EPA-HQ-OAR-2019-0055-1201-A1, p.2]

7 See e.g. South Coast AQMD, Overview of 2022 Air Quality Management Plan (2022 AQMP Overview) (March 4, 2022), available at http://www.aqmd.gov/docs/default-source/Agendas/Governing-Board/2022/2022-Mar4-020.pdf?sfvrsn=6, Slide 3 (Ozone Trends in the South Coast Air Basin).

The combined impact of air quality control programs at the local, state, and federal levels have provided significant reductions in emissions of harmful pollutants over time. As a consequence of regulations and efforts enacted to date, ozone planning inventory emissions are projected to be 379 tons per day (tpd) of VOC and 255 tpd of NOx by 2023.8 By 2031, emissions are projected to be further reduced to approximately 362 tpd of VOC and 214 tpd of NOx.9 Total NOx emissions in the Basin will have been reduced by nearly 51% between 2012 and 2023 due to state and local efforts alone. However, reaching attainment in 2023 without corresponding reductions from federal sources would require total elimination of nearly all AQMD and CARB regulated sources. This is neither reasonable nor feasible. It is simply not possible for State and local reductions to attain National Ambient Air Quality Standards (NAAQS) for ozone without reductions from federal sources. The Basin is in extreme nonattainment for the 8-Hour Ozone (2015) NAAQS.10 [EPA-HQ-OAR-2019-0055-1201-A1, pp. 4-5]

9 Id.

10 EPA, 8-Hour Ozone (2015) Nonattainment Areas, available at https://www3.epa.gov/airquality/greenbook/jnc.html.

For the 1997 ozone standard alone, the Basin needs a total of 67-69 tpd of NOx reductions from federally-regulated sources by 2023 in order to meet its attainment goals on time. In fact, it is projected that the Basin will need a 45% reduction in NOx emissions beyond existing regulations by 2023, a 55% reduction by 2031. Emissions must be reduced to a carrying capacity of 141 tpd by 2023.11 As a result, the Basin must reduce expected 2023 emissions by 128 tpd. The region also needs approximately 54 tpd of NOx reductions from federally-regulated sources by 2037 to attain the 2015 standard. Overall, emissions must be reduced by 72% beyond the 220 tpd baseline NOx emissions in 2037 to achieve the 62.8 tpd carrying capacity.12 [EPA-HQ-OAR-2019-0055-1201-A1, p.5]

12 2022 AQMP Overview at Slides 5 & 6 (Key Pollutants for Ozone Attainment & NOx Emissions and Reduction Goals).

Per California's EMission FACtors (EMFAC) 2021 emissions inventory model, nearly two million heavy duty vehicles operate in California each year. These include long-haul trucks, transit buses, and drayage trucks, which are a significant source of NOx emissions. In California alone, these sources account for 31% of all statewide NOx emissions.13 Existing mobile source programs are expected to reduce NOx emissions by over 50% in the Basin by the 2031.14 Still, on-road heavy-duty vehicles will remain one of the largest contributors to the state's NOx emissions inventory as well as a sizeable portion of the Basin's emissions inventory.15 As noted in the EPA's Notice of Proposed Rulemaking (NPRM), heavy-duty engines are expected to represent 32% of mobile source NOx emissions in Calendar Year (CY) 2045 and 89% of the on-road NOx inventory in CY 2045.16 [EPA-HQ-OAR-2019-0055-1201-A1, p.5]

California is not alone in its need for more stringent regulation of NOx emissions. For instance, during public testimony on the NPRM, the Northeast States for Coordinated Air Use Management indicated that a significant portion of its region, which covers New England, New York, and New Jersey, 'struggles to comply' with the 2008 8-hour ozone standard.17 The National Association of Clean Air Agencies also testified that over a third of the nation's population lives in areas of the country designated non-attainment for the ozone NAAQS, while 'many others live in areas just on the cusp of non-attainment.'18 Testimony from Maryland's Department of the Environment indicated that although the state has taken aggressive measures to meet its air quality goals, including adoption of California's Light-Duty Vehicle Emission Program, a majority of the population continues to reside in areas designated as non-attainment for the 2015 ozone standard, with a significant additional portion of the state set to be bumped up to non-attainment status this year.19 Echoing similar sentiments, the Oregon Department of Environmental Quality noted that in spite of adoption of several more stringent California rules, increases in ozone concentrations are likely, with Oregon at risk of losing its attainment status in several communities.20 Numerous other examples exist but the sentiment remains the same – a strong nationwide low-NOx standard is essential. Organization: *States of California, et al. (The States)*

As stated, heavy-duty engines are a significant source of inhalable particulate matter PM2.5 and NOx emissions in the country. The CAA requires EPA to set and regularly review and revise federal health-based ambient air quality standards for "criteria pollutants," including PM2.5, NOx, and ground-level ozone.28 These National Ambient Air Quality Standards (NAAQS) aim to provide States with achievable goals to protect the health of their residents from air pollution resulting from emissions of criteria air pollutants and precursors. The NAAQS for ozone, established in 2015 and retained in 2020, is an 8-hour standard with a level of 70 parts per billion, although EPA recently announced that it may reconsider the previous administration's decision to retain the ozone NAAQS.29 EPA is also implementing the previous 8-hour ozone standard, set in 2008 at a level of 75 parts per billion. For PM2.5, there are two NAAQS that were set in 1997, revised in 2006 and 2012, and retained in 202030: an annual standard (12.0 micrograms per cubic meter) and a 24-hour standard (35 micrograms per cubic meter). [EPA-HQ-OAR-2019-0055-1255-A1, pp. 9 - 10]

28. 42 U.S.C. §§ 7408-7409.

29. See EPA, "EPA to Reconsider Previous Administration's Decision to Retain 2015 Ozone Standards," available at https://www.epa.gov/ground-level-ozone-pollution/epa-reconsider-previous-administrations-decision-retain-2015-ozone.

30. On June 10, 2021, EPA announced that it will reconsider the previous administration's decision to retain the PM NAAQS. See Press Release, EPA, EPA to Reexamine Health Standards for Harmful Soot that Previous Administration Left Unchanged (June 10, 2021), available at https://www.epa.gov/newsreleases/epa-reexamine-health-standards-harmful-soot-previous-administration-left-unchanged.

Depending on whether the air quality in an area meets the NAAQS for a particular pollutant, EPA designates the area as being in "attainment" or "nonattainment." EPA further classifies areas that are in nonattainment according to the severity of their air pollution problem, and areas with more severe pollution levels are given more time to meet the standard while being subject to more stringent control requirements under State Implementation Plans. [EPA-HQ-OAR-2019-0055-1255-A1, p. 10]

As of May 31, 2021, there were 34 ozone nonattainment areas for the 2008 ozone NAAQS and 50 ozone nonattainment areas for the 2015 ozone NAAQS, which amounts to 122 million people living in ozone nonattainment areas.31 Sixteen of the 8-hour ozone nonattainment areas are located in California and the only two extreme nonattainment areas in the nation are located in the South Coast Air Basin and San Joaquin Valley of California.32 Indeed, for the South Coast Air Basin to meet the federal ozone standards, overall NOx emissions need to be reduced by 70 percent from today's levels by 2023, and approximately 80 percent by 2031.33 The Greater Connecticut and New York-Northern New Jersey-Long Island ozone nonattainment areas failed to meet the deadline for moderate nonattainment of the 2008 ozone NAAQS and were re-designated to serious nonattainment status for that NAAQS. These areas must now meet the attainment date of 2021 for the 2008 standard. Many areas of the country are also currently in nonattainment for the PM2.5 NAAQS standards, and as of May 31, 2021, more than 32 million people live in PM2.5 nonattainment areas.34 [EPA-HQ-OAR-2019-0055-1255-A1, p. 10]

33. CARB, Staff Report, Initial Statement of Reasons – Public Hearing to Consider the Proposed Heavy-Duty Engine and Vehicle Omnibus Regulation and Associated Amendments, at II-2 (June 23, 2020), EPA-HQ-OAR-2019-0055-0632 ("Omnibus ISOR").

34. Draft RIA at § 6.1.1.

Given the extraordinary challenges that California and many States are facing to attain and maintain ozone and PM2.5 NAAQS, substantial emission reductions beyond those currently being achieved by state regulatory programs are critically necessary. Reducing emissions from heavy-duty vehicles will help States attain and maintain NAAQS for these pollutants.

According to California's EMission FACtors (EMFAC) 2017 emissions inventory model, almost a million heavy-duty vehicles operate on California roads each year and contribute 31 percent of all statewide NOx emissions.35 In the South Coast Air Basin, heavy-duty vehicles are responsible for 32 percent of mobile source NOx emissions.36 In New York, medium and heavy-duty vehicles are responsible for 52 percent of the NOx and 45 percent of the PM2.5 emitted by on-road vehicles. Further, regulating only heavy-duty engines certified for use in California and other States is not sufficient because heavy-duty vehicles play an important role in the transport of goods for interstate commerce and frequently cross state borders.37 Therefore, the Proposed Rule would assist States with attaining and maintaining the NAAQS, and ease the burden on nonattainment areas that already have stringent state and local regulations.38 [EPA-HQ-OAR-2019-0055-1255-A1, pp. 10 - 11]

35. Omnibus ISOR at ES-1.

36. CARB, Measures for Reducing Emissions from On-Road Heavy-Duty Vehicles (June 3, 2021) available at http://www.aqmd.gov/docs/default-source/clean-air-plans/air-quality-management-plans/2022-air-quality-management-plan/heavy-duty-trucks-presentations-06-03-21.pdf?sfvrsn=8 (last accessed May 16, 2022).

37. See Omnibus ISOR at ES-17.

38. See Draft RIA at § 6.1.2

The emission reductions achieved by Option 1 are also critical for States seeking to attain and maintain the NAAQS for ozone and PM2.5. For example, given California's extraordinary challenges in attaining both the ozone and PM2.5 NAAQS, its state implementation plan is designed with stringent emissions reductions across all sources. But even with the expected emission reductions from California's mobile source programs, on-road heavy-duty vehicles are projected to remain one of the largest contributors to the state's NOx emissions inventory.64 And operators in many States, including in California, purchase used heavy-duty vehicles that have been certified to meet federal, not state, standards. Indeed, federally certified heavy-duty vehicles account for over half of the total miles traveled by heavy-duty vehicles in California.65 For the heaviest vehicles (Class 8 vehicles over 33,000 pounds GVWR), over 60 percent of vehicle miles traveled in California are by federally certified heavy-duty vehicles.66 Thus, the adoption of Option 1 is critical to provide the maximum emission reductions necessary for California and other States to attain and maintain the NAAQs for ozone and PM2.5. [EPA-HQ-OAR-2019-0055-1255-A1, p. 15]

Organization: *Western States Air Resources Council (WESTAR)*

Mobile emissions represent approximately 65% of the current NOx inventory in the 13 contiguous WESTAR states. For clarification, mobile sources include on-road, non-road, rail, and commercial marine. Comparatively, oil and gas sources contribute 11.7% and electrical generating units contribute 9.1%. For additional perspective, percentage contributions from all source sectors are shown in Figure 1. The Western states projected that the mobile source NOx emissions will still comprise 44.5% of the western inventory in 2028. Most of the reductions in this sector will come from the Tier 3 Motor Vehicle Emission and Fuel Standards program established in 20142. However, the Tier 3 program is projected to be fully implemented by 2025 and it is important to continue reducing mobile source emissions to reduce particulate matter and ozone concentrations in the west. Additional mobile source emissions reductions will be necessary for western states to continue to improve visibility in Class I areas as well. Of the 156 Mandatory Class I Federal areas, 118 (75 percent) are in the West. Western states have made considerable progress in controlling stationary source emissions. Mobile source emission reductions must be accomplished at a similar pace. Reductions in emissions that can be controlled are particularly important as catastrophic wildfire smoke impacts western states with increasing severity and frequency. A recent study by the National Center for Atmospheric Research shows that the increase in wildfires has begun to reverse the last ten years of clean air gains and is changing the annual pattern of air quality in North America.3 [EPA-HQ-OAR-2019-0055-1230-A1,pp.1-3]

> 2 WRAP Technical Support System (TSS); The Western Regional Air Partnership (WRAP) and the Cooperative Institute for Research in the Atmosphere (CIRA), 19 Apr 2022, http://views.cira.colostate.edu/tssv2
>
> 3 Buchholz, R.R., Park, M., Worden, H.M. et al. New seasonal pattern of pollution emerges from changing North American wildfires. Nature Communications 13, 2043 (2022). https://doi.org/10.1038/s41467-022-29623-8

One of EPA's stated goals with this proposed rule is to help states comply with the ozone NAAQS and improve visibility as part of the Regional Haze program. The proposal states that "The proposed Option 1 standards would significantly decrease ozone concentrations across the country, with a population- weighted average decrease of over 2 ppb in 2045.4 " In terms of emissions reductions, EPA estimates that Option 1 would reduce NOx emissions from heavy-duty vehicles in 2040 by more than 50 percent and by 60 percent in 2045. Most nonattainment areas for the 2008 and 2015 ozone NAAQS are required to attain the standard within the next six years (2028). While the proposed emission reductions are welcome, they will be too late to impact current ozone nonattainment areas and won't prevent the short-term transport of pollution throughout the western states. For this reason, we encourage EPA to find ways to foster quicker adoption of heavy-duty engine controls and technology within the industry through incentives and the proposed early adoption credits. [EPA-HQ-OAR-2019-0055-1230-A1,pp.3-4]

> [4] Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards, 87 Fed Reg. 17427 (March 28, 2022)

Organization: *Wisconsin Department of Natural Resources (WDNR)*

This proposed rule would provide critical relief to Wisconsin's ozone nonattainment areas by reducing NOx emissions from heavy-duty trucks by up to 90%. [EPA-HQ-OAR-2019-0055-1162-A1, p. 1]

Wisconsin's Lake Michigan shoreline experiences complex, persistent ozone issues due to a combination of emissions, meteorology, and geography. As a result, Wisconsin's lakeshore has historically struggled to attain federal ozone standards, and the state currently has multiple areas in nonattainment of the 2015 ozone standard. Ensuring Wisconsin can attain current and future ozone National Ambient Air Quality Standards (NAAQS) requires a long-term, multi-sector strategy that reduces region-wide NOx and VOC emissions. Since Wisconsin does not have the authority to regulate emissions from on-road sources, the state relies upon federal action to reduce NOx and VOC emissions from this sector. It is therefore crucial that EPA exercise its authority to develop and implement the most stringent, technically feasible NOx standards for all mobile sources, including heavyduty vehicles. [EPA-HQ-OAR-2019-0055-1162-A1, p. 1]

The on-road mobile sector is the largest contributor of NOx emissions in Wisconsin, with the 2017 National Emissions Inventory reporting that the on-road mobile sector accounted for 38% of the NOx inventory in Wisconsin; this percentage is typical of other states in the region.1 Heavy-duty diesel vehicles constitute nearly half of the emissions from that sector, a sector only the federal government is able to regulate. Additionally, recent ozone modeling done by the Lake Michigan Air Directors Consortium indicates on-road diesel vehicles, most of which are heavy-duty vehicles, contribute up to 8 parts per billion or 11% of ozone at Wisconsin's lakeshore nonattainment monitors. EPA's air quality modeling done to support this proposal shows Sheboygan County would remain in nonattainment through at least 2045 without this rule, 30 years after the standard was promulgated. [EPA-HQ-OAR-2019-0055-1162-A1, pp. 1 - 2]

1. 2017 National Emissions Inventory

Wisconsin's ozone nonattainment areas are located downwind of major population centers, including transportation and freight hubs that are a significant source of heavy-duty vehicle emissions, the vast majority of which originate outside of Wisconsin. Based on EPA's recent transport modeling, Wisconsin contributes only 8- 16 percent of the ozone in its own nonattainment areas while other states directly contribute between 42-48 percent of the ozone to these areas. A comprehensive federal rule to address heavy-duty NOx emissions is therefore needed to reduce upwind state emissions from this sector and help Wisconsin meet its attainment obligations. [EPA-HQ-OAR-2019-0055-1162-A1, p. 2]

EPA Summary and Response

Summary:

Commenters stated that the emissions reductions from this rule are needed to reduce ozone concentrations and attain and maintain the ozone NAAQS. Commenters indicated that NOx emissions are driving their ozone concentrations and that heavy-duty trucks are significant contributors to the NOx emissions and ozone concentrations in their areas, including heavy-duty traffic associated with freight movement and ports. Commenters mentioned that satellite data is helping illustrate the onroad NOx emissions which contribute to ozone and PM concentrations. Commenters also described the contribution to their ozone from NOx emissions from heavy-duty trucks from upwind states, and a commenter from California pointed out that most of the trucks on roads in the state are registered in other states, so this rule is important to their attainment plans. Several states and other organizations noted that other cost-effective state and local regulatory options for reducing emissions of NOx have been exhausted and remaining options are less cost-effective than federal heavy duty vehicle standards. Some commenters also noted that additional NOx emission reductions will help them demonstrate transportation conformity.

Several commenters highlighted that their area is in the process of having their ozone classification bumped up, meaning that they are not able to meet the ozone NAAQS by their attainment deadline. Commenters specifically noted that EPA proposed to bump up 30 areas that were not attaining the 2008 and 2015 ozone NAAQS in April 2022. Commenters said that reductions in NOx emissions from heavy-duty vehicles will help those areas as well as other areas struggling to maintain the ozone NAAQS. A commenter noted that EPA was required to use modeling to help put into place more stringent standards so that areas would actually attain the NAAQS as expeditiously as possible. Another commenter felt that EPA should optimize the emission reductions needed from HD on-road vehicles to ensure attainment of the ozone and $PM_{2.5}$ NAAQS within the deadlines established by the CAA.

One commenter mentioned that much of the country has NOx-limited chemistry, which means that reductions of NOx are needed to reduce ozone, and that in some East Coast areas reducing one pound of NOx leads to reductions of greater than one pound of ozone. Another commenter highlighted that even ozone concentrations below the level of the standard contribute to risk of premature death in sensitive populations.

Numerous commenters mentioned that EJ communities are located in nonattainment areas or areas at risk of becoming nonattainment areas. A commenter noted that NAAQS monitors are often not cited to protect EJ communities and that makes it difficult to understand their risk and suggested that EPA should include in the rule additional requirements for increased air monitoring for pollutants of concern near transportation corridors in overburdened communities to document whether these existing and proposed regulatory approaches are working.

A commenter also stated that EPA is currently reconsidering the ozone NAAQS, and that regardless of whether the standard is strengthened, many areas across the country need NOx reductions just to meet the current standards and provide clean air to their citizens. Commenters also noted that NOx reductions are important for decreasing PM concentrations and meeting the PM NAAQS as well. One commenter mentioned that EPA is currently reconsidering the PM NAAQS as well and CASAC has recommended making the standards more protective. A few commenters provided satellite data showing NO_2 concentrations along highways and illustrating how NO2 emissions have a longer lifetime in winter and can contribute to PM and visibility concerns in the winter. Commenters pointed out that reducing emissions of NOx can help reduce ozone concentrations in the summertime and $PM_{2.5}$ concentrations in the wintertime as well as helping improve visibility. Commenters concerned with meeting the ozone and $PM_{2.5}$ NAAQS asked for the most stringent and timely rule possible. A commenter noted that the rule is needed for ozone attainment but that there is also need for flexibilities. A commenter also stated that zero emission standards are needed to help all areas of the country attain the NAAQS and that EPA should analyze more stringent alternatives.

Response:

EPA agrees that reductions in NOx are generally necessary to attain and maintain the ozone and $PM_{2.5}$ NAAQS across the country and that NOx reductions will help with other CAA responsibilities like the regional haze rule and transportation conformity. EPA also agrees that monitoring is important to helping EPA and the general public understand the quality of the air they are breathing and its potential impacts on their health. The comments requesting additional monitoring are outside the context of this specific rule, which is more narrowly focused on setting emission standards under CAA section 202. The monitoring objectives, requirements, and network design criteria for Ozone, PM, NO_2, and CO are specified in 40 CFR part 58 appendix D. Monitoring objectives include providing data to the general public in a timely manner, supporting compliance with the NAAQS, and providing data for research purposes. The monitoring requirements include monitoring sites that serve a variety of needs and are often higher than EPA's minimum requirements provide. In addition to the existing regulatory network, EPA is improving ambient air quality monitoring for communities with American Rescue Plan funds (see https://www.epa.gov/arp/enhanced-air-quality-monitoring-funding-under-arp).

This final rule will reduce emissions from heavy-duty engines that contribute to ambient levels of ozone, PM, NO_X, and CO, which are all pollutants for which EPA has established health-based NAAQS, and we agree that there is a significant need for the emissions reductions, air quality improvements, and health benefits provided by this final rule. As documented in our RIA for this final rule (Chapters 5 and 6) and described in the Preamble (Sections VI and VII), the HD2027 program will significantly reduce heavy duty truck emissions, leading to significant air quality improvements and helping state and local areas attain and maintain the existing health-based air quality standards in a cost-effective and timely way.[3]

In setting heavy-duty highway engine emission standards for NO_X, PM, HC, and CO, Clean Air Act section 202(a)(3)(A) requires EPA to set standards that ''reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology.'' EPA's authority to set such standards must be based on appropriate consideration of these specified factors, and EPA has fully analyzed and explained the basis for the final standards under this authority, as discussed further in the Preamble (Sections I and III). We recognize and acknowledge the concerns raised by several commenters related to attaining and/or maintaining the NAAQS. As discussed in this section and preamble Section VII, we

[3] In response to the commenter requesting that EPA include in this final action direction to states that would encourage collaborative management of mobile emissions from heavy duty trucks, we note that such direction is outside the scope of this final rule; however, as discussed in this section and preamble Section VII, we expect the air quality improvements of this rulemaking to be widespread across the country.

expect this final rule to result in widespread reductions in ozone and PM, which will assist many areas across the country with NAAQS attainment or maintenance. However, the amount of reductions necessary for each area to attain the NAAQS is not a factor used to determine the stringency of heavy-duty engine emissions standards.

States with ozone and $PM_{2.5}$ nonattainment areas are required to take action to bring those areas into attainment. Since this rule will reduce emissions of NOx from trucks across the country, this rule will help states and municipal areas in their efforts to attain the ozone and $PM_{2.5}$ NAAQS "as expeditiously as practicable" and may relieve areas with already stringent local regulations from some of the burden associated with adopting additional local controls. The final rule could also assist counties with ambient concentrations near the level of the ozone and $PM_{2.5}$ NAAQS who are working to ensure long-term attainment or maintenance of the ozone and $PM_{2.5}$ NAAQS. The air quality modeling done for the proposed rule illustrates the impact on projected concentrations of ozone and $PM_{2.5}$. Our air quality modeling indicates this action will meaningfully decrease ozone concentrations in many areas of the country. Furthermore, numerous state air quality agencies and organizations representing geographic groups of these state agencies have affirmed in their comments that air quality improvements from this rule will be a critical part of areas' strategies to attain and maintain the NAAQS. Our analysis of the air quality impacts of the proposed standards clearly shows these improvements. While we agree that understanding the impact of the rule on future attainment is important, due to time and resource constraints, we focused our air quality modeling on a future year with substantial fleet turnover (2045) rather than on years with specific attainment deadlines.

Responses to comments about the EJ need for this rule are in Section 23.EPA is not taking final action at this time as part of this final rule on the portion of the HD 2027 NPRM regarding proposed changes to HD GHG Phase 2 standards. For the comments received on this portion of the proposal, see Section 28 of this document.

2.3 Human and environmental health impacts of greenhouse gases (GHGs) and climate change

Comments by Organizations

Organization: *350Marin*

The IPCC's 2022 report warns that irreversible climate impacts are happening now. [EPA-HQ-OAR-2019-0055-2474, p.1]

We in California are feeling the effects of Climate Change for five years already. Eight of the largest wild fires in state history have occurred since 2017. Additionally, we are dealing with increased drought and longer fire seasons. We are in a Climate Emergency. [EPA-HQ-OAR-2019-0055-2474, p.1]

To stop global heating and stabilize the climate, Greenhouse gas emissions have to be cut drastically. [EPA-HQ-OAR-2019-0055-2474, p.1]

Here in California transportation is the largest instate source of such emissions. Nationwide transportation makes up 29% of the carbon footprint, with heavy-duty vehicles emitting nearly one-third. Reducing vehicle GHG emissions is key. New trucks covered by these new EPA standards will be on the road long beyond 2050; they should be zero emission starting as soon as possible. [EPA-HQ-OAR-2019-0055-2474, p.1]

Organization: *Agricultural Retailers Association (ARA) (1241 and 1421)*

In addition, American biofuels like ethanol reduce greenhouse gas (GHG) emissions by 46 percent compared to regular gasoline and are key to achieving any climate goals.2 [EPA-HQ-OAR-2019-0055-1251-A1, p. 3]

> 2. https://growth energy. org/2022/04/12/growth-energy-thanks-biden-for-delivering-lower-cost-fuel-options-for-families/

Organization: *American Soybean Association (ASA)*

Biomass-based diesel offers lower emissions solutions in the transportation sector and as the Administration seeks to move toward an electric vehicle-focused approach to lowering greenhouse gas emissions, biomass-based diesel can offer greenhouse gas emissions reductions of at least 50% compared to petroleum diesel in aging vehicles that still require liquid fuel and in heavy-duty vehicles that are more difficult to electrify. [EPA-HQ-OAR-2019-0055-1309-A1, p.2]

As the federal government seeks to address climate change both today and long-term, biomass based diesel will remain an important tool in the toolbox in both existing diesel engines and new ultra-low carbon liquid fuel engine technologies. Carbon emissions continue to accumulate, and increased utilization of biomass-based diesel and other biofuels can help mitigate increasing emissions occurring at present. The Intergovernmental Panel on Climate Change notes in its sixth assessment report that using existing low carbon technologies is a crucial component to avoiding catastrophic temperature increases, stating that 'biodiesel and renewable diesel fuels…could offer important near-term reductions' for a number of technologies, including buses, rail, and long-haul trucking.2 [EPA-HQ-OAR-2019-0055-1309-A1, p.2]

Organization: *Anne Mellinger-Birdsong*

4. CO2 is one of the main greenhouse gases causing climate change. Numerous health agencies and medical institutions have declared that climate change is a public health emergency (https://doi.org/10.1056/NEJMe2113200). The World Health Organization states that “Climate

change is the single biggest health threat facing humanity.” (https://www.who.int/news/item/11-10-2021-who-s-10-calls-for-climate-action-to-assure-sustained-recovery-from-covid-19) [EPA-HQ-OAR-2019-0055-1244]

Organization: *CALSTART*

The climate crisis is also at a critical stage. Reports from the Intergovernmental Panel on Climate Change (IPCC) document the urgency to reduce global warming emissions. In the IPCC’s recently released Sixth Assessment Report, global greenhouse gas (GHG) emissions peak between 2020 and 2025 in pathways that limit warming to 1.5°C with a 50 percent probability and no or limited overshoot (IPCC, 2022). Global warming emissions must be reduced by 43 percent from 2019 levels by 2030 to limit warming to 1.5°C with a 50 percent probability (IPCC, 2021). Aligned with this emission target is the commitment by the United States to reduce national net GHG emissions by 50-52 percent compared to 2005 levels by 2030.2 If emissions are not reduced to these levels by 2030, it will be even more difficult to limit warming later this century (IPCC, 2018). [EPA-HQ-OAR-2019-0055-1313-A1, p.2]

> 2 50 percent below 2005 levels (7,435 MMT CO2e) of US emissions corresponds to roughly the same level of reductions as 43 percent below 2019 levels (6,571 MMT CO2e) (UNFCCC, 2021; EPA, 2022).

The global decline in emissions must occur despite emissions continuing to grow globally over the last decade (IPCC, 2022a). While we are behind the pace needed to stabilize global temperatures at safe levels, we can still limit warming to 1.5°C through actions in the next couple of years (IPCC, 2021). If global carbon dioxide emissions continue at current rates, the remaining carbon budget for limiting warming to 1.5°C will likely be exhausted before 2030 (IPCC, n.d.). About 410±30 Gt of CO2 were emitted between 2010 and 2019. This is about the same size as the remaining carbon budget for keeping global warming to 1.5°C with a 67 percent probability (about 400 Gt CO2 from 2020 onwards or a 500 Gt CO2 budget with a 50 percent probability of limiting warming to 1.5°C) (IPCC, 2021). [EPA-HQ-OAR-2019-0055-1313-A1, pp.2-3]

Organization: *ChargePoint, Inc. (ChargePoint)*

With 21% of all transportation sector GHG emissions traced to MHDVs (including buses),3 continuing to target the lowering of MHDV emissions through thoughtful regulatory action will aid tremendously in improving air quality nationwide, especially in roadside communities. [EPA-HQ-OAR-2019-0055-1294-A1, p. 1]

Organization: *Chesapeake Bay Foundation, Inc. (CBF)*

In addition, the devastating effects of climate change have solidified the need to drastically reduce greenhouse gas emissions (GHGs). [EPA-HQ-OAR-2019-0055-1295-A1, p.1]

The increasingly dramatic impacts from climate change have begun and will continue to add stress to the Bay.36 In November 2018, Volume II of the Fourth National Climate Assessment found 'that climate change is affecting the natural environment, agriculture, energy production and use, land and water resources, transportation, and human health and welfare across the U.S. and its territories.'37 The Bay region has already experienced several of these impacts, including increased temperatures and sea level rise.38 Like excess nitrogen, warm waters contribute to dead zones due to their decreased capacity to hold dissolved oxygen. Rising sea levels have submerged islands and coastline, including CBF property. Some scientists predict that the Bay region could see as much as a three- to four-foot sea level rise this century.39 The 2014 Chesapeake Bay Agreement sets a goal to improve climate resiliency in the Bay, and EPA is charged with ensuring states make progress toward achieving and maintaining this goal.40 [EPA-HQ-OAR-2019-0055-1295-A1, p.9]

Climate change will also make it more difficult to reduce nitrogen loads to the Bay as rainfall becomes increasingly extreme and sporadic, pouring nutrients and sediment into Bay waterways.41 In 2018, the Bay experienced record-setting rainfall, which was followed by one of the Bay’s largest dead zones in 35 years.42 The impacts from climate change threaten the Bay’s recovery and future, and will require even greater pollution reduction efforts to maintain the progress made through the Bay TMDL. [EPA-HQ-OAR-2019-0055-1295-A1, p.9]

EPA must finalize a rule that accelerates the transition to a zero-emission truck fleet that will drastically reduce the sector's emissions of greenhouse gases and its contribution to the devastating impacts of climate change. [EPA-HQ-OAR-2019-0055-1295-A1, p.9]

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

Strong emissions standards are also necessary to curtail HDVs' outsized contribution to climate change. Over twelve years ago, based upon a massive scientific record, EPA found that new motor vehicles and engines contribute to the GHGs that force climate change and endanger the public health and welfare of current and future generations. 74 Fed. Reg. 66,496 (Dec. 15, 2009). The Endangerment Finding specifically included emissions from heavy-duty trucks and buses. 74 Fed. Reg. at 66,499. At the time, the transportation sector was responsible for 23% of total annual U.S. GHG emissions. Id. Since then, transportation sector emissions have only increased as a share of U.S. emissions, surpassing the electric power sector as the largest U.S. source of GHG emissions, contributing 29% of total GHG emissions in 2019 and 27.2% in 2020.29 [EPA-HQ-OAR-2019-0055-1302-A1, p.17]

> 29 EPA, Inventory of U.S. Greenhouse Gas Emissions and Sinks at ES-21 (Apr. 15, 2022), https://www.epa.gov/system/files/documents/2022-04/us-ghg-inventory-2022-main-text.pdf.

On April 29, 2022, EPA denied four petitions to reconsider the Endangerment Finding. 87 Fed. Reg. 25,412 (Apr. 29, 2022). In denying the petitions, EPA stated: The science supporting the Administrator's finding that elevated concentrations of greenhouse gases in the atmosphere may reasonably be anticipated to endanger the public health and welfare of current and future U.S. generations is robust, voluminous, and compelling, and has been strongly affirmed by recent scientific assessments of the National Academies, the US Global Change Research Program, and the Intergovernmental Panel on Climate Change.30 [EPA-HQ-OAR-2019-0055-1302-A1, p.17]

> 30 EPA, Decision Document, EPA's Denial of Petitions Relating to the Endangerment and Cause or Contribute Findings for Greenhouse Gases Under Section 202(a) of the Clean Air Act 1 (Apr. 1, 2022), https://www.epa.gov/system/files/documents/2022-04/decision_document.pdf; see also id. at 11–13 (documenting the continued advances in climate science that bolster the Endangerment Finding).

HDVs are the second largest domestic contributor of GHGs in the transportation sector. From 1990 to 2019, transportation GHG emissions from fossil fuel combustion increased by 20.9%.31 Medium- and heavy-duty truck GHG emissions nearly doubled between 1990 and 2019.32 This increase was driven, in part, by substantial growth in medium- and heavy-duty truck vehicle miles traveled (VMT), which increased by 107% between 1990 and 2020.33 Transportation sources also produce other climate-forcing pollutants such as CH4, N2O and HFCs.34 [EPA-HQ-OAR-2019-0055-1302-A1, p.17]

31 EPA, Inventory of U.S. Greenhouse Gas Emissions and Sinks at 3-23 (The COVID-19 pandemic led to a 13.7% decrease from 2019–2020 and is considered an outlier.). These comments incorporate and build upon the comments submitted by environmental and public health NGOs, including some signatories here, on EPA's Proposed Rule Regarding Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emission Standards.35 Those comments were a continuation of a series of comments updating the record underlying the Endangerment Finding with increasingly dire evidence of the current and future impacts of climate change and the transportation sector's outsized contribution. [EPA-HQ-OAR-2019-0055-1302-A1, pp.17-18]

35 Comments of Center for Biological Diversity et al., Regarding Proposed Rule Regarding Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emission Standards (Docket No. EPA-HQ-OAR-2021-0208) (Sept. 27, 2021).

Since the NGOs' most recent set of transportation comments were filed, the United Nations Intergovernmental Panel on Climate Change (IPCC) released several constituent pieces of the Sixth Assessment Report.36 The report warns that the world must quickly and drastically cut its dependence on fossil fuels or face climate disaster. GHGs from human activities are the most significant driver of observed climate change since the mid-20th century.37 As GHG emissions from human activities increase, they build up in the atmosphere and warm the climate, leading to increasingly destructive changes around the world—in the atmosphere, on land, and in the oceans.38 Steep and swift reductions in GHG emissions are essential to avoid the most catastrophic consequences of climate change.39 [EPA-HQ-OAR-2019-0055-1302-A1, p.18]

In 2019, GHG emissions from the global transport sector accounted for 23% of global energy-related CO2 emissions—with 70% of those emissions coming from road vehicles.40 Overall global transport emissions have increased 57% since 1990, growing at an average of 2% per year between 2010 and 2019, and faster than any other sector.41 Global freight transport grew 68% between 2000 and 2015.42 To have a chance at limiting global temperature increase to 1.5â„ƒ and avoid the worst impacts of climate change, current GHG emissions from the transportation sector must drop by 59% by 2050 as compared to 2020 emissions.43Analysis conducted by ICCT finds that new HD ZEV sales of 45% or higher by 2030 is necessary to avoid greater than 2â„ƒ of warming.44 Meanwhile, the IPCC predicts that without intervention, CO2 emissions from transport could grow in the range of 16% to 50% by 2050.45 The IPCC concluded that '[l]and-based, long-range, heavy-duty trucks can be decarbonised through battery-electric haulage… complemented by hydrogen[-based]…fuels in some contexts.'46 [EPA-HQ-OAR-2019-0055-1302-A1, p.18]

In another report issued since the last set of NGO comments, the Office of Management and Budget (OMB) assessed the costs of climate change to the federal government, estimating that they could grow to as much as $128 billion annually due to disaster relief, flood insurance, crop insurance, healthcare expenditures, wildland fire suppression, and flood risk.47 OMB considered costs that damage physical infrastructure, social conditions, health of people and ecosystems, and economic productivity. The OMB report underscores the IPCC's stark warnings. [EPA-HQ-OAR-2019-0055-1302-A1, pp.18-19]

47 See generally OMB, Federal Budget Exposure to Climate Risk (Apr. 2022), https://www.whitehouse.gov/wp-content/uploads/2022/04/ap_21_climate_risk_fy2023.pdf.

To stave off the worst impacts of climate change, the U.S. has set a goal of reaching net zero emissions no later than 2050.48 This commitment, along with the Clean Air Act's commands, require reducing and ultimately eliminating GHG emissions from the heavy-duty truck sector as rapidly as feasible. This rulemaking is an important step in achieving that critical goal. [EPA-HQ-OAR-2019-0055-1302-A1, p.19]

Organization: *Edison Electric Institute (EEI)*

The mix of resources used to generate electricity in the United States has changed dramatically over the last decade and is increasingly cleaner. 2016 marked the first year that natural gas exceeded coal as the main source of electricity generation in the United States. In 2021, natural gas powered about 38 percent of the country's electricity, compared to coal-fired generation at about 22 percent.1 Renewables2 generated approximately 21 percent of total generation.3 In total, approximately 40 percent of America's electricity came from clean carbon-free resources in 2021, including nuclear energy, hydropower, solar, and wind.4 [EPA-HQ-OAR-2019-0055-1282-A1, p. 2]

1. See Energy Information Administration (EIA), Electric Power Monthly: with Data for December 2021 12 (Feb. 2022), https://www.eia.gov/electricity/monthly/current_month/february2022.pdf.

2. Renewables here are defined as wind, hydroelectric, solar, biomass, and geothermal energy.

3. See n. 3, supra.

4. See id.

Energy storage is a key asset in helping the grid integrate increasing amounts of renewables and offering resilience and reliability. Electric companies are the largest users and operators of the approximately 25 gigawatts (GW) of operational storage in the country—representing 96 percent of active energy storage projects.5 [EPA-HQ-OAR-2019-0055-1282-A1, p. 3]

5. See EEI, Harnessing the Potential of Energy Storage (June 2021), https://www.eei.org/-/media/Project/EEI/Documents/Issues-and-Policy/Energy-Storage/Harnessing_Energy_Storage_Factsheet.pdf?la=en&hash=F1AB8CC768C880975C5AD28DA798B2AAF01DA2FF.

Renewable energy deployments will continue. By 2025, EIA projects approximately 125 GW of renewables capacity will be online.6 Further, EIA projects that in the United States the share of renewables in the electricity generation mix will more than double by 2050.7 EIA projects that wind will continue to be responsible for most of the growth in renewables generation through 2024, accounting for more than two-thirds of those increases in electricity generation during that period and that solar will dominate deployments thereinafter until 2050.8 [EPA-HQ-OAR-2019-0055-1282-A1, pp. 3 - 4]

6. See EIA, Annual Energy Outlook 2022: Reference Case Projections Tables – Table 16. Renewable Energy Generating Capacity and Generation (Mar. 3, 2022), https://www.eia.gov/outlooks/aeo/data/browser/#/?id=16-AEO2022&cases=ref2022&sourcekey=0.

7. See EIA, Annual Energy Outlook 2022: With Projections To 2050 – Narrative 17 (Mar. 3, 2022), https://www.eia.gov/outlooks/aeo/pdf/AEO2022_Narrative.pdf. EIA estimates are intentionally conservative, focusing on policies currently on the books and not other potential drivers of increased renewable energy deployment, including a suite of clean energy tax credits currently being considered by Congress. These credits will drive reductions in the costs of a range of clean energy sources, increasing both deployment and emissions reductions relative to the EIA base case. See, e.g., Michael Greenstone, et al., Assessing the Costs and Benefits of Clean Electricity Tax Credits, Build Back Better Act Policy Memo, Energy Policy Institute, University of Chicago, and Rhodium Group (Feb. 9, 2022), https://rhg.com/research/assessing-the-costs-and-benefits-of-clean-electricity-tax-credits/#:~:text=Building%20on%20previous%20modeling%20conducted,a%20scenario%20without%20these%20policies.

8. See id.

These changes have profoundly decreased the sector's carbon dioxide (CO_2) emissions, the primary greenhouse gas emissions associated with electricity production. Preliminary full-year estimates are that electric power sector emissions were 36 percent below 2005 levels as of the end of 2021, as low as they were in 1984.9 These reductions will continue. Fifty EEI members have announced forward-looking carbon reduction goals, two-thirds of which include a net-zero by 2050 or earlier equivalent goal, and members are routinely increasing the ambition or speed of their goals or altogether transforming them into net-zero goals. [EPA-HQ-OAR-2019-0055-1282-A1, p. 4]

9. See EIA, Monthly Energy Review, Table 11.16—Electric Power Sector (Mar. 29, 2022), https://www.eia.gov/totalenergy/data/monthly/.

In addition, the electric industry has significantly reduced air pollutants such as mercury, hazardous air pollutants (HAPs), sulfur dioxide (SO_2), and nitrogen oxides (NO_x). As of 2021, SO_2 and NO_x emissions have declined 94 and 88 percent, respectively, since 1990.10 In addition, mercury emissions have declined by 90 percent since 2010,11 and total HAPs—

including all acid gas emissions—declined by 96 percent between 2010 to 2017.12 [EPA-HQ-OAR-2019-0055-1282-A1, p. 4]

10. See EPA, EPA Issues Power Plant Emissions Data for 2021 (Feb. 22, 2022), https://www.epa.gov/newsreleases/epa-issues-power-plant-emissions-data-2021.

11. See id.; EPA, Regulatory Impact Analysis for the Final Mercury and Air Toxics Standards 2-7 (Dec. 2011), https://www.epa.gov/sites/default/files/2015-11/documents/matsriafinal.pdf

12. See 84 Fed. Reg. 2,670, 2,689 (Feb. 7, 2019).

EEI's member companies see a clear path to continued emissions reductions over the next decade using current technologies, including nuclear power, natural gas-based generation, energy demand efficiency, energy storage, and deployment of new renewable energy—especially wind and solar—as older coal-based and less-efficient natural gas-based generating units retire. These technologies will continue to enable significant, cost-effective carbon reductions. In addition, EIA notes that coal use will continue to decline with the retirement of most of the relatively old and inefficient coal-fired electricity generating units in the United States.13 [EPA-HQ-OAR-2019-0055-1282-A1, p. 5]

13. See n. 9, supra at 18.

In the long term, reaching net-zero carbon emissions also will require the deployment of next-generation, carbon-free, 24/7, dispatchable technologies not currently available commercially. Developing a broad range of advanced clean energy technologies can help further expedite the transition of the electric power sector to one that is low- or non-emitting while keeping electricity affordable and reliable for customers. [EPA-HQ-OAR-2019-0055-1282-A1, p. 5]

Organization: *Elders Climate Action*

ECA, its chapters and members have a stake in this decision both because 2) we are the parents and grandparents of children who will be compelled to live their lives in the extreme conditions that are now occurring and will worsen as a result of the climate heating caused by the GHG pollutants emitted from combustion of carbon fuels in motor vehicles. [EPA-HQ-OAR-2019-0055-1218-A1, p. 1]

ECA requests this action to –

1) respond meaningfully to the urgency of the climate crisis that threatens to destroy the future for our children and grandchildren by turning the planet into an unsustainable Hell on Earth; [EPA-HQ-OAR-2019-0055-1218-A1, p. 1]

EPA's proposed Heavy duty vehicle (HDV) rule will allow millions of polluting diesel heavy duty vehicles to be sold in the U.S. in 2027 and beyond without requiring any manufacturer to sell a single zero emission vehicle. The proposed standards fail to implement the call from the

Intergovernmental Panel on Climate Change for immediate action to transform the transportation sector to zero CO2 emissions as soon as possible to avoid the worst impacts of the looming climate disaster. [EPA-HQ-OAR-2019-0055-1218-A1, p. 2]

The transportation sector is the leading source of climate pollution in the US, but the proposal fails to make any progress toward ending CO2 emissions from transport to avoid the worst consequences of a warming climate. Your proposal allows millions more new diesel trucks and buses in 2027-29 that will lock-in over the next 20 years 1.7 billion tons of additional CO2. [EPA-HQ-OAR-2019-0055-1218-A1, p. 2]

EPA acknowledges that the proposed rule reduces CO2 emissions by only 221,000 metric tons (MT) (0.75%) compared to the current rule (from 29.088 million MT to 28.867 million MT in 2027), allowing new HDVs sold in 2027, 2028 and 2029 to emit an estimated 86.6 million MT annually after 2029, totaling 1.78 billion metric tons of CO2 over the 20 year useful life of those HDVs. CO2 from these vehicles would be equivalent to adding 21 new large coal-fired power plants. [EPA-HQ-OAR-2019-0055-1218-A1, p. 2]

Total CO2 emissions from future vehicles will double these emissions for each additional three to four model years that these standards apply after 2029. If Congress blocks further rulemaking after 2022, or a President opposed to climate action is elected, these may be the last CO2 standards adopted for a decade. [EPA-HQ-OAR-2019-0055-1218-A1, p. 2]

CO2 from these model years will effectively prevent the US from achieving the IPCC's call for a 50% cut in CO2 by 2030, and make it difficult to achieve the zero emission economy promised by President Biden by 2050. These vehicles will remain on the road for at least 20 years, add to CO2 and prevent the U.S. from achieving the CO2 reductions identified by the Intergovernmental Panel on Climate Change (IPCC) as necessary to keep within the 1.5o C target to avoid a climate catastrophe. [EPA-HQ-OAR-2019-0055-1218-A1, p. 2]

The Nation needs strong action from EPA now to achieve sharp reductions in CO2 emissions to slow the warming. Losses from climate related events cost the Nation an estimated $145 billion in 2021. Damage is expanding rapidly year over year. Delaying major reductions from the transport sector will have devastating consequences. [EPA-HQ-OAR-2019-0055-1218-A1, p. 2]

The warmer climate has triggered a massive increase in damage from wildfire in the American West where an average of 1 million acres burned just 20 years ago, to over 15 million acres each in 2020 and 2021. Thousands of families have lost homes to fire, businesses were destroyed and communities lost schools, health care facilities, water and power supplies and other infrastructure. Smoke pollution smothered much of the West with dangerous levels of air pollution that added thousands of premature deaths across the region. The record setting heat wave in the Pacific NW last year also took hundreds of lives. Wildfire studies estimate deepening drought in the West will likely double the annual area destroyed by fire in this decade. We submit a review of the impacts of wildfire in the West and the expected impacts this decade because the social cost of carbon developed by the Interagency Working Group does not include wildfire impacts when estimating the damages associated with GHG emissions. [EPA-HQ-OAR-2019-0055-1218-A1, pp. 2 - 3]

In other regions of the U.S. more powerful hurricanes, extreme floods and massive tornadoes have caused devastation to hundreds of communities across the Gulf Coast, Mid- West and Northeast. These extreme weather events have become more powerful, more frequent and more destructive. [EPA-HQ-OAR-2019-0055-1218-A1, p. 3]

The Nation needs your help now to slow the warming to protect our families and communities. Medium and heavy-duty vehicles are a major contributor to the warming. Medium- and heavy-duty trucks emit a quarter of climate pollution from transportation despite being only 10% of vehicles on the road. You must take action now that accelerates the transition to a zero emission transport sector. [EPA-HQ-OAR-2019-0055-1218-A1, p. 3]

A zero emission standard also promotes the health protection purpose of the Act by reducing the adverse impacts on health caused by climate warming. The Administrator's 2009 Endangerment Finding4 found that GHG emissions have a significant direct adverse impact is on health as a result of fatalities caused by heat waves, and indirect effects through reductions in food production and rising concentrations of air pollutants such as ozone which forms more quickly in a warmer atmosphere. HDVs with zero emission power trains protect public health by slowing the warming caused by CO2 emitted from fossil fuel vehicles. Battery electric vehicles (BEVs) and fuel cell electric vehicles (FCVs) powered by hydrogen do not involve combustion of C fuels, and do not create or emit the pollutants that are the products of C combustion. The recently issued IPCC Impacts report5 makes clear that growing harm to public health and welfare caused by GHG pollutants cannot be avoided without reducing vehicle emissions to zero. [EPA-HQ-OAR-2019-0055-1218-A1, pp. 8 - 9]

> 4. The Administrator found that elevated concentrations of greenhouse gases in the atmosphere may reasonably be anticipated to endanger the public health and welfare of current and future U.S. generations. See 74 Fed. Reg. 66496, December 15, 2009. The Administrator recently reviewed and re-affirmed this Finding in response to Petitions to vacate the Finding. See 2204-21 decision_doc deny PET re Endgmnt Fndg.pdf. 5. Climate Change 2022: Impacts, Adaptation and Vulnerability | Climate Change 2022: Impacts, Adaptation and Vulnerability (ipcc.ch) (April 2022).

The science is clear: stabilizing the climate before it becomes too hot to support human civilization is another reason beyond attaining the ozone NAAQS in all of America's 230 nonattainment counties why GHG emissions from on-road vehicles must be reduced to zero as soon as possible. In his Climate Executive Order President Biden declared that the policy of the United States is to "put the United States on a path to achieve net-zero emissions, economywide, by no later than 2050."11 [EPA-HQ-OAR-2019-0055-1218-A1, p. 17]

> 11. Executive Order to Tackle Climate Change (January 27, 2021). Sec. 201. Policy. Even as our Nation emerges from profound public health and economic crises borne of a pandemic, we face a climate crisis that threatens our people and communities, public health and economy, and, starkly, our ability to live on planet Earth. Despite the peril that is already evident, there is promise in the solutions — opportunities to create well-paying union jobs to build a modern and sustainable

> infrastructure, deliver an equitable, clean energy future, and put the United States on a path to achieve net-zero emissions, economy-wide, by no later than 2050. We must listen to science — and act. We must strengthen our clean air and water protections. We must hold polluters accountable for their actions. We must deliver environmental justice in communities all across America. The Federal Government must drive assessment, disclosure, and mitigation of climate pollution and climate-related risks in every sector of our economy, marshaling the creativity, courage, and capital necessary to make our Nation resilient in the face of this threat. Together, we must combat the climate crisis with bold, progressive action that combines the full capacity of the Federal Government with efforts from every corner of our Nation, every level of government, and every sector of our economy. It is the policy of my Administration to organize and deploy the full capacity of its agencies to combat the climate crisis to implement a Government-wide approach that reduces climate pollution in every sector of the economy; increases resilience to the impacts of climate change; protects public health; conserves our lands, waters, and biodiversity; delivers environmental justice; and spurs well-paying union jobs and economic growth, especially through innovation, commercialization, and deployment of clean energy technologies and infrastructure. Successfully meeting these challenges will require the Federal Government to pursue such a coordinated approach from planning to implementation, coupled with substantive engagement by stakeholders, including State, local, and Tribal governments.

The President's declared policy responds to and is supported by the science which makes clear that the climate will continue to heat up so long as humanity continues to increase GHG levels in the atmosphere. The global mean temperature reached 1.2 o C above the pre-industrial baseline in 2020 12 which has produced massive damage and destruction to property and natural systems, and caused hundreds of deaths, displacement, homelessness and loss of livelihoods for tens of thousands of Americans from extreme floods, drought, wildfires, hurricanes and tornadoes. [EPA-HQ-OAR-2019-0055-1218-A1, p. 17]

> 12. World Meteorological Organization, State of the Global Climate, 6 (April 2021); available at doc_num.php (wmo.int). WMO uses the "1850–1900 baseline as an approximation of pre-industrial levels." Id.

The latest climate modeling report (AR6) from the Intergovernmental Panel on Climate Change (IPCC) now makes clear that exceeding 1.5o C before 2050 is "more likely than not" even with implementation of the most aggressive GHG reduction scenario, but that the excursion above 1.5o C can be limited to a few decades if we reduce GHG emissions by half before 2030, and achieve net zero emissions by 2050. But if we fail to meet either of those targets, it is "more likely than not" that global temperatures will reach 2.0 o C with dire consequences for humanity. [EPA-HQ-OAR-2019-0055-1218-A1, pp. 17 - 18]

To achieve net-zero emissions economy wide by 2050, zero emission technologies currently available must be deployed as soon as possible to put GHG emissions from our largest source of emissions – transportation – on the path toward zero. EPA's proposed rule merely reduces carbon fuel combustion by less than 1%. A zero emission economy cannot be achieved if vehicles continue to burn carbon fuels. Internal combustion engines (ICEs) must be replaced as quickly as possible by zero emission vehicles (ZEVs). [EPA-HQ-OAR-2019-0055-1218-A1, p. 18]

EPA's proposed HDV rule does not chart a course toward implementing either the national policy declared by President Biden or reflect the urgent need to cut GHG emissions in half by 2030 to avoid much worse future climate catastrophes. The rule preamble acknowledges that the proposed rule changes will reduce HDV CO2 emissions by only .2 MMT during MY 2027 from 29 MMT to 28.8 MMT. Over the 20 year useful life of vehicles sold in MYs 2027-29 the rule will allow millions of diesel and gasoline vehicles to be added to the Nation's highways which will emit an estimated 1.7 billion MT of CO2. These emissions will wipe out more than half of the 3.1 billion MT of CO2 reduction achieved by EPA's SAFE 2 rule for light duty vehicles. These HDV emissions are the equivalent of operating 21 new coal-fired power plants. A large fraction of these emissions could be avoided if EPA adopted the CARB zero emission standard for HDVs in the ACT rule. The rule does not achieve, or describe how it will contribute to achieving, zero emissions by 2050. [EPA-HQ-OAR-2019-0055-1218-A1, p. 18]

Harm to public health and the environmental, property and economic resources of our communities incorporated into the CAA definition of "public welfare" was anticipated and comprehensively described in the Administrator's Endangerment Finding that established the basis for regulating six GHGs under the CAA.14 All of the harms anticipated in 2009 have now been demonstrated to varying degrees, and are accelerating rapidly as the planet continues to heat up. [EPA-HQ-OAR-2019-0055-1218-A1, p. 19]

14. 74 Fed. Reg. 66,496 (December 15, 2009).

Since the Endangerment Finding, EPA's catalogue of risks have been augmented by much more comprehensive modeling of warming trends, the warming expected from a range of global emission scenarios, and a description of the emission limitations that must be implemented to avoid more catastrophic climate outcomes. [EPA-HQ-OAR-2019-0055-1218-A1, p. 19]

The IPCC's 2018 report reviews and analyzes the then-available scientific literature to provide the best information available to answer two critical questions posed by world leaders at the Paris Climate conference: 1) What are the differences between the consequences of allowing the planetary climate system to rise 1.5o C compared to 2o C above the pre-industrial background? 2) What limitations on CO2 and other GHG emissions must be achieved to avoid overshooting a 1.5o C or a 2o C rise in global temperature? [EPA-HQ-OAR-2019-0055-1218-A1, p. 20]

The IPCC's 2018 report catalogues numerous expected adverse consequences of both a 1.5o C and a 2o C rise and in global mean temperature.15 Some of the effects of greatest concern are – 1) increases in mean summer temperatures and the frequency of hot days above the 99th%ile of the baseline temperature range, and the increased duration of the summer dry season that, together, will more quickly desiccate the coastal and Cascade forests each year, increase the ignitability of forest fuels, increase the frequency and intensity of wildfires, increase the production of hazardous concentrations of fine particle pollution (smoke), and increase the adverse health consequences of public exposure to multi-day extreme hazard pollution episodes; [EPA-HQ-OAR-2019-0055-1218-A1, p. 20]

15. Global Warming of 1.5o C, Chapter 3: “Impacts of 1.5o C of global warming on natural and human systems.”

2) diminished summer stream flows that force curtailment of water for agricultural operations dependent on irrigation water, and contribute to warmer surface water temperatures that interfere with the survival of cold water fish species (e.g., salmonids) and contribute to algal blooms that produce toxic contamination of municipal and agricultural water supplies and fishery habitats; [EPA-HQ-OAR-2019-0055-1218-A1, p. 20]

3) increasing ocean acidification and ocean temperatures that together prevent reproduction and survival of some marine species, cause some native local species to abandon Oregon waters in search of cooler waters, and diminish productivity of species remaining in the local water column which in turn will reduce the catch, make commercial fishing unprofitable, and further reduce the food supply for human populations dependent on marine sources of protein and resident coastal orca populations that are now starving because of diminished food supply; [EPA-HQ-OAR-2019-0055-1218-A1, p. 20]

4) the frequency and duration of extreme precipitation events that cause flooding, erosion, displacement of human populations in flood-prone areas, the destruction of freshwater and anadromous fish spawning habitat and contamination of municipal water supplies; [EPA-HQ-OAR-2019-0055-1218-A1, p. 20]

5) warmer winter temperatures that convert winter snow precipitation events to rainfall thereby reducing the high altitude storage of water which diminishes water resources available for agriculture and municipal uses during the spring and summer, and increases the severity of drought by reducing stream flows, causing crop loss, loss of fishery habitat, and inadequate water supplies for residential and industrial users and fire fighting. [EPA-HQ-OAR-2019-0055-1218-A1, pp. 20 - 21]

6) longer wildfire seasons and expanded burn zones that increase human exposure to hazardous levels of air pollution, including multi-week exposure to levels of fine particles (smoke) known to cause pre-mature death and other adverse health outcomes among vulnerable populations, and elevated concentrations of ground level ozone harmful to public health exacerbated by warmer summer temperature regimes that govern the chemistry of ozone formation in the atmosphere.16 [EPA-HQ-OAR-2019-0055-1218-A1, p. 21]

16. “More Days With Haze: How Oregon is Adapting to the Public Health Risks of Increasing Wildfires,” p. 5 (Oregon Health Authority, 2019) available at OHA 2688 More Days with Haze (oregon.gov).

All of these effects are occurring now, and are expected to increase in severity as the climate warming accelerates. [EPA-HQ-OAR-2019-0055-1218-A1, p. 21] The IPCC found that global mean temperature was about 1.0o C above the pre-industrial baseline in 2010. By 2010, the climate regime had not yet triggered large increases in wildfire conditions compared to historical fire patterns in the American West. But as the global mean advanced from 1.1 o C to 1.2 o C, new records were being set. The World Meteorological Organization (WMO) concluded that "[i]n 2020 – one of the three warmest years on record – the global average temperature was 1.2 °C above the pre-industrial baseline."17 [EPA-HQ-OAR-2019-0055-1218-A1, p. 21]

17. World Meteorological Organization, State of the Global Climate, 6 (April 2021); available at doc_num.php (wmo.int). WMO uses the "1850–1900 baseline as an approximation of pre-industrial levels." Id.

As the global temperature approached 1.2 °C, the frequency, intensity, areal extent and duration of wildfires have increased significantly in the last five years. In 2020 burns set records across the American West. California's burn area grew to nearly 5 million acres, and the total area burned in the 11 Western states exceeded 10 million acres: 2020 Western United States wildfire season - Wikipedia. The increasing area burned by wildfire in the American West tracks the Australian experience where annual fire zones expanded rapidly in response to drought leading to a massive wildfire season burning 46 million acres (an area equal to the State of Washington) during their 2019-20 austral summer.18 [EPA-HQ-OAR-2019-0055-1218-A1, p. 21]

18. List of major bushfires in Australia - Wikipedia, see Sept. 2019-March 2020.

During the 2017 fire season, wildfire in Oregon destroyed one-half million acres for the first time in the State's history. In 2018 wildfire consumed 660,000 acres of forest. In 2020 Oregon wildfires consumed 1.2 million acres,19 forced 500,000 Oregonians to evacuate their homes ahead of the flames, incinerated 4,000 homes displacing 10,000 Oregonians, leaving many families homeless, and killed 11. The 2020 burn area doubles the 2017 burn area, and is an order of magnitude greater than the statewide average of 120,000 acres burned during the 1990-2010 period. [EPA-HQ-OAR-2019-0055-1218-A1, pp. 21 - 22]

19. https://en.wikipedia.org/wiki/2020_Oregon_wildfires (1,221,324 acres burned in 2020).

The 2018 IPCC report states that the global mean temperature is rising about 0.2o C per decade,20 twice the warming rate during the 20th Century. This accelerated warming rate suggested in 2018 that 1.5o C rise would be reached about 2035 unless large reductions in GHG emissions were achieved before 2030. New modeling performed for the 2021 IPCC report, AR6, indicates that 1.5o C above the pre-industrial baseline will be reached by 2030 if GHG emissions are held to current rates, and 2o C rise reached by 2050.21,22 WMO has since announced its estimate that the first annual 1.5o C rise in global temperature will likely occur by 2026.23 [EPA-HQ-OAR-2019-0055-1218-A1, p. 22]

20. Global Warming of 1.5o C, Chapter. 1 (Section 1.2.1.3).

21. "Analysis: When might the world exceed 1.5C and 2C of global warming? | Carbon Brief (Dec. 4, 2020).

22. Climate Change 2021: The Physical Basis (IPCC, 2021), Summary for Policy Makers, B.1.2. available at 2108-09 IPCC_AR6_WGI_SPM.pdf.

23. World Meteorological Organization, press release (May 27, 2021) available at https://public.wmo.int/en/media/press-release/new-climate-predictions-increase-likelihood-of-temporarily-reaching- 15-%C2%B0c-next-5.

Given that the frequency and ferocity of wildfire in the American West began to increase significantly after 2015 under the climate conditions associated with 1.1° C to 1.2° C rise above the 1850–1900 baseline, the march higher toward a 1.5o C rise between 2025 and 2030 can be expected to accelerate the frequency, severity and areal extent of damage caused by wildfire. [EPA-HQ-OAR-2019-0055-1218-A1]

The Oregon Climate Assessment (OCAR5.pdf | Powered by Box, January 5, 2021) anticipates that the destruction of property, disruption of daily life, large costs to the economy, pollution of the atmosphere and water supplies, impairment of human health, and damage to wildlife, the environment and habitats will worsen in coming years as the climate continues to warm more rapidly. The Assessment cites studies predicting the effects of warming on seasonal heat causing a six-fold increase in hot days (>90o F) in Oregon counties west of the Cascades during future Oregon summers (pp. 12-13), and reductions in summer precipitation (Table 2). Summers will be hotter and drier, and summer heat will start earlier and persist longer.24 The Assessment concludes that these conditions are conducive to "high-severity" wildfires: High-severity fires dominate wet, cool forests, including remnant old growth forests, in Oregon's Coast Range and western Cascade Range. High-severity wildfires in wet, cool forests typically are … facilitated by extremely dry and warm springs and summers or high winds. [EPA-HQ-OAR-2019-0055-1218-A1, p. 22]

24. Id., 3.

As these conditions become more extreme, the area incinerated by wild fires is expected to increase (pp. 48-54). A 2017 forest modeling analysis "projected a 200% increase in median annual area burned in Oregon" during the 2010-2039 period compared to 1961-2004.25 Another 2017 study looking at fires across the American West estimates a 200-400% increase in the "annual probability of very large fires."26 Going forward, the Assessment makes clear that all "empirical models … consistently project that the area burned in Oregon will increase."27 [EPA-HQ-OAR-2019-0055-1218-A1, pp. 22 - 23]

25. Climate Assessment, 53.

26. Id., 54.

27. Id., 53.

The fire zone doubled between 2017 and 2020. As predicted by forest science modeling, another doubling of the acres burned annually by 2025-30 is highly plausible as global temperature approaches 1.5° C above the pre-industrial baseline. [EPA-HQ-OAR-2019-0055-1218-A1, p. 23]

If fire zones expand to predicted levels in the Pacific NW, 25% to 40% of Oregon (15 to 25 million acres) and Washington (11 to 20 million acres) will be incinerated during this decade, economic activity will collapse and hazardous air quality will make the Northwest inhospitable to human habitation for most residents during the fire season. [EPA-HQ-OAR-2019-0055-1218-A1, p. 23]

The data and modeling estimates presented in the Oregon Climate Assessment and other sources predict a future in which the destruction of Oregon's forest resources by wildfire will continue until either 1) the cool and wet conditions that sustained Cascadia's forests during the 8,000 years before 1980 are restored, or 2) most of the standing forests are reduced to shrub or grasslands. [EPA-HQ-OAR-2019-0055-1218-A1, p. 23]

The climate will need to be stabilized as soon as possible to – o protect public health from the deadly effects of heat waves and wildfire smoke particles; o preserve the health, safety and quality of life in the American West from the devastation caused by massive uncontrollable wildfires; o preserve the health, safety and quality of life for millions of Americans living along the Gulf Coast from the devastation caused by super hurricanes, o preserve the health, safety and quality of life for hundreds of millions of Americans living in the Mid-West and Northeast from the deaths and devastation caused by massive flooding, o to protect the health, safety and quality of life for millions living in Tornado Alley from the Great Plains to the upper South; o to protect forests so that they may serve as a sink for CO2 rather than as an emission source; o preserve habitat for wildlife and a resource for forest products and other industries dependent on them, and o protect the vitality of the marine web of life from collapse as a result of acidification. [EPA-HQ-OAR-2019-0055-1218-A1, p. 25]

The IPCC provided clear guidance in its 2018 report that to stop the warming and stabilize the climate, the economy must transition to a zero carbon (CO2 and methane) emission energy system, and forests must be expanded to extract CO2 from the atmosphere. Climate stability can be achieved only by reducing GHG emissions to net-zero. [EPA-HQ-OAR-2019-0055-1218-A1, p. 25] To stabilize global temperature at any level, 'net' CO2 emissions would need to be reduced to zero. This means the amount of CO2 entering the atmosphere must equal the amount that is removed. Achieving a balance between CO2 'sources' and 'sinks' is often referred to as 'net zero' emissions or 'carbon neutrality'.34 [EPA-HQ-OAR-2019-0055-1218-A1, p. 25]

34. Global Warming of 1.5o C, Chapter 2, FAQs.

Limiting warming to 1.5°C implies reaching net zero CO2 emissions globally around 2050 and concurrent deep reductions in emissions of non-CO2 forcers, particularly methane35 (high confidence). Such mitigation pathways are characterized by energy-demand reductions, decarbonization of electricity and other fuels, electrification of energy end use, deep reductions in agricultural emissions, and some form of CDR [carbon dioxide reduction] with carbon storage on land or sequestration in geological reservoirs.36 [EPA-HQ-OAR-2019-0055-1218-A1, p. 25]

35. Methane (CH4, i.e, unburned natural gas) is 20 times more powerful than CO2 as a climate forcer.

36. Id., Exec, Summary.

Zero GHG emissions to stabilize the climate must be achieved sooner than later to minimize the losses and deaths associated with devastating warmer climate effects. Zero emissions cannot be achieved without transforming transportation which is the largest source of GHG emissions. For most transportation sources such as on-road vehicles, zero emissions can be cost-effectively achieved by electrification with batteries or fuel cells. [EPA-HQ-OAR-2019-0055-1218-A1, p. 26]

The latest IPCC modeling report (AR6, 2021) concludes based on the latest climate data and updated modeling that – Under the five illustrative [GHG emissions] scenarios, in the near term (2021-2040), the 1.5°C global warming level is very likely to be exceeded under the very high GHG emissions scenario (SSP5-8.5), likely to be exceeded under the intermediate and high GHG emissions scenarios (SSP2-4.5 and SSP3-7.0), more likely than not to be exceeded under the low GHG emissions scenario (SSP1-2.6) and more likely than not to be reached under the very low GHG emissions scenario (SSP1-1.9).37 [EPA-HQ-OAR-2019-0055-1218-A1, p. 26]

37. Climate Change 2021, Summary for Policymakers, B.1.3. (available at IPCC_AR6_WGI_SPM.pdf.)

The opportunity to stay below 1.5°C and to prevent the additional devastation that such level of warming will cause, has been frittered away by inaction and delay. At the current global mean temperature, the climate has warmed enough to endanger public health, cause devastating destruction of homes and businesses, loss of life and the disruption of natural systems by extreme floods, drought, wildfires, hurricanes and tornadoes. The harm we will experience above 1.5°C will be orders of magnitude greater. [EPA-HQ-OAR-2019-0055-1218-A1, p. 26]

But the IPCC offers the hope that "for the very low GHG emissions scenario (SSP1-1.9), it is more likely than not that global surface temperature would decline back to below 1.5°C toward the end of the 21st century, with a temporary overshoot of no more than 0.1°C above 1.5°C global warming."38 [EPA-HQ-OAR-2019-0055-1218-A1, p. 26]

38. Id.

That hope turns on cutting global CO2 emissions in half by 2030, and to net-zero by 2050 along with large reductions in non-CO2 climate forcers such as methane. EPA has not set out a regulatory path for achieving those reductions. EPA's current proposed rule will not achieve anywhere near those reductions, and fails to identify any future strategy for achieving those reductions. To fulfill the Agency's statutory mission to protect public health and welfare it must issue regulations that achieve these targets. [EPA-HQ-OAR-2019-0055-1218-A1, p. 26]

Based on these data and other available evidence, we petition the Administrator to find that – 1) climate warming already caused by GHG emissions harms the public health and is causing unacceptable adverse impacts on public welfare and the human environment, and 2) the expected increase in the severity and frequency of harms to health and the public welfare that will be caused by more extreme events that will occur as the global mean temperature advances toward and above the 1.5°C level resulting from growing GHG concentrations in the atmosphere, establish the need for a zero GHG emissions standard for HDVs pursuant to section 202(a)(1) and (3)(A) of the Clean Air Act. [EPA-HQ-OAR-2019-0055-1218-A1, p. 27.]

We petition the Administrator to make this finding as the predicate for re-opening this rulemaking for the purpose of promulgating a zero emission standard for HDVs, and a phase-in schedule that prescribes for each automaker a share of total HDV sales that must be ZEVs beginning with the 2027 MY. [EPA-HQ-OAR-2019-0055-1218-A1, pp. 27-28.]

Organization: *Energy Innovation, LLC*

The climate crisis is wreaking havoc on weather, ecosystems, agriculture, water supplies, and public health, and the timeline for reducing emissions to limit global warming to 1.5 degrees Celsius is now perilously short. The two most recent working group contributions to the Intergovernmental Panel on Climate Change (IPCC) Sixth Assessment Report (from Working Groups II and III) make clear societal choices and actions taken this decade will determine our collective climate future.ii The transportation sector remains the largest contributor to U.S. GHG emissions, constituting 29 percent of total emissions, with 24 percent coming from heavy-duty vehicles.iii From 1990 to 2019, GHG emissions from medium- and heavy-duty trucks increased 92.9 percent, and during that time GHG emissions from buses increased 162 percent.iv [EPA-HQ-OAR-2019-0055-1310-A1, pp.1-2]

iv U.S. Environmental Protection Agency, Fast Facts: U.S. Transportation Sector Greenhouse Gas Emissions, 1990-2019, December 2021, 2, https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P1013NR3.pdf

Such trends are inconsistent with a climate stable future and must be reversed as quickly as possible. The EPA can and should promulgate more stringent GHG tailpipe standards that align with the U.S. Nationally Determined Contribution under the Paris Climate Agreement and achieve the emissions reductions in 2030 required for a 1.5°C trajectory. Strong tailpipe standards will also ensure compliance with Executive Order 14037, Strengthening American Leadership in Clean Cars and Trucks, aimed at making zero-emission vehicles (ZEVs), including EVs, 50 percent of all new cars sold in 2030.v They will help achieve the goals of Executive Order 14008, Tackling the Climate Crisis at Home and Abroad, as well, reducing economy-wide GHGs by 50 to 52 percent by 2030.vi [EPA-HQ-OAR-2019-0055-1310-A1, p.2]

Organization: *Evangelical Environmental Network (EEN)*

As a climate scientist, I know we have no time to wait to act on climate change. [EPA-HQ-OAR-2019-0055-1134-A1, p.2]

The transportation sector is the biggest source of greenhouse gas emissions in the United States. Trucks and buses are responsible for 25 percent of total transportation sector greenhouse gas emissions, despite accounting for only 4 percent of vehicles on the road. [EPA-HQ-OAR-2019-0055-1134-A1, p.2]

To keep our climate as safe as possible for our children and other vulnerable people, including people of color who are disproportionately exposed, we need Strong vehicle standards to provide relief from the burden of diesel fumes and air pollution and help address climate change. [EPA-HQ-OAR-2019-0055-1134-A1, p.2]

Organization: *Jessica Stevens*

I am writing in support of the Environmental Protection Agency in the proposed regulation to reduce air pollution from highway heavy duty vehicles and engines. Greenhouse gasses, ozone, and other particulate matter are primary contributors in our current climate crisis, so any recommendation to reduce these is urged. In addition, these have direct consequences in public health and environmental justice, which was put under consideration in constructing this report. I will outline why this regulation is essential in taking steps against climate change and why it is important in our quality of life, as well as providing some recommendations and other items to take under consideration. [EPA-HQ-OAR-2019-0055-1028]

Transportation is currently the greatest source of greenhouse gasses in the United States. In 2020, it accounted for 27% of the emissions produced, mostly coming from petroleum based fuel for trucks, cars, planes, etc. (Sources of Greenhouse Gas Emissions). Over half of the emissions in this industry come from cars, light, medium, and heavy duty trucks, while the other half result from other forms of transportation like planes, ships, and trains. The National Institute of Environmental Health Services (NIEHS) outlines the air pollution produced by the transportation sector and the potential health impacts this has. The NIEHS states that Traffic Related Air Pollution (TRAP) includes ground level ozone, carbon, hydrocarbons, and particulate matter (Air Pollution and Your Health). This can result in various forms of respiratory disease, like asthma or chronic obstructive pulmonary disease. Additionally, air pollution increases the risk for cardiovascular disease and certain cancers, particularly breast and lung cancer. The NIEHS also found that nine out of 10 people living in urban areas worldwide were found to be affected by air pollution (Air Pollution and Your Health). This report specifically mentions that lower income families and people of color possess higher risk for air pollution by being more likely to be located near truck routes. This is a public health and environmental justice problem that needs to be addressed. [EPA-HQ-OAR-2019-0055-1028]

Not only are their human health impacts from emissions, but the environment, and therefore our existence as a species, suffers as well. Global warming of 1.5 degrees celsius would be extremely dangerous for the survival of our planet, but a warming of 2 degrees celsius would be even more vital to prevent. Effects of warming from greenhouse emissions include extreme weather patterns like heat waves, rising sea levels from melting ice glaciers, changes in precipitation patterns leading to floods and droughts, and in general more unpredictable and severe weather events (Human health impacts of climate change). These changes can directly or indirectly lead to illness or death. The changes in precipitation and temperature can have effects on animal and insect living patterns, affecting their own survival or behaviors. Changes in their interactions and interactions with humans can give rise to the spread or prevalence of infectious diseases. Rises in water related infections may also be a result of changes in rain patterns, increase in storms, and rising sea levels. [EPA-HQ-OAR-2019-0055-1028]

Organization: *Maine Department of Environmental Protection*

The transportation sector is also the largest source of greenhouse gas (GHG) emissions in the United States, with heavy-duty vehicles being the second-largest contributor within that sector. Reducing GHG emissions from heavy-duty vehicles is an important step in addressing the growing climate emergency that is already impacting our residents. [EPA-HQ-OAR-2019-0055-1288-A1,p.1]

Organization: *Mass Comment Campaign sponsored by American Lung Association (248)*

Trucks and buses are also a source of the greenhouse gas emissions fueling climate change. The most recent report from the Intergovernmental Panel on Climate Change made clear that the world remains incredibly vulnerable to catastrophic impacts of a warming climate. We see this in our communities. From extreme heat to flooding to wildfires, individuals' lives and livelihoods are at risk. [EPA-HQ-OAR-2019-0055-1609-A1, p.1]

Organization: *Mass Comment Campaign sponsored by Evangelical Environmental Network (EEN) (67,755)*

Pollution from transportation is a major cause of air-pollution-related death and disease, and recently transportation became the top source of global warming pollution in the United States. Heavy-Duty Trucks, like tractor-trailers, are a leading source of lung-damaging air pollutants—including smog-forming NOx pollution and particle pollution (soot). In 2020, trucks emitted an estimated 561 million metric tons of greenhouse gases, 1.5 million metric tons of nitrogen oxides (NOx) and 38,000 metric tons of particulate matter (soot) (PM), filling the air we breathe with life-threatening air pollution. The largest single source of these pollutants is heavy duty trucks. [EPA-HQ-OAR-2019-0055-1610-A1, p.1]

Organization: *Mass Comment Campaign sponsored by Moms Clean Air Force and Arizona Climate Action Coalition (198)*

The climate crisis is harming our families and our communities today and medium and heavy-duty vehicles are a major contributor to this pollution. In fact, despite making up only 10% of the total number of vehicles on the road, medium- and heavy-duty trucks contribute a quarter of the total climate pollution from the transportation sector. [EPA-HQ-OAR-2019-0055-1192-A1, p.1]

Organization: *Mass Comment Campaign sponsored by Neighbors for Clean Air and Elders Climate Action (43)*

The warmer climate has triggered a massive increase in wildfire in Oregon from an annual average of 120,000 areas burned just 20 years ago, to over 1 million acres each in 2020 and 2021. Wildfire studies reported in Oregon's Climate Assessment (2021) estimates wildfire will likely double in this decade to 2 million acres annually. Thousands of families lost homes to fire, businesses were destroyed and communities lost schools, health care facilities, water and power supplies and other infrastructure. Smoke pollution smothered the state with dangerous levels of air pollution that added hundreds of premature deaths. The record setting heat wave last year also took more than one hundred lives. [EPA-HQ-OAR-2019-0055-1619-A1,pp.1-2]

Oregon needs your help now to slow the warming to protect our families and communities. Medium and heavy-duty vehicles are a major contributor to this pollution. Despite making up only 10% of vehicles on the road, medium- and heavy-duty trucks emit a quarter of climate pollution from the transportation sector. Oregon has adopted the California rule to reduce heavy duty vehicle emissions, but Oregon's emissions are a small fraction of CO_2 emitted from vehicles nationwide. National emission reductions are needed to slow climate warming. [EPA-HQ-OAR-2019-0055-1619-A1,p.2]

Organization: *Mass Comment Campaign sponsored by The Climate Reality Project (10,820)*

Robust national standards will not only help reduce greenhouse gas emissions at a critical time, but prevent thousands of asthma cases – especially among children – hospital visits, and even deaths. [EPA-HQ-OAR-2019-0055-1083-A1, p.2]

Organization: *Mass Comment Campaign sponsoring organization unknown - 1 (2,443)*

Heavy-duty vehicles are also one of the nation's top sources of climate pollution. Nearly all of America's national parks are threatened by the symptoms of a warming climate including more frequent heat waves, drought, sea level rise, coastal flooding, and extreme wildfires. [EPA-HQ-OAR-2019-0055-1594-A1,p.1]

Organization: *Moving Forward Network (MFN)*

Add to all of this the reality that these same communities are also most at risk from the coming climate disaster. Today, global freight transport accounts for about 36 percent of overall transportation emissions, which itself accounts for one-quarter of overall CO_2 emissions, and therefore has a direct and significant impact on climate change.26 Put another way, while road transport makes up only 18 percent of total freight activity, it constitutes more than half of all freight-related CO_2 emissions. So, in addition to the clear need to address the health and air quality issues from the freight industry, there are also massive climate benefits to decarbonizing this sector. In its 2022 report "Zeroing in on Healthy Air," the American Lung Association found that a nationwide transition to zero-emission light-, medium-, and heavy-duty vehicles, powered by non-combustion electricity, would save 110,000 lives and secure $1.2 trillion in public health benefits nationwide from 2020-2050.27 These are health and economic savings that we cannot afford to waste. Yet this trend is even more worrisome than current figures indicate, since global freight traffic is accelerating substantially and emissions levels are therefore continuing to increase at an alarming rate. [EPA-HQ-OAR-2019-0055-1277-A1, p. 10]

The effects of a growing climate crisis are already being felt by port-adjacent communities in deadly and dangerous ways. These effects range from deadly heat waves, to flooding, to superstorms, and hurricanes.28 Indeed, storm surge and hurricane events have significantly increased in severity and frequency in recent years. These superstorms, like Superstorm Sandy, have forced port-adjacent communities to confront new issues that are a direct result of an under-regulated freight transportation system. [EPA-HQ-OAR-2019-0055-1277-A1, p. 10]

Organization: *National Parks Conservation Association (NPCA)*

National parks are incredibly vulnerable to the changing climate.15 As the temperature warms in the national parks at twice the rate of the United States as a whole, climate effects are felt across all park geographic regions and locations, from coastal areas to mountain ranges.16 Climate effects include: (1) rising sea levels; (2) increasingly intense wildfires; (3) threat and harm to wildlife habitats and lifestyles; (4) the rapid growth of disruptive, invasive species; (5) extreme weather damage; (6) drier conditions leading to difficult droughts; (7) loss of snow and ice; (8) changing landscapes and disrupted ecosystems; (9) destruction of irreplaceable park structures and artifacts; and (10) altered visitation patterns and significant losses to valuable tourism revenue.17 Due to the propensity of so much further damage being done to national parks including historic and cultural sites , climate change has been cited as a significant concern for 80 percent of the nation’s parks.18 If climate change continues at this rate and the climate effects continue to wreak havoc across the nation, wildlife and plant species’ populations will plummet, and possible additional extinctions could occur.19 However, this EPA rule can help address the climate crisis and in so doing, protect our parks’—reducing greenhouse gas emissions from heavy-duty vehicles is a massively helpful step to slowing climate change, as the transportation section is now the largest source of these emissions in the United States.20 [EPA-HQ-OAR-2019-0055-1314-A1, pp.3-4]

Organization: *National Religious Partnership for the Environment*

Transportation is the largest contributor to climate change in the U.S. Trucks and buses, which only account for 4 percent of vehicles on the road, produce nearly 25 percent of the transportation sector's greenhouse gases.

Organization: *National Tribal Air Association (NTAA)*

The Administration's Clean Trucks Plan, and this proposed component of that plan are exceedingly important to sovereign Tribes and the millions of Indigenous people who suffer from breathing unhealthy air. Additionally, we are all threatened by climate change. Emissions from trucks, buses, large engines, and internal combustion engines of all types are major contributors to these unacceptable conditions and well-documented threats.[EPA-HQ-OAR-2019-0055-1382-A2, p.1]

Our organization has consistently urged the U.S. EPA, Congress and States to do more to protect the health and quality of life of our members. Concurrently, Tribes are doing their part to reduce emissions including the many harmful pollutants from heavy-duty vehicles. For example, 119 Tribes and Alaska Native Villages have reduced diesel emissions through use of the VW settlement fund. Even more have participated, and continue to participate, in EPA's Diesel Emissions Reduction Act (DERA) program. [EPA-HQ-OAR-2019-0055-1382-A2, pp.1-2]

Organization: *Next Level Farmer, LLC*

There are multiple other factors affecting climate. 'Contact Info@Biochar-International.Org for credible research information'. What about forest fires? They produce toxic gasses, hazardous smoke, and airborne ash particles. What efforts are being made to stop forest fires in their tracks? Not enough I would say if 50,000 to 100,000acres are burned per fire. What about Third World Populations like China and Inda that burn wood to cook their food? This is a large percentage. However, if global efforts were made to provide a Pyrolylic Wood Burning Stove that burns wood in an oxygen-limiting environment this would have a huge impact on emissions. Plus, by burning wood or biomass through a Pyrolysis Furnace in an oxygen-limiting environment you get way more heat energy from the wood than from burning it with oxygen. What about countries in Africa that run diesel engines with limited to no pollution control devices? How is the United Nations Influencing their part in limiting pollution? What about holes in the Ozone Layer created by repeated rocket launches to put satellites in space? The heat from the rocket engines and heat from capsules re-entering the earth's atmosphere destroy the Ozone Layer. As an example NASA's launchpad is in one place and I am sure they use a simular flight pattern every time which punches holes into the earths Ozone Layer in one location. This would cause weak areas in the Ozone Layer and Sun Light would be get more and more intense on heating the ocean and affection the amount of evaporation and storm systems created at sea. Studies suggest that climate change is linked to the rise of the Industrial Revolution. The Space Race and Rocket tecnology has the same growth curve as the Industrial Revelution. Also, Tesla is planning 1,000 rocket launches to put his Global Satilite Internet Service into space. This is a 1,000 more holes in the Ozone Layer. What about the effects of the Moon on our weather? Why aren't those studies published? The Moon's Gravitational Pull effects our weather. What about the effects of Volcanos? One volcano eruption creates more ash and pollution than man does in a year. There are over 100 volcanos globally. What about the effects of large cities? Large cities put off a lot of heat. Many storm systems that come through Minnesota often go around Minneapolis and the surrounding suburbs because, of all the heat that is generated by the city. This is diverting the natural flow of weather systems. What I am saying is that it is not just one thing that is causing climate change. There are multiple factors that influence our weather. 'Contact Info@Biochar-International.Org for credible research information'. [EPA-HQ-OAR-2019-0055-2785, pp.1-2]

Organization: *Our Children's Trust*

These proposed rules will allow ‘air pollution from highway heavyduty vehicles and engines, including ozone, particulate matter, and greenhouse gases,’ (i.e., climate pollution) at levels that continue to endanger the climate system, locking in harm for the youngest generation. The RIA and Federal Register analysis of the proposed rule paint a very skewed picture of the real economic and health toll on children by continuing to unlawfully discount their lives and their health and by relying on economic analyses that by the agency’s own admission do not attempt to quantify some of the most significant economic costs and cost to lives by continuing to permit vehicles and engines to be fueled with fossil for the foreseeable future, with no plan in sight to cease this unconstitutional conduct that is quite literally destroying the quality of the air and the health of children. The science is clear—every ton of greenhouse gas emissions matters and causes more danger, more temperature rise, and more harm to children’s health and safety.2 While cast as a rule ‘to reduce air pollution,’ with no comprehensive standards for climate and air protection, this is another piecemeal authorization of ongoing unsafe levels of air pollution that are destroying our climate system. [EPA-HQ-OAR-2019-0055-1317-A1, pp.1-2]

2 IPCC, Summary for Policymakers, in Climate Change 2021: The Physical Science Basis, 28 (2021) ('Every tonne of CO_2 emissions adds to global warming.').

EPA makes no finding that the proposed regulation will protect public health and welfare and air quality, namely our climate. EPA makes no finding that these regulations are aligned with what is necessary to stabilize the climate system by preventing additional contributions of air pollution that push our climate system to further dangerous instability. These proposed regulations do not appear tied to any standard for protecting our nation's children or future generations. Instead, this rule purports to consider 'lead time, costs, and other [unidentified] factors, including market shifts to zero-emission technologies in certain segments of the heavyduty vehicle sector.' Instead of setting protective standards and leading the way to health and welfare, which are already compromised, EPA continues to follow the lead of the polluting technologies themselves. Please describe what scientific standards this proposed rule will meet in protecting air and human health and welfare. [EPA-HQ-OAR-2019-0055-1317-A1, p.2]

EPA's Actions Must Be Aligned with Restoring Earth's Energy Imbalance and Cease Infringing the Constitutional Rights of Youth. EPA has Public Trust and Constitutional Obligations to use its Authority to Protect the Atmosphere. [EPA-HQ-OAR-2019-0055-1317-A1, p.4]

Please explain how the proposed rule aligns with restoring Earth's Energy Imbalance? [EPA-HQ-OAR-2019-0055-1317-A1, p.4]

Excess accumulation of greenhouse gases in our atmosphere results in an Earth energy imbalance and thus an accumulation of heat in our climate system.7 The best available science informs that Earth's energy balance can only be restored by returning the atmospheric CO2 concentration to below 350 ppm by 2100.8 Experts have opined that it is economically and technically feasible to achieve the science-based greenhouse gas emission reduction target of close to 100% by 2050, while simultaneously enhancing sequestration capacity of sinks to drawdown historical cumulative CO2 emissions, placing the U.S. on an emissions trajectory consistent with returning atmospheric CO2 to below 350 ppm by 2100.9 [EPA-HQ-OAR-2019-0055-1317-A1, p.4]

Current increased average temperatures of 1°C and greater (now 1.2°C) are already dangerous. Basing policies and decisions that align with temperature targets of 1.5°C is exponentially more catastrophic for our children and posterity.10 The IPCC special report on Global Warming of 1.5°C (2018) stated that allowing a temperature rise of 1.5°C 'is not considered 'safe' for most nations, communities, ecosystems and sectors and poses significant risks to natural and human systems as compared to the current warming of 1°C (high confidence).'11 Medical experts have recently recognized that '[t]he science is unequivocal; a global increase of 1.5°C above the pre-industrial average and the continued loss of biodiversity risk catastrophic harm to health that will be impossible to reverse.'12 As such, 1.5°C should not be used to guide U.S. policy that is required to be based on best available science. The EPA should not be advancing policies that knowingly make the climate crisis worse, and potentially unsolvable. [EPA-HQ-OAR-2019-0055-1317-A1, p.5]

10 See IPCC, Overarching Frequently Asked Questions: FAQ 3: How will climate change affect the lives of today's children tomorrow, if no immediate action is taken? in Climate Change 2022: Impacts, Adaptation and Vulnerability (2022) ('[T]oday's children and future generations are more likely to be exposed and vulnerable to climate change and related risks such as flooding, heat stress, water scarcity, poverty, and hunger. Children are amongst those suffering the most . . . [C]hildren aged ten or younger in the year 2020 are projected to experience a nearly four-fold increase in extreme events under 1.5°C of global warming by 2100[.]')

11 M.R. Allen et al., Technical Summary, in Global Warming of 1.5°C, at 44 (2018); see also Assessing 'Dangerous Climate Change'. This was similarly noted in the IPCC, Summary for Policymakers, in Climate Change 2022: Impacts, Adaptation and Vulnerability, at 15 (2022): 'Global warming, reaching 1.5°C in the near-term, would cause unavoidable increases in multiple climate hazards and present multiple risks to ecosystems and humans (very high confidence).'

12 Lukoye Atwoli et al., Call for Emergency Action to Limit Global Temperature Increases, Restore Biodiversity, and Protect Health, The Lancet (2021) (emphasis added), https://doi.org/10.1016/S0140-6736(21)01915-2.

Climate change is causing a public health emergency that is already adversely impacting the physical and mental health of American children through, among other impacts, extreme weather events, rising temperatures and increased heat exposure, decreased air quality, altered infectious disease patterns, and food and water insecurity.13 Children are uniquely vulnerable to climate change impacts because of their developing bodies, higher exposure to air, food, and water per unit body weight, unique behavior patterns, dependence on caregivers, political powerlessness, and longevity on the planet.14 The protection of constitutional rights of children, by following the science, is of the utmost importance and must be incorporated in all relevant EPA rulemaking and policies. [EPA-HQ-OAR-2019-0055-1317-A1, p.5]

13 IPCC, Summary for Policymakers, in Climate Change 2022: Impacts, Adaptation and Vulnerability, at 11, 17 (2022). This summary found that the current level of global warming is already driving heat waves that cause human morbidity, heavy rains, flooding, extreme fires and drought, coral bleaching and demise, massive shifts in species habitats, loss of glaciers, snow and permafrost, as well as more destructive hurricanes. Id. at 11.

Pacheco & Council on Environmental Health, Global Climate Change and Children's Health, 136 Pediatrics e1468 (2015); Rebecca Pass Philipsborn & Kevin Chan, Climate Change and Global Child Health, 141 Pediatrics e20173774 (2018); Wim Thiery et al., Intergenerational Inequities in Exposure to Climate Extremes, 374 Science 158 (2021).

Our Children's Trust represents twenty-one youth plaintiffs, including eleven Black, Brown, and Indigenous youth, in the constitutional climate lawsuit, Juliana v. United States, in which the Administrator, in his official capacity, and EPA are defendants. This case asserts that, through the government's past and ongoing affirmative actions that cause climate change, it has violated the youngest generation's constitutional rights to life, liberty, property, and equal protection of the law, as well as failed to protect essential public trust resources. In this litigation, federal courts have affirmed 'that the federal government has long promoted fossil fuel use despite knowing that it can cause catastrophic climate change'15 and 'has long understood the risks of fossil fuel use and increasing carbon dioxide emissions'.16 The Ninth Circuit Court of Appeals found that there was evidence showing that the federal government was a substantial factor in causing the youth's constitutional injuries because '[a] significant portion of [GHG] emissions occur in this country; the United States accounted for over 25% of worldwide emissions from 1850 to 2012, and currently accounts for about 15%.'17 Without immediate effective action, our children and future generations will continue to suffer injury with long-lasting and potentially irreversible consequences.18 These judicially-recognized facts should guide EPA's policies and practices so they can identify, and alter, those policies that exacerbate American youth's existing climate change injuries. [EPA-HQ-OAR-2019-0055-1317-A1, pp.5-6]

17 Juliana v. United States, 947 F.3d 1159, 1169 (9th Cir. 2020).

18 See Assessing 'Dangerous Climate Change'; James Hansen et al., Ice Melt, Sea Level Rise and Superstorms: Evidence from Paleoclimate Data, Climate Modeling, and Modern Observations that 2°C Global Warming Could be Dangerous, 16 Atmos. Chem. & Phys. 3761 (2016); U.S. Global Change Research Program, Fourth National Climate Assessment, Vol. II (2018).

Our children and future generations are suffering injury with long-lasting and potentially irreversible consequences at present levels of heating and thus EPA must do everything in its power to facilitate greenhouse gas emissions reductions in line with best available science. Moreover, all young people seeking environmental and climate justice, especially youth from frontline and environmental justice communities that have contributed the least to emissions and have long suffered from systemic environmental racism and social and economic injustices, must not only have their voices heard, but have their rights protected. [EPA-HQ-OAR-2019-0055-1317-A1, p.6]

We seek to emphasize the need for EPA to align its rulemaking, policies, and initiatives with protecting the fundamental, constitutional rights of children. [EPA-HQ-OAR-2019-0055-1317-A1, p.6]

To learn more about how young people are being harmed, please watch the award-winning, independent feature-length documentary film now streaming on Netflix, YOUTH v GOV. These stories constitute just a small sample of what American children are experiencing due to the climate crisis the federal government continues to exacerbate by and through its national energy system. We request that the EPA incorporates the protection of children’s fundamental rights to a safe climate system, defined by the best available science, into future rulemaking, policies, and initiatives. Human laws must respect the laws of nature; our government ignores the natural laws of energy imbalance and climate destabilization at the peril of our children. We encourage you to consider additional details on our position as noted in Our Children’s Trust’s prior September 27, 2021 Comment to the EPA on the Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards - Proposed Rule (Docket No. EPA–HQ–OAR–2021–0208) attached below. [EPA-HQ-OAR-2019-0055-1317-A1, pp.6-7]

Please include all cited evidence in the administrative record. We are also happy to provide any of the cited evidence on request. All Juliana v. United States expert reports and related evidence are in the files of the Department of Justice, which represents EPA and the Administrator in the case, as its clients. Thus, you have access to all of those documents and evidence, along with the legal bases for the comments made herein. [EPA-HQ-OAR-2019-0055-1317-A1, p.7]

Organization: *Retail Industry Leaders Association (RILA)*

The threat of climate change is a critical issue that must be addressed with urgent action, which includes the implementation of effective climate change mitigation policies. Since heavy-duty transportation is a major source of GHG emissions in the United States, federal standards that reduce vehicular GHG emissions are a critical tool in the fight against climate change. It is also important for these standards to be updated to accurately track against any major shift or trends in the transportation market to ensure that these standards continue to reduce as much GHG as is technologically feasible. [EPA-HQ-OAR-2019-0055-1189-A2, p.6]

Organization: *Southern Environmental Law Center (SELC)*

Air quality can also be worsened by rising temperatures, one of the many effects of climate change. GHG emissions are a major driver of climate change, and the transportation sector is the largest source of GHG emissions in the nation.13 This is also true for most states in the South. The transportation sector is the largest source of carbon dioxide (CO2)—a significant component of GHGs14—in every state in SELC's region except for Alabama, where it is the second largest source.15 Within the transportation sector, medium- and heavy-duty vehicles are the second largest contributor of GHG emissions—behind only light-duty vehicles—accounting for about 24 percent of emissions.16 This amounts to roughly 7 percent of the nation's total GHG emissions. [EPA-HQ-OAR-2019-0055-1247-A1, p.3]

The U.S. is already experiencing climate change impacts beyond worsening air quality. Sea level rise is affecting coastal communities around the country, and the South is particularly vulnerable. For example, the Hampton Roads region in Virginia has one of the highest rates of sea level rise on the East Coast, with scientists predicting a rise of 1.5 to 2 feet by 2025.17 The frequency of extreme weather events, including heavy precipitation, high tides, storm surges, and heat waves, also continue to increase.18 These weather events can lead to public emergencies and infrastructure disruptions, stressing health services and communities. There is also an economic cost to climate change. Studies have found that climate change could cost the U.S. approximately 1.2 percent of the gross domestic product for every additional degree of warming, with the South expected to experience greater impacts than other part of the country.19 [EPA-HQ-OAR-2019-0055-1247-A1, p.3]

Organization: *States of California, et al. (The States)*

The transportation sector is also the largest source of greenhouse gas (GHG) emissions in the United States, with heavy-duty vehicles being the second-largest contributor within that sector. Reducing GHG emissions from heavy-duty vehicles is thus an essential element of addressing the growing climate emergency that is already impacting our residents. For instance, during the summer of 2021, multiple deadly heatwaves with record-breaking high temperatures ravaged the western United States while hurricanes of historic force swept across the southern and eastern United States, resulting in mass power outages and producing record-breaking rainfall and fatal flash floods. Scientists project climate change-related impacts like these to worsen, and climate harms will disproportionately impact historically marginalized communities underscoring the urgent need for reductions in GHG emissions from this sector. [EPA-HQ-OAR-2019-0055-1255-A1, p. 2]

Organization: *Tesla, Inc. (Tesla)*

In addition to medium- and heavy-duty vehicles being one of the largest sources of other pollutants that negatively impact public health, including PM and NOx, they are also major emitters of climate-warming greenhouse gases (GHGs). As EPA acknowledges: Transportation is the largest source of GHG emissions in the United States, making up 29 percent of all emissions. Within the transportation sector, heavy-duty vehicles are the second largest contributor, at 23 percent. Reducing GHG emissions is a critical step in reducing the probability of impacts from climate change, including heat waves, drought, sea level rise, extreme climate and weather events, coastal flooding, and wildfires.44 [EPA-HQ-OAR-2019-0055-1219-A1, p.7]

44 EPA, Heavy-Duty 2027 and Beyond: Clean Trucks Proposed Rulemaking (March 2022) at 3.

As EPA has already determined, vehicle GHG emissions endanger public health and welfare.45 Since the issuance of the Endangerment Finding continued peer-reviewed scientific analysis has further elucidated the level of GHG emission reduction needed to adequately protect the public welfare. Per EPA's request for comment,46 the agency should look first toward the consensus UNFCCC and IPCC goal of limiting global warming to well below 2 degrees Celsius, preferably to 1.5 degrees, compared to pre-industrial levels as its baseline.47 The U.S. has adopted an international commitment to put policies in place consistent with this protective aim. 48 To meet this new target the U.S. has committed is to achieve a 50-52 percent reduction from 2005 levels in economy wide GHG pollution in 2030.49 This commitment is part of the national effort to prevent significant domestic impacts from climate change50 and embodies near term action commensurate with meeting this benchmark.51 As part of this effort, numerous studies have highlighted that electrifying the medium- and heavy-duty fleet as rapidly possible will enable the U.S. to meet its commitment and equitably contribute to emissions reductions that adequately protect the country's health and welfare.52 For example, a central component of the U.S. long-term climate strategy in transportation is the 'rapid expansion of zero-emission vehicles—in as many applications as possible across light-, medium-, and heavy-duty applications.'53 More specifically, 'addressing legacy diesel vehicles and emissions associated with ports, including from ships, port equipment, and trucks, would further contribute to meeting national climate, health, and climate justice goals.'54 Moreover, ALA found that the environmental benefits from electrifying the transportation in the form of avoided climate change impacts, as expressed as the Social Cost of Carbon,55 could surpass $113 billion in 2050 as the transportation systems combust far less fuel and our power system comes to rely on cleaner, non-combustion renewable energy.56 [EPA-HQ-OAR-2019-0055-1219-A1, pp.7-8]

45 74 Fed. Reg. 66496 (Dec. 15, 2009) (Endangerment Finding).

56 ALA, The Road to Clean Air Benefits of a Nationwide Transition to Electric Vehicles, at 6.

Further, numerous studies show that the medium- and heavy-duty trucking sector must rapidly decarbonize beginning this decade to meet the U.S. commitments. A recent ICCT study found that a 2030 target of 45% zero emission sales in the U.S. heavy-duty vehicle sector is compatible with limiting warming to less than 2°C.57 Even more is needed to ensure that the protective limiting of overall warming to 1.5°C is reached.58 Another recent analysis found that if 70% of the Class 8 regional haul tractors in the US and Canada were electrified, it would result in the avoidance of almost 29 MMT CO2e annually.59 Other analyses indicate reaching net zero emissions requires 100% BEV sales in the heavy- duty sector by no later than 2045.60 [EPA-HQ-OAR-2019-0055-1219-A1, p.8]

Organization: *United Methodist Church - General Board of Church and Society*

The United Methodist Church affirms the importance of efforts to 'conserve energy and increase energy efficiency' understanding that a just transition 'to energy efficiency and renewable energy sources will combat global warming, protect human health, create new jobs, and ensure a secure, affordable energy future' (2016 Book of Resolutions, 1001: Energy Policy Statement). Trucks and buses, which account for only 4 percent of vehicles on US roadways, produce 25 percent of the nation's total transportation related greenhouse gas emissions. These proposed regulations would capitalize on existing cleaner, more affordable zero-emissions medium and heavy-duty trucks. [EPA-HQ-OAR-2019-0055-1042-A1, p.1]

Organization: *University of California, Berkeley, The Goldman School, Center for Environmental Policy*

Our research shows that EPA proposed truck rules fall significantly short in meeting President Biden’s climate commitment, as detailed in the attached working paper, “Clean truck deployment consistent with President Biden’s climate commitment can save $1 trillion for consumers and avoid 70,000 premature deaths by 2050”. [EPA-HQ-OAR-2019-0055-1327-A1, p. 1]

Organization: *Ute Mountain Ute Tribe Environmental Programs Department*

Climate Change has directly impacted the Tribal Reservation lands. The Four Corners Area is home to the methane hot-spot and temperatures have risen almost two degrees in the last 100 years, with an accelerated increase since 1980. Water, which has historically been a scarce and valued commodity in the southwest is now even more threatened resource with the 'mega drought' the area is experiencing. Emissions from trucks, buses, large engines, and internal combustion engines of all types are major contributors to these unacceptable conditions and well-documented threats. [EPA-HQ-OAR-2019-0055-1259-A1, p. 2]

Organization: *Volvo Group*

Similarly, we believe the Paris Climate Accord goals must be realized to minimize the negative societal impacts of climate change. The Volvo Group acknowledges that it must work aggressively to achieve these goals and believes the best solution to jointly solve our climate change and air quality challenges lies in the acceleration of zero-emission vehicle penetration in the marketplace. [EPA-HQ-OAR-2019-0055-1324-A1, p. 2]

Organization: *William F. Limpert*

The recent UN International Panel on Climate Change sixth report also underscores in very frightening, yet scientifically accurate terms, how fossil fuel driven climate change will continue to negatively impact us, especially in the future. Among other impacts the report states:

- It is unequivocal that human influence has warmed the atmosphere, ocean and land. Widespread and rapid changes in the atmosphere, ocean, cryosphere and biosphere have occurred.

- The likely range of total human-caused global surface temperature increase from 1850–1900 to 2010–2019 is 0.8C (centigrade) to 1.3C, with a best estimate of 1.07C.

- Global warming will exceed 2C this century unless deep reductions in GHG emissions are made.

- Under the very high emission scenario a 2.4C increase is likely by around 2050, and a 4.4C increase by around 2090.

- Under the very low emission scenario a 1.6C increase is likely by around 2050 dropping back to 1.4C increase by around 2090.

- CO2 levels are the highest in 2 million years.

- Methane levels have increased 154%, and are at the highest level in the past 800,000 years

- Weather extremes are more frequent and intense, including heat, precipitation, and category 3-5 tropical cyclones.

- Heavy precipitation events are likely to continue to increase with rising temperatures, including more category 3-5 tropical cyclones.

- The global water cycle is expected to become more variable and extreme

- Natural carbon sinks in the land and ocean will be less effective in removing carbon emissions, leaving more carbon in the atmosphere.

- Sea level is up 0.2 meters since 1900.

  - Relative to 1995-2014, the likely global mean sea level rise by 2100 is 0.41 meters under the very low emissions scenario, and 0.82 meters under the very high emissions scenario. A meter rise cannot be ruled out due to uncertainty about ice sheet processes.

- Sea level will be up 13 feet by 2300 even under the very low emissions scenario.

  - Sea level is committed to rise for centuries to millennia due to continuing deep ocean warming and ice sheet melt, and will remain elevated for thousands of years.

  - Changes in sea level, ice sheets and glaciers, and ocean acidification and deoxygenation will occur, and be irreversible for centuries or millennia.

These changes will especially negatively impact the very young, and the yet to be born. Those who will follow us will inherit a diminished and hostile world that we have passed on to them. These changes could very well end civilization as we know it. We need to make reducing the causes of climate change our biggest national priority, and these rules for the heavily polluting transportation sector will help move us in that direction. [EPA-HQ-OAR-2019-0055]

Organization: *World Resources Institute (WRI)*

EPA studies confirm that medium- and heavy-duty vehicles also generate 23 percent of the transportation sector's greenhouse gas emissions (GHG), contributing to the severity of climate change impacts, including heat waves, drought, sea level rise, extreme climate and weather events, coastal flooding, and wildfires. Some populations may be especially vulnerable to these and other climate change impacts, including low-income communities, people with disabilities, people of color, and Indigenous populations. Furthermore, studies (such as the recent 'Zeroing in on Healthy Air' from the American Lung Association) show that regulations and policies designed to reduce GHG emissions, such as through accelerating electric transportation, will have the added benefit of reducing other forms of pollution, such as air toxics and particular matter, that impact public health and disproportionately impact overburdened communities. [EPA-HQ-OAR-2019-0055-1298-A1, p.2]

<u>EPA Response</u>

EPA is not taking final action at this time as part of this final rule on the portion of the HD 2027 NPRM regarding proposed changes to HD GHG Phase 2 standards. EPA intends to undertake a separate rulemaking regarding more stringent HD GHG standards in the future (i.e., HD GHG Phase 3 standards).

3 Criteria pollutant standards

3.1 General comments criteria pollutant standards

3.1.1 General comments on stringency of criteria pollutant standards

<u>Comments by Organizations</u>

Organization: *Alliance for Vehicle Efficiency (AVE)*

AVE supports EPA's effort to reduce emissions, specifically nitrogen oxides (NOx), and particulate matter (PM) from this important segment of the transportation sector.

AVE supports EPA's proposed Option 1 standard, with a modification of the proposed full useful life timelines and warranty requirements, as the best option for driving more rapid adoption of advanced engine and emission control technologies. In 2020 at the commencement of this rulemaking, AVE urged EPA to use this last in a generation opportunity to vastly improve air quality across the country.1 Since EPA's prior rulemaking in 2001 for NOx emissions for heavy-duty (HD) vehicles, automotive suppliers have continued investing in new engine and emission control technology to improve performance and emissions. [EPA-HQ-OAR-2019-0055-1280-A1, p. 2]

1. See https://www.regulations.gov/comment/EPA-HQ-OAR-2019-0055-0460

Today, new engine architecture and advanced emission control technologies are available as cost-effective options for manufacturers to reduce NOx emissions by over 90% from current standards. Since January of 2020, data has emerged that confirms the readiness of technology to meet the most aggressive low-NOx standards. [EPA-HQ-OAR-2019-0055-1280-A1, p. 2]

Without continual developments in ICE technology, the U.S. could miss out on environmental gains that could significantly advance our nation's climate goals. ICE engine advancements can help make faster, impactful improvements, particularly for at-risk communities. [EPA-HQ-OAR-2019-0055-1280-A1, p. 5]

AVE urges EPA to adopt a true "all-of-the-above" strategy that fosters all types of automotive innovation. In 2012, EPA contended that at times it is "…worthwhile to forego modest additional emissions reductions in the near term in order to lay the foundation for the potential for much larger ''game-changing'' GHG emissions and oil reductions in the longer term." 8 We believe such a trade-off can actually stifle innovation and could easily lead to technology backsliding. Supporting improvements to ICE vehicles will also benefit technologies being manufactured in the U.S. that provide hundreds of thousands of direct jobs, making it the nation's largest sector of manufacturing jobs with employees in all 50 states.9 [EPA-HQ-OAR-2019-0055-1280-A1, p. 5]

8 See Federal Register / Vol. 77, No. 199 / October 15, 2012; Federal Register / Vol. 86, No. 151 / August 10, 2021

9 U.S. Labor and Economic Impact of Vehicle Supplier Industry, MEMA and IHS Markit. February 2021.

Organization: *Allison Transmission, Inc. (Allison)*

- Allison believes a single-phase approach to the imposition of emission standards, as in Option 2, is a better long-term strategy given technology disruptions and need for industry to focus on research and development needs associated with reducing carbon dioxide ("CO2") emissions as required by the proposed revisions to the Phase 2 rule and the scheduled Phase 3 rule to address Model Year ("MY") 2030 and later year vehicles. A two-phase approach to new standards would lead to serious gaps in the availability of technology for many segments of the fragmented vocational vehicle market. In the proposed rule, EPA does not account for necessary periods of time, often several years in length, that are needed to validate new technology in the vocational vehicle sector. [EPA-HQ-OAR-2019-0055-1231-A1, p.5]
- EPA has proposed two-different options with regard to the stringency of new standards to control emissions of nitrogen oxides ("NOx") from heavy-duty vehicles ("HDVs"). EPA is also taking comments on the range of alternative standards that lie between the two options.5 On the whole, Allison supports the single-phase regulatory structure of Option 2, rather than imposing two different sets of standards in Model Years ("MYs) 2027 and 2031 under Option 1. As indicated in more detail below, the imposition of new standards for heavy-duty commercial vehicles has historically been preceded by a "pre-buy" period where trucking companies and other fleet and individual purchasers seek to avoid a step-up in price and change in emissions architecture for vehicles that will be used in their business. This is followed by a downturn in business after the new standards take effect (the "low-buy" period). Thus, rather than smoothing out any pre-buy period by phasing-in two sets of standards taking effect within four years of each other, Allison believes that EPA's Option 1 would likely exacerbate the turmoil that normally attaches to the imposition of new standards. [EPA-HQ-OAR-2019-0055-1231-A1, p.7]

Should EPA determine to have a phased-in program, the four-year period between implementation of the MY 2027 and 2031 standards under Option 1 is far too short. While it may comply with the minimum statutory period provided for in the Clean Air Act ("CAA"), for most vehicle categories, the stringency level of NOx standards will be reduced by 50% or more during the second-phase of the Option 1 standards.6 In that four-year timeframe, many OEMs and component suppliers will simply have insufficient resources to accommodate the necessary research, development and testing required to ensure compliance with the MY 2031 standards. This is especially true given that companies will need to allocate their resources on two different pathways for improvement in conventional engine/vehicle emissions and developing new ZEV technology. OEMs will struggle to support installation refreshes of conventional powertrain technology across all vehicle classes in multiple steps. [EPA-HQ-OAR-2019-0055-1231-A1, p.7]

6 The sole exception would be for low-load performance for heavy heavy-duty engines in 2031.

While Allison recognizes that EPA has proposed various flexible compliance mechanisms during this period, all segments of the HDV industry will need to simultaneously prioritize their economic resources towards lower GHG technology, rather than incremental improvements in NOx reduction technology. EPA risks segmenting the industry into “haves” and “have nots” based on the sheer financial capacity of larger companies and OEMs to invest in a broader range of lower NOx and lower GHG technology at the same time. [EPA-HQ-OAR-2019-0055-1231-A1, pp.7-8]

After reviewing EPA’s proposed rule and the supporting documentation available in the docket, Allison believes the Option 2 stringency levels of 50 mg/hp-hr (0.05 g/hp-hr) for all HDV engines as measured by the FTP and the SET duty cycles and 100 mg/hp-hr (0.1 (g/hp-hr) as measured pursuant to the new Low- Load Conditions (“LLC”) cycle is most consistent with EPA’s authority under CAA section 202. [EPA-HQ-OAR-2019-0055-1231-A1 p.8]

EPA is proposing to set standards pursuant to CAA section 202(a) and 202(a)(3)(A). The first authority allows EPA to set standards that “take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.” The second authority specifies that with regard to certain criteria air pollutants, including NOx, standards are to “reflect the greatest degree of emission reduction achievable through application of technology which the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology.”7 Option 2 standards best reflect this statutory balancing of the factors EPA must take into account when specifying standards that will cover a wide range of commercial vehicles designed specifically to accomplish numerous work tasks and conditions. [EPA-HQ-OAR-2019-0055-1231-A1, p.8]

7 See 87 Fed. Reg. at 17420.

Option 2 standards are also the preferable option for the final rule due to the inherent challenges and lead-time required for the validation of new emission control technologies. In this regard, EPA is concurrently proposing to extend useful life periods for both spark-ignition and compression ignition HDVs. Like the stringency of required NOx emission levels, useful life periods are more aggressive under Option 1 than Option 2 when fully phased-in by MY 2031, although the first phase of Option 1 is somewhat less aggressive than Option 2 as applied to MY 2027 and later MY vehicles.8 Whatever useful life periods are contained in the final rule, however, the longer useful life periods will impose substantial upfront engineering and materials costs. As EPA is aware, systems will need to be designed and built to ensure sufficient “head room” for compliance over many years, which in the case of EPA’s proposed standards, may be up to 15 years. Companies that supply original equipment manufacturers (“OEMs”) with various systems, like Allison, will need to ensure that the lengthy proposed mileage/time periods can be accommodated. Because EPA intends to move this regulation forward to completion in 2022, there will be only four years (perhaps less) time from the finalization of the regulation to the time where fully-engineered vehicle systems will need to be developed, produced, and sold to ultimate purchasers. This means that interim dates for design, testing, validation, production, and distribution will be challenging even under the least stringent options being considered by EPA. [EPA-HQ-OAR-2019-0055-1231-A1, p.8]

8 Table 1 – Proposed Options 1 and 2 Emission Standards for Heavy-Duty CI and SI Engines on Specific Duty Cycles, Id. at 17,422.

The final Southwest Research Institute ("SWRI') report9 contained in the docket for this rulemaking indicates that a diesel engine platform "present[s] a much greater challenge to achieving ultra-low NOx emissions. As with all diesel engines, the combination of lean exhaust and lower exhaust temperatures makes NOx control particularly difficult."10 In the SWRI analysis, traditional approaches to NOx control were not capable of meeting the target 0.02 level; advanced technology approaches were necessary to even approach, much less achieve this level on a consistent basis.11 And, while the advanced approaches examined by the SWRI achieved results showing the potential to even go below 0.02, considerable alterations were necessary to address various issues, including cold start. Relatedly, despite a long-standing California program to allow for certification of vehicles as 0.02, to date, it is notable that only natural gas and liquefied petroleum gas engines have been certified to this level,12 not the diesel and gasoline-powered engines that are the explicit focus of this rulemaking. [EPA-HQ-OAR-2019-0055-1231-A1, p.9]

9 Evaluating Technologies and Methods to Lower Nitrogen Oxide Emissions from Heavy Duty Vehicles, Final Report, April, 2007, Prepared for California Air Resources Board ("CARB Final Report").

10 Id. at xxxv.

11 Id. at xl.

12 87 Fed. Reg. at 17,433

In the SWRI analysis, there were even more issues with maintaining the 0.02 level over time. While a "full useful life" duration of 435,000 was used – substantially less than proposed by EPA in this rulemaking -- the results from this study showed that aged parts achieved levels above 0.02 -- approximately 0.035 -- on a composite FTP duty cycle.13 EPA's Draft Regulatory Impact Analysis ("RIA") also showed measured values above the 0.02 standard after 1,000 hours of accelerated thermal and chemical aging to simulate 435,000 miles of operation. While not at the level of SWRI, EPA's results were above the level of the proposed Option 1.14 Finally, while EPA has proposed longer useful life periods apply, data showing compliance with the 0.02 standard over such time periods were not available in the docket upon Federal Register publication.15 [EPA-HQ-OAR-2019-0055-1231-A1, p.9]

13 CARB Final Report at xlvii, xlix.

14 Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards, Draft Regulatory Impact Analysis, Table 3-7, at 115 (“Draft RIA”).

15 EPA indicates that data for 800,000 miles of operation is not available yet, but will be added to the docket when completed. Draft RIA at 129.

EPA should keep in mind several additional perspectives when determining the final standards to apply to MY 2027 and later HDVs:

- Allowing for an adequate compliance margin is absolutely necessary for near-term standards, given the costs, engineering challenges, required testing and verification efforts that are needed to address both stricter standards and longer useful life periods that require increased part durability. Thus, in seeking to impose standards starting in MY 2027, EPA must allow for sufficient “headroom” that is reflective of real-world production and not base standards solely on the thorough – but selective -- testing that has been performed by SWRI or other organizations.
- Setting standards that reflect more stringent levels in the near term could actually inhibit the development of new emission control technologies by incentivizing industry to utilize only the most conservative approaches to controlling emissions. Industry will logically pursue the most tested and verified technologies to reduce compliance risk even if newer technologies could result in additional reductions over the near and long term. [EPA-HQ-OAR-2019-0055-1231-A1 pp.9-10]

EPA must also create a regulatory environment that encourages industry innovation to develop best technology for customer needs and environmental targets over the long-term which can require an assessment and balancing of near-term priorities to improve air quality and reduce GHGs with longer term goals to ensure that the best technology choices are available and sustainable reductions in air pollution are achieved. Different technological approaches can result in different environmental benefits within different timeframes. EPA should not mandate (or preclude) in the final rule the ability for industry to utilize different technological options such as vehicle electrification or alternative fuel pathways like hydrogen. And requirements and timeframes should allow sufficient time and flexibility for private sector investment in different options which may have different tailpipe and “upstream” emissions.[EPA-HQ-OAR-2019-0055-1231-A1, p.34]

EPA should strive to better analyze this larger picture for the development and deployment of vehicles in the vocational vehicle sector where several factors (e.g., the carbon content of electricity used, the production process for hydrogen, the availability of charging/fueling stations) can determine the level of overall emissions. In some cases, longer timeframes may be necessary to allow for full development and market confidence in different equipment and fueling approaches, but these longer timeframes would result in better overall environmental outcomes. In addition, as cited above, it is essential to fully validate new technologies in vocational vehicle applications prior to commercial sale. Further consideration of the timeframes and effort involved in transition to cleaner medium- and heavy-duty vehicles will pay off in the end; it will help obtain the most cost-effective transition for vehicle owners while ensuring that emission reductions can be sustained.[EPA-HQ-OAR-2019-0055-1231-A1, p.35]

One current example of this dynamic lies within EPA's own experience with the Diesel Emissions Reduction Act program ("DERA"). EPA's most recent assessment of this program indicates that $629 million in funding was awarded in Fiscal Years 2008-2016 resulting in approximately $19 billion in monetized health benefits, producing a cost-to-benefit ratio of 27:1.70 These health and environmental gains have largely been achieved through the funding of various technologies, including aerodynamic technologies, diesel oxidation catalysts ("DOCs"), diesel particulate filters, DOC+ Closed Crankcase Ventilation, engine replacement, idling reduction technologies, truck stop electrification and vehicle replacement.71 In other words, no one particular pathway was taken and incremental improvements to the medium- and heavy-duty diesel fleet produced substantial, cost-effective benefits. EPA should consider this past experience in designing programs that will apply prospectively to newly manufactured engines and vehicles and not selectively favor one technological approach to reducing NOx. [EPA-HQ-OAR-2019-0055-1231-A1, p.35]

> 70 DERA Fourth Report to Congress, EPA Office of Transportation and Air Quality, July 2019 at 1.
>
> 71 Id. at 4.

- Allison does not support Option 1 and further believes that attempts to make Option 1 more flexible in implementation (e.g., by shortening useful life or warranties or allowing for additional compliance margins) would not overcome the fundamental issue of the stringency of the NOx standard being imposed. As detailed above, Allison believes that the stringency of the Option 1 NOx standard will dictate that only limited technological pathways will be adopted, excluding other potential options to reduce emissions on a more cost-effective basis over the longer-term. OEMs and vendors will necessarily have to design "to the number" of the final emission standard and will only choose options that have the most proven performance. This dynamic will forfeit the possibility of industry investing in a broad range of alternatives. [EPA-HQ-OAR-2019-0055-1231-A1, p.37]

- EPA will likely receive comments questioning the technical feasibility of engines, vehicles and equipment meeting the Option 1 20 mg/hp-hr (0.02 g/hp-hr) standard. As a transmission manufacturer, Allison does not seek to offer specific comments on the ability of vehicles and equipment to meet the Option 1 standard on an engine-out basis, but believes that the wide variety of vehicle applications and vehicle options in the vocational vehicle sector strongly favors the adoption of Option 2. As pointed out in our comments this is due to several factors including: (a) allowing for a variety of technological options; (b) allowing sufficient time for research, development and validation of technology; (c) recognition that not all options will be available/validated in the vocational vehicle sector at the same time; and (d) our concerns that the two-phase structure of Option 1 will exacerbate issues of pre-buy and low-buy. If EPA proceeds with finalization of a 0.02 g/hp-hr standard, it should strongly consider limiting application of this standard to segments of the market outside of the vocational vehicle sector. [EPA-HQ-OAR-2019-0055-1231-A1, p.37]

Organization: *American Bus Association (ABA) (1070 and 1308)*

In terms of the Proposal, ABA comments are in response to the proposed revisions to the emissions control program outlined in the Notice, and do not address the proposed changes to the Greenhouse Gas Phase 2 program. Specifically, ABA has a number of specific concerns relating to the effect the Proposal will have on feasibility, cost, and operational reliability. [EPA-HQ-OAR-2019-0055-1308-A1, p.5]

As repeated throughout the Notice, EPA must also consider technological feasibility, compliance cost, and lead time, in addition to reducing pollution when establishing or revising standards as part of its statutory mandate. In terms of technological feasibility, based on discussions with engine manufacturers and by reviewing prior submissions to the California Air Resources Board (CARB) Omnibus rulemaking1, ABA is concerned about the technological feasibility of the Proposal, particularly with regard to EPA's favored Option 1. The ABA, as representatives of heavy-duty vehicle users and lacking resources to evaluate the technical complexities involved in developing engines and emissions control systems, must rely on the expertise of such manufacturers. Based on the opinions expressed by the engine manufacturing and the vehicle components manufacturing industries, there remain questions as to the feasibility of complying with the proposed revised standards, particularly Option 1's step 2. Although we understand research conducted by the Southwest Research Institute demonstrated promise, in terms of establishing feasibility for the proposed revised standards pursuant to Option 2, we further understand the research was limited and not actually evaluated in terms of an actual vehicle, let alone a fully loaded motorcoach, or other real-world scenario. Based on the lack of consensus of whether the proposed revised emissions standards are technically feasible, ABA believes EPA should reconsider the underlying data and focus on its proposed Option 2. As the vehicle components manufacturing industry noted in their comments to the CARB Omnibus regulation, technologies continue to develop and can be improved as they are implemented. Since the technology evaluated by the Southwest Research Institute has yet to be actually deployed in an actual vehicle, of any sort, it seems premature for EPA, even with its "technology-forcing" authority, to attempt to impose standards beyond MY 2031, per Option 1. [EPA-HQ-OAR-2019-0055-1308-A1,p.6]

> 1 "Proposed Heavy-Duty Engine and Vehicle Omnibus Regulation and Associated Amendments," California Air Resources Board, Aug. 2020.

EPA should also consider that by acting prematurely, relying on its "technology-forcing" approach, it may again find itself in the position it is now in, seeking revisions to its 2016 Greenhouse Gas Emissions Phase 2 program. As noted in the Notice, EPA premised the 2016 rule on the unlikelihood of the heavy-duty market becoming electrified in the time frame of the program. However, the Agency's outlook has now apparently changed regarding targeted segments of the heavy-duty market. As technological advancement is sure to occur during the proposed Option 2 timeline, as engine and component manufacturers heavily invest in research and development, ABA believes EPA should not consider imposing standards beyond Option 2. [EPA-HQ-OAR-2019-0055-1308-A1, p.6]

If EPA determines to proceed with the Proposal, ABA supports Option 2 only. [EPA-HQ-OAR-2019-0055-1308-A1, p.6]

Organization: *American Truck Dealers (ATD)*

New NOx Standard. Based on a review of information provided by HDE and CMV manufacturers (OEMS), ATD urges EPA to adopt proposed “Option 2,” which will require dramatic but arguably feasible HDE NOx reductions starting with MY 2027. ATD strongly opposes proposed “Option 1” which would mandate an unacceptable two-step set of new standards in MY 2024 and MY 2031 that will not be feasible to comply with without significantly compromising expected vehicle performance characteristics, including fuel economy. [EPA-HQ-OAR-2019-0055-1321-A1, p. 3]

Zero Emission CMVs: Almost daily an HDE or CMV OEM announces a new alternative fuel or technology (natural gas, hydrogen fuel cell, battery-electric, etc) product they are developing. ATD’s members are committed to educating prospective new CMV customers about these exciting new products, to selling, leasing, servicing, and repairing those products as they come to market, and to making the investments in on-site fueling, tooling, and education necessitated by those products. And as evidenced by activities at the March 2022 NADA/ATD Show6, and by its work with the U.S. Departments of Transportation and Energy on the deployment of critical public charging facilities, ATD is likewise committed. But ATD urges EPA to recognize that, while alternative fueled and new technology vehicles are on coming, this NOx rulemaking should focus exclusively on feasible and cost-effective strategies for reducing NOx emissions from the significant number of new CMVs powered by ICE diesel and gasoline HDEs that also will be coming to market in MY 2027 and beyond. [EPA-HQ-OAR-2019-0055-1321-A1, p. 3]

6. See Attachment C, NADA, Everything Electric at NADA/ATD Show 2022 (2022).

As discussed above, ATD urges EPA to move forward with a single set of technologically achievable and customer acceptable national HDE NOx standards for MY 2027 and later, while relegating any consideration of new HDE GHG mandates to a separate “Phase 3” rulemaking. [EPA-HQ-OAR-2019-0055-1321-A1, p. 8]

Organization: *American Trucking Associations (ATA)*

ATA has established 12 fleet Guiding Principles that should be considered in the development of HD2027 including:

- Standards should not adversely impact existing or future regulatory requirements currently in effect whether by EPA or other federal agencies.
- New emission standards should be uniform across the country.
- The wide diversity in truck operations, duty-cycles, and fleet turnover rates must be considered.
- Technologies under consideration should be thoroughly tested in a multitude of fleet operations under varying duty cycles under all climatic conditions.

- The rule should not impede the transition towards the purchase of ZEVs. [EPA-HQ-OAR-2019-0055-1326-A1, p. 5]

HD2027 is closely intertwined with the forthcoming Phase 3 rule to be implemented beginning in 2030. The current low-NOx effort will likely be the final Agency NOx emissions standard for fossil-fueled trucks as our industry begins it efforts towards decarbonization. HD2027 serves as one final step towards clean diesel technology improvements as the future focus of trucking will be redirected towards ZEV technologies. [EPA-HQ-OAR-2019-0055-1326-A1, p. 6]

Manufacturers need certainty in terms of planning, timing, research and development, and investments. Establishing NOx emission milestones beyond 2030, as envisioned under Option 1, creates another layer of technological difficulty as resources will be stretched thin to ensure technology pathways are achievable between both rules. Research and development are never free. Fleets ultimately pay for new technologies as OEMs recoup their investments one increased invoice at a time. [EPA-HQ-OAR-2019-0055-1326-A1, p. 6]

ATA appreciates the opportunity to submit these comments on HD2027. We ask that the agency continue to proceed in a deliberative manner that weighs science over empathy and facts over speculation. EPA's proposed Option 1 is not technologically or economically feasible and we urge that the final rule be set at a place where EPA, fleets, and manufacturers can successfully develop the next pathway for a cleaner tomorrow and keep the nation's supply chains strong. [EPA-HQ-OAR-2019-0055-1326-A1, p. 20]

Organization: *Anonymous 1035*

Reducing the emissions of ozone, oxides of nitrogen (NOx), particulate matter, and greenhouse gases (GHG) in heavy-duty vehicles is critical. While heavy-duty vehicles make up less than 5% of vehicles on the road, they contribute 20% of transportation emissions because commercial heavy-duty vehicles tend to drive further than passenger vehicles [1]. While passenger transportation slowed during the pandemic, freight demand has only grown. The heavy-duty truck market is set to grow by 7% in the next five years, making the regulation of NOx and other emissions in these vehicles a high priority [2]. [EPA-HQ-OAR-2019-1035]

Oxides of nitrogen have detrimental effects on both environmental and human health. It can damage human respiration and sense of smell [3]. As the docket covers in detail, people of color and low-income communities are the most likely populations to be exposed to NOx and suffer from its effects, yet another example of the large trend of environmental harm disproportionately affecting already socially marginalized groups. On the environmental side, high levels of nitrogen dioxide have been known to damage vegetation and reduce crop yields [3]; this threatens growing regions, many of which are already projected to shrink and buckle under demand due to climate change [4]. [EPA-HQ-OAR-2019-1035]

I support the EPA's recommendation of proposed Option 1. Option 1 takes the most aggressive stance on reducing NOx emissions; it is projected to cut the emissions of nitrogen oxides from heavy-duty vehicles in half by 2040, and by 60% in 2045. It is important to note that the world is currently not on track to meet most environmental targets, such as the UN Sustainable Development Goals or the Paris agreement [5]. It is important to overshoot and take an ambitious stance against NOx and other emissions with this reality in mind. To this end, I encourage my fellow readers to weigh both options' economic potential by considering the lower discount rate of 3%. Discount rates take into account that future generations will be wealthier than today's; thus, a dollar today has higher marginal utility than one in the future. Discount rates also take into account reduced future value due to inflation. A higher discount rate signals that we would much rather limit our spending against climate change today, even if it pushes higher expenses to the future because it assumes we will value future dollars less. However, we would err to use a high discount rate when weighing policy towards nitrogen oxides emissions. Firstly, these emissions will have long-term ramifications that we may not fully understand or foresee. Second, the assumption that future generations will be much more prosperous and able to absorb the costs of today's emissions on their society is dubious: global growth is expected to slow through 2023, particularly in developing countries [6]. In some future time, we may hit a breaking point where expenditures may only focus on addressing the immediate severe effects of climate change. To affirm the belief in intergenerational environmental justice, we should apply a prescriptive approach and use a lower discount rate. This would also return to the standard 3% discount rate used by the Obama administration to calculate the social cost of carbon [7]. [EPA-HQ-OAR-2019-1035]

I would like to react to a few particular topics in the docket. It is commendable that Option 1 has followed the guidance of Executive Order 12898, and is suggesting an option they believe will not adversely impact minority and low-income populations. By enacting the emissions reductions, it would actually disproportionately benefit the marginalized populations currently most heavily subject to transportation emissions. These policies would also reduce the atmospheric concentration of ozone and particulate matter, resulting in "avoidance of many adverse environmental and human health impacts in 2045, including reductions in premature deaths and many non-fatal illnesses" (p. 17643). This is important because, in addition to having worse health outcomes [8], minority populations experience the impact of emissions disproportionate to their own consumption [9]. One thing I would have liked to see is more analysis of the impacts of these policies on the Global South, both from an economic and environmental viewpoint. [EPA-HQ-OAR-2019-1035]

This docket is a step in the right direction, but I also encourage the EPA to continue exploring zero-emissions vehicles and trends in the trucking industry. As trucking demand explodes, a growth not even stifled by the pandemic, the freight industry has considered pivoting to more efficient solutions such as powertrains [10]. The EPA should assess that new transportation technologies are also properly and aggressively regulated, especially as more companies may turn in this direction amidst trucker shortages. On the bright side, interest in fuel-efficient fleets and optimized trucking routes (ie. shorter and less fuel-intensive) from the industry side may lead to a useful collaboration with the EPA toward environmental goals. Organization: *Arizona Public Health Association*

The Arizona Public Health Association urges USEPA to select Option 1 for heavy and medium duty truck emissions. We also urge EPA to include emission limits on particulate pollution in addition to the NOx standards. As it stands, the current rule only sets new goals for NOx – not particulate matter. While cutting NOx emissions can cut particulate matter emissions including more stringent particulate standards will motivate engineers to ensure that both goals are achieved. [EPA-HQ-OAR-2019-0055-2114, p. 1]

Organization: *BorgWarner*

2. EPA's proposed Option 1 standards are technically feasible, once the caveats above on FUL and warranty have been recognized. The proposed Option 1 has the potential to drive more rapid adoption of advanced engine and emission control technologies, benefitting both the environment and economy. In addition, we appreciate EPA's consideration for the following factors for the final rule: [EPA-HQ-OAR-2019-0055-1234-A1, p. 2]

Option 1 represents better harmonization of future national standards with California's Omnibus rules, which would bring the country together to a more unified national program. Vehicle performance and emissions are determined by fundamental vehicle and propulsion architectures which should not change from one state to another. Decisions regarding long-term investment in R&D, capital and tooling are challenging for suppliers like BorgWarner, who support all major automakers in all U.S. markets. Therefore, state-to-state variations in emissions standards create the need for automotive suppliers to invest in multiple technology solutions to meet our customers' needs. With several states already choosing to adopt California's low-NOx Omnibus rules, harmonization of the standards is necessary to provide industry with certainty for investments and efficiencies in product development and manufacturing, and a common technology approach for the full national market. [EPA-HQ-OAR-2019-0055-1234-A1, pp. 2 - 3]

BorgWarner opposes technology mandates, including any Zero-Emissions Vehicle (ZEV) mandate. We consistently urge regulators to develop standards that are technology neutral and performance based to encourage innovation. All technology pathways with practical applications should be included as potential solutions to assist the U.S. in achieving its environmental goals. Regulations based on the end goals of a clean environment, minimizing CO2 emissions and preserving resources should not give preferential treatment to a specific technology. Public policies should let innovation and market dynamics determine the most effective solutions. [EPA-HQ-OAR-2019-0055-1234-A1, p. 3]

Technologies to meet the most stringent NOx standards are available today and ready to deploy to improve air quality across the country. These engine and emission control technologies, if deployed quickly, present an opportunity to significantly lower NOx emissions. This quick deployment is urgently needed in disadvantaged communities, located near highways and heavy truck traffic, that experience poor air quality and the associated health risks. EPA should allow for a review of increased stringency should technology pathways demonstrate earlier readiness to maximize environmental benefits in the near-term as EV trucks become a larger part of the marketplace. [EPA-HQ-OAR-2019-0055-1234-A1, p. 4]

Organization: *California Air Resources Board (CARB)*

Ultimately, the future of heavy-duty vehicles is a full transition to zero emission vehicles (ZEV). But there will be a substantial number of combustion vehicles placed into service even under

California's nation-leading ZEV rules, and there are no such rules nationally. Though CARB urges U.S. EPA to accelerate efforts to promote ZEVs, the agency must also ensure combustion emissions are as low as possible. To achieve the needed oxides of nitrogen (NOx) reductions and healthy air for Californians, future heavy-duty trucks must be dramatically lower emitting than today's new trucks and must stay clean over their entire useful lives. Heavy-duty trucks comprise the largest NOx emission source category in the State, contributing a third of all statewide NOx emissions and over a quarter of total statewide diesel particulate matter emissions. It is also the category that has the biggest impact on our disadvantaged and low income communities. With 50 percent of the heavy-duty truck NOx emissions in California originating from federally certified trucks, it is crucial for U.S. EPA to adopt stringent standards and test procedures that protect our communities as those federal compliant trucks drive through our neighborhoods and highways. [EPA-HQ-OAR-2019-0055-1186-A1, p.1]

U.S. EPA's proposal includes three sets of proposed emissions standards: Option 1, Option 2, and Alternative standards. The most stringent standards are associated with the Alternative standards, followed by the proposed Option 1 standards and the least stringent Option 2 standards. CARB staff is pleased that the proposed Option 1 standards incorporate many elements that are generally aligned with California's Omnibus regulation, although on a delayed timetable, and additionally include some elements that establish requirements that are more stringent than the requirements in the Omnibus regulation. U.S. EPA indicates that its preferred standards for final consideration are either the proposed Option 1 standards, the proposed Option 2 standards, or standards that are in-between those standards. It is clear that Option 1 is feasible for many reasons, including the fact that one major HD manufacturer, Ford, publicly stated at U.S. EPA's public hearing on April 13, 2022, that Option 1 is feasible and should be selected. [EPA-HQ-OAR-2019-0055-1186-A2, p.31]

As set forth in greater detail below, CARB staff strongly opposes the adoption of any standards that are less stringent than the proposed Option 1 standards, but additionally urges U.S. EPA to incorporate CARB staff recommended modifications to Option 1 that are needed to both ensure the associated emissions benefits are not unduly diluted and to better align the Option 1 standards with the Omnibus regulation. CARB staff additionally believes that the proposed adoption of the Option 2 standards is unlawful, because it is directly inconsistent with CAA Section 202(a)'s mandate that U.S. EPA must adopt emissions standards that reduce emissions from heavy-duty engines and vehicles to the greatest extent possible, and is also arbitrary and capricious, in light of U.S. EPA's findings that the emissions technologies needed to comply with the Option 1 standards will be available by the applicable model years, that the Option 1 standards will produce greater emissions reductions and provide greater public health benefits than the Option 2 standards. Option 1 would be more cost effective due to the overall lower costs and greater benefits compared to Option 2. [EPA-HQ-OAR-2019-0055-1186-A2, p.31]

The adoption of the Option 2 standards would be unlawful because such standards are inconsistent with CAA Section 202(a)'s mandates that U.S. EPA must adopt emissions standards that reduce emissions from heavy-duty engines and vehicles to the greatest extent possible, through the application of technology that U.S. EPA '[d]etermines will be available … giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology,'60 and that U.S. EPA must also ensure such emission standards are sufficiently protective of the public health and welfare.61 The adoption of the Option 2 standards would also be arbitrary and capricious, in light of U.S. EPA's findings that the emissions technologies needed to comply with the Option 1 standards will be available by the applicable model years, that the Option 1 standards will produce greater emissions reductions and provide greater public health benefits than the Option 2 standards, and thus Option 1 would be more cost effective than Option 2. CARB staff therefore urge U.S. EPA to adopt the Option 1 standards, in conjunction with CARB staff recommended modifications to Option 1 that are needed to ensure that the emissions benefits associated with Option 1 are not unduly diluted, and to better align the Option 1 standards with the standards of the Omnibus regulation. CARB staff's comments regarding the recommended modifications are set forth in Comments [2.b, 3.a, 4.b, 5.f, 6.f, 9.a, and 10.k.] [EPA-HQ-OAR-2019-0055-1186-A2, p.32]

60 CAA section 202(a)(3)

61 CAA section 202(a)(1).

Applicable Legal Standards

Courts determine the propriety of U.S. EPA's interpretations of the federal CAA using the standard established by the U.S. Supreme Court in Chevron U.S.A. Inc. v. Natural Resources Defense Council, Inc. 467 U.S. 837, 842-843 (1984)62 or the 'statute is silent or ambiguous with respect to the specific issue, the question for the court is whether the agency's answer is based on a permissible construction of the statute.' [EPA-HQ-OAR-2019-0055-1186-A2, p.32]

62 Utility Air Regulatory Group v. EPA, 573 U.S. 302, 315 (2014).

467 U.S. 837, 842-843.
'The question for a reviewing court is whether in doing so the agency has acted reasonably and thus has 'stayed within the bounds of its statutory authority.'63 [EPA-HQ-OAR-2019-0055-1186-A2, p.32]

63 Utility Air Regulatory Group, 573 U.S. 302, 315 citing Arlington v. FCC, 133 S.Ct. 1863, 1868 (emphasis deleted).

Section 307(d)(9) of the CAA authorizes the U.S. Court of Appeals for the District of Columbia to reverse a U.S. EPA action that is 'in excess of statutory jurisdiction, authority, or limitations, or short of statutory right,' or that is 'arbitrary, capricious, an abuse of discretion, or otherwise not in accordance with law.' Blue Water Network v EPA, 370 F.3d 1 (D.C. Cir. 2004). [EPA-HQ-OAR-2019-0055-1186-A2, p.33]

The 'arbitrary and capricious' standard of review specified in section 307(d)(9) is essentially the same standard of review as specified in the federal Administrative Procedure Act, 5 U.S.C. 706(2)(A). Ethyl Corp. v. EPA, 51 F.3d 1053, 1064 (D.C. Cir. 1995). 5 U.S.C. 706(2)(A) requires a reviewing court to 'ensur[e] that EPA has 'examine[d] the relevant data and articulate[d] a satisfactory explanation for its action, including a rational connection between the facts found and the choice made,' that the Agency's 'decision was based on a consideration of the relevant factors,' and that the Agency has made no 'clear error of judgment.' ' Blue Water

Network, 370 F.3d 1, 11 quoting Motor Vehicle Mfrs. Ass'n v. State Farm Mut. Auto. Ins. Co., 463 U.S. 29, 43, (1983) (internal citations and quotation marks omitted), (hereinafter ‘State Farm’). [EPA-HQ-OAR-2019-0055-1186-A2, p.33]

An agency action is arbitrary and capricious if the agency relies on factors which Congress has not intended it to consider, the agency has entirely failed to consider an important aspect of the problem, offers an explanation for its decision that runs counter to the evidence before the agency, or its explanation is so implausible that it could not be ascribed to a difference of view or the product of agency expertise. State Farm 463 U.S. at 43. [EPA-HQ-OAR-2019-0055-1186-A2, p.33]

An agency that is proposing a change in preexisting policy must show that ‘the new policy is permissible under the statute, that there are good reasons for it, and that the agency believes it to be better...’ FCC v. Fox Television Stations, Inc., 556 U.S. 502, 515 (2009). (Emphasis in original removed). [EPA-HQ-OAR-2019-0055-1186-A2, p.33]

The Proposed Adoption of the Option 2 Standards Is Unlawful, Because Such Standards Are Directly Inconsistent With CAA 202(a)’s Directives That U.S. EPA Must Reduce Emissions From Heavy-Duty Engines and Vehicles to the Greatest Extent Possible [EPA-HQ-OAR-2019-0055-1186-A2, p.33]

CAA section 202(a)(1) provides, in pertinent part, that the Administrator of U.S. EPA shall prescribe emission standards for new motor vehicles or new motor vehicle engines in order to protect the public's health and welfare. CAA section 202(a)(2) provides that ‘[a]ny regulation prescribed under paragraph (1) of this subsection (and any revision thereof) shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.’ CAA Section 202(a)(3) provides, in pertinent part, that emissions standards applicable to HC, carbon monoxide (CO), NOx and PM emitted from heavy-duty engines or heavy-duty vehicles must ‘reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology.’ [EPA-HQ-OAR-2019-0055-1186-A2, pp.33-34]

Although CAA section 202(a)(2) provides that U.S. EPA must determine that the technology needed to comply with proposed standards will be available within applicable time periods, considering associated compliance costs, and CAA section 202(a)(3) provides that U.S. EPA, in determining the availability of technology needed to achieve the greatest degree of reductions can consider cost, energy, and safety factors associated with such technologies, it is clear that the overriding directive of CAA section 202(a)(1) is the protection of the public’s health and welfare, and the nation’s air quality. Motor and Equipment Mfrs. Ass’n, Inc. v. v EPA, 627 F.2d 1095, 1117-1118 (D.C. Cir. 1979); Massachusetts v EPA, 549 U.S. 497, 532, 533 (2007) (stating 202(a)(1) obligates U.S. EPA to protect the public health and welfare). Courts have interpreted CAA section 213(a)(3), which contains virtually identical language to section 202(a)(3),64 to require U.S. EPA, in determining appropriate compliance technologies and associated emissions standards, to primarily consider the impacts on air quality. ‘The overriding goal of the section is air quality and the other listed considerations, while significant, are subordinate to that goal.’ Husqvarna AB v. EPA, 254 F.3d 195, 200 (D.C. Cir. 2001); American Petroleum Inst. v. EPA, 52 F.3d 1113, 1120 (D.C. Cir. 1995). [EPA-HQ-OAR-2019-0055-1186-A2, p.34]

> 64 ‘Such standards shall achieve the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available … giving appropriate consideration to the cost of applying such technology within the period of time available to manufacturers and to noise, energy, and safety factors associated with the application of such technology.’ CAA section 213(a)(3).

Section 202(a)(3)’s express directive that U.S. EPA must achieve ‘the greatest degree of emission reduction possible’ is reinforced by legislative history that reflects Congress’ clear intent that U.S. EPA must affirmatively act to reduce emissions from heavy-duty engines and vehicles to the greatest extent possible. Although U.S. EPA was first authorized to regulate heavy-duty vehicle emissions by the CAA Amendments of 1965,65 it apparently had ‘done little’ to regulate such emissions by the mid-1970’s.66 Congress accordingly enacted mandatory emissions standards for 1979 through 1982 model year heavy-duty vehicles and engines, and emissions targets for 1985 and later model year heavy-duty vehicles or engines in the 1977 Amendments to the CAA.67 The legislative history indicates Congress’ impatience with U.S. EPA’s failure to promulgate sufficiently stringent emissions standards for heavy-duty vehicles. H.R. Rep. No. 95-294, 95th Cong., 1st Sess. at 271-273 (1977) (noting that 1977 federal standards required no reduction of HC, CO or NOx emissions from uncontrolled diesel engines, and citing reports that ’inadequate’ truck emissions standards will cause emissions from heavy-duty vehicles to comprise ‘more than half of all transportation emissions,’) 68 and expresses Congress’ insistence that U.S. EPA promulgate technology-forcing emissions standards for heavy-duty vehicles to achieve needed reductions in emissions from heavy-duty vehicles and engines.69 [EPA-HQ-OAR-2019-0055-1186-A2, pp.34-35]

> 65 Natural Resources Defense Council v. Thomas, 805 F.2d 410, 414 (D.C. Cir. 1986), Clean Air Act Amendments of 1965, Pub. L. No. 89–272 202(a), 84 Stat. 992

>
> 69 Id. at 273-274.

The U.S. Court of Appeals for the District of Columbia Circuit has interpreted the structure and legislative history of the 1977 Amendments to the CAA that explicitly directed U.S. EPA to regulate heavy-duty vehicles and heavy-duty vehicle engines as evidencing Congress’ intent that U.S. EPA establish heavy-duty emission standards that are technology forcing.70 ‘That the provisions at issue in this case seek to promote technological advances while also accounting for cost does not detract from their categorization as technology-forcing standards.'71 U.S. EPA acknowledges that CAA section 202(a)(3) constitutes a technology forcing provision that reflects Congress' intent that U.S. EPA establish standards achievable as a result of future advances of pollution control technology.72 [EPA-HQ-OAR-2019-0055-1186-A2, p.35]

70 NRDC v. Thomas, 805 F.2d 410, 430 (D.C. Cir, 1986).

71 Id. at 428, fn. 30.

72 NPRM at 17436.

That congressional directive to achieve needed emissions reductions is also evidenced by the technology-forcing directives of CAA section 202(a). Courts interpreting section 202(a) of the CAA have recognized that Congress intended U.S. EPA to rely upon projected future developments and advances in pollution control technology in establishing emission standards, and expected U.S. EPA to 'press for the development and application of improved technology rather than be limited by that which exists today.' Natural Resources Defense Council v. U.S. EPA, 655 F.2d 318, 328 (D.C. Cir. 1981) (NRDC). The NRDC court noted that a longer lead time 'gives the EPA greater scope for confidence that theoretical solutions will be translated successfully into mechanical realizations,'73 and further stated that 'the presence of substantial lead time for development before manufacturers will have to commit themselves to mass production of a chosen prototype gives the agency greater leeway to modify its standards if the actual future course of technology diverges from expectation.'74 Furthermore, in assessing the feasibility of developing and applying technology needed to comply with proposed standards, U.S. EPA may determine whether such standards are attainable by a predominant segment of the regulated industry.75 [EPA-HQ-OAR-2019-0055-1186-A2, p.35]

73 NRDC, 655 F.2d 318, 329 (D.C. Cir. 1981).

74 Ibid.

75 Natural Resources Defense Council v. Thomas, 805 F.2d 410, 423 (D.C. Cir. 1986).

In this NPRM, U.S. EPA has considered two distinct sets of emissions standards that it has determined can be achieved by heavy-duty engines and vehicles in the 2027 and subsequent model years, through the application of technology it has determined will be available by specified years, referred to as Option 1 and Option 2.76 The emissions standards associated with Option 2 are less stringent than the emissions standards associated with Option 1, and it would accordingly be unlawful to adopt the Option 2 standards, because that action would be directly inconsistent with CAA 202(a)'s directives that U.S. EPA must reduce emissions from heavy-duty engines and vehicles to the greatest extent possible, through the application of emission control technology that U.S. EPA has determined will be available. [EPA-HQ-OAR-2019-0055-1186-A2, p.36]

76 NPRM at pp. 17436, 17440, 17458, 17459, 17461-17464, 17467-17468, 17475-17476, 17481, 17487, 17489, 17495-17496, 17500, and 17550.

The proposed adoption of the Option 2 standards would be unlawful because it would necessarily rely upon an interpretation of CAA section 202(a)(3) that is unambiguously precluded by the statutory phrase ‘the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply.’ That statutory mandate is clear – it requires U.S. EPA to prescribe standards associated with the greatest degree of emissions reduction achievable through technologies that U.S. EPA finds will be available by applicable future years. The proposed adoption of the Option 2 standards would necessarily contravene that mandate and would accordingly be precluded, because U.S. EPA has determined that the Option 1 standards represent ‘the greatest emission reductions achievable for the model years to which they are proposed to apply, pursuant to CAA section 202(a)(3),’77 and that the technology needed to achieve compliance with the Option 1 standards will be available by the specified model years.78 Given those findings, the proposed adoption of the less stringent Option 2 standards impermissibly contravenes both the text and the purpose of section 202(a)(3). Chevron, 467 U.S., 842-843.79 [EPA-HQ-OAR-2019-0055-1186-A2, p.36]

77 NPRM at 17436.

78 See Section III.B.3 of NPRM; NPRM at 17436, 17475.

79 Further note that any proposed interpretation of CAA 202(a)(3) that disregards the phrase ‘greatest degree of emissions reduction achievable’ is impermissible, since ‘[i]t is axiomatic that a statute must be construed to avoid that result so that no provision will be inoperative or superfluous.’ Motor & Equip. Mfrs. Ass’n v. EPA, 627 F.2d. 1095, 1108 (D.C Cir. 1979) cert denied, 446 U.S. 952, 100 (1980).

Both of U.S. EPA’s findings are now discussed in greater detail. In the NPRM, U.S. EPA determined that the emissions standards associated with Option 1 are both more stringent than, and are also applicable over longer useful life periods, than the emissions standards of Option 2, 80 and also determined that the Option 1 standards will achieve significantly greater reductions of exhaust emissions than the Option 2 standards. U.S. EPA estimated that the Option 1 standards will produce greater reductions of pollutants than the Option 2 standards, approximately 121,000 short tons per year of NOx reductions and approximately 149 short tons of PM 2.5 reductions, as compared to the Option 2 standards in calendar year 2045.81 U.S. EPA also determined that the Option 1 standards are also more protective of the public health and welfare than the Option 2 standards; the Option 1 standards are estimated to provide present values of monetized health benefits resulting from Option 1 in 2045 between $52 to $150 billion dollars,82 while Option 2 is estimated to provide present values of monetized health benefits in 2045 between $ 41 billion and $ 120 billion dollars.83,84 [EPA-HQ-OAR-2019-0055-1186-A2, pp.36-37]

80 See, e.g., NPRM at 17422 ‘[we consider proposed Option 2 to be less stringent than the standards in the proposed Option 1 because proposed Option 2 has higher numeric NOx emission standards with similar useful life periods as the proposed Option 1 in MY 2027, and shorter length of useful life periods than the proposed Option 1 in MY 2031’. Also see NPRM at pp. 17422-17423, 17427, ‘Table 5 -Projected Heavy-Duty Emission

Reductions in 2045 From The Proposed Options 1 and 2 Standards', 17578, and p. 17427.

82 At a 7 percent discount rate, (2017$), Table IX-1, NPRM at p. 17589.

83 Ibid.

84 The health benefits account for the reduction of premature deaths and illnesses resulting from the reductions of ozone and PM2.5 emissions associated with Options 1 and 2. NPRM at 17588.

U.S. EPA has additionally reasonably determined that the technologies needed to comply with the Option 1 standards will be available by the requisite time periods.85 U.S. EPA determined that technology packages comprised of cylinder deactivation (CDA) or other valvetrain-related air control strategies and dual selective catalytic reduction (SCR) systems have demonstrated capabilities to reduce emissions of NOx from CI engines by 90 percent.86 CARB also evaluated the same emission control technologies when it developed the California Omnibus regulation, and determined that the technologies that manufacturers will likely use to comply with the California 2024 model year NOx emission standards from CI engines are presently commercially available, and that manufacturers will have sufficient time to develop and implement future technologies or to refine existing emission control technologies needed to comply with the California 2027 and subsequent model year NOx emission standard,87 which is equivalent in stringency to U.S. EPA's Option 1 NOx standard for 2031 MY engines. [EPA-HQ-OAR-2019-0055-1186-A2, p.37]

85 See Section III.B.3 of NPRM; NPRM at 17436, 17475.

86 NPRM at 17467; See also Sections III.B.3 and III.C.3 of NPRM

87 CARB, 2020, Staff Report: Initial Statement of Reasons, Public Hearing to Consider the Proposed Heavy-Duty Engine and Vehicle Omnibus Regulation and Associated Amendments, (hereinafter Omnibus Staff Report) Section III.A.1.2; HD Omnibus ISOR: Revised on 7-9-2020 for Errata (ca.gov); Appendix I to Omnibus Staff Report; Appendix I: Current and Advanced Emission Control Strategies and Key Findings of CARB/SwRI Demonstration Work

For SI engines, U.S. EPA has reasonably determined that the Option 1 standards are currently nearly achievable through the application of existing emissions control technologies.88 In developing the Omnibus regulation, CARB determined that SI engines could comply with California's 2027 MY NOx standard, which is equivalent in stringency to U.S. EPA's Option 1 NOx standard for 2031 MY engines, by incorporating minor refinements to existing compliance technologies.89 [EPA-HQ-OAR-2019-0055-1186-A2, p.38]

88 NPRM at 17480; See Section III.D.3

89 See footnote 86

U.S. EPA has estimated the projected costs of compliance for the proposed emission standards associated with both Option 1 and Option 2. Although the incremental technology costs for the Option 1 emission standards are generally higher than the corresponding technology costs for the Option 2 emission standards, the difference in such costs is minor (the maximum difference in technology costs between Options 1 and 2 is $716 in technology costs for a Class 8 heavy heavy-duty vehicle), and the largest incremental costs associated with the Option 1 standards only constitute a fraction of the base technology costs of new vehicles,90 thereby falling within the range of allowable cost increases. [EPA-HQ-OAR-2019-0055-1186-A2, p.38]

90 For example, the incremental cost of the Option 1 2031 MY standards for Class 8 heavy heavy-duty diesel vehicles is $3931; the base price of a Class 8 heavy heavy-duty diesel vehicle is $8465 (NPRM at 17570).

Furthermore, it is especially notable that U.S. EPA has also determined that the total technology and operating costs associated with Option 1 are lower than the costs associated with Option 2.

91 The total technology and operating costs associated with Option 1 and Option 2's criteria pollutant standards are similar in the early years, but overall (during the 2027 to 2045 time period) the costs for Option 1 are lower than the costs for Option 2 over the 2027 though 2045 time period by $2 to $3 billion dollars.92 [EPA-HQ-OAR-2019-0055-1186-A2, pp.38-39]

91 Compare Table V-16, (Option 1 costs), 17576, with Table V-17 (Option 2 costs), 17577.

92 Discounted at 3 and 7 percent rates, ($2017)

Given those findings, U.S. EPA cannot justify its adoption of the less stringent Option 2 standards on the basis that weaker standards are warranted because the Option 1 standards are associated with higher costs. In Motor and Equip. Mfrs Assoc. v. EPA, 627 F.2d 1095 (D.C. Cir. 1979), the court addressed issue regarding the cost of compliance associated with CAA section 202(a)(2) and stated:

Section 202's 'cost of compliance' concern, juxtaposed as it is with the requirement that the Administrator provide the requisite lead time to allow technological developments, refers to the economic costs of motor vehicle emission standards and accompanying enforcement. See S. Rep. No. 1922, 89th Cong., 1st Sess. 5-8 (1965); H.R. Rep. No. 728 90th Cong., 1st Sess. 23 (1967), U.S. Code Cong. & Admin. News 1967, p. 1938. It relates to the timing of a particular emission control regulation rather than to its social implications. Congress wanted to avoid undue economic disruption in the automotive manufacturing industry and also sought to avoid doubling or tripling the cost of motor vehicles to purchasers. It therefore requires that emission control regulations be technologically feasible within economic parameters. Therein lies the intent of the 'cost of compliance' requirement. 627 F.2d at 1118. [EPA-HQ-OAR-2019-0055-1186-A2, p.38]

Finally, the emissions standards for both Options 1 and 2 are not anticipated to adversely impact safety, because they can be achieved through the use of emission control technologies that are largely being used today.93 Consequently, it is clear that the adoption of the Option 2 standards would contravene the directives of CAA section 202(a), because those standards do not reduce the emissions from heavy-duty engines and vehicles to the greatest extent possible, considering the technology that will be available within the requisite model years. [EPA-HQ-OAR-2019-0055-1186-A2, p. 39]

93 NPRM at 17460.

As explained in detail above, U.S. EPA has determined that the technology needed to comply with the Option 1 standards will be available within the times needed to comply with Option 1's 2027 and 2031 MY requirements, that the Option 1 standards will achieve greater emission reductions than the Option 2 standards, that the Option 1 standards will only fractionally increase the costs of new vehicles, that the total technology and operating costs of the Option 1 standards are lower than the comparable costs of the Option 2 standards, and that the Option 1 standards will produce greater societal benefits than Option 2 standards. These findings fully support U.S. EPA's multiple determinations that Option 1 appears to be more consistent with U.S. EPA's obligation under CAA section 202(a)(3) than Option 2.94 [EPA-HQ-OAR-2019-0055-1186-A2, p. 39]

94 NPRM at pp. 17417,17440, 17459.

The rulemaking record contains no information that would support a determination that the adoption of the less stringent Option 2 standards instead of the more stringent Option 1 standards would be consistent with the text, intent, or goals of CAA section 202(a). It is therefore apparent that any proposed decision to adopt weaker standards that would only increase emissions and consequential harms to the public health and welfare compared to Option 1, while also imposing greater costs to regulated entities and producing fewer benefits, compared to Option 1, could only occur if an agency improperly failed to examine relevant data, failed to consider the factors in section 202(a), or made a clear error of judgment. State Farm, 463 U.S. at 43. 95 CARB staff accordingly reiterates its recommendation that U.S. EPA adopt the Option 1 standards, in conjunction with CARB staff recommended modifications to Option 1 that are needed to ensure that the emissions benefits associated with Option 1 are not unduly diluted, and to better align the Option 1 standards with the standards of the Omnibus regulation. [EPA-HQ-OAR-2019-0055-1186-A2, pp. 39-40]

95 Chemical Mfs. Ass'n v. EPA, 217 F.3d 861, 867 (D.C. Cir. 2000) (EPA regulation was arbitrary and capricious because it did not advance statutory objectives - EPA conceded it had no evidence indicating the regulation was consistent with 'ascertainable legislative intent.')

As discussed in the NPRM and as demonstrated in the CARB Stage 3 and U.S. EPA Stage 3 rework (Stage 3 RW) low NOx demonstration programs, the proposed Option 1 standards together with CARB staff's recommended modifications are technically feasible and cost effective. The proposed Option 1 NOx and PM standards are identical to CARB's Omnibus standards for MYs 2031 and later HDEs. However, for MYs 2027 through 2030, they are less stringent than the corresponding Omnibus standards and fall short of realizing the maximum technically feasible emission reductions for those MYs. CARB staff strongly urges U.S. EPA to adopt in its final rulemaking the proposed Option 1 standards with the following recommended modifications. [EPA-HQ-OAR-2019-0055-1186-A2, p.40]

In fact, significant industry activity has occurred since CARB adopted the Omnibus regulation, and a number of additional technologies, not considered in the Stage 3 demonstration programs, are currently being evaluated by suppliers that are showing potential to further reduce both NOx and GHG emissions. As summarized below, these efforts and ongoing activities further support the feasibility and timing for 2027 MY alignment with California's Omnibus standards:

- Development of integrated high efficiency diesel aftertreatment systems is not limited to CARB and U.S. EPA sponsored demonstrations cited in the Omnibus package. In Europe, the emissions control trade association has fielded an advanced demonstrator showing similar emissions controls NOx reduction efficiency results despite not necessarily having exploited engine calibration to the extent of the CARB and U.S. EPA sponsored demonstrations or adding the additional engine technology levers available to engine manufacturers.98 They report In Service Conformity test trips averaging below 0.030 g/bhp-hr and discuss how the trips that exceed that are due to their engine hardware set's lack of thermal management capability (such as CDA or opposed piston architecture affords for examples) needed to maintain continuous control across numerous stop and go repetitions. These corroborative results were accomplished from an approximately 4 g/bhp-hr average engine out NOx rate--somewhat higher than the CARB and U.S. EPA demonstration engine calibrations. [EPA-HQ-OAR-2019-0055-1186-A2, p.42]

98 Mendoza Villafuerte, Pablo, J. Demuynck, D. Bosteels, P. Recker, T. Wilkes, L. Menne-Robb, 'Ultra-Low NOx Emissions with a Close-Coupled Emission Control System on a Heavy-Duty Truck Application' SAE Technical Paper 2021-01-1228, 2021, https://doi.org/10.4271/2021-01-1228

- Achates Power has announced that the cleaner, HD diesel opposed piston engine it developed in a project funded by CARB and several partners has entered fleet service with Walmart Corporation in a Peterbilt 579 tractor. It is a diesel engine operating on the road currently capable of meeting CARB's 2027 Omnibus regulation, which requires a 90 percent reduction in NOx compared to current standards.99 Work has progressed with the Achates opposed piston Class 8 tractor demonstration program, and early reports of field portable emissions monitoring system (PEMS) testing is demonstrating significant reduction of NOx and GHG emissions. PEMS emissions data evaluated using the three-Bin Moving Average Window (3B-MAW) methodology showed average in-use emissions of 0.15 g/hr for the idle bin, 0.042 g/hp-hr for the low load bin, and 0.020 g/hp-hr for the medium- and high-load bin. These results are significantly lower than what is proposed in the CTP's 2031 MY off-cycle standards. The Class 8 opposed piston demonstration tractor is currently in revenue service and is showing a cost-effective path for meeting both California's 2027 MY Phase 2 GHG and Omnibus NOx levels.100,101,102 CARB and South Coast Air Quality Management District have funded an add-on $1.4 million full UL emissions demonstration for the subsequent next generation version of this engine.103 This adds to the growing body of work on opposed piston technology including $5M of 2020 DOE VTO funding to adapt this technology as a two-cylinder engine for Class 3-6 vehicle applications and another $5M of 2021 DOE VTO funding for hybridization of a two-cylinder opposed piston engine.104,105 The U.S. Army has made significant investments in the related four-cylinder 1000 hp opposed piston Advanced Combat Vehicle Engine that is nearing production under an $87 million contract. [EPA-HQ-OAR-2019-0055-1186-A2, pp.42-43]

CARB staff strongly supports the proposed Option 1 PM, HC, and CO standards and recommends that they be included in the final rule, since they are technically feasible as demonstrated in the Stage 3 RW testing and from current certification data.116 The proposed Option 1 PM standards would also align with the Omnibus requirements, allowing manufacturers to produce a single PM aftertreatment design nationally. [EPA-HQ-OAR-2019-0055-1186-A2, p.46]

116 Sanchez, James. 'Test Results from EPA Diesel Demonstration'. Memorandum to Docket: EPA-HQ-OAR-2019-0055. February 10, 2022.

CARB staff believes the proposed Option 2 is too weak to be considered as reasonable on all aspects of the requirements, especially regarding the proposed emissions standards, UL, and warranty period requirements. The proposed Option 2 standards are not technology forcing standards and undermine the maximum feasible emission reductions achievable as demonstrated in CARB and U.S. EPA led Stage 3 engine testing programs. Based on U.S. EPA emission impacts analysis, in 2045, proposed Option 2 would result in approximately 22 percent less NOx emission reductions nationally compared to Option 1.117 CARB staff strongly opposes U.S. EPA's consideration of the proposed Option 2 standards for the final rule. In fact, as discussed above, CARB staff opposes the adoption of any standards that are less stringent than the proposed Option 1 standards. [EPA-HQ-OAR-2019-0055-1186-A2, p.47]

117 Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards. Draft Regulatory Impact Analysis. EPA-420-D-22-001 March 2022. (Table 5-

34: National Heavy-duty Vehicle NOx Emissions (Annual US Tons) For Calendar Years Between 2027 and 2045. Page 262

The proposed Alternative standards are the most stringent compared to both proposed Options 1 and 2. Although the Alternative has the potential to provide much needed NOx emission reductions, CARB staff understand that U.S. EPA believes that currently no data exists to unequivocally establish the feasibility of the Alternative 20 mg/hp-hr standard over the proposed longer 850,000 mile UL for MY 2027. However, CARB staff strongly supports that U.S. EPA adopt in its final rulemaking the proposed Option 1 standards with CARB staff recommended modifications that would align it with the Omnibus standards as well as strengthen the LLC and idling NOx standards to reflect recently demonstrated emissions performance in the CARB Stage 3 and U.S. EPA Stage 3 RW engine testing as well as the On-Road PEMS demonstration and further engine testing results from the Achates 10.6L Class 8 engine project. Ongoing work is expected this summer from both a second EPA low NOx engine configuration at SwRI and from a CARB and South Coast Air Quality Management District sponsored 800,000 mile aging follow-on emissions demonstration utilizing the second generation Achates engine and simplified aftertreatment. [EPA-HQ-OAR-2019-0055-1186-A2, p.47]

Similar to the proposed Option 2 requirements for CI engines, the proposed Option 2 for SI engines is also a very weak proposal on all aspects of the requirements including the proposed numeric standards, UL, and warranty period requirements. The proposed Option 2 standards are not technology forcing standards and undermine the maximum feasible emission reductions achievable as demonstrated by U.S. EPA's own testing as well as CARB certification data for optional low NOx engines. CARB staff strongly opposes U.S. EPA's consideration of the proposed Option 2 standards for the final rule. [EPA-HQ-OAR-2019-0055-1186-A2, p.48]

CARB staff supports that U.S. EPA adopt the proposed Option 1 SI engine standards including CARB staff proposed modifications that would align federal and CARB requirements. [EPA-HQ-OAR-2019-0055-1186-A2, p.49]

The NOx and PM SI engine standards for the Alternative proposal are numerically identical to MY 2027 Omnibus standards. However, they are applicable for UL periods that are slightly longer than those in the Omnibus, making the Alternative proposal slightly more stringent than the Omnibus standards. Based on the analysis of optional low NOx engine certification data discussed above, the Alternative proposal seems to be technically feasible for MY 2027, since optional low NOx SI engines are currently being certified to the existing CI test procedures which includes more rigorous durability demonstration and longer UL periods. Since the Alternative proposal is technically feasible, CARB staff recommends that U.S. EPA adopt it in its final rulemaking. This would be identical to Omnibus except for the slightly longer UL periods. If U.S. EPA does not feel comfortable with increasing the UL periods, CARB staff urges U.S. EPA to at least align NOx standards and UL periods for SI engines with the Omnibus standards. [EPA-HQ-OAR-2019-0055-1186-A2, p.49]

Organization: *CALSTART*

The Clean Trucks Plan represents a critical opportunity and milestone in the pursuit of a clean transportation system. The emissions and economic benefits of strong standards for combustion engines and the transition to zero-emission medium- and heavy-duty vehicles are well documented (Sen, 2022; Ledna, 2022). The urgency to reduce global warming and criteria emissions is paramount to human health and the economy. While analyses show we must achieve widespread adoption of zero-emission vehicles to attain healthy air and limit the most severe impacts of global warming, combustion vehicles will comprise significant vehicle sales within this decade and will remain on the road for decades more. For this reason, we strongly support NOx emission standards in the final rule that are technology forcing, reflect best-in-class technologies, and result in a net 90 percent reduction in NOx emissions compared to today's engines and vehicles. Option 1 in the proposal is a step in this direction. The larger the fraction of combustion vehicles expected into the future, the stronger the emissions standards must be for these vehicles and their engines. CALSTART supports policy that brings the best available technologies to the marketplace, drives global leadership, and continues to encourage innovation. [EPA-HQ-OAR-2019-0055-1313-A1, p.2]

Many combustion engines will continue to be sold in the transition to zero-emission vehicles. EPA's assessment of the Class 4-8 market indicates just 1.5 percent of vehicles sold in model year 2027 will be zero-emission (below we discuss why we think this estimate is low and should be accelerated). Even in states that have adopted the ACT standard, for example, combustion trucks will comprise a majority of Class 4-8 vehicle sales until model year 2031 and roughly one-third of sales in 2035 and onward.3 Absent federal policy, sales of combustion vehicles will comprise even greater fractions of Class 4-8 vehicles in states that have not adopted the ACT, i.e., 44 states with roughly 80 percent of the national Class 2b-8 vehicle population.4 Thus, combustion engines must incorporate the best available emissions reductions technologies. [EPA-HQ-OAR-2019-0055-1313-A1, p.4]

> 3 In model year 2031, zero-emission vehicles will comprise 55 percent of Class 4-8 straight vehicles and 35 percent of Class 7-8 tractors, or a sales-weighted average of roughly 50 percent. In model year 2035, those percentages increase to 75 percent and 40 percent, respectively, or a sales weighted average of roughly 67 percent.
>
> 4 Class 2b-8 vehicle registrations are based on Atlas' evaluation of 2019 IHS Markit registration data, available at: https://www.atlasevhub.com/materials/medium-and-heavy-duty-vehicleregistrations- dashboard/.

A strong NOx emission standard will result in significant emission reductions, health benefits, and bring innovative best-in-class emissions technologies to the market. Figure 1, for example, shows the annual emission reductions expected if 12 states and the District of Columbia adopted NOx standards in the Heavy-Duty Omnibus regulation compared to those achieved from potential adoption of the ACT. The Heavy-Duty Omnibus results in roughly two times the NOx emission reductions as the ACT through 2050 (ICCT, 2022).5 In some states, such as California, the Heavy-Duty Omnibus will achieve 2.5 times or more cumulative NOx emission reductions as the ACT (CARB, 2019; CARB, 2020). [EPA-HQ-OAR-2019-0055-1313-A1, p.4]

5 Based on ICCT's analysis of emission reductions from the Heavy-Duty Omnibus and Advanced Clean Trucks standard in Colorado, Connecticut, District of Columbia, Maine, Maryland, Massachusetts, North Carolina, New Jersey, Oregon, Pennsylvania, Rhode Island, Vermont, and Washington based on policies taking effect in 2025.

CALSTART supports a final rule that results in engines and vehicles with net NOx emissions that are 90 percent lower than engines in today's vehicles. [EPA-HQ-OAR-2019-0055-1313-A1, p.5]

In addition, it is important for this policy to ensure emission reductions are achieved over the life of the vehicle and that engine warranties protect fleets from liabilities associated with emission controls over similar timeframes. [EPA-HQ-OAR-2019-0055-1313-A1, p.5]

The final rule should result in engines and vehicles with net NOx emissions 90 percent lower than engines in today's vehicles. [EPA-HQ-OAR-2019-0055-1313-A1, p.26]

Organization: *Capital Area Council of Governments (CAPCOG) and Central Texas Clean Air Coalition (CAV)*

The CAC further supports the proposed Option 1 over Option 2 as it represents a greater O3 and PM2.5 reduction. [EPA-HQ-OAR-2019-0055-1274-A1, p.1]

Organization: *Ceres BICEP (Business for Innovative Climate and Energy Policy) Network*

In addition, in order to prevent increased emissions, EPA should preserve the Phase 2 stringency requirements for ICE vehicles and phase out advanced technology credit multipliers as soon as feasible. Finally, a recent Ceres analysis [https://www.ceres.org/resources/reports/electrifying-american-trucking-promise-and-challenges] concluded that, while shifting to electric vehicles increasingly makes economic sense for manufacturers and suppliers, as well as fleet owners and shippers, a federal ZEV mandate and fleet purchasing requirements, similar to California's Advanced Clean Truck (ACT)1 and Advanced Clean Fleet (ACF) standards, will be necessary to accelerate this transition at the rate and scale necessary to meet climate goals, and to ensure the global competitiveness of the U.S. truck industry. Accordingly, we urge you to adopt a ZEV mandate consistent with the targets outlined above. [EPA-HQ-OAR-2019-0055-2714-A1, pp.1-2]

1 The ACT has drawn significant business and investor support. Importantly, given that MHDVs are the largest source of nitrogen oxides (NOx) in the transportation sector, it is critical to strengthen the proposed NOx standards.

Disadvantaged communities, located near highways, ports and distribution centers, have long borne the brunt of negative health and air quality impacts from truck pollution, and it is necessary to reduce this pollution as quickly as possible during the transition to electrification (which in turn, will have additional health benefits). Accordingly, EPA should adopt a strengthened Option 1, requiring a 90% reduction in NOx by 2027, and phase out advanced technology credit multipliers for NOx as soon as feasible. [EPA-HQ-OAR-2019-0055-2714-A1, p.2]

Further, given that medium- and heavy-duty vehicles are the largest source of nitrogen oxides (NOx) in the transportation sector, it is critical to strengthen the proposed NOx standards, which were last updated twenty years ago. Disadvantaged communities have long borne the brunt of negative health and air quality impacts from truck pollution, and we need to reduce these pollutants to the maximum extent possible. [EPA-HQ-OAR-2019-0055-2714-A2, p.1]

Further, given that MHDVs are the largest source of NOx in the transportation sector, it is critical to strengthen the standards to the maximum extent possible in order to reduce air pollution from MHDVs during the transition, which disproportionately increases health and air quality risks in disadvantaged communities located near truck routes, ports, and distribution centers. [EPA-HQ-OAR-2019-0055-2714-A3, p.2]

Organization: *Chesapeake Bay Foundation, Inc. (CBF)*

This rulemaking is an opportunity to achieve considerable reductions in both NOx and GHG pollution, and their associated harms. CBF urges EPA to seize this opportunity by swiftly finalizing a rule that is a modified version of Option 12 requiring achievement of a 90% reduction of NOx by model year 2027. CBF also urges EPA to quickly finalize a rule that accelerates the transition to an entirely zero-emissions heavy-duty fleet. [EPA-HQ-OAR-2019-0055-1295-A1, pp.1-2]

2 87 Fed. Reg. at 17417.

While NOx emissions have decreased since the 1990s, EPA acknowledges that '[h]eavy-duty engines will continue to be one of the largest contributors to mobile source NOx emissions nationwide in the future, representing 32 percent of the mobile source NOx emissions in calendar year 2045.' 87 Fed. Reg. 17418. Pursuant to the Clean Air Act, EPA must finalize a rule that protects public health, especially disproportionately impacted communities near major roadways and in areas with high levels of ozone pollution. 42 U.S.C. 7521(a)(1); see also Exec. Order No. 14,008, 86 Fed. Reg. 7,619 (Jan. 27, 2021) ('Agencies shall make achieving environmental justice part of their missions by developing programs, policies, and activities to address the disproportionately high and adverse human health, environmental, climate-related and other cumulative impacts on disadvantaged communities, as well as the accompanying economic challenges of such impacts.'). [EPA-HQ-OAR-2019-0055-1295-A1, pp.9-10]

As the federal signatory to the 2014 Chesapeake Bay Agreement, and as discussed above, EPA also has an ongoing requirement to ensure that the goals of the Agreement are achieved. NOx emissions from heavy-duty trucks contribute algae-fueling nitrogen to the Bay watershed and therefore interfere with the Agreement's water quality and habitat goals. Because heavy-duty trucks travel nationwide, it is critical that EPA implement a standard that will reduce NOx from interstate, heavy-duty trucks travelling within the Bay airshed and watershed. [EPA-HQ-OAR-2019-0055-1295-A1, p.10]

EPA's obligation to protect water quality also stems from the Clean Air Act's directive to issue emission standards for pollutants that threaten environmental resources, including water quality. See 42 U.S.C. 7521(a)(1) (directing Administrator to prescribe standards for pollutants from motor vehicles which endanger public health or welfare); see also 42 U.S.C. 7602(h) (defining effects on welfare to include effects on 'waters'). In July 2020, six Chesapeake Bay jurisdictions—Virginia, Pennsylvania, New York, Maryland, and the District of Columbia—signaled the importance of reducing NOx and GHG from the heavy-duty vehicle sector by signing the Multi-State Zero Emission Medium- and Heavy-Duty Vehicle Memorandum of Understanding ('MOU').43 In an effort to reduce harm to public health and the devastating impacts of climate change, signatories to the MOU agreed to 'strive to make sales of all new medium- and heavy-duty vehicles' in their jurisdictions 'zero emission vehicles by no later than 2050.'44 [EPA-HQ-OAR-2019-0055-1295-A1, p.10]

43 Multi-State Zero Emission Medium- and Heavy-Duty Vehicle Memorandum of Understanding (July 2020), https://www.nescaum.org/documents/mhdv-zev-mou-20220329.pdf/.

44 Id.

In the Proposed Rule, EPA notes that 'Option 1 may be a more appropriate level of stringency as it would result in a greater level of achievable emission reduction for the model years proposed, which is consistent with EPA's statutory authority under Clean Air Act section 202(a)(3).' 87 Fed. Reg. at 17417. While CBF agrees that Option 1 is more stringent and because these human health and environmental benefits are urgently needed, long overdue, promote the administration's environmental justice priority, and are technically and economically feasible45, we urge EPA to swiftly adopt a modified Option 1 requiring reductions of 90% NOx in model year 2027.46 [EPA-HQ-OAR-2019-0055-1295-A1, pp.10-11]

45 See, e.g., Energy.gov, DOE Projects Zero Emissions Medium- and Heavy-Duty Electric Trucks Will Be Cheaper than Diesel-Powered Trucks by 2035 (Mar. 7, 2022), https://www.energy.gov/articles/doe-projects-zero-emissions-medium-and-heavy-duty-electric-trucks-will-be-cheaper-diesel ('by 2030, nearly half of medium- and heavy-duty trucks will be cheaper to buy, operate, and maintain as zero emissions vehicles than traditional diesel-powered combustion engine vehicles.').

46 This standard is achievable. See, e.g., California Air Resources Board, Heavy-Duty Omnibus Regulation, https://ww2.arb.ca.gov/rulemaking/2020/hdomnibuslownox; California Air Resources Board, Facts about the Low NOx Heavy-Duty Omnibus Regulation, at 2, https://ww2.arb.ca.gov/sites/default/files/classic/msprog/hdlownox/files/HD_NOx_Omnibus_Fact_Sheet.pdf.

Organization: *City of Seattle, Office of Sustainability & Environment*

Seattle strongly encourages EPA to finalize stringent NOx engine standards this year. EPA has proposed two options for setting new engine standards:

- Option 2 is deeply problematic because it does not reflect a technology-forcing standard that sufficiently protects public health and welfare.
- Option 1 comes closer to realizing technology potential and provides for a transition period from 2027-2030, where higher emitting engines would continue to be sold. Since we know that trucks sold in 2030 will be on the road and polluting for decades, it is our hope that Option 1 can be strengthened to achieve greater NOx reductions and improve the health of our most-impacted communities. **Please consider building on the success of the Advanced Clean Trucks (ACT) rule adopted by six states, including Washington, and set expectation that at least 50 percent of sales should be zero-emission by 2030, putting the United States on track for all truck sales to be zero-emission by 2035.** [EPA-HQ-OAR-2019-0055-1287-A1, p.1]

Through our city partnership with The International Council on Clean Transportation, we have learned that the U.S. must achieve at least 45% zero-emission truck sales in 2030 and 100% no later than 2040 to meet domestic and global climate goals to limit warming to below 2 degrees Celsius. **EPA risks not meeting these goals if the agency waits until 2030 to require zero-emission HDV sales.** [EPA-HQ-OAR-2019-0055-1287-A1, p.2]

We know that the transition to zero-emission vehicles will not be easy, and funding will be needed to expedite the transition and ensure that drivers benefit from the transition. Seattle has set a goal of 30% of goods delivery to be zero-emission by 2030 to set a clear target for our own electrification effort, and we are deeply committed to a just-transition for workers. We understand there are some 2,000 drayage trucks operating regularly in Seattle, many of which are operated by independent African immigrant drivers. We are committed to ensuring that independent operators/owners are not left behind in the technology transition. In 2021, to begin to tackle the issue, the City established funding for first-in-the-nation city-funded heavy duty electric truck incentive program specifically aimed at electrifying Heavy Duty Trucks in the Duwamish Valley, with a focus on independent and small operators. [EPA-HQ-OAR-2019-0055-1287-A1, p.2]

Organization: *Clean Air Board of Central Pennsylvania*

EPA is proposing two regulatory options for NOx. We support Option 1, which will implement stronger NOx standards in two steps. The first improvement would be required in 2027 with a second more stringent standard 2031 (a NOx standard that would be 90% lower than today's standards). We support Option 1 with longer useful life and warranty periods. Ensuring that the warranty and useful life requirements meet 100% of the expected life of these vehicles will ensure health benefits throughout the life of the vehicles. [EPA-HQ-OAR-2019-0055-1305-A1, p.1]

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

Section 202 of the Clean Air Act requires EPA to promulgate emissions standards that prioritize public health and welfare. To enable EPA to carry out this mandate, Congress directed the Agency to set technology-forcing standards that spur improvements in emissions control technologies. The record of HDVs' negative impacts on public health, environmental justice, climate change, and national parks and wilderness areas shows that protective emissions standards are desperately needed. To satisfy its statutory mandate and to fulfill its duty to engage in reasoned decision-making, EPA must promulgate standards that are supported by the record and that reduce emissions of dangerous air pollutants from heavy-duty vehicles and engines as much as possible. [EPA-HQ-OAR-2019-0055-1302-A1, p.7]

Beyond making those changes, Commenters urge EPA to adopt Option 1 with further improvements to testing provisions, numerical emissions standards, warranty and useful life periods, and implementation schedule. In addition, EPA should revise the proposed durability demonstration, strengthen the proposed anti-tampering and inducement provisions, reject exemptions for vocational vehicles, and finalize the proposed particulate matter (PM) standard and closed crankcase requirements. [EPA-HQ-OAR-2019-0055-1302-A1, p.8]

To carry out its statutory mandate in this rulemaking, EPA must promulgate emissions standards that prioritize public health and welfare by harnessing advancements in emissions reduction technology. The Clean Air Act makes clear that EPA's primary duty is to protect public health and welfare by minimizing harmful air pollution. Congress declared that the express purpose of the Clean Air Act is to 'protect and enhance the quality of the Nation's air resources so as to promote the public health and welfare.' 42 U.S.C. 7401(b)(1). [EPA-HQ-OAR-2019-0055-1302-A1, p.9]

Section 202(a)(1), the source of EPA's general authority to regulate motor vehicles and engines, directs EPA to promulgate standards that 'prevent or control' emissions of air pollutants that 'cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare.' 42 U.S.C. 7521(a)(1). The Supreme Court held in Massachusetts that Congress clearly provided EPA with 'the statutory authority to regulate the emission of [greenhouse] gases from new motor vehicles' pursuant to Section 202(a)(1)–(2). Massachusetts v. EPA, 549 U.S. 497, 532 (2007) (concluding that there is 'nothing counterintuitive' to EPA regulating GHG emissions from vehicles considering the statutory factors). Under the terms of the statute, then, EPA must choose a regulatory response commensurate with the 'endanger[ment]' that pollution from heavy-duty vehicles and engines cause to public health and welfare. C.f. id. at 532 (noting that Section 202(a) 'charge[s] [EPA] with protecting the public's 'health' and 'welfare''); Coal. for Responsible Regulation v. EPA, 684 F.3d 102, 117, 122 (D.C. Cir. 2012) (stating that EPA must carry out 'the job Congress gave it in 202(a)—utilizing emission standards to prevent reasonably anticipated endangerment from maturing into concrete harm.'). Any 'balancing' of factors, such as costs, availability of technology, and lead time, must prioritize the principal harm-reduction mandate animating the statute. See Husqvarna AB v. EPA, 254 F.3d 195, 200 (D.C. Cir. 2001) (emphasizing, in case involving similar statutory language in Section 213, that '[t]he overriding goal of the section is air quality and the other listed considerations, while significant, are subordinate to that goal'). [EPA-HQ-OAR-2019-0055-1302-A1, p.9]

Section 202(a)(3), which gives EPA specific authority to set standards regulating criteria pollutant emissions from heavy-duty vehicles and engines, affirms the central importance of this protective mandate. The Act requires that these standards reflect the '*greatest degree of* *emission reduction achievable* through the application of technology which the Administrator determines will be available for the model year to which such standards apply.' 42 U.S.C. 7521(a)(3)(A)(i) (emphasis added). While EPA must also consider 'cost, energy, and safety factors associated with…such technology,' id., it must place primary importance on achieving the greatest degree of emissions reduction. See Husqvarna, 254 F.3d at 200 (concluding that ''EPA did not deviate from its statutory mandate or frustrate congressional will by placing primary significance on the 'greatest degree of emission reduction achievable' and by considering cost, noise, energy and safety factors as important but secondary factors'). [EPA-HQ-OAR-2019-0055-1302-A1, pp.9-10]

To bring about critical air quality improvements, Congress authorized EPA to set technology-forcing standards that require manufacturers to develop entirely new technologies or significantly improve existing ones. See NRDC v. EPA, 655 F.2d 318, 328 (D.C. Cir. 1981) (stating that 'Congress intended the agency to project future advances in pollution control capability'); 87 Fed. Reg. at 17,436 & n.97. Section 202(a)(2), which pertains to EPA's general motor vehicle and engine authority, provides that emissions standards 'shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology.' 42 U.S.C. 7521(a)(2). This language embodies Congress's intent that EPA 'press for the development and application of improved technology rather than be limited by that which exists today.' NRDC v. EPA, 655 F.2d at 328 (quoting S. Rep. No. 1196, 91st Cong., 2d Sess. 24 (1970)). EPA embraced this 'technology-forcing approach' in its Heavy-Duty Greenhouse Gas Emissions Phase 2 Rule (the subject of targeted updates in this Proposal), promulgating standards 'predicated on performance of technologies not only currently deployed but those which reasonably can be developed during the phase in period.' 81 Fed. Reg. 73,478, 73,493, 73,809 (Oct. 25, 2016). Similarly, Section 202(a)(3)(A)(i) prescribes a technology-forcing approach by directing EPA to establish standards that are 'achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply.' 42 U.S.C. 7521(a)(3)(A)(i); Crete Carrier Corp. v. EPA, 363 F.3d 490, 491 (D.C. Cir. 2004) (stating that this section 'is a technology-forcing provision; it mandates regulations with which manufacturers can comply only by adopting new technologies as they become available'); NRDC v. Thomas, 805 F.2d 410, 428–30 & n.30 (D.C. Cir. 1986) ('Congress intended the EPA…to engage in reasonable predictions and projections in order to force technology.'). [EPA-HQ-OAR-2019-0055-1302-A1, p.10]

While EPA has considerable discretion to set emissions standards that rely on ambitious technological developments, Congress made the important policy decisions. Congress directed EPA, the expert agency with authority over air pollution from vehicles and engines, to develop a record and apply the Section 202(a) criteria to the facts to develop standards. See Gundy v. United States, 139 S. Ct. 2116, 2136 (2019) (Gorsuch, J., dissenting). In doing so, the Agency is 'not obliged to provide detailed solutions to every engineering problem, but ha[s] only to identify the major steps for improvement and give plausible reasons for its belief that the industry will be able to solve those problems in the time remaining.' Nat'l Petrochemical & Refiners Ass'n v. EPA, 287 F.3d 1130, 1136 (D.C. Cir. 2002) (internal quotation marks and citations omitted). Indeed, courts have consistently upheld EPA's technology-forcing vehicle and engine regulations over manufacturers' objections about technological readiness. Id. at 1136–41 (upholding NOx and PM regulations predicated on future developments in pollution control technology); NRDC v. Thomas, 805 F.2d at 428–34 (upholding PM regulation over manufacturers' concerns about the feasibility of trap-oxidizer technology); NRDC v. EPA, 655 F.2d at 331–36 (same). And manufacturers have consistently risen to the challenge, later complying with the very standards they previously claimed were impossible to meet. See, e.g., 87 Fed. Reg. at 17,536 (explaining that manufacturers deployed technologies that EPA had not predicted to meet the 2001 heavy-duty criteria pollutant standards, which they had unsuccessfully challenged in National Petrochemical & Refiners Association). [EPA-HQ-OAR-2019-0055-1302-A1 pp.10-11]

Under the Clean Air Act, EPA's action may be reversed if it is arbitrary, capricious, an abuse of discretion, not in accordance with law, or in excess of statutory authority. 42 U.S.C. 7607(d)(9)(A), (C). 'To withstand review, the agency must have examined all relevant facts and data and articulated a rational explanation for its decision, including a reasonable connection between the facts and ultimate outcome.' Hearth, Patio & Barbecue Ass'n v. EPA, 11 F.4th 791, 805 (D.C. Cir. 2021). 'A rule is arbitrary and capricious if the agency: (1) 'has relied on factors which Congress has not intended it to consider,' (2) 'entirely failed to consider an important aspect of the problem,' (3) 'offered an explanation for its decision that runs counter to the evidence before the agency,' or (4) 'is so implausible that it could not be ascribed to a difference in view or the product of agency expertise.'' U.S. Sugar Corp. v. EPA, 830 F.3d 579, 606 (D.C. Cir. 2016) (quoting Motor Vehicle Mfrs. Ass'n v. State Farm Mut. Auto. Ins. Co., 463 U.S. 29, 43 (1983) and applying the same standard of review under the CAA as under the Administrative Procedure Act). [EPA-HQ-OAR-2019-0055-1302-A1, p.11]

The Proposal's underestimate of the baseline market penetration of HD ZEVs and its failure to propose standards that further drive adoption of zero-emission technologies ignores the Agency's obligations under the Clean Air Act and weakens the proposed standards in several ways:

1. Considering more accurate (higher) baseline HD ZEV market penetration 'could lead to a more stringent NOx emission standard,' as EPA acknowledges. 87 Fed. Reg. at 17,561.
2. Underestimating the baseline market penetration of HD ZEVs will lead to the generation of a significant amount of credits that will dramatically undermine the goals of the NOx standards and fail to protect public health and welfare. 87 Fed. Reg. at 17,561.55 Allowing for ZEVs to generate NOx emissions credits is a significant departure from EPA's prior rules,56 and a revised, more accurate baseline HD ZEV penetration estimate would require reconsideration of these credits to ensure that the rule reflects the greatest degree of emission reduction achievable, as is EPA's statutory mandate.
3. Disregarding the feasibility of zero-emission technologies in establishing the stringency of the proposed criteria pollutant standards unjustifiably takes proven emission reduction technologies off the table. [EPA-HQ-OAR-2019-0055-1302-A1, pp.20-21]

55 EPA notes that it includes an FEL cap on NOx emissions to help limit the impact credits generated from BEVs or FCEVs could have in enabling vehicles to exceed the NOx standard. However, if HD ZEV market penetration is higher than EPA projects, 'there is the potential for a greater portion of CI engines to emit up to the level of the FEL cap,' 87 Fed. Reg. at 17,560, further undermining the goals of the regulatory program. EPA notes the importance of 'consider[ing] what impact NOx emissions credits generated from BEVs and FCEVs

might have on the NOx emission reductions expected from the proposed rulemaking. Id. at 17,561. Further, as discussed in Section IV.D.2.c of these comments, EPA's proposed FEL cap is unreasonably high.

56 See 87 Fed. Reg. at 17,556 ('However, under the current criteria pollutant program, manufacturers do not have a pathway to generate NOx emission credits for HEVs, BEVs, or FCEVs. For BEVs and FCEVs, current 40 CFR 86.016-1(d)(4) stipulates that these technologies may not generate NOx emission credits…'); id. at 17,561–62 (proposing to allow ZEVs to generate NOx emissions credits); 40 CFR 86.016-1(d)(4) ('Electric heavy-duty vehicles may not generate NOx or PM emission credits.').

[EPA-HQ-OAR-2019-0055-1302-A1, p.21]

EPA's inaccurate estimate of baseline HD ZEV market penetration undermines its proposed criteria pollutant standards, but the Agency must also remedy other aspects of its criteria pollutant proposal. EPA must reject proposed Option 2, which fails to achieve the emissions reductions necessary to protect public health and welfare and flouts the Clean Air Act's technology-forcing directive. EPA should incorporate zero-emission technologies into its feasibility analysis, setting stronger emissions standards that both account for the technological feasibility and baseline market penetration of zero-emission technologies *and* accelerate the deployment of those technologies. In addition, EPA must modify its crediting proposal to ensure that credits for electric vehicles and 'transitional' credits do not undermine the effectiveness of its criteria pollutant program. Apart from making those changes, EPA should finalize Option 1, with Commenters' recommended improvements to testing provisions, numerical emissions standards, warranty and useful life periods, and implementation timelines. Finally, regardless of which option it ultimately selects, EPA should revise the proposed durability demonstration, strengthen the proposed anti-tampering and inducement provisions, reject exemptions for vocational vehicles, and finalize the proposed PM standard and closed crankcase requirements. [EPA-HQ-OAR-2019-0055-1302-A1, p.49]

In setting emissions standards, EPA 'must also provide a reasoned explanation of its basis for believing that its projection is reliable. This includes a defense of its methodology for arriving at numerical estimates.' Bluewater Network v. EPA, 370 F.3d 1, 22 (D.C. Cir. 2004) (quoting NRDC v. EPA, 655 F.2d at 328). To comply with the Administrative Procedure Act, the Agency must examine the relevant data and show that the data is accurate and defensible. See Dist. Hosp. Partners v. Burwell, 786 F.3d 46, 57 (D.C. Cir. 2015). Courts require agencies to use 'the best information available.' Catawba County v. EPA, 571 F.3d 20, 45 (D.C. Cir. 2009). If the agency receives new and better data, it must deal with it in a reasonable fashion and cannot blindly accept outdated or inaccurate information. See Dist. Hosp. Partners, 786 F.3d at 57; Flyers Rights Educ. Fund v. FAA, 864 F.3d 738, 745 (D.C. Cir. 2017) ('Agency reasoning…must adapt as the critical facts change.'). [EPA-HQ-OAR-2019-0055-1302-A1, p.11] Finalizing proposed Option 2 would be arbitrary and capricious because it embodies a wholly inappropriate balancing of the statutory factors set forth Section 202(a)(3)(A)(i). See 42 U.S.C 7521(a)(3)(A)(i) (requiring 'appropriate consideration' of cost, energy, and safety). In comparison to Option 1 and the alternative approaches we advocate for in Sections IV.B–H below—all of which would achieve greater public health and welfare gains without imposing unreasonable costs or technological challenges—Option 2 is contrary to EPA's statutory mandate and unsupported by the record. Cf. Bluewater Network v. EPA, 370 F.3d 1, 21–22 (D.C. Cir. 2004) (holding that EPA had not adequately explained its balancing of technological feasibility against cost and other statutory factors in setting emissions standards under Section 213). [EPA-HQ-OAR-2019-0055-1302-A1, p.49]

Second, Option 2 falls far short of the Clean Air Act's technology-forcing directive 231 by letting manufacturers off the hook from improving the durability of emission control components, thereby eroding Option 2's already limited emissions benefits. See 87 Fed. Reg. at 17,437–38. [EPA-HQ-OAR-2019-0055-1302-A1, p.50]

> 231 As discussed in Section IV.B below, both Options 1 and 2 fail to reflect the superiority and feasibility of electrification and other zero-emission technologies that eliminate criteria pollutant tailpipe emissions from HDVs.

In sum, Option 2 amounts to an industry giveaway that sacrifices critically important public health and welfare benefits in favor of political expediency and technological complacency. EPA understands this, flatly admitting that 'Option 1 may be a more appropriate level of stringency as it would result in a greater level of achievable emission reduction for the model years proposed, which is consistent with EPA's statutory authority under Clean Air Act section 202(a)(3).' 87 Fed. Reg. at 17,417, 17,440. Because Option 2 fails to achieve the statutory mandate, finalizing it would constitute an abuse of discretion and arbitrary and capricious agency action. [EPA-HQ-OAR-2019-0055-1302-A1, p.51]

Finally, Option 2's inferior performance on emissions reduction, public health, and technological feasibility grounds cannot be justified by cost, energy, safety, or lead time considerations. Despite its leniency, Option 2 manages to produce higher costs, and fewer net benefits, than Option 1. 87 Fed. Reg. at 17,589; DRIA at 403. Sufficient lead time also exists for manufacturers to comply with both options. See 87 Fed. Reg. at 17,436. And both options present the same safety and energy profiles, with neither having a negative impact on those factors relative to the baseline. 87 Fed. Reg. at 17,440, 17,459–60. Because the Clean Air Act's 'overriding' goal of improving air quality weighs against Option 2, and the Act's 'subordinate' considerations of cost, energy, safety, and lead time point in the same direction or are neutral, EPA must reject Option 2. Husqvarna AB, 254 F.3d at 200; see Bluewater Network, 370 F.3d at 21 (explaining that EPA's standards 'must be grounded in 'appropriate consideration' of the relevant statutory factors,' with support from 'analysis and evidence' in the record). [EPA-HQ-OAR-2019-0055-1302-A1, pp.50-51]

Second, notwithstanding the feasibility and cost-effectiveness of zero-emission technologies, EPA has failed to account for BEV and FCEV technologies in proposing the stringency of its underlying emissions standards. The Proposal's treatment of those technologies is therefore inappropriately asymmetric: EPA excludes their emergence from its assessment of the 'greatest degree of emission reduction achievable,' 42 U.S.C. 7521(a)(3)(A)(i); but it allows that emergence to result in higher-polluting engines through its crediting mechanism. See U.S. Sugar Corp. v. EPA, 830 F.3d 579, 631 (D.C. Cir. 2016) (The Clean Air Act 'demands that [EPA] take the bitter with the sweet,' so that 'if the EPA includes a source in a [regulated category]' it must ‘take into account that source’s emissions levels in setting’ standards.). [EPA-HQ-OAR-2019-0055-1302-A1, p.53]

EPA must remedy these flaws. EPA requests comment on the following scenario: if ‘BEV and FCEV technologies’ are ‘projected to reach a greater degree of market penetration than [the Agency’s current] projections,’ could EPA ‘incorporate that [higher] level of BEV and FCEV penetration into [its] calculation of an appropriate numerical standard to represent the combined benefits of achieving NOx control from engines along with zero tailpipe NOx emissions from BEV and FCEV technologies.’ 87 Fed. Reg. at 17,561. BEV and FCEV technologies are indeed projected to reach far greater market penetration than EPA has assumed. See Section III, supra. The availability and cost-competitiveness of those technologies alone warrants their inclusion in EPA’s standard-setting analysis. See Section IV. B, supra. The need for such inclusion is substantially more acute if EPA allows BEVs and FCEVs to generate credits for use in the standards’ Averaging, Banking and Trading (ABT) program. EPA cannot permit compliance with the standards through technologies that will be relatively widely adopted in the relevant model years, while ignoring those technologies in its standard-setting analysis. A ‘combined’ standard, 87 Fed. Reg. at 17,561, if appropriately based on foreseeable levels of BEV and FCEV penetration (as well has HEV development), would allow the standards and credits to function as they should, and bring EPA’s standards into conformity with the Clean Air Act’s command to require the greatest achievable emission reduction. 42 U.S.C. 7521(a)(3)(A)(i). [EPA-HQ-OAR-2019-0055-1302-A1, p.53]

In addition to incorporating zero-emission technologies into its feasibility analysis and rectifying its BEV and FCEV crediting proposal, as described in Sections IV.B-C above, EPA should improve several features of its proposed Option 1. Below, Commenters recommend changes to EPA’s proposed testing provisions and emissions standards that would achieve greater emissions reductions through the application of feasible technologies. We also highlight the importance of adopting warranty and useful life provisions at least as stringent as those proposed in Option 1, and implementing standards and testing procedures that better control NOx emissions that occur when engines are operating at low speeds or idling. [EPA-HQ-OAR-2019-0055-1302-A1, p.54]

EPA determines whether engines comply with emissions limits using two types of tests, laboratory-based and in-use testing, neither of which currently captures the higher emissions happening at lower speeds when trucks are often nearest to people. [EPA-HQ-OAR-2019-0055-1302-A1, p.55]

EPA’s laboratory-based test procedure measures emissions while an engine is operating over precisely defined ‘duty cycles.’ The current duty cycles involve operating under sustained high load, or transitioning from low to high loads, ‘but do not provide for demonstrating emission control under sustained low-load operations.’ 87 Fed. Reg. at 17,422. [EPA-HQ-OAR-2019-0055-1302-A1, p.55]

EPA also requires compliance with ‘Not-To-Exceed’ (NTE) standards to be shown while engines are in use on the road in the real world. Measurements of emissions occurring below certain torque, power, and speed values are currently excluded from consideration, however, as are data occurring in certain ambient conditions or when aftertreatment temperatures are below a certain level. 87 Fed. Reg. at 17,472. EPA's Proposal notes that less than 10% of the data collected during a typical in-use test is actually subject to EPA's current in-use emissions standards, and that in-use testing data indicates that low load operation could account for more than half of a vehicle's NOx emissions during a typical workday. 87 Fed. Reg. at 17,472. [EPA-HQ-OAR-2019-0055-1302-A1, p.55]

While Commenters prefer the more stringent numerical emissions standards of Option 1 to the unjustifiably lax standards of Option 2, we urge EPA to further strengthen the standards in certain key areas: (1) duty cycle and in-use (off-cycle) standards, (2) idle standards, and (3) the FEL cap. EPA should also reject its proposed two-step approach for Option 1, finalizing the more stringent standards in MY 2027 instead of delaying their application until MY 2031. [EPA-HQ-OAR-2019-0055-1302-A1, p.57]

Commenters urge EPA to consider setting stricter duty cycle and in-use standards. While Option 1 is far superior to Option 2, it still fails to fully capture the emissions reductions that can be achieved by various diesel engine technologies. As outlined in the technical comments of MFN, EPA's feasibility analysis does not give sufficient credit to the emissions reduction capabilities of variable valve actuation strategies (such as cylinder deactivation), mild hybridization, and opposed-piston engines. See Comments of MFN, to be filed in Docket EPA-HQ-OAR-2019-0055 on May 16, 2022. Similarly, a recent analysis by Roush Industries confirmed the technological feasibility of cylinder deactivation, mild hybridization, and limiting auxiliary emissions control devices.239 [EPA-HQ-OAR-2019-0055-1302-A1, p.57]

> 239 Vishnu Nair & Gary Rogers, Reducing Medium- and Heavy-Duty Fuel Consumption and Criteria Pollutants 6, 8, 23–28, 38–40, Roush Industries (Sept. 2021).

Life-saving emissions reductions must be achieved as swiftly as possible in light of the public health crisis wrought by HDV emissions and the availability of feasible and cost-effective pollution control technologies. Commenters urge EPA to apply the NOx emissions standards for both laboratory-based duty cycle testing and in-use 'off-cycle' testing in a single step, finalizing the more stringent standards in MY 2027 instead of delaying their application to MY 2031. See 87 Fed. Reg. at 17,421–22. There is no reason to wait until 2031. The proposed Option 1 FTP, SET, and LLC NOx standards for MY 2027 are too lenient because they fail to reflect the application of feasible technologies that are already available or can be refined well in advance of that model year, let alone MY 2031. See 42 U.S.C. 7521(a)(3)(A)(i). Commenters support and incorporate by reference comments by MFN and CARB demonstrating the technological feasibility of implementing the more stringent standards in a single step in MY 2027. See Comments of (1) MFN and (2) CARB, to be filed in Docket EPA-HQ-OAR-2019-0055 on May 16, 2022. And while Commenters urge EPA to strengthen its off-cycle standards, see Section IV.D.2.a, supra, at the bare minimum, the Agency should apply its proposed MY 2031 off-cycle numerical requirements to MY 2027. [EPA-HQ-OAR-2019-0055-1302-A1, p.59]

Commenters also agree with the Manufacturers of Emission Controls Association (MECA) and the Advanced Engine Systems Institute that the technology required by Option 1 is neither new, nor untested, but rather reflects the 'evolution of familiar technology.'268 As these organizations correctly point out: '2027 is not like 2007/2010 when emission controls were put on trucks for the first time. Truck manufacturers and operators have 20 years of experience with hardware and maintenance of systems.'269 [EPA-HQ-OAR-2019-0055-1302-A1, p.72]

268 Rasto Brezny (Manufacturers of Emission Controls Association) & Patrick Quinn (Advanced Engine Systems Institute), Supporting EPA's Clean Trucks Rule 8 (Jan. 18, 2022).

269 Id. at 5.

This rulemaking presents an opportunity for EPA to set a strong foundation for ambitious future rules that will achieve significant emissions reductions through widespread deployment of zero-emission technologies within the heavy-duty sector. Given HDVs' contribution to widespread public health problems and dangerous climate change, it is critical that this sector transition to zero-emission technologies as rapidly as possible. [EPA-HQ-OAR-2019-0055-1302-A1, p.72]

While this Proposal should do more to accelerate the deployment of those technologies to bring about greater emissions reductions, Commenters welcome the opportunity to comment on the goals and principles EPA should follow as it undertakes a series of future rulemakings to clean up the transportation sector. See 87 Fed. Reg. at 17,420 (referencing future light- and heavy-duty rulemakings and requesting comment 'on how the Agency can best consider the potential for ZEV technologies to significantly reduce air pollution from the heavy-duty vehicle sector'). Each rulemaking must be viewed as a stepping stone for the next and with recognition of the interrelationship with other sectors to adequately protect public health and welfare. This rulemaking will be followed by another to set new stringent GHG emissions standards for heavy-duty engines and vehicles starting in MY 2030, and EPA must lay the groundwork now for a rule that protects human health and welfare and leads to the necessary acceleration of zero-emission technologies. Setting insufficiently stringent standards in this rulemaking could jeopardize EPA's ability to fulfill its statutory obligations not only now but in future rulemakings. [EPA-HQ-OAR-2019-0055-1302-A1, pp.72-73]

EPA must finalize a strong rule this year to curtail dangerous emissions from heavy-duty vehicles and engines. Adopting Commenters' recommendations would result in a feasible, cost-beneficial, and technology-forcing rule that fulfills EPA's statutory duty to protect public health and welfare. [EPA-HQ-OAR-2019-0055-1302-A1, p.76]

Organization: *Clean Energy (CE)*

Specifically, **CE supports EPA's proposed 'Option 1' NOx standard which takes a two-step approach by implementing a 0.035 g/bhp-hr standard starting in 2027 and a 0.02 g/bhp-hr standard starting in 2031**. Near-zero heavy-duty truck engines, certified by the California Air Resources Board (CARB), meet or exceed the proposed 2031 standard today and are being deployed in the thousands by American fleets. In-use testing has revealed that NOx emission reductions are greater than their 0.02 g/bhp-hr certification, achieving reductions of up to 98 percent.1 [EPA-HQ-OAR-2019-0055-1350-A1, p.1]

1 'Ultra-Low NOx Natural Gas Vehicle Evaluation,' University of California Riverside, CE-CERT, November 2016. Available at: https://cngvc.org/wp/wp-content/uploads/2017/03/UCR-UltraLow-NOx_NGV-Evaluation_Final-Report.pdf.

Clean Energy supports U.S. EPA's 'Option 1' which establishes a NOx standard of 0.035 g/bhp-hr in 2027 and later lowered to 0.02 g/bhp-hr in 2031. Near-zero engines are already certified by CARB to meet the 0.02 g/bhp-hr standard and we believe compliance with the proposed EPA standard will be met well in advance of 2031. With close to a decade of lead time for other types of engines to comply with the 2031 standard, Clean Energy finds Option 1 both reasonable and necessary given climate and air quality challenges. [EPA-HQ-OAR-2019-0055-1350-A1, p.4]

Organization: *CleanAirNow (CANKC)*

ANKC supports the following recommendations from the Moving Forward Network:

- EPA to pass stringent and protective emission standards that require mandatory emission reduction in EJ communities as well as a sales mandate. [EPA-HQ-OAR-2019-0055-1239-A1, p.2]
- EPA to have 100% zero emission across the freight sector by **2035** at the latest
- Retirement of all combustion trucks, trains and ships on or before **2045.** [EPA-HQ-OAR-2019-0055-1239-A1, p.2]
- The EPA truck rule should be moving towards zero emission solutions to address the freight and logistics system. These policies need to center EJ communities and frontline workers [EPA-HQ-OAR-2019-0055-1239-A1, p.2]
- EPA must move towards a Zero Emissions agenda now. This agenda must cross the freight sector and prioritize environmental justice communities. [EPA-HQ-OAR-2019-0055-1239-A1, p.2]
- EPA to reduce emissions from the heavy-duty vehicle fleet through the most protective and stringent emission standards. [EPA-HQ-OAR-2019-0055-1239-A1, p.2]
- The cumulative impacts from freight need to be considered and addressed. EPA should be requiging lifetime pollution regulations for new trucks as well as legacy pollution from aging diesel polluting trucks [EPA-HQ-OAR-2019-0055-1239-A1, p.3]

Organization: *ClearFlame Engine Technologies (ClearFlame)*

We strongly urge you to include Option 1 in your final Rule, which will reduce emissions of nitrogen oxides (NOx) more quickly and provide deeper reductions than Option 2. [EPA-HQ-OAR-2019-0055-1261-A1, p. 2]

As EPA knows, disadvantaged communities have suffered the health impacts of disproportionate levels of diesel exhaust for decades. These health impacts include increased asthma, bronchitis, cancer, heart disease, and premature death. These communities need NOx reductions as soon as possible. [EPA-HQ-OAR-2019-0055-1261-A1, p. 2]

More broadly, more than 127 million Americans, spread across 209 counties in 23 states and the District of Columbia, live in areas that either have not attained the 8-hour National Ambient Air

Quality Standard for ozone or that are required to take ongoing steps to maintain their attainment of this standard. [EPA-HQ-OAR-2019-0055-1261-A1, p. 2]

For both of these reasons, we support Option 1. We are confident that we will be able to produce our engines at the NOx levels and on the MY 2027 timetable that has been proposed in Option 1. [EPA-HQ-OAR-2019-0055-1261-A1, p. 2]

Organization: *ClearFlame Engine Technologies (ClearFlame), Remora, and SixWheel*

With respect to reducing emissions of nitrogen oxides (NOx) from heavy-duty vehicles and engines, we strongly support Option 1. Option 1 will provide deeper, faster NOx emission reductions that are critical to protecting air quality and human health. [EPA-HQ-OAR-2019-0055-1329-A2, p. 2]

We strongly encourage the Agency to finalize Option 1 for NOx emissions. We encourage the Agency to adopt fuel-neutral, technology-neutral, and performance-based GHG emissions standards that allow industry members to choose how to meet emissions goals, while creating opportunities for technology developers to advance novel solutions. [EPA-HQ-OAR-2019-0055-1329-A2, p. 4]

Organization: *Colorado Energy Office, et al.*

Given the advances in emissions control technology and the need for strong national standards to achieve the significant health benefits estimated from the proposed rule, we strongly urge EPA to pursue and strengthen Option 1 for the proposed NOx engine standards. We recommend EPA consider the following improvements to Option 1 to achieve the greatest health benefits possible, and align with the Low NOx Omnibus rule wherever possible:

- The rule considers a “Potential Alternative” more stringent than Option 1 of 0.020 g NOx/hp-hr engine standard for MY 2027, but requests data on the feasibility of achieving this standard in the MY 2027 time frame. Several studies from CARB, EPA, and other research institutes support the feasibility of introducing a 0.020 gram NOx standard in 2027.1,2,3,4,5,6 Adoption of this standard would align with the Low NOx Omnibus rule nationally, which ICCT modeling estimates would avoid $1.3 trillion in health damages associated with ambient PM2.5 and ozone pollution from 2027-2050.[EPA-HQ-OAR-2019-0055-1297-A1, p.2]

- Additionally, truck manufacturers have already developed the technology to prepare for and comply with California’s standards, and all states could benefit from this research and development. [EPA-HQ-OAR-2019-0055-1297-A1, p.2]

Organization: *Connecticut Department of Energy and Environmental Protection (CTDEEP)*

CTDEEP believes that EPA must establish a stringent, technology-forcing federal rule that will reduce HD truck NOx emissions by at least 90 percent and implement other key requirements to ensure that these reductions will continue to be realized over the full useful life of vehicles beginning not later than model year (MY) 2027. The outcome of this regulatory action is critically important for Connecticut as a state struggling with a persistent ozone non-attainment problem which is due in part to HD NOx emissions. [EPA-HQ-OAR-2019-0055-1306-A1, p.1]

While Connecticut continues to implement programs above and beyond those required by the Clean Air Act, EPA has waited two decades to update its HD truck standards. There is a clear and compelling public health need for much tighter restrictions on HD truck NOx emissions. In the past 20 years, the technical capacity to identify and reduce these emissions has flourished and tremendous experience has been gained. The opportunity to require and achieve deeper reductions in NOx emissions is enormous as reaffirmed through the California Air Resources Board (CARB) Heavy-Duty Omnibus Regulation, which was adopted in August 2020, and ultimately finalized in December 2021, after an extensive public process that was preceded by several years of informal stakeholder input.8 EPA should be leveraging the early experience with the already-final Omnibus 2024-2026 phase-in as well as the finalized 2027 Omnibus standards to the benefit of the final rule rather than ignoring the engineering and commercialization progress made in order to comply with the Omnibus in California and in other states like New York, New Jersey, Massachusetts and other states that have adopted it. [EPA-HQ-OAR-2019-0055-1306-A1, p.5]

8 Heavy-Duty Omnibus Regulation | California Air Resources Board

EPA includes two options in the proposal for HD engine emissions standards, one more stringent than the other. The agency notes that Proposed Option 1, the more stringent of the two, would come with greater public health and environmental benefits; nonetheless, as proposed, this option is insufficient. Proposed Option 2 is wholly unacceptable as the requirements do not reflect the level of control technology that is possible, nor would it lead to meaningful emission reductions. Connecticut supports modifications that would strengthen the overall stringency of Proposed Option 1 by aligning it with the technology-forcing mandate of the CAA and the recently adopted Low NOx Omnibus regulation in California. *Specifically, Connecticut recommends that EPA should revise Proposed Option 1 to pull forward to 2027 the 20 mg/hp-hr NOx emission standard for all classes with an interim useful life standard of 435,000 miles for heavy HD engines*. In fact, the Clean Air Act under CAA section 202(a)(3)(A) requires EPA when setting federal NOx emission standards for HD trucks to reflect 'the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy and safety factors associated with the application of such technology.' [emphasis added] [EPA-HQ-OAR-2019-0055-1306-A1, p.5]

Connecticut citizens have suffered from unhealthy air quality for generations, the magnitude of the State’s ozone noncompliance and the impact on the public health and welfare of our citizens, especially the most vulnerable demands EPA’s action to adopt a rule that achieves a 90% reduction in NOx emissions by 2027. Connecticut strongly supports the comments submitted by NACAA, NESCAUM and OTC. [EPA-HQ-OAR-2019-0055-1306-A1, p.5]

Organization: *Consumer Reports (CR)*

For the NOx emission standards, EPA is proposing two options, Option 1 and Option 2. EPA’s obligations under the CAA to set standards that reflect the greatest degree of emission reduction achievable5 require the agency to adopt Option 1. Compared to Option 2, Option 1 sets stronger NOx emission standards and sets more stringent useful life and warranty periods and is economically and technologically feasible. a. EPA should ensure that credits do not limit the effectiveness of the NOx standards. To this end, EPA should eliminate all multipliers, lower family emission caps, and eliminate or minimize the use of credits for ZEVs. [EPA-HQ-OAR-2019-0055-1285-A1, p.2]

5 The CAA requires the Administrator to set standards that 'reflect the greatest degree of emission reduction achievable through the application of a technology which the Administrator determines will be available for the modely year to which such standards apply. 43 U.S.C. 7521(a)(1).

EPA must adopt Option 1 of the proposed rule; Option 2 simply does not go far enough. [EPA-HQ-OAR-2019-0055-1285-A1, p.3]

Section 202(a) of the CAA requires the Administrator to prescribe ‘standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in his judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare.'17 Both NOx and GHG have been found to endanger public health and welfare. Section 202(a)(3)(A) of the CAA further requires standards for emissions of NOx, particulate matter, hydrocarbon and carbon monoxide to 'reflect the greatest degree of emission reduction achievable through the application of a technology which the Administrator determines will be available for the model year to which such standards apply, given appropriate consideration to cost, energy, and safety factors associated with the application of such technology.'18 This language authorizes the Administrator to set performance levels that, 'while not achievable immediately, are demonstrated to be achievable in the future based on information available today.'19 Zero-emission technology for many classes of heavy-duty vehicles currently exists,20 and ZEV technology is rapidly advancing.21 By underestimating market penetration of ZEVs, the current proposed standards do not account for this technology, thus do not represent the 'greatest degree of emission reduction achievable,' and thus do not meet EPA's obligations under the CAA. [EPA-HQ-OAR-2019-0055-1285-A1, p.4]

17 43 U.S.C. 7521(a)(1).

EPA must meet its obligations under the CAA by setting standards that reflect 'the greatest emission reduction achievable.' To do so, standards must accurately reflect both current and future technology. Moreover, standards should encourage growth of this technology in the future. [EPA-HQ-OAR-2019-0055-1285-A1, p.5]

As stated, CR supports EPA's efforts to reduce NOx emissions from heavy-duty vehicles. Because it is technologically and economically feasible, EPA must adopt Option 1.37 [EPA-HQ-OAR-2019-0055-1285-A1, p.6]

37 California Air Resources Board, Facts about the Low NOx Heavy-Duty Omnibus Regulation. Available at: https://ww2.arb.ca.gov/sites/default/files/classic/msprog/hdlownox/files/HD_NOx_Omnibus_Fact_Sheet.pdf

As stated above, section 202(a)(1) of the CAA requires the Administrator to ‘prescribe standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in his judgment cause, or contribute to air pollution which may reasonably be anticipated to endanger public health or welfare.’ 38 Section 202(a)(3) of the CAA further states that the standards prescribed under paragraph (1) applicable to emissions of hydrocarbons, carbon monoxide, oxides of nitrogen, and particulate matter from classes or categories of heavy-duty vehicles or engines must ‘reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors.’39 [EPA-HQ-OAR-2019-0055-1285-A1, p.6]

38 42 U.S.C. 7521(a)(1)

39 42 U.S.C. 7251(a)(3)

As proven by EPA’s own regulatory analysis, as well as California Air Resource Board (CARB) studies, Option 1 is both technologically and economically feasible.40 Compared to Option 2, Option 1 sets more stringent NOx emissions standards, and requires longer useful life and warranty periods. Option 1 will result in a 90% reduction in NOx emissions by 2030, whereas Option 2 will only result in a 75% reduction in emission standards by 2030.41 As such, Option 1 reflects 'the greatest degree of emission reduction achievable… given appropriate consideration to cost, energy and safety factors.' Moreover, the benefits of Option 1 more significantly outweigh the costs than is the case with proposed Option 2.42 As such, Option 2 simply does not meet EPA’s obligations under the CAA. [EPA-HQ-OAR-2019-0055-1285-A1, pp.6-7]

Organization: *Cummins Inc. (Cummins)*

Cummins has decades of experience using a proprietary methodology to assess the design targets needed for engines to comply with standards of varying stringency, throughout the regulated useful life. The design target represents our own upper limit for the mean emissions of a sample of the population of production engines in an engine family to ensure compliance with an emissions standard throughout useful life. Sufficient margin, called compliance margin, is necessary between our design target and the standard to account for additional factors required by regulation (including deterioration factors and infrequent regeneration adjustment factors, as applicable), as well as production variability, test procedure and measurement variability, and in-use variables that are not within an engine manufacturer's control. Using inputs for the elements of compliance margin based on Cummins' experience and historical data, plus results from EPA's own ongoing research at Southwest Research Institute (SwRI), we can calculate design targets for various combinations of potential NOx standards and emissions useful life periods. [EPA-HQ-OAR-2019-0055-1325-A1, p. 3]

Cummins shared our methodology and an initial analysis as confidential business information (CBI) with EPA in September 2021, six months before EPA's proposal was published. Our analysis concluded that a 20 mg/hp-hr NOx standard at 435,000 miles useful life, which is both California Air Resources Board's (CARB's) model year (MY) 2027 heavy-heavy duty intermediate useful life standard and EPA's proposed Option 1 MY 2031 corresponding standard, results in a negative NOx design target for diesel engines, which, of course, is not feasible. [EPA-HQ-OAR-2019-0055-1325-A1, p. 3]

Now that EPA's proposal, plus additional data from EPA's ongoing research at SwRI, have been made public, Cummins has completed additional design target analyses with updated inputs. Again, the results show that EPA's Option 1 2027 and 2031 NOx standards and associated emissions useful life periods are not feasible. The calculated design targets are lower than can be achieved by diesel engines in production without placing undue compliance risk of recall and other penalties on the manufacturer, due to insufficient compliance margin. That is true even after applying the most optimistic assumption that variability decreases entirely in proportion to the design target. Cummins is prepared to share results of our recent analyses with EPA as CBI. [EPA-HQ-OAR-2019-0055-1325-A1, pp. 3 - 4]

Since Option 1 is not achievable with diesels, it would have negative impacts on the environment if finalized. In the absence of new diesel engines, some customers looking to purchase new diesel engines could switch to purchasing natural gas engines, gasoline engines, or zero emission vehicles (ZEV), which are capable of meeting the Option 1 standards. However, most customers cannot readily switch to those alternatives, due to product capabilities, costs, refueling and recharging infrastructure, and other limitations. Those customers would be left with buying new diesel engines before the new standards take effect or holding on to their older diesels much longer. In either case, the environment does not benefit from improved emissions, which would have been driven by feasible standards that can be met with reliable technologies customers can readily adopt. Option 1 even could be worse for the environment than no new standard at all. With no new standard, customers at least would be able to continue to replace older higher emitting products with current advanced clean diesels. Cummins therefore does not support the adoption of EPA's proposed Option 1 NOx standards, in the same way that Cummins never supported CARB's adoption of its Omnibus 2027+ standards. [EPA-HQ-OAR-2019-0055-1325-A1, p. 4]

EPA additionally proposed an alternative option (called the "Alternative"), which is even more stringent than EPA's proposed Option 1 or CARB's Omnibus standards. Among the elements included in the Alternative is a 20 mg/hp-hr FTP/SET NOx standard for MY 2027 Heavy HDE engines at 850k miles UL. EPA was unable to conclude that the Alternative is feasible in the MY 2027 timeframe due to deterioration in the emission control technologies that EPA has evaluated to date. Given Cummins' design target analysis discussed above and negative impacts to the environment, we agree with EPA that the Alternative is not feasible and warrants no further consideration. [EPA-HQ-OAR-2019-0055-1325-A1, p. 4]

Based on Cummins' technology evaluations, EPA's proposed Option 2 NOx standard of 50 mg/hp-hr will drive a range of additional technologies onto diesel engines, similar to the ones evaluated by EPA and SwRI, e.g., cylinder deactivation (CDA) and dual selective catalytic reduction (SCR) systems, which can achieve NOx improvements over a wide range of real-world operation. While technologies such as CDA and dual SCR are in production already in light-duty applications, they are not in production for heavy-duty vehicles at these emission levels, so considerable effort is still needed to develop, package, and validate the new components, especially considering the more diverse drive trains and vehicle configurations, duty cycles, applications, and much longer useful life of heavy-duty vehicles. [EPA-HQ-OAR-2019-0055-1325-A1, p. 4]

Cummins supports a stringent but feasible single-step NOx standard in 2027. Further NOx reductions should come from zero and near-zero emission technologies, and EPA's anticipated Phase 3 GHG rule should deliver those NOx reductions. Setting aside Option 1's infeasible standards, Option 1's second step in 2031, at any stringency, would be especially disruptive for manufacturers' investments that currently are committed to the development and implementation of zero and near-zero emissions technologies in that same timeframe. A 2031 NOx step would force manufacturers to decrease investments in zero and near-zero technologies in order to increase investments to implement another step of internal combustion engine NOx control technologies. [EPA-HQ-OAR-2019-0055-1325-A1, p. 5]

In these comments, Cummins has discussed the reasons why Option 1 is not the right solution to achieve such a goal. We have also discussed changes that are needed to Option 2 to ensure manufacturers can offer products that are not only compliant to the challenging 50 mg/hp-hr NOx standard but also cost-effective. [EPA-HQ-OAR-2019-0055-1325-A1, pp. 20-21]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

The zero-emission transition is best achieved by encouraging technological innovation in a cost-effective manner that is realistic in terms of timing and implementation. Environmental regulators such as EPA and CARB have an important role to play in facilitating this transition by balancing requirements and incentivizes in their regulatory programs. Unfortunately, the Proposed Rule does not strike the proper balance because, among other things, it:

- Introduces significant technical risk for manufacturers—particularly with respect to long-term recall liability and in-use testing—and contains numerous standards and requirements that are likely not achievable within the timeframes given;
- Dramatically under-estimates technology costs and the anticipated market impacts (including pre-buy, low-buy, and no-buy scenarios) associated with the high costs of compliance that will threaten jobs and increase the cost of transporting goods, impacts

that ultimately will be felt at every level of society and will exacerbate existing inflation and supply chain challenges;

- Will require manufacturers to divert finite resources into development of conventional vehicle technology to meet the Proposed Rule requirements within the timeframes proposed, which has limited environmental benefits and detracts from ZEV research and development (R&D); and
- Proposes stringent emission standards that are based upon a technology demonstration that does not reflect real-world conditions, account for appropriate design margins, cannot be packaged on an actual vehicle, ignores the effects of fuel quality issues on aftertreatment effectiveness, and fails to address the complexities of NOx/CO2 emission tradeoffs. [EPA-HQ-OAR-2019-0055-1168-A1, pp.1-2]

Congress has given EPA clear direction for setting emission standards for new motor vehicles and new motor vehicles engines under Clean Air Act (CAA or the Act) Section 202(a), and the bounds of EPA's authority have been well-established in case law interpreting the provisions of this section. As EPA acknowledges in the Proposed Rule, CAA Section 202(a) sets forth the following key requirements for and limitations on emissions standard-setting for new vehicles and engines:

- First, emission standards promulgated under Section 202(a) may only take effect after the period of time necessary to permit the development and application of the requisite technology, giving 'appropriate consideration to the cost of compliance within such period.'1
- Second, EPA regulations governing HC, CO, NOx, and PM emissions from heavy-duty vehicles or engines must contain standards reflecting the 'greatest degree of emission reduction achievable' through the application of technology that EPA determines will be available for the model year to which such standards apply, giving 'appropriate consideration to cost, energy, and safety factors associated with the application of such technology.'2
- Third, in revising heavy duty vehicle or engine emission standards to address public health effects of air pollutants from the sector, EPA must 'tak[e] costs into account.'3
- Fourth, EPA must give consideration to lead time and stability in setting heavy-duty emission standards, as any standard promulgated under CAA Section 202(a) must apply for a period of no less than three model years and begin no earlier than the model year commencing four years after any revised standard is promulgated.4 [EPA-HQ-OAR-2019-0055-1168-A1, pp.5-6]

1 42 U.S.C. 7521(a)(2).
2 Id. at 7521(a)(3)(A)(i).
3 Id. at 7521(a)(3)(B)(i).
4 Id. at 7521(a)(3)(C).

While EPA has discretion in weighing the various statutory factors that it is to consider in heavy-duty emission standard-setting, there are limits to this discretion. EPA may, for example, look to the future to project anticipated advances in pollution control capability, but these projections are 'subject to the restraints of reasonableness' and do not 'open the door to 'crystal ball' inquiry.'5

Further, the Agency ‘must . . . provide a reasoned explanation of its basis for believing that its projection is reliable. This includes a defense of its methodology for arriving at numerical estimates.’6 [EPA-HQ-OAR-2019-0055-1168-A1, p.6]

> 5 See National Resources Defense Council, Inc. v. U.S. EPA, 655 F.2d 318, 328 (D.C. Cir. 1981) (‘NRDC’) (citing International Harvester Co. v. Ruckelshaus, 478 F.2d 615, 629 (D.C.Cir.1973)).
> 6 Id.

With respect to technical feasibility, ‘where the facts pertinent to [a] standard’s feasibility are available and easily discoverable by technical means,’ EPA is held to a higher standard of demonstrating achievability by relying upon available data.7 Where the feasibility of an emissions control standard turns on the development of a particular technology, the Agency must identify the major steps that are necessary for the development of this technology and must ‘give plausible reasons’ for its belief that industry will be able to solve any impediments to its implementation ‘in the time remaining’ before the standard will be enforced.8 [EPA-HQ-OAR-2019-0055-1168-A1, p.6]

> 7 National Lime Ass’n v. EPA, 627 F.2d 416, 454 (D.C. Cir. 1980).
> 8 NRDC, 655 F.2d at 333.

The Company believes that EPA’s proposal disregards key considerations, including failure to analyze certain costs, for new heavy duty vehicle and engine emission standard-setting, in contravention of the specific congressional directives in CAA Section 202(a). Specifically, if finalized, EPA’s Proposed Rule would:

- Impose inordinate costs on manufacturers and consumers that EPA has not accounted for in its cost analysis. These costs would have significant adverse effects on the heavy-duty transportation market by causing ‘pre-buy’ and ‘no-buy’ scenarios, leading to significant job losses, major market and freight disruption, and other adverse economic impacts. Because its cost analyses are flawed, EPA has not fulfilled its statutory duty to give ‘appropriate consideration’ to costs.
- Be infeasible in implementation and thus impose standards that are not commensurate with the greatest degree of emission reduction that is ‘achievable’ giving appropriate consideration to cost, energy, safety, and other factors.
- Undermine regulatory stability if EPA determines to increase stringency of the Phase 2 GHG standards for certain vocational vehicles and tractor categories starting in MY 2027, upsetting manufacturer reliance on those standards coming out of the Phase 2 rulemaking.
- Disincentivize ZEV development and commercialization, as the Proposed Rule would require manufacturers to invest in conventionally-powered vehicle programs to achieve compliance with the upcoming standards instead of focusing on ZEV technology, which would have significantly greater environmental benefit. Each of these concerns are explained in more detail elsewhere in these comments. [EPA-HQ-OAR-2019-0055-1168-A1, p.7]

Daimler Truck believes that any new HD emission standards that EPA develops in this rulemaking process must be guided by the following principles:

- ***One-Step NOx Stringency***. A one-step program for sensible increases in NOx stringency is key to ensuring manufacturers are able to deliver the technologies needed to develop and commercialize the ZEVs of the future. Daimler Truck strongly believes that ZEVs are the future of the commercial vehicle industry. Keeping next-tier EPA regulations to one NOx standard down-step will help manufacturers focus on the development of ZEV technology, instead of diverting resources to meet an interim NOx standard for conventionally-powered vehicles that has little environmental benefit and may not be technologically achievable.
- ***Feasibility and Cost-Effectiveness***. EPA's next-tier standards must be technologically feasible and cost-effective and, to this end, must be based upon accurate and realistic technical, cost, and market analyses. In evaluating the relative costs and benefits of its proposal, the Agency must take into account widely available literature on cost impacts associated with standard stringency, as well as key manufacturing cost drivers such as meeting extended regulatory useful life and emission warranty requirements.
- ***Realistic NOx Standards.*** EPA's next-tier NOx standards should be realistic and achievable and should be developed in recognition of the inevitable trade-offs between NOx and CO2 emission reductions. The Agency's standards should present manageable and predictable risk in terms of in-use emissions and compliance evaluations, and they should reflect real-world operations and performance.
- ***Lead Time, Stability, and Certainty.*** The timing of standard implementation should allow for sufficient R&D, and should give long-term consideration to manufacturer investments in the technologies of the future.
- ***Incentivizes for ZEV Market Penetration***. EPA should build upon the successes of the compliance flexibility programs that have long been a part of its vehicle emissions regulations. The Agency's NOx and CO2 regulations should enhance (and not diminish) opportunities for manufacturers to generate credits for ZEV development and commercialization and should appropriately incentivize ZEVs with credit multipliers. [EPA-HQ-OAR-2019-0055-1168-A1, p.10]

In proposing adoption of NOx standards below 0.050 g/bhp-hr, EPA has failed to account for appropriate design margins and the inherent technical challenges of meeting the standards as proposed. Since the evolution of 0.2 g/hp-hr NOx standards and related selective catalytic reduction (SCR)-based aftertreatment technologies, Daimler Truck has consistently found it necessary to account for design margins to meet the relevant standards. The Company endorses the section of EMA's comments on this topic entitled 'EMA Assessment of Technical Feasibility of Complying with a 0.020 g/bhp-hr NOx Standard for Heavy-Duty Diesel Engines' and adopts such comments as its own.63 [EPA-HQ-OAR-2019-0055-1168-A1, p.24]

63 See Truck and Engine Manufacturers Association, Comments on EPA-HQ-OAR-2019-0055 (May 13, 2022) ('EMA Proposed Rule Comments').

DTNA strongly believes that a one-step approach, with an aggressive 75% increase in NOx stringency, no earlier than 2027, is the feasible, economical, and environmentally sound approach to emissions reductions for diesel vehicles. [EPA-HQ-OAR-2019-0055-1168-A1, p.53]

Two steps of increasing stringency, as EPA has proposed under Option 1, will force manufacturers to invest in two development programs, closely spaced in time, doubling the necessary investment in R&D, validation, and verification of the new systems needed for compliance with each set of standards. Additionally, releasing new products in both 2027 and 2031 will leave orphaned products sold by manufacturers for the three interim model years before the second tier standards take effect. Under a 'two-step' scenario, manufacturers will struggle to recapture their investment in MY2027-MY2030 vehicles and will not have adequate time to optimize product performance and cost through ongoing improvement efforts. Manufacturers will also have to split their resources between two different programs, likely leading to increased quality issues. [EPA-HQ-OAR-2019-0055-1168-A1, p.53]

Similarly, a two-step approach to increasing emission standard stringency will double the adverse economic effects anticipated from the Proposed Rule (and detailed in Section II.B.2), as the market will likely face two pre-buy scenarios, and fleet operators will face the adoption and integration of new technology twice, in rapid succession. Or worse, a two-step approach may simply cause a more dramatic one-time pre-buy effect, if fleet owners choose to delay new purchases altogether until after 2031 to avoid having to integrate new technology into their fleet twice. Either way, a two-step approach to emissions stringency as EPA has proposed under Option 1 will cause more significant job losses, economic damage, and market frustration, and these adverse effects may further reduce the emissions benefits of EPA's proposed programs. [EPA-HQ-OAR-2019-0055-1168-A1, p.53]

We firmly believe that the future of the commercial trucking segment is in ZEVs—namely, battery-electric and hydrogen powertrains. Daimler Truck is making significant investments in these technologies, and—as EPA notes in the Proposed Rule—Daimler Truck AG, our parent company, has set a goal that all new vehicles sold in Europe, North America and Japan be CO2-neutral by 2039. However, this aggressive strategy for decarbonization requires unprecedented investment in the development of new technologies to meet the wide array of commercial vehicle applications. Further investment in incremental improvements to conventional powertrains, as will be needed to comply with EPA's Option 1 approach, competes with the investments necessary for ZEVs. In other words, EPA's proposal to have two stringent emission reduction steps directly reduces investments OEMs can make in ZEVs, and thereby will slow their market penetration. [EPA-HQ-OAR-2019-0055-1168-A1, p.53]

Organization: *David Luedtke*

The trucking industry has made great strides in pollution control & will move to gain on those strides without further mandates. If there are new mandates the Fed's want to add made they need to look at a long faze in process to get the old equipment out of production. Look at a 10 year process that will allow the older trucks to retire & scrap out. This same time frame will allow manuf. the time to ramp up pollution items so the cost isn't astronomical! [EPA-HQ-OAR-2019-0055-1541]

Organization: *David Wong*

Third, the guidelines seem too gradual and reasonable to be considered radical, when a radical change is needed for the radical improvement in air quality we seek. I am recommending the EPA add amendments to increase the strictness of emission guidelines exponentially every year, or at least every 2 or 3 years for implementation.

Organization: *Delaware Department of Natural Resources and Environmental Control (DNREC)*

The rule should be stringent and technology forcing. The rule should reduce HD truck NOx emissions by at least 90 percent and implement other key requirements to make sure these reductions will continue to be realized over the full useful life of vehicles, beginning no later than MY 2027. Such standards should require not only advanced and emerging technologies, but also technologies consistent with CAA Section 202(a)(3)(A): NOx emission standards for HD trucks are to "reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy and safety factors associated with the application of such technology." [EPA-HQ-OAR-2019-0055-1200-A1, p.2]

In the proposed action, EPA is co-proposing two regulatory options for new NOx standards: Proposed Option 1 and Proposed Option 2. EPA seeks comments on the two options and seeks comment on an alternative option for different numeric levels of the standards and lengths of useful life and warranty periods. Delaware prefers the numeric standards, extended useful life periods and warranty periods of Proposed Option 1. [EPA-HQ-OAR-2019-0055-1200-A1, p.2]

Proposed Option 1 is expected to reduce NOx emissions from HD vehicles in 2040 by more than 50%; by 2045, a year by which most of the regulated fleet would have turned over, HD NOx emissions would be more than 60% lower than they would have been without this action. Proposed Option 2 is expected to reduce HD NOx emissions by 47% in 2045. Proposed Option 1 would result in total annual monetized ozone- and PM2.5-related benefits of $12 and $33 billion at a 3% discount rate, and $10 and $30 billion at a 7% discount rate by 2045. Proposed Option 2 would result in total annual monetized ozone- and PM2.5-related benefits of $9 and $26 billion at a 3% discount rate, and $8 and $23 billion at a 7% discount rate for the same year. [EPA-HQ-OAR-2019-0055-1200-A1, p.2]

Given the analysis presented, Delaware believes that Option 1is a more appropriate level of stringency as it would result in a greater level of achievable emission reduction, health benefits and monetized benefits than Proposed Option 2. Delaware urges EPA to revise Proposed Option 1 to require the 20-mg/hp-hr NOx standard for HD trucks beginning in 2027 with an intermediate useful life of 435,000 miles (versus EPA's Proposed Option 1 approach of 35 mg/hp-hr NOx in 2027); these requirements are entirely feasible. [EPA-HQ-OAR-2019-0055-1200-A1, p.3]

EPA should not exempt any engines from complying with the adopted new emission standards for any amount of time and, therefore, should not adopt the production volume allowance option described in the Notice of Proposed Rulemaking. Delaware supports an increase to the Option 1 regulatory useful life mileage values for new HD engines to better reflect real-world usage, extend the emissions durability requirement for HD engines, and ensure certified emission performance is maintained throughout an engine's operational life. [EPA-HQ-OAR-2019-0055-1200-A1, p.3]

For all these reasons, Delaware urges EPA to act quickly to fully adopt a federal regulation requiring a 20-mg/hp-hr NOx standard for HD trucks by the end of this calendar year so that it will take effect with MY 2027 to reduce air pollution from highway HD vehicles and engines. [EPA-HQ-OAR-2019-0055-1200-A1, p.3]

Organization: *District of Columbia Department of Energy and the Environment (DOEE)*

DOEE has submitted comments to the EPA on this matter before, writing in October 2021 to urge the EPA to accelerate their proposal after the January 2020 Advanced Notice of Proposed Rulemaking. DOEE remains concerned about the delays in issuing stricter heavy-duty engine standards because delays harm the health of the residents of the District, especially historically disadvantaged communities that have long had to live with poor air quality levels due to their proximity to highways such as those in Southeastern Washington, DC. [EPA-HQ-OAR-2019-0055-1299-A1, p. 1]

When EPA finalizes this proposed rulemaking it will mark the first time since 2001 that EPA has taken action to cut harmful NOx emissions from medium- and heavy-duty vehicles. There is a clear and compelling public health need for much tighter restrictions on heavy-duty truck NOx emissions. In the past 20 years, technical capacity to reduce these emissions has flourished and the opportunity to require and achieve deeper reductions in NOx emissions across the many operations would be enormous. [EPA-HQ-OAR-2019-0055-1299-A1, p. 4]

Ideally, EPA's proposed "Alternative Option" would be adopted. The Alternative Option has stricter emission standards implemented four years earlier, compared to the 2031 second-step implementation date in "Option 1." The Alternative Option most closely aligns with the California Heavy-duty NOx Omnibus Regulation, which has been demonstrated as technologically feasible through joint research with the EPA, conducted by the Southwest Research Institute (SwRI). The Alternative Option would give the District a head start in reducing transportation emissions in the District. We understand the reservations the EPA has about implementing the Alternative Option, particularly regarding the timeline for putting this regulation into effect. [EPA-HQ-OAR-2019-0055-1299-A1, p. 5]

If the Alternative Option is not possible, then Option 1 should be selected over Option 2. Option 1 best represents the available emission control technologies that "reflect the greatest degree of emission reduction achievable through the application of technology," as is mandated by under Clean Air Act § 202 (a)(3)(A)(i). Option 1 requires heavy-duty vehicles and engines to meet strict emission standards for NOx and provides for extended warranties and other provisions that ensure trucks are able to meet this strict emission standard for over 800,000 miles of operation. Because Option 1 meets stricter emission standards and is feasible, Option 2 cannot be considered. If EPA decides not to implement the Alternative Option, DOEE urges the EPA to implement Option 1 in accordance with the Clean Air Act § 202 (a)(3)(A)(i). [EPA-HQ-OAR-2019-0055-1299-A1, p. 5]

It is vital that the EPA promulgates new emission standards for heavy-duty engines in a timely fashion, but the rules must also be strict enough for tangible and significant emission reductions. The final rule should be as strict as possible, and the Alternative Option is the strictest option that EPA has presented. The timeline is also an important factor; our residents need cleaner air now. To that end, Option 1 provides real emission reductions on an acceptable timeline, and this is the option EPA should implement if the alternative cannot be implemented in a timely fashion. The EPA has already demonstrated the technologies exist for Option 1 to become a reality and should act without haste. EPA should also set a mandatory idle standard and maintain a strong SCR inducement schedule. DOEE urges the EPA to take immediate action to adopt Option 1 for the health and safety of District residents. [EPA-HQ-OAR-2019-0055-1299-A1, p. 7]

Organization: *Eaton Vehicle Group (Eaton)*

3. Long term regulatory certainty allows the transportation industry to continue to invest in product development and deploy needed capital. Emissions levels must be set such that societal needs for air quality, including GHG and future non-attainment, are in fact achieved without the need of additional local restrictions or short-term changes. [EPA-HQ-OAR-2019-0055-1252-A1, p.4]

The transportation industry needs long term regulatory certainty to enable investments in both Low NOx and Zero Emissions technologies and allocate capital to bring these to the market. A standard that does not resolve the long-term needs of air quality would insert uncertainty and thus inhibit the bold investments that are needed. For example, the Green House Gas rule in effect from 2014 to 2030 drove significant benefits, technology and cost-out, all possible because of (a) long term and (b) societal-acceptable stringencies. We recommend the Agency apply the same approach to the proposed rule. [EPA-HQ-OAR-2019-0055-1252-A1, p.4]

Organization: *Elders Climate Action*

Elders Climate Action requests that EPA revise the standards for HDVs to set a zero emission standard for nitrogen oxides (NOx), PM2.5 and CO2 for the classes of HDVs or types of HDVs that operate in duty cycles for which zero emission power trains are currently in use or which EPA expects will be available by 2027. [EPA-HQ-OAR-2019-0055-1218-A1, p. 1]

The CAA declares that the primary purpose of the Act is "to protect and enhance the quality of the Nation's air resources so as to promote the public health and welfare and the productive capacity of its population." 42 U.S.C. §7401(b)(1). To implement this purpose, section 202(a)(3) requires that for HDVs EPA "shall [set] standards which reflect the greatest degree of emission reduction achievable through the application of [available] technology…." The proposed rule does not satisfy that test. [EPA-HQ-OAR-2019-0055-1218-A1, p. 4]

By setting zero emission standards for NOx beginning in 2027 for the vehicle types currently available as zero emission vehicles (ZEVs), EPA could avoid an estimated 20,440 tons of NOx in South Coast and 22,630 tons in San Joaquin Valley. A zero emission standard for CO2 would avoid 54 million MT of CO2 from these three model years between now and 2050. The urgency of the public health and climate crises demands that the U.S. must not forego those reductions. [EPA-HQ-OAR-2019-0055-1218-A1, p. 5.]

We include a legal analysis that demonstrates EPA's failure to set standards that will achieve the maximum deployment of zero emission technologies fails to achieve the public health purpose of the Act, and is not consistent with the statutory text and the legislative history of the Act. [EPA-HQ-OAR-2019-0055-1218-A1, p. 5]

The proposed rule violates numerous duties established by law, including –

1) the statutory duty to set for HDVs "standards which reflect the greatest degree of emission reduction achievable through the application of [available] technology…."

2) the duty to identify, evaluate and propose for consideration a rule that will optimize the implementation of the primary purpose of the Act declared by Congress, to wit, standards that will most effectively "promote the public health and welfare and the productive capacity of its population." 42 U.S.C. §7401(b)(1). [EPA-HQ-OAR-2019-0055-1218-A1, p. 5]

3) the duty to make available to the public when a proposed action is published for public comment the data developed by the Agency and used for making its decision. [EPA-HQ-OAR-2019-0055-1218-A1, p. 5]
4) the duty under Title VI of the Civil Rights Act to avoid actions that create disparate impacts on communities of color and low income communities that are most at risk of suffering the adverse health outcomes caused by exposure to emissions from HDVs. [EPA-HQ-OAR-2019-0055-1218-A1, p. 6]

The proposed standards for NOx and GHGs are not consistent with CAA section 202(a)(3)(A) that mandates the standards for HDVs — "regulations … applicable to emissions of hydro-carbons, carbon monoxide, oxides of nitrogen and particulate matter from classes or categories of heavy duty vehicles or engines … shall contain standards which reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology." 42 U.S.C. 7521(a)(3)(A). [EPA-HQ-OAR-2019-0055-1218-A1, p. 6]

The standard setting authority granted to EPA by section 202 must be viewed in light of the statutory framework which declares the purpose of the Act is "to protect and enhance the quality of the Nation's air resources so as to promote the public health and welfare and the productive capacity of its population." 42 U.S.C. §7401(b)(1). Under the structure of the Act, the NAAQS promulgated pursuant to section 109 provide the relevant benchmarks for determining whether the primary purpose of the Act, i.e., protecting public health, is being implemented. [EPA-HQ-OAR-2019-0055-1218-A1, p. 8.]

Here EPA has investigated the impact that the proposed standards will have on attainment and found that 1) controlling emissions from HDVs are necessary for attainment in many ozone NAs because the reductions required by the proposed rules will contribute to attainment in some NAs, but 2) that the reductions are not enough to demonstrate attainment in the worst polluted air pollution control regions.3 [EPA-HQ-OAR-2019-0055-1218-A1, p. 8.]

3. The modeling analysis results reported in the Technical Support Document are useful for drawing these inferences, but the modeling is not adequate to determine the emission reductions needed for timely attainment by the statutory deadlines for each NA. Regional modeling for NAs that are not expected to attain before the statutory deadline should be performed, in collaboration with regional air quality planning agencies, to obtain more precise data regarding the emission reductions needed for attainment.

This statutory mandate to achieve “the greatest degree of emission reduction achievable…”for heavy duty vehicles does not apply to standards for light duty vehicles (LDVs). Section 202(i) specifically authorizes EPA to forego more stringent standards for LDVs if they are not needed for attainment, but that provision does not apply to HDVs. For HDVs, the duty to set standards that reflect “the greatest degree of emission reduction achievable…” is continuing, and is not limited by the need for reductions to attain NAAQS. These differences imply 1) that standards for both HDVs and LDVs must continue to be strengthened as necessary to support the states in developing implementation plans that can attain the NAAQS; and 2) that for HDVs the progressive emission reductions that become available from more advanced technology must continue to be reflected in more stringent standards. [EPA-HQ-OAR-2019-0055-1218-A1, p. 9.]

Prior to the 1977 Amendments, section 202(a) contained general language first enacted in 1963 that authorized the predecessor to EPA to promulgate regulations establishing emission standards for motor vehicles. The statutory directive to set standards for HDVs that “reflect the greatest degree of emission reduction achievable” was first added to the Act in the 1977 Amendments. [EPA-HQ-OAR-2019-0055-1218-A1, p. 9]

That language came from the House bill which enacted authority for the Administrator to “prescribe regulations [that] … shall contain standards which reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to the cost of applying such technology within the period of time available to manufacturers,...”6 [EPA-HQ-OAR-2019-0055-1218-A1, p. 9]

6. House Report, bill text adding paragraph 202(a)(3)(A), at 407.

The Senate bill only required that “regulations shall contain standards which require a reduction of emissions of such pollutants established by the application of the best available control technology, taking into account the cost of compliance….”7 [EPA-HQ-OAR-2019-0055-1218-A1, p. 9]

7. Senate Report, at 92.

The differences between the House and Senate provisions are significant for this rulemaking. The Senate language only required the “application” of “control technology” which limited EPA’s authority to considering technology that could be applied to control emissions from an engine. In contrast the House language was broadly written to allow the Administrator to consider not only control technology, but also engine technology or alternative technologies that can achieve “emission reduction[s].” The House language also authorized the Administrator to consider technology that would become available by the model year when the standard would apply, whereas the Senate language limited EPA to considering control technology that was “available” when the standard was set. [EPA-HQ-OAR-2019-0055-1218-A1, pp. 9 - 10]
In conference, the Senate accepted the House language.8 [EPA-HQ-OAR-2019-0055-1218-A1, p. 10]

8. Clean Air Act Conference Report,

The 1977 Amendments applied the “greatest degree of emission reduction” test to interim standards promulgated by EPA during the period prior to the statutory deadline for achieving percent reduction targets enacted by Congress. That language applied percentage emission reduction targets for CO, VOCs and NOx, but “[r]ecognizing that attainment of the 1985 targets levels may not be achieved in time, the Committee adopted a provision which permits the Administrator to revise these standards temporarily.” 9 The bill required that to revise any standard “the Administrator shall determine the maximum degree of emission reduction that can be achieved by means reasonably expected to be available for production for such period and shall prescribe a revised emission standard in accordance with such determination.” Thus the “greatest degree of emission reduction” test was not a continuing obligation. Once the statutory emission reduction targets were met, EPA’s authority to set additional more stringent standards was at an end. [EPA-HQ-OAR-2019-0055-1218-A1, p. 10]

9. House Report, at 274.

When the 1990 Amendments were enacted, the statutory emission reduction targets enacted in 1977 had been met. Those targets were repealed, but the “greatest degree of emission reduction achievable” language was retained as the current test for standard setting under section 202(a)(3)(A). This history demonstrates congressional intent to progressively continue to advance the stringency of standards as technology improvements make further emission reductions “achievable.” [EPA-HQ-OAR-2019-0055-1218-A1, p. 10]

The question the Administrator is required to answer when setting standards for HDVs is what standard “reflect[s] the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year [2027] to which such standards apply”? [EPA-HQ-OAR-2019-0055-1218-A1, p. 10]

For these reasons, Elders Climate Action asks that EPA adopt zero emission standards for NOx, PM and CO2 for HDVs that EPA has identified in short-haul duty cycles for which zero emission power trains are currently available, and for which zero emission power trains are expected to be available by 2027. At a minimum, zero emission standards should apply to the share of HDVs covered by the ZEV requirement in the CARB ACT rule. [EPA-HQ-OAR-2019-0055-1218-A1, p. 13.]

As discussed above in section II, the Clean Air Act requires EPA to set emission standards for HDVs that "reflect the greatest degree of emission reduction achievable…." [EPA-HQ-OAR-2019-0055-1218-A1, p. 19.]

Given the science informing the world that the climate cannot be stabilized short of achieving "net zero" GHG emissions, and the Presdient's commitment to achieving a net zero economy by 2050, we ask the Administrator to make the determination that emissions of both GHGs and precursors to the criteria pollutants PM and ozone emitted from light duty vehicles must be reduced to zero to protect the public health and welfare from the many adverse effects of climate warming. [EPA-HQ-OAR-2019-0055-1218-A1, p. 19.]

The Act provides that "[a]ny such [standard] under this subchapter may provide for a phase-in of the standard."13 We ask the Administrator to begin phasing in a zero emission standard by establishing a sales mandate that requires each manufacturer to achieve ZEV sales during the 2027 MY that are comparable to CARB's ACT rule with the goal of achieving 100% HDV ZEV sales by 2035 in order to achieve zero emissions from on-road vehicles by 2050. [EPA-HQ-OAR-2019-0055-1218-A1, p. 19.]

13. Id.

Commenters understand that additional rulemaking will be required to establish a zero emission standard and phase-in schedule for HDV classes not addressed by this rule. However, the current proposal can be revised to incorporate this approach for the HDV classes and categories addressed by this proposal. We ask that the Administrator not delay completion of the current proposed rule so that it can apply to 2027-29 MY vehicles. We ask that the Administrator open a rulemaking for the additional vehicle classes to promulgate a zero emission standard and a phase-in schedule that begins with the 2027 MY. [EPA-HQ-OAR-2019-0055-1218-A1, p. 19.]

Organization: *Energy Innovation, LLC*

The EPA's leadership on climate and clean air is more critical than ever. We appreciate the EPA's efforts to initiate a long-overdue update to heavy-duty vehicle pollution and emissions standards. Because vehicles sold over the next few years will remain on the road for decades, the EPA should seize the opportunity to adopt the most stringent standards for greenhouse gas (GHG) emissions, nitrogen oxides (NOx) and other pollutants for heavyduty trucks (HDTs) Model Years 2027-2029 (MY 2027-2029), aligning these standards with science-based emissions targets and relevant policy goals. [EPA-HQ-OAR-2019-0055-1310-A1, p.1]

While the HDT market is still evolving to include more electric models and lower upfront vehicle costs, current market trends and potential consumer savings support the adoption of strong standards. Performance standards are a powerful tool for leveraging accelerated technology advancements and sending clear market signals that spur the private sector to increase deployment of zero-emission, heavy-duty electric vehicles (HDEVs) within this decade. [EPA-HQ-OAR-2019-0055-1310-A1, p.1]

The EPA should adopt the most stringent NOx standard for HDTs, while also considering the role zero-emission electric vehicles can and should play in eliminating NOx and other pollutants altogether. Proposed Option 1 is a start and should be significantly strengthened. Similarly, the EPA should forgo any credit approaches that erode the strength of the standard. We elaborate on these points herein. [EPA-HQ-OAR-2019-0055-1310-A1, p.1]

In the context of this and future rulemakings, we encourage the EPA to set a higher standard to prompt private sector investments and accelerate the adoption of proven technologies that can mitigate the climate crisis and improve public health, especially in the most burdened communities. [EPA-HQ-OAR-2019-0055-1310-A1, p.4]

However, the EPA need not wait for major breakthroughs in technologies to reduce NOx from combustion engines. Zero-emission electric vehicles emit no NOx emissions or other harmful pollutants, and their scaled adoption in the heavy-duty sector offers a streamlined path to reduce not just GHG emissions but all transportation air pollution throughout the U.S. Proposed Option 1 is a start but should be significantly strengthened, and the EPA should consider how to further facilitate the adoption of HDEVs in the context of the NOx rule. Along similar lines, the EPA should forgo any credit approaches that significantly erode the standard to avoid further burdening communities and individuals with future pollution. [EPA-HQ-OAR-2019-0055-1310-A1, p.7]

Organization: *Engine and Truck Organizations*

The U.S. EPA has proposed a new rule to significantly increase the stringency of the national nitrogen oxide (NOx) emissions standard for medium- and heavy-duty commercial vehicles. As a Mack Trucks dealer, I fully support clean air improvements and healthier communities for all. But my concern EPA's proposal risks significant unintended consequences for our medium- and heavy-duty vehicle customers, for the trucking industry generally, and for the U.S. economy as a whole. [EPA-HQ-OAR-2019-0055-1177-A1, p.1]

Based on our assessment, EPA's "Option 1" rule as proposed will be:

- **Cost prohibitive**. The additional technology required for diesel engines will drive new and used vehicle prices higher, reducing or delaying fleet turnover to newer, cleaner, safer trucks. Higher operating costs will also deter the attractiveness of those trucks.
- **Disruptive of business**. The additional costs and downtime associated with increased repairs and maintenance will directly impact our customers' day-to-day operations and inhibit their ability deliver goods and services.
- **Bad for jobs**. As was caused by previous EPA NOx rules, we anticipate a pre-buy/no buy scenario, that could result in dramatic job losses for our employees.
- **Counter to environmental goals**. When new truck prices rise and their costs of operation increase, customers will hold onto older, higher emitting trucks longer, undermining the continuous improvements in air quality we all seek. [EPA-HQ-OAR-2019-0055-1177-A1, p.1]

I urge EPA to reject "Option 1" and to instead work with industry stakeholders to develop a final is workable and cost-effective, that keeps the trucking industry healthy, and that accelerates, not undermines, environmentally beneficial fleet turnover. [EPA-HQ-OAR-2019-0055-1177-A1, p.1]

[Additional comment provided by two companies that joined this letter campaign:] Based on our assessment, EPAs “Option 1” rule as proposed will be … Product Limiting. Our truck manufacturer suppliers may be forced to reduce their product portfolios, limiting the options we can make available for our customers, and their ability to provide vital freight transportation for their customers. [EPA-HQ-OAR-2019-0055-1179 and EPA-HQ-OAR-2019-0055-1235]

Organization: *Environmental Defense Fund (EDF) (1265 and 2855)*

EPA has clear authority to establish technology-forcing emission standards for medium and heavy-duty trucks under Section 202(a)(1). The text of Section 202(a)(1) directs EPA to promulgate ‘standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines’.73 Such regulations are to ‘take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.’74 Authority to regulate GHGs under this section was confirmed in 2007, with Massachusetts v. EPA.75 [EPA-HQ-OAR-2019-0055-1265-A1, p.17]

73 42 U.S.C. 7521(a)(1).

74 Id. at 7521(a)(2).

75 549 U.S. 497 (2007).

EPA has a long history of promulgating technology-forcing emission standards that have driven innovation and secured pollution reductions. For instance, EPA standards under section 202 resulted in the development and proliferation of the catalytic converter in 1975 and the three-way catalyst in 1981.76 Particulate and NOx standards for heavy-duty vehicles also resulted in the development of the diesel particulate filter and NOx aftertreatment.77 [EPA-HQ-OAR-2019-0055-1265-A1, p.17]

76 See, e.g., David Gerard and Lester B. Lave, Implementing technology-forcing policies: The 1970 Clean Air Act Amendments and the introduction of advanced automotive emissions controls in the United States, 72 TECHNOLOGICAL FORECASTING AND SOCIAL CHANGE 761 (2005), available at http://repository.cmu.edu/tepper/1356/

77 See, e.g., Chris Wold, Climate Change, Presidential Power, and Leadership: We Can’t Wait, 45 CASE WESTERN RESERVE J. OF INT’L LAW 303, 346, available at http://law.case.edu/journals/jil/Documents/45CaseWResJIntlL1&2.15.Article.Wold.pdf.

Courts have consistently and specifically affirmed EPA's authority to establish technology-forcing standards under section 202(a)(1)78 Section 202(a)(3), which addresses emissions of NOx and certain other pollutants, but not GHGs, from medium and heavy duty vehicles, directs EPA to promulgate standards 'reflect[ing] the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology.'79 Courts have interpreted this to mean that section 202(a)(3) authorizes EPA to force the development of new technology that does not yet exist.80 EPA's authority under section 202(a)(1) is similar: in promulgating standards under 202(a)(1) EPA may make projections about future technology 'subject' only 'to the restraints of reasonableness,'81 and a 'finding that the requisite technology exists or may be feasibly developed'.82 [EPA-HQ-OAR-2019-0055-1265-A1, pp.17-18]

78 See, e.g., Natural Res. Def. Council v. Envtl. Prot. Agency, 655 F.2d 318, 328 (D.C. Cir. 1981) (upholding EPA's technology-forcing standards under Section 202(a)(1)-(2) authority); Natural Res. Def. Council, Inc. v. Reilly, 983 F.2d 259, 268 (D.C. Cir. 1993) (referencing Natural Res. Def. Council v. Envtl. Protection Agency, 655 F.2d at 322 and affirming EPA's technology-forcing authority under Section 202(a)(1)-(2)).

79 42 U.S.C. 7521(a)(3)(A)(i) (emphasis added).

80 For an example of the D.C. Circuit upholding 202(a)(3) regulations which forced the development of new technology, see Nat. Res. Def. Council v. Thomas, 805 F.2d 410 (1986). In that case, the D.C. Circuit upheld EPA's 1985 regulations for PM emissions from heavy-duty vehicles, and emphasized that Section 202(a)(3) authorizes EPA to force development of new technology to meet EPA's standards. Id. at 429. The 'PM standards provision, on its face, does not constrict the agency to technology that is 'now' available,' wrote the court. Id. Further, it was 'impossible for [the court] to conclude that Congress clearly intended to restrict PM standards to adequately demonstrated technology.' Id. at 430. Instead, noting that 'Congress intended the EPA in promulgating standards with an adequate lead period to engage in reasonable predictions and projections in order to force technology,' the court 'recognize[d] a Congress concerned with promoting advances in emissions control technology for PM as well as other substances.' Id; See also Nat'l Petrochemicals & Refiners Ass'n v. EPA, 287 F.3d 1130, 1136 (D.C. Cir. 2002) (upholding EPA's MY 2007 PM and NOx emissions standards against industry challenge because 'EPA is authorized to adopt 'technology-forcing' regulations, [and] a petitioner's evidence that current technology is inadequate is not enough to show that the EPA was arbitrary in predicting future success.').

81 655 F.2d at 328 (citing International Harvester Co. v. Ruckelshaus, 478 F.2d 615, 629 (D.C.Cir.1973)).

82 Natural Res. Def. Council, Inc. v. Reilly, 983 F.2d 259, 268 (D.C. Cir. 1993).

In 1980, for example, EPA promulgated PM emission standards for light-duty diesel vehicles and trucks under Section 202(a)(1) authority, requiring that emissions decrease to 0.20 grams per mile in the 1985 model year.83 EPA determined that the standard would be achievable in 1985 with the perfection of a particle trapping device (a ‘trap oxidizer’), which at the time had achieved only partial success in a prototype stage.84 In NRDC v. EPA, the D.C. Circuit upheld these standards, holding that EPA ‘will have demonstrated the reasonableness of its basis for prediction if it answers any theoretical objections to the . . . method, identifies the major steps necessary in refinement of the device, and offers plausible reasons for believing that each of those steps can be completed in the time available.’85 Further, although EPA had identified a number of other technological strategies in addition to the trap oxidizer, the court acknowledged that the standard had been ‘set in reliance on [that] one preferred method.’86 In upholding the rule, therefore, the court established that the existence and utility of the trap-oxidizer alone was sufficient for the rule to survive.87 [EPA-HQ-OAR-2019-0055-1265-A1, p.18]

83 655 F.2d at 328. The regulation was promulgated by the agency under 202(a)(3)(iii), but the court held that the agency should have cited Section 202(a)(1).

84 655 F.2d at 328 (citing International Harvester Co. v. Ruckelshaus, 478 F.2d at 629).

85 655 F.2d at 331.

86 Id. at 332.

87 Id. at 332 n.25.

We urge EPA to strengthen its NOx standards to ensure they deliver the maximum possible reductions in harmful NOx pollution, consistent with reductions California and other states need to protect public health, and in a manner that ensures diesel vehicles are fully deploying available technologies to reduce harmful NOx pollution and that the standards drive adoption of ZEV technologies. EPA’s standards must be strengthened in several important regards to achieve these goals. First, we urge EPA to adopt a multipollutant approach that considers the availability of ZEV technologies in reducing NOx pollution. We then discuss a series of critical improvements to EPA’s proposed NOx standards for diesel vehicles, including recommended adjustments to the ZEV NOx credits, and the importance of strengthening the idle standards. Finally, we address and rebut claims by other stakeholders that protective NOx standards will result in a pre-buy of high-polluting diesel vehicles. [EPA-HQ-OAR-2019-0055-1265-A1, p.21]

If EPA relies on just the GHG standards to drive the deployment of ZEVs in its final rule, it must strengthen its proposed NOx standards for diesel vehicles to deliver the maximum possible NOx reductions, ensuring full technology development. EPA must strengthen its proposed NOx standards for diesel vehicles to deliver maximum possible NOx reductions, consistent with the needs of California and other section 177 states. In particular, EPA should adjust its approach to ZEV NOx credit generation. And regardless of whether EPA adopts multipollutant standards, we urge the agency to finalize stronger idle standards, consistent with those in the Omnibus Rule. We discuss each of these recommendations more fully below. [EPA-HQ-OAR-2019-0055-1265-A1, p.22]

Organization: *Environmental Protection Network (EPN)*

EPN recommends that EPA's decision be guided by the demonstrated need for very large NOx reductions from the heavy-duty (HD) sector. This need is especially great for those populations living near major traffic areas. The goal should be to achieve the lowest feasible NOx standard, which will provide California, other states, and disadvantaged communities the NOx reductions they desperately need. [EPA-HQ-OAR-2019-0055-1233-A1, p. 1]

EPN advocates that decisions on the level of the standards, the useful life period, the applicable Model Years (MY), and other standard-setting and compliance related issues should all be guided by this goal. This means that when EPA balances the various relevant factors, EPN recommends that EPA place great weight on the clear need for major NOx reductions to protect public health and welfare. EPN suggests that EPA should be clear in its reasoning that this factor appropriately carries great weight, and that it is an important part of EPA's justification for deciding to make changes in the direction of more, not less, reduction of NOx emissions. [EPA-HQ-OAR-2019-0055-1233-A1, p. 1]

Organization: *Evangelical Environmental Network (EEN)*

With so many lives and so much of our future dependent on heavy-duty truck pollution reduction, we strongly urge EPA to require maximum NOx and PM2.5 standards in a single-phase rulemaking to be in effect model year 2027. Secondly, we urge 100% zero emission medium and heavy-duty trucks sales by 3035. [EPA-HQ-OAR-2019-0055-0993-A1, p.2]

These standards are achievable and readily available today and will deliver critical cost savings for operators and drivers.

- Dozens of zero-emission medium- and heavy-duty trucks already available or coming to the market within a couple of years.
- Today, electric trucks and buses are already capable of supporting most freight, delivery, and transit uses and needs.
- Across nearly every vehicle class, zero-emission electric trucks and buses are projected to be cheaper to own and operate than their combustion engine counterparts within 5 years. [EPA-HQ-OAR-2019-0055-0993-A1, p.2]

In fact, a recent DOE study predicts that by 2030, zero-emission trucks could grow to 42% of sales just based on the fact that they will be cheaper to buy and own, but we need strong policies to incentive this reality. [EPA-HQ-OAR-2019-0055-0993-A1, p.2]

The reality is that trucks regulated by this standard will be on the road for decades, so these vehicles must be cleaned up as soon as possible. [EPA-HQ-OAR-2019-0055-1134-A1, p.2]

Zero-emission electric trucks are the best available technology to both reduce harmful NOx and carbon pollution. The EPA must put our national bus and truck fleet on a clear path to 100% zero-emission all-electric vehicles by 2035 – as a matter of life and a matter of justice. [EPA-HQ-OAR-2019-0055-1134-A1, p.2]

While the proposed rules are a good start, they must be strengthened. Specifically

o Regarding proposed Option 1of the NOx part of the rule. As written, it would result in higher emissions of smog and soot-causing NOx pollution than California's Heavy Duty Omnibus rule, which should be the bare minimum baseline for smog and particulate matter reduction goals. EPA must also eliminate credit giveaways that significantly erode the standard and proposed Option 2 shouldn't be seriously considered. [EPA-HQ-OAR-2019-0055-1134-A1, p.2]

Organization: *Evergreen Action*

We offer support for Proposed Option 1 to reduce nitrogen oxide (NOx) emissions in a manner that is consistent with the need to reduce the public health burdens caused by heavy duty vehicle emissions, and align emissions standards with the administration's climate goals. [EPA-HQ-OAR-2019-0055-1289-A1, p.1]

This is why we support Proposed Option 1 for reducing NOx emissions, as this plan would provide greater pollution reduction over Option 2, thereby better protecting Americans from MHDV pollution while reducing greenhouse gas emission while maintaining technological and financial feasibility. [EPA-HQ-OAR-2019-0055-1289-A1, p.1]

Organization: *Ford Motor Company (Ford)*

Ford supports EPA's effort to increase the stringency of the heavy-duty emission and greenhouse gas standards, starting in 2027 model year. We believe that the Option 1 alternative, along with the recommendations outlined in our attached comments, represents the appropriate level of stringency. [EPA-HQ-OAR-2019-0055-1300-A1, p. 2]

Ford supports the criteria emission standards in Option 1. The standards proposed in Option 1 would reduce NOx and particulate matter (PM) standards to the same level as the California Low NOx regulation by 2031 MY. In addition, the EPA proposal would reduce hydrocarbon (HC) emissions by 71% and Carbon Monoxide (CO) emissions by 60% versus the current standards. [EPA-HQ-OAR-2019-0055-1300-A1, p. 3]

Ford believes that complying with the 2031 model year and later 20 mg/bhp-hr NOx standard will require the same robust and durable technological solutions as are needed to comply with the CARB requirements in 2027 model year. [EPA-HQ-OAR-2019-0055-1300-A1, p. 3]

Organization: *General Motors LLC (GM)*

GM supports EPA's effort to finalize more stringent criteria emissions regulations than today's standards for medium- and heavy-duty engines and vehicles, in 2027 and beyond. [EPA-HQ-OAR-2019-0055-1246-A1, p.2]

GM supports efforts to improve air quality and is committed to a zero emissions future. Diesel and gasoline engines can reduce real world emissions of the fleet today and meet customer requirements in many medium- and heavy-duty applications. Reasonable updates to criteria emissions standards can recognize advancements in emissions reducing technologies, while markets mature for ZEV deployment and widespread adoption. GM supports more stringent criteria emissions regulations than today's standards for medium- and heavy-duty engines and vehicles. [EPA-HQ-OAR-2019-0055-1246-A1, p.3]

When finalizing standards, EPA should consider that manufacturers may have limited time to recoup the investment in internal combustion engine technologies incorporated to comply with the standard. Developing new products and production capacity to meet higher standards takes years of development. Major markets may adopt ZEV mandates, curtailing the addressable market for internal combustion engine vehicles and limiting the number of years that emissions reducing internal combustion engine technologies may be sold. [EPA-HQ-OAR-2019-0055-1246-A1, p.3]

Other technologies, such as battery electric vehicles or fuel cell vehicles will be necessary for manufacturers to meet high stringency standards. EPA does not fully consider the cost of these technologies in the technology pathways considered in the proposal. These technology pathways, with an ABT program, are appropriate to consider for cost-benefit analysis of high stringency proposals, though the costs of equipment and costs of fuel will differ significantly from those considered by the agency in Option 1 and Option 2 of the proposal. [EPA-HQ-OAR-2019-0055-1246-A1, pp.3-4]

In Option 1, the EPA proposes to decrease NOx emissions from the current standard by 82.5% in 2027, and 90% In 2031. At the same time, the agency proposed to revise upwards the useful life and warranty of new equipment in 2027, and then again in 2031. Different technology packages may be necessary to achieve these different requirements.7 Proposed restrictions to averaging, banking, and trading credits decrease a manufacturer's ability to respond to these stepped changes. [EPA-HQ-OAR-2019-0055-1246-A1, p.4]

7 Engine hardware, emissions systems, on-board diagnostic software, electrification, etc.

GM encourages the agency to consider a one-step standard that considers technological feasibility, and the air quality goals of the standard. A program with a straightforward one-step structure, with full ABT, that includes ZEVs is preferred.[EPA-HQ-OAR-2019-0055-1246-A1, p.4]

GM supports EPA's effort to finalize medium- and heavy-duty emissions regulations that are more stringent than today's standards. As the market matures for infrastructure, and as operators get more comfortable with ZEVs in many applications, battery electric vehicles and fuel cell vehicles will be increasingly attractive, and adoption will accelerate over time. Over the next decade, new gasoline and diesel engines can reduce transportation emissions, especially when replacing older vehicles. GM encourages EPA to finalize standards that are technologically feasible, and economically practicable. [EPA-HQ-OAR-2019-0055-1246-A1, p.7]

Organization: *Hyliion, Inc.*

We encourage new HD NOx emissions standards and additional test cycles that will drive additional NOx emissions reductions on the road and encourages best-in-class technologies. These standards should be performance-based and technology-neutral and the test-cycles should reflect real use of vehicles. Both the standards and test cycles should enable multiple technology paths to achieve compliance. [EPA-HQ-OAR-2019-0055-1238-A1, pp. 4 - 5]

Organization: *Institute for Policy Integrity at New York University School of Law (Policy Integrity)*

In the Proposed Rule, EPA presents two regulatory options, as well as one more stringent alternative. Because EPA is statutorily required to set standards for heavy-duty vehicles reflecting the "greatest degree of emission reduction achievable," at a minimum it should select Option 1 in the Final Rule, as this regulatory proposal is feasible, net beneficial, and would produce the largest emission reduction of the options considered in the Proposed Rule. However, given the numerous overly conservative economic assumptions outlined below, EPA should also revise its cost-benefit and distributional analyses to better reflect the considerable benefits to society from strong emission standards for heavy-duty trucks. This revised analysis may show that even more stringent alternatives beyond Option 1 are feasible and net beneficial. EPA should presumptively select the alternative that maximizes net benefits, and, if it does not select that policy, should offer an adequate justification for rejecting the alternative that is most economically efficient. [EPA-HQ-OAR-2019-0055-1256-A1, p. 1]

In the Proposed Rule, EPA acts under the authority of the Clean Air Act section 202.3 Unlike the open-ended discretion provided to EPA in setting standards for light-duty vehicles, EPA is required to set standards for heavy-duty vehicles that "reflect the greatest degree of emission reduction achievable" for the model year, with "appropriate considerations to cost, energy, and safety factors associated with the application of such technology."4 Also in contrast to its discretion with respect to lead time in setting standards for light-duty vehicles, EPA is required to provide at least 4 years of lead time when it sets new standards for heavy-duty vehicles.5 This extended lead time evidences Congress' intent that EPA set stringent, technology-forcing standards to reduce emissions from heavy-duty vehicles.6 [EPA-HQ-OAR-2019-0055-1256-A1, p. 4]

3. 85 Fed. Reg. at 17,420.

4. Clean Air Act § 202(a)(3); 42 U.S.C. § 7521(a)(3).

5. Compare Clean Air Act § 202(a)(2) (standards "shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance") with § 202(a)(3)(B) (heavy-duty vehicle standards "shall apply… beginning no earlier than the model year commencing 4 years after such revised standard is promulgated").

6. See Nat. Res. Def. Council v. EPA, 655 F.2d 318, 328 (D.C. Cir. 1981) ("The legislative history of both the 1970 and the 1977 amendments demonstrates that Congress intended the agency to project future advances in pollution control capability. It was 'expected to press for the development and application of improved technology rather than be limited by that which exists today.'") (quoting S.Rep.No.1196, 91st Cong., 2d Sess. 24 (1970)).

Congress has prioritized the dangers of heavy-duty truck pollution since it amended the Clean Air Act in 1977, recognizing that EPA needed to "require rigorous control of heavy-duty vehicles… which have become an increasing pollution problem."7 While the 1970 Clean Air Act required a 90% reduction in light-duty vehicle emissions, it did not set a comparable target for heavy-duty vehicles.8 Congress addressed this shortcoming in 1977 when it required EPA to set initial heavy-duty vehicle standards reflecting the "best available control technology" that were designed to achieve a 90% reduction in hydrocarbons and carbon monoxide, and a 75% reduction in nitrogen oxides by 1981.9 EPA failed to act as Congress directed until March 1985, when it promulgated heavy-duty regulations for the 1991 and 1994 model years—a decade later than Congress intended, and only upon court order.10 Thus, Congress once again intervened, amending the Clean Air Act's heavy-duty provisions in 1990 to limit the sulfur content of diesel fuels after significant testimony regarding the dangers of diesel exhaust and other pollution from heavy-duty vehicles.11 The Proposed Rule is the first time EPA has acted to reduce heavy-duty vehicle emission in more than two decades, since it last issued standards in 2000. This history of intermittent agency action, continually pushed by Congress and the courts to go further, shows the necessity for EPA to act now by issuing strong, protective standards. [EPA-HQ-OAR-2019-0055-1256-A1, p. 4]

8. Id. at 65.

9. Id. at 66.

10. S.Rep.228, 101st Cong., 1st Sess. (1989) at 111.

11. Id.

Instead, even the most stringent of the two options EPA has proposed can hardly be said to be the "greatest emission reduction achievable" when California has already issued similar heavy-duty vehicle standards that are being implemented three years earlier.12 [EPA-HQ-OAR-2019-0055-1256-A1, p. 5]

12. See Cal. Air Res. Bd., Comparison of CARB Heavy-Duty Omnibus Regulation (Omnibus) and U.S. Environmental Protection Agency (U.S. EPA) Clean Trucks Plan (CTP) Proposed Options, ("Option 1 includes many elements of CARB's Omnibus program and is approximately as stringent, although it takes effect about three years later… Option 1 is significantly weaker and the standards do not reflect the performance of demonstrated emission control technologies."), https://perma.cc/9PNB-JNPY.

EPA has "co-proposed" two regulatory options, along with one more stringent alternative for which EPA was unable to determine feasibility.13 Option 2 is the "less stringent" of the two co-proposals.14 EPA found that the more stringent emission standards in Option 1 are "achievable" and "feasible."15 And EPA acknowledges that proposed Option 1 will result in greater emission benefits,16 lower costs,17 and higher net benefits.18 Thus, as EPA acknowledges, Option 1 is the "more appropriate level of stringency as it would result in a greater level of achievable emission reduction for the model years proposed, which is consistent with EPA's statutory authority[.]"19 Yet EPA "co-proposes" both options as "potentially appropriate."20 This cannot be true. Finalizing standards equivalent to Option 2—when at least one other regulatory option produces greater emission benefits, has higher net benefits, and is feasible—would be inconsistent with EPA's statutory duty under the Clean Air Act. At a minimum, EPA must finalize standards that are at least as stringent as Option 1. [EPA-HQ-OAR-2019-0055-1256-A1, p. 5]

14. Id. at 17,421.

15. Id. at 17,438–39.

16. Id. at 17,438 (projecting that Option 1 would reduce NOx emissions by 44% by 2040, while Option 2 would reduce NOx emissions by 55% over the same period).

17. Id. at 17,589 (annualized costs at 3% discount rate of $1.9 billion for Option 1 versus $2.1 billion for Option 2).

18. Id. (net present benefits at 3% discount rate of $61-220 billion for Option 1 versus $41-170 billion for Option 2).

19. Id. at 17,440

20. Id.

EPA should fully evaluate the costs and benefits of all regulatory options presented and should strongly consider including at least one more stringent alternative than proposed. In order to fulfill its statutory duty, EPA should compare the costs and benefits of all regulatory alternatives under consideration in order to ensure that it selects the net-beneficial alternative that will generate the greatest emission reduction. It should also consider whether more stringent alternatives would also be cost-justified and generate greater emission reductions than the options in the Proposed Rule. [EPA-HQ-OAR-2019-0055-1256-A1, p. 1]

It is well established that agencies should consider a range of regulatory alternatives in order to properly evaluate the costs and benefits of a regulatory proposal. Executive Order 12,866 explains that "agencies should select those approaches that maximize net benefits" when "choosing among alternative regulatory approaches."21 Accomplishing such a goal of maximizing net benefits is impossible without first considering a broad range of alternatives at different levels of stringency.22 The Office of Management and Budget ("OMB") Circular A-4 directs agencies to "describe the alternatives available to [the agency] and the reasons for choosing one alternative over another."23 When, as here, there is a continuum of possible alternatives based on the level of stringency, agencies "generally should analyze at least three options: the preferred option; a more stringent option that achieves additional benefits (and presumably costs more) beyond those realized by the preferred option; and a less stringent option that costs less (and presumably generates fewer benefits) than the preferred option."24 Circular A-4 makes clear that an analysis that, as here, does not discuss the incremental costs and benefits of alternatives is not adequate.25 [EPA-HQ-OAR-2019-0055-1256-A1, pp. 5 - 6]

Since the Supreme Court held in State Farm that the National Highway Traffic Administration ("NHTSA") had acted arbitrarily and capriciously by refusing to consider a "technological alternative within the ambit of [its] existing standards,"26 the U.S. Court of Appeals for the D.C. Circuit has repeatedly held that rational decisionmaking by administrative agencies requires consideration of "significant alternatives to the course it ultimately chooses."27 Agencies must consider "obvious" alternatives and provide an explanation when alternatives are rejected.28 And in explaining why alternatives are rejected, agencies may not "put a thumb on the scale by undervaluing the benefits and overvaluing the costs of more stringent standards."29 EPA's failure to fully evaluate alternatives is particularly egregious here, where proposing and evaluating alternative performance standards with varying levels of stringency is such a "familiar tool in [EPA]'s tool kit."30 [EPA-HQ-OAR-2019-0055-1256-A1, p. 6]

With a full analysis of only Option 1,31 and only a limited analysis of the less-stringent Option 232 and the more stringent alternative, EPA cannot rationally determine which of its proposed regulatory options is the most reasonable approach. At a minimum, EPA should fully evaluate the costs and benefits of Option 2 and the more stringent alternative described in the Proposed Rule, as Circular A-4 recommends.33 The agency should presumptively select the alternative that maximizes net benefits,34 and, if it does not select that policy, should offer an adequate justification for rejecting the alternative that is most economically efficient.35 [EPA-HQ-OAR-2019-0055-1256-A1, p. 6]

31. Even EPA's analysis of Option 1 is oddly incomplete, as it acknowledges that there are differences between the scenario modeled in the DRIA and the standards presented in the rule. See 85 Fed. Reg. at 17,589 n.781("As noted in draft RIA Chapter 5.4, there are differences between the standards, emission warranty, and useful life provisions of proposed Option 1 presented in Sections III and IV and those included in our control case scenario modeled for the air quality analysis (as noted in Section VII, due to resource constraints we only conducted air quality modeling for the proposed Option 1). As detailed in draft RIA Chapter 8, estimates of health benefits are based on our air quality analysis, and thus differences between proposed Option 1 and modeling are not reflected in the benefits analysis.") (emphasis added).

32. See id.

33. CIRCULAR A-4, supra note 23, at 16.

34. Exec. Order 12,866, supra note 21, §1(a) ("[A]gencies should select those approaches that maximize net benefits…, unless a statute requires another regulatory approach.").

35. EPA, Guidelines for Preparing Economic Analyses 1-4 (2010) ("The policy that maximizes net benefits is considered the most efficient").

EPA's draft regulatory impact analysis ("RIA" or "DRIA") indicates the strong potential that more stringent regulations would produce additional social benefits.36 It is important that EPA consider more stringent alternatives than Option 1 in order to identify whether the agency is leaving incremental net benefits on the table.37 In the Proposed Rule, EPA introduces one more stringent alternative, but cannot determine whether it is technologically feasible and therefore does not analyze its costs and benefits.38 Instead of ending its analysis there, EPA should consider other options in between Option 1 and the more stringent alternative. Showing whether a more stringent alternative would, or would not, produce higher net benefits would improve the overall transparency of the rulemaking process. Further, consideration of more than three alternatives would be consistent with past regulatory practice, such as the SAFE Rule's contemplation of eight different regulatory options.39 [EPA-HQ-OAR-2019-0055-1256-A1, p. 7]

36. See, e.g., 85 Fed. Reg. at 17,438 (a more stringent alternative will reduce NOx emissions by 44% by 2040, as compared to 55% over the same period for a less stringent alternative); Id. at 17,589 (net present benefits at a 3% discount rate of $61-220 billion for more stringent alternative versus $41-170 billion for less stringent alternative).

37. See CIRCULAR A-4, supra note 23, at 16.

38. 85 Fed. Reg. at 17,589 n.782.

39. 83 Fed. Reg. 42,986, 42,990 (Aug. 24, 2018) (proposing 8 different regulatory alternatives).

EPA's distributional and employment analyses of the regulation further support the consideration of strong alternatives. Specifically, EPA's current analysis demonstrates that strong regulation as represented by Option 1 improves the air quality faced by disadvantaged groups in the most polluted areas. A wider distributional analysis as recommended in Section II, infra, combined with a wider set of alternatives would allow EPA to analyze the extent to which stronger regulations could benefit disadvantaged communities already suffering from high levels of air pollution. Moreover, since the current analysis finds little to no negative impact on sales or employment from Option 1,40 the additional benefits of further reducing air pollution could substantially increase the incremental net benefits of more stringent regulation. Indeed, the effect of building and installing the necessary technologies for vehicle improvements required by more stringent standards could even lead to higher levels of employment at the manufacturing level and overall. Ideally, EPA should quantify the overall employment impacts along with the wider set of alternatives to determine the direction and magnitude of these employment effects, though EPA could consider making these points qualitatively at a minimum. [EPA-HQ-OAR-2019-0055-1256-A1, p. 7]

40. See sections V & VI, infra.

Organization: *International Council on Clean Transportation (ICCT)*

EPA has proposed two options for setting new engine standards for nitrogen oxides. Since Option 2 does not require maximum technically feasible emission reductions, we recommend this option be dismissed. Option 1 is technically feasible and is cost effective, with a benefit-to-cost ratio of 5.3. Option 1 comes closer to realizing technology potential, but it would allow for a transition period from MY2027-2030 where higher emitting engines continue to be sold. Strengthening Option 1 to align with state HDV omnibus rules for model year 2027 would avoid this delay in NOx emission benefits. We disagree with concerns expressed by the Engine Manufacturers Association with respect to cost, warranty and compliance margin. We view this engine standard as the most important opportunity EPA has under this Administration to address transportation-related environmental injustice and exposure disparities in disadvantaged communities across this country. We find that adopting and strengthening EPA's Option 1 will especially benefit communities exposed to high traffic emissions near major roadways across all states. [EPA-HQ-OAR-2019-0055-1211-A1, p. 3] RECOMMENDATION: We recommend EPA dismiss Option 2 and adopt a strengthened Option 1 to fully align with a 90% NOx reduction in MY2027. [EPA-HQ-OAR-2019-0055-1211-A1, p. 3]

Combination long-haul trucks, combination short-haul trucks, and single unit short-haul trucks account for nearly 89% of estimated NOx reductions in 2035 under EPA's Option 1. Combination long-haul trucks alone account for more than 60% of the NOx benefits of EPA's Option 1. Our analysis of the spatial patterns of vehicle emissions shows that securing these benefits would especially reduce the impacts of transportation pollution in communities living near interstates and highways. Since each of these segments have distinct spatial patterns, any relaxation of requirements for any one of these modes in EPA’s final rule – such as for combination unit long-haul vehicles - would be expected to generate an unequal and disproportionate burden in disadvantaged communities. [EPA-HQ-OAR-2019-0055-1211-A1, p. 6]

Full alignment of federal NOx requirements with state HDV Omnibus rules and the adoption of GHG requirements consistent with 100% zero-emission HDV sales by 2035 could avoid $5.7 billion in health damages annually in 2035, 46% of which would benefit communities that meet at least one of the criteria defined by the EPA Climate and Environmental Justice Screening Tool. This estimate represents a 15% increase in NOx benefits in 2035 compared with Option 1 benefits in this year. These additional benefits are approximately evenly divided among combination unit long-haul trucks, combination unit short-haul trucks, and single-unit short-haul trucks. These combined emission reductions would benefit communities across the U.S., especially population centers and areas near major freight corridors. The most populous states such as California and Texas have among the highest potential health benefits in absolute terms. Yet multiple states are projected to experience outsized benefits compared to their population, such as Pennsylvania, Delaware and several states in the Midwest and South, including Indiana, Arkansas, Ohio, Missouri, North Carolina, and Georgia. [EPA-HQ-OAR-2019-0055-1211-A1, p. 6]

Technical feasibility. EPA has provided a comprehensive analysis of the feasibility of the proposed Option 1 NOx standards in its technical support document. Its conclusion is clear: The standards proposed for all three test cycles for large, long-life engines are feasible. [EPA-HQ-OAR-2019-0055-1211-A1, p. 7]

The Stage 3 SWRI test programs sponsored by California Air Resources Board (CARB) and EPA demonstrate that the NOx standards can be met with available technologies, using optimized SCR aftertreatment and cylinder deactivation. EPA has provided proof of feasibility that goes far beyond that provided in previous rulemakings, such as the rulemaking for the current 2010 NOx and PM standards. The remaining issues are proof of emission durability beyond 600,000 miles to the full useful life of 800,000 miles, with early results showing NOx levels below the standard at 800,000 miles, and the emission margin available to assure production and in-use compliance. [EPA-HQ-OAR-2019-0055-1211-A1, p. 8]

Regarding durability beyond 600,000 miles, an EPA test program with aftertreatment aged to full useful life is nearing completion. The proposed 2031 NOx standard for 800,000 miles is double the mid-life standard at 435,000 miles, providing room for emission deterioration as the engine ages. Projecting the data at 600,000 miles to full useful life, EPA shows that the demonstration engine will emit below the full life standard on the FTP (Figure 3-16, EPA TSD). The projected 2031 NOx emissions for the new, low-load cycle are about 25% below the proposed mid-life standard and more than 50% below the proposed full life standard (Figure 3-17, EPA TSD), suggesting adequate margin for compliance. The EPA figures are reproduced below. [EPA-HQ-OAR-2019-0055-1211-A1, p. 8]

Manufacturers also claim that the Stage 3 aged-engine does not consistently meet the in-use NOx standards when laboratory tested on "road-cycles" that mimic real-world operation. [EPA-HQ-OAR-2019-0055-1211-A1, p. 10]

Based on a thorough review of the EPA proposal and the most recent findings from SwRI, we draw the following conclusions:

• The research conducted by SwRI provides compelling evidence of the feasibility of achieving the EPA proposed Option 1 FTP emission standards for both MY2027-2030 and MY2031 and later models. Compliance margins are sufficient for Option 1, especially given the 8 years remaining to increase margins if needed.

• Adoption of a supplemental low-load cycle with corresponding emission standards is necessary to assure emission reductions during urban driving, and the SwRI data show emission levels well below the proposed standards throughout the full useful life.

• A highly capable single research group with limited funding and only a few years working with a suitable technology package (Stage 3) was able to demonstrate emission levels at or below the EPA's most stringent proposed standards. Based on its results, SwRI has pointed out additional possible advancements that could result in further reduction in NOx emissions, such as catalyst size increases and reformulations, and control algorithm improvements. EPA has provided proof of feasibility that goes far beyond that provided in previous rulemakings, such as the rulemaking for the current 2010 NOx and PM standards. It is reasonable to conclude that the industry as a group, with their enormously greater resources and 8 more years of time before the final standards and useful life go into effect, will be able to produce durable engines with even lower emissions and greater emission compliance margins both in certification and in-use over the future extended UL.

• By law, heavy-duty engine standards must reflect "the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which standards apply". The technologies developed by SwRI and their demonstrated ultra-low NOx emissions are consistent with the technology-forcing statutory requirements and the EPA proposed Option 1 standards for 2027 and 2031. The statutory requirement would not be met if EPA chose to adopt less stringent standards. [EPA-HQ-OAR-2019-0055-1211-A1, p. 11]

The NOx benefits of EPA's proposal are determined, in part, by the degree of future ZEV uptake. To understand this relationship, we modeled several scenarios for ZEV uptake under both proposed Options for new NOx engine standards. More detailed modeling methodology and scenario descriptions can be found in Attachment 1 – Appendix A. [EPA-HQ-OAR-2019-0055-1211-A1, p. 15]

We find that EPA Option 1 and 2 standards combined with faster future ZEV deployment can lower overall NOx emissions, as shown in Table 3. We estimate EPA's Option 1 would reduce NOx emissions by 0.4 to 5.1 million tonnes over the period 2027–2050 compared to EPA 2010 standards. Strengthening EPA's Option 1 to align with state HDV Omnibus rules would increase NOx emission benefits by an additional 0.1- 0.5 million tonnes over this period. We find the greatest NOx reductions - up to 5.9 million tonnes - would come from both accelerating ZEV uptake in line with the most ambitious Alternative 3 scenario and adopting requirements similar to state HDV Omnibus rules (compared to Baseline EPA 2010). [EPA-HQ-OAR-2019-0055-1211-A1, p. 15]

The Clean Air Act requires heavy-duty standards for new engines to "reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year which the standards apply, …" (section 202(a)(3)(A) of the Act). EPA has clearly stated its finding (see quote from the NPRM in the section of our comments on Technical Feasibility) that Option 1 standards are technically feasible within the lead time provided. The Option 2 proposed NOx standards are much less stringent than Option 1: 1.4 times higher in 2027 and 2.5 times higher in 2031+ for the FTP cycle. Clearly Option 2 standards do not meet the Clean Air Act definition of the greatest degree of emission reduction achievable, given EPA's definitive statement that Option 1 standards are technically feasible. [EPA-HQ-OAR-2019-0055-1211-A1, p. 16]

Under a scenario in which 17 states adopt and implement an Advanced Clean Trucks Rule, we estimate that Option 2 standards will result in nearly 1 million additional cumulative tonnes of NOx emitted from 2027 through 2050, compared to Option 1, as shown in Figure 7. EPA estimates Option 1 will deliver over 1.25 million additional tons of NOx reductions when compared with Option 2 (Table 5-34, EPA RIA). The additional health damages of Option 2 are $9–$16 billion (Table 8-8, EPA RIA). [EPA-HQ-OAR-2019-0055-1211-A1, pp. 16 - 17]

Less stringent emission standards proposed in Option 2 higher proposed FEL caps explain the emission differences with Option 1. For example, the highest allowed 2031+ FTP FEL in Option 2 is 150 mg NOx for HHD engines —3 times the proposed standard of 50 mg and only 25 percent below the current standard. By comparison, the highest 2031+ HHD FTP FEL under Option 1 is 70 mg at full useful life—only 1.75 times the proposed standard of 40 mg and less than half the Option 2 FEL. These are shown in the table below. [EPA-HQ-OAR-2019-0055-1211-A1, p. 17]

One implication of low FELs under Option 2 is many trucks that operate in or near disadvantaged communities could be allowed to achieve only a 25% NOx reduction compared to the current standards. Residents living in these communities are already exposed to a higher air pollution burden. The results of EPA's analysis indicates that environmental justice would not be served by adoption of Option 2, with its laxer standards, much higher FELs, shorter useful life and a warranty more than 40% shorter in mileage coverage and 50% lower in years compared to Option 1. [EPA-HQ-OAR-2019-0055-1211-A1, p. 18]

For the above reasons, ICCT recommends Option 2 be dismissed. [EPA-HQ-OAR-2019-0055-1211-A1, p. 18]

Combination long-haul trucks, combination short-haul trucks, and single unit short-haul trucks are the segments with the greatest potential NOx emissions reductions from strengthened policies. [EPA-HQ-OAR-2019-0055-1211-A1, p. 52]

These 3 segments account in our modeling for nearly 89% of estimated NOx reductions in 2035, assuming adoption of EPA's Option 1. (Table 18) These segments also account for more than 85% of the additional NOx reduction potential we assume is still available. Compared to EPA's Option 1, a strategy to reduce HDV tailpipe NOx emissions by at least 90% via NOx engine standards and increase ZEV uptake in line with reaching 100% zero-emission HDV sales by 2035 via GHG standards, could reduce NOx emissions across all vehicle segments by 46,400 tonnes in 2035—a 15% increase in NOx benefits compared to EPA Option 1. [EPA-HQ-OAR-2019-0055-1211-A1, p. 52]

EPA's Option 1 will especially benefit communities living near interstates and highways in all states. More than 60% of the NOx benefits of EPA's Option 1 are expected to come from combination long-haul trucks; these emission reductions are estimated to be concentrated on major roads across the U.S. Securing these benefits is especially important to reduce the impacts of transportation pollution in communities living near interstates and highways (Figure 15). EPA's Option 1 would also significantly reduce emissions from combination unit short-haul and single unit short-haul trucks; the latter are especially concentrated in densely populated areas. [EPA-HQ-OAR-2019-0055-1211-A1, p. 52.]

Adopting requirements similar to state HDV Omnibus rules and accelerating ZEV uptake would further benefit communities all over the U.S., including in densely populated areas and communities near interstates and highways. [EPA-HQ-OAR-2019-0055-1211-A1, p. 54.]

Compared to EPA's Option 1, the additional benefits of EPA action represented by our modeling scenarios Federal omnibus + Alternative 3 are approximately evenly divided among combination unit long-haul trucks, combination unit short-haul trucks, and single-unit short-haul trucks. Since each of these segments have distinct spatial patterns, these combined emission reductions would benefit communities across the U.S., especially population centers and areas near major freight corridors (Figure 16). [EPA-HQ-OAR-2019-0055-1211-A1, p. 54.]

We analyzed health benefits at a census tract level for communities meeting select environmental justice criteria versus all others. The definitions of these groups of census tracts are mostly based on criteria in EPA's Climate and Environmental Justice Screening tool83:

1. Disadvantaged: Communities designated as disadvantaged are considered overburdened both in terms of environmental or climate indicators and underserved socioeconomically. This definition is not limited to impacts from transportation;

2. High diesel particulate exposure (diesel PM): Communities at or above the 90th percentile for diesel particulate matter exposure, or the top 10% that are adversely impacted by diesel particulate matter exposure in the U.S., and above the threshold for socioeconomic indicators;

3. High traffic (traffic): Communities at or above the 90th percentile for traffic proximity and volume and above the threshold for socioeconomic indicators;

4. High ambient PM2.5 exposure (PM): Communities at or above the 90th percentile for PM2.5 in the air on an annual average basis and above the threshold for socioeconomic indicators;

5. High rates of air pollution related diseases (disease): Communities at or above the 90th percentile for asthma OR diabetes OR heart disease OR low life expectancy and above the threshold for socioeconomic indicators;

6. High proportion of low-income households (income): Communities at or above the 65th percentile for low income versus all others. Low income is defined as ‘Percent of a census tract's population in households where household income is at or below 200% of the Federal poverty level’;

7. High proportion of people of color (POC): Communities at or above the 65th percentile for percent people of color, people of color defined as Latinos of any race and any non-Latino, nonwhite people;

8. Meets any criteria (any): Communities that meet any of the criteria above. This group represents 47.3% of total population in 48 states and the District of Columbia as shown in Table 19. [EPA-HQ-OAR-2019-0055-1211-A1, pp. 54 - 55]

> 83. Methodology. Climate and Economic Justice Screening Tool. https://screeningtool.geoplatform.gov/en/methodology

Nearly half of the health benefits of aligning federal NOx engine standards with state Omnibus rules and accelerating ZEV uptake would occur in EJ communities. [EPA-HQ-OAR-2019-0055-1211-A1, p. 55]

Our modeling results show that a scenario represented by Federal omnibus + Alternative 3 could avoid an additional $753 million in health damages annually in 2035 compared to EPA’s Option 1; 47% of these benefits ($350 million) are projected to occur in communities that meet at least one of the selected environmental justice criteria, which represent over 150 million people. Communities with high proportions of people of color and low-income households, two of the most populous groups we identified, are projected to benefit the most from accelerating ZEV uptake, followed by disadvantaged communities and those that experience high rates of air pollution related disease. Those that experience high rates of air pollution related disease are also the group that experience the largest benefits relative to their population, benefitting 13% more than average on a per-capita basis. [EPA-HQ-OAR-2019-0055-1211-A1, pp. 55 - 56]

EPA's Option 1 will benefit communities in all states; adopting requirements similar to the scenario represented by Federal omnibus + Alternative 3 would further increase benefits by approximately 15% across U.S. states. [EPA-HQ-OAR-2019-0055-1211-A1, p. 57.]

The most populous states, such as California and Texas have among the highest potential health benefits in absolute terms from heavy-duty vehicle emission regulations. Yet multiple states are projected to experience outsized benefits compared to their population, such as Pennsylvania and Delaware, as well as Midwest and Southern states, including Indiana, Arkansas, Ohio, Missouri, North Carolina, and Georgia. [EPA-HQ-OAR-2019-0055-1211-A1, p. 57.]

Organization: *International Union, United Automobile, Aerospace & International Union, United Automobile, Aerospace & Agricultural Implement Workers of America - UAW Region 1A*

Commercial vehicle manufacturers are committed to partnering with EPA and other stakeholders to further reduce emissions from heavy-duty trucks without diverting resources necessary to foster a phased transition to ZEVs. **We urge you to work with them – not against them – to finalize a cost-effective rule that will further reduce emissions, protect American jobs, and result in cleaner air and healthier communities for all.** [EPA-HQ-OAR-2019-0055-1062-A1, p.2]

Please do not discount the concerns expressed by commercial vehicle manufacturers. The economy of Michigan – indeed, the entire country – is dependent on their continued growth, research, and reinvestment as we collectively work toward a cleaner environment. [EPA-HQ-OAR-2019-0055-1062-A1, p.2]

Organization: *International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)*

The heavy-duty vehicle industry is complex and crafting new regulations on nitrogen oxides (NOx) and other pollutants for medium and heavy-duty engines and vehicles is an extremely arduous task for a variety of reasons. For instance, unlike CAFE and GHG (greenhouse gas) regulations, NOx reductions do not provide a financial benefit to purchasers through improved fuel efficiency. Despite this additional challenge, we know from experience that it is possible to craft a regulation that sets reasonable standards while promoting good jobs and protecting public health and the environment. Striking this careful balance will be difficult and the challenge it presents should not be understated. We stand ready to work with the EPA and all other stakeholders on developing standards that are good for working people and our environment. [EPA-HQ-OAR-2019-0055-1138-A1, p.1]

We are urging the EPA to reject Option 1 and to develop a final rule that is workable, cost-effective, and minimizes the disruptions in truck production levels that jeopardize good paying manufacturing jobs that benefit all Americans. Proposed Option 1 raises major concerns about feasibility, costs, job impacts, unintended consequences, and lack regulatory certainty. The industry has demonstrated its commitment to producing more efficient vehicles and investing in a zero-emission future, but policies designed with flawed assumptions could inadvertently set back those goals while doing significant harm to workers and the economy. Option 2 sets ambitious targets for the industry that lowers the heavy-duty NOx standard by 75% and is better suited to serve as the basis for crafting final regulations with the understanding that modifications will be needed as final rules are crafted. [EPA-HQ-OAR-2019-0055-1138-A1, p.1]

Over the last decade, UAW members have played a vital role in reaching a hard-fought consensus among a wide variety of stakeholders to significantly reduce both heavy-duty and passenger vehicle emissions. We hope that the EPA will pursue a final rule based on a similar consensus-driven process that incorporates input from a variety of stakeholders. In this, we encourage all stakeholders to be transparent and keep an open mind as all will need to compromise to reach a consensus. A standard that does not have buy-in from major stakeholders makes it even more likely that standard will be held up in the courts and politicized, potentially creating significant uncertainty and delaying progress. We proudly worked with other stakeholders to contribute to rulemaking for Phase 2 GHG reduction and fuel efficiency targets. We again urge the EPA to pursue a consensus-driven process and promulgate rules that reduce NOx and harmful pollutants, are compatible with Phase 2 requirements, and establish regulatory clarity and stability for the truck manufacturing industry. This rulemaking process should avoid extended political or legal battles that create uncertainty, which discourage investment and harm workers in the industry. [EPA-HQ-OAR-2019-0055-1138-A1, pp.2-3]

Organization: *King County, Washington County Executive*

The final rule should strengthen EPA's proposed Option 1 to set the expectation that at least 50 percent of sales should be zero-emission by 2030, and to put the United States on track for all truck sales to be zero-emission by 2035, in order to support the science-based targets to reduce global warming. As we advance our goals to transition to zero-emission trucks as quickly as possible, EPA must ensure the remaining new diesel truck purchases operate as cleanly as possible to protect public health, especially in our most overburdened communities. [EPA-HQ-OAR-2019-0055-1188-A2, p.2]

It is critical that EPA's truck rule:

- Provides pollution reduction that is at least as protective as the reductions that are codified in California's recent Heavy-Duty Omnibus Rule. This means, at a minimum, EPA should meet or exceed California's Heavy-Duty Omnibus program by setting a standard that achieves a greater than 90 percent reduction in NOx emissions by 2027. [EPA-HQ-OAR-2019-0055-1188-A2, p.2]
- Builds on the successes of the Advanced Clean Trucks (ACT) rule adopted by six states and sets the expectation that at least 50 percent of new truck sales should be zero-emission by 2030, putting the United States on track for all new truck sales to be zero-emission by 2035. [EPA-HQ-OAR-2019-0055-1188-A2, p.2]
- Offers a unified national program that will provide needed equity and ensure cleaner air for all communities. [EPA-HQ-OAR-2019-0055-1188-A2, p.2]

Organization: *Labor Network for Sustainability (LNS)*

Specifically, LNS recommends the following actions:

- EPA must not leave emission reductions and requirements to future rule and should transition to zero-emission trucks and buses by setting stringent emission standards and zero-emission-vehicle sales mandates now.
- EPA should require that all new trucks have zero emissions beginning in 2035 and retire all combustion trucks before 2045. [EPA-HQ-OAR-2019-0055-1257-A1, p.15]

Organization: *Lion Electric Co. USA Inc. (Lion)*

Lion appreciates the EPA's efforts in estimating the costs and benefits for multiple proposed options for lowering NOx and GHG emissions starting in Model Year 2027. This gives stakeholders a clear picture of how each option might affect air quality, health, and fleets. After reviewing the proposed data, Lion supports several aspects of Option 1, which offers the most stringent nitrogen oxide (NOx) and greenhouse gas (GHG) emission reductions of the two options presented. We believe that the EPA should take most of the actionable steps presented in Option 1 to urgently address the need for strong emission controls. However, we encourage the EPA to consider some flexibility in implementation to accommodate smaller fleets, which might struggle to meet these proposed regulations without adequate incentives and guidance. [EPA-HQ-OAR-2019-0055-1151-A2, p. 1]

Organization: *Maine Department of Environmental Protection (Department)*

The Department would first like to commend EPA's efforts to strengthen criteria pollutant emission standards for heavy-duty engines for the first time in almost 20 years. [EPA-HQ-OAR-2019-0055-1288-A1, p.1]

In-use testing data suggest that real-world NOx emissions are higher than modeled estimates, underscoring the need to achieve substantial NOx emission reductions from the heavy-duty diesel truck sector.7 [EPA-HQ-OAR-2019-0055-1288-A1, p.4]

> 7 Tan, et al., "On-Board Sensor-Based NOx Emissions from Heavy-Duty Diesel Vehicles," Environmental Science and Technology, 53: 5504-5511 (2019).

In Maine, heavy-duty on-road vehicles account for 28 percent of mobile source NOx emissions, exceeded only by the on-road (non-diesel) light duty vehicles as shown in Figure 4. In the absence of stringent new engine NOx standards, emissions from heavy-duty vehicles will only increase in future years as truck vehicle miles traveled (VMT) grows. The Federal Highway Administration (FHWA) projects that HDV VMT will increase by approximately 20 percent over the next 25 years, as shown in Figure 5. This growth in VMT, if not counteracted by increased stringency of new engine emissions standards, will result in significantly increased heavy-duty truck emissions. [EPA-HQ-OAR-2019-0055-1288-A1,pp.4-5]

Additional NOx reductions from heavy-duty vehicles are critical for addressing public health and environmental concerns not only in Maine, but throughout the country. Given this, the Department strongly recommends the adoption of heavy-duty NOx emission limits that are consistent with those in the CARB Heavy-Duty Omnibus Regulation. More specifically, Maine supports the adoption of a 0.020 gram NOx engine standard in 2027 at intermediate useful life and a 0.035 gram NOx standard at full useful life as specified in the Omnibus Regulation. The heavy-duty NOx limits and useful life requirements established in the Omnibus Regulation have been thoroughly vetted, and there is a range of data from CARB, EPA, and other research programs supporting the feasibility of introducing a 0.020 gram NOx standard at intermediate useful life in 2027. 9,1011,12,13,14 [EPA-HQ-OAR-2019-0055-1288-A1, p.6]

EPA’s Proposed Option 1 Should be Revised to Provide Additional Technologically-Feasible and Cost-Effective Emission Reductions. Once fully implemented, Option 1, which phases in a 35 mg/bhp-hr NOx limit beginning with model year 2027 and a more stringent 20 mg/bhp-hr beginning with model year 2031, will reduce heavy-duty vehicle NOx emission by 90% in comparison with the 2001 (current) standards. While this represents a significant improvement over the current standards, Option 1 unfortunately fails to fully capitalize on recent technological advancements for both internal combustion engines and zero emission vehicle (ZEV) technology. [EPA-HQ-OAR-2019-0055-1288-A1, p.6]

EPA's Proposed Option 2. The Department is strongly opposed to Option 2 in EPA's proposal. Technical analyses demonstrate that substantially more stringent NOx controls are feasible and cost-effective for model year 2027 and later heavy-duty engines and vehicles than would be required under this option. Certification data from current model year engines show that mass NOx emissions from some engines are close to the level proposed for the Option 2 FTP and SET NOx standards for model year 2027 and later engines.19,20,21 The standards proposed for Option 2 would only require minor calibration adjustments and minimal hardware modification. Further, EPA's own analysis found that Option 2 is less cost-effective than Option 1. Option 2 will not deliver the needed emissions reductions in Overburdened Communities or provide sufficient assistance to states in attaining the ozone NAAQS and would leave substantial and cost-effective NOx reductions on the table. [EPA-HQ-OAR-2019-0055-1288-A1, p.8]

> 21 DDC's 0.06 13L Executive Order: 2019 DETROIT DIESEL CORPORATION HHDD A-290-0168-1 (ca.gov).)

While the Department recognizes that NOx reductions are EPA's top priority for this rule, the proposed updates can provide benefits in the form of increased fuel efficiency and reduced fuel consumption, thereby setting the stage for a more ambitious rule to be implemented as soon as MY2030. [EPA-HQ-OAR-2019-0055-1288-A1, p.8]

In summary, EPA should finalize a stringent and technology forcing rule in accordance with Section 202(a)(3)(A) of the Clean Air Act23 that will reduce heavy-duty vehicle emissions by at least 90 percent and implement other key requirements to make sure these reductions will continue to be realized over the full useful life of vehicles, beginning not later than model year 2027. [EPA-HQ-OAR-2019-0055-1288-A1, p.9]

> 23 CAA Section 202(a)(3)(A): NOx emission standards for HD trucks are to "reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy and safety factors associated with the application of such technology."

Organization: *Manufacturers of Emission Controls Association (MECA)*

Technology commercialization has a long cycle, including design, testing, vehicle integration and real-world deployment across many trucks in the field to make sure systems are reliable and durable. This cycle is why long-term regulatory certainty and stringent standards are a critical signal to industry to begin making investments and collaborating with their suppliers of technologies that will be needed in the future. MECA members have been engaged in developing a large portfolio of technology options that can be installed on a vehicle to optimize the lowest

NOx and CO2 emissions. MECA supports standards founded on technologically feasible and cost-effective solutions that allow communities to meet their air quality goals. In 2013, SwRI was granted a contract to demonstrate the technical feasibility for achieving a 90% reduction in NOx emissions below current standards while not negatively impacting CO2, N2O, methane, ammonia and other criteria pollutants including PM. This demonstration program has evolved and grown through EPA's support and continues to yield results to this day. [EPA-HQ-OAR-2019-0055-1320-A1, p.4]

MECA supports EPA's proposed phased-in implementation dates beginning with MY 2027 and fully phased in by MY 2031, as these align with CARB's second phases of the Omnibus Regulation. The initial implementation starting with MY 2027 coincides with the final step in the Heavy-Duty GHG Phase 2 standards. Aligning criteria and GHG standard implementation dates enables optimization of NOx and CO2 emission reductions from engines and aftertreatment simultaneously. This alignment is the most cost-effective approach for engine manufacturers and suppliers as many technologies described below offer simultaneous and synergistic reductions in both NOx and CO2. [EPA-HQ-OAR-2019-0055-1320-A1, p.4]

Based on the technical work of Manufacturers of Emission Controls Association (MECA), it is estimated that a 90% reduction in NOx emissions from these mobile sources (to a rate of 0.02 g/bhp-hr) is both technically feasible and cost effective adding only 1% to 1.6% to the cost of a model year (MY) 2027 Class 8 truck. See 'STATEMENT OF THE MANUFACTURERS OF EMISSION CONTROLS ASSOCIATION ON THE U.S. ENVIRONMENTAL PROTECTION AGENCY'S ADVANCED NOTICE OF PROPOSED RULEMAKING: CONTROL OF AIR POLLUTION FROM NEW MOTOR VEHICLES: HEAVY-DUTY ENGINE STANDARDS' February 20, 2020, EPA-HQ-OAR-2019-0055-0365. According to MECA's estimate of a cost benefit of $1,000-$5,000 per ton of NOx reduced is cost effective relative to most remaining stationary controls. [EPA-HQ-OAR-2019-0055-1272-A1, p.6]

MECA supports regulations that set fuel neutral standards for vehicles and engines. [EPA-HQ-OAR-2019-0055-1320-A1, p.31]

In conclusion, MECA appreciates EPA's work in demonstrating pathways to meeting future heavy-duty low-NOx engine standards. We strongly support a modified Proposed Option 1 as outlined in our comments above. Proposed Option 1 along with our suggested modifications would result in cost effective air quality benefits for millions of Americans living in ozone and PM nonattainment areas. MECA believes that the standards in Proposed Option 1 are technically achievable for implementation by 2027 and stepping down, as proposed, in 2031. The test program at Southwest Research Institute has shown that engines equipped with advanced technologies paired with state-of-the-art aftertreatment systems can achieve levels consistent with the standards in Proposed Option 1 over certification cycles. Off-cycle testing over low load operation using real-world duty cycles, is showing that comfortable compliance margins exist in all three compliance bins. Furthermore, it has been demonstrated that low load and idle standards can be tightened to levels below those proposed.. [EPA-HQ-OAR-2019-0055-1320-A1, p.34]

Organization: *Mass Comment Campaign sponsored by Environment America (11,390)*

We write to urge you to create the strongest possible limits on heavy-duty vehicle pollution. [EPA-HQ-OAR-2019-0055-1611-A1, p.1]

Transportation is the largest source of global warming pollution in the United States. To avoid the worst impacts of climate change, we need to zero out emissions from transportation by 2050. That means replacing trucks, buses, freight vehicles, delivery vans, and any other vehicle that relies on fossil fuels with a clean, electric version. [EPA-HQ-OAR-2019-0055-1611-A1, p.1]

EPA should strengthen this rule to meet two key goals. 1) reduce deadly NOx pollution 90% by 2027, and 2) put our heavy duty vehicle fleet on a clear path to 100% zero-emission all-electric vehicles by 2035. [EPA-HQ-OAR-2019-0055-1611-A1, p.1]

Proposed Option 1 for NOx pollution is a start, but it must be strengthened to protect public health. Environment America supports requiring a 90% reduction in nitrogen oxide pollution from trucks and buses by 2027. Reducing smog and soot-causing NOx pollution from trucks will improve air quality and save lives. [EPA-HQ-OAR-2019-0055-1611-A1, p.1]

Cleaner trucks can deliver cleaner air. EPA should go back to the drawing board to create a rule that will accelerate the market for electric trucks and produce significant reductions in the pollution that harms our health and climate. [EPA-HQ-OAR-2019-0055-1611-A1,p.2]

Organization: *Mass Comment Campaign sponsored by Moms Clean Air Force and Arizona Climate Action Coalition (198)*

To protect our children's health and future as well as our large Senior citizen population, and to address environmental injustice, EPA needs to immediately take urgent and bolder action. The proposed rule for heavy duty vehicle pollution should be strengthened. On the NOx portion of the rule, Option 1 is a start but is insufficient. It would result in higher emissions of smog and soot-causing NOx pollution than California's Heavy Duty Omnibus rule, which should be the baseline for smog and particulate matter reduction goals. [EPA-HQ-OAR-2019-0055-1192-A1, pp.2-3]

Organization: *Mass Comment Campaign sponsored by Sierra Club (11,740)*

Sierra Club collected 11,740 public comments urging the Environmental Protection Agency to pass a rule for curbing emissions from heavy duty trucks by setting a smog reduction target that makes engines 90% cleaner by 2027 and a greenhouse gas target that puts zero-emission trucks on the road to protect our climate and the health of our communities. [EPA-HQ-OAR-2019-0055-1620-A1, p.1]

To deliver on the Biden Administration's environmental justice, public health, and climate goals, the EPA must finalize a strong heavy-duty vehicle rule this year that sets us on a rapid path to cleaning up and electrifying the most polluting vehicles on the roads: our trucks and buses. [EPA-HQ-OAR-2019-0055-1620-A1, p.1]

We appreciate President Biden making clean transportation a day-one priority and EPA moving quickly to propose long-overdue regulations to clean up pollution from dirty heavy-duty vehicles. However, our communities and our planet require bolder standards that will reduce health-harming smog and cut greenhouse gas emissions to a degree that matches the urgency of the climate and public health crisis. That can only happen if both the NOx standard and the greenhouse gas standards are strong enough to make trucks cleaner while moving quickly to get zero-emission trucks on the road. [EPA-HQ-OAR-2019-0055-1620-A1, p.1]

Moreover, the standards must not be undermined by giveaways to an industry that would allow manufacturers to keep producing fossil fuel trucks far into the next decade. EPA must strengthen the final rule by accelerating the trajectory towards zero-emission vehicles and eliminating the various credit giveaways that significantly erode the standard. [EPA-HQ-OAR-2019-0055-1620-A1, p.1]

Thank you for initiating action on this important issue. We look forward to EPA once again responding to health, equity, and environmental advocates, and particularly frontline communities bearing the brunt of the toxic diesel pollution, by making much-needed improvements to this rule. [EPA-HQ-OAR-2019-0055-1620-A1, p.1]

Organization: *Mass Comment Campaign sponsored by Union of Concerned Scientists - 2 (959)*

We, the undersigned scientists, researchers, health professionals, economists, engineers, and planners respectfully submit this comment in support of the strongest possible heavy-duty nitrogen oxides (NOx) truck pollution standards. [EPA-HQ-OAR-2019-0055-1608-A1, p.1]

First, the rule falls short in setting us on a clear path to all electric trucks. The science and technology, as well as the urgency of this health crisis, are clear on this front: zero-emission trucks are available today and must be the number one priority.2 This has also long been an ask of environmental justice communities across the country. Electric trucks are here today, and new research demonstrates that by 2027, pollution-free trucks will be cost competitive with diesel over the lifetime of the vehicle.3 At the same time, as this rule acts to accelerate the deployment of electric trucks, it must reduce emissions from diesel trucks to the maximum extent possible. The EPA's own data shows that the strong diesel tailpipe standards adopted by states are achievable—the EPA must strengthen its 2027 targets to be at least as protective as these state rules. [EPA-HQ-OAR-2019-0055-1608-A1, p.1]

2 https://ucsusa.org/resources/electrify-trucks
3 https://www.edf.org/media/new-study-finds-rapidly-declining-costs-zero-emitting-freight-trucks-and-buses

The urgency of this issue demands a strong response. For far too long, truck pollution has been devastating the health of communities across the country.5 The solutions are here—and we urge the EPA to stand up to this moment and enact the strongest truck pollution standards in history. [EPA-HQ-OAR-2019-0055-1608-A1, p.2]

Organization: *Mass Comment Campaign sponsoring organization unknown - 3 (605)*

As a supporter of the League of Conservation Voters I am urging the EPA to adopt the strongest rules possible on heavy-duty vehicles and accelerate toward 100% electrification of new big rigs, trucks, and buses by 2035. [EPA-HQ-OAR-2019-0055-1606, p.1]

I'm doing my part. I drive an all electric car, have rooftop solar, compost garbage. But we will not be able to tackle the climate crisis without cleaner trucks on our roads. The transportation sector is our countrys largest source of carbon pollution, with heavy-duty vehicles contributing substantially to our total greenhouse gas emissions. In order to curb our emissions by at least 50% by 2030, a pace that scientists agree is necessary to mitigate the worst effects of climate change, we must adopt the strongest possible standards for trucks and buses. This will promote a transition to fully electric vehicles and slow the sale of dirty diesel trucks over the next decade. [EPA-HQ-OAR-2019-0055-1606, p.1]

We have the technology and the ability to cut pollution and save money today. At this moment, electric trucks and buses are already capable of supporting the majority of the United States freight, delivery, and transit uses and needs and there are dozens more zero-emission vehicles coming to the market within a couple of years, which are projected to be cheaper to own and operate than their combustion engine counterparts within five years. [EPA-HQ-OAR-2019-0055-1606, p.1]

Time is running out fast. We need this administration to get serious about climate change by setting the strongest standards possible because many lives depend on it. While Option 1 is a start, the standards should at least align with Californias recent clean trucks rule. These standards must reduce deadly pollution from nitrogen oxides by 90% by 2027, and put our nations buses and trucks on a clear path to 100% zero-emission all-electric vehicles by 2035 [EPA-HQ-OAR-2019-0055-1606, p.1]

Organization: *Mass Comment Campaign sponsoring organization unknown - 7 (4,668)*

I urge the EPA to set the strongest standards possible to reduce greenhouse gas and nitrogen oxides emissions from medium- and heavy-duty trucks manufactured in 2027 and beyond:

--At a minimum, adopt Option 1 for nitrogen oxide standards to meet the EPAs obligations under the Clean Air Act and to bring the most benefit to our health, air, and environment.

--Adopt more stringent greenhouse gas standards which are necessary to achieve the nations goal of a 60% reduction in new vehicle greenhouse gas emissions by 2030.

--Eliminate credits and loopholes that would severely limit the effectiveness of these standards. [EPA-HQ-OAR-2019-0055-1604]

Organization: *Mass Comment Campaign sponsoring organization unknown - 10 (1,087)*

As a person of faith and conscience, I recognize that we have a moral obligation to cut carbon emissions and other pollutants that harm our health and our communities. People of all faiths and spiritual traditions share a common bond to care for their neighbor and this planet we all share. [EPA-HQ-OAR-2019-0055-1602]

To stop climate change and ensure our national security we MUST get off fossil fuels! It's NOT an option! That means electric vehicles. Again, NOT an option. This is a NECESSITY. Stop denying the obvious, bite the bullet, do what needs to be done, and switch to electric vehicles! Don't waste our time and money on fossil fuel vehicles when you KNOW our use of fossil fuels has a very limited shelf life at this point (because if they don't, WE DO). [EPA-HQ-OAR-2019-0055-1602]

President Biden's larger climate agenda cannot be accomplished without a strong rule on America's 13 million heavy-duty trucks and buses. I view much of this rule as a good starting point, but I would like to see it strengthened given the urgency of the climate crisis, the rapid advancement of EV technology and the increasingly understood human health impacts, particularly on communities of color and our most vulnerable residents. [EPA-HQ-OAR-2019-0055-1602]

The EPA should use these standards to rapidly accelerate the transition to electric trucks and put our nation's medium- and heavy-duty vehicles on a pathway to 100% zero-emission electric vehicles by 2035. [EPA-HQ-OAR-2019-0055-1602]

I urge the EPA to set the strongest standards possible recognizing the health and well being of current and future generations who will be impacted by this rule. [EPA-HQ-OAR-2019-0055-1602]

It is essential that the final standards reduce dangerous NOx pollution 90% by 2027 and put our buses and trucks on a clear path to 100% zero-emission all-electric vehicles by 2035. [EPA-HQ-OAR-2019-0055-1602]

Organization: *Mass Comment Campaign sponsoring organization unknown – 11 (1,027)*

As EPA develops the final rule on tailpipe emissions from heavy-duty trucks as part of the "Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards," I urge you to amend the proposed rule so that it reduces emissions, protects American jobs, and results in cleaner air and healthier communities for all. [EPA-HQ-OAR-2019-0055-1598]

Specifically, EPA must reject Option 1 and revise Option 2. An overly aggressive standard will result in higher costs for fleet operators, jeopardize thousands of good-paying jobs, slow the transition to zero- emission vehicles, and fail to achieve the desired environmental benefits. [EPA-HQ-OAR-2019-0055-1598]

Instead, EPA must recognize the importance of a single-step, national rule. To be effective, the final rule must be:

- Customer-acceptable. If truck owners and operators choose not to purchase new trucks due to cost or reliability concerns that result from a bad federal rule, older trucks will stay on the roads longer and environment goals will not be achieved.

- Economically viable. If the final rule results in higher costs for manufacturers and fleet owners, manufacturers and small business owners may have no choice but to lay off workers and eliminate jobs.

- Environmentally beneficial. An unworkable rule will delay fleet turnover and prevent environmental progress, creating greater harm in communities most at-risk for high air pollution.

- A bridge to a zero-emissions future. The final rule must not prevent continued progress toward zero- emission commercial vehicles by forcing excessive, costly redesigns of traditional combustion engines at the expense of investments in the research and development of zero-emission vehicles. [EPA-HQ-OAR-2019-0055-1598]

I hope you will listen to this feedback and develop a final rule that meets the needs of the industry, the environment, and the economy. [EPA-HQ-OAR-2019-0055-1598]

Organization: *Mayor, City of Albuquerque, NM et al.*

The heavy-duty rule must accelerate deployment of zero-emission vehicles in order to safeguard clean air and improve public health in our communities. Our residents cannot wait a decade for cleaner air. Thankfully, due to strong state and local action, the medium- and heavy-duty zero-emission truck market is growing. Today there are over 100 commercially available models of zero-emissions medium- and heavy-duty trucks and buses, with additional models expected to enter into production this year.2 EPA has a critical role to play to ensure that zero-emission technologies for all types of trucks and buses are deployed in all communities. [EPA-HQ-OAR-2019-0055-1316-A1, p.1]

2 https://californiahvip.org/vehicles

The final rule should strengthen EPA's proposed Option 1 to set the expectation that at least 50 percent of sales should be zero-emission by 2030, and put the United States on track for all truck sales to be zero-emission by 2035. This target is aligned with the Moving Forward Network's3 zero-emission truck recommendation, which was recently outlined in a letter [https://www.movingforwardnetwork.com/wp-content/uploads/2021/11/MFN-Zero-Emission-in-Freight-Letter-to-EPA-10_26_21.pdf] urging the EPA to prioritize environmental justice by aggressively advancing zero-emission technology and solutions across the freight sector. As we advance our goals to transition to zero-emission trucks as quickly as possible, EPA must ensure the remaining new diesel truck purchases operate as cleanly as possible to protect public health, especially in our most overburdened communities. [EPA-HQ-OAR-2019-0055-1316-A1, pp.2-3]

3 The Moving Forward Network (MFN) is a national network of organizations that center grassroots, frontline knowledge, expertise, and engagement with the communities across

the US that bear negative impacts of the global freight transportation system. In collaboration with allies and partners, MFN identifies local solutions that call for community, industry, labor, government, and political action that advances equity, environmental justice, and a zero-emissions focused just transition.

It is critical that EPA's truck rule:

- Provides pollution reduction that is at least as protective as the reductions that are codified in California's recent Heavy-Duty Omnibus Rule. This means, at a minimum, EPA should meet or exceed California's Heavy-Duty Omnibus program by setting a standard that achieves a greater than 90% reduction in NOx emissions by 2027.
- Builds on the successes of the Advanced Clean Trucks (ACT) rule adopted by six states, and sets the expectation that at least 50 percent of new truck sales should be zero-emission by 2030, putting the United States on track for all new truck sales to be zero-emission by 2035.
- Offers a unified national program that will provide needed equity and ensure cleaner air for all communities. [EPA-HQ-OAR-2019-0055-1316-A1, p.3]

Electric vehicle technology is here and it will be cost competitive with diesel over the lifetime of the vehicles starting in 2027. Zero-emission trucks produce substantial savings, even more than zero-emission cars due to reduced fuel and maintenance costs and more predictable maintenance schedules.5 Municipalities will benefit from transitioning to zero-emission truck fleets based on truck operation and maintenance cost savings and from local job growth through the deployment of charging infrastructure. [EPA-HQ-OAR-2019-0055-1316-A1, p.2]

5 https://eta-publications.lbl.gov/sites/default/files/updated_5_final_ehdv_report_033121.pdf

Organization: *Minnesota Pollution Control Agency (MPCA)*

Minnesota needs NOx reductions from heavy-duty vehicles to reduce ozone formation, address disparities in air pollution exposure, and improve overall air quality and related health outcomes. Future NOx reductions from heavy-duty trucks will help Minnesota reach its Regional Haze targets and reduce ozone transport. [EPA-HQ-OAR-2019-0055-1044-A1, p. 1]

Minnesota has sought and achieved significant NOx reductions at industrial and electric generation sources, but needs federal leadership to achieve on-road transportation reductions. The MPCA looks to EPA to develop appropriately protective policies for heavy duty vehicle-related pollution. [EPA-HQ-OAR-2019-0055-1044-A1, p. 2]

The MPCA requests that EPA adopt Option 1 as an appropriately stringent and feasible standard. Given the range of available pollution control technologies and the emission reductions already achieved without regulation, the MPCA feels that EPA has an obligation to pursue standards at the highest stringency within the proposed range. As described in the proposed rulemaking, ninety percent reductions by Model Year 2027 (MY27) are technically and economically feasible. Delaying or weakening the standards would allow excess NOx emissions, which would subsequently negatively impact human health. [EPA-HQ-OAR-2019-0055-1044-A1, p. 2]

Organization: *Motor & Equipment Manufacturers Association (MEMA)*

EPA's last update of the HD NOx standards was nearly 20 years ago. EPA's proposed rulemaking presents a unique opportunity for further reductions in HD NOx emissions standards and sets a signal for best-in-class emission control technologies that will ultimately preserve U.S. competitiveness globally. The U.S. has a strong history of being a global leader in HD emissions technology innovation and is uniquely positioned to continue to lead the world in HD advanced fuel efficiency and emissions-reducing technologies. A comprehensive federal HD NOx rulemaking will advance U.S. innovation in these technologies. Maintaining stringency in the HD NOx standards will improve the environment and support a strong motor vehicle supplier manufacturing sector, which is the largest sector of manufacturing jobs in the U.S. and is critical for the U.S. to secure its position as the global technology leader.[EPA-HQ-OAR-2019-0055-1322-A1, p. 3]

MEMA supports new HD NOx emissions standards and additional test cycles that will drive additional NOx emissions reductions on the road and encourages best-in-class technologies. These standards should be performance-based and technology-neutral and the test-cycles should reflect real use of vehicles. Both the standards and test cycles should enable multiple technology paths to achieve compliance. [EPA-HQ-OAR-2019-0055-1322-A1, p. 3]

MEMA supports a NOx rule that relies on certification cycles and in-use tests that better represent real-world use and will encourage best-in-class technology adoption while effectively meeting lower NOx emissions requirements. [EPA-HQ-OAR-2019-0055-1322-A1, p. 3]

MEMA opposes the Alternative Option as it could harm suppliers, places unnecessary strain on the industry, and lacks research and technical support as already indicated by EPA. [EPA-HQ-OAR-2019-0055-1322-A1, p. 3]

MEMA supports an NOx rule that relies on certification cycles and in-use tests that better represent real-world use and will encourage best-in-class technology adoption while effectively meeting lower NOx emissions requirements. MEMA supports Option 1 with important modifications to warranty time period/mileage, covered warranty parts, and FUL. MEMA believes the technology exists to comply with this emissions standard and it also has a two-step approach to implementation. The staged approach will be beneficial and allow time to gain significant additional data as we approach the second step in 2031. [EPA-HQ-OAR-2019-0055-1322-A1, p. 4]

MEMA opposes the Alternative Option as it could harm suppliers, places unnecessary strain on the industry, and lacks research and technical support. [EPA-HQ-OAR-2019-0055-1322-A1, p. 5]

EPA suggests that new emission control technologies (i.e., not based on CDA and a dual SCR) would be needed to meet the Alternative NOx standards for Heavy HDEs. MEMA opposes the

Alternative Option and agrees with EPA that not enough data and research has been done to support this Option. [EPA-HQ-OAR-2019-0055-1322-A1, p. 5]

Regarding EPA's request for comments on whether technologies are available that would enable a PM standard lower than 5 mg/bhp-hr, MEMA does not yet view this as a workable option due to the lack of specific supporting data and the fact that it is even more stringent than the CARB Omnibus. Further testing is required to determine if current technologies are capable of reaching this lower PM standard. [EPA-HQ-OAR-2019-0055-1322-A1, p. 5]

MEMA supports a NOx rule that relies on certification cycles and in-use tests that better represent real-world use and will encourage best-in-class technology adoption while effectively meeting lower NOx emissions requirements. Therefore, MEMA recommends Option 1 with modifications to warranty time period/mileage, covered warranty parts, and full useful life as well as modified standards for vocational vehicles. [EPA-HQ-OAR-2019-0055-1322-A1, p. 9]

Organization: *Moving Forward Network (MFN)*

The following section describes how ZE truck requirements must be properly incorporated into the final rule to meet the Clean Air Act's technology forcing mandate for criteria pollution standards. EPA's failure to require this available cleaner technology is unconscionable given the impacts in freight-adjacent communities and will actually undermine combustion engine emission reductions. [EPA-HQ-OAR-2019-0055-1277-A1, p. 16]

EPA's proposed NOx emission standards violate the law and must be fixed in this rulemaking. The Clean Air Act requires EPA to adopt "technology-forcing" standards to regulate emissions of NOx, carbon monoxide, hydrocarbons, and particulate matter from heavy-duty vehicles and engines. 42 U.S.C. § 7521(a)(3). As courts have explained, EPA cannot satisfy this mandate by adopting status quo standards. EPA's NOx emission standards should "project future advances in pollution control capability . . . [and] press for development and application of improved technology rather than be limited by that which exists today." Nat. Res. Def. Council v. EPA, 655 F.2d 318, 328 (D.C. Cir.1981) (quoting S.Rep. No. 91-1196, at 24 (1970) S.Rep. No. 91-1196, at 24 (1970)). The Act contemplates strong action to "force substantial change on the status quo on an industry-wide basis." Cent. Valley Chrysler-Jeep, Inc. v. Goldstene, 529 F. Supp. 2d 1151, 1178 (E.D. Cal. 2007), as corrected (Mar. 26, 2008). Specifically, the Act mandates that these regulations "shall contain standards which reflect the greatest degree of emission reduction achievable" by applying technology which "the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology." Id. § 7521(a)(3)(A)(i). Importantly, the "overriding goal" of section 202 is addressing air quality and public health. Husqvarna AB v. EPA, 254 F.3d 195, 200 (D.C. Cir. 2001).65 "[T]he other listed considerations, while significant, are subordinate to that goal." Id. [EPA-HQ-OAR-2019-0055-1277-A1, pp. 16 - 17]

65 While Husqvarna AB relates to Section 213 of the Clean Air Act, the court's conclusions are just as relevant here because the statutory text of Section 213 and

> Section 202 are almost identical, and the court itself relied on cases interpreting the Section 202 language to support its analysis. Husqvarna AB, 254 F.3d at 201.

In light of this clear directive, EPA must revise its proposed NOx standards because neither Option 1 nor Option 2 come close to meeting this statutory obligation. MFN urges EPA to adopt a zero-emission NOx standard that appropriately reflects not merely the current and projected availability of zero-emission heavyduty truck technology across the United States, but a level of transition to ZE truck technologies that is technologically feasible. The Clean Air Act plainly authorizes EPA to propose stringent NOx emission standards that rely on a reasoned prediction that a particular control technology “will be available for the model year to which such standards apply,” so long as this prediction is supported by substantial evidence. Id. at 331-32; 42 U.S.C. § 7521(a)(3). EPA can demonstrate the reasonableness of its technology projections where it “answers any theoretical objections to the technology, identifies the major steps necessary for development of the technology, and gives plausible reasons for its belief that the industry will be able to solve these problems in the time remaining.” Nat. Res. Def. Council, 655 F.2d at 331-32. Critically, EPA is “not required to rebut all speculation that unspecified factors may hinder ‘real world’ emission control.” Nat. Res. Def. Council v. Thomas, 805 F.2d 410, 434 (D.C. Cir. 1986) (quoting id., 655 F.2d at 334). EPA has made such forward-looking predictions that certain technology will be available, and should do so again here. See, e.g., Husqvarna AB, 254 F.3d at 201 (“Substantial evidence . . . supports EPA’s determination that the continued rapid development of engine technologies makes it probable that [specified engine technologies] will enable manufacturers to comply with the emission standards within the phase-in period.”). [EPA-HQ-OAR-2019-0055-1277-A1, p. 17]

If EPA insists on retaining ZE trucks in a vehicle NOx standard,85 EPA must lower the NOx standard to reflect the greatest degree of emission reductions achievable across the entire truck fleet based on the feasibility of widespread transition to ZE trucks. As discussed further below, the current proposed NOx standards, even under the more stringent Option 1, do not reflect the greatest degree of emission reductions achievable even looking only at feasible combustion technologies. The addition of ZE trucks to the compliance average entirely undermines any claim that the standards meet the technology-forcing requirements of the Act. [EPA-HQ-OAR-2019-0055-1277-A1, p. 20]

> 85. EPA's proposed regulations label 40 C.F.R. Part 1036 as standards for heavy-duty "engines," but as EPA clarifies in the preamble, the standards for all regulated pollutants apply to all heavy-duty vehicle types including EVs. See 87 Fed. Reg at 17457- 58.

EPA acknowledges that Option 1 of the proposed Criteria Pollutant Program is the strongest of the two co-proposals it is considering and claims that setting the level of standard outlined in Option 1 would be consistent with the agency’s statutory authority.86 However, even Option 1 contains glaring deficiencies, including failing to match the stringency of state trucks standards in the Heavy-Duty Omnibus (Omnibus) rule, improperly incorporating ZEV, excessive family emission limit (FEL) caps, and enabling false solutions through early crediting. [EPA-HQ-OAR-2019-0055-1277-A1, p. 21]

86. 87 Fed. Reg. at 17436.

Meanwhile, Option 2 is woefully inadequate and does not warrant serious consideration. By EPA's own analysis, "Option 1 may be a more appropriate level of stringency, as it would result in a greater level of achievable emission reduction." Option 2 underperforms on all meaningful public health, environmental, and economic metrics and would be a disaster if adopted. [EPA-HQ-OAR-2019-0055-1277-A1, p. 21]

We request comment, including relevant data and other information, on the feasibility of the implementation model year, numeric levels of the emission standards, and useful life and warranty periods included in the Alternative, or other alternatives outside the range of options covered by the proposed Options 1 and 2 standards." (87 FR 17471) [EPA-HQ-OAR-2019-0055-1277-A1, p. 28]

Data from the CARB Phase 3 and EPA Phase 3 RW projects at SwRI are the most thorough assessments of the technical capability to reduce diesel emissions in the 2027 timeframe.118 Additional projects, including those mentioned above, extend some of that capability or provide manufacturers with alternate strategies to achieve levels of compliance that are at least as stringent as those in the Omnibus rule. [EPA-HQ-OAR-2019-0055-1277-A1, p. 28]

118. See, Sharp, C.A., Further development and validation of technologies to lower oxides of nitrogen emissions from heavy-duty vehicles: Low NOx demonstration program – Stage 3. Final report, prepared for California Air Resources Board, April 16, 2021; Sharp, C.A., "Update on continuing progress towards 2027 heavy-duty low NOx targets," presented to the 32nd CRC real world emissions workshop, March 14, 2022; and Draft RIA Tables 3-3 through 3-9.

Organization: *National Association of Chemical Distributors (NACD)*

NACD appreciates the EPA's transparency in sharing the two options the agency is considering for implementation of this rule. Giving stakeholders this information in proposed rules allows impacted entities to understand better the EPA's thought process and tailor comments to what is being considered. [EPA-HQ-OAR-2019-0055-1279-A1, p. 3]

With that said, while NACD is concerned with both proposed options for reasons stated above, we find the second option to be much more realistic and palatable for the chemical distribution industry. First, by taking a one-step approach, the EPA builds in necessary flexibility with this rulemaking. Emission regulation in the vehicle industry has proven to be extremely complicated, fast moving, and unpredictable. By only taking a one-step approach, the EPA would allow more information to be gathered prior to future rulemakings. The two-step approach taken in option 1 removes this flexibility until 2031. There may be unforeseen developments that require a shift from what is expected, making regulating in multiple steps farther into the future less practical. A pertinent example of this is the reconsideration of Phase 2 greenhouse gas emissions (GHG) in this rule as discussed below. [EPA-HQ-OAR-2019-0055-1279-A1, p. 3 - 4]

Furthermore, when assessing the impacts of both options, there are insignificant differences for roughly the first decade after implementation. According to EPA estimates, there would be a difference of only six percent in the reduction of NOx in calendar year 2036 between the two options. While this deviation widens as option 1 does not have any more requirements after Model Year (MY) 2027, the EPA can add a second step after option 1 is implemented in a separate rulemaking that would have the availability of more present data and stakeholder input from additional comment processes. This additional step would undoubtedly close that gap and may even lead to more NOx reduction than option 1 in the long term if technology and consumer behavior points to more stringent measures being possible. [EPA-HQ-OAR-2019-0055-1279-A1, p. 4]

Organization: *National Association of Clean Air Agencies (NACAA)*

On multiple occasions over the past seven years NACAA has urged EPA to set cleaner standards for nitrogen oxide (NOx) emissions from heavy-duty (HD) trucks. We are pleased that the agency has now reached the milestone of putting forth a proposal for public comment. [EPA-HQ-OAR-2019-0055-1232-A1, p. 1]

As we have described to EPA over the years, NACAA strongly supports establishment of a stringent, technology-forcing federal rule that will reduce HD truck NOx emissions by at least 90 percent and implement other key requirements to ensure these reductions will continue to be realized over the full useful life of vehicles beginning not later than with model year (MY) 2027. [EPA-HQ-OAR-2019-0055-1232-A1, p. 1]

We have consistently highlighted the importance of such a federal program adopted no later than 2022 so implementation will begin no later than MY 2027. We are now at the “final hour.” If EPA does not finalize a rule before the end of this calendar year it will not take effect with MY 2027. With clean air and public health on the line, our nation cannot afford to sacrifice another year of NOx reductions from this significant source of emissions. [EPA-HQ-OAR-2019-0055-1232-A1, p. 1]

It has been over 21 years since EPA last set federal NOx emission standards for HD trucks. Given the interstate nature of trucking – both cross-border operations and downwind atmospheric transport – federal standards are necessary to achieve the broad NOx reductions needed across the nation. Over the past two decades, technological advances to reduce HD truck NOx emissions have soared as has the potential for even further advances, but EPA failed to take regulatory advantage of the opportunities these advances afford. At the same time, emission limits for most other major NOx sources have been ratcheted down repeatedly. HD trucks will continue to be one of the largest contributors to the national mobile source NOx inventory in 2028 without additional regulations to reduce emissions. [EPA-HQ-OAR-2019-0055-1232-A1, p. 2]

The Puget Sound Clean Air Agency (PSCAA) in Seattle, WA seeks a technology-forcing standard to reduce NOx emission from HD trucks due to several ozone-related concerns. Reducing NOx would help reduce exposure in the near-road communities, which are disproportionately affected by air pollution, and also assist in addressing ozone-impacted areas.

More important to PSCAA, however, are the proposed rule's requirements for better longevity of the PM controls' performance under more-varied duty cycles and for longer warranty requirements. Combined, these would help alleviate the expensive breakdowns that reports say are leading truck owners to tamper with the PM controls on trucks used in drayage service, where the typical duty cycle for these older trucks includes low speeds, lots of queueing and short trips that clog diesel particulate filters (DPF) designed for long-haul, high-temperature operation. Over the last decade, EPA has provided millions of dollars in Diesel Emission Reduction Act (DERA) grants nationwide to replace older diesel drayage trucks with newer, 2007+ trucks to reduce their emissions in, and adverse impacts on, port-adjacent communities; the U.S. Department of Transportation has also provided millions in funding under the Congestion Mitigation and Air Quality Improvement (CMAQ) program for the same purpose. PSCAA and local ports received over $10M of these grant funds and replaced more than 400 pre-2007 drayage trucks with 2007+ and 2010+ trucks, reducing PM2.5 by 17 tons per year and NOx by 390 tons per year. Unfortunately, the sustainability of these and other DERA- and CMAQ-funded emission reductions is in question due to the poor performance of the PM emissions controls under these duty cycles and the risk of tampering to disable the controls as a result. Had the PM standards for 2007+ engines included the more-diverse testing scenarios for meeting emissions standards and the longer warranties that are in EPA's current proposal, the public's investments would have resulted in more durable emission reductions and health benefits. [EPA-HQ-OAR-2019-0055-1232-A1, p. 5]

When EPA finalizes a HD truck rule it will mark the first time since 2001 that EPA has taken action to cut harmful NOx emissions from these vehicles. There is a clear and compelling public health need for much tighter restrictions on HD truck NOx emissions. In the past 20 years, technical capacity to reduce these emissions has flourished and tremendous experience has been gained; the opportunity to require and achieve deeper reductions in NOx emissions across the many operations is enormous. [EPA-HQ-OAR-2019-0055-1232-A1, p. 8]

In August 24, 2020, written comments to CARB,16 NACAA supported the state's proposed Heavy-Duty Omnibus Regulation, which was adopted on August 27, 2020, and ultimately finalized in December 2021, after an extensive public process that was preceded by several years of informal stakeholder input.17 The research supporting CARB's Omnibus – including research jointly funded by EPA and the California Air Resources Board and conducted by the Southwest Research Institute (SwRI) – is rigorous and the data and findings solidly supportive of the Omnibus standards. Structurally, EPA's Proposed Option 1 numeric standards are similar to the Omnibus. However, despite the affirmative data and the unyielding nationwide public heath need, the agency's Proposed Option 1 falls far short in some very critical ways, including by failing to align with the Omnibus' on a number of key provisions, including, among others, on the heavy HD NOx emission standard and interim useful life (IUL) in 2027, and by proposing important program elements that lack the stringency of the Omnibus and/or that severely erode the benefits of the numerical standards. Moreover, in some cases, which we discuss below, research and findings that have emerged since adoption of the Omnibus support even more stringent standards and approaches. EPA's Proposed Option 2 conclusively misses the mark and leaves on the table critical tons necessary for attainment, maintenance and the protection of underserved communities while being, by EPA's own analysis, less cost effective. Proposed Option 2 is inherently unacceptable in light of the CAA mandate for maximum feasible stringency in HD standard setting, as evidenced by EPA's proposal of Option 1 as a viable option. [EPA-HQ-OAR-2019-0055-1232-A1, pp. 8 - 9]

17. https://ww2.arb.ca.gov/rulemaking/2020/hdomnibuslownox

Finally, in his August 5, 2021, Executive Order (EO), "Strengthening American Leadership in Clean Cars and Trucks,"18 President Biden, in calling upon EPA to develop this heavy-duty truck rule, states, "Given the significant expertise and historical leadership demonstrated by the State of California with respect to establishing emissions standards for light-, medium-, and heavy-duty vehicles, the Administrator of the EPA shall coordinate the agency's activities pursuant to sections 2 through 4 of this order [including establishing NOx standards for heavy-duty engines and vehicles for 2027 and later] as appropriate and consistent with applicable law, with the State of California as well as other States that are leading the way in reducing vehicle emissions, including by adopting California's standards." [EPA-HQ-OAR-2019-0055-1232-A1, p. 9]

18. https://www.whitehouse.gov/briefing-room/presidential-actions/2021/08/05/executive-order-on-strengthening-american-leadership-in-clean-cars-and-trucks/

We urge EPA to pursue this EO-directed collaboration and coordination with the states, openly and in a manner that will meaningfully contribute to the agency's ultimate decision on the final rule. In the Multi-State Medium- and Heavy-Duty Zero Emissions Vehicle Memorandum of Understanding (MOU) 17 states and the District of Columbia acknowledge the "introduction of low-NOx heavy duty trucks" as essential for reducing harmful emissions of NOx, PM and toxic air contaminants that adversely affect public health.19 This MOU establishes a ZEV sales goal under which at least 30 percent of all medium HD trucks sold in the MOU states by 2030 would be ZEVs. Five states have already individually exercised their right of self-determination under section 177 of the Clean Air Act and joined California with adoption of heavy-duty new vehicle policies.20,21,22,23,24,25 A sixth state has passed enabling legislation26 and others are considering similar bills or have taken public process steps related to regulatory development. States are also demonstrating non-regulatory leadership by taking collaborative action through efforts such as the Regional Electric Vehicle Midwest MOU with five signatories.27 We urge EPA to actively and collaboratively leverage the tremendous expertise, interest and commitment of states toward the most effective final rule in line with these efforts. [EPA-HQ-OAR-2019-0055-1232-A1, p. 9 - 10]

27. https://www.michigan.gov/-/media/Project/Websites/leo/REV_Midwest_MOU_master.pdf?rev=6dd781b5a4eb4551b3b3a5b875d67fb9

EPA includes two options in the proposal, one more stringent than the other. The agency notes that Proposed Option 1, the more stringent of the two, would come with greater public health and environmental benefits; nonetheless, as proposed, this option is insufficient. Proposed Option 2 is wholly unacceptable. NACAA supports modifications that would strengthen the overall stringency of Proposed Option 1 by aligning it with the technology-forcing mandate of the CAA. [EPA-HQ-OAR-2019-0055-1232-A1, p. 10]

When setting federal NOx emission standards for HD trucks, EPA is required, under CAA section 202(a)(3)(A), to reflect “the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy and safety factors associated with the application of such technology.” [emphasis added] [EPA-HQ-OAR-2019-0055-1232-A1, p. 10]

Just because a regulated entity is not already producing, or committing to produce, engines incorporating a particular technology does not mean that the technology does not exist or will not exist by 2027 or that standards based on that technology are not achievable by 2027 – which is over four years from today. EPA must fully comply with this statutory technology-forcing mandate. However, the agency utterly fails to do so in Proposed Option 2 and even in Proposed Option 1. [EPA-HQ-OAR-2019-0055-1232-A1, p. 10]

Although Proposed Option 1 comes closer to meeting this requirement than Proposed Option 2, Proposed Option 1 does not meet the statutory bar. Falling short is insupportable given that there are emission controls that are technologically feasible, commercially available and justified based on benefits relative to costs not only for meeting the Proposed Option 1 emission standards and deadlines, but also for meeting a cleaner 2027 standard – 20 mg/hp-hr – for heavy HD engines, and without the need for the excessive and indefensible flexibilities EPA proposes or on which the agency seeks comment (which NACAA discusses below) and which would seriously erode any emission standards finalized by EPA. Additionally, there has been more than adequate time to prepare for a substantially more rigorous federal standard; EPA and stakeholders have been aware for years that such a standard was necessary and forthcoming. Manufacturers must prepare for these MY 2027 standards across a growing number of states anyway. EPA should be leveraging the early experience with the already-final Omnibus 2024-2026 phase-in as well as the finalized 2027 Omnibus standards to the benefit of the final rule rather than ignoring the engineering and commercialization progress made in order to comply with the Omnibus in California and in other states that have adopted it. [EPA-HQ-OAR-2019-0055-1232-A1, p. 10]

EPA should revise Proposed Option 1 to pull forward to 2027 the 20 mg/hp-hr NOx emission standard for all classes with an IUL standard of 435,000 miles for heavy HD engines. [EPA-HQ-OAR-2019-0055-1232-A1, p. 10]

Importantly, as EPA reports in the NPRM, Proposed Option 1 will result in substantially superior emission, health and monetized benefits than Proposed Option 2. The agency also states, "Given the analysis we present in this proposal, we currently believe that proposed Option 1 may be a more appropriate level of stringency as it would result in a greater level of achievable emission reduction for the model years proposed, which is consistent with EPA's statutory authority under Clean Air Act section 202(a)(3)."28 While NACAA appreciates and agrees with EPA's recognition that the greater stringency of Proposed Option 1 would result in "a greater level of achievable emission reduction," we challenge the agency's statement that this "is consistent with EPA's statutory authority under Clean Air Act section 202(a)(3)." The CAA requires not a greater level of achievable emission reduction but "the greatest degree of emission reduction achievable." [emphasis added] [EPA-HQ-OAR-2019-0055-1232-A1, pp. 10 - 11]

28. Supra note 1, at 17,440

Proposed Option 2, or anything remotely similar, is entirely unacceptable and must be rejected. As discussed above, it has been demonstrated that significantly more rigorous NOx emission standards and other program requirements are feasible and cost effective for 2027 and beyond. The standards in Proposed Option 2 require virtually no effort on the part of manufacturers beyond negligible calibration adjustments and minor hardware modification – nowhere near the technology-forcing standards required by CAA section 202(a)(3)(A). Further, EPA acknowledges in the proposal that Option 2 would deliver inferior emission, health and cost benefits, thus sacrificing emission reductions and health protections sorely needed in areas struggling to attain or maintain health-based NAAQS and overburdened communities. In addition, the flexibilities EPA proposes to offer, or on which it seeks comment, that are excessive and indefensible for Proposed Option 1 are even more unjustified for Proposed Option 2. [EPA-HQ-OAR-2019-0055-1232-A1, p. 11]

Organization: *National Association of Small Trucking Companies (NASTC)*

We are well aware of the tremendous clean-air strides our transportation industry has made over the past 30 years, such as the implementation of low-sulfur fuel, the implementation of ultralow-sulfur fuel, the diminishing of idling time through the use of auxiliary power units (APUs), the implementation of catalytic converters and DEF, and a myriad of fuel efficiency practices in tires and aerodynamics. The costs of reaching these gains have been paid by trucking and, ultimately, by end-users through higher costs and inflated prices. We reject proposed, unrealistic mandates that seek the immediate replacement of fossil fuels. The subsidies for wind, solar, and battery solutions to our energy problems have documented failure after failure. “Green New Deals,” government largesse for electrification and corporate welfare, and empty billion-dollar bullet trains have not and won’t take the place of a free market-based, forward-thinking, ecofriendly evolution into using all power sources to get the job done. [EPA-HQ-OAR-2019-0055-1130-A1, p. 1]

In addition to rectifying the overly aggressive inducement and imbalanced serviceability rules that presently affect commercial motor carriers, there are other important reasons to enact the above and most of the other proposed regulatory reforms in these areas. As NASTC members and other transportation industry commenters in the ANPRM made clear, the present rules, including those relating to inducement and serviceability, cause extensive unpredictability, uncontrollability, and unduly burdensome and economically harmful effects, such as unreasonable costs and delays for truckers and supply chain disruptions for businesses and consumers. [EPA-HQ-OAR-2019-0055-1130-A1, pp. 3 - 4]

The reason for far too many of the consequences suffered under present inducement and serviceability rules is the underlying emissions standards and the highly complex, expensive equipment created in response to the mandates on newer model diesel engines and heavy-duty vehicles. [EPA-HQ-OAR-2019-0055-1130-A1, p. 4]

As welcome as regulatory relief from the status quo is regarding these respects, the underlying proposed NOx and GHG emissions reduction standards in this NPRM will certainly result in OEMs introducing even more complex, expensive diesel engines and associated systems. The mandates on OEMs will surely result in unpredicted, adverse spillover effects on commercial vehicle owners—including even more equipment unreliability, unpredictability, additional uncontrollable expenses, delays keeping truckers from productive use of time and resources, lost business, and sweeping adversity and deprivation visited upon businesses and consumers across the nation. [EPA-HQ-OAR-2019-0055-1130-A1, p. 4]

As welcome as the proposals such as more sensors, monitors, an engine “health” system, in-cab displays, etc. are, each of these novel inventions introduces additional risks of new problems, more tows and repairs, etc. We need the proposed relief just to stay even. [EPA-HQ-OAR-2019-0055-1130-A1, p. 4]

These facts cast the proposed rule as overly ambitious, particularly in light of the significant realities constraining long-haul trucking and the supply chain. These include significantly higher costs on new models, which slows turnover of older trucks, compounded parts (including semiconductor) shortages and the scale of complex technologies’ malfunctions, and throw a green monkey wrench into a highly uncertain economic situation that involves both sky-high inflation and interest rate hikes that may tip the economy into recession. Notably, semiconductor delivery time has more than doubled since the onset of the COVID pandemic and economic whipsaw. It now takes more than 26 weeks—half a 2 year—between chip order and delivery. And semiconductors are in practically every electronic device, from cell phones to toys to computers to automobiles. Thus, the net effects of the rule, under either Option 1 or Option 2, will be to increase costs and headaches for consumers, as well as motor carriers and truckers, and to underachieve on the promised health and environmental goals. [EPA-HQ-OAR-2019-0055-1130-A1, pp. 4 - 5]

2. Ian King, "Wait Times for Chips Grow Modestly in March," Transport Topics, April 5, 2022. https://www.ttnews.com/articles/wait-times-chips-grow-modestly-march

At a minimum, the proposed rule will inconvenience and at most endanger consumers while stressing the already stressed, just-in-time inventory systems and supply chains that most industrial and commercial players depend on. The rule will cause unnecessary harm to our economy in many ways. The EPA's ill-timed regulatory emissions changes come right when businesses, companies, and consumers struggle under 40-year-high inflation; interest rate increases meant to stem inflation but are as likely to overcool the economy; and business sectors including trucking experience an unusually tight labor market. At what point are the cumulative costs—to truck owners, OEMs, customers, and consumers—greater than the estimated benefits? The answer depends on how rosy one's assumptions and choice of facts and data. Let's just say that the underlying assumptions, data, and estimates employed to justify this rulemaking's emissions goals are very much rosier than are NASTC's. [EPA-HQ-OAR-2019-0055-1130-A1, p. 5]

The proposed rule would change from the present 0.2 gram per brake horsepower-hour (PBHPH), the standard as of 2010, to 0.035 gram PBHPH for model years (MY) '27-'30 and then 0.02 gram PBHPH beginning in MY '31 under Option 1 or, alternatively, to 0.05 gram PBHPH starting in MY '27. Both options set extremely ambitious goals for diesel engines in heavy-duty vehicles, such as the power units NASTC members operate in interstate commerce. The more ambitious of the two proposed alternatives is breathtaking—setting a standard an order of magnitude below the current standard. [EPA-HQ-OAR-2019-0055-1130-A1, p. 5]

This rulemaking comes amidst serious challenges detrimentally affecting the trucking sector. Supply chain stresses, component and parts shortages, tight labor markets facing certain motor carriers, and the resulting downstream effects will affect both trucking and the economy at large. Also, war in Ukraine, a lagging pandemic, tensions in China with Taiwan (home to the world's primary maker of semiconductor chips), and other stress points continue to pose problems for the global supply chain, the world economy, and national security. Together, these translate into hurdles to keeping America supplied with everything from consumer goods to manufacturers' raw materials. [EPA-HQ-OAR-2019-0055-1130-A1, pp. 6 - 7]

The COVID-19 pandemic has had a huge impact on supply chains in every industry. In trucking, this includes the global microchip shortage causing American trucking companies extreme hardship because of the unavailability of new vehicles (which makes used vehicles scarcer and more expensive) and replacement parts such as diesel exhaust fluid (DEF) sensors. [EPA-HQ-OAR-2019-0055-1130-A1, p. 7]

Nevertheless, the chip shortage affects both the availability of replacement parts for currently owned commercial vehicles and installation parts for new trucks at manufacturing plants. This is a double-edged sword that threatens the ability of many trucking businesses to remain in business. [EPA-HQ-OAR-2019-0055-1130-A1, p. 7]

The residual adverse effects of the supply chain problems and the dangerous combination of high inflation, rising interest rates (which obviously increase carriers' costs of financing truck purchases), and the probability of a slowed or receding economy will likely cause long-haul trucking to suffer. Adding the sort of ambitious proposed emissions reduction to the emerging combination will only worsen the harmful effects. This rule's emissions goals will thus make life harder on the American people, including the middle class and the environmentalists who would like even stricter emissions standards imposed on large trucks. [EPA-HQ-OAR-2019-0055-1130-A1, p. 7]

It should be remembered that trucking is vital to America's economic health.6 The serious problem at several of our busiest ports of ships waiting months for their freight to be offloaded and then transported by trucks just scratches the surface if sufficient numbers of heavy-duty diesel trucks and truck drivers are not available. Truckers who haul 80 percent of America's freight proved their essential service throughout the COVID pandemic and economic shutdowns, keeping U.S. hospitals, clinics, and medical research labs supplied and groceries, pharmacies, and retail stores and online retailers' warehouses adequately stocked—even as roadside bathrooms and restaurants became inaccessible to truckers. [EPA-HQ-OAR-2019-0055-1130-A1, p. 7]

> 6. "When Trucks Stop, America Stops," American Trucking Associations. https://www.trucking.org/sites/default/files/2019-12/When%20Trucks%20Stop%20America%20Stops.pdf

To everything that trucking touches, this proposed rule will add to its cost to consumers and business customers. Forcing long-haul trucking to bear significantly higher costs for vehicles and maintenance of more complicated engines that have novel emissions technologies, whose kinks are yet to be worked out over several product lifecycles, for instance, necessarily contributes to higher wholesaler, retailer, and consumer prices. Thus, 40-year-high inflation rates should be expected to rise higher still, in part due to this rule. This fact is already recognized by many; the rest of the American public will realize the economic costs this rule places on them very soon and very often.7 [EPA-HQ-OAR-2019-0055-1130-A1, pp. 7 - 8]

> 7. Carrie Sheffield, "Biden is waging a war on truckers and everyone will pay the price," New York Post, March 8, 2022. https://nypost.com/2022/03/08/bidens-war-on-truckers-will-makeeverything- more-expensive/

In closing, it would be most prudent to set any new heavy-duty vehicle and engine standards at more modest, reasonable emissions levels. As the current proposal stands, any cleaner air is likely to be accompanied by unintended economic consequences that could include costing jobs, families' paychecks and means of putting food on the table and gas in the tank, and our country's economic health sufficient to ensure U.S. prosperity and security. Assuming the agency will press forward with new emission reduction standards anyway, the proposed inducement and serviceability reforms would help mitigate current and future problems affecting truckers. [EPA-HQ-OAR-2019-0055-1130-A1, p. 8]

Organization: *National Parks Conservation Association (NPCA)*

The Clean Air Act (CAA) explicitly calls on EPA to promulgate emission standards for motor vehicles that 'cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare.'1 This duty applies to both the traditional air pollutants covered under this rule, (i.e., NOx), as well as to greenhouse gas (GHG) pollutants. As held by the Supreme Court in Massachusetts vs. EPA, CO2 and other GHGs qualify as air pollutants that endanger public welfare under 202(a)(1).2 EPA, thus, has an affirmative duty to develop both NOx and GHG standards for HD vehicles that reflect the 'greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply.'3 While the CAA provides some room for considerations of cost, energy, and safety,4 'it must place primary importance on achieving the greatest degree of emissions reduction.'5 It is through this mandate that we urge EPA to both finalize these heavy-duty vehicle regulations by the end of this calendar year, as well as to strengthen its proposal to achieve the greatest degree of reductions that protect public health and welfare. [EPA-HQ-OAR-2019-0055-1314-A1, pp.1-2]

1 42 U.S.C. 7521(a)(1).

2 See generally, 549 U.S. 497, 531 (2007).

3 42 U.S.C. 7521(a)(3)(A)(i).

4 Id.

5 See Husqvarna AB v. EPA, 254 F.3d 195, at 200 (D.C. Cir. 2001).

While we are pleased to see EPA moving forward with this rulemaking to control one of the largest remaining underregulated sources of air and climate pollution in the US, we believe improvements to EPA's proposal must be made to ensure the final rule is in line with the CAA's mandate that the agency enact the greatest level of emission reductions achievable to protect public health and welfare.35 First and foremost, NPCA urges EPA to move quickly to finalize this rule before the end of the calendar year to guarantee emission reductions can begin at the earliest possible date. We further ask that EPA take steps to improve upon the options provided to achieve greater NOx and GHG reductions. [EPA-HQ-OAR-2019-0055-1314-A1, p.6]

35 See Supra note 1, 3, and 5.

Of the two options proposed by EPA, NPCA supports proceeding with a final rule that is no less stringent than Option 1's 90% reduction in HD NOx emissions by 2031. However, we disagree with EPA's assessment that Option 1 provides the greatest emission reductions feasible for HD engines, and request that EPA strengthen this option to mirror the 2027 deadline for 90% HD NOx reduction, which is already required under the HD omnibus low-NOx rules adopted by

California and a growing number of additional states. We believe the omnibus rule’s 2027 date is technologically and economically feasible, especially when considering recent advances in low NOx engine technologies and the growing pace of zero-emission vehicle (ZEV) technologies, including short and long-haul HD electric vehicle (EV) advancements. Moreover, given this feasibility we believe additional stringency is required under the CAA as it is necessary to protect the health and welfare of the millions of individuals impacted by HD vehicle air pollution. [EPA-HQ-OAR-2019-0055-1314-A1, p.6]

NPCA strongly opposes Option 2, which achieves only a 75% reduction in NOx emissions from HD vehicles and would result in far more emissions compared to Option 1 between 2027-2050. In 2045 alone, Option 2 would result in 120,000 tons more NOx than Option 1 and achieve only a 47% reduction in NOx emissions from the baseline, compared to Option 1’s 61% reduction.36 This option is an obvious giveaway to industry and is inadequate to protect health and welfare. There is more than sufficient lead time to require a more stringent standard than Option 2. Moreover, EPA itself states that Option 1 is technologically feasible, thus it would be arbitrary and capricious and a violation of EPA’s mandate under CAA 202(a)(3)(A)(i) to push through standards that weigh technological obstacles and economic costs to industry over public welfare. [EPA-HQ-OAR-2019-0055-1314-A1, pp.6-7]

36 87 Fed. Reg. at 17,579.

We strongly encourage EPA move quickly to improve upon the NOx reductions proposed under Option 1 and require additional GHG reductions under the Phase II standards. [EPA-HQ-OAR-2019-0055-1314-A1, pp.7-8]

Organization: *National Propane Gas Association (NPGA) and Propane Education & Research Council (PERC)*

In response to the agency’s request for industry feedback, Option 1 of the proposal presents the most advantageous scenario for the propane industry to assist the agency in meeting its GHG and criteria pollutant reduction goals.6 Our research on the currently available propane engine equipment and future progress indicates the timelines suggested under Option 1 are feasible for the industry. Current generation propane engines are certified to the California Optional Low NOx standard,7 which is the same as the 0.02g brake horsepower hour (g/bhp-hr) standard EPA proposed for MY 2031 and later medium and heavy-duty engines. [EPA-HQ-OAR-2019-0055-1263-A1, p.2]

6 Supra note 1, at 17422.

7 Press Release, Power Solutions International, Power Solutions International 8.8-liter Ultra-Low NOx Propane Engine Receives EPA Certification (Oct. 21, 2020), https://psiengines.com/power-solutions-international-8-8-liter-ultra-low-nox-propane-engine-receives-epa-certification/; see also CARB Certifies Next-Generation Propane Engine in Blue Bird School Buses to Lowest NOx in Market, BUSINESSWIRE (Jan. 18, 2022), https://www.businesswire.com/news/home/20220118005991/en/CARB-Certifies-Next-Generation-Propane-Engine-in-Blue-Bird-School-Buses-to-Lowest-NOx-in-Market.

Organization: *National Tribal Air Association (NTAA)*

Option 1 in Section IX clearly is preferable to Option 2 and would more closely reflect that which is as clean as possible with respect to nitrogen oxide emissions reductions. [EPA-HQ-OAR-2019-0055-1382-A2, p.2]

Organization: *Natural Gas Vehicles for America (NGVAmerica)*

We support the setting of more stringent standards but believe that tighter standards do not necessarily translate directly to significant reductions in emissions or cleaner air where it is most needed. Other factors such as vehicle miles traveled, life of vehicles in service, and fleet turnover, and where and how vehicles are deployed are also very important. We encourage EPA to ensure that other programs intended to affect these issues also allow for flexibility and encourage a variety of available, scalable, and cost-effective technologies. [EPA-HQ-OAR-2019-0055-1330-A1, p.2]

NGVAmerica and its members submit the following recommendations for policies and programs that the EPA and other federal agencies can advance to encourage the use of cleaner trucks.

5) Implement proposed new test cycles and conditions for verifying emissions that are performance based and technology neutral; these test cycles should reflect the real use of vehicles. [EPA-HQ-OAR-2019-0055-1330-A1, p.13]

Organization: *Navistar, Inc. (Navistar)*

In particular, we support: Reducing NOx emissions from HDOH vehicles beginning in MY 2027 by setting feasible standards with adequate compliance margins and no negative fuel efficiency impacts; [EPA-HQ-OAR-2019-0055-1318-A1, p. 2]

In particular, we support: A single national rule with the broadest support; [EPA-HQ-OAR-2019-0055-1318-A1, p. 3]

In particular, we support: Alignment with existing OBD, inducements and compliance levels; and [EPA-HQ-OAR-2019-0055-1318-A1, p. 3]

Navistar supports EPA's rulemaking objectives to: "(1) control emissions over a broader range of operating conditions; (2) maintain emissions control over a greater portion of an engine's operational life; and (3) provide manufacturers with flexibilities to meet the proposed standards." 87 Fed. Reg. at 17420-21. However, EPA's analysis, which focuses on whether a specific provision or proposed standard is technically feasible, fails to capture the magnitude and severity of EPA's proposed rule. EPA's proposal represents a fundamental change to all aspects of the HDOH diesel-emissions control program. The proposed rule includes a 90% reduction of the applicable NOx standard, a new certification test procedure for operating modes not previously regulated, a stringent new in-use emissions protocol, significant increases to the mileage over which compliance will be required, and extended useful life and warranty requirements. When taken together, these changes undercut EPA's claims of feasibility. [EPA-HQ-OAR-2019-0055-1318-A1, p. 3]

EPA is requesting comment on whether "a margin between the demonstrated emissions performance and the proposed standards should be included, and, if so, what that value should be." 87 Fed. Reg. at 17471. Navistar, like other manufacturers, designs our engines to perform significantly better than the NOx compliance standards when first sold in order to ensure that the emissions are below the standard throughout useful life, even as the emissions controls deteriorate. Compliance margins, which allow manufacturers to show compliance with increasingly stringent NOx standards, typically range from less than 25 percent to 100 percent of the family emission limit ("FEL"). See 87 Fed. Reg. at 17467. Compliance margins are necessary to account for production, fuel and emissions-testing variabilities, real-world operating conditions, and for the expected emissions deterioration over the proposed lengthened full useful life periods of HDOH engines. [EPA-HQ-OAR-2019-0055-1318-A1, p. 3]

Navistar agrees with EPA's statements on the importance of compliance margins. Specifically, that "manufacturers generally aim to design and build vehicles not only with a sufficient margin to ensure the emissions control technology is meeting the applicable standards throughout the full useful life, but also an additional margin to reflect the fact that not every vehicle manufactured and every vehicle application will perform identically to the laboratory tests." 87 Fed. Reg. at 17564. EPA noted that a compliance margin "is particularly important, and challenging for manufacturers, when new technologies and test procedures are being implemented." Id. (emphasis added). [EPA-HQ-OAR-2019-0055-1318-A1, p. 3]

Navistar supports EPA's adoption of the proposed Option 2 NOx certification standard of 50 mg/hp-hr beginning in MY 2027, provided that in the final rule EPA set higher interim in-use standards for NOx (i.e., using a 2x conformity factor as opposed to a 1.5x conformity factor). This approach is consistent with EPA setting "interim in use standards to account for uncertainties about potential variabilities in performance during the early years of implementing new technology." 87 Fed. Reg. at 17564. It also addresses the compliance margin considerations discussed above. Notably, in the proposed rule, EPA sought comment on "providing engine manufacturers with higher (numerical) standards for an interim period to gain experience with the additional emissions control technologies needed to meet the proposed Heavy HDE standards (and their rates of deterioration) while those technologies are operating in the field." 87 Fed. Reg. at 17563. [EPA-HQ-OAR-2019-0055-1318-A1, p. 4]

Organization: *North Carolina Assembly House of Representatives, John Faircloth*

The commercial vehicle sector literally drives the American economy. As you well know, trucks move first responders on critical missions, deliver all goods and services to consumers, and serve as an integral component to the rebuilding of American infrastructure. The production, sale, service, and operation of these vehicles also provides quality, high-paying jobs to hundreds of thousands of American workers. [EPA-HQ-OAR-2019-0055-2446, p. 1]

As you know, North Carolina – your home state and ours – has the largest concentration of commercial vehicle companies, suppliers and employees in America. Therefore, we are especially interested in the continued success of this critical sector. [EPA-HQ-OAR-2019-0055-2446, p. 1]

That is why we write today: we are concerned that the proposed rule from EPA on tailpipe emissions from heavy-duty trucks as part of the “Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards,” may not be technologically feasiable. That means Original Equipment Makers(OEMs) will spent hundreds of millions of dollars chasing at worst an unattainable standard, and at best a costy standard, rather than strategically deploying critical resources on proven technologies. [EPA-HQ-OAR-2019-0055-2446, p. 1]

We share your commitment to the environment and applaud the accomplishments already achieved by commercial vehicle manufacturers to reduce nitrogen oxides (NOx) emissions from heavy-duty trucks. We support the ongoing efforts for cleaner air and healthier communities for all. But we also recognize the importance of preserving – not effectively dismantling through higher costs and wasted expenditures –this critical industry. [EPA-HQ-OAR-2019-0055-2446, pp. 1 - 2]

We urge you to amend the proposed rule so that it reduces emissions, protects American jobs, and results in cleaner air and healthier communities for all. To be effective, the final rule must be customer-acceptable, economically viable, environmentally beneficial, and a bridge to a zero-emissions future. [EPA-HQ-OAR-2019-0055-2446, p. 2]

Organization: *North Carolina General Assembly, Philip E. Berger*

Simply put, the commercial vehicle sector literally drives the American economy. As you well know, trucks move first responders on critical missions, deliver all goods and services to consumers, and serve as an integral component to the rebuilding of American infrastructure. The production, sale, service, and operation of these vehicles also provides quality, high-paying jobs to hundreds of thousands of American workers. [EPA-HQ-OAR-2019-0055-1105-A1, p. 1]

As you know, North Carolina - your home state and ours - has the largest concentration of commercial vehicle companies, suppliers and employees in America. Therefore, we are especially interested in the continued success of this critical sector. [EPA-HQ-OAR-2019-0055-1105-A1, p. 1]

That is why we write today: we are concerned that the proposed rule from EPA on tailpipe emissions from heavy-duty trucks as part of the "Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards," has not been demonstrated to be technologically feasiable. That means Original Equipment Makers (OEMs) will spent hundreds of millions of dollars chasing at worst an unattainable standard, and at best a costy standard, rather than strategically deploying critical resources on proven technologies. [EPA-HQ-OAR-2019-0055-1105-A1, p. 1]

We are also concerned about the proposed rules attempts to add new certification, warranty and useful life requirements to zero emission vehicles. This will add cost to ZEV and delay their deployment. [EPA-HQ-OAR-2019-0055-1105-A1, p. 1]

We share your commitment to the environment and applaud the accomplishments already achieved by commercial vehicle manufacturers to reduce nitrogen oxides (NOx) emissions from heavy-duty trucks. We support the ongoing efforts for cleaner air and healthier communities for all. But we also recognize the importance of preserving - not effectively dismantling through higher costs and wasted expenditures - this critical industry. [EPA-HQ-OAR-2019-0055-1105-A1, p. 1]

We urge you to amend the proposed rule so that it reduces emissions, protects American jobs, and results in cleaner air and healthier communities for all. To be effective, the final rule must be: Customer-acceptable. If truck owners and operators choose not to purchase new trucks due to cost or reliability concerns that result from a bad federal rule, older trucks will stay on the roads longer and environment goals will not be achieved. [EPA-HQ-OAR-2019-0055-1105-A1, p. 2]

To be effective, the final rule must be: Economically viable. If the final rule results in higher costs for manufacturers and fleet owners, manufacturers and small business owners may have no choice but to lay off workers and eliminate jobs. [EPA-HQ-OAR-2019-0055-1105-A1, p. 2]

To be effective, the final rule must be: Environmentally beneficial. An unworkable rule will delay fleet turnover and prevent environmental progress, creating greater harm in communities most at-risk for high air pollution. [EPA-HQ-OAR-2019-0055-1105-A1, p. 2]

To be effective, the final rule must be: A bridge to a zero-emissions future. The final rule must not prevent continued progress toward zero-emissions commercial vehicles by forcing excessive, costly redesigns of traditional combustion engines at the expense of investments in the research and development of zero emissions vehicles, nor add cost to these new technologies. [EPA-HQ-OAR-2019-0055-1105-A1, p. 2]

Organization: *North Central Texas Council of Governments (NCTCOG)*

EPA’s Option 1 is the preferred proposal that, if achievable, can result in significant emission reductions and health benefits. Option 1 approaches reductions in a faster timeframe and remains sensitive to multi-pollutant impacts, including particulate matter (PM). For the Dallas-Fort Worth (DFW) nonattainment area under two ozone standards (see graph below), emissions reductions need to occur as soon as possible. [EPA-HQ-OAR-2019-0055-1254-A2, p.2]

The North Central Texas Council of Governments (NCTCOG) observes that the proposed and significantly lower NOx engine standards will be difficult to achieve and maintain for diesel engines due to literature suggesting diesel vehicles operating in real world environments with current technologies are unable to meet existing 0.2 g/bhp-hr NOx standards. A 2019 EPA report1 covering the Motor Vehicle Emission Simulator (MOVES) model points out that selective catalyst reduction (SCR) technology, when employed at low speeds in real world operations, did not achieve the NOx reduction that the Model Year 2010 diesel emissions standard intended. When a diesel vehicle is traveling on nonfreeway facilities, such as arterials, collectors, and local streets, the diesel engine is experiencing low temperatures at which current technologies are unable to function properly. In addition, when a diesel vehicle is on the freeway in either recurring congested conditions or within a non-recurring situation (i.e., crash or accident) the diesel engine experiences low temperatures and, therefore, excessive emissions.

The two graphics below from EPA's MOVES model show that when diesel engine equipped trucks are experiencing speeds below approximately 35 mph, their emission rates significantly increase. These conditions are more likely to occur around neighborhoods and heavily populated areas, compounding local health impacts. [EPA-HQ-OAR-2019-0055-1254-A2, pp.2-3]

> 1 U.S. EPA. Updates to MOVES Heavy Duty Running Exhaust Rates: Diesel, Gasoline, and Natural Gas. https://www.epa.gov/sites/production/files/2019-06/documents/04-updates-hd-running-exhaust-rates- 2019-04-10.pdf.

(Please note that the Heavy-Duty Diesel Truck (HDDT) in the graphs below is the Combination Long-Haul Truck (Diesel) vehicle type in the EPA's MOVES model.) Proposed lower standards need to have Original Equipment Manufacturers' (OEM) buy-in to develop appropriate technologies, and the certification rules on these technologies need to take into account real-world operating conditions so outcomes in the lab are reflected in the environment. [EPA-HQ-OAR-2019-0055-1254-A2, p.3]

Organization: *Northeast States for Coordinated Air Use Management (NESCAUM)*

Given the urgent need to reduce NOx emissions from heavy-duty vehicles to improve public health and air quality, we strongly encourage EPA to finalize model year 2027 engine NOx emission limits equivalent to those in the California Air Resources Board (CARB)'s Heavy-Duty Omnibus Regulation. The Clean Air Act requires ozone NAAQS attainment "as expeditiously as practicable," and EPA's proposed Options 1 and 2 do not meet this requirement. Since the introduction of EPA's 2007/2010 heavy-duty engine emissions standards, there have been significant technology advances that provide a foundation for reducing NOx emissions a further 90 percent beyond current standards. To do this, manufacturers can introduce hardware upgrades and new aftertreatment systems that, while significant, build upon the architecture of current emissions control systems. Manufacturers will have ample time to integrate new technologies into heavy-duty engines assuming standards will be implemented for model year 2027 engines and vehicles. [EPA-HQ-OAR-2019-0055-1249-A1, p. 9]

We note that the Clean Air Act is a "technology forcing" statute in which Congress clearly intended to pull technology forward, rather than wait for technology to advance before setting future requirements.26 Even if the technology feasibility record was less robust, and it is already quite robust, it would be contrary to congressional intent to promulgate a NOx limit that aims low. The introduction of readily foreseeable effective and available heavy-duty engine and vehicle pollution reduction technologies capable of achieving a 0.02 gram NOx standard in MY 2027 will assist jurisdictions in the NESCAUM region to reach attainment of the ozone standards. This is the most "expeditiously as practicable" path called for by the Clean Air Act and anything less than this will not be acceptable.[EPA-HQ-OAR-2019-0055-1249-A1, pp. 9 - 10.]

> 26. See Krier. J.E.; Ursin, E., "Pollution and Policy: A Case Essay on California and Federal Experience with Motor Vehicle Air Pollution 1940–1975," University of California Press: Berkeley, CA, 1977, quoting Sen. Edmund Muskie of Maine during debate on 1970 Clean Air Act: The first responsibility of Congress is not the making of

> technological or economic judgments—or even to be limited by what is or appears to be technologically feasible. Our responsibility is to establish what the public interest requires to protect the health of persons. This may mean that people and industries will be asked to do what seems to be impossible at the present time. But if health is to be protected, these challenges must be met.

We strongly oppose Option 2 in EPA's proposal. EPA is proposing to establish an FTP and SET standard of 50 milligrams or 0.05 g/bhp-hr for 2027 and subsequent model year engines. Technical analyses demonstrate that substantially more stringent NOx controls are feasible and cost effective for model year 2027 and subsequent heavy-duty engines and vehicles than would be required under this option. Certification data from current model year engines show that mass NOx emissions from some engines are already close to the level proposed for the Option 2 FTP and SET NOx standards for model year 2027 and later engines.45,46,47 The standards proposed for Option 2 would only require minor calibration adjustments and minimal hardware modification. Further, EPA's own analysis found that Option 2 is less cost effective than Option 1. Option 2 will not deliver the needed emissions reductions in Overburdened Communities or provide sufficient assistance to states in attaining the ozone NAAQS and would leave substantial and cost-effective NOx reductions on the table. [EPA-HQ-OAR-2019-0055-1249-A1, p. 16]

Organization: *NTEA - The Association for the Work Truck Industry*

The EPA recently proposed regulations that could add as much as $40,000 to the cost of a new truck. The proposed regulations aim to further reduce NOx (nitrogen oxides) emissions from heavy duty engines and possibly set more stringent greenhouse gas (GHG) emissions. [EPA-HQ-OAR-2019-0055-1164-A1, p. 2]

Currently, heavy duty truck emissions are 98% cleaner than in 2010 and truck manufacturers are diligently working on the development of ZEV's (zero emission vehicles) that will eliminate tailpipe emissions. [EPA-HQ-OAR-2019-0055-1164-A1, p. 2]

NTEA opposes the EPA's first, and most expensive, option which would take a two-phased approach to reach its goal NOx emissions by 2031. The proposal would increase the regulatory useful life of a truck from 435,000 miles to 800,000 and increase the emissions warranty by 500% from 100,000 to 600,000 miles by 2031. [EPA-HQ-OAR-2019-0055-1164-A1, p. 2]

The second option under consideration is a single-step, 75% reduction in remaining NOx emissions by 2027, with a 38% increase in the useful life period (from 435,000 to 600,000 miles) and a 250% increase in the emission warranty period (from 100,000 to 350,000 miles). [EPA-HQ-OAR-2019-0055-1164-A1, p. 2]

According to engine manufacturers, the California-like option 1 is currently not technologically feasible. [EPA-HQ-OAR-2019-0055-1164-A1, p. 2]

EPA should focus on Option 2, which is challenging, but working with truck chassis and engine manufacturers to further modify the proposal it could form the basis for a workable national rule. [EPA-HQ-OAR-2019-0055-1164-A1, p. 2]

Organization: *Our Children's Trust*

EPA must set stronger NOx, PM, and CO2 standards for heavy duty trucks, and other combustion engines, beginning in model year ("MY") 2027, that tracks with and signals the end of production and sales of the internal combustion engine by 2030. [EPA-HQ-OAR-2019-0055-1317-A1, p.3]

Organization: *Owner-Operator Independent Drivers Association (OOIDA)*

Clean air is a priority for everyone, including truckers, but the technology used in heavy-duty trucks to improve air quality has to be affordable and reliable. Small-business truckers and owner-operators should not be used as trial cases for testing new technology, while getting priced out of business in the process. Unfortunately, each of the proposed timelines to achieve nitrogen oxides (NOx) emissions reductions leave us wondering if the same mistakes from previous rulemakings will be repeated. [EPA-HQ-OAR-2019-0055-1266-A1, p.2]

EPA must consider a more feasible implementation timeline that would provide reliable and affordable heavy-duty vehicles for consumers, particularly small trucking businesses and individual owner-operators. We believe there is a more realistic path forward to reducing commercial vehicle emissions that involves listening to the men and women of the trucking industry. EPA should continue seeking out feedback from these stakeholders as the agency develops any final rule. Truckers know all too well that poorly implemented regulations will result in breakdowns, downtime, and ultimately set back the goal of achieving cleaner air. [EPA-HQ-OAR-2019-0055-1266-A1, p.2]

As currently proposed, both option 1 and option 2 introduced in the NPRM fail also fail to provide adequate production timelines to ensure vehicle reliability for motor carriers. Again, other hurried emissions timelines have led to breakdowns, downtime, and ultimately set back the goal of achieving cleaner air. [EPA-HQ-OAR-2019-0055-1266-A1, p.5]

As an initial matter, EPA is required under the Clean Air Act to consider "cost, energy and safety factors" in proposing standards of emissions for new heavy-duty motor vehicles or engines. As referenced in the NPRM: "Under CAA section 202(a)(3)(A), standards for emissions of NOx, PM, HC, and CO emissions from heavy-duty vehicles and engines are to 'reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology.'" Id. at 17420. [EPA-HQ-OAR-2019-0055-1266-A1, p.8]

42 U.S.C. §7521(a)(2) provides that "[a]ny regulation prescribed under paragraph 1 … shall take effect after such period as the administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period." Id. The "cost of compliance" criteria in 42 U.S.C. §7521(a)(2) apply to users of new motor vehicles or engines, i.e., in addition to manufacturers. See, e.g., American Trucking Associations, Inc. v. E.P.A., 600 F. 3d 624, 629 (D.C. Cir. 2010) (considering national trucking association's challenge to EPA's approval of California emissions rule for failure to give "appropriate consideration to cost of compliance" under 42 U.S.C. §7521(a)(2)). [EPA-HQ-OAR-2019-0055-1266-A1, pp.8-9]

Organization: *Ozone Transport Commission (OTC) and Mid-Atlantic/Northeast Visibility Union (MANE-VU)*

Absent adoption of stringent new engine NOx standards, emissions from HDVs will increase in future years as truck vehicle miles traveled (VMT) grows. The Federal Highway Administration (FHWA) projects that HDV ton miles travelled will increase by more than 30 percent over the next 25 years, as shown in Figure 4. This growth, if not counteracted by increased stringency of new engine emissions standards, will result in a significant increase in heavy-duty truck emissions. [EPA-HQ-OAR-2019-0055-1250-A1, p.7]

We also note that highway trucks often travel long distances and can be registered in states far from where they operate. Therefore, a strong national program is needed to reduce highway truck emissions and maximize public health benefits in the OTR and nationally. [EPA-HQ-OAR-2019-0055-1250-A1, p.7]

Because of the importance of HDVs to air quality and public health in the OTR, in 2019, the OTC requested that EPA make the Cleaner Trucks Initiative one of its most urgent priorities.12 In February of 2020, the OTC and MANE-VU provided comments on EPA's Advanced Notice of Proposed Rulemaking calling on EPA to set emission standards for heavy-duty vehicles at 90 percent below the current standard and to harmonize with the California Omnibus regulation.13 In June of 2020, the OTC sent a letter to EPA calling on the Agency to expeditiously propose a heavy-duty engine NOx standard 90 percent below current levels.14 And in October of 2021, the OTC Mobile Sources Committee wrote to the EPA Administrator and to the Council on Environmental Quality asking EPA to act expeditiously to set stronger standards for heavy-duty engines and vehicles.15 EPA's response to a 2016 petition joined by a number of the OTC states recognized the importance of NOx emission reductions for the OTC region and across the country.16 In addition, EPA's Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles –Phase 2 final regulation also detailed the importance of NOx reductions to the Northeast and Mid-Atlantic regions, stating that: EPA received compelling letters and comments from [NACAA, NESCAUM, OTC, and SCAQMD], explaining the critical and urgent need to reduce NOx emissions that significantly contribute to ozone and fine particulate air quality problems in their represented areas. The comments describe the challenges many areas face in meeting both the 2008 and recently strengthened 2015 ozone NAAQS. These organizations point to the significant contribution of heavy-duty vehicles to NOx emissions in their areas.17 [EPA-HQ-OAR-2019-0055-1250-A1, pp.8-9]

17 81 Fed. Reg. 73478 (Oct. 25, 2016), at 73523.

Emission standards for medium- and heavy-duty trucks were last finalized in 2001, more than 20 years ago. Since then, extensive experience in implementation and monitoring has provided a substantial body of evidence supporting more stringent standards over the Federal Test Procedure (FTP), Supplemental Emissions Test (SET), and Ramped Modal Cycle (RMC). [EPA-HQ-OAR-2019-0055-1250-A1, p.12]

Advanced catalyst formulations, passive and active thermal management strategies, approaches to reducing pumping losses, engine calibration and hardware changes, and electrification are examples of technologies that can be used to substantially reduce NOx emissions while maintaining carbon dioxide emissions at levels required by the Phase 2 heavy-duty greenhouse gas (GHG) standards. Some of these technologies will most likely be explored prior to model year 2027 to meet the EPA Phase 2 GHG and California Air Resources Board (CARB) 2024 Low NOx programs. [EPA-HQ-OAR-2019-0055-1250-A1, p.13]

Heavy-Duty Engine NOx Standards in 2027: Given the urgent need to reduce NOx emissions from heavy-duty vehicles to improve public health and air quality, we strongly encourage EPA to finalize NOx emission limits equivalent to those in the CARB Heavy-Duty Omnibus Regulation. Specifically, OTC supports the adoption of a 0.020 gram NOx engine standard in 2027 at intermediate useful life and a 0.035 gram NOx standard at full useful life, as specified in CARB's Omnibus regulation. There is ample data from CARB, EPA, and other research programs that support the feasibility of introducing a 0.020 gram NOx standard at intermediate useful life in 2027. 22,23,24,25,26,27 [EPA-HQ-OAR-2019-0055-1250-A1, p.13]

Proposed Option 2: We strongly oppose Option 2 in EPA's proposal. Technical analyses demonstrate that substantially more stringent NOx controls are feasible and cost effective for model year 2027 and later heavy-duty engines and vehicles than would be required under this option. Certification data from current model year engines show that mass NOx emissions from some engines are close to the level proposed for the Option 2 FTP and SET NOx standards for model year 2027 and later engines.41,42,43 The standards proposed for Option 2 would only require minor calibration adjustments and minimal hardware modification. Further, EPA's own analysis found that Option 2 is less cost effective than Option 1. Option 2 will not deliver the needed emissions reductions in Overburdened Communities or provide sufficient assistance to states in attaining the ozone NAAQS and would leave substantial and cost-effective NOx reductions on the table. [EPA-HQ-OAR-2019-0055-1250-A1, p.17]

Organization: *PACCAR, Inc (PACCAR)*

In particular, PACCAR agrees with the following aspects of EMA's comments: The feasibility of centering a program around a 0.02 g/bhp-hr FTP/RMC NOx standard (as opposed to a core standard set at or above Option 2-like levels) has not been, and cannot be, established. [EPA-HQ-OAR-2019-0055-1346-A1, p.2]

In particular, PACCAR agrees with the following aspects of EMA's comments: The low-NOx regulations, if centered around a 0.02g/bhp-hr standard, could result in decreased fuel-efficiency, which could threaten the feasibility and implementation of the HDOH Phase 2 GHG standards, especially the 2027 MY standards, which should not be revised. [EPA-HQ-OAR-2019-0055-1346-A1, p.2]

PACCAR is pleased that EPA included two options in the Proposed Rule and supports a stringent, but implementable, single step low-NOx standard in MY 2027. The data and supporting information provided herein will demonstrate that Option 2 with certain flexibilities, and features of Option 1, represent a reasonable, technically-feasible regulation. By contrast, Option 1 on its own is technically infeasible. [EPA-HQ-OAR-2019-0055-1346-A1, pp.2-3]

PACCAR agrees with EMA's assessment that the proposed standards are technically infeasible and incorporates below certain aspects of EMA's comments, sometimes verbatim, in addition to providing our own comments. [EPA-HQ-OAR-2019-0055-1346-A1, p.4]

CARB's recently promulgated Heavy-Duty Omnibus low-NOx Regulation aims to reduce NOx emission standards by 90% compared to the current 2010 emission standards and prescribes a 50% reduction in the PM mass standard. This aggressive action seeks to reduce the last one to two percent of HDOH NOx engine emissions. [EPA-HQ-OAR-2019-0055-1346-A1, p.4]

EPA's proposed 'Option 1' mirrors the CARB Omnibus requirements in nearly every respect, including the proposed 0.020 g/bhp-hr NOx certification standard for MY 2031. However, the a 90% NOx reduction, coupled with the proposed new 'low-load' certification cycle and a completely new in-use emissions testing and compliance protocol (with barely measurable NOx limits), presents an inherently infeasible technical challenge for HDOH diesel engines. [EPA-HQ-OAR-2019-0055-1346-A1, p.4]

Adopting a single-step feasible rule for MY 2027 will enable manufacturers to focus on the multiple different development paths required for future powertrain solutions. [EPA-HQ-OAR-2019-0055-1346-A1, p.16]

PACCAR summarizes below the major issues that EPA should take into account as it moves forward with this rulemaking:

- PACCAR encourages EPA to adopt a single-step, technologically-feasible rule introduced in MY 2027 to enable manufacturers to focus on the several different development paths required for future powertrain solutions.
- PACCAR supports the proposed Option 2 regulatory levels (0.05 NOx) in laboratory controlled demonstrations, such as durability aging (DF programs) and SEA.
- In commerce, PACCAR requests EPA provide a 'variability allowance' of 30 mg/hp-hr to address emissions variation due to the real-world conditions and production variability. This allowance would apply to testing engines that are acquired from field systems, such as DF verification, and other compliance conformity testing. [EPA-HQ-OAR-2019-0055-1346-A1, p.59]

Organization: *Pennsylvania Chamber of Business and Industry (PCBI)*

Pennsylvania is home to the 8th largest manufacturing base in the country and continues to see substantial development and investment into logistics and distribution infrastructure across the state. The state's proximity to several major interstate highways and ports afford companies across multiple industrial categories, such as consumer packaged goods, pharmaceuticals and medical devices, automotive components, and electronics, to site and distribute goods across North America. According to the American Transportation Research Institute, trucking alone supports more than 300,000 Pennsylvania workers and their families, and approximately 86 percent of the state's total manufactured goods are moved by truck each year. It is imperative that as regulatory requirements are implemented, engine manufacturers are given sufficient time to incorporate new controls into product lines, supply chain vendors are able to scale up production of controls as well, and end-users are able to effectively and affordable transition their fleets during turnover. [EPA-HQ-OAR-2019-0055-1319-A1, p.2]

To that end, the options outlined in EPA's most recent Notice of Proposed Rulemaking are overly aggressive and threaten to reduce investment and increase costs in the logistics sector at a time of significant inflation and supply chain constraints. These options also threaten to impede environmental progress. The PA Chamber supports a single-step, national rule that encourages adoption of more efficient trucks, that is economically feasible for logistics companies and trucking fleets, and that is environmentally beneficial. Of the two options outlined in the NOPR, we recommend EPA reject Option 1 and substantially revise Option 2 in line with the concerns outlined in this letter and that of other stakeholders. [EPA-HQ-OAR-2019-0055-1319-A1, p.2]

Organization: *Public Citizen and Healthy Port Communities Coalition (HPCC)*

Option 1 of the Proposal would clearly provide significant benefit to communities, and the EPA should not consider any rulemaking less stringent than Option 1. [EPA-HQ-OAR-2019-0055-1417-A2, p. 1]

Option 2 within the Proposal should be rejected by the EPA. Option 2 does not adequately protect human health. [EPA-HQ-OAR-2019-0055-1417-A2, p. 1]

Improvements to compression ignition engines are welcome but may be better directed toward advancing electrification. [EPA-HQ-OAR-2019-0055-1417-A2, p. 2]

The Proposal states that "emission levels demonstrated for certification are not achieved under the broad range of real-world operating conditions," and thus proposes strategies to increase the efficiency of emissions controls of compression ignition (CI) engines. [EPA-HQ-OAR-2019-0055-1417-A2, p. 2]

This statement in the proposal reflects our understanding based on our experience examining heavy duty truck emissions in Texas. Research centered on the greater Houston region reported similar findings. A 2018 study by the Texas Transportation Institute2 for the Houston-Galveston Area Council that analyzed PAMS and GPS data found that the vehicles studied operated at low speeds, 18 mph on average, with 63% of time at speeds less than 10 mph. Vehicles idled for 54% of the time (185 minutes per day) with most of the activity happening during weekdays between 6 am and 7 pm, when nearby residents are active. This study found that truck engines operated at temperatures suboptimal for SCR functionality almost 60% of the time, meaning that the SCR would be unable to achieve the expected emissions reductions. [EPA-HQ-OAR-2019-0055-1417-A2, p. 2]

2. https://www.h-gac.com/getmedia/12a1530d-ad4f-4705-8e8b-68ccd2f29787/Vehicle-Activity-Data-09192018

EPA's efforts in this proposal to increase stringency of emissions testing of compression ignition engines is welcome. However, vehicle manufacturers have lost a tremendous amount of faith from the public due to diesel emissions cheating scandals. [EPA-HQ-OAR-2019-0055-1417-A2, p. 2]

Prohibition of diesel defeat devices will not ensure compliance. Furthermore, SCRs and other emissions controls on heavy-duty diesel trucks can easily fail, making it more difficult for emissions targets to be met. Extending regulatory emission warranties may help prevent tampering while also ensuring that operators are covered for necessary repairs should their emission control devices fail. However, the best defense against pollution is to stop it before it begins. Transitioning to zero emissions trucks ensures full compliance with emissions standards, and we recommend that the EPA prioritize the deployment of zero emission vehicles. [EPA-HQ-OAR-2019-0055-1417-A2, p. 3]

Organization: *Rivian Automotive, LLC (Rivian)*

EPA "co-proposed" two potential regulatory options for addressing NOx emissions. Because of the immediate public health impacts of NOx emissions, finalizing a proposal that achieves the greatest reductions is of paramount importance. EPA's own findings show that of the options weighed, Option 1 is most protective, delivering larger reductions by 2045 of NOx, PM2.5, volatile organic compounds, and carbon monoxide than Option 2. These reductions in pollutants would "significantly decrease" ozone concentrations across the country with benefits for areas attempting to attain, or avoid nonattainment of, national air quality standards.5 And even more importantly, EPA estimates that the ozone and PM2.5 benefits will accrue in greater measure in parts of the country with the "worst baseline air quality," and "where larger numbers of people of color are projected to reside."6 This analysis is a testament to the power of a strong NOx emissions standard to deliver real-world benefits to Americans. [EPA-HQ-OAR-2019-0055-1229-A1, p.3]

5 Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards, 87 Fed. Reg. 59, 17,427 (Mar. 28, 2022) (revising 40 C.F.R. Parts 2, 59, 60, 80, 85, 86, 87, 600, 1027, 1030, 1033, 1036, 1037, 1039, 1042, 1043, 1045, 1048, 1051, 1054, 1060, 1065, 1066, 1068, and 1090).

6 Id. at 17,427.

Balanced against the costs, EPA again finds that Option 1 is the most compelling of the two options analyzed. The agency calculates that by 2045 the annual net benefits of Option 1 would be as much as 50 percent greater than those for Option 2.7 In Rivian's view, these clear findings compel EPA to finalize a NOx standard at least as stringent as Option 1, consistent with both the Biden Administration's stated goals and priorities and, perhaps most significantly, with the directive of Executive Order 12,866, later reaffirmed by Executive Order 13,563, that "in choosing among alternative regulatory approaches, agencies should select those approaches that maximize net benefits…"8 Finalizing Option 2 would not be justifiable on cost-benefit grounds. Accordingly, Rivian supports the EPA finding that Option 1 is the most compelling of the options proposed. [EPA-HQ-OAR-2019-0055-1229-A1, p.3]

7 Id. at 17,428.

8 Exec. Order No. 12,866, 58 Fed. Reg. 190 (Oct. 4, 1993); Exec. Order No. 13,563, 76 Fed. Reg. 14 (Jan. 21, 2011).

Organization: *South Coast Air Quality Management District*

It has been over 20 years since EPA last issued a heavy-duty NOx standard. Emissions from heavy-duty diesel mobile sources represent a significant and ever-increasing portion of the emissions inventory in the Basin, resulting in adverse impacts on public health and regional air quality. Legal authority to regulate these sources of pollution primarily sits with EPA and the California Air Resources Board (CARB). CARB has taken significant steps to address NOx emissions from heavy-duty trucks through its Heavy-Duty Engine and Vehicle Omnibus Regulation (Omnibus Regulation). Federal regulation, however, is needed for trucks initially registered outside of California. As the South Coast AQMD noted in its 2016 Petition for Rulemaking to Adopt Ultra-Low NOx Exhaust Emission Standards for On-Board Heavy-Duty Trucks and Engines (2016 Petition), a nationwide standard is necessary because the majority of heavy-duty trucks operating in California are purchased out of state and operated as part of a nationwide fleet. [EPA-HQ-OAR-2019-0055-1201-A1, pp.1-2]

CARB's 2020 Mobile Source Strategy noted that by 2030, NOx emissions from federally regulated sources in the South Coast will exceed emissions from California-regulated sources.2 It is also worth noting that without a proposed rule in place, EPA's own analysis shows that by Calendar Year 2045, 8-hour ozone design values in certain nonattainment areas will remain in the range of 92-98 ppb.3 Thus, substantial NOx emission reductions are urgently needed from the nationwide fleet to not only help with the extreme ozone non-attainment status in Southern California but with other areas nationwide. [EPA-HQ-OAR-2019-0055-1201-A1, p.2]

2 CARB, 2020 Mobile Source Strategy, available at https://ww2.arb.ca.gov/sites/default/files/2021-09/Proposed_2020_Mobile_Source_Strategy.pdf, pg. 6.

3 EPA, Regulatory Impact Analysis (RIA), available at https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10144K0.pdf, pg. 291, Table 6-2 (Change in 8-hour Ozone Design Values for Counties Projected to be Above the Level of the 2015 8-hour Ozone NAAQS in 2045).

The South Coast AQMD continues to have high confidence that a 0.02 g/bhp-hr standard is technologically feasible and can be commercially proven. We also believe a technological pathway can be implemented in a commercial product prior to 2027. The majority of today's Otto-cycle heavy-duty engines have already been certified far below a low-NOx standard of 0.02 g/bhp-hr. Projects undertaken by the Southwest Research Institute (SwRI), and the availability of advanced engine technologies and aftertreatment systems, all support the conclusion that conventional diesel standards can achieve a low-NOx standard of 0.02 g/bhp-hr. The advances in engine technology have been successfully demonstrated and proven to be cost-effective, including 6.7, 8.9, and 12-liter natural gas engines from Cummins, diesel engines that are 70% cleaner than the current standard, idle reduction technology, engine down-speeding, and advances in exhaust after-treatment technologies. Zero emission technologies, including battery-electric and fuel cell power trains, continue to emerge and see rapid advancement. [EPA-HQ-OAR-2019-0055-1201-A1, p.2]

Because of the critical need for NOx reductions, the South Coast AQMD urges EPA to adopt the most stringent rule with the fastest implementation timeline supported by the record. We support EPA's proposed Alternative Option to the extent that it is modified to include a low NOx standard of 0.05 g/bhp-hr on the low load cycle (LLC), as envisioned by CARB's Omnibus Regulation and supported by SwRI's latest test results. The Alternative Option, which already includes longer useful life and warranty mileages than either Option 1 or the Omnibus Regulation, will elicit the greatest emission reductions of all proposed options, so long as it is modified to harmonize its LLC limit with the limit proposed by CARB. However, to the extent that pursuit of the Alternative Option will delay rule implementation beyond 2027 we support Option 1 so long as it can be aligned with CARB's Omnibus Regulation, setting implementation of a 0.02 g/bhp-hr standard in Model Year (MY) 2027. [EPA-HQ-OAR-2019-0055-1201-A1, pp.2-3]

Above all else, the South Coast AQMD believes that a revised NOx standard should be finalized as swiftly as possible, by the end of 2022. To be clear, Option 1, as written, is less than ideal as it would allow for more emissions than adoption of a standard equivalent to CARB's own Omnibus Regulation, particularly in the early years of the program. South Coast AQMD staff is also concerned that the flexibilities built into the current version of the proposal may result in a strong standard only on paper. For instance, enabling manufacturers to generate overly generous NOx credits from sales of zero-emission engines may disincentivize investments in clean technologies for internal combustion engines, thereby delaying needed emission reductions. For these reasons, it is imperative that EPA adopt its proposed Alternative Option, with the modifications suggested above or, if doing so delays the rulemaking process beyond 2022, adopt Option 1 to align with Omnibus. Newer, stronger standards for on-highway heavy-duty engines and vehicles are long overdue, and we ultimately support EPA taking the necessary, decisive action to help clear the air of truck emissions for all residents in the South Coast Air Basin and nationwide, including those disadvantaged communities that are most likely to live near highways, port complexes, and warehouses. [EPA-HQ-OAR-2019-0055-1201-A1, p.3]

EPA proposes two primary options for consideration –Option 1 and Option 2 – stating that both include emissions standards based on technology improvements that have become available over the course of the past 20 years since the last major heavy-duty engine rule revisions. Option 1 is a two-step process wherein a 0.035 g/bhp-hr standard is implemented for MY 2027 through 2030 and then ratcheted down to 0.02 g/bhp-hr for MY 2031 and beyond. Option 2 would implement a 0.05 g/bhp-hr standard for MY 2027 and beyond. EPA also proffers an Alternative Option which it suggests is more stringent than either Options 1 or 2. We believe that both the Alternative and Option 1 are technologically feasible. [EPA-HQ-OAR-2019-0055-1201-A1, p.7]

Under the Alternative Option, heavy duty HDEs will be subject to a 0.02 g/bhp-hr standard beginning in MY 2027. The Alternative also includes useful life and warranty mileages that are longer than those proposed in either Option 1 or the Omnibus Regulation. However, we believe that the Alternative will achieve maximum emission reductions only to the extent that it is amended to include a NOx standard of 0.05 g/bhp-hr on the LLC, beginning in MY 2027. As written, the Alternative has a higher LLC standard of 0.10 g/bhp-hr which mirrors EPA's least stringent proposal, Option 2. Alternatively, CARB's Omnibus Regulation will reduce the current heavy-duty NOx standard for FTP/RMC-SET from 0.20 g/bhp-hr to 0.05 g/bhp-hr from MY 2024-2026, and down to 0.02 g/bhp-hr starting MY 2027, while setting the initial 0.2 g/bhp-hr LLC from MY 2024-2026 down to 0.05 g/bhp-hr starting MY 2027 at 435,000 miles. Omnibus also includes slightly higher levels for both FTP/RMC-SET and LLC to account for deterioration at full useful life. EPA appears to dismiss the viability of its proposed Alternative Option by noting that less lead time to a 0.02 g/bhp-hr standard, a lower numeric standard for hydrocarbon, and longer useful life and mileage constraints 'would be very challenging to meet in the MY 2027 timeframe.'26 As we will discuss in further detail below, a 0.02 g/bhp-hr NOx standard is most certainly feasible for MY 2027.

Still, to the extent that EPA reasonably believes it cannot finalize rulemaking on a modified Alternative Option before 2023, for implementation by MY 2027, we believe there is ample evidence, including EPA's own analysis, showing that Option 1, modified to achieve an Omnibus Nationwide scenario in 2027, would bring significant NOx reductions. As alluded to above, EPA has improperly rushed to dismiss the viability of implementing a 0.02 g/bhp-hr standard in MY 2027. The research backing California's Omnibus Rule proves as much. CARB's Omnibus rule provides for an interim decrease in NOx emission standards as early as 2024.

To reiterate, in order to avoid delay, we are willing to support a modified Option 1 to the extent that it would align with CARB's Omnibus by requiring the most stringent feasible standard – a 0.02 g/bhp-hr – for MY 2027. Based on data presented in EPA's own draft RIA, an Omnibus Nationwide scenario in MY 2027 would bring 160,395 tons of NOx reduction annually for CY 2030, exceeding all three options outlined in the NPRM.39 A 0.02 g/bhp-hr standard is doubtlessly feasible and achievable for MY 2027, even as full commercialization is not realized as of today. [EPA-HQ-OAR-2019-0055-1201-A1, pp.9-10]

39 RIA at pg. 277, Table 5-49.

The South Coast AQMD continues to urge that EPA's highest priority should be to secure the maximum emission reductions possible and without delay. We do not believe pursuit of a modified Option 1 that would track CARB's Omnibus Regulation would delay this rulemaking effort beyond 2022. This alignment would include, among other things, a required idle-NOx standard of 10 g/hr, a lower FTP/RMC-SET standard of 0.02g/bhp-hr and a more stringent LLC standard at 435,000 miles. As acknowledged in the RIA, the standards and useful life periods in both steps of CARB Omnibus are not only feasible but would result in emission reductions for the applicable model years.40 While Option 1 would see significant NOx reductions of 16.4%, 55.9% and 60.5% in 2030, 2040, and 2045, respectively, an Omnibus Nationwide scenario in 2027 is projected to achieve additional NOx reductions of 4.2%, 0.6% and 0.2% in the same respective years over Option 1, with consistent 3-4% additional benefit between MY 2027 and MY 2031.41 [EPA-HQ-OAR-2019-0055-1201-A1, p.10]

40 87 Fed. Reg. at 17459.

41 RIA at pgs. 245-46.

When compared to the single level proposed for Option 2 and the Alternative Option, Option 1 would provide the second highest NOx reductions at full useful life, aligning with the Omnibus Regulation. The South Coast AQMD further notes that the feasibility of Option 1 has already been demonstrated based on more recent data presented by SwRI at the 2022 SAE WCX conference in April 2022. At 800,000 miles, the Stage 3 'Re-work' results were 0.037 g/bhp-hr NOx on the composite FTP, 0.030 g/bhp-hr NOx on the RMC-SET, and 0.034 g/bhp-hr NOx on the LLC.42 More data is also set to become available for the Achates engine aging to 800,000 miles. [EPA-HQ-OAR-2019-0055-1201-A1, p.10]

42 EPA, OAR, Test Results from EPA Diesel Engine Demonstration (May 3, 2022), available at https://www.regulations.gov/document/EPA-HQ-OAR-2019-0055-1082.

Should EPA move forward with Option 1 modified to achieve a 2027 Omnibus nationwide scenario, the South Coast AQMD strongly urges against deferring implementation of the second step standards to an uncertain future rulemaking effort involving heavy-duty GHG emissions. As we have stressed above, not only does Option 1 delay alignment with CARB's Omnibus Rule but it also overlooks the fact that low-NOx technology is available within the relevant timeframes. To unnecessarily put implementation of a tighter standard on hold in order to review additional options – options which CARB, MECA, SwRI and others have already reviewed –will have a devastating impact on air quality throughout the nation. EPA also requests comment and data to support higher penetrations of HD ZEV's in the MY 2027-2029 timeframe. Specifically, EPA floats the idea of supporting HD ZEV penetration rates of 5-10 percent or higher in this timeframe in conjunction with permitting HD ZEV manufacturers to generate NOx emission credits so long as CO2 standards were made more stringent for specific Phase 2 vehicle subcategories based on higher projected penetrations of HD ZEVs in the allotted timeframe.43 EPA proposes to permit HEV, BEV and FCEV technologies to generate these emission credits as a form of flexibility for manufacturers to spread out their investments and prioritize technology adoption in way that makes the most sense for their businesses while transitioning to meet the more stringent proposed standards. [EPA-HQ-OAR-2019-0055-1201-A1, pp.10-11]

43 87 Fed. Reg. at pg. 17599.

South Coast AQMD generally opposes overly generous flexibilities that will result in manufacturing of engines with higher NOx emissions. Not only is this antithetical to the goals of the Clean Air Act but it would also weaken the intent of this rulemaking. [EPA-HQ-OAR-2019-0055-1201-A1, p.11]

The South Coast AQMD cannot meet its upcoming attainment deadlines without significant emission reductions from sources under federal authority. As has been made clear above, there is ample evidence to support the feasibility of a stringent 0.02 g/bhp-hr standard by MY 2027. As we have noted previously, we believe this can be done via implementation of a modified Alternative Option that harmonizes its LLC standard with CARB's Omnibus Regulation. To avoid unnecessary delay, and only insofar as EPA reasonably believes it cannot complete rulemaking on the Alternative option in 2022, we believe the necessary emission reductions can be achieved via implementation of a version of Option 1 that *fully* aligns with CARB Omnibus. Given upcoming attainment deadlines, there is also a significant need to achieve the greatest level of emissions reductions as soon as possible. [EPA-HQ-OAR-2019-0055-1201-A1, p.11]

EPA itself acknowledges that it is compelled by Clean Air Act Section 202(a)(3)(A) to set NOx emission standards that ‘reflect the greatest degree of emission reduction achievable through the application of technology that will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology.’45 Further, EPA is required to prescribe ‘and from time to time revise standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines[.]’46 These standards are to take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such a period.’47 These regulations may apply no sooner than the model year commencing four years after a revised standard is promulgated and will apply for at least three model years.48 [EPA-HQ-OAR-2019-0055-1201-A1, pp.11-12]

45 87 Fed. Reg. at 17418; 42 U.S.C. Section 7521(a)(3)(A).

47 Id.

48 Id. at Section 7521(a)(3)(C).

In its 2016 petition to the EPA, the South Coast AQMD urged the importance of ‘cooperative federalism’ as ‘a defining feature of the [Clean Air Act].’49 As EPA has explained, the Clean Air Act sets out the ‘blueprint’ by which nonattainment areas will attain the NAAQS— a blueprint that couples locally-directed reductions with ‘Federal measures such as reductions from mobile source measures promulgated by EPA under Title II of the Act.’50 The South Coast AQMD has advanced the most stringent air quality regulations in the nation, but it requires EPA to give heed to cooperative federalism principles. The District’s emissions inventory puts the issues in stark relief; the Basin will not be able to meet the 70 ppb standard without a stringent rule. Going further, attainment will also require other controls on sources within federal regulatory authority, such as locomotives, marine vessels, and aircraft Thus, here and elsewhere, the South Coast AQMD needs EPA to follow blueprint of the Clean Air Act by adopting the strongest rule possible, as soon as possible, without any further unwarranted delay. [EPA-HQ-OAR-2019-0055-1201-A1, p.12]

Organization: *Southern Environmental Law Center (SELC)*

As discussed further below, proposed Option 1 for the criteria pollutant emissions standards and the revised Phase 2 greenhouse gas (GHG) emissions standards do not go far enough. [EPA-HQ-OAR-2019-0055-1247-A1, p.1]

Under the Clean Air Act, EPA must set criteria pollutant emissions standards 'that reflect the greatest degree of emissions reduction achievable' after considering certain statutory factors.31 EPA determined that more-stringent Option 1 is feasible, and EPA should, at minimum, adopt these proposed standards.32 However, California recently adopted the Heavy- Duty Omnibus Regulation (the Omnibus Regulation), which is even more stringent. This indicates that standards stricter than Option 1 are feasible. In line with the Omnibus Regulation, EPA should adopt NOx standards that are 90 percent below current standards starting in model year 2027. [EPA-HQ-OAR-2019-0055-1247-A1, p.5]

31 The standards shall 'reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology.' 42 U.S.C. 7521(1)(3)(A)(i).

32 Control of Air Pollution From New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards, 87 Fed. Reg. 17414, 17436 (proposed Mar. 28, 2022). EPA should not consider less-stringent Option 2, which it found to be feasible in model year 2027 but also to 'result in lower levels of emissions reductions compared to proposed Option 1.' Id.

Beyond more stringent numeric standards, EPA is also proposing important improvements to test procedures, life periods, and warranty requirements to ensure that medium and heavy-duty vehicles run cleanly under more operating conditions across the lifetime of a vehicle.36 These improvements contribute to the effectiveness of the standards. Longer regulatory useful life and emissions-related warranty requirements will also help to maintain emissions control through more of the operational life of these vehicles and we urge EPA to consider whether these requirements can be better aligned with the Omnibus Regulation. [EPA-HQ-OAR-2019-0055-1247-A1, p.6]

36 See e.g., Control of Air Pollution From New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards, 87 Fed. Reg. at 17422-26.

37 Id. at 17464.

38 Letter from Paul J. Miller, NORTHEAST STATES FOR COORDINATED AIR USE MGMT., to Mary D. Nichols, CAL. AIR RES. BD. 3 (Aug. 25, 2020), https://www.nescaum.org/documents/nescaum-comments-carb-hdv-nox-omnibusregulation-20200825.pdf/.

39 The proposed voluntary certification is based on California's Clean Idle NOx standard. Control of Air Pollution From New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards, 87 Fed. Reg. at 17464.

At a minimum, EPA should fully align its criteria pollutant emissions standards with the California Heavy-Duty Omnibus Regulation in in 2027, establish minimum ZEV production requirements, and preserve the stringency of GHG emissions requirements for internal combustion engine vehicles. [EPA-HQ-OAR-2019-0055-1247-A1, p.8]

Organization: *States of California, et al. (The States)*

Recognizing the critical need to address emissions from this significant source, President Biden's Executive Order 14037, "Strengthening American Leadership in Clean Cars and Trucks," directed EPA to establish new standards for emissions from heavy-duty engines and vehicles beginning with model year 2027 through at least model year 2030. Specifically, EPA is co-proposing two regulatory options for reducing NOx emissions: Option 1 implements stronger NOx standards in a two-step approach by first increasing stringency in model year 2027 and then increasing stringency again for model year 2031; Option 2 sets a one-time stringency for only model year 2027 and would achieve less NOx emissions than Option 1. Option 1 will achieve greater emission reductions than Option 2, will reduce NOx emissions from heavy-duty vehicles by almost 60 percent in 2045, and "will provide society with a substantial net gain in welfare, notwithstanding the health and other benefits [that EPA was] unable to quantify."4 [EPA-HQ-OAR-2019-0055-1255-A1, p. 2]

4. EPA, Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards: Draft Regulatory Impact Analysis, § 9.2, pp. 403-4 (March 2022), EPA-HQ-OAR-2019-0055-0979 ("Draft RIA").

The States strongly encourage EPA to adopt Option 1, which is the regulatory option that reflects "the greatest degree of emission reduction achievable" as required by Clean Air Act (CAA) section 202(a)(3) and most closely aligns with the Heavy-Duty Engine and Vehicle Omnibus Regulation (Omnibus Rule) recently adopted by the California Air Resources Board (CARB). Given the record supporting the Proposed Rule, and CARB's robust record supporting the Omnibus Rule, Option 1 is unquestionably both technologically feasible and cost-effective, better addresses the significant impact of emissions from the heavy-duty vehicles on environmental justice communities,5 and enhances the States' ability to attain and maintain national ambient air quality standards for ozone and particulate matter. EPA's proposed adoption of Option 2 would be inconsistent with CAA section 202(a)(3) and would be arbitrary and capricious in light of the rulemaking record. [EPA-HQ-OAR-2019-0055-1255-A1, pp. 2 - 3]

5. Environmental justice is defined by EPA as the "fair treatment and meaningful involvement of all people regardless of race, color, national origin or income with respect to development, implementation, and enforcement of environmental laws, regulations and policies." EPA, EPA-300-B-1-6004, EJ 2020 Action Agenda: The U.S. EPA's Environmental Justice Strategic Plan For 2016-2020, at 1 (Oct. 2016) ("EJ 2020 Action Agenda"). For the purpose of this comment, the term "environmental justice community"

> refers to a community of color or community experiencing high rates of poverty that, due to past and/or current unfair and inequitable treatment, is overburdened by environmental pollution and the accompanying harms and risks from exposure to that pollution.

As noted above, under Section 202(a)(3) of the CAA, EPA must adopt criteria pollutant emissions standards that "reflect the greatest degree of emission reduction achievable through the application of technology that the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology."58 In light of this statutory mandate, the States strongly encourage EPA to adopt Option 1 because Option 1 would "result in a greater level of achievable emission reduction for the model years proposed, which is consistent with EPA's statutory authority under Clean Air Act section 202(a)(3)."59 According to EPA's analysis, Option 1 would achieve greater emission reductions from highway heavy-duty vehicles than Option 2. Specifically, Option 1 will reduce NOx emissions by 61 percent, primary exhaust PM 2.5 emissions by 26 percent, volatile organic compounds by 21 percent, and carbon monoxide by 17 percent nationwide in 2045.60 Thus, EPA is compelled to adopt standards that are at least as stringent as Option 1 to meet its obligations under 202(a)(3) and EPA's proposed adoption of Option 2 is both inconsistent with 202(a)(3) and would be arbitrary and capricious given EPA's findings that the Option 1 standards are technologically feasible and cost effective. [EPA-HQ-OAR-2019-0055-1255-A1, p. 14]

58. 42 U.S.C. § 7521(a)(3)(A)(i).

59. 87 Fed. Reg. at 17,417.

60. Id. at 17,579; Draft RIA at § 5.3.1.

These emission reductions are essential to begin to reduce the inequitable burden on to environmental justice communities. Under Executive Order 12,898, each federal agency has been directed, "to the greatest extent practicable and permitted by law" to "make achieving environmental justice part of its mission by identifying and addressing as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations in the United States and its territories . . . ."61 Additionally, EPA recently committed to "make achieving environmental justice part of [its] mission[] by developing programs, policies, and activities to address the disproportionately high and adverse human health, environmental, climate-related and other cumulative impacts on disadvantaged communities, as well as the accompanying economic challenges of such impacts."62 The adoption of proposed Option 1 is consistent with EPA's commitment to ameliorating existing environmental injustices by achieving the maximum emission reductions and thus reducing air pollution that disproportionately impacts environmental justice communities.63 [EPA-HQ-OAR-2019-0055-1255-A1, pp. 14 - 15]

61. 64 Fed. Reg. 7629 (Feb. 16, 1994).

62. Exec. Order 14,008, § 219.

63. Id.

Option 1's emissions standards, useful life, and warranty periods also most closely align with CARB's Omnibus Rule, and as the records for both the Proposed Rule and CARB's Omnibus Rule demonstrates, Option 1 is technologically feasible and cost-effective.67 Option 1 provides a harmonization of standards that allows manufacturers to design a single engine nationally, thereby reducing complexity and costs. [EPA-HQ-OAR-2019-0055-1255-A1, p. 15]

67. See Comments of CARB, to be filed in Docket EPA-HQ-OAR-2019-0055 on May 16, 2022.

The States share EPA's goal of achieving effective NOx reductions without unnecessary hardship to manufacturers or vehicle owners or operators. Many of the compliance flexibilities set forth in the Proposed Rule—such as NOx credits for averaging, banking, and trading—are also components, to a degree, of the Omnibus Rule, and the States support including these where they would not reduce the stringency of the final standards and are justified by the record. However, the combined effect of multiple and redundant flexibilities contemplated in the Proposed Rule would be to, in practical effect, adopt standards weaker than those ostensibly adopted in regulation. Such a discrepancy between the emission standards "on paper" and "in the real world" would be problematic for at least three reasons. [EPA-HQ-OAR-2019-0055-1255-A1, pp. 15 - 16.] [EPA-HQ-OAR-2019-0055-1255-A1, p. 15]

First, were EPA to adopt compliance flexibilities that effectively loosen the emission standards' stringency, the final regulation would not "reflect the greatest degree of emission reduction achievable through the application of [available] technology," in violation of the CAA's plain mandate. 42 U.S.C. § 7521(a)(3)(A)(i). Moreover, because the CAA obligates EPA to choose the most effective achievable standards, adopting standards that in reality will be far less effective than purported would also undermine the "rational connection between the facts found and the choice made" and disregard "an important aspect of the problem." Motor Vehicle Mfrs. Ass'n of U.S., Inc. v. State Farm Mut. Auto Ins. Co., 463 U.S. 29, 43 (1983). The arbitrariness of such a result is especially pronounced where multiple, cumulative flexibilities and leniencies overlap to address the same industry concern. Cf. Amer. Lung Ass'n v. EPA, 134 F.3d 388, 392 (D.C. Cir. 1998) (agencies must "explain their decisions with precision"). [EPA-HQ-OAR-2019-0055-1255-A1, p. 16]

Second, the Proposed Rule is of critical importance for States' attainment or maintenance of NAAQS. As described in Section I.C, heavy-duty vehicles are nationally the largest mobile-source contributor of NOx emissions, and in nonattainment areas near Los Angeles and New York City, contribute roughly one third to one half of the on-road NOx emissions, respectively. States risk nonattainment and corresponding penalties if a final rule in fact secures far less NOx emissions reduction than EPA projects—especially where the States premise their SIPs on these ostensible federal reductions. For many of the States, every ton of NOx that heavy-duty engines emit above the ostensible emission limit is another ton the State will have to eliminate from other sources within its regulatory authority. Nat'l Ass'n of Clean Air Agencies v. EPA, 489 F.3d 1221, 1227 (D.C. Cir. 2007) ("[W]hen EPA allows higher NOx emissions from [federally regulated sources], state agencies have no choice but to impose greater restrictions on other sources of NOx.”). Reducing NOx from many of these other state-jurisdictional sources will be far more costly than controlling heavy-duty truck emissions.68 Thus, lost emissions reductions disrupt the cooperative federalism that is the backbone of the CAA’s statutory and regulatory scheme and defeat the goals of carefully crafted SIPs. [EPA-HQ-OAR-2019-0055-1255-A1, p. 16]

> 68. For example, the Northeast States for Coordinated Air Use Management (NESCAUM) estimate the costs of additional NOx controls from industrial, commercial, and institutional boilers as ranging from $2,700 to $21,000 per ton of NOx reduced, as compared to a cost range of $1,000 to $5,000 per ton of NOx reduced from heavy-duty vehicles. Comment submitted by Paul J. Miller, Executive Director, NESCAUM, at pp. 4-5 & nn.4,5 (Feb. 23, 2022), EPA-HQ-OAR-2019-0055-0001.

Third, flexibilities that would, in practical effect, undermine the projected reductions from the final emission standards would violate EPA’s (and States’) commitment to addressing environmental injustice. As described further in Section I.B, environmental justice communities would bear the brunt of the negative health and environmental effects of NOx emissions that are left unmitigated due to outsized and redundant compliance flexibilities, due to proximity to the major transportation corridors and logistics facilities. These already overburdened communities should not continue to bear the inequitable costs of pollution for the sake of unwarranted and unnecessary industry protections. Following that path would harm these communities and further erode trust. [EPA-HQ-OAR-2019-0055-1255-A1, pp. 16 - 17]

Accordingly, EPA should scale back or reject altogether flexibilities whose aggregate effect will be to significantly reduce the real-world emission benefits of Option 1. In particular, EPA should (1) reject the proposed interim in-use standards;69 (2) adopt a stricter inducement schedule that meaningfully incentivizes real-world compliance;70 and (3) further limit the use of NOx credits, especially those generated from heavy-duty electric vehicles.71 [EPA-HQ-OAR-2019-0055-1255-A1, p. 17]

> 69. 87 Fed. Reg. at 17,563-5.
>
> 70. Id. at 17,536-46.
>
> 71. Id. at 17,556-62.

In sum, the States support Option 1 of EPA’s Proposed Rule, and as detailed in these comments, respectfully request that certain elements of the Proposed Rule be revised and strengthened before finalization. Further, due to statutory lead time requirements, the States strongly urge EPA to finalize the Proposed Rule by the end of this year to support standards for model year 2027. [EPA-HQ-OAR-2019-0055-1255-A1, p. 28]

Organization: *Truck and Engine Manufacturers Association (EMA)*

It is important to highlight from the outset that while there are various details of EPA’s rulemaking proposal (particularly with respect to Option 1) that EMA and its members fundamentally disagree with, there are multiple major points of substantial agreement. In that regard, EMA agrees with EPA that:

> (i) The NOx emission standards for HDOH vehicles should be reduced substantially starting in model year ("MY") 2027, perhaps by as much as 75% from the current standards; [EPA-HQ-OAR-2019-0055-1203-A1, p. 5]
>
> (ii)
>
> (iii) The current emission warranty and useful life periods for HDOH engines and vehicles should be revised to increase the durability and efficacy of in-use emissions compliance; [EPA-HQ-OAR-2019-0055-1203-A1, p. 5]
>
> (iv) Most or all of the multiple aftertreatment components that the Southwest Research Institute ("SwRI") has configured and assessed in testing its "Stage 3" prototype engine systems should be utilized by OEMs to achieve optimal NOx emission reductions from HDOH engines starting in MY 2027; [EPA-HQ-OAR-2019-0055-1203-A1, p. 5]
>
> (v) ...
>
> (vi) The proposed low-NOx rulemaking should serve as a cost-effective bridge to the transition of HDOH trucks to zero-emission vehicles ("ZEVs") in as many applications as possible, and as soon as practical. ["…" above indicates text is included in other sections of this Response to Comments document] [EPA-HQ-OAR-2019-0055-1203-A1, p. 5]

Accordingly, EMA supports the Agency's overall objectives to: "1) control emissions over a broader range of operating conditions; 2) maintain emissions control over a greater portion of an engine's operational life; and 3) provide manufacturers with flexibilities to meet the proposed standards." (87 FR at pp. 17420-21.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 5]

In light of all of these major points of agreement, EMA is hopeful that the Agency's final rule will be consensus-based, highly cost-effective, and fully implementable starting with the 2027 MY. EMA also hopes that all stakeholders will take note of the multiple major points of agreement spelled out in these comments, and will not unduly focus on the finer points where EMA and its members have data-driven disagreements with the Agency regarding the technical feasibility of what the Agency has proposed, especially as pertains to Option 1. Again, notwithstanding those differing fact-based assessments of what is feasible at the margins of EPA's proposal, a consensus based rulemaking should be achievable. [EPA-HQ-OAR-2019-0055-1203-A1, p. 5]

In that regard, EMA and its members acknowledge the significant ozone air quality attainment problems that still exist in several highly-populated areas of the country, and we recognize why EPA is seeking additional HDOH NOx emission reductions and regulatory improvements. EMA's members are willing to develop and introduce advanced low-NOx technology solutions to effect very significant NOx reductions, including through the types of "Stage 3" emission-control componentry being demonstrated at SwRI. Indeed, EMA encouraged prior

Administrations to take the lead in proposing such next-tier low-NOx regulations. EMA remains willing to collaborate on the finalization of an ambitious technology-forcing low-NOx program that will yield substantial in-use NOx reductions, while avoiding the unintended consequences of setting standards beyond the technical capabilities and compliance margins that frame what a cost-effective program should be. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 5 - 6]

Simply stated, EMA is fully committed to making this rulemaking a fully implementable success. [EPA-HQ-OAR-2019-0055-1203-A1, p. 6]

In order to ensure the adoption of fully achievable and cost-effective HDOH low-NOx regulations, and notwithstanding our broader agreement, the Agency should revise the proposed standards in the following manner:

> (i) Any low-NOx program that the Agency finalizes must be a one-step program with one set of new standards, not a multi-step program with increasingly stringent requirements. All stakeholders should recognize that one of the core objectives of this rulemaking is to establish a cost-effective “clean-diesel” bridge to a ZEV-truck future, which future will be mapped out, in part, through EPA’s anticipated “Phase 3” GHG rulemaking, set to be proposed next year. The low-NOx requirements of this rule should not spill over into the operative years of the envisioned Phase 3 rule. Otherwise, one of the unintended consequences of this low-NOx rule will be to divert manufacturers’ limited research and development resources away from the primary long-term goal of transitioning the commercial trucking industry to ZEVs. [EPA-HQ-OAR-2019-0055-1203-A1, p. 6]
>
> (ii) ...
>
> (iii) Manufacturers will not produce Option 1-compliant products because the Option 1 standards are not feasible. Accordingly, the FTP/RMC certification standards for NOx must be set at Option 2-like levels, not 0.02 g/bhp-hr. Otherwise, the standards will fail to provide the requisite compliance margins, which will render them infeasible in practice, and will cause unacceptable compliance and recall risks for manufacturers. In addition, a program centered around Option 2-like levels will be more beneficial from an emissions-inventory perspective, once potential fleet turnover market responses, including pre-buy/no-buy responses, are taken into account. [EPA-HQ-OAR-2019-0055-1203-A1, p. 6]
>
> (iv) ...
>
> (v)-(vi) ...
>
> (vii) ...
>
> (viii) The proposed low-NOx program should be revised so that there is a better overall match of the program’s costs and monetized health benefits, and, as noted, to guard against counter-productive pre-buy/no-buy market responses

(ix) .... ["…" above indicates text is included in other sections of this Response to Comments document] [EPA-HQ-OAR-2019-0055-1203-A1, p. 7]

As already noted, EMA's comments are being submitted to facilitate the full and successful implementation of new HDOH emission standards, not to block that implementation. [EPA-HQ-OAR-2019-0055-1203-A1, p. 8]

The Agency will need to fashion a final rule that can meet the broader goal at issue — to build a cost-effective and accessible regulatory bridge to a ZEV-truck future. To that end, the Agency will need to finalize just one set of HD low-NOx standards to take effect in MY 2027, not multiple regulatory steps with multiple standards phasing-in through 2031 and beyond. Otherwise, the low-NOx program for diesel engines will overlap with and undermine the implementation of the "Phase 3" GHG standards (which are slated to lead to the broader transition to ZEV trucks), and will divert OEM's inherently limited R&D resources to multiple iterations of diesel engine enhancements instead of focusing those resources on the needed advancements in HD ZEV technologies. All stakeholders recognize that diesel technologies will start to phase-out over the next decade. The scope and costs of this rulemaking need to account for and reflect that reality as well. [EPA-HQ-OAR-2019-0055-1203-A1, p. 8]

Section 202 of the federal Clean Air Act ("CAA"), 42 U.S.C. §7521, governs the Agency's establishment of emission standards for new mobile sources, including HDOH engines and vehicles. CAA section 202(a)(3)(B) specifically governs the Agency's establishment of "revised standards for heavy-duty trucks." Unlike the general standard-setting provisions contained in section 202(a)(3)(A) – which call for the establishment of emission standards that "reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply" – section 202(a)(3)(B), the specific provision that applies here, simply states that the Administrator may set revised emissions standards "taking costs into account." [EPA-HQ-OAR-2019-0055-1203-A1, pp. 15 - 16]

Consequently, in assessing the details for the proposed revised low-NOx regulations at issue, costs, not the absolute limits of potential technological feasibility, are a paramount consideration. In this case, a full and fair consideration of costs and benefits leads to the conclusion that a low-NOx program centered around an Option 2-like program will yield an optimized final rule, while a program centered around the Option 1 proposal is simply not workable. [EPA-HQ-OAR-2019-0055-1203-A1, p. 16]

CARB's recently promulgated Omnibus low-NOx regulations include a NOx standard reduced by another 90% from the US10 limit, and another 50% reduction in the PM mass standard. The PM reduction is intended primarily to serve as a backstop against the potential adoption of less effective DPF designs than the current ceramic wall-flow systems capable of performing well below the US10 limit. The additional 90% NOx reduction, however, especially when coupled with a new "low-load" certification cycle, and a completely new in-use emissions testing and compliance protocol (with barely measurable NOx limits), presents an inherently infeasible technical challenge for HDOH diesel engines. It should be noted that these aggressive targets are actions to reduce the last 1 to 2% of NOx emissions from these engines. EPA's proposed

"Option 1" mirrors the CARB Omnibus requirements in almost every respect, including a 0.020 g/bhp-hr NOx certification standard proposed to be effective in MY 2031. [EPA-HQ-OAR-2019-0055-1203-A1, p. 17]

Throughout the rulemaking process for the Omnibus low-NOx regulations, CARB asserted that its new low-NOx requirements are technically feasible. The primary basis for CARB's assertion, like EPA's here, is the technology demonstration effort undertaken by Southwest Research Institute ("SwRI"). CARB contracted with SwRI to develop a diesel engine and aftertreatment prototype capable of meeting a 0.020 g/bhp-hr NOx certification standard when aged to the equivalent of 435,000 miles of operation. The 435,000 mile threshold is the current US10 heavy heavy-duty Useful Life requirement (CARB's rule extends that Useful Life requirement to 800,000 miles, but with a doubling of the NOx standard (to 0.04 g/bhp-hr) for the interval from 435,000 miles to 800,000 miles). SwRI modeled a variety of combinations of aftertreatment components, coupled with engine improvements intended to elevate exhaust temperatures, and ultimately focused on what came to be known as the "Stage 3" technology package for the 435,000 mile-aged emissions demonstration prototype. [EPA-HQ-OAR-2019-0055-1203-A1, p. 17]

To support its low-NOx rulemaking, EPA also contracted with SwRI to perform an aged emissions demonstration with a technical solution very similar to the CARB "Stage 3" technology package. Thus, the laboratory experiment that SwRI has run on the "Stage 3" prototype is the sole source of actual emissions data supporting EPA's assertion regarding the purported feasibility of the 0.020 g/bhp-hr NOx standard. In some instances, that support amounts to a single data point. [EPA-HQ-OAR-2019-0055-1203-A1, p. 17]

EMA has been engaging with EPA and CARB from the outset on these HDOH low-NOx rulemakings, including the underlying SwRI demonstration program. Our conclusion is that the Omnibus/Option 1 low-NOx standards have not been demonstrated to be technically feasible, and are in fact infeasible, for the following reasons: [EPA-HQ-OAR-2019-0055-1203-A1, p. 17]

Our conclusion is that the Omnibus/Option 1 low-NOx standards have not been demonstrated to be technically feasible, and are in fact infeasible, for the following reasons:

1) The aged-engine "Stage 3" NOx emissions results do not meet the proposed future 0.020 g/bhp-hr NOx standard across all required certification cycles, nor do they consistently meet the in-use NOx standards when laboratory tested using "road cycles" that mimic real world operation (which, practically speaking, makes the case that the SwRI program was a demonstration of technical infeasibility.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 18]

   [see section 3.2.1 of this Response to Comments document for additional reasons provided by the commenter]

EMA shares broad agreement with the Agency on all of the core concepts of the proposed regulations. EMA's comments are therefore directed at the margins of EPA's proposal, particularly with respect to Option 1, not at the NPRM's core objectives. To that end, EMA has offered detailed recommended revisions, along with a more over-arching recommendation that the proposed regulations should be centered around revised Option 2-like requirements to enhance the feasibility and cost-effectiveness of the Agency's proposal. The changes that EMA recommends are not material from an overall emissions inventory perspective, but are vitally important to the finalization of a fully implementable low-NOx rulemaking that can serve as a cost-effective bridge to a ZEV-truck future. [EPA-HQ-OAR-2019-0055-1203-A1, p. 173]

The stakes of this rulemaking are very high. Indeed, if EPA were to finalize its proposed Option 1, that would, as a practical matter, preclude the production and sale of HD diesel engines starting in 2027. OEMs cannot and so will not be able to build Option 1-compliant products. Such an unacceptable outcome from this rulemaking must be avoided. EMA is ready to work with the Agency to fashion the necessary revisions that will lead to the finalization, adoption and implementation of the fully optimized low-NOx program for new HDOH engines and vehicles that all stakeholders are seeking. [EPA-HQ-OAR-2019-0055-1203-A1, p. 173]

EPA's "Clean Trucks Plan" is a rulemaking that will significantly impact all of the core elements of EPA's HDOH diesel-emissions control program. The NPRM proposes sweeping changes to those core regulatory program components, including up to a 90% reduction of the applicable NOx standard, reopened reductions to the Phase 2 CO2 emissions standards, an entirely new certification test procedure targeting operating modes never-before regulated, and a completely overhauled in-use emissions protocol, which requires a careful analysis of PEMS-based (and OBD) in-use measurement capabilities and procedures. [EPA-HQ-OAR-2019-0055-1203-A1, p. 170]

Until all of the foregoing research needs are met in a comprehensive and credible manner, the record supporting the Agency's rulemaking will be at risk of being deemed incomplete and insufficient. This is a fundamental problem that will require collaboration to resolve. Falling that, this is a problem that could preclude the implementation of a final rule on the timeline that EPA is trying to maintain. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 172 - 173]

Organization: *Truck Renting and Leasing Association (TRALA)*

Accordingly, TRALA supports the Option 2 certification standard of .05. That said, we urge EPA to work with CARB and the other states who have pledged to adopt CARBs standards for NOx, to persuade those states not to proceed with regulations that would exceed the EPA's standard. TRALA urges the EPA to adopt regulations based on Option 2 and to work with every state including California to agree to a new national low-NOx certification standard of .05. TRALA believes that a national standard would reduce the regulatory burden on the OEMs that would not have to meet multiple standards in a shortened time period. A national standard of .05 would reduce the catastrophic disruption these rules could have on the new and used truck markets. [EPA-HQ-OAR-2019-0055-1180-A1, p. 4]

Organization: *U.S. Chamber of Commerce*

While we are supportive of a national standard that drives cutting-edge technology deployment and lowers emissions, the Chamber has strong concerns that, as proposed, EPA's preferred

Option 1 fails to adhere to these core principles, and as a result would likely lead to unintended negative consequences for both the economy and the environment. [EPA-HQ-OAR-2019-0055-1245-A1, pp. 2 - 3]

Relatedly, we have concerns that the reasoning and factual predicates for aspects of the proposed rule are undermined by weaknesses that give rise to legal vulnerabilities. As EPA acknowledges, section 202(a)(2) of the Clean Air Act provides that standards to regulate air pollutants from mobile sources “shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.” Accordingly, as EPA notes, in establishing or revising such standards, “EPA also must consider issues of technological feasibility, compliance cost, and lead time,” and “may consider other factors such as safety,” as well as “the impacts of potential standards on the heavy-duty industry, fuel savings, oil conservation, energy security and other energy impacts.” (See also Clean Air Act section 202(a)(3), as further discussed in the preamble to the proposed rule.) Careful attention to each relevant factor must be given in proposing and promulgating new standards; and to the extent that an agency decision ignores significant factual problems, including questions of practicability, or otherwise is incomplete or erroneous, the agency risks invalidation of its decision pursuant to the Clean Air Act and the Administrative Procedure Act. [EPA-HQ-OAR-2019-0055-1245-A1, p. 3]

Opportunity cost impacts associated with diversion of capital away from Zero-Emissions Vehicle (ZEV) investments. Original Equipment Manufacturers (OEM) are undertaking enormous investments to develop zero-emissions vehicles that will power the future transportation system. The Chamber has serious concerns that if finalized as proposed, EPA’s rulemaking will require OEMs to divert significant amounts of capital investment -- currently planned for ZEV development -- into compliance with this rulemaking. This would not just impact the trucking industry’s efforts to plan for the energy transition; it would have implications for a broad range of economic sectors in the form of customers and fleet owners working to address greenhouse gas emissions throughout their supply chain. [EPA-HQ-OAR-2019-0055-1245-A1, p. 8]

The framework outlined in Option 2 would provide more of an incentive for turnover of older fleet vehicles due to more familiar technology and lower costs for replacement vehicles, particularly those heavy-duty trucks that were certified prior to model year 2010. Around fifty percent of trucks on the road today are certified to meet EPA’s 2010 standards, so a large percentage of the fleet is still emitting significantly higher levels of NOx due to lack of fleet turnover. For example, the emissions from one truck certified to 2006 standards is equivalent to 10 trucks certified to the 2010 standards, and one truck certified to the 1990 standards is equivalent to 30 trucks certified to the 2010 standards. The air quality improvements attributable to retiring these older vehicles are tremendous, especially in communities where there is a large concentration of diesel vehicles. [EPA-HQ-OAR-2019-0055-1245-A1, p. 8]

The opportunities for this rulemaking are similar and illustrate why it is so important to set durable, achievable, and cost-effective standards. The framework described in Option 2 offers the best ability to achieve emissions reductions that will benefit communities most impacted by medium- and heavy-duty vehicles. [EPA-HQ-OAR-2019-0055-1245-A1, p. 9]

Technological feasibility and compliance costs go hand in hand. Establishing standards that are technologically feasible will help ensure that standards are achievable and cost-effective. Although the agency views these standards to be technology-forcing, the timeline for actual adoption of those technologies in the marketplace will in significant part depend upon the increased cost to consumers for the new vehicles. Other aspects of the design and successful deployment of new technologies needed to meet more stringent environmental standards can sometimes be difficult for companies and the agency to anticipate. [EPA-HQ-OAR-2019-0055-1245-A1, p. 9]

Many companies are investing significantly in new, lower-emitting and zero-emitting medium-duty and heavy-duty vehicles across various vehicle classes; however, overcoming consumer acceptance is one challenge that is difficult to anticipate and to model. This is a particularly important issue when considering major shifts in technology or compliance costs, as mentioned above. [EPA-HQ-OAR-2019-0055-1245-A1, p. 9]

Other challenges also remain for engine and vehicle manufacturers as consumers and fleet owners may need to make significant investments in charging infrastructure necessary to support zero-emitting vehicles. For smaller fleets, it raises more uncertainty as they will increasingly rely on infrastructure investments made at the federal and state levels. Adding better performing engine or post-combustion emissions control technologies to meet the proposed requirements for Option 2 will pose challenges, and the specific provisions of Option 2, as proposed, should be carefully considered and adjusted to ensure feasibility and to avoid imposing unnecessary costs and burdens; however, Option 2 would likely not require the same shift in infrastructure that Option 1 would demand. [EPA-HQ-OAR-2019-0055-1245-A1, pp. 9 - 10]

Some additional costs attributable to Option 1 also merit thorough consideration. First, consumers and fleet owners who choose to adopt zero or near-zero emitting vehicles would need to consider the cost and time needed to install recharging and other fueling infrastructure at appropriate distances across their distribution supply chains to avoid disruptions. Second, EPA should consider the costs due to optimization of distribution routes, as companies would spend significant resources on optimizing their supply chains to reduce operating costs. [EPA-HQ-OAR-2019-0055-1245-A1, p. 10]

The Chamber supports EPA's efforts to continue making progress to reduce emissions from the mobile source sector and strongly recommends that the agency avoid the numerous potential counterproductive economic and environmental consequences that could result from Option 1 of the proposal. Instead, EPA should proceed toward a final rule based on the framework outlined in Option 2, while making sensible modifications and clarifications in the framework as appropriate to ensure feasibility, maximize legal defensibility, and promote reductions in a cost-effective fashion, while reducing unwarranted and unnecessary burdens on innovation and investment. [EPA-HQ-OAR-2019-0055-1245-A1, p. 11]

Organization: *University of California, Berkeley, The Goldman School, Center for Environmental Policy*

We find the differences between the President's climate commitment scenario and the current EPA proposal to be notable across many elements of analysis:

Air pollution: While the EPA Proposed rules would reduce NOx emissions from new trucks, President's Climate Commitment scenario would nearly eliminate them, which would dramatically reduce the PM2.5 exposures and avoid 70,000 premature deaths over the EPA proposed rules. This is an important environmental justice issue. Studies have shown that low income groups and minorities bear a disproportionate proportion of the environmental burden from freight movement. For instance, it is estimated that in California, African American, Latino, and Asian Californians experience, respectively, 43, 39, and 21% higher levels of PM2.5 pollution from cars, trucks, and buses relative to white Californians. [EPA-HQ-OAR-2019-0055-1327-A1, p. 2]

In total, the air pollution and CO2 emissions reductions in the President's Climate Commitment scenario equate to over $500 billion in health and environmental savings through 2050, compared with the EPA Proposed rules. The net economic and environmental benefit of the President's Climate Commitment case over the EPA proposed case is over $1.5 trillion through 2050. [EPA-HQ-OAR-2019-0055-1327-A1, p. 3]

Organization: *Union of Concerned Scientists*

[*From Hearing Testimony, April 13, 2022, Dr. David Cooke, Union of Concerned Scientists*]
The heavy-duty truck rules proposed by EPA are the first step the Agency has taken and over 20 years to limit the harmful particulate and smog-forming emissions from heavy-duty trucks. USCIS is concerned that even after so much time, EPA's proposal matches neither the need nor the technical capacity to reduce these harmful emissions. Today, we have the opportunity to eliminate the harmful truck emissions that plague local communities. Unfortunately, EPA's rule chooses to treat these zero-emission vehicles as a curiosity, and yet even as the Agency ignores the market readiness and technical potential of such zero-emission vehicles, its proposal also fails to propose a standard for diesel trucks that reflects the best available conventional technologies. UCS is an advocate for science-based policy. As such, we simply ask EPA to look at the data. Together with the California Air Resources Board, EPA has funded millions of dollars of research at the Southwest Research Institute, yet it has in inexplicably deviated from what that data supports, which is the omnibus regulations. EPA must align it standards, beginning in 2027, with the omnibus. The Agency has already chosen to adopt the structure of the omnibus, which UCS supports, including the addition of a low load cycle, a more robust in-use testing program, and extended full useful lifetimes and warranties. The omnibus was adopted by California and now other states after a successful multi-year process, and the Agency's own data supports the diesel emission reductions required under the omnibus, so it's unclear why EPA has chosen to adopt these structural elements while not also proposing stringencies in line with that program. With regards to electric vehicles, EPA's proposal has unfortunately adopted the worst of all options. It has chosen to credit these vehicles under the NOx Program while ignoring them as a NOx solution in setting the standard. This means that every electric truck

sold, including those already required under state policies, will lead to a dirtier diesel truck being sold. This is untenable for communities dealing with truck pollution. EPA must make a choice: either fully recognized zero-emission vehicles and set a NOx standard predicated on the sale of such vehicles, or it should exclude credits for electric trucks entirely to guarantee emissions reductions from the dirty diesel trucks driving through freight-impacted communities. UCS can provide technical and economic data to support our various asks regarding EPA's policy, and we will continue to engage with EPA to strengthen the rule. If EPA is to uphold its technology-forcing mandate under the Clean Air Act, we expect a final rule that will reduce emissions from diesel trucks in line with the omnibus regulation and for EPA to ensure 50 percent of new trucks sold in 2030 are zero-emission vehicles. [EPA-HQ-OAR-2019-0055-2867]

Organization: *Ute Mountain Ute Tribe Environmental Programs Department*

Option 1 in Section IX clearly is preferable to Option 2 and would more closely reflect that which is as clean as possible with respect to nitrogen oxide emissions reductions. [EPA-HQ-OAR-2019-0055-1259-A1, p. 2]

Organization: *Valeria Trujilo Aguilar*

Therefore, on behalf of private citizens living and working in Denver exposed to dangerous levels of NOX and O3, I submit comments in support of the advanced notice of proposed rule for Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine Standards or Cleaner Trucks Initiative (CTI) released on January 6, 2020. A recommendation to reduce criteria pollutant emission standards and shorter useful life periods for new heavy-duty diesel and gasoline engines used in Class 2b through 8 vehicles by 2027 as proposed in Option 2 is highly favorable due to the potential to help states like Colorado meet National Air Quality Standards sooner and combat air quality challenges such as ozone pollution. [EPA-HQ-OAR-2019-0055-1223]

I fully support the implementation of stringent NOx emission standards proposed in Option 2 of ANPR Clean Trucks Initiative [EPA-HQ-OAR-2019-0055-1223]

Organization: *Valero Energy Corporation**:** Valero Energy Corporation*

EPA is required to consider impacts on endangered species of any action that may affect a listed species or any critical habitat for a listed species. In the proposal, however, EPA does not mention consideration of impacts on endangered species or any consultation required by the Endangered Species Act. EPA's proposal to shift the heavy-duty engine/vehicle market to electric vehicles should account for the emissions expected from production of electric vehicles, batteries, and the electricity for the vehicles, including the harm to endangered species from mines, windmills, and solar fields as well as the environmental impacts from any new mineral extraction facilities, including open-pit and subsea mining, as well as mineral processing and battery manufacturing facilities. [EPA-HQ-OAR-2019-0055-1328-A2, p.8]

Organization: *Volvo Group*

The Volvo Group strongly supports the Environmental Protection Agency's (the Agency) goal of significantly decreasing criteria pollutant emissions from heavy-duty engines, particularly for those local communities where air quality does not meet National Ambient Air Quality Standards (NAAQS). [EPA-HQ-OAR-2019-0055-1324-A1, p. 2]

If we are to truly maximize emission reductions, it is critical that this new federal oxides of nitrogen (NOx) standard under the Clean Trucks Plan be stringent enough to improve air quality – particularly in environmental justice communities – without creating unintended consequences that could postpone market adoption of cleaner technology vehicles and undermine the goals the regulation is seeking to achieve. [EPA-HQ-OAR-2019-0055-1324-A1, p. 2]

While both options proposed by the EPA in the NPRM are extremely aggressive, we are convinced that, as currently drafted, both would fail to produce the anticipated real-world emission reductions. In fact, it is precisely because we believe both options would foster unintended consequences that would undermine the agency's air quality and climate change goals that we are advocating for a modified version of Option 2 as providing the best opportunity for success. Without some modifications to finalize a robust, achievable version of Option 2, we fear the regulation could worsen air quality as older technology stays on roads longer, and the introduction of ZEVs (Zero Emission Vehicles) across the medium- and heavy-duty vehicle market is delayed due to overly burdensome costs on both fleets and OEMs (Original Equipment Manufacturers). [EPA-HQ-OAR-2019-0055-1324-A1, p. 2]

Having said this, the Volvo Group agrees with EPA that the NOx emission standards for heavy duty on highway (HDOH) vehicles should be reduced substantially starting in model year (MY) 2027; we also agree with EMA that this reduction could be as much as 75% from the current standard. Achieving our air quality and climate change goals requires a pragmatic accounting of the many factors that must be addressed if we are to be successful. The Volvo Group is working towards a commercial ZEV future. We want to manufacture the cleanest possible diesel vehicles which encourage fleet adoption, while maximizing our investment in accelerating zero emission technology in the marketplace. [EPA-HQ-OAR-2019-0055-1324-A1, pp. 2 - 3]

The Volvo Group, the industry, and a host of other stakeholders have worked with the Agency in good faith over several decades to reduce NOx and particulate matter (PM) emissions from heavy-duty trucks and buses by 98% from unregulated levels. The industry has invested billions of dollars to develop advanced, durable technical solutions and engine calibrations to meet this challenge, just as our customers invest heavily in clean air with every new truck purchase. These efforts have paid huge dividends in air quality improvements. Even today, the level of improvement is remarkable, especially given that less than 50% of the heavy-duty fleet is operating with the latest advancements in NOx emissions control as driven by EPA's fully phased-in 2007/2010 standards. [EPA-HQ-OAR-2019-0055-1324-A1, p. 3]

EPA's analysis when setting new NOx standards must give full weight to the gains that will naturally play out as the remainder of the fleet is steadily upgraded to the latest control technology. New vehicles compliant to the new 2027 NOx standards promulgated under the

Cleaner Trucks regulation will not begin to have an appreciable environmental impact until some years later. Any technological advancements needed to chip away at the remaining 1 to 2% of residual NOx emissions will come at a much higher cost per ton than the achievements of the previous two decades. Such costs and the associated development efforts will be additive to the technology advancements already committed by EPA's comprehensive, technology-forcing greenhouse gas regulations. These requisite costs, the current positive trajectory toward widespread ozone attainment, and the inevitable negative consequences to greenhouse gas requirements present and future, demand that the Agency take extreme care when establishing this next set of NOx standards and related protocols. [EPA-HQ-OAR-2019-0055-1324-A1, p. 3]

The Volvo Group is fully aligned with EMA's comments in opposition to the Proposed Option 1 Certification NOx Standard. As EMA noted, EPA has not demonstrated the full useful life feasibility of this standard with the associated CO2 standard. The exhaust thermal management required to achieve this lower NOx standard makes the existing GHG (Greenhouse Gas) CO2 reduction even more challenging. Technical feasibility must consider the needed margin for aging, production, fuel quality, and measurement variability. The premise that this standard can be reached is based on only one set of data as part of a prototype engine operating in a test environment and not in a vehicle operating under real world conditions across the full range of customer applications. [EPA-HQ-OAR-2019-0055-1324-A1, p. 3]

The proposed longer 600,000-mile and 800,000-mile useful life requirements drive greater aging margin and greater warranty challenges, making the extrapolation of test cell results as proof for real life durability at those levels to be impracticable. Demonstrating the technical feasibility of such an aggressive standard requires a broad full useful life in-use evaluation of the vehicle achieving all the requirements with sufficient margin. [EPA-HQ-OAR-2019-0055-1324-A1, p. 3]

It is important to elaborate further that NOx reductions are always paid for with CO2. Even if there is a technology capable of reducing both NOx and CO2, it does not eliminate the diesel engine NOx/CO2 tradeoff governed by the laws of physics, but merely shifts the tradeoff curve. As the graphic below illustrates, once EPA has committed manufacturers to the deployment of costly technology through rulemaking, the Agency controls where along the new NOx/CO2 tradeoff curve the engine is to be calibrated. The lower the NOx standard, the higher the CO2 emissions. Whether motivated by future GHG rules or market pressures for fuel economy, the lower NOx standard will limit current and future potential CO2 gains. The point is, EPA should be certain that the NOx reductions demanded by these new standards will be considered of higher priority in the timeframe that compliant products will have a meaningful environmental impact (post-2030) than the CO2 reductions they will forever preclude. [EPA-HQ-OAR-2019-0055-1324-A1, p. 4]

In conclusion, the Volvo Group believes the following principles must be reflected in the final regulation: a single step NOx reduction which accounts for the additional CO2 emission reductions required of OEMs under the existing Greenhouse Gas Phase 2 regulation in 2027. [EPA-HQ-OAR-2019-0055-1324-A1, p. 10]

Organization: *WE ACT for Environmental Justice*

With respect to the NOx portion of the proposal, we urge the EPA to disregard Option 2, which would require full implementation of the NOx standard starting with model year 2027. The EPA should not opt for the weakest proposal. As the Agency rightly points out, Option 2 would achieve 75% less NOx emissions reductions than today's standards in addition to having less stringent useful life and warranty periods. The Agency should be ambitious to safeguard low-income communities of color throughout the country and not pander to internal pressures or industry polluters. [EPA-HQ-OAR-2019-0055-1347-A1, p.3]

Instead, the EPA should pursue and enhance Option 1,which can achieve 90% NOx emissions reductions from medium- and heavy-duty vehicles and engines by 2027 relative to 2010 standards and aligns with California's Heavy-Duty Omnibus rule.18 Meeting or exceeding the omnibus program is the level of lifesaving ambition needed to deliver clean air to overburdened communities before 2031. Research shows that alignment with the rule could avoid $1.3 trillion in health damages linked to fine particulates and ozone pollution from 2027-2050.19 In addition, the EPA should not allow crediting as it compromises the NOx emission standard, and allows dirty diesel trucks and buses to continue to be sold, compounding air pollution and health burdens for the 72 million people, many of which are low-income and people color living within 200 meters of major trucking routes for years to come.20 [EPA-HQ-OAR-2019-0055-1347-A1, p.3]

Organization: *Western States Air Resources Council (WESTAR)*

As noted in the proposal, it has been over 20 years since the last revisions to NOx standards for on-highway heavy-duty trucks and engines, while the total vehicle miles traveled by these mobile sources has steadily increased. We agree that emission control technologies have improved and will continue to improve. Along with implementing better technologies, it is important that EPA accelerate fleet changes so that emissions reductions in both urban and rural vehicle populations benefit state Clean Air Act planning requirements due within the next 10 years. [EPA-HQ-OAR-2019-0055-1230-A1, p.1]

Reducing mobile emissions is important to Western states because they are a large part of the emissions inventory in the West. These reductions can be achieved with existing emission control technologies that were funded and fostered through partnerships between EPA, California and other states, and industry. While several western states that adopted California's vehicle standards under Section 177 of the Clean Air Act1 will benefit from these newer technologies, the greater benefit will be achieved when emissions reductions are implemented through a national rule. [EPA-HQ-OAR-2019-0055-1230-A1, p.1]

[1] 42 U.S.C. §7507.

One of EPA's stated goals with this proposed rule is to help states comply with the ozone NAAQS and improve visibility as part of the Regional Haze program. The proposal states that "The proposed Option 1 standards would significantly decrease ozone concentrations across the country, with a population- weighted average decrease of over 2 ppb in 2045.4 " In terms of emissions reductions, EPA estimates that Option 1 would reduce NOx emissions from heavy-duty vehicles in 2040 by more than 50 percent and by 60 percent in 2045. Most nonattainment areas for the 2008 and 2015 ozone NAAQS are required to attain the standard within the next six years (2028). While the proposed emission reductions are welcome, they will be too late to impact current ozone nonattainment areas and won't prevent the short-term transport of pollution throughout the western states. For this reason, we encourage EPA to find ways to foster quicker adoption of heavy-duty engine controls and technology within the industry through incentives and the proposed early adoption credits. [EPA-HQ-OAR-2019-0055-1230-A1,pp.3-4]

[4] Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards, 87 Fed Reg. 17427 (March 28, 2022)

Organization: *William F. Limpert*

I appreciate EPA's work in proposing these rules, and in protecting our environment, our climate, and our fellow citizens. Full adoption of these rules will offer great public benefit, and I am very grateful for President Biden through his August 5, 2021 Executive Order, and EPA for moving forward with these major steps toward a better future, including full electrification of this industry as soon as possible. [EPA-HQ-OAR-2019-0055-1190]

I agree with EPA's assessment that failure to act to reduce NOx and greenhouse gas emissions would result in continued negative health impacts, further catastrophic impacts to our climate, both now, and in the future, poor air quality and visibility, and higher costs, especially for those who would be most impacted by negative health and climate impacts, generally our fellow citizens of low income status. [EPA-HQ-OAR-2019-0055-1190]

I would like to see EPA adopt Proposed Option 1 for reducing NOx emissions from heavy duty vehicles, since this option would achieve more emission reductions than Proposed Option 2. [EPA-HQ-OAR-2019-0055-1190]

I would like to see EPA require longer useful life periods for engines, and longer emission warranties to better assure decreased NOx emissions over the life of the vehicle. [EPA-HQ-OAR-2019-0055-1190]

I would like to see EPA further tighten the "Phase 2" GHG standards for certain subcategories of vehicles, and to further increase the stringency of the standards beyond what is currently proposed for MYs 2027 through 2029, including progressively stronger CO2 standards. [EPA-HQ-OAR-2019-0055-1190]

I would like to see EPA set stronger emission standards for MY 2027 and later commercial pickup trucks and vans. [EPA-HQ-OAR-2019-0055-1190]

I would also prefer that the time frames for adoption of these standards be shortened as much as possible, and the new limits be tightened as much as possible beyond what EPA has proposed. Any delays or compromised limits will cause more health issues, and drive us further down a catastrophic climate hole that we may not be able to escape. [EPA-HQ-OAR-2019-0055-1190]

Organization: *Wisconsin Department of Natural Resources (WDNR)*

EPA should finalize the more stringent Option 1. By 2045, Option 1 will reduce nationwide NOx emissions by about 120,000 tons more per year than Option 2. These additional NOx reductions are a critical part of the multi-sector, regional strategy required to ensure Wisconsin's ozone nonattainment areas are able to attain the 2015 ozone NAAQS. EPA modeling shows that without this rule Sheboygan County would remain in nonattainment through at least 2045, 30 years after the standard was promulgated. The same modeling shows that under Option 1, ozone at Sheboygan would decrease by 1.9 ppb by 2045, helping the area to attain the 2015 ozone NAAQS. [EPA-HQ-OAR-2019-0055-1162-A1, p. 2]

Highway heavy-duty NOx controls have simply not kept pace with reductions from other sectors. Prior to this proposal, heavy-duty NOx standards had not been updated for 20 years, despite the availability of demonstrated technology. EPA must take this opportunity to set more stringent NOx standards for heavyduty vehicles as soon as possible, but no later than MY 2027. Per 40 CFR 1036.150(a)(2), manufacturers must have four or more model years of lead time to meet revised criteria pollutant standards that would begin to apply. Therefore, revised standards applicable to MY 2027 must be finalized before January 1, 2023. [EPA-HQ-OAR-2019-0055-1162-A1, p. 3]

Emission control technology for heavy-duty vehicles will continue to advance. It is critical that EPA plan to review the NOx standards for heavy-duty vehicles more frequently moving forward and commit to revising standards soon after new technologies are adequately demonstrated. [EPA-HQ-OAR-2019-0055-1162-A1, p. 3]

Achieving GHG emission reductions from onroad vehicles, including heavy-duty vehicles, is a critical component to achieving long-term climate goals. EPA's continued efforts to improve the current Phase 2 GHG program for heavy-duty vehicles and upcoming commitment to set new GHG and fuel efficiency standards for MY 2030 are welcome.3 EPA's efforts to reduce GHG emissions must not delay final action on the much-needed NOx engine standards. [EPA-HQ-OAR-2019-0055-1162-A1, p. 4]

> 3. Executive Order 14037, Executive Order on Strengthening American Leadership in Clean Cars and Trucks. August 2021.

As previously described, the NOx standards must be finalized by December 2022. Should EPA determine it is not able to finalize the targeted updates to the Heavy-Duty GHG Phase 2 program on the same timeline, the updates to the Phase 2 program should be finalized separately. [EPA-HQ-OAR-2019-0055-1162-A1, p. 4]

Organization: *Worldwide Equipment Enterprises, Inc.*

Because of this role, Worldwide Equipment opposes this additional regulatory burden as it is being proposed. [EPA-HQ-OAR-2019-0055-1275-A1, p.1]

Worldwide Equipment's opposition to the Proposed Rule is due to several reasons. The first, and primary, reason is that the new requirements within Option #1 are technologically infeasible and, therefore, not realistic. [EPA-HQ-OAR-2019-0055-1275-A1, p.1]

Organization: *Zero Emission Transportation Association (ZETA)*

Based on ZETA's comprehensive understanding of the EV market and our shared goals to improve public health and environmental protection, we urge EPA to adopt NOx emissions standards at least as stringent as Option 1. EPA's Option 2 is not stringent enough compared to Option l because it has lower NOx emission standards and assumes shorter useful life periods. Therefore, adopting Option 2—which would reduce nitrogen oxide (NOx) emissions by just 47% in 2045—would ensure that we fall far short of our emissions reduction goals. In turn, this would have significant public health and corresponding economic consequences. The resulting analysis shows that Option 1 is technically feasible and would result in a greater reduction of emissions. However, based on available technologies, we believe that EPA should adopt a standard even more stringent than Option 1. The market for Class 2b and heavier electric vehicles (EVs) is prepared for a more stringent rule than EPA determined in its initial assessment. EPA should also increase the stringency of the Model Year (MY) 2027–2030 GHG standards by eliminating multipliers for HDEVs. Issuing a more stringent rule will send a strong market signal to manufacturers that zero- and low-emission vehicles are the future, which will enable EPA to issue strong Phase 3 greenhouse gas (GHG) standards that align with California's standards. Strong Phase 3 standards will be necessary to achieve the electrification goals President Biden called for in his executive order,1 and they will be imperative in our collective effort to meet international climate commitments. [EPA-HQ-OAR-2019-0055-1283-A1, p.1]

> 1https://www.whitehouse.gov/briefing-room/presidential-actions/2021/08/05/executive-order-on-strengthening-american-leadership-in-clean-carsand-trucks/

EPA should implement a more stringent rule than Option 1. The proposed options do not adequately reflect advancements in zero-emission vehicle (ZEV) technology. The number of HDVs on the road has grown significantly and can be expected to increase further as a result of the ongoing global e-commerce boom.16 [EPA-HQ-OAR-2019-0055-1283-A1, p.3]

> 16 https://www.bloomberg.com/news/newsletters/2021-11-16/theelectric-vehicle-invasion-is-already-here

<u>EPA Summary and Response</u>

Numerous commenters provided general input on the stringency of the proposed criteria pollutant standards. This section briefly summarizes the main themes across comments, which include: 1. General Support for One of the Proposed Options or Opposition to the Proposed Rule; 2. Consideration of ZEVs in the Final Standards; 3. Single- or Two-step Program. EPA's responses to each theme immediately follow the theme summary; given the general nature of comments in this section, our responses point readers to other relevant sections of this Response to Comments document, or the preamble for detailed discussion relevant to these comments.

General Support for One of the Proposed Options, or Opposition to the Proposed Rule

Many commenters supported proposed Option 1; some of these commenters suggested specific modifications to proposed Option 1. For example, some of these commenters urged EPA to adopt standards more stringent than proposed Option 1, with several commenters stating that EPA should fully align with the CARB HD Omnibus program and/or adopt the Alternative presented in the proposal. In addition, many of these commenters further stated what they characterized would be necessary for EPA to meet the Clean Air Act requirements to adopt standards that reflect the greatest degree of emission reduction achievable, with some stakeholders stating that only proposed Option 1 standards would fulfill the requirements, while others stated neither proposed Options 1 or 2 would fulfill the requirements and only standards more stringent than proposed Option 1 (e.g., full alignment with the CARB Omnibus or the Alternative included in the proposal) would fulfill the requirements. One commenter further stated that the proposed rule did not fulfill EPA's duty to set standards that will "most effectively 'promote public health and welfare and the productive capacity of its population'". A subset of commenters also raised concerns that some of the compliance flexibilities in the proposed rule would reduce the stringency of the final standards.

In addition, some of these commenters stated that adopting standards at least as stringent as proposed Option 1 would be consistent with EPA's commitment to addressing environmental injustices and reducing air pollution that disproportionately impacts environmental justice communities. One commenter further stated that the proposal did not fulfill EPA's duty under Title VI of the Civil Rights Act to avoid actions that create disparate impacts on communities of color and low-income communities. A subset of commenters also stated that EPA's feasibility analysis did not fully credit the emissions reductions capabilities of different types of emission control technologies (i.e., variable valve actuation strategies, mild hybridization, and opposed-piston engines); these commenters pointed to a report on the technological feasibility of cylinder deactivation, mild hybridization, and limiting auxiliary emissions control devices

Many other commenters stated that proposed Option 1 standards would not be technologically feasible, and urged EPA to adopt proposed Option 2, or something similar in terms of stringency of the standards. Some engine manufacturers pointed to concerns related to meeting the proposed Option 1 standards over multiple duty-cycles and stated that the engine demonstration testing EPA has conducted did not adequately show the proposed standards are feasible; some commenters further pointed to concerns related to packaging emission control systems in existing vehicles. Some engine manufacturers also stated that, in their view, reducing NO_X emissions would result in higher emissions of CO_2. Other commenters note that improving fleet turnover is important for reducing emissions from heavy-duty engines and state that the proposed Option 2 standards, or standards similar in terms of stringency would better encourage fleet turnover. Still other commenters expressed concerns related to meeting the proposed standards over the longer useful life periods included in either of the proposed options, but particularly the useful life periods in proposed Option 1. In addition, several commenters opposed both of the proposed options and urged EPA to consider unintended consequences of setting standards that are too stringent (e.g., reduced fleet turnover). For example, while one commenter welcomed the proposed updates to inducements and serviceability, they expressed concerns that more stringent emissions standards would result in more complex and expensive engines and emission control technologies.

Some of these commenters also discussed their views on the need for adequate compliance margin in the final standards. Several engine manufacturers stated that additional margin is needed under either proposed option, but particularly the most stringent step of proposed Option 1 to ensure that the final standards will be met throughout the useful life period of the final standards. In contrast, other commenters, including suppliers of heavy-duty emission control components, stated that existing data show sufficient margin to meet the proposed Option 1 standards.

In addition, some commenters provide perspectives on lead time for the final standards. A subset of some commenters stated additional lead time would be needed to meet the proposed standards, particularly the proposed Option 1 MY 2031 standards; some of these commenters further expressed concerns that the reliability and affordability of new trucks would be impacted without additional lead time to meet the MY 2027 standards under either of the proposed options. In contrast, other commenters stated that work funded by CARB, EPA, and others has been ongoing for years and should serve as a basis for setting very stringent standards starting in MY 2027. One commenter suggested EPA should "increase the strictness" annually or every 2-3 years. Still other commenters noted that the final standards would not be in place in a timely enough manner from their perspectives (e.g., to impact current ozone nonattainment areas), and thus urged EPA to incentivize the early introduction of emission control technologies.

Finally, some commenters reference the proposed averaging, banking, and trading (ABT) program, with several commenters urging EPA to lower the proposed Family Emission Limit (FEL) caps, not include the proposed NO_X emission credit multipliers, or otherwise adjust the proposed ABT program. Commenters also provided varying perspectives on some of the proposed compliance flexibilities. For instance, some commenters strongly opposed the EPA request for comment in the proposal to allow manufacturers to produce up to five percent of their production volume in model years 2027 through 2029 as compliant with the existing standards; however, other commenters stated that this type of allowance would be necessary to ensure a smooth transition to new standards, particularly for small volume products.

Response:

Section 1 of this Response to Comments document discusses EPA responses to more general comments that support or oppose the proposed rule. Preamble Sections I III, and IV include more detailed discussion on the final standards. Specifically, as discussed in Sections I.D and III.A, EPA is promulgating the new heavy-duty engine criteria pollutant standards under our authority in CAA section 202(a)(3)(A)[4] and the final standards reflect the greatest degree of emission reduction achievable through the application of technology that we have determined will be available for MY 2027, giving appropriate consideration to the statutory factors. EPA's assessment of the statutory factors in CAA section 202(a)(3)(A) justify the final emission standards. As an initial matter, we disagree with commenters that seemingly assert EPA must demonstrate technical feasibility through demonstration data of an engine actually meeting the standards at the time of promulgating the standards; rather, our technology-forcing statutory authority under CAA 202(a)(3)(A) is such that we must project future technology and provide a reasoned explanation for believing that projection is reliable.[5]. Nevertheless, data from our engine demonstration programs do meet the final standards, supporting our determination that the final standards are technically feasible. The final standards are appropriately based on further consideration of the data included in the proposed rule, as well as additional supporting data from our own test programs, and consideration of the extensive public input EPA received in response to the proposed rule.[6]

As discussed in the preamble of the proposed rule (87 FR 17417, March 28, 2022), we have considered a range of options (proposed Options 1 and 2, and the range between them); in setting the final standards, we gave appropriate consideration to the statutory factors as those factors would apply for each of the options. We note that, in reference to commenters' assertions that EPA stated in the proposed rule that proposed Option 1 would meet the requirements of CAA section 202(a)(3), we have refined in the final rule our assessments and consideration of the feasibility of the combination of the standards and useful life periods, particularly for the largest CI engines (Heavy heavy-duty engines (Heavy HDEs)), such that the final standards and requirements reflect our assessment of the CAA section 202(a)(3) factors, as discussed immediately above in this section. We further note that, as described in the preamble of the proposed rule (87 FR 17421, March 28, 2022), EPA is unable to conclude that the Alternative is feasible in the MY 2027 timeframe over the useful life periods in the Alternative in light of deterioration in the emission control technologies that we have evaluated, and we did not receive additional supporting data or other information that leads us to be able to conclude that the

[4] Regarding the comment stating that EPA is setting standards under CAA section 202(a)(3)(B), the commenter has failed to adequately explain why CAA section 202(a)(3)(B) does not allow EPA to set the technology-forcing standards we are promulgating in this rule. CAA section 202(a)(3)(B) is not so limited nor does it require EPA to give greater weight to reducing costs. We also note that, as explained elsewhere in this response, EPA has considered costs in setting the final standards.

[5] *See, e.g.*, Nat. Res. Def. Council v. EPA, 655 F.2d 318, 331-334 (D.C. Cir. 1981) (determining that there is substantial room for deference to EPA's expertise in projecting the likely course of development; that a reasonable basis would be demonstrated where EPA answers any theoretical objections to control technologies, identifies the major steps necessary to refine the technology, and offers plausible reasons for believing that each of those steps can be completed in the time available; and that EPA is not required to rebut all speculation that unspecified factors may hinder "real world" emission control); Nat. Res. Def. Council v. Thomas, 805 F.2d 410, 434 (D.C. Cir. 1986).

[6] In response to one commenter's statement that EPA has a "to make available to the public when a proposed action is published for public comment the data developed by the Agency and used for making its decision", the data supporting the proposed rule was included in the public docket for this rulemaking at the time of publication of the proposal; as appropriate, we have continued to added relevant, supporting information for transparency with the public.

Alternative is feasible in the MY 2027 timeframe.[7] Preamble Sections III and IV, and RIA Chapter 3, as well as section 3.2 of this document, include additional details on our assessment of the final standards, including our consideration of the technologies available to achieve the greatest degree of emission reduction in MY 2027, meeting the final standards over the useful life periods in the final rule, emission control performance over multiple test cycles, packaging constraints, impacts on CO_2 emissions, compliance margin, and lead time in the final rule.[8] In response to the commenter requesting annual changes to the emission standards, we note that our authority under CAA section 202(a)(3) requires that we provide three years of stability in promulgating criteria pollutant emission standards for heavy-duty vehicles or engines. In response to comments that EPA's technical feasibility analysis did not fully credit emission control technologies, we refer to RIA Chapter 3 for our analysis of the emissions reductions from the technologies included in our engine demonstration programs, and note that manufacturers may choose other technology pathways to comply with the final performance-based standards (see preamble Section III and section 3.10 of this Response to Comments document for additional discussion on other technology pathways to meet the final standards). As discussed, in RIA Chapter 3, the technologies we expect to be used to meet the final standards build upon the technologies used in today's light- and heavy-duty engines, which we expect will significantly reduce the potential complexity, reliability, and affordability concerns some commenters raise. Our costs analysis of the final standards (i.e., cost of compliance for manufacturer associated with the application of such technology) is included in preamble Sections III and V, with additional detail in RIA Chapters 3 and 7 and section 18 of this document. As explained in preamble Sections V-X and XII and sections 17-27 this document, we also evaluated additional factors, including factors to comply with E.O. 12866; our assessment of these factors lend further support to the final rule.

Our discussion of environmental justice and the impacts of this final rule on communities overburdened by pollution is included in preamble Sections VII and XII, with additional information in section 23 of this Response to Comments document. EPA is committed to taking decisive action to advance environmental justice and civil rights as part of its FY2022-2026 Strategic Plan. This rulemaking advances that strategic goal by setting stronger national emission standards for heavy duty engines and vehicles. In response to commenters who discuss the

[7] We disagree with one commenter's perspective that EPA should conduct additional analyses of the Alternative presented in the proposal, as well as proposed Option 2. As described in the proposed rule, and noted here, EPA lacked information on what technology pathway(s) would be necessary to meet the standards of the Alternative presented, and therefore was unable to conduct an analysis of costs and benefits. Similarly, as discussed in this section and preamble Sections I and III of the final rule, the final standards reflect the maximum emission reductions achievable based on our analyses and consideration of relevant statutory factors, and our assessment is that the more stringent aspects of the proposed Option 1 not adopted in the final rule would necessitate additional or different technology than what we analyzed at proposal. Also as noted in the proposed rule, due to resource constraints, we only conducted air quality modeling for the proposed Option 1.

[8] We note that some commenters point to certification data some engine manufacturers provided to CARB as evidence that manufacturers are currently capable of controlling emissions below the existing standards; however, some engine manufacturers stated in their comments that they chose not to generate emission credits from these engines certified to NO_X emission levels below the existing standards. Manufacturers further stated in their comments that, in their view, the certification data indicated that they had accounted for deterioration and other factors that can impact emissions performance in the field over the current useful life period, rather than declaring an FEL below the standard to generate credits as they likely were not confident they could comply with a lower emission limit in-use for the existing full useful life.

importance of fleet turnover for reducing emissions, we point to discussion in preamble Section X and section 25 of this Response to Comments document; section 26 of this document includes additional discussion on other potential economic impacts of the final rule. In addition, preamble Section IV, and sections 5 and 8 of this Response to Comments document discuss approaches to improve serviceability and update inducements, respectively in this final rule. In response to comments suggesting modifications to one or more of the proposed duty-cycle standards for CI or SI engines, we point to discussion included in Sections 3.2 and 3.3 of this Response to Comments document, with additional information available in preamble Section III. Finally, in response to comments on the proposed useful life and warranty periods, we point to discussion in sections 3.8 and 4 of this document, with additional information included in preamble Section IV.

We acknowledge that several commenters urged EPA to finalize proposed Option 1 or to modify proposed Option 1 to more closely align with the HD Omnibus; while we are not finalizing Option 1 as proposed, as further explained in preamble Section III, our independent evaluation of the greatest degree of emission reduction achievable for a national program includes consideration of the points the commenters raised. Section 3.1.2 of this document includes further discussion regarding our evaluation, and the different considerations relevant to setting Federal standards under CAA 202(a) relative to considerations relevant to reviewing California's submission of a waiver of preemption under CAA section 209(b) for the HD Omnibus program. Section 2 of this document further discusses how we considered comments relevant to the need for additional air quality improvements and CAA requirements related to public health and welfare.

Finally, information on the final ABT program, including our rationale for the FEL caps in the final rule, is included in preamble Section IV.G, with additional information on comments received relevant to the proposed ABT program included in section 12 of this Response to Comments document. We note that the request for comment in the proposal for a compliance flexibility to allow manufacturers to certify a limited production volume as compliant with the existing standards is also discussed in preamble Section IV.G, with additional information in section 12 of this document. Additional discussion on the compliance flexibilities in the final rule is included in preamble Section III.B.

Consideration of ZEVs in the Final Standards

Several commenters stated that EPA should or must consider the use of ZEV technologies when setting the final criteria pollutant standards, and/or that EPA should reconsider the proposed allowance for ZEVs to generate NO_X emissions credits. Some commenters also included discussion of GHG standards when providing input on the proposed criteria pollutant standards. Other commenters stated that EPA should not mandate that certain technologies be used to meet the final standards. Finally, some commenters noted that emissions that occur upstream of the vehicle (e.g., from electricity generation) should be part of EPA's considerations of the emissions impacts of various technologies.

<u>Response:</u>

As discussed in the preamble of the proposed rule, we did not rely on the use of ZEV technologies in the development of the proposed options because we did not expect that existing or projected market penetration rates in the MY 2027 timeframe would meaningfully impact our analysis for developing the numeric level of the proposed standards (87 FR 17458, March 28, 2022). While recent Federal actions, such as the Inflation Reduction Act of 2022, include incentives to encourage the production of ZEV technologies in the MY 2027 timeframe beyond what was expected at the time of the proposed rule, these actions and related events took place in a timeframe that precluded additional analysis for the final heavy-duty engine criteria pollutant standards starting in MY 2027.[9] As explained in preamble Sections I and II, it is imperative that we finalize such criteria pollutant standards in calendar year 2022 in order that we may meet the minimum CAA lead time requirements and begin achieving emission reductions starting in MY 2027, consistent with the goals of the statute. Consistent with our CAA 202(a)(3)(A) authority, the final, performance-based heavy-duty engine standards that we are setting include consideration of comments submitted, including comments related to the use of ZEV technologies in setting the standards. As discussed in preamble Section III.A, the final standards in this rule are not based on the projected utilization of ZEV technology, though manufacturers may choose to comply with the standards through using ZEV technologies, or other technology pathways than included in our demonstration program.

In addition to considering comments on including ZEV technologies in setting the standards, we have considered comments related to the proposed allowance for manufacturers to generate NO_X emissions credits from ZEV technologies. We agree with comments that raised a concern with allowing ZEV technologies to generate NO_X emissions credits given that ZEVs were not utilized in setting the standards and the potential for higher than anticipated penetration of ZEV technologies. In preamble Section IV.G, we discuss our decision not to finalize the proposed allowance for manufacturers to generate NO_X emissions credits from heavy-duty ZEVs (see section 12 of this Response to Comments document for additional details on our decision not to finalize this proposed allowance). We further explain in preamble Section IV.G that we have designed the final ABT program to best ensure the expected emission reductions from the final standards.

As noted in preamble Section I, EPA is not taking final action at this time on the portion of the HD 2027 NPRM regarding proposed changes to HD GHG Phase 2 standards. EPA intends to undertake a separate rulemaking regarding more stringent HD GHG standards in the future (i.e., HD GHG Phase 3 standards); we intend to consider ZEV technologies in developing that separate proposed rulemaking. Section 28 of this Response to Comments document details the comments we received specific to the proposed revisions to the GHG Phase 2 standards. Section 3.10 of this document provides additional comments received relevant to multiple technology pathways to meet the final standards, as well as EPA's responses to those comments. Finally, section 19.3 of this document includes additional comments relevant to upstream emissions impacts and EPA's response to those comments.

[9] The Inflation Reduction Act (IRA) has many incentives for promoting zero-emission vehicles, including support for refueling infrastructure (e.g., Section 13404 Alternative Fuel Refueling Property Credit); however, it was finalized in August 2022, which is well beyond the close of the comment period for this final rule. We intend to consider the implications of the IRA and other Federal actions in future rulemakings focused on heavy-duty vehicle standards for the heavy-duty sector.

Single- or Two-step Program

Several commenters also provided input on whether EPA should finalize a single- or two-step program. Commenters broadly supported finalizing a single-step program, but based on different considerations. For instance, some commenters supported a single-step program due to considerations related to implementation (e.g., commenter viewed the two-step approach as potentially resulting in market disruptions; commenters suggested single-step approach will better allow manufacturers to focus on ZEV development) or general stringency (e.g., commenter believes a two-step approach would require additional lead time to validate new technology for an additional step in stringency). Other commenters supported a single-step program in order to avoid a delay in the most stringent standards proposed (i.e., commenters urged EPA to implement all or some of the proposed MY 2031 standards starting in MY 2027). Similarly, one commenter discussed the value of regulatory certainty to enable industry investments and meet long-term air quality goals.

Response:

As noted immediately above in this response, preamble Section III.A discusses our assessment of the final standards, including our decision to implement a single-step program beginning in MY 2027. We believe the combination of the single step program and the final standards will provide regulatory certainty for the industry and provide meaningful air quality benefits across the country.

Analyses Supporting the Rule

Finally, several commenters provided input on the analyses that supported the proposed rule. For example, one commenter stated that EPA should conduct regional scale air quality modeling to evaluate the impacts of the rule on nonattainment areas. As also noted above, other commenters provided perspectives on our analyses of costs, benefits, and/or economic impacts, particularly pre- and low-buy. Some commenters also provided input relevant to our analysis of impacts to small businesses.

Response:

Information on our final analyses can be found in preamble Sections V through X and XII, with additional information in RIA Chapters 5 – 10 and our responses to comments in sections 17-27 of this document. Regarding one commenter's statement that the "cost of compliance" criteria in 42 U.S.C. §7521(a)(2) applies to users of new motor vehicles or engines (in addition to manufacturers), we first note that new standards like those being promulgated in this rule were not at issue in the case cited by the commenter. Additionally, as explained above and in section 17 of this document (which includes additional discussion on comments relevant to small businesses), we disagree and maintain that cost of compliance under CAA section 202(a) includes only costs for regulated entities under the final standards, i.e. manufacturers. *See, e.g., Coalition for Responsible Regulation v. EPA*, 684 F. 3d 102, 129 (D.C. Cir. 2012). Our response to the comment on conducting regional scale air quality modeling is included in section 2.2 of this Response to Comments document. We note that some comments relevant to analyses to support the rule may not have specified if they were relevant to GHG or criteria pollutant portions of the rule, see Section 28.5 of this document for additional discussion.

3.1.2 Nationwide standards and CARB alignment

<u>Comments by Organizations</u>

Organization: *Achates Power, Inc.*

Achates Power supports a strong federal heavy duty vehicle standard that harmonizes with California's Omnibus ultralow NOx regulations, albeit with more phase-in time for the federal regulation (i.e. full stringency in 2031). We base the position based on demonstrations that suggest the fully implemented CARB omnibus regulations can be met in a robust, practical, and cost-effective manner. In addition, Achates Power fully supports the California Air Resources Board's position regarding the use of emissions credits in the proposed standard. [EPA-HQ-OAR-2019-0055-1216-A1, p. 1]

Organization: *Alliance for Vehicle Efficiency (AVE)*

AVE Supports harmonization of future national standards. [EPA-HQ-OAR-2019-0055-1280-A1, p. 4]

In July 2021, AVE, South Coast Air Quality Management District, and other stakeholders wrote to EPA seeking for harmonization of EPA's low-NOx rulemaking with California's Omnibus regulations.6 A unified national program will enable heavy vehicle manufacturers and suppliers to streamline the engine and aftertreatment integration to simultaneously meet GHG and criteria pollutant standards. [EPA-HQ-OAR-2019-0055-1280-A1, p .4]

> 6. See Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards

Harmonization is also a top priority of President Biden. On August 5, 2021, the President explicitly instructed EPA to coordinate its Heavy-duty NOx standards with California. [EPA-HQ-OAR-2019-0055-1280-A1, p. 4]

(c) Given the significant expertise and historical leadership demonstrated by the State of California with respect to establishing emissions standards for light-, medium-, and heavy-duty vehicles, the Administrator of the EPA shall coordinate the agency's activities pursuant to sections 2 through 4 of this order, as appropriate and consistent with applicable law, with the State of California as well as other States that are leading the way in reducing vehicle emissions, including by adopting California's standards.7 [EPA-HQ-OAR-2019-0055-1280-A1, p. 4]

> 7. https://www.whitehouse.gov/briefing-room/presidential-actions/2021/08/05/executive-order-on-strengthening-american-leadership-in-clean-cars-and-trucks/

Alignment in MY2027 and MY2030 would provide a national heavy-duty regulation that is important to automotive vehicle suppliers. Suppliers have invested significant resources in research and development for new engine and emission control technologies so that new heavy-duty trucks meet future lower NOx standards. Harmonization with California's Omnibus standards will provide suppliers with the necessary certainty to keep investing in the next generation of vehicle technologies. Regarding FUL, EPA could consider reevaluating its standard based on new data once it becomes available. [EPA-HQ-OAR-2019-0055-1280-A1, p. 4]

Organization: *Allison Transmission, Inc. (Allison)*

- Allison supports efforts to align EPA standards with programs that have been recently promulgated by the California Air Resources Board ("CARB"). However, alignment is not an unmitigated good; there are areas where EPA should not adopt CARB requirements but rather seek to have state requirements become more consistent with EPA's approach to regulating criteria and GHG emissions. In general, EPA should avoid predicating new standards on assumptions that predict the adoption of limited technology avenues for reducing emissions, such as overreliance on market adoption of ZEVs. Apart from technological challenges, efforts should be made to further assess the broader environmental footprint of different options for address both criteria and GHG emissions to ensure that sufficient time is allowed to develop and validate different technological pathways. [EPA-HQ-OAR-2019-0055-1231-A1, pp.6-7]

Given the federal/state relationship in the mobile source sector as defined in the Clean Air Act, Allison also believes there is significant in value in the coordination of CARB and EPA requirements. This extends far beyond just the stringency of criteria and GHG emission limits. Testing, certification, recordkeeping and reporting procedures (as well as the potential for parallel compliance and enforcement provisions) have a very large potential to affect the overall cost-effectiveness of federal and state HDV programs. The chart below illustrates current disparities as between existing CARB requirements and EPA's Proposed Rule:[EPA-HQ-OAR-2019-0055-1231-A1, p.33]

		Mobile emissions regulations (US/CAN)	Current	2024-2026	2027 / 2028 / 2029 / 2030	2031 / 2032 / 2035
Option 1 has more in common with CARB HD Omnibus Two step 27/31	EPA	SI & CI MHD & HHD Engine Certification NOx	0.20 g/bhp-hr		0.035 g/bhp-hr (82.5% reduction) on FTP/SET	0.02 g/bhp-hr (90% reduction) on FTP/SET through IUL; 0.04 g/bhp-hr through EUL
		CI/Compression Ignition Engine Emissions Warranty / EUL (MHD/HHD*) *HHD includes certain SI engines (e.g. natural-gas fuel engines in CL8)	5Y/100K mi ; 10Y/185K mi 5Y/100K mi ; 10Y/435K mi, or if 22K hours is reached		7Y/[illegible] 7Y/450K mi/22K hr; 11Y/[illegible]	10Y/[illegible] 10Y/[illegible] or 40K hours
		CI/Compression Ignition Engine Intermediate Useful Life (IUL) for HHD/CL8				[illegible]
		SI/Spark Ignited Engines Emissions Warranty/ EUL (MHD)	5Y/50K mi; 10Y/110K mi		7Y/110K mi; 12Y/155K miles	10Y/[illegible] mi; 15Y/200K miles
		Low Load Cycle			[illegible] g/bhp-hr on new Low Load Cycle	[illegible]
		HDE Off-Cycle NOx Standards 3-bin (idle / low-load/ med-high load) IUL to EUL only applyies to HHD/CL8	no current standard	CARB only standard	idle 20 (g/hr); low load [illegible] (mg/hp-hr); [illegible] medium high load (mg/hp-hr)	[illegible]
CARB HD Omnibus Three steps 24/27/31	CARB	Engine Certification NOx	0.20 g/bhp-hr	0.05 g/bhp-hr	0.02 g/bhp-hr to intermediate useful life [illegible] then 0.035 g/bhp-hr	0.02 g/bhp-hr to intermediate useful life [illegible] then 0.04 g/bhp-hr
		Additional Compliance /testing		Low Load Cycle, Moving Average Window, OBD REAL In-use compliance	Revised Low-load cycle & intermediate Useful life used for [illegible]	
		HD Diesel Emissions Warranty ; EUL (MHD/HHD)	5Y/100K mi; 10Y/185K mi 5Y/100K mi; 10Y/435K mi	5Y/150K mi; 10Y/185K mi 5Y/350K mi; 10Y/435K mi	7Y/220K mi/11K hr; 11Y/270K mi 7Y/450K mi/22K hr; 11Y/[illegible]	10Y/280K mi or 14K hr; 12Y/350K mi 10Y/[illegible] or 40K
Option 2 like CARB HD Omnibus 2024-2026	EPA	SI & CI MHD & HHD Engine Certification NOx	0.20 g/bhp-hr		0.05 g/bhp-hr (75% reduction) on FTP/SET	
		CI/Compression Ignition Engine Emissions Warranty / EUL (MHD/HHD*) *HHD includes certain SI engines (e.g. natural-gas fuel engines in CL8)	5Y/100K mi ; 10Y/185K mi 5Y/100K mi ; 10Y/435K mi, or if 22K hours is reached		5Y/150K mi; 10Y/325K mi 5Y/350K mi; 10Y/[illegible] or 22K hours	
		SI/Spark Ignited Engines Emissions Warranty/ EUL (MHD)	5Y/50K mi; 10Y/110K mi		5Y/110K mi; 10Y/150K miles	
		Low Load Cycle	no current standard	CARB only standard	[illegible] g/bhp-hr on new Low Load Cycle	
		HDE Off-Cycle NOx Standards 3-bin (idle / low-load/ med-high load)			idle 15 (g/hr); low load 150 (mg/hp-hr); 75 medium/high load (mg/hp-hr)	

Allison Transmission, Inc. comparison of regulations Option 1 and Option 2 vs. CARB HD Omnibus

- Allison appreciates the challenge EPA faces in weighing differing stakeholder perspectives regarding importance of full alignment with CARB HD Omnibus versus other alternatives approaches. These comments are based on our interest in maintaining a regulatory landscape that strengthens American industry and supports vocational workforce while achieving clean air and long-term environmental goals. Allison believes there is significant in value in coordinating requirements between CARB and EPA for testing and certification procedures, as well as compliance provisions. Alignment of federal and state programs can, if set at the right level of stringency, help to reduce costs and achieve better efficiency in research and development expenses, allowing for shared product lines. However, Allison believes that EPA needs to consider that alignment is not an unmitigated good in all cases; as reflected in comments above, a different set of considerations and challenges need to be considered when promulgating regulations for products that will serve diverse applications in commercial vehicle markets. These include the need for reasonable access to energy and fueling infrastructure where a transition to different systems to power commercial vehicles is contemplated. Either explicit or implicit mandates for certain vehicle types cannot be reasonably achieved unless there is corresponding availability of the necessary fueling infrastructure. [EPA-HQ-OAR-2019-0055-1231-A1, p.34]

In the comments above, Allison has referenced several areas where EPA's Proposed Rule could be improved. Specifically, with respect to the interrelationship of EPA and CARB standards, Allison would offer several additional comments and perspectives: [EPA-HQ-OAR-2019-0055-1231-A1, p.35]

- CARB's Omnibus NOx standards post MY 2027 are based on assumptions concerning certain alternative fuels and the electric grid; but these assumptions may or may not prove out over the next few years and choosing one technology pathway like ZEVs could realistically constrain participation by other technologies and emerging alternative fuels in the heavy-duty sector. Again, Allison would urge EPA to continue promulgating standards that may be achieved by a variety of different technological approaches and, consistent with its CAA authority, only promulgate standards that appropriately consider costs as well as allow for a sufficient timeframe for necessary research, development and demonstration. [EPA-HQ-OAR-2019-0055-1231-A1, pp.35-36]

- The CARB HD Omnibus Rule utilizes standards and measures that are meant to address regional air quality concerns. The standards also require coordination with supporting infrastructure. Such coordination is inherently more feasible to take in a regional context, which is more capable of supporting and targeting infrastructure development for ZEV deployments, necessary alternative fuels and fueling capacity. Such efforts are likely impracticable and potentially unattainable at the federal level within the same timeframes. Several factors distinguish California's efforts from EPA capability in this area:
    - From a practical standpoint, California has exhibited unwavering support for statewide greenhouse gas reductions and electrification goals and incentives for the transportation sector. Starting with approval of the Global Warming Solutions Act of 2006, California has developed a legal and regulatory framework to enable a noteworthy push to accelerate ZEV technology. In more recent rulemakings, ZEV technology has become a primary focus for efforts in the mobile source sector.
    - In this effort, CARB has conducted multiple workshops and engaged in extensive coordination with the California Energy Commission to plan the infrastructure development necessary to support ZEVs at an accelerated pace. While there are currently some federal efforts in this area, including through passage of the 2021 infrastructure package,72 similar efforts do not exist throughout the United States at the same level of legal/regulatory commitment or public funding. [EPA-HQ-OAR-2019-0055-1231-A1, p.36]

72 Infrastructure Investment and Jobs Act, Pub. L. 117-58.

- CARB HD Omnibus NOx standards post 2027 are based on certain alternative fuels and grid assumptions considered at the time of rulemaking. As a result, these standards may not consider the benefits of other emerging alternative fuels that could be applied to heavy duty internal combustion engines as a tool to achieve near-term criteria air pollutant and long-term CO_2 reduction goals in vehicle applications that resist electrification. They also may not fully consider the need to leverage existing infrastructure when transitioning to stricter standards. Given these limitations, variation from the structure of CARB regulatory requirements is both justified and necessary. [EPA-HQ-OAR-2019-0055-1231-A1, p.36]
- Otherwise, one of the reasons that the CARB HD Omnibus Rule may be able to achieve its aggressive standards and implementation schedule is by leveraging federally certified engines through allowable exemptions that serve to mitigate impacts to end-user productivity (e,g., numerous exemptions were included by CARB in the final rule because transit, motorcoach, refuse, and heavy haul end-users provided information that justified additional flexibility. Again, the state's ability to take particular regulatory approach to reducing emissions does not mean that similar approaches are justified or workable at a federal level. [EPA-HQ-OAR-2019-0055-1231-A1, pp.36-37]

Organization: *American Trucking Associations (ATA)*

In developing the next pathway to further reduce NOx emissions from the trucking sector, ATA worked closely with EPA and other stakeholders with our overall aim to further advance our positive record of environmental progress. We believe in the establishment of one national low-NOx standard that is flexible, considers the wide diversity of trucking operations, is based upon technology paths that are thoroughly tested and affordable, and does not disrupt fleet operations and the economy. Interstate trucks are not bound by geographic boundaries. Trucks purchased anywhere in the country should be compliant wherever their business may take them. [EPA-HQ-OAR-2019-0055-1326-A1, p. 5]

Non-uniformity of national NOx pathways is of particular concern to ATA member fleets. If the final HD2027 rule differs from the California Air Resources Board ("CARB") approach, and CARB and opt-in states under Clean Air Act Section 177 continue implementation of the California standard, there will be two different NOx programs in play across the country – a proposition that is unworkable and problematic. For example, manufacturers would not only face the prospect of two different product lines but also two different sets of engine certification requirements and two different review and approval processes for these products. This will undoubtedly add to the cost of bringing new engines to market and create duplication in the administrative approval process. [EPA-HQ-OAR-2019-0055-1326-A1, pp. 5 - 6]

ATA does not define "harmonization" as federal standards mirroring those of a single state such as California. California has unique air quality issues given its large population and unique geographical features. Their regulation should not automatically become the template in establishing the next national low-NOx standard. Our definition of "harmonization" is the setting of one federal standard that will reduce NOx emissions nation-wide, not impede trucking operations or purchase plans across the country, and is both technologically and economically achievable. Option 1 is the CARB standard and ATA does not support California's extreme and unattainable approach as the next national standard for diesel freight trucks for the rest of the country. [EPA-HQ-OAR-2019-0055-1326-A1, p. 6]

If one national standard across the country is not established, fleets will become creative in where, when, and what type of equipment to purchase if patchwork standards are to remain in effect and expand. For example, while states such as California will not allow you to register a new truck purchased outside the state that does not meet CARB's low-NOx and warranty requirements, such vehicle can be purchased and operated outside the state and then be registered in California once its odometer hits 7,500 miles. Other states may have similar registration provisions. [EPA-HQ-OAR-2019-0055-1326-A1, p. 6]

While California has its unique topography and associated air quality issues, it is imperative that the state and EPA find common ground in plotting a path forward. Putting differences aside, ATA encourages EPA and CARB to ultimately unify their approaches. Fleets have choices and if one harmonized national standard cannot be achieved, fleets may be forced to change their business models and purchasing decisions. [EPA-HQ-OAR-2019-0055-1326-A1, p. 6]

Organization: *California Air Pollution Control Officers Association (CAPCOA)*

CAPCOA supports proposed Option 1, with modifications that would align the proposal with the California Air Resources Board's (CARB) recently adopted Heavy-Duty Omnibus Regulation. This technology forcing regulation will reduce in-use nitrogen oxide (NOx) emissions from new heavy-duty engines and trucks sold in California by 90% beginning in 2027. Such a federal standard would ensure that model year 2027 and later trucks operating in California would meet the most stringent standards achievable regardless of their origin. [EPA-HQ-OAR-2019-0055-1253-A1, p.1]

Despite these significant efforts by air districts and CARB, federal action to reduce emissions is critical if we are to attain the National Ambient Air Quality Standards. For example, data shows that in the South Coast air basin, considering only emissions from ships, locomotives, and aircraft which are under federal authority, the region needs an additional 46 tons per day of NOx reductions by 2023 to attain standards in a timely manner. When also considering the emissions from on-road heavy-duty trucks that are subject to federal authority, the region needs a total of 67 – 69 tons per day of NOx reductions from federal sources. Extrapolating this example to the rest of California, it is clear that without significant progress in reducing mobile source emissions, especially at the federal level, it will be extremely difficult if not impossible to meet our air quality mandates. Absent strong federal action, extreme nonattainment areas such as the South Coast and San Joaquin Valley air basins face Clean Air Act penalties and sanctions due to mobile source emissions under federal jurisdiction. Such air districts will be forced to implement additional stationary source regulations that are much less cost effective than federal mobile source measures and in regions that already impose the most stringent regulations in the nation. To this end, CAPCOA strongly encourage U.S. EPA to promulgate technology forcing regulations in the mobile sector that are directly and solely under U.S. EPA authority that yield as much emissions reductions as possible as quickly as possible. The health of our residents depends on it. [EPA-HQ-OAR-2019-0055-1253-A1, p.2]

Organization: *California Air Resources Board (CARB)*

U.S. EPA should align its standards with those that CARB has already demonstrated are feasible. CARB adopted major revisions to our heavy-duty requirements, known as the 'Heavy-Duty Omnibus Low NOx Regulation' (HD Omnibus Regulation), in 2021. CARB's HD Omnibus Regulation includes a comprehensive set of revisions designed to ensure that NOx emissions from heavy-duty engines are significantly reduced from the time the vehicle/engine is first sold until the end of its useful life. During the development of the Omnibus Regulation over seven years, CARB coordinated closely with U.S. EPA staff. In fact, U.S. EPA contributed significant funding to California's Low NOx heavy-duty engine demonstration work at the Southwest Research Institute, which demonstrated NOx levels on order of 90 percent lower than today's standards with no greenhouse gas impact. U.S. EPA's CTP NPRM contains almost identical programmatic elements to the HD Omnibus Regulation but offers a range of possible stringencies. Option 1, as U.S. EPA notes, is the more stringent option and reflects alignment with the HD Omnibus Regulation. [EPA-HQ-OAR-2019-0055-1186-A1, p.2]

Accordingly, it is absolutely crucial that U.S. EPA finalize standards in line with Option 1 in the CTP NPRM – and strengthen Option 1 to eliminate undue loopholes that could weaken its ability to ensure in-use compliance with its standards. The Option 1 proposal is technologically feasible and cost-effective and closely aligned with CARB's HD Omnibus Regulation. Some of the flexibilities discussed in the NPRM would effectively set higher, less stringent standards for compliance. Such flexibility would allow standards to appear more stringent and health protective than they actually are, thereby providing a 'backdoor' method to set looser standards. For example, such flexibilities could make the regulation's 35 milligrams per brake-horsepower hour (mg/bhp-hr) standard effectively a 70 mg/bhp-hr standard. Option 2 is too weak to be considered as reasonably, especially regarding the proposed emissions standards, useful life, and warranty period requirements. Option 2 would forego desperately needed emission reductions and fail to meet U.S. EPA's statutory requirements under the Clean Air Act. [EPA-HQ-OAR-2019-0055-1186-A1, p.2]

- CARB recommends that U.S. EPA consider only the Option 1 standards, with modifications to the 2027 through 2030 standards that would align with CARB's heavy-duty Omnibus standards. [EPA-HQ-OAR-2019-0055-1186-A1, p.2]

U.S. EPA has proposed a 20 mg/hp-hr NOx standards on the FTP and SET duty cycles and a 50 mg/hp-hr NOx on the LLC for MY 2031 and later light and medium HDEs for full UL and heavy HDEs through IUL of 435,000 miles. These standards are technically feasible and align with the Omnibus 2031 MY standards. [EPA-HQ-OAR-2019-0055-1186-A2, p.40]

However, for MY 2027, the proposed Option 1 FTP, SET, and LLC NOx standards are less stringent than is technically feasible. CARB staff recommends that U.S. EPA align with the 2027 MY Omnibus NOx standards by adopting a 20 mg/hp-hr NOx on the FTP and SET and a 50 mg/hp-hr NOx on the LLC for light and medium HDEs through UL and heavy HDEs through IUL. As discussed below, these standards are technically feasible for MY 2027. [EPA-HQ-OAR-2019-0055-1186-A2, p.40]

The proposed Alternative standards are the most stringent compared to both proposed Options 1 and 2. Although the Alternative has the potential to provide much needed NOx emission reductions, CARB staff understand that U.S. EPA believes that currently no data exists to unequivocally establish the feasibility of the Alternative 20 mg/hp-hr standard over the proposed longer 850,000 mile UL for MY 2027. However, CARB staff strongly supports that U.S. EPA adopt in its final rulemaking the proposed Option 1 standards with CARB staff recommended modifications that would align it with the Omnibus standards as well as strengthen the LLC and idling NOx standards to reflect recently demonstrated emissions performance in the CARB Stage 3 and U.S. EPA Stage 3 RW engine testing as well as the On-Road PEMS demonstration and further engine testing results from the Achates 10.6L Class 8 engine project. Ongoing work is expected this summer from both a second EPA low NOx engine configuration at SwRI and from a CARB and South Coast Air Quality Management District sponsored 800,000 mile aging follow-on emissions demonstration utilizing the second generation Achates engine and simplified aftertreatment. [EPA-HQ-OAR-2019-0055-1186-A2, p.47]

Organization: *Coalition for Clean Air*

Because a significant percentage of the trucks on California roads are based in other states, we rely on USEPA to set a health-protective ultra-low NOx standard. [EPA-HQ-OAR-2019-0055-1139-A1, p.1]

EPA proposes two options for cutting NOx emissions – the biggest cause of smog and soot -- from heavy-duty vehicles. Under Option 1, EPA's plan would work in two phases, reaching 0.035 grams per brake horsepower-hour (g/bhp-hr) in model year (MY) 2027 and 0.02 g/bhp-hr in MY31. This would represent a tenfold increase in stringency over the existing federal standard of 0.2 g/bhp-hr. EPA's weaker "Option 2" would cut NOx to 0.05 g/bhp-hr in a single-step starting in MY27. Option 2 is completely inadequate to address truck pollution. [EPA-HQ-OAR-2019-0055-1139-A1, p.1]

EPA should adopt Option 1, which would produce far deeper NOx cuts than 'Option 2,' but EPA also needs to tighten the plan further to align with California's 'omnibus' heavy-duty truck rule. California's rule reaches the same emissions limit of 0.02 g/bhp-hr of NOx as EPA's 'Option 1,' but does so faster, in MY27. Furthermore, EPA's rule should emulate California's improvements to test procedures, regulatory useful life, emission-related warranty, and other requirements that will meaningfully reduce actual on-road emissions. [EPA-HQ-OAR-2019-0055-1139-A1, pp.1-2]

Organization: *Colorado Energy Office, et al.*

Our agencies strongly support EPA's development of NOx and GHG emission standards. Colorado is planning to initiate a rulemaking at the state Air Quality Control Commission in late 2022 to consider adoption of both the Advanced Clean Trucks rule and the Low NOx Omnibus rule to help address state air quality challenges. Nevertheless, our agencies are highly supportive of a national standard that is as robust as possible to ensure strong progress nationwide on air pollution and equity. A strong national standard is particularly important for trucks because they frequently travel between states supporting interstate commerce, so greater consistency across the country is better for clean air and business. [EPA-HQ-OAR-2019-0055-1297-A1, p.1]

Organization: *Eaton Vehicle Group (Eaton)*

1. **Implementing one national standard is critical for the transportation industry**. The EPA has an opportunity to create a single regulatory approach to emissions. In our assessment, <u>Option 1 of the NPRM is close enough to the California Air Resource Board (CARB) Omnibus</u>, and we believe convergence is both feasible and desirable [EPA-HQ-OAR-2019-0055-1252-A1, p.1]

The absence of a single national standard carries serious risks and introduces uncertainties and confusion in the market, ultimately stifling innovation, investment and the potential for economies-of-scale. This possibility is realistic, as a similar situation happened over the past five years in the light-duty space, when part of the market decided to adopt more stringent CARB CO_2 standards, while another part followed less stringent federal standards, which introduced significant uncertainty in investment strategies of suppliers like Eaton. [EPA-HQ-OAR-2019-0055-1252-A1, p.1]

Besides the uncertainty in the supplier base investments, different emissions levels in some parts of the nation creates the risk of a patchwork of local rules that in effect will lead to disruption in freight with unpredictable effects on the economy. (CARB Omnibus certification represent 20% of the market, with a strong potential that many of the other NESCAUM MOU states would adopt those standards, covering up to 40% of the market). [EPA-HQ-OAR-2019-0055-1252-A1, p.2]

Agency Request / Topic: We are requesting comment on the proposed Options 1 and 2, as well as the Alternative, standards for each duty cycle, as well as the one and two-step approaches in proposed Options 1 and 2, respectively, and the implementation dates of MYs 2027 and 2031 [EPA-HQ-OAR-2019-0055-1252-A1, p.7]

Eaton Comment Strategy / Materials: As explained, Eaton believes that Option 1 is very close to the CARB omnibus (20 mg FTP and 50mg LLC at IUL), there are multiple technology packages that can already achieve these limits, with 40% or better compliance margin, at reasonable costs and based on life-long components. Thus, according to the overriding interest of a single national standard, we believe it is best to harmonize Option 1 with the Omnibus rule. [EPA-HQ-OAR-2019-0055-1252-A1, p.7]

Agency Request / Topic: Throughout Sections III and IV, we discuss areas where our proposal differs from the California Air Resources Board (CARB) Heavy-Duty Omnibus Rulemaking, and request comment on our proposal, including whether it is appropriate to harmonize the federal and CARB regulatory programs more in light of the authority and requirements of CAA section 202, and the benefits or challenges if EPA were to finalize particular aspects of its program that are or are not fully aligned with the Omnibus. [EPA-HQ-OAR-2019-0055-1252-A1, p.9]

Eaton Comment Strategy / Materials: We believe that a single national standard is paramount to the health of the transportation sector. Furthermore, we believe Option 1 is close to the Omnibus. We also believe there are validated technologies that achieve the Option 1 and Omnibus limits with significant compliance margin, at reasonable cost, with truck-life durability. Therefore, we strongly recommend the EPA takes the opportunity to implement a single national standard, in accord with CARB [EPA-HQ-OAR-2019-0055-1252-A1, p.9]

Organization: *Hyliion, Inc.*

The majority of these comments will request cohesiveness between both the California and Federal standards to allow for predictability in the industry. In both warranty and testing cycles we would recommend following the established standards set by California's Air Resource Board. Many in the industry have taken steps to be compliant with these standards and we recommend a unified and certain approach. [EPA-HQ-OAR-2019-0055-1238-A1, p. 2]

Organization: *International Council on Clean Transportation (ICCT)*

Several differences exist between state HDV omnibus regulations first adopted by CARB nearly two years ago and EPA's proposed regulation. These differences could result in engine manufacturers producing different engines depending on whether trucks are being sold in California and Section 177 states, or sold elsewhere, resulting in unnecessary costs. Our view is that a single national program, reflecting even closer alignment between federal standards and those adopted by individual states, including not only California but also Massachusetts, Oregon, and other states intending to adopt, would reduce manufacturer compliance risk and production costs. [EPA-HQ-OAR-2019-0055-1211-A1, p. 18]

Testing of the CARB engine at SwRI achieved an emissions level of 23 mg at 435K mi. Testing of an improved system sponsored by EPA reduced NOx emissions to 20 mg. Four years of lead time remain for OEMs to refine solutions they are already expected to deliver in California. A national requirement would justify OEM research and development at greater scales than what they may consider necessary to meet California requirements alone. For these reasons we support the development of a single national program together with California and other states who have adopted an HDV Omnibus program. [EPA-HQ-OAR-2019-0055-1211-A1, p. 18]

Organization: *Maine Department of Environmental Protection (Department)*

Using the CARB Heavy-Duty Omnibus Regulation as a bellwether, the Department requests the following revisions to the federal proposal: [EPA-HQ-OAR-2019-0055-1288-A1, p.6]

NOx emission limits. Option 1 should be revised to require a 20mg/bhp-hr NOx limit beginning in model year 2027 at intermediate useful life and a 0.035 gram NOx standard at full useful life. A 20mg/bhp-hr NOx limit is technically feasible and consistent with requirements under the CARB Heavy-Duty Omnibus Regulation. [EPA-HQ-OAR-2019-0055-1288-A1, p.7]

Organization: *Motor & Equipment Manufacturers Association (MEMA)*

EPA requests comments on whether it is appropriate to harmonize the federal and CARB regulatory programs more in light of the authority and requirements of CAA section 202, and the benefits or challenges if EPA were to finalize particular aspects of its program that are or are not fully aligned with the Omnibus. [EPA-HQ-OAR-2019-0055-1322-A1, p. 8]

MEMA strongly discourages any technology mandates (i.e., avoid ZEV mandates). In addition, it would be helpful for the EPA to use broader, more flexible definitions of emissions reducing technology. Then the industry can design to performance-based standards and users' unique requirements. As we have advocated in the past, it would also be beneficial to look at the entire lifecycle rather than just "tailpipe" emissions. As vehicles become significantly more fuel efficient, both upstream and downstream emissions become much more important when attempting to truly compare them. Significant infrastructure requirements would also come along with these rules, so if EPA were to try to match CARB there would need to be significant coordination with DOE in terms of planning for the national electric grid. [EPA-HQ-OAR-2019-0055-1322-A1, p. 8]

Organization: *Moving Forward Network (MFN)*

Option 1 should immediately harmonize with state action in model year (MY) 2027. Instead of allowing a four-year delay in matching state-level stringency, Option 1 should immediately impose a NOx emission standard of 0.02 g/bhp-hr for spark ignition, light-, medium-, and heavy-duty engines through intermediate useful life and a 0.035 g/bhp-hr for heavy heavy-duty engines from intermediate useful life to full useful life. [EPA-HQ-OAR-2019-0055-1277-A1, p. 21]

Delaying alignment with the cost-effective Omnibus rule unnecessarily allows dirtier engines to continue to be sold, knowing they will stay on our roads for decades, denying life saving emissions reductions. The most stringent standard – already adopted by three states and being pursued by several more – must be immediately phased-in at the start. [EPA-HQ-OAR-2019-0055-1277-A1, p. 21]

EPA has not adequately explained its deviation from the standards of the Omnibus rule. While disparity between the rules may pose some challenge for manufacturers, central import is that EPA upholds its requirements under Section 202(a) of the Clean Air Act, to promulgate "standards which reflect the greatest degree of emission reduction achievable." In deviating from the Omnibus program, EPA has deviated from years of studies providing robust evidence supporting stronger standards. [EPA-HQ-OAR-2019-0055-1277-A1, p. 22]

Organization: *Ozone Transport Commission (OTC) and Mid-Atlantic/Northeast Visibility Union (MANE-VU)*

Heavy-Duty Engine NOx Standards in 2027: Given the urgent need to reduce NOx emissions from heavy-duty vehicles to improve public health and air quality, we strongly encourage EPA to finalize NOx emission limits equivalent to those in the CARB Heavy-Duty Omnibus Regulation. Specifically, OTC supports the adoption of a 0.020 gram NOx engine standard in 2027 at intermediate useful life and a 0.035 gram NOx standard at full useful life, as specified in CARB's Omnibus regulation. There is ample data from CARB, EPA, and other research programs that support the feasibility of introducing a 0.020 gram NOx standard at intermediate useful life in 2027. 22,23,24,25,26,27 [This comment copied in 3.1.2] [EPA-HQ-OAR-2019-0055-1250-A1, p.13]

Organization: *Retail Industry Leaders Association (RILA)*

Certain areas of EPA's proposed rule relating to the reduction of criteria pollutant emissions align substantially with existing rules in California, introduced by the California Air Resources Board (CARB) in December 2021 as the 'Heavy-Duty Omnibus Regulation'. This proposed rule will therefore harmonize several important federal and state policies for the regulation of heavy-duty engines. Such policy alignment would ensure consistency across the United States and avoid creating bifurcated regulatory frameworks for stakeholders to navigate that would introduce additional compliance costs.[EPA-HQ-OAR-2019-0055-1189-A2, p.5]

Alignment benefits retailers, who operate or rely on complex nationwide freight logistics as a core component of their business. The harmonization of policies would mitigate the complexities that fleet operators might face in managing the availability of vehicles that meet the emissions standards to be registered in most of the country, but not in certain states (e.g., California).[EPA-HQ-OAR-2019-0055-1189-A2, p.5]

Since the trucks that transport freight for retailers often travel across jurisdictions, such as California, it would be beneficial to harmonize where possible. EPA is therefore encouraged to maintain its proposed alignment with CARB's 'Heavy-Duty Omnibus Regulation' where economically justifiable, in order to avoid inducing unnecessary complexity to fleet logistics operations. [EPA-HQ-OAR-2019-0055-1189-A2, p.6]

Organization: *San Joaquin Valley Air Pollution Control District (District)*

On August 27, 2020, the California Air Resources Board (CARB) adopted the Heavy- Duty Engine and Vehicle Omnibus Regulation. This regulation will have significant, and highly important, impacts in reducing NOx emissions in the Valley, and will play an important role in the District’s efforts to attain the federal NAAQS. However, the regulation only applies to engines and vehicles purchased in the state, and many vehicles in use in the Valley are out-of-state vehicles. In fact, CARB's mobile source emissions model, EMFAC, projects that 44% of vehicle miles traveled and 47% of NOx from heavy heavy-duty diesel trucks operated within the District boundaries in 2037 will be due to out-of-state trucks. That single category of mobile sources alone represents 27% of the District's total 2037 NOx emissions from all anthropogenic sources. Given the significance of heavy duty trucking emissions, on June 22, 2016, the District submitted a petition requesting that the U.S. EPA consider adopting new national heavy-duty truck engine emissions standards. [EPA-HQ-OAR-2019-0055-1291-A1, p.2]

Given the need for emissions reductions in the Valley, and the significance of this category within the total emissions inventory, the District strongly supports EPA adopting the most stringent controls possible and recommends adoption of Option 1. Given the challenges faced by the San Joaquin Valley, and the durability of trucks, selecting a less stringent option would burden our residents with unnecessary emissions for decades. Additionally, the District urges EPA to consider modifications to Option 1 to align with the CARB Omnibus Regulation to make nationwide compliance simpler, lead to less confusion nationally, and improve the overall emissions benefit of the regulation. [EPA-HQ-OAR-2019-0055-1291-A1, p.2]

Organization: *Southern Environmental Law Center (SELC)*

The standards should also be fully aligned with the California Heavy-Duty Omnibus Regulation in 2027, establish minimum ZEV production requirements, and preserve the stringency of GHG emissions requirements for internal combustion engine vehicles. [EPA-HQ-OAR-2019-0055-1247-A1, p.1]

As currently proposed, Option 1 does not harmonize with the Omnibus Regulation until model year 2031. This delay in alignment is projected to result in almost 72,000 more tons of NOx emissions through 2045.33 [EPA-HQ-OAR-2019-0055-1247-A1, p.5]

> 33 U.S. ENV'T PROT. AGENCY, Control of Air Pollution from New Motor vehicles: Heavy-Duty Engine and Vehicle Standards Draft Regulatory Impact Analysis, EPA-420-D-22-001, at app. 5, tbl. 5-49 (Mar. 2022).

Given the localized nature of many of the impacts of tailpipe pollution—which, as discussed above, can seriously affect public health and disproportionately impact communities of color and low-income communities—any delay in adopting the strongest possible standards will harm communities nationwide. This is especially true in the near-term, when failure to align with the Omnibus Regulation starting in model year 2027 will result in over 4 percent less NOx reduction each year from model years 2027 through 2030.34 Less stringent standards will also continue to make it difficult for many state and Tribal governments to meet their obligations under the NAAQS. [EPA-HQ-OAR-2019-0055-1247-A1, pp.5-6]

> 34 Id.

As noted by commenters during the public hearing on this proposed rule, localities have limited authority to address criteria pollutant emissions from mobile sources and strong federal tailpipe emissions standards are one of the most important tools available to address this type of pollution. Moreover, a single-step alignment would create a single national standard for medium- and heavy-duty engine and vehicle manufacturers, making planning and compliance easier.35 [EPA-HQ-OAR-2019-0055-1247-A1, p.6]

35 'The heavy-duty engine and vehicle manufacturing industry has consistently maintained a strong preference for harmonized regulations across the U.S. and Canada, given the highly integrated nature of the North American market and the desire to avoid the additional costs associated with having to develop specialized products.' INT'L COUNCIL ON CLEAN TRANSP., California's Heavy-Duty Omnibus Regulation: Updates to Emission Standards, Testing Requirements, and Compliance Procedures 10 (Jan. 2022), https://theicct.org/publication/california-us-hdvomnibus-reg-jan22/.

Organization: *Truck Renting and Leasing Association (TRALA)*

TRALA supports the efforts to reduce emissions and to increase the development of cleaner trucks onto our nation's highways. [EPA-HQ-OAR-2019-0055-1180-A1, p. 1]

TRALA believes that there is a desire in the trucking industry to incorporate newer and cleaner trucks into the marketplace, especially as the cost comes down. However, TRALA remains concerned that government mandates to adopt these technologies on shortened timelines will only slow the process of getting newer trucks onto the road. [EPA-HQ-OAR-2019-0055-1180-A1, p. 2]

TRALA remains determined that the EPA needs to set a national standard for emissions. For too long, the trucking industry has dealt with two manufacturing standards when purchasing new trucks, a truck that meets the EPA's standard, and a truck that meets CARB's standard. In its comments to the EPA on their Greenhouse Gas Phase 2 rule, TRALA urged the EPA to work with CARB to adopt a national standard for NOx that was not an ultra-low standard. These competing standards increase manufacturing costs and add complexity to the operation of national fleets. As we are seeing now, the requirements on manufacturing set by CARB and the EPA are diverging even further. [EPA-HQ-OAR-2019-0055-1180-A1, p. 3]

This growing divergence between CARB and EPA regulations will continue to create a chaotic regulatory patchwork of state requirements that EPA regulations are meant to avoid. Several states have already indicated that they will adopt CARB standards as well. By permitting CARB to supersede EPA's standard for NOx, the EPA is shirking its responsibility to take the lead in setting national standards for clean air. TRALA strongly encourages EPA to make Option 2 the basis for nationwide standards, and to work to ensure that California and other states align their NOx requirements with the Option 2-based standards that EPA establishes through a final rule. [EPA-HQ-OAR-2019-0055-1180-A1, p. 3]

TRALA has significant concerns with how the dual standard model would impact the new and secondary truck markets. As previously stated, TRALA members purchase vehicles, but they do not operate them, nor do they choose where their customers domicile these vehicles. If additional non-attainment states choose to adopt CARB's standard over EPA's, it will create major interstate commerce concerns for TRALA customers who operate in states that have competing

NOx standards. The decisions on where to operate will be constrained by the OEM's ability to meet the demands for EPA and CARB trucks. For instance, the timeline to acquire an EPA truck may be much longer than the timeline to acquire a CARB truck, forcing a business to either wait longer for the truck they need, or pay a premium to receive the CARB truck they don't want. Furthermore, TRALA members are concerned that the dual standards will significantly harm the secondary market as non-CARB trucks will not be able to be sold in certain states. That will leave smaller motor carriers in CARB states with the option to buy older trucks or used CARB trucks which are vastly more expensive due to the NOx rule's impacts on product availability and price. It is unlikely that smaller motor carriers that are the most price-sensitive would be able to absorb those cost increases and remain competitive in the trucking industry. [EPA-HQ-OAR-2019-0055-1180-A1, p. 3]

Accordingly, TRALA supports the Option 2 certification standard of .05. That said, we urge EPA to work with CARB and the other states who have pledged to adopt CARBs standards for NOx, to persuade those states not to proceed with regulations that would exceed the EPA's standard. TRALA urges the EPA to adopt regulations based on Option 2 and to work with every state including California to agree to a new national low-NOx certification standard of .05. TRALA believes that a national standard would reduce the regulatory burden on the OEMs that would not have to meet multiple standards in a shortened time period. A national standard of .05 would reduce the catastrophic disruption these rules could have on the new and used truck markets. [EPA-HQ-OAR-2019-0055-1180-A1, p. 4]

Organization: *Valero Energy Corporation*

There are several critical deficiencies in the data and analysis on which the proposed rule revisions rely. In addition to these specific deficiencies identified below, Valero incorporates as part of these comments a report prepared by Ramboll U.S. Consulting, Inc. for Western States Petroleum Association that evaluates CARB's Heavy Duty Truck strategy1 and concludes that CARB's approach does not deliver results as early and as cost-effectively as an approach that incorporates low-nitrogen oxides ('NOx') emission vehicles coupled with increased introduction of renewable liquid and gaseous fuels. Since EPA's proposal relies heavily on analysis performed by CARB, the conclusions in the Ramboll study are relevant to EPA's proposal. EPA must not blindly follow CARB, but should take these comments, including the Ramboll study, into account. [EPA-HQ-OAR-2019-0055-1328-A2, p.3]

Organization: *Wisconsin Department of Natural Resources (WDNR)*

Option 1 includes program elements such as low load cycle NOx standard, full useful life standard and emission warranty (miles) identical to California Air Resources Board's (CARB) heavy-duty engine and vehicle omnibus regulation for both MY 2027 and 2031. EPA should consider revising remaining Option 1 program elements to fully align with CARB omnibus regulation beginning in MY 2027. Having to comply with different federal and California standards may impose unnecessary burden on engine manufacturers. [EPA-HQ-OAR-2019-0055-1162-A1, pp. 2 - 3]

EPA should work with CARB to evaluate the technical elements of the proposal that are not as stringent as those required in CARB's omnibus rule. For example, EPA's proposed durability demonstration program is weaker than that required by CARB's rule and may not adequately simulate real-world engine aging. Should EPA finalize any program elements that are less stringent than those in CARB's omnibus rule, it must ensure they do not result in an overall decrease in program stringency. [EPA-HQ-OAR-2019-0055-1162-A1, p. 3

EPA Summary and Response

Several commenters provided input on whether and how EPA should align the standards and requirements in the final Federal program with the standards and requirements in the California Air Resources Board (CARB) Heavy-Duty Omnibus Low NOx Regulation (HD Omnibus). Many state organizations, some suppliers of heavy-duty emissions control technologies, and environmental justice organizations support a Federal program that fully aligns with the HD Omnibus starting in MY 2027. In contrast, other heavy-duty emission control technology suppliers and retail organizations support a Federal program that only partially aligns with the HD Omnibus (i.e., commenters support a Federal program that aligns with some parts, but not other parts, of the HD Omnibus program); for instance, one commenter suggested EPA align with the HD Omnibus test procedures, but not the numeric stringency. Finally, the trade organization for large heavy-duty fleets support a Federal program that fully aligns with a California program, but does not support the level of stringency in the HD Omnibus, rather they encourage EPA and CARB to ultimately unify approaches such that a single federal standard "reduces NOx emissions nation-wide while not impede trucking operations or purchase plans across the country". In this Section 3.1.2 of the Response to Comments document, we briefly discuss the perspectives of each of these commenter groups, and then provide the EPA response to these comments.

Commenters who support a Federal program that fully aligns with the HD Omnibus starting in MY 2027 provide several points of discussion. First, these commenters stress the importance of full alignment with the level of stringency in the HD Omnibus because trucks frequently travel between states. Commenters note that out-of-state trucks contribute significantly to emissions in CA, and potentially to other states that may adopt the HD Omnibus program, and thus a national program is important for reducing emissions from all trucks; commenters also point to the importance of reducing emissions from all trucks in areas working to achieve or maintain National Ambient Air Quality Standards. Given the significant contribution of emissions from heavy-duty trucks, some of these commenters petitioned EPA in 2016 to consider adopting new national heavy-duty truck engine emissions standards. Second, commenters note that full alignment with the HD Omnibus would allow both engine manufacturers and suppliers to streamline their development processes, as well as provide certainty in their investments in the next generation of vehicle technologies. Third, commenters state that a Federal program fully aligned with the HD Omnibus would simplify nationwide compliance, lead to less confusion nationally, and improve the overall emissions benefit of the Federal regulation. They further note that full alignment between Federal and California standards could avoid the risk of a patchwork of local rules that could then disrupt freight transport, with unpredictable effects on the economy.

One commenter further stated that EPA did not adequately explain the deviation in the proposed standards from the HD Omnibus; stating that under Section 202(a) of the Clean Air Act, EPA is required to promulgate “standards which reflect the greatest degree of emission reduction achievable,” and noting that deviating from the HD Omnibus program deviates from studies providing evidence that support stronger standards than proposed. In addition, another commenter stated that if EPA finalizes any program elements that are less stringent than those in the HD Omnibus, then EPA should ensure the overall program maintains the same level of stringency. This commenter pointed specifically to the proposed durability demonstration program and raised a concern that it may not adequately simulate real-world engine aging. Finally, one commenter noted that Executive Order (EO) 14037 explicitly instructed EPA to coordinate its Heavy-duty NOx standards with California.[10]

Commenters supporting a Federal program that only partially aligns with the HD Omnibus also provide several lines of discussion. For instance, one commenter states that there is significant value in EPA coordinating with CARB on requirements for testing, certification, recordkeeping, reporting procedures, as well as compliance and enforcement provisions; however, they do not support harmonization on all areas of the standards. Another commenter stated that EPA should seek to have CARB’s requirements become more consistent with EPA’s approach to regulating criteria and GHG emission, rather than adopting the CARB requirements. Another commenter supports EPA adopting proposed Option 1, which they characterize as very close to the HD Omnibus program. The commenter notes that there are multiple technology packages that can already achieve the proposed Option 1 standards with 40% or better compliance margin over the useful life periods, and at what the commenters states are reasonable costs. Some commenters further urged EPA to promulgate standards that may be achieved by a variety of different technological approaches (i.e., avoid a mandate of any one technology) and, consistent with its CAA authority, only promulgate standards that appropriately consider costs as well as allow for a sufficient timeframe for necessary research, development and demonstration. Commenters further noted that there are a different set of considerations and challenges that need to be considered when promulgating regulations for products that will serve diverse applications in commercial vehicle markets across the country (e.g., fueling infrastructure, electric grid capacity). Another commenter stated that it would be beneficial to align with the HD Omnibus where economically justifiable, in order to avoid inducing unnecessary complexity to fleet logistics operations.

The trade organization for large heavy-duty fleets similarly stated that a lack of a unified national program could result in fleets changing their business models and purchasing decisions. They support full alignment of a Federal program with a CARB program, but do not support the stringency of the HD Omnibus. Rather, this commenter encouraged EPA and CARB to ultimately unify approaches for a single federal standard that does not disrupt the business operations of fleets. Similarly, another commenter stated that EPA should not simply follow CARB, but rather should take into account additional information, including information submitted in their comments that they state shows the HD Omnibus does not deliver results as early and as cost-effectively as an approach that incorporates low-nitrogen oxides ('NOx') emission vehicles coupled with increased introduction of renewable liquid and gaseous fuels.

[10] President Joseph Biden. Executive Order on Strengthening American Leadership in Clean Cars and Trucks. 86 FR 43583, August 10, 2021.

Response:

As discussed in preamble Section III.A.3, our evaluation of available information and data shows that the final standards and useful life periods are technologically feasible and will result in the greatest degree of emission reduction achievable for MY 2027, pursuant to our authority under CAA section 202(a)(3) that applies to setting this final rule's standards, giving appropriate consideration to cost, lead time, and other statutory factors.[11] We acknowledge that several commenters urged EPA to finalize proposed Option 1 since it closely aligned with the HD Omnibus; while we are not finalizing proposed Option 1, as further explained in preamble Section III our independent evaluation of the greatest degree of emission reduction achievable for a national program includes consideration of the points the commenters raised. For example, EPA determined an appropriate compliance margin for manufacturers within the context of this rule's low numeric emission standards and long regulatory useful life mileages and included compliance flexibilities like the in-use compliance margin in our assessment of the projected emission reductions from the final rule. In addition, we have considered one commenter's concern that the proposed durability demonstration program did not align with the HD Omnibus and may not adequately simulate real-world engine aging; as discussed in preamble Section IV and section 10 of this document, the final durability demonstration program includes updates from the proposal, which allow for closer alignment with the HD Omnibus. In our assessment the final durability demonstration program will account for real-world aging while providing a significantly shortened aging time for demonstration out to useful life.

We disagree with the commenter who stated that "deviating" from the HD Omnibus program "deviates" from available evidence supporting stronger standards. As discussed immediately above, our evaluation of available information and data shows that the final standards and useful life periods will result in the greatest degree of emission reduction achievable for MY 2027, giving appropriate consideration in EPA's judgment to the statutory factors.[12] Further, California has submitted a waiver of preemption under CAA section 209(b) for the HD Omnibus program; a waiver of preemption enables California to enforce its own standards that would otherwise be preempted under section 209(a). EPA's decision on that waiver proceeding is still pending, and until EPA grants the waiver, the HD Omnibus program is not enforceable.

Even assuming that EPA subsequently grants the waiver, however, that does not mean that EPA must issue the same standards as California or otherwise suggest any defect with this final rule.

[11] We note that CAA section 202(a)(3) neither requires that EPA consider all the statutory factors equally nor mandates a specific method of cost analysis; rather EPA has discretion in determining the appropriate consideration to give such factors. See, e.g., Sierra Club v. EPA, 325 F.3d 374, 378 (D.C. Cir. 2003) (explaining that similar technology forcing language in CAA section 202(l)(2) ''does not resolve how the Administrator should weigh all [the statutory] factors in the process of finding the 'greatest emission reduction achievable' ''); Husqvarna AB v. EPA, 254 F.3d 195, 200 (D.C. Cir. 2001) (explaining that under CAA section 213's similar technology-forcing authority that ''EPA did not deviate from its statutory mandate or frustrate congressional will by placing primary significance on the 'greatest degree of emission reduction achievable' '' or by considering cost and other statutory factors as important but secondary).

[12] We note that the commenter did not explicitly state which studies they were referring to in their statement regarding "years of studies"; however, our response includes consideration of the CARB engine demonstration program.

Rather, the statute directs EPA to establish standards under 202(a)(3) and there is a separate review process under 209(b) for waiving preemption of California's standards, which are established under state law. Congress developed these two entirely different administrative proceedings, and Congress also intended that California have the authority to adopt and enforce its own motor vehicle program, subject to the limited waiver criteria in section 209(b), to address its compelling and extraordinary conditions. Thus, the statute contemplates that California and EPA may adopt different motor vehicle programs. And while EPA and California have aligned programs in the past, that result is plainly not required by statute. Accordingly, in this final rule, we are focused on achieving the greatest emission reductions achievable in the MY 2027 timeframe under our authority in 202(a)(3), and have applied our judgment in determining the appropriate standards starting in MY 2027 under this authority for a national program. We further note that, while, as one commenter noted, EO 14037 states that EPA should coordinate with California on heavy-duty NO_X standards, the EO also directs EPA to do so in a manner that is appropriate and consistent with applicable law; as discussed in this section of the Response to Comments document and further detailed in the preamble, this is the approach that we have taken in developing this final rule.

Moreover, the HD Omnibus program differs from the federal program in multiple aspects, such that a facile comparison is not appropriate. These differences result in part from there being different considerations for a national regulation compared to a state or regional program, as some commenters note. For instance, we acknowledge one commenter's perspective that there are several factors that distinguish California's efforts from Federal efforts (e.g., California has undertaken several state actions to accelerate ZEV adoption, including providing funding and support for ZEV charging and re-fueling infrastructure).[13] In addition, as noted immediately above, the factors for establishing standards under 202(a)(3) are separate from the process under 209(b) for waiving preemption of California's standards.

Some commenters urged EPA to take ZEVs into account when setting the final standards, while other commenters urged EPA to set standards that may be achieved by a variety of different technological approaches. As explained in preamble Section III, the final standards in this rule are not based on the projected utilization of ZEV technology, though manufacturers may choose to comply with the standards through using ZEV technologies.

Regarding the study one commenter points to that they state shows the HD Omnibus does not deliver results as early and as cost-effectively as an approach that incorporates low-nitrogen oxides ('NOx') emission vehicles coupled with increased introduction of renewable liquid and gaseous fuels, EPA is setting performance-based standards that EPA has demonstrated to be technology-forcing, feasible, and appropriate under our CAA section 202(a)(3)(A) authority and that do not require a certain technology be applied to comply with the standards; thus, the comment and cited study generally support the feasibility of the final standards to the extent the

[13] While we note that the Inflation Reduction Act (IRA) has many incentives for promoting zero-emission vehicles, including support for refueling infrastructure (e.g., Section 13404 Alternative Fuel Refueling Property Credit), we intend to consider the implications of the IRA and other Federal actions in future rulemakings focused on heavy-duty vehicle standards for the heavy-duty sector. We further note that, as discussed in preamble Section IV, the final ABT program does not allow manufacturers to generate NO_X emissions credits from ZEVs because we are concerned that allowing NO_X emissions credits from ZEVs would result in fewer emissions reductions than intended from this rule.

application of such technology may be used in the future to meet these standards. As noted immediately above, manufacturers may elect to comply through alternate pathways, such as renewable liquid or gaseous fuels, if they find them more cost-effective or otherwise more preferable.

We acknowledge the concerns that some commenters raised that differences between the Federal program and CARB HD Omnibus could lead to business and/or logistical challenges for fleets and other members of the heavy-duty industry. As an initial matter, we note that these same kinds of concerns — regarding additional costs and implementation challenges associated with developing and producing vehicles to meet multiple standards — were raised to Congress during the development of the Clean Air Act. Nonetheless, Congress enacted section 209(b), which authorizes California to adopt and enforce its own motor vehicle emissions program, clearly contemplating the possibility for two different motor vehicle regulatory programs in the United States.

As explained further in the final rule preamble Sections III and IV, and this section 3 of this document, in setting the final standards EPA considered the required statutory factors, including giving appropriate consideration to the cost associated with the application of technology that can achieve the emission reduction of the final standards. To the extent consistent with our authority and within the scope of this rulemaking, we have aligned with testing and other requirements in the HD Omnibus. For instance, we are adopting the same LLC duty cycle procedure and incorporating by reference the 2019 CARB OBD regulations (see preamble Section III for details on the idle standard in the final rule and preamble Section IV for details on the OBD requirements in the final rule). EPA staff intend to continue working closely with CARB staff and other stakeholders where possible to ensure as smooth an implementation of the Federal program as possible.

3.2 Criteria pollutant standards for FTP and SET testing

3.2.1 FTP and SET standards and testing for compression-ignition engines

Comments by Organizations

Organization: *Alliance for Vehicle Efficiency (AVE)*

AVE supports additional modifications to Option 1 to provide the best opportunity for driving more rapid adoption of advanced engine and emission control technologies. These additional modifications include:

- Considering a stricter PM standard than what is being proposed to prevent backsliding under the proposed lower NOx limits. [EPA-HQ-OAR-2019-0055-1280-A1, p. 3]

Organization: *Allison Transmission, Inc. (Allison)*

- Allison also believes that finalizing a 50 mg/hp-hr NOx standard, as measured on the Federal Test Procedure ("FTP") and Supplemental Emission Test ("SET") cycles, offers a much better chance of programmatic and environmental success across medium- and heavy-duty vehicle fleet. Conversely, imposing a 20mg /hp-hr NOx standard, with limited validation of the necessary technology and longer useful life periods, carries with it a considerable risk of failure and disruption to the HDV market. Allison does not believe that the 20 mg/hp-hr standard has been validated in the vocational vehicle market to degree that would be required by Option 1 or any more stringent Alternative under consideration.[EPA-HQ-OAR-2019-0055-1231-A1, p.5]

Organization: *American Trucking Associations (ATA)*

Technology Issues Present Hurdles to Achieving Overly Stringent NOx Standards

ATA and fleets are concerned that manufacturers will not be capable of producing Option 1-compliant products that meet 0.02 g/bhp-hr in 2031. As shown in Figure 1, meeting a 0.02 g/bhp-hr standard under the FTP through 435,000 miles was not demonstrated as part of laboratory testing preceding the rulemaking. To reach such stringency levels, the requisite compliance margins could, hypothetically, have to dip into the "negative emission" compliance range. Stringency levels teetering a notch above zero cause great hesitation for fleets that can ill afford more false-positive NOx sensor readings and greater potential for manufacturer recalls. After all, a truck in a service bay is an unproductive truck – even if such truck is still under a warranty for repairs. [EPA-HQ-OAR-2019-0055-1326-A1, p. 7]

While it is true that CARB has certified a limited number of natural gas and liquefied petroleum gas heavy-duty engine families that can achieve a 0.02 g/bhp-hr NOx limit, these engines do not incorporate NOx sensors (See Table 1). Whereas there are limited niche markets for certain natural gas vehicles, natural gas technologies are largely being used by school and municipal buses and the refuse industry – not the freight sector. The fact remains that trucking is and will be for the foreseeable future a diesel-driven industry. [EPA-HQ-OAR-2019-0055-1326-A1, p. 8]

More importantly, according to manufacturers, current NOx sensors are incapable of accurately sensing 0-5 ppm tailpipe NOx concentrations that are typical at 0.02 g/bhp-hr NOx certification levels, especially because current NOx sensors have a nearly 1:1 cross-sensitivity to ammonia slip. Given there are also no accurate ammonia sensors either, separately sensing and subtracting ammonia to correct for the NOx sensor's ammonia cross-sensitivity doesn't work either. OEMs have already tried such an approach to no avail. [EPA-HQ-OAR-2019-0055-1326-A1, p. 9]

Organization: *California Air Resources Board (CARB)*

U.S. EPA's Stage 3 RW engine platform at 435,000 equivalent miles of accelerated aging resulted in tailpipe NOx emissions of 20, 17, and 29 mg/hp-hr respectively on the FTP, Ramped-modal cycle (RMC), and LLC duty cycles. Since the proposed useful lives for MY 2027 light and medium HDEs are much less than 435,000 miles, it can be concluded that, with application of emission control technologies similar to the Stage 3 RW, these engine classes could meet CARB staff recommended standards of 20 mg/hp-hr NOx on the FTP and SET and a 50 mg/hp-hr NOx on the LLC. [EPA-HQ-OAR-2019-0055-1186-A2, pp.40-41]

On page 17471 of the NPRM, U.S. EPA asks for comments regarding the issue of certification compliance margins. Specifically: '… if a margin between the demonstrated emissions performance and the proposed standards should be included and if so, we request comment on if a specific margin should be used and what that value should be. Commenters requesting a specific margin are encouraged to provide data and analysis to support the numeric value of the margin(s)'. [EPA-HQ-OAR-2019-0055-1186-A2, p.50]

> Compliance margin (CM) is defined as CM = Applicable Standard - Certification emission level / Applicaple Standard x 100%, where the certification emission level represents the highest NOx emission level for all production engines within the engine family at the end of UL and includes the infrequent regeneration adjustment factors. [EPA-HQ-OAR-2019-0055-1186-A2, p.50]

At the time of certification, manufacturers sign a statement of compliance for each engine family certifying that all production engines within the engine family are in all material respects described in the certification application and comply with all regulatory requirements (including the emission standards). Adding CMs to the adopted standards effectively sets higher, less stringent standards for compliance. Such CMs in effect allow standards to appear more stringent and health protective than they actually are, thereby providing a 'backdoor' method to set looser standards. CARB strongly opposes applying such CMs. The standards should be set at the attainable levels and measured against those levels when compliance determinations are made by regulatory agencies. [EPA-HQ-OAR-2019-0055-1186-A2, pp.50-51]

CARB staff has performed an exhaustive study124 of CMs for diesel-fueled engines covering all California certified on-road HDEs from 2010 through 2020 MYs. The result from this study is shown in Figure 5-3. As shown, four percent of the engine families were certified with no CM, while another 10 percent of the engine families were certified with less than a 5 percent CM. It should also be noted that only 19 percent of the certified engine families had CMs between 50-75 percent. [EPA-HQ-OAR-2019-0055-1186-A2, p.51]

> 124 CARB certification data. https://ww2.arb.ca.gov/new-vehicle-and-engine-certification-executive-orders-compression-ignition-and-heavy-duty-engines

The data in Fig. 5-3 indicates that engine manufacturers do not have a universal, one-size fits all approach when it comes to certifying their product portfolio with a built-in compliance margin. In fact, for the referenced period, seven out of eight on-road HD diesel engine manufacturers had certified engine families with a 15 percent compliance margin or less as shown in Fig 5-4. [EPA-HQ-OAR-2019-0055-1186-A2, pp.51-52]

For HHDD engines a similar analysis is shown in Fig. 5-5. As shown, three percent of the HHDD engine families were certified with no compliance margin, while another seven percent of the engine families were certified with less than a five percent CM. [EPA-HQ-OAR-2019-0055-1186-A2, p.52]

Based on analysis of historical certification data in Fig. 5-3, 5-4 and 5-5, CARB staff strongly believes that U.S. EPA should not consider the inclusion of any compliance margins in establishing new emissions standards. In other words, the standard should be set based on the demonstrated emission rates achievable with the anticipated technology, without adding some margin on top of that. The manufacturers determination as to what margin they desire when meeting emission standards is an aftertreatment design consideration and a business decision. U.S. EPA should not set minimum or maximum margin considerations when establishing standards. [EPA-HQ-OAR-2019-0055-1186-A2, p.53]

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

Finally, Commenters support EPA's proposals to adopt a revised PM standard and to require closed crankcase ventilation systems for compression-ignition engines, both of which will achieve important reductions in PM pollution. 87 Fed. Reg. at 17,461–62, 17,466–67. The proposed PM standard of 5 mg/hp-hr is unquestionably feasible (even allowing for measurement variability), as manufacturers are already certifying engines well below this level. Id. at 17,462. Finalizing a PM standard at least that low will preserve these gains by preventing backsliding in the future.

Organization: *Coach USA, Inc. (Coach USA)*

Further, the proposed rule leaves major open questions about its impact on engine size and weight. Any significant increase in either the size or weight of engines could counter-productively serve to reduce the number of passengers that could be transported on a motorcoach. For example, both under federal and state laws buses are subject to strict weight limits. See, e.g., 23 U.S.C. 127. However, the proposed rule contains no useful analysis of its bus weight implications. [EPA-HQ-OAR-2019-0055-1307-A1, p. 3]

Finally, Coach USA urges EPA to obtain information from engine manufacturers to assess implications from the added weight and increased temperatures associated with SCR and derate-related equipment. As noted above, interstate buses are subject, throughout the country, to heavily-enforced weight restrictions; any exceedance caused by SCR or derate-related equipment that causes a bus to be overweight would be unacceptable to sustaining interstate bus operations. Likewise, any increased temperatures caused by such equipment – which may cause buses to be less reliable or otherwise potentially impair driver/passenger safety – would also be unacceptable to Coach USA. [EPA-HQ-OAR-2019-0055-1307-A1, p. 7]

Organization: *Cummins Inc. (Cummins)*

Analysis of the compliance margin needed for robust compliance also shows the Option 2 NOx standard of 50 mg/hp-hr to be challenging but achievable, assuming current emission useful life periods. (Our concerns with EPA's longer proposed Option 2 useful life periods are described below.) EPA should finalize the Option 2 NOx FTP/ SET standard of 50 mg/hp-hr, at appropriate useful life, across all spark-ignition (SI) and compression-ignition (CI) primary intended service classes. [EPA-HQ-OAR-2019-0055-1325-A1, p. 4]

1036.505(d)(4) - Figure 1

Figure 1 seems to indicate SET 5 cycle would be cold cycle. This is not equivalent to engine SET where engine and aftertreatment are pre-conditioned before running the emission test. Cummins suggests skipping the cycle where engine starts for first time and use the following cycle to report criteria emissions. For example, skip SET 5 and 6, report result from SET 7 (not shown in the picture). A similar approach should be considered for cycle average fuel map process. [EPA-HQ-OAR-2019-0055-1325-A1, p. 24]

1036.505(h)

This requirement forces to capture PM on the two separate idle modes of the SET duty cycle which may require additional PM system. Additionally, the PM during the idle modes will be similar to background levels and this could lead to negative brake-specific PM data due to measurement uncertainty. Subsequently, these negative brake-specific PM will serve as emission standards for clean idle test. Therefore, this paragraph should allow a manufacturer to use other methods to ensure that the emissions of PM, HC, and CO are not adversely affected by meeting clean idle requirements. [EPA-HQ-OAR-2019-0055-1325-A1, p. 24]

1036.510(g)

This requirement forces to capture PM on the idle modes of the FTP duty cycle which may require additional PM system. Additionally, the PM during the idle modes will be similar to background levels and this could lead to negative brake-specific PM data due to measurement uncertainty. Subsequently, these negative brake-specific PM will serve as emission standards for clean idle test. Therefore, this paragraph should allow a manufacturer to use other methods to ensure that the emissions of PM, HC, and CO are not adversely affected by meeting clean idle requirements. [EPA-HQ-OAR-2019-0055-1325-A1, p. 25]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

While we fully endorse EMA's comments on this topic and encourage EPA to consider them carefully, we also highlight and recommend herein a few important design margin parameters for incorporation into EPA's next-tier NOx standards. EMA's industry-wide analysis of all HD engines shows that design margins of ~ 40% are appropriate for meeting the EPA 2010 0.2 g/hp-hr standard on composite FTP (below is the chart presented in EMA's technical feasibility document illustrating the margin). This margin is the difference between the emission standard and the lower 'as-designed' emissions performance that diesel OEMs target for their products. Daimler Truck designs and calibrates its products to provide sufficient margin to ensure robust compliance after accounting for numerous factors that can compromise real-world emissions performance. As emission standards become more stringent, these design margins become more and more important and carry significant weight in the design of new technologies to meet future low-NOx standards. The following Figure 2, adopted from the EMA comments, shows that

>60% margins are needed for any future NOx reduction regulations: [EPA-HQ-OAR-2019-0055-1168-A1, pp.24-25]

To meet the current EPA 2010 0.2 g/hp-hr NOx emission standard, the 40% design margin from the standards that OEMs are taking is driven by field degradation concerns, production components variability, and in-use testing standards (due to fuel contaminants), and not from FTP or RMC-based test cell demonstrations (as demonstrated during the EPA Stage 3 research studies). In the Proposed Rule, it is apparent that EPA has failed to perform any field demonstration of the new technology on the vehicle. In our experience, even the most sophisticated test cell-based thermal aging procedures fail to account for real world chemical degradation due to the variability of field fuel quality. Below are examples of key design margins that an OEM considers during the design of aftertreatment technologies, which are not addressed in the Proposed Rule:

1. Catalyst aging impact due to field fuel quality and NOx increase due to biodiesel.
2. Different configurations (ratings, exhaust length configurations, etc.) not considered by EPA in demonstration.
3. Components, sensor variability and test-to-test variabilities that are not considered by EPA in the proposal. [EPA-HQ-OAR-2019-0055-1168-A1, p.25] Apart from the above design margins not considered in the Proposed Rule, there are a number of overarching issues that EPA did not consider as a part of its low-NOx technology feasibility demonstration:
4. EPA’s demonstrated technology is not available.
5. The Stage 3 / RW system demonstrated in Proposed Rule cannot be packaged on a vehicle.
6. EPA’s Stage 3 / RW demonstration system doesn’t meet GHG Phase 2 standards for MY 2027.
7. In-use 3B-MAW issues.
8. SWRI test data does not demonstrate the feasibility of the standards proposed by EPA. [EPA-HQ-OAR-2019-0055-1168-A1, pp.25-26]

EPA’s low-NOx demonstration failed to account for the full range of expected engine configurations. [EPA-HQ-OAR-2019-0055-1168-A1, p.32]

EPA low-NOx test cell demonstration work at SWRI was performed on a Cummins MY2017 X15 and considered only one engine rating, 500HP/1850 lb-ft, and only one exhaust configuration. The parent rating combination along with the short exhaust pipe is likely the best case scenario for tailpipe low-NOx emissions. When an OEM certifies an engine family with EPA and CARB, there are multiple engine ratings and configurations represented by the certified engine family. The parent test engine configuration selection for criteria pollutants is defined in 40 CFR 86.096-24. When certifying the parent engine test configuration, an OEM also has to ensure all the lower engine ratings within the engine family will meet the relevant criteria pollutant and GHG standards with adequate margins to account for the various field deterioration variables (e.g., range of field fuels, field aging, production components and sensors variability, cold ambient conditions etc.). [EPA-HQ-OAR-2019-0055-1168-A1, p.32]

These various engine ratings within an engine family cover a wide variety of customer applications. A few examples of various customer chassis applications are shown in Figure 6 below, including line haul/regional distribution, crane, dump truck, logging, snow plow, construction, bulk haul, tanker, refuse, food and beverage hauler etc. In these various customer chassis applications, there is no space in the engine compartment (near the engine exhaust) to package the aftertreatment devices that would be required, due to the positioning of the various engine components and interferences with the structural frame rails. [EPA-HQ-OAR-2019-0055-1168-A1, pp.32-33]

For these reasons, the main aftertreatment devices (DOC, DPF, SCR) are packaged downstream from the engine where space is available for packaging aftertreatment components while accounting for vehicle safety and application needs. In the various chassis applications, connecting exhaust pipe lengths from the engine exhaust to the aftertreatment varies, depending on the type of vehicle chassis. In Figure 6 below, Daimler Truck also highlights an example of two such exhaust pipe length configurations. Configuration (2) in the chassis application has a significantly longer exhaust pipe when compared to a sleeper cab, which is configuration (I). Various lengths of exhaust pipe configurations exist to cover various customer chassis applications: [EPA-HQ-OAR-2019-0055-1168-A1, p.33]

In the EPA demonstration of the Stage 3 engine investigations at test cell, only one exhaust configuration and only one parent rating were tested. The worst case scenarios of longer exhaust pipe configurations and other ratings were not tested in any of the EPA Stage 3 investigations, which were the basis for the Proposed Rule. These worst case scenarios are expected to have lower exhaust temperatures, and higher temperature losses between the engine and the aftertreatment, leading to lower exhaust gas temperatures entering into the aftertreatment and consequently lower SCR performance. Consequently, these scenarios will result in higher tailpipe NOx emissions compared to those demonstrated in the EPA Stage 3 test results. To ensure robust emissions compliance, during certification an OEM absorbs the effect of exhaust pipe lengths and engine ratings within the engine family by ensuring during development testing and validation that all configurations meet the desired standard. EPA has not done so for its demonstration engine-and it is unlikely such configurations would pass. [EPA-HQ-OAR-2019-0055-1168-A1, pp.33-34]

SCR conversion efficiency is reduced at lower temperatures. This is well explained and acknowledged by EPA in the draft RIA. 71 Since the introduction of SCR technologies in the U.S. HD market in 2010, catalyst suppliers have been working to improve low-temperature SCR kinetics for over a decade, but there are only minor improvements in the low temperature zones. No such quantum leap in the low temperature SCR conversion efficiency improvements has been seen till date. [EPA-HQ-OAR-2019-0055-1168-A1, p.34]

> 71 See Draft RIA at 11 ('SCR functionality is particularly reduced at lower exhaust temperatures due to difficulties with low-temperature urea decomposition and due to slower SCR reaction kinetics (Figure 1-3). ').

As explained in the draft RIA and shown in Figure 7 below, SCR fast reactions are dominated by temperature, and in temperatures below 320 degrees Celsius (at the SCR Inlet), SCR conversion efficiency is significantly reduced, as shown by arrows in the figure. When comparing longer and shorter exhaust pipes, longer exhaust pipes configurations tend to have higher heat loss, thereby leading to lower SCR Inlet temperature. Accordingly, SCR reaction kinetics move towards lower conversion efficiencies, hence higher tailpipe NOx emissions. In addition to effects from longer exhaust systems for some applications, lower engine horsepower ratings reduce cycle temperature, causing the net SCR reaction kinetics to reduce conversion efficiency, as shown on the arow on Figure 7. Although EPA understood the SCR reaction kinetics issues in the draft RIA, no such combinations of testing was conducted by EPA for low-NOx feasibility in support of the Proposed Rule. [EPA-HQ-OAR-2019-0055-1168-A1, p.34]

Under EPA's proposed 40 C.F.R. 1036.235(a), OEMs would need to demonstrate on a worst case scenario, as EPA proposes to require manufacturer demonstrations with 'the engine configuration most likely to exceed (or have emissions nearer to) an applicable emission standard or FEL.'73 EPA has not done this demonstration with the SWRI system. If EPA were to follow its own proposed standards, the Agency would still need to demonstrate low-NOx feasibility with the longest possible exhaust pipe and the worst possible engine rating. In the Agency's feasibility study, EPA has not performed this analysis using the parameters proposed in Section 1036.235(a). Rather, EPA's feasibility study is performed on the best-case engine rating and shortest possible exhaust pipe configuration. Effectively, EPA has tested the 'best-of-the-best' and declared it representative for all possible configurations. EPA must demonstrate compliance with other configurations and ratings to adequately demonstrate feasibility. [EPA-HQ-OAR-2019-0055-1168-A1, p.35]

73 See Proposed Rule, 87 Fed. Reg. at 17,680.

EPA's proposed NOx standards fail to account for component, sensor, and test-to-test variability. [EPA-HQ-OAR-2019-0055-1168-A1, p.35]

EMA's study submitted in support of its comments on the Proposed Rule reflects that, to protect 97.7% of production population, a design margin of 0.026 g/hp-hr is needed for low-NOx 'dyno based standards.'74 These margins, reflected in Figure 8 below, are necessary to account for variability induced by production variability, soot and sulfur accumulation, ash accumulation, field deterioration, and more. Similarly, to account for additional sources of variability that may be experienced in-use, EMA calculates that a design margin of 0.036 g/hp-hr is necessary. In-use testing requires higher margin levels due to the broad range of test conditions that are not accounted for on the dyno, including altitude operation, cold temperature operation, fuel quality, DEF quality, and field deterioration due the various parameters listed in the sections above. EPA and SWRI did not attempt to account for any of these sources of variability in their study, and accordingly, have not demonstrated that their proposed standards are feasible. [EPA-HQ-OAR-2019-0055-1168-A1, p.35]

74 See EMA Proposed Rule Comments, 'EMA Assessment of Technical Feasibility,' Table II.B.3.3.1 incorporated herein by reference.

Daimler Truck continues to collaborate with catalyst suppliers for developing coating technologies that are more effective at controlling emissions and more durable for extended full-useful life. However, after extensive product screenings, the Company has observed only minor improvements in the 2027 catalyst formulations offered compared to current production offerings. [EPA-HQ-OAR-2019-0055-1168-A1, p.36]

As demonstrated in Figure 9 above, catalysts offered by suppliers for MY 2027 have not shown improved durability, as compared to current production catalysts, to suppo1t extended full useful life. Catalyst suppliers are unwilling to accept additional durability requirements. One of the three major heavy duty coaters declined to bid on a 2027 Daimler Truck product, citing unreasonably onerous durability requirements. The Company does not believe the catalyst products commercially offered support EPA's proposed NOx stringency at extended full useful life, and does not believe that technologies likely to be on offer for MY 2027 will fundamentally change the assumptions about catalyst aging and degradation that unde1pin our analysis of EPA's proposed standards and their infeasibility. [EPA-HQ-OAR-2019-0055-1168-A1, p.36]

Daimler Truck continues to investigate the DEF doser supplier landscape and has identified only one supplier that is actively developing a heavy-duty heated-DEF doser technology. However, availability of an adequately-validated heated-DEF doser is not feasible in the MY 2027 timeframe due to insufficient maturity of the technology. Daimler Truck is also investigating other heated-DEF technologies, which may provide production-feasible timing at the expense of cost, complexity and reliability. Based upon our investigation, the EPA-demonstrated heated-DEF doser technology will not be production-feasible for the 2027 timeframe. [EPA-HQ-OAR-2019-0055-1168-A1, p.37]

Daimler Truck sees very little development of future sensors technology considered necessary to maintain adequate control of UL NOx systems. Sensor suppliers are rapidly moving towards electrification technology, rather than continuing to invest in diesel technology. In fact, we see no evidence of NOx sensor improvement in the necessary timeframe. To adequately control a system to 90% less NOx with the same accuracy as today’s systems, a 90% improvement in NOx sensor accuracy would be necessary, but no such improvements are planned. Today’s NOx sensors have variability of +/- 10 ppm below 100 ppm, which is greater than the absolute values of the proposed NOx emission limits. Similarly, EPA considers NH3 sensors as necessary inputs to an UL NOx control system, but no supplier today offers an NH3 sensor capable of the accuracy needed for required useful life. Daimler Truck’s understanding is that sensor manufacturers will not invest significantly in developing new technology for combustion engines in this timeframe, as suppliers dedicate resources to future ZEV technologies and divest from expensive combustion technology development. Given the anticipated lack of necessary sensor technology, EPA’s standards will likely be infeasible. [EPA-HQ-OAR-2019-0055-1168-A1, p.37]

SWRI has provided the dimensions of the close-coupled SCR (also known as LO-SCR) system and the associated hardware as tested by EPA in the Stage 3 test cell demonstration. The dimensions obtained from SWRI for the EPA Stage 3 rework testing are for the following components:

1. Turbine to DEF tube elbow
2. DEF injector mounting tube

3. Inlet LO-SCR Cone
4. LO-SCR Catalyst
5. Outlet LO-SCR Cone [EPA-HQ-OAR-2019-0055-1168-A1, p.37]

A photograph of the SWRI LO-SCR system is provided above in Figure 10. This photograph demonstrates the infeasibility of the system tested by the EPA—the LO-SCR is mounted extremely closely to the engine, in a manner infeasible in commercial vehicles. Daimler Truck took all the new hardware boundary dimensions (as mentioned above) of the EPA technology demonstrator at SWRI and performed in-depth packaging feasibility studies in all vehicle chassis configurations. [EPA-HQ-OAR-2019-0055-1168-A1, p.38]

The results of the packaging study in our highest-volume chassis, the Freightliner Cascadia, is shown in Figures 11 (side view) and 12 (top view) below. LO-SCR and associated hardware packaging studies illustrates significant interferences with the cab floor, structure, and frame rails. The Company's packaging study on a high volume chassis clearly shows only two options: first is to redesign the whole cab (Option 1); and the second is to move the LO-SCR downstream of the exhaust flow where space is available (Option 2). Under Option 1, a cab redesign is not a feasible option, due to inferences of the aftertreatment system package with the frame rails, a major structural component of a vehicle. The only feasible option is Option 2, which would entail packaging the LO-SCR further downstream, further away from the engine outlet. Moving the LOSCR to this downstream location introduces longer exhaust pipes from turbocharger outlet to the LO-SCR catalyst. As described in Figure 6, longer exhaust pipes will have higher temperature loss and hence worse tailpipe NOx emission performance when compared EPA's demonstration in support of the Proposed Rule. If EPA's proposed system were packaged in such a way as to fit on a truck, the LO-SCR effectiveness would be significantly reduced since it would operate at colder temperatures, which runs contrary to its designed purpose.[EPA-HQ-OAR-2019-0055-1168-A1, p.38]

EPA also requests comments on issues with low-volume applications. In response, Daimler Truck refers EPA to the industry-wide study submitted with EMA's comments.76 A notable finding of the EMA study is that ''[p]ackaging' requirements (i.e., fitting emission systems under the hood or cab) to 'close-couple' the new light-off SCR ('LO-SCR') to the turbocharger turbine exit will be extremely difficult, and/or will require cab retooling. Such retooling costs come at a very high cost (on the order of $500M) for low-volume products with potentially abbreviated amortization schedules, especially as those same vehicles transition to battery-electric and other 'zero-emissions' technologies driven, at least in part, by other regulations.'77 [EPA-HQ-OAR-2019-0055-1168-A1, p.39]

> 76 See EMA Proposed Rule Comments, 'EMA Assessment of Technical Feasibility of Complying with a 0.020 g/bhp-hr NOx Standard for Heavy-Duty Diesel Engines.'
> 77 Id.

In the draft RIA, EPA notes with regard to its low-NOx demonstration program that 'the under-cab EAS will also be installed in a MY2018 Navistar Daycab Class 8 Tractor equipped with a second EPA developmental X15 engine. The engine and cab are instrumented to allow evaluation of NVH characteristics during truck operation when using CDA.'78 EPA has not, however, shared corresponding results of its vehicle testing investigations to date. Daimler Truck understands that this is because no such vehicle testing has been performed by EPA to substantiate that real-world test results are similar to the Agency's low-NOx test cell demonstration results.[EPA-HQ-OAR-2019-0055-1168-A1, p.39]

78 Draft RIA at 122.

We expect that, if such testing were performed, the in-use tailpipe results would be significantly higher on the aftertreatment demonstration technology considered for this evaluation. This is because, due to packaging and other constraints, the proposed technology for vehicle demonstration is significantly less capable than what EPA has demonstrated in the test cell. We would also expect this result because:

- The LO-SCR volume considered for vehicle demonstration is 25% lower than what is demonstrated by EPA in its test cell program.
- The main SCR/ASC considered for vehicle demonstration is 37% lower than what is demonstrated by EPA in its test cell program.
- Even the Diesel Particulate Filter (DPF) considered for vehicle demonstration is 13% lower than what is demonstrated by EPA in its test cell program.
- The vehicle exhaust pipe length is not documented by EPA in the draft RIA, but, as evidenced in our packaging study, above, must necessarily be significantly longer than what EPA used for its test cell program. [EPA-HQ-OAR-2019-0055-1168-A1, pp.39-40]

EPA and SWRI make these design compromises specifically to have 'minimal impact on existing EPA Class 8 day cab tractors'-because they are concerned that the Stage 3 system will not fit in a truck. [EPA-HQ-OAR-2019-0055-1168-A1, p.40]

The reduced volume of LO-SCR (-25%), reduced volume of SCR/ASC (-37%), along with the longer exhaust pipes would be expected to yield lower SCR perfo1mance results on real-world vehicle testing as compared to EPA's demonstration in a test cell with Stage 3 technology. [EPA-HQ-OAR-2019-0055-1168-A1, p.40]

These reduced volumes will likely have significant impact on tailpipe emissions, if EPA performs back-to-back emissions testing in a test cell for the two systems configurations when adequately aged to represent end of useful life. Tailpipe NOx test results for the system considered for vehicle testing with 'aged' reduced SCR catalyst volumes are expected to exceed the proposed NOx standards. EPA's demonstration with the larger, more capable system does not show compliance with all of EPA's proposed standards and provides no margin to others—as the composite FTP test results are 0.038 g/hp-hr, barely meeting 0.040 g/hp-hr standard before accounting for the Infrequent Regeneration Adjustment Factor (IRAF). Substantially reduced catalyst volumes (as considered by EPA for in-vehicle testing) after aging would further worsen these results and will exceed the proposed low-NOx standards. [EPA-HQ-OAR-2019-0055-1168-A1, pp.40-41]

Figure 14 shows initial test cell results at SWRI of EPA's proposed candidate system for installation in a vehicle. Even before aging, this system was determined to have unacceptable performance by SWRI and EPA, as follows:

> 1. System backpressure was 40kpa, significantly higher versus 28kpa with Stage 3 system;
>
> 2. Significant impact noted on RMC CO2;
>
> 3. Turbomachinery and air-handling component design limits (and Peak Cylinder Pressure limits) prevent much re-tuning to recover high load CO2 impact, even at higher NOx levels. [EPA-HQ-OAR-2019-0055-1168-A1, p.41]

EPA itself noted that it 'did not proceed due to CO2 impact.' [EPA-HQ-OAR-2019-0055-1168-A1, p.41]

These technology considerations are prime examples of real-world technical challenges and compromises that an OEM will face when placing low-NOx technology on a vehicle. This further shows that EPA's technology demonstration does not support the proposed low-NOx standards, because it cannot be successfully packaged on a vehicle—and a system that can be packaged would not meet EPA's proposed standards. [EPA-HQ-OAR-2019-0055-1168-A1, p.41]

Additionally, as noted in Figure 14, the demonstration engine meets only the MY 2017 GHG standards and will have to achieve 7.2% fuel efficiency measures to meet the MY 2027 GHG Phase 2 standard without margin. As shown in Figure 14, the addition of NOx-reduction technology reduced GHG performance by up to 2% in a few cycles, as compared to the baseline engine. This further proves that additional GHG technologies are needed to offset the GHG deficit produced by low-NOx technology on a tractor (RMC Standard), which EPA did not envision in the GHG Phase 2 rulemaking. EPA has never demonstrated an engine that meets the existing GHG standards for MY 2027 and even approaches meeting their proposed NOx standards. [EPA-HQ-OAR-2019-0055-1168-A1, p.41]

In summary, EPA recognizes the technical challenges that manufactures have repeatedly raised, e.g., vehicle installation challenges, CO2 emission increases, hardware component limitations, NVH issues, and more. EPA also recognizes the need to demonstrate any proposed new hardware in a vehicle. However, due to these very technical challenges, EPA has not demonstrated any ultra-low NOx engine in a vehicle. The candidate system that the Agency evaluated for vehicle installation will not meet the proposed low-NOx standards, and even this system has been abandoned due to real world technical challenges. [EPA-HQ-OAR-2019-0055-1168-A1, p.41]

The Proposed Rule creates a number of contradictions, gaps, and conflicts that will make compliance exceedingly difficult. One such area is the infeasibility of meeting Phase 2 MY 2027 GHG emission standards while simultaneously implementing the low-NOx technology needed to achieve the proposed NOx standards. EPA appears to assume that OEMs will simply make required engine efficiency changes to meet Phase 2 standards in addition to adding low-NOx aftertreatment systems (e.g., SCR and associated hardware technologies), and that no changes will be needed on the engine side. This assumption is flawed for the following reasons:

- None of the EPA test demonstration data shows that the SWRI Stage 3 engine can meet EPA Phase 2 GHG standards for MY 2027. All of EPA's test cell research demonstration work was done on a Cummins MY 2017 engine that would need ~ 6% more CO2 reduction to meet the MY 2027 GHG RMC standard without margin. The Stage 3 engine does not meet the MY 2021 or 2024 CO2 standards. If we apply 6% engine fuel efficiency measures to EPA's low-NOx demonstration engine to meet MY 2027 standards (e.g., better in-cylinder fuel burn, mixing, and other measures), the result will be a colder exhaust – all fuel economy improvements to an engine are achieved by extracting more work from the fuel, leaving less energy to be delivered to the exhaust. This would mean that more and more thermal exhaust measures (i.e., heated exhaust measures) will be needed beyond what was used in EPA's demonstration. In other words, an engine that met EPA's MY 2027 GHG standards would have an even harder time complying with EPA's proposed NOx standards, since, according to first principles of combustion physics, it will run colder than EPA's demonstration engine.
- Not only do EPA's low-NOx demonstration and investigations at SWRI testing ignore the complexities of CO2-NOx emission trade-offs, they also ignore the increased backpressure from low-NOx demonstration-related hardware, which will further harm GHG performance.
- As seen in EPA's low-NOx demonstration data at SWRI, the Stage 3 / RW system had slightly higher tailpipe GHG results over the baseline production configuration. Overcoming this additional CO2 to bring the Stage 3 / RW system into GHG compliance (with margin) will require additional CO2-reducing technology over and above what EPA included in their feasibility demonstration. [EPA-HQ-OAR-2019-0055-1168-A1, p.43]

The tradeoff between NOx emissions and CO2 emissions are well understood by the industry; EPA cannot claim that the Agency has demonstrated the feasibility of its proposed standards without demonstrating an engine that can meet the relevant NOx and CO2 standards simultaneously. In some vehicle classes, EPA's proposed NOx regulations will be so at odds with existing GHG regulations that they may generate perverse incentives to sacrifice GHG performance for the sake of improved NOx performance. A key example may unfold in the MHD truck market, which is sensitive to initial purchase cost, while being less sensitive to fuel consumption. It is also worth noting that under EPA GHG Phase 2 regulations, vocational vehicles powered by SI-gasoline engines are allowed 17% higher CO2 emissions than their diesel-fueled counterparts. Due to this conflict between GHG Phase 2 and the proposed NOx standards, it may be expected that medium duty market shifts to SI-gasoline, which can more easily meet EPA's proposed standards. Such a shift in the market will significantly increase CO2 emissions from the national fleet, and minimize the efforts of the commercial vehicle sector to combat global warming. [EPA-HQ-OAR-2019-0055-1168-A1, pp.43-44]

EPA must consider the tradeoff between NOx and CO2 emissions performance, and must not set NOx standards that are so stringent that they have unintended consequences for CO2 emissions compliance. [EPA-HQ-OAR-2019-0055-1168-A1, p.44]

EPA has not demonstrated that its proposed FTP emissions standards are feasible. Daimler Truck believes that an FTP NOx standard of 50 mg/hp-hr is appropriate, in combination with further changes to the FTP to better represent the real world contribution of cold-start operations. Additionally, the PM standard should be set to 7.5 mg/hp-hr to reflect the state of available technology. [EPA-HQ-OAR-2019-0055-1168-A1, p.54]

Daimler Truck provides in these comments exhaustive evidence to show that EPA has not demonstrated the feasibility of the FTP standards set forth in the Proposed Rule (see Section II.B.3 of these comments). Notably, *no vehicle* has been demonstrated that can meet EPA's proposed standards when considered in their totality (including GHG standard compliance, exposure to real world maintenance and fueling practices, installation on a real vehicle with acceptable Noise, Vibration and Harshness (NVH) profiles, drivability characteristics etc.). EPA attempts to demonstrate feasibility with the technical demonstrator system that the Agency has developed in collaboration with SWRI, but the Agency's feasibility analysis does not adequately consider the following key factors: [EPA-HQ-OAR-2019-0055-1168-A1, p.54]

Adequate emissions margin to the certification standard. Manufacturers must develop and certify systems with an adequate level of margin to account for a number of factors. EMA has developed an analysis concluding that manufacturers require margin between the certification emissions of their UL NOx systems and any reasonable UL NOx standard of at least 0.026 g/hp-hr NOx.83 By contrast, EPA's results from SWRI do not provide for any margin from the standard—with NOx results at the proposed standard in SWRI's latest testing of the EPA Stage 3 rework system (the EPA Stage 3/RW System).84 [EPA-HQ-OAR-2019-0055-1168-A1, p.54]

83 See EMA Proposed Rule Comments, 'EMA Assessment of Technical Feasibility.'

84 See Sharp, C. et al., 'An Update on Continuing Progress Towards Heavy-Duty Low NOx and CO2 in 2027 and Beyond – SAE Detroit' (April 5-7, 2022).

Further, EMA includes in its sources of variability aging impacts from fuel contamination, production variability, measurement variability, packaging limitations, accumulation of sulfur, soot, and ash, maintenance variability, and the direct impact of biodiesel on NOx emissions. EPA does not adequately account for any of these limitations. [EPA-HQ-OAR-2019-0055-1168-A1, p.54]

Additionally, SWRI data shows that in some conditions, PM values exceed the proposed emissions standards (even before the IRAF is applied). Although SWRI points out that this data occurs immediately after ash cleaning, and eventually returns below the threshold, manufacturers are required to meet the threshold in all conditions. [EPA-HQ-OAR-2019-0055-1168-A1, p.54]

Real-world application of proposed low NOx technologies. The proposed system demonstrated in the 'Stage 3' technical solution has never been installed and operated in a truck, and has never been demonstrated to be acceptable in terms of impact on NVH, drivability, or durability, especially in the broad range of custom-tailored vehicles and duty cycles in the heavy-duty industry. [EPA-HQ-OAR-2019-0055-1168-A1, p.54]

The EPA Stage 3/RW System cannot be adequately packaged in a heavy-duty vehicle; specifically, its CCSCR cannot be placed as close to the engine as SWRI uses in its demonstrator. Placing the system further away, which will be necessary in commercial vehicles, will further degrade its emissions performance, which EPA does not consider. [EPA-HQ-OAR-2019-0055-1168-A1, p.55]

EPA does not consider the wide range of applications, ratings, and other criteria that force design compromises and reduced emissions control performance. EPA's demonstration only covers one configuration, with one rating. EPA proposes that manufactures must demonstrate emissions compliance with the worst-case rating; however, in its feasibility study, the Agency has not accounted for the worst case configuration for emissions performance. Indeed, it has only one configuration, with one rating—which is likely to be favorable. [EPA-HQ-OAR-2019-0055-1168-A1, p.55]

Competing need for CO2 reductions. The EPA Stage 3/RW System does not meet EPA's 2027 CO2 emissions standards. While EPA has demonstrated low-NOx performance without dramatically increasing CO2 emissions, the Stage 3 engine does not meet these requirements. The changes necessary to improve CO2 performance will necessarily reduce the system's NOx control effectiveness, as CO2 improvements will reduce the engine's exhaust temperatures, which are critical to SCR performance. There is an unavoidable trade-off between NOx and CO2 that the EPA does not consider in their study. [EPA-HQ-OAR-2019-0055-1168-A1,p.55]

In light of the above challenges, summarized in more detail elsewhere in these comments, and in the EMA Proposed Rule Comments, Daimler Truck believes that EPA has not demonstrated the feasibility of the proposed FTP emission standards for NOx and PM. [EPA-HQ-OAR-2019-0055-1168-A1, p.55]

CAA Section 202(a)(3)(A) requires that EPA's heavy-duty criteria pollutant standards 'reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology.'85 Since the EPA has not demonstrated that its proposed NOx or PM emission standards reflect the greatest degree of emission reduction achievable, they would not be enforceable under the CAA. [EPA-HQ-OAR-2019-0055-1168-A1, p.55]

85 42 U.S.C. 7521(a)(3)(A)(i).

Daimler Truck submits that an FTP NOx standard of **50 mg/hp-hr, or 0.05 g/hp-hr** better reflects the greatest degree of emissions reduction achievable. This standard accounts for the real world emissions contributions of various operating conditions and gives appropriate consideration to the cost factors associated with the application of available technology. [EPA-HQ-OAR-2019-0055-1168-A1, p.55]

Similarly, in light of SWRI's post DPF ash cleaning procedure data, Daimler Truck believes that EPA has not demonstrated feasibility for its proposed PM standard. DTNA recommends a PM standard of **7.5 mg/hp-hr on the FTP**, for the reasons provided above. [EPA-HQ-OAR-2019-0055-1168-A1, p.55]

Daimler Truck believes that the current weighting methodology of the composite FTP— namely, 1/7 contribution from emissions from the Cold FTP, weighted with 6/7 contribution from the emissions from the Hot FTP—over-represents the emissions from the initial cold-start drive off of the vehicle compared to real world operation. [EPA-HQ-OAR-2019-0055-1168-A1, p.56]

In fact, nearly all of the NOx released in the composite FTP is emitted during the first several minutes of the Cold FTP. Once the aftertreatment reaches proper operating temperatures, NOx emission contributions to the overall composite FTP are nearly inconsequential. Daimler Truck provides an example in the below Figure 21. [EPA-HQ-OAR-2019-0055-1168-A1, p.56]

In this example, Daimler Truck provides the cold FTP emissions trace of a candidate emissions control system designed to provide as much emissions reduction as possible. For the purposes of this evaluation, Daimler Truck will consider 'Cold Start' as all operation before the engine has accumulated 4.72 bhp-hr of work. This threshold was selected to differentiate operation during which the system had reached appropriate light-off temperature for adequate emissions control, and when it had not. The appropriate threshold of accumulated work to differentiate 'Cold Start' operation would necessarily vary from engine to engine, or could be determined via other proxies, such as coolant temperature (approximately 63 degrees Celsius in this case). All other operation in the remainder of the Cold Start FTP, and in the subsequent Hot Start FTP is classified as 'Hot' operation. [EPA-HQ-OAR-2019-0055-1168-A1, p.56]

Using this differentiation, it is possible to apply the current Cold/Hot weighting factor (1/7th and 6/7th, respectively) to determine, on a work-weighted basis and on a time-weighted basis, how this section of duty cycle is weighted in the composite FTP. [[See Table 9 on p. 57 for Daimler's Work-based and Time-based estimates of the contribution of the 'Cold Start' operation portion of the Cold FTP to the overall duty cycle of a Cold/Hot weighted FTP.]] [EPA-HQ-OAR-2019-0055-1168-A1, p.56]

So, although the 'Cold Start' operation of the FTP in this example represents only 5% of the time of a weighted FTP, and only 2.1 % of the work in a weighted FTP, it accounts for >95% of the NOx emissions ultimately compared to the standard for a weighted FTP. Daimler Truck believes that this significantly over-weights the relevance of these emissions compared to the impact of these 'Cold Start' operations on real world emissions inventories. [EPA-HQ-OAR-2019-0055-1168-A1, p.57]

To illustrate this over-weighting of Cold Start emissions, Daimler Truck has analyzed real-world data captured in a joint project between West Virginia University (WVU) and the EMA. Details of Data Analyzed:

- Daimler Truck Data acquired from EMA-WVU 100-vehicle study
- Vehicle Type: Day Cab

- Engine MY 2013-2019
- Application: Customer operation of goods movement in southern California
- Sample Size: 16 vehicles
- Approximately 1 month of data collection for each vehicle
- 202 total shift-day trips analyzed [EPA-HQ-OAR-2019-0055-1168-A1, p.57]

Daimler Truck believes that a larger data set, containing more applications, manufacturers, and duty cycles could prove more instructive. However, since this dataset specifically analyzes the operation of day-cab tractors performing goods movement, it is illustrative. Other applications, such as sleeper-cab, long-haul tractors are dominated by operation represented by the Hot FTP and the RMC, and the Hot FTP best represents pickup-and-delivery applications, with frequent starts and stops. [EPA-HQ-OAR-2019-0055-1168-A1, p.57]

Daimler Truck analyzed each shift-day using the same metrics presented above for the Cold FTP contribution of 'Cold Start' operation versus 'Hot' operation, using the same differentiation of a cumulative 4.72 bhp-hr of work. The analysis was performed to calculate both the 'Time Weighted' and 'Work Weighted' contribution percentage for each shift-day. The statistical analysis for each approach is presented below in Figures 22 and 23, respectively. [EPA-HQ-OAR-2019-0055-1168-A1, p.58]

This analysis shows that current FTP weighting, comparatively, over-represents the 'Cold Start' operation in its evaluation of emissions. For example, the 'Work Weighted' analysis of vehicles shows that for nearly 75% of trips, 'Cold Start' operation contributes *less than half* of the work during the shift-day (1.1%) than an FTP assumes (2.1%). Daimler Truck summarizes this analysis below in Table 10. [EPA-HQ-OAR-2019-0055-1168-A1, p.58]

Daimler Truck's data demonstrates that the current Cold/Hot weighting factor (1/7th cold, 6/7th hot) inappropriately over-weights the contribution of vehicle operation before the aftertreatment system has reached operating temperatures. This implies that a more appropriate weighting factor for the Cold FTP may be approximately 1/12th to 1/18th. Daimler Truck believes EPA should reevaluate the Cold FTP weighting factors in light of this information, and determine if the current test procedures and weighting factors are appropriate. [EPA-HQ-OAR-2019-0055-1168-A1, p.59]

EPA should add a 300-second idle warm-up period to the beginning of the Cold FTP, to reflect the way that trucks are operated in the real world. [EPA-HQ-OAR-2019-0055-1168-A1, p.59]

As explained above, Daimler Truck believes that the current Cold FTP test procedure and weighting protocol inappropriately weights the emissions performance during the period of engine operation before the emissions controls can be employed effectively. This procedure most obviously diverges from real world operation in the way it treats start and the first acceleration events of the test. [EPA-HQ-OAR-2019-0055-1168-A1, p.59]

In the Cold FTP, during the first New York Non-Freeway segment of the test, the engine is started, and is accelerated to represent vehicle movement within 25 seconds of engine start.

Figure 24 shows the profile of an FTP the first acceleration after vehicle start. [EPA-HQ-OAR-2019-0055-1168-A1, p.59]

These first early acceleration events, before the emissions control system are fully effective, are responsible for most of the emissions measured as part of the Cold FTP, as demonstrated in Figure 25: [EPA-HQ-OAR-2019-0055-1168-A1, p.60]

The Cold FTP has the first acceleration event 25 seconds after engine start, and the first three major cold start events contribute the great majority of the emissions captured during the FTP. As Daimler Truck discusses above, these events are overweighted in terms of real-world contribution to the emissions inventory. Additionally, they stand in stark contrast to the way vehicles are operated in the real world. [EPA-HQ-OAR-2019-0055-1168-A1, p.60-61]

Most drivers idle their vehicles for some extended period of time before driving off for the first time of the day. The driver is required to complete a pre-trip inspection and fill out their log books and work instructions for the day, all of which might be completed while the vehicle is idling. Additionally, the system must be allowed to accumulate pressurized air for operation of the air brakes, parking brake, and more, again, all of which requires the vehicle to idle before it can be driven for the first time. [EPA-HQ-OAR-2019-0055-1168-A1, p.61]

Daimler Truck analyzed the data from the EMA-WVU dataset, described above, and found that most shift-days start with a significantly longer idle period than represented by the Cold FTP. The distribution of data is provided below in Figure 26: [EPA-HQ-OAR-2019-0055-1168-A1, p.61]

Daimler Truck's analysis shows that the average idle period for a day-cab vehicle in California is 227 seconds, in contrast with the 25 seconds provided in the Cold FTP. Daimler Truck believes that other application types, such as long-haul sleeper trucks, or trucks operating outside of California (which actively discourages idling) would be likely to see even longer idle operation before the first acceleration event. In this manner, the Cold FTP significantly misrepresents the way vehicles are actually operated, and accordingly, misrepresents the emissions impacts of early acceleration events. Combined with the mis-weighting of cold operation previously discussed, Daimler Truck believes that the current FTP significantly penalizes early, cold-engine operation compared to real world emissions impact. [EPA-HQ-OAR-2019-0055-1168-A1, p.61]

Daimler Truck believes that the EPA should add a 300-second idle period to the beginning of the Cold FTP to better reflect real-world operational profiles. This would allow the full application of emissions controls technologies to be adequately represented in the FTP emissions evaluation. The emissions during this idle period should be measured as part of the Cold FTP emissions and weighted accordingly. [EPA-HQ-OAR-2019-0055-1168-A1, p.61]

If the Agency is concerned about any vehicles that regularly drive off immediately after their cold start, it could address this with a requirement to prevent such operation. For example, EPA could require manufacturers implement an emissions control, which prevents significant engine work until the emissions system is active and effective—such as a vehicle speed limit until the aftertreatment system reaches operating temperature. Such limits on vehicle operation, and customer acceptance of said limits, has precedence in the world of diesel engines, with Wait-to-Start lamps being common emissions controls. [EPA-HQ-OAR-2019-0055-1168-A1, p.62]

EPA could also consider addressing this issue by further de-weighting the first minutes of the cold FTP, or by otherwise introducing a warm-up protocol which would make the composite FTP emissions represent real-world emissions profiles more accurately. [EPA-HQ-OAR-2019-0055-1168-A1, p.62]

In any case, if EPA does not adequately adjust the Cold/Hot FTP to accurately reflect real world operation, manufacturers will be forced to optimize their systems to target these initial FTP acceleration events. Since temperature is the most critical factor to these emissions, manufacturers will be forced to select systems with less thermal inertia to maximize warmup, including smaller CCSCRs, reduced SCR substrate volume or wall thickness, lighter, less durable materials, and implement control technologies that increase system temperature, which necessarily come at the cost of CO_2 emissions. Manufacturers may be able to optimize systems for these early Cold FTP emissions to reduce on-cycle NOx, but it will come at the cost of real world emissions reductions, in terms of CO_2 and NOx over the rest of the vehicle's operation. [EPA-HQ-OAR-2019-0055-1168-A1, p.62]

EPA has not demonstrated that the proposed RMC emissions standards are feasible, in particular that the NOx limits proposed under Option 1 are appropriate. Additionally, the PM standard should be set to 7.5 mg/hp-hr to reflect the state of available technology. [EPA-HQ-OAR-2019-0055-1168-A1, p.62]

Similar to the FTP standards, EPA has not adequately demonstrated feasibility of a 20 mg/hp-hr NOx standard for the RMC, when considering the totality of the Agency's proposal. While there are new emission control systems that can be used to improve emissions characteristics by improving SCR temperature, such new control systems do not provide any emissions benefit in operations best represented by the RMC. RMC operations are intended to represent warmed-up, steady-state duty cycles, where SCR technology is already being fully leveraged. [EPA-HQ-OAR-2019-0055-1168-A1, p.62]

Proposed catalyst candidates for potential UL NOx systems do not show any benefit compared to existing catalyst systems in the area best represented by the RMC. In Figure 27 below, Daimler Truck compares current SCR technology to a proposed UL NOx system, demonstrating that in areas of high temperature, little to no improvement is possible beyond today's performance. Similarly, the proposed catalysts do not show any significantly improved aging behavior compared to the catalysts in production today. [EPA-HQ-OAR-2019-0055-1168-A1, p.62]

Since RMC emissions performance is dominated by high-temperature SCR conversion efficiency, and since the high NOx flux experienced in the RMC makes systems particularly susceptible to aging behavior, Daimler Truck finds that new technology offers no improvement to RMC emissions potential. While EPA offers that manufacturers could select larger catalysts to improve conversion efficiency or aging, doing so would come at the cost of increased thermal inertia, and accordingly, reduced cold start and low-load emissions perfo1mance. EPA also does not consider the impact of such increased catalyst size on packaging the proposed system on the many vehicle configurations offered today. [EPA-HQ-OAR-2019-0055-1168-A1, p.63]

Accordingly, Daimler Truck recommends that EPA set the RMC NOx threshold to **50 mg/hp-hr, or 0.05 g/hp-hr,** to reflect the greatest degree of emission reduction achievable through the application of technology that will be available. [EPA-HQ-OAR-2019-0055-1168-A1, p.63]

Similarly, in light of SWRI's post DPF ash cleaning procedure data, Daimler Truck believes that EPA has not demonstrated feasibility for the proposed PM standard. Daimler Truck submits that a PM standard of **7.5 mg/hp-hr** on the RMC would be the greatest degree of emission reduction achievable, given the state of current technology. [EPA-HQ-OAR-2019-0055-1168-A1, p.63]

Organization: *Manufacturers of Emission Controls Association (MECA)*

In addition, MECA supports EPA's proposed PM standard of 0.005 g/bhp-hr on the FTP and RMC cycles for MY 2027 and later engines. This PM standard is technologically feasible with currently available DPF technology as supported by the certification data of current heavy-duty diesel engines that implement DPFs, which report substantially lower PM measurements. This more stringent standard will prevent backsliding by ensuring the best available DPFs remain an integral component in aftertreatment systems. In response to tighter PM limits signaled by the EU and CARB's Omnibus, DPF suppliers are delivering improved filter substrates that have smaller mean pore size and more uniform pore size distribution, resulting in higher filtration efficiency and reduced pressure drop as the filter loads with soot. These improvements result in reduced particle number and mass emissions by up to 50%, even on a clean or freshly regenerated filter, better light-off performance necessary for soot regeneration and potential fuel economy benefits [7]. [EPA-HQ-OAR-2019-0055-1320-A1, pp.5-6]

> [7] Y. Kurimoto, R. Mishina, K. Kato, T. Aoki, K. Tanaka, T. Honda, A. Kaneda and C. Vogt, 'Next Generation Diesel Particulate Filter for Future Tighter HDV/NRMM Emission Regulations (SAE 2022-01-0545),' SAE WCX, April 2022.

The proposed emission limits have been derived from years of technology demonstration and testing at Southwest Research Institute under CARB and EPA contracts that began in 2014 and have been enhanced under multiple phases to expand duty cycles, technologies and engines. MECA and our members have committed millions of dollars in cash and in-kind contribution to provide hardware and funding into this program to demonstrate multiple pathways for meeting a 90% reduction in NOx while not increasing GHG emissions and controlling other regulated and unregulated pollutants. This seminal demonstration program also benefited from in-kind contribution from Volvo and Cummins who provided engines and calibration assistance, funding from South Coast AQMD and the Port of Los Angeles, among others, to deliver a robust technology feasibility demonstration through partnership between industry and regulators. [EPA-HQ-OAR-2019-0055-1320-A1, p.6]

The first stage of the program that concluded in 2016 relied on an advanced MY 2014 diesel engine that included turbo-compounding technology for meeting future 2017 Phase 1 GHG limits. Although this engine provides impressive fuel saving at highway speeds, it posed thermal management challenges at cold start and low load operation. This could be overcome through the use of active heating based either on electric or fuel burner components. In spite of these challenges, this first ever demonstration of ultra-low NOx emissions served as a great learning opportunity through screening of thirty-three different aftertreatment configurations and advanced calibration to demonstrate that future 0.02 g/bhp-hr emission limits are feasible. The learning from this stage of the program served as the starting point for technology selection in future stages of this multi-year program. This work was published in 2017 in a number of SAE technical papers [8] [9] [10]. [EPA-HQ-OAR-2019-0055-1320-A1, p.6]

>
> [10] C. Sharp, C. C. Webb, G. Neely, J. V. Sarlashkar, S. B. Rengarajan, S. Yoon, C. Henry and B. Zavala, 'Achieving Ultra Low NOx Emissions Levels with a 2017 Heavy-Duty On-Highway TC Diesel Engine and an Advanced Technology Emissions System - NOx Management Strategies (SAE 2017-01-0958),' SAE International Journal of Engines, vol. 10, no. 4, pp. 1736-1748, 2017.

The primary objective of stage two of the program was to develop a low load certification cycle based on real world truck operation derived from duty cycles collected by the National Renewable Energy Lab (NREL) and UC-Riverside on over 800 trucks operating in California and across the U.S. The methodology developed under this program by NREL and SwRI was a completely original approach to certification cycle development and will serve as a model for future regulations around the world for years to come. The stage 1 engine and aftertreatment system was operated over the newly developed certification cycle and demonstrated that when engine calibration and aftertreatment are optimized for real world operation, it is possible to achieve NOx reductions over 95% from the baseline system under the most challenging conditions. Although overcoming the thermal mass of the turbo-compound unit at low loads required active thermal management at a fuel penalty of about 2%, we did learn about aftertreatment architecture and design optimization to reduce emissions from both cold-start and low load operation, and this knowhow was carried into stage 3 of the program. [EPA-HQ-OAR-2019-0055-1320-A1, p.6]

Stage 3 of the program began in 2017 and employed a different state-of-the-art 15L engine that met the 2017 Phase 2 GHG limits without the use of turbo-compounding. The aftertreatment system options were narrowed down based on all of the learning in stages 1 and 2. Furthermore, replacing the use of active burner thermal management, we applied cylinder deactivation (CDA) on this engine and further calibration to get rapid heat-up of the aftertreatment from cold-start as well as maintaining SCR temperature during coasting, idling and low speed operation. The CDA was further able to provide thermal management while reducing fuel consumption and CO2 emissions. Other technology options for simultaneous thermal management and GHG reductions were also evaluated and are discussed below. These include driven turbochargers among others that OEMs could employ to build additional compliance margin against tighter NOx limits and future Phase 2 standards. This stage of the program was another first of its kind demonstration of achieving both ultra-low NOx emissions and simultaneous GHG reductions that have long been considered a challenging trade-off by engine developers. [EPA-HQ-OAR-2019-0055-1320-A1, pp.6-7]

It should also be noted that technology demonstration on a vehicle has been conducted to support the European Union ongoing process of considering more stringent heavy-duty criteria emission standards in a Euro VII rulemaking. This work, conducted by the Association for Emission Controls by Catalyst (AECC) is showing that stringent NOx emission limits can be met on a vehicle in real world driving conditions by employing similar technologies demonstrated in the program at SwRI [11]. The integration onto an existing truck chassis required a slightly modified close-coupled catalyst architecture and demonstrates yet another pathway to achieving low NOx emissions. Further work by AECC demonstrated that integrating an electrically heated catalyst (EHC) with the close-coupled DOC yielded an additional 60-77% reduced NOx during cold start in an urban delivery drive cycle [12]. [EPA-HQ-OAR-2019-0055-1320-A1, p.7]

Over the course of this multi-year program, the technology innovation was not static, and in fact new technologies came on midstream as they became commercially viable. Even the aftertreatment components that remained fundamentally unchanged from today’s systems on trucks benefitted from multiple generations of substrate improvements and new catalyst formulations that occurred over the 8 years of testing under this program. Further improvements in catalysts and architectures have been tested in the latest EPA-led portion of the test program that built on the learnings of the CARB funded portion of the program. [EPA-HQ-OAR-2019-0055-1320-A1, p.7]

Catalyst suppliers have already developed a next generation of SCR catalysts with higher NOx reduction efficiency and better durability compared to the Stage 3 parts tested in the SwRI demonstration program. Through the use of sophisticated models that incorporate the latest learnings on both thermal and chemical aging effects, it is possible to project the gains in efficiency provided by these new materials. A similar methodology was used to that discussed in the MECA 2027 white paper, incorporating exhaust information from the latest engine calibration from SwRI and an optimized dosing calibration for the new downstream SCR catalyst. The catalysts were laboratory aged both thermally and chemically using sulfur containing simulated exhaust gas to represent 435,000 miles of equivalent engine aging. The catalysts were modeled over the FTP, RMC and LLC certification cycles and demonstrated lower emissions than the Stage 3 system at SwRI. The not yet published results suggest that the latest generation SCR catalyst would provide OEMs with additional margin to a 0.02 g/bhp-hr standard. [EPA-HQ-OAR-2019-0055-1320-A1, pp.7-8]

Furthermore, even in the short time since the latest emission control system was provided to SwRI for the demonstration program, improvements continue to be made to substrates and catalysts. For example, a recent paper published at the 2022 SAE WCX conference describes development of high-porosity honeycomb substrates with thinner wall thickness and high cell density that can be coated with SCR catalyst. The combination of developments on this substrate enables higher surface area and lower thermal mass, which improves coating efficiency, reduces catalyst heat-up time, and reduces pressure drop. These result in performance improvements that are especially prominent at low temperature operation. At engine exhaust temperatures of 175â„ƒ, the NOx conversion efficiency improved by 14% compared to earlier generation substrates [13]. [EPA-HQ-OAR-2019-0055-1320-A1, p.8]

> [13] Y. Ido, K. Kinoshita, C. Goto, H. Toyoshima, S. Hirose, E. Ohara, T. Honda, A. Kaneda, A. Wells and C. Vogt, ‘High-Porosity Honeycomb Substrate with Thin-Wall and High Cell Density Using for SCR Coating to Meet Worldwide Tighter Emission Regulations (SAE 2022-01-0550),’ in SAE WCX, Detroit, MI, 2022.

This example of continual improvement and optimization is a testament to the ongoing innovative technology development occurring in the industry between suppliers and their OEM customers. Each time a test is run, new information is obtained and applied to the next iteration. This has been going on continually over the past 15 years of advanced emission controls on trucks. In fact, over the life of the SwRI program, catalyst suppliers have deployed new catalyst formulations and coating techniques to continually improve the durability and performance of the SCR system in order to build greater compliance margin relative to the program targets. Our industry has seen a tremendous amount of innovation on both engines and aftertreatment since the U.S. 2010 on-road diesel standards were implemented. This learning has been applied to improve manufacturing and reduce variability that has allowed systems to be downsized by about 60% and reducing their costs by about 30% (costs will be further addressed later). [EPA-HQ-OAR-2019-0055-1320-A1, p.8]

This regulation will complement CARB’s Omnibus to set the goals for engineers at OEMs and suppliers who will work together to make these systems more robust and durable as they are integrated on trucks and tested in the field. This collaboration is only possible once new standards are set and our industry is motivated to work with our OEM customers to meet them. As part of this process, over the next several years, a number of observations from the SwRI program will be evaluated and applied to make further improvements to the engine-out and tailpipe NOx limits. This partnership between suppliers and their customers will lead to improvements in durability while delivering the compliance margins that OEMs rely upon when certifying engines and emission control systems. Some of the areas for improvement that have been identified include:

1) Applying improved substrates and catalyst formulations that target poisoning resistance at low temperatures while retaining high temperature ammonia selectivity.
2) Adjustments in catalyst volume and engine calibration to accommodate catalyst aging for longer useful life.
3) Packaging improvements for passive thermal management and ammonia mixing and distribution for optimal urea utilization.
4) Modified catalyst component architectures that take advantage of passive thermal management, NO oxidation capability and further reduced fuel consumption.
5) Close attention to engine and urea dosing calibration over all duty-cycles to ensure optimal ammonia surface coverage of the upstream and downstream SCR to optimize catalyst utilization.
6) Improvements in NOx and ammonia sensor accuracy and detection. [EPA-HQ-OAR-2019-0055-1320-A1, p.9]

Over the past 12 years of diesel aftertreatment experience, our industry has learned a great deal about the design and operation of advanced diesel aftertreatment systems based on a DOC, DPF and SCR and the use of liquid urea to reduce NOx. The next 5 years will build on that learning to essentially use the same fundamental components to achieve a further 90% reduction in NOx. Passenger cars have had the benefit of 45 years of engine and aftertreatment development to achieve SULEV emissions. The SwRI program has demonstrated that near SULEV emissions are also achievable from heavy-duty engines to match the NOx emissions from natural gas engines that have operated at 0.02 g/bhp-hr levels for years. A more detailed discussion of the multiple technology pathways to achieving the emission limits proposed in this rule is provided below. [EPA-HQ-OAR-2019-0055-1320-A1, pp.9-10]

Commercially available technologies have been demonstrated to meet a 0.035 g/bhp-hr FTP NOx standard at 600,000 miles full useful life by 2027. These technologies can also enable a 0.02 g/bhp-hr intermediate FTP NOx standard at 435,000 miles. [EPA-HQ-OAR-2019-0055-1320-A1, p.10]

Engine technologies, advancements in engine calibration, thermal management, and catalysts can be combined to enable engines plus aftertreatment systems to achieve FTP and RMC emissions below 0.02 g/bhp-hr NOx [15]. Ongoing work by MECA members is aimed at demonstrating emission levels that will provide sufficient compliance margins that OEMs need for full useful life durability. Recent testing funded by EPA further optimized the engine and aftertreatment system based on lessons learned during Stage 3 of the CARB Low-NOx Demonstration Project. During cold-start and low-load operation, which are challenging conditions for emission control, engine technologies can be combined with calibration and thermal management to reduce engine-out NOx emissions and achieve real-world NOx reductions. Engine calibration and thermal management combined with advanced catalysts and substrates have improved to the point where a current technology engine plus aftertreatment system can achieve FTP emissions below 0.05 g/bhp-hr NOx by 2024 to meet the CARB stage 1 standards. [EPA-HQ-OAR-2019-0055-1320-A1, p.10]

[15] MECA, 'Technology Feasibility for Heavy-Duty Diesel Trucks in Achieving 90% Lower NOx Standards in 2027,' 2020. Online at https://www.meca.org/wp-content/uploads/resources/MECA_2027_Low_NOx_White_Paper_FINAL.pdf.

New aftertreatment architectures, that employ a close-coupled selective catalytic reduction (SCR) catalyst before the diesel oxidation catalyst (DOC) and diesel particulate filter (DPF) in a twin SCR system arrangement with dual urea dosing, can meet future FTP/RMC NOx limits of 0.02 g/bhp-hr after 435,000 miles by 2027. Several potential future aftertreatment layouts have been demonstrated in the SwRI test program. MECA has published two white papers that outline the technologies and models used to design catalyst, substrate and architectures to meet ultra-low NOx levels [16] [15]. Over the past 8 years of demonstration work at SwRI, testing has confirmed MECA's modeled results while also showing the need for modest enhancement of emissions control durability to provide margin for the FTP and RMC cycles over extended useful life. Over the next five years, industry will embrace any remaining challenges as suppliers continue to optimize their components and engine manufacturers hone their calibrations to exceed what has been demonstrated to date. This continued improvement work is why MECA believes that an intermediate limit of 0.02 g/bhp-hr is a technologically achievable up to 435,000 miles for a national program by 2027. PM and particle number emissions from MD and HD gasoline engines can be reduced further. [EPA-HQ-OAR-2019-0055-1320-A1, p.32]

EPA is proposing to tighten PM by 50% to 0.005 g/bhp-hr for diesel engines and MECA believes that would not require any change in technology but only serve as a backstop to prevent backsliding under a tighter NOx limit. As fuel efficiency standards tighten and GDI injection technology becomes more common on commercial vehicle engines, the PM emissions from medium and heavy-duty gasoline engines are likely to increase dramatically. The European Commission, China and India have adopted a particle number emission standard for light-duty vehicles powered by gasoline direct injection (GDI) engines as a part of their Version 6 light-duty emission standards. These standards were set at a stringency to require best available controls at the time being GPFs. Since 2019 high pressure fuel injection technology has further advanced to a point that it too can meet these stringent particle number limits. Europe implemented the PN limit for all vehicles in 2019, and China in 2020. India will implement it in 2023. China will require all vehicles to meet this limit in 2023, including gasoline port fuel injected vehicles. This PN standard established a more stringent particle emission limit for GDI vehicles in the same timeframe as EPA's 3 mg/mile PM standard that will complete phase-in with the 2021 model year. The Euro 6 GDI particle number limit has been set at 6 X 1011 particles/km, measured using the European PMP particle measurement protocol and is approximately equivalent to 0.5 mg/mile. This European particle number limit combined with Euro 6d Real Driving Emission testing has motivated auto manufacturers to introduce these cleaner technologies on vehicles. Nearly all auto manufacturers that sell into the European or

Chinese markets are using particulate filters on gasoline direct injection vehicles as well as some PFI vehicles. [EPA-HQ-OAR-2019-0055-1320-A1, pp.32-33]

MECA funded a study at the National Renewable Energy Laboratory (NREL) that summarized statistics of real world operation from two major data sources: NREL's Fleet DNA database that includes 435 conventional, diesel-powered trucks from 25 different vocations and from 24 fleets across the U.S. and University of California Riverside's CE-CERT database that consists of 79 diesel-powered vehicles from 10 different vocations and from 23 fleets operating in California [22]. Results from this report provide some insights into the causes for NOx emission reduction challenges due to real world operation. [EPA-HQ-OAR-2019-0055-1320-A1, p.17]

> [22] C. Zhang, E. Miller, A. Kotz, K. Kelly and M. Thornton, 'Characterization of Medium- and Heavy-Duty Vehicle Operations from In-Use Data: An Analysis of Starts, Soak Time, and Warm-Up Duration,' Golden, CO, 2019.

Some observations from this work are shown in Figure 4 and include:

- Cold starts represent approximately 12% of total real-world starts, and this is appropriately reflected by the FTP composite weighting of 14.3%.
- Cold operation time is also well captured by the FTP certification cycle (1.5%) versus 1.3% in the real-world.
- Current cold and hot start definitions are based on coolant temperature, which does not often correlate with SCR inlet temperature and thus SCR performance.
- Much of real-world operation (30-70%) involves restarting a hot engine (based on coolant temperature), but the aftertreatment has cooled off below the optimal operating temperature and must be warmed back-up quickly to minimize NOx emissions.

Engines idle much more in the real world than captured by inventory emission models or certification cycles. [EPA-HQ-OAR-2019-0055-1320-A1, pp.17-18]

Impacts of fuel quality on future aftertreatment systems: In order to achieve reductions in harmful emissions from heavy-duty diesel engines, federal regulations were designed to allow for an engineered systems approach that combines advanced engine designs, advanced exhaust control technologies, and improved diesel fuel quality. In current diesel engine regulations, fuel quality requirements set a limit on the amount of sulfur allowed in fuel. The reason for this is two-fold; first, when sulfur is present in fuel that participates in combustion, the resulting emissions contain sulfur oxides (SOx) as well as sulfate particulate matter. Second, sulfur oxides are known compounds that reversibly affect the performance of precious metal and SCR catalysts found in diesel emission control components through a number of deactivation mechanisms. The current limit of 15 ppm sulfur in ultra-low sulfur diesel was established based on precious metal (PGM) in diesel catalyst. The PGM oxidizing function of the DOC and DPF can reversibly deactivate over time in the presence of sulfur. The DOC serves to oxidize NO2 from the engine so it is in the proper oxidation state to be reduced by the SCR using ammonia as the reductant. Similarly, the PGM on the DOC, upstream of the SCR, oxidizes SO2 to SO3 which is a stronger poison for the SCR. Because it is positioned upstream of the DOC/DPF, the front SCR in a close-coupled dual-SCR aftertreatment architecture is primarily exposed to SO2, which is a less severe poison for the zeolite SCR catalyst. [EPA-HQ-OAR-2019-0055-1320-A1, p.23]

Well established thermal sulfur removal strategies are employed to reverse the negative impacts of sulfur on these catalysts. Commercial DOCs begin to recover from sulfur poisoning between 350-600°C, depending on the catalyst design. SCR catalysts are generally tolerant to sulfur found in today's fuels; however, long term exposure may cause gradual deactivation via two potential poisoning mechanisms. A less often occurring mechanism is the irreversible reaction of sulfuric acid with the zeolite catalyst washcoat. More often, sulfur can chemisorb onto catalyst active sites and block further NOx reduction reaction from occurring at the active site. If recovery is necessary, copper zeolite SCRs show nearly full recovery at 500°C. The SCR catalyst downstream of the DPF is typically regenerated during the periodic high temperature excursion used to regenerate soot from the DPF. [EPA-HQ-OAR-2019-0055-1320-A1, p.23]

An aftertreatment architecture likely to be employed to meet the Proposed Option 1 standards may include a twin SCR arrangement with a close-coupled SCR that is upstream of today's aftertreatment systems. In the absence of an upstream DOC, the close-coupled SCR will be mainly exposed to SO2 rather than SO3, the latter being a more severe poison. Research suggests that sulfur effects on the close-coupled SCR can be reversed by heating the catalyst to 500°C, which can be achieved through late post injection or other engine thermal management strategies, including cylinder deactivation and variable valve actuation (VVA) strategies. The SwRI Low-NOx Test Program has demonstrated that upstream SCRs in a dual SCR system can be brought up to temperature for desulfation via engine calibration to optimize short periods of higher temperature operation without incurring a fuel penalty or significant catalyst deterioration. The strategy employed by SwRI successfully removed sulfur from the SCR catalyst and reversed the marginal performance loss experienced due to sulfur deposition. [EPA-HQ-OAR-2019-0055-1320-A1, pp.23-24]

EPA has funded a continuation of the SwRI program with accelerated aging and durability demonstration out to 800,000 mile equivalent useful life using a new aging protocol being developed with industry partners and MECA. The results of this program are helping to inform about the long-term impacts of fuel sulfur on SCR catalysts. Aging experience from catalyst manufacturers suggests that the greatest impact may be on the close-coupled SCR since this is closest to the engine and sees the highest temperature and the major portion of lube oil metal exposure. The downstream, underfloor SCR is somewhat protected from fuel metals by the DOC and DPF. However, it will see higher temperatures during DPF regeneration. Results of the aging demonstration conducted at SwRI have confirmed some loss of performance from 435,000 miles to 800,000 miles. However, the rate of performance loss was cycle specific. For example, the SwRI program results showed minimal loss of performance over the LLC (0.029 g/bhp-hr to 0.032 g/bhp-hr) from 435,000 miles to 800,000 miles for the latest system ('Stage3 RW') tested as of April 2022. The same deterioration over the FTP cycle test resulted in a 0.020 g/bhp-hr level at 435,000 miles compared to 0.037 g/bhp-hr at 800,000 miles. It should be noted that all of these results are under the Proposed Option 1 standards at 800,000 miles for MY 2031 engines. [EPA-HQ-OAR-2019-0055-1320-A1, p.24]

Organization: *Moving Forward Network (MFN)*

EPA has erroneously set a standard of 35 mg/bhp-hr NOx on the FTP/SET cycle for light-heavy- and medium-heavy-duty diesel (LHDD and MHDD) and heavy-duty Otto-cycle (HDO) engines. This standard is inconsistent with EPA's own data on the capability of these engines, in addition to the requirements of the Omnibus. [EPA-HQ-OAR-2019-0055-1277-A1, p. 22]

California engaged in an extensive, multi-year process with significant stakeholder engagement to justify its Omnibus standards. Much of this work was done in collaboration with EPA—as such, the agency should be well apprised of the latest available technologies to reduce emissions from diesel engines. Generally, we find the agency's Draft RIA to reflect up-to-date information on technical potential. Unfortunately, not all of that work appears to be reflected in its feasibility analysis. Below, we assess some deficiencies in the agency's analysis and include additional references to support stronger emissions reductions requirements from conventionally powered trucks. [EPA-HQ-OAR-2019-0055-1277-A1, p. 23]

> 128. https://ww2.arb.ca.gov/sites/default/files/classic/research/apr/past/13-312.pdf
>

EPA is proposing two changes which have the potential to significantly reduce particulate matter emissions: 1) a reduced PM standard and 2) requiring closed crankcase emissions. Our support for these changes is discussed below. [EPA-HQ-OAR-2019-0055-1277-A1, p. 35]

EPA's certification program as well as its in-use test data both confirm that today's diesel trucks emit significantly less particulate pollution than pre-2007/2010 vehicles. In fact, every 2021-2022 certified diesel engine achieves an FTP/SET standard below EPA's proposed standard for 2027,145 indicating that there is currently more than a 50 percent compliance margin. Furthermore, the most recent data on EPA's Stage 3RW system indicates PM values below 5 mg/bhp-hr on all test cycles, all the way up to 800,000 miles.146 On the FTP and SET test cycles, in particular, the SwRI data exhibit more than a 70 percent margin at the 2031 FUL, indicating that diesel technology can meet a standard well below the proposed 5 mg/bhp-hr on the FTP and SET cycles. [EPA-HQ-OAR-2019-0055-1277-A1, pp. 35 - 36]

> 145 EPA. 2022. Heavy-duty highway gasoline and diesel certification data (Model years: 2015-present), updated February 2022. https://www.epa.gov/system/files/documents/2022-02/heavy-duty-gas-and-diesel-engines-2015-present.xlsx.

It is critical that EPA eliminate any potential for backsliding on the progress made to date on direct particulate matter emissions and encourage even further gains by setting mandatory PM standards for heavy-duty engines that are at least as stringent as the proposed Option 1 standards. [EPA-HQ-OAR-2019-0055-1277-A1, p. 36]

The proposed full useful life (FUL) of LHDD engines is 190,000 miles in 2027 and 270,000 miles in 2031. The proposed FUL of MHDD engines is 270,000 miles in 2027 and 350,000 miles in 2031. At 435,000 miles of accelerated aging, the SwRI demonstration of the Phase 3 RW system achieved a 20 mg/bhp-hr level of NOx emissions on the FTP cycle, 17 mg/bhp-hr on the SET, and just 29 mg/bhp-hr on the LLC (Draft RIA Table 3-8). This level of aging (435,000 miles) exceeds the level of deterioration of even the 2031 FUL for either engine. [EPA-HQ-OAR-2019-0055-1277-A1, p. 22]

EPA's proposed stringency for LHDD and MHDD engines exceeds the feasibility demonstrated at SwRI by 75 percent on the FTP cycle (35 compared to 20 mg/bhp-hr), 106 percent on the SET cycle (35 compared to 17 mg/bhp-hr), and 210 percent on the LLC cycle (90 compared to 29 mg/bhp-hr). Such levels well exceed any reasonable compliance margin, and the agency has not explained anywhere its rationale for such gross differences. Perhaps even more evidence of its error is that its proposed 2031 standards are much more consistent with the available data, aligning with the Omnibus standards of 20 (FTP), 20 (SET), and 50 (LLC) mg/bhp-hr. This discrepancy between the 2027 and 2031 capabilities for LHDD and MHDD engines, is unaccounted for in both the Draft RIA or NPRM and is particularly surprising given the extended FULs in 2031 for these engines. [EPA-HQ-OAR-2019-0055-1277-A1, p. 22]

While the demonstration engine was a heavy-heavy-duty diesel (HHDD) engine, this cannot explain the gross error in EPA's proposal. Other demonstration projects on an MHDD engine were able to achieve the 20 mg/bhp-hr FTP standard.87 Moreover, EPA's data shows relatively similar behavior across engine sizes when appropriately normalized.88 [EPA-HQ-OAR-2019-0055-1277-A1, p. 22]

88. Draft RIA, Table 3-21

Given the proposed FUL schedule, EPA should align its numerical stringency in 2027 with its values in 2031, which would thus align with the Omnibus and the available evidence. [EPA-HQ-OAR-2019-0055-1277-A1, p. 22]

As noted by EPA, variable valve actuation (VVA) has been used for decades in light-duty vehicles (LDVs) to reduce fuel use, but recent advances in controls now allow for new efficiency strategies like part-time Atkinson and Miller cycles. VVA strategies for heavy-duty vehicles can build on those controls advancements to develop novel diesel valve control that can fine-tune intake/exhaust valve timing to reduce emissions and fuel use at the same time. [EPA-HQ-OAR-2019-0055-1277-A1, p. 23]

Early exhaust valve opening (EEVO) is one example of a strategy to utilize VVA in an effort to reduce emissions.90 In this case, the exhaust valve is opened before completing the power stroke, which can thus significantly increase exhaust temperature, albeit at the expense of increased fuel use, and in some cases with trade-offs on other pollutants (HC, CO, PM2.5). EPA notes these trade-offs in its Draft RIA (16). Careful optimization is key to EEVO, and these trade-offs can be managed through more advanced controls.91 With such advanced controls in place, VVA can be used to compensate for any fuel penalty from EEVO through improved efficiency, such as early and late intake valve closing (EIVC, LIVC)—such strategy can even be used to implement Miller cycle operation in the diesel engine. A forthcoming analysis as part of the Volvo SuperTruck program shows that Miller cycle operation can enable reduced NOx emissions without compromising on efficiency.92 [EPA-HQ-OAR-2019-0055-1277-A1, pp. 23 - 24]

One particular VVA strategy which helps both reduce fuel consumption and address low-load emissions is cylinder deactivation (CDA), which EPA and CARB have incorporated into their heavy-duty engine demonstration work with SwRI. CDA has already been proven effective and durable in light-duty vehicles, but recent research shows the strong benefits of CDA in heavy-duty diesel vehicles as well. CDA essentially allows the engine to be downsized in real time—this has the effect of dramatically increasing the temperature of low load operation (about 100°C in an MHD engine) while improving overall fuel efficiency.93 Importantly, this study found fuel savings (3.2 to 7.8 percent) and NOx reduction (33 to 86 percent) over a range of real-world driving cycles emphasizing low load operation, without any modification to the production aftertreatment system. Even at low-load operation and idle conditions, heavy-duty CDA saw increases of 60-80°C with fuel savings of 8 to 28 percent.94 EPA's own data, which was for some reason not cited in the Draft RIA, shows similar behavior, reducing tailpipe NOx on the low-load cycle (LLC) by 77 percent, thanks to an average increase in temperature at the SCR inlet by 38°C.95 Data on a third VVA system shows the same behavior but extends the applicability to medium-duty engines.96 While this study was only a simulation, it shows tailpipe NOx reductions of 29 to 49 percent while reducing CO2 emissions by 1.6 to 3.5 percent over a range of representative cycles. A follow-up bench study by the same company on a heavy-heavy-duty engine saw a similar range of behavior, suggesting robustness of the original findings.97 [EPA-HQ-OAR-2019-0055-1277-A1, p. 24]

EPA seems to have determined that there is a significant amount of certainty needed in the selection of VVA as an emissions reductions tool.98 However, recent work shows that the same turbocharger can be used with and without CDA, and that there are multiple calibration strategies that can be deployed to keep the aftertreatment system warm while simultaneously reducing fuel use.99 [EPA-HQ-OAR-2019-0055-1277-A1, p. 24]

98. Draft RIA, p. 16.

99. Morris, A. and McCarthy, J., “The Effect of Heavy-Duty Diesel Cylinder Deactivation on Exhaust Temperature, Fuel Consumption, and Turbocharger Performance up to 3 bar BMEP,” SAE Technical Paper 2020-01-1407, 2020, doi:10.4271/2020-01-1407.

EPA additionally noted concerns about noise, vibration, and harshness (NVH) with CDA; however, recent data from Eaton shows that relatively simple adjustments in mounting and damping can dramatically reduce such NVH issues.100 Tula used a flywheel setup to reduce oscillations but showed that such a design could be accomplished without any additional modifications to packaging.101 [EPA-HQ-OAR-2019-0055-1277-A1, pp. 24 - 25]

101. Srinivasan et al. 2021

EPA suggested that vocational vehicles in particular may not be able to take full advantage of CDA,102 but these data on NVH and the applicability to reduced engine sizes suggests that CDA is broadly applicable to all heavy-duty applications and must be considered as a viable strategy to simultaneously reduce fuel consumption and both CO2 and NOx emissions across a broad range of heavy-duty vehicle categories. Organization: *National Association of Chemical Distributors (NACD)*

This rule is being considered under a backdrop of severe supply chain disruptions that are forcing goods to reach their end destinations late or not at all. These disruptions have also contributed to record high inflation as the cost to transport goods has risen dramatically — costs being passed on to the average American. While the general cause of these disruptions can be traced to the COVID-19 pandemic, the current crisis we are facing exposed how fragile the supply chain was originally. [EPA-HQ-OAR-2019-0055-1279-A1, pp. 2 - 3]

The supply chain as presently constructed lacks resilience, as each piece of the puzzle had just been barely working until the added demand and workforce disruptions sparked by the pandemic caused it to fall apart. The Biden administration’s Council of Economic Advisors’ Economic Report of the President, published in April 2022, supports this as it concludes that modern supply chains have become more fragile and 'supply chain fragility will continue to be a problem.' [EPA-HQ-OAR-2019-0055-1279-A1, p. 3]

Adding increased regulations to heavy-duty vehicles will make it more difficult for necessary resilience to be built into the trucking side of the supply chain. When another surge in demand or some other added strain is put on the supply chain, each link must be able to withstand it. With this proposed rule, trucks would be less affordable making it more difficult for fleet owners to add additional trucks and accommodate an already unpredictable and unstable supply chain. [EPA-HQ-OAR-2019-0055-1279-A1, p. 3]

Furthermore, the proposed rule would add several new requirements to heavy-duty vehicles and engines that would require more parts to be added into their production and detection systems, creating additional possible chokepoints in heavy-duty vehicle manufacturing. Currently, an NACD member company has been awaiting a shipment of new power units that has been 8-9 months delayed and is still without a delivery date. Data referenced by The Wall Street Journal also shows 55% fewer orders being complete from manufacturers in 2022 compared to early 2021 due to equipment struggles.2 NACD fears that difficulties getting new trucks and components assembled and on the road would worsen under this proposed rule. [EPA-HQ-OAR-2019-0055-1279-A1, p. 3]

2. The Wall Street Journal, 'Truckers Want More Trucks Than Industry Can Build,' WSJ.com, WSJ https://www.wsj.com/articles/truckers-want-more-trucks-than-industry-can-build-at-the-moment-11652094004?mod=pls_whats_news_us_business_f

Lastly, during the public testimony on this proposed rule, several stakeholders raised concerns that increased emission requirements could result in lower truck reliability. Decreased truck reliability would further exacerbate future supply chain challenges. [EPA-HQ-OAR-2019-0055-1279-A1, p. 3]

Organization: *National Association of Clean Air Agencies (NACAA)*

NACAA also notes the potent toxicity and impact of diesel PM and welcomes EPA’s proposal of a PM anti-backsliding standard, based on use of a DPF, of 5 mg/hp-hr, down from the current level of 10 mg/hp-hr. EPA should finalize this standard. [EPA-HQ-OAR-2019-0055-1232-A1, p. 16]

Organization: *Navistar, Inc. (Navistar)*

The NOx certification standards proposed under Option 1 do not provide room for adequate compliance margins and are therefore infeasible and unworkable. The foundation of proposed Option 1 is based on the CARB SWRI Stage 3 proof of concept engine, which is based on one of the highest ratings for the Cummins X-15 engine family 500hp/1850ft-lbs. This rating is not reflective of greater than 97% of the Class 7-8 tractors and severe service applications sold by Navistar over the last 4 years. This engine would not comply with either the current engine selection criteria under 40 CFR 86.096-24(b)(3)(ii) or proposed 40 CFR 1036.235(a). If adopted by EPA, Option 1 will likely have the effect of preventing manufacturers from developing new and cleaner HDOH diesel engines by MY 2027. [EPA-HQ-OAR-2019-0055-1318-A1, p. 3]

Emission reductions are driven by trade-offs. The current CARB/SWRI Stage 3 engine is no different. The demonstration illustrates these same tradeoffs when attempting to reduce NOx to 20 mg/hp-hr, which has resulted in increases to CO2. Currently the Stage 3 engine has been specifically configured to operate at a 500hp/1850 ft-lb. power rating that should provide higher brake specific fuel economy, as well as provide the greatest enthalpy to the aftertreatment, which aids NOx conversions efficiency. However, the Stage 3 engine does not meet any of the 2021, 2024 or 2027 CO2 standards for line haul or vocational trucks. [EPA-HQ-OAR-2019-0055-1318-A1, p. 5]

Selecting a more representative power rating would likely increase NOx levels due to the lower enthalpy and fuel economy either would remain the same or be reduced. Base engine trade-offs would also extend to vehicle aerodynamics losses. The current SWRI configuration will not fit in the current space allotted for production aftertreatment. This would require increasing the width or height of the hood and cab to accommodate the changes, resulting in increased aerodynamic drag and loss of fuel economy. [EPA-HQ-OAR-2019-0055-1318-A1, p. 5]

Organization: *Northeast States for Coordinated Air Use Management (NESCAUM)*

Should EPA instead promulgate Option 1, we urge the Agency to make the following changes to the proposed standards: NESCAUM notes the potent toxicity and impact of diesel particulate (PM2.5) and welcomes EPA's proposal of a PM anti-backsliding standard, based on use of a diesel particulate filter, of 5 mg/hp-hr, down from the current level of 10 mg/hp-hr. We encourage EPA to finalize this standard. [EPA-HQ-OAR-2019-0055-1249-A1, p. 15]

Organization: *Belli, Mike and Cheryl (OOIDA)*

I'm not gonna mince words with you at the EPA. If you want these standards met, you need to give engine manufacturers time to design a prototype first. Allow them to build 10-20 engines and put them out for testing allowing a million miles each. Allow the manufacturers time to compile data with things that worked and things that failed so they can produce an engine that will not be so problematic as the engines you all forced to be built before they could be adequately tested. You all have made a disaster out of engine designs being forced to adhere to your time frames. No one can properly do what you are requiring without causing major issues. As an owner operator, the EGR, DPF, DEF engines have cost me in excess of $35k over the last several years. You have created problems that will never go away, as engines today are like a cancer that will never go away. Your ideas are killing engines because none of you has any idea what the hell you doing. Just another government agency imposing their will at the cost of those who will suffer from your decisions. There ya have it. You don't like it, well neither do I having to continually put my hard earned money fixing the same issues over and over and over. [EPA-HQ-OAR-2019-0055-1266-A2, p.5]

Organization: *Imhausen, Jim (OOIDA)*

"Cummins 2010 after treatment system on a 2012 Kenworth cost me $50,000 by the time I gave up and sold the truck. All of the estimated life of service and maintenance intervals were phony. Field service technicians weren't trained. Government forced the manufacturers and the manufacturers misrepresented the capabilities of the products. Big companies had spare trucks in place and could deal with the situation, but I couldn't." [EPA-HQ-OAR-2019_0055-1266-A2, p.2]

Organization: *Dudek, Nick (OOIDA)*

"I stand behind you guys 100%, the government continuing to put their unproven technology on our backs will continue to put people out of business especially the little guy, I have had to dig very deep in my pockets because of emission issues on my semi-truck, had I not had some extra money put away it would've buried me and put me out of business." [EPA-HQ-OAR-2019_0055-1266-A2, p.2]

Organization: *Elison, Doyle (OOIDA)*

Please allow enough time for technology to become reliable before it is required. What is already required is barely there now after 10 years. It is still too expensive to repair when some little sensor fails. Thank you. [EPA-HQ-OAR-2019-0055-1266-A2, p.5]

Organization: *PACCAR, Inc (PACCAR)*

Proposed 1036.522 additionally requires manufacturers to determine the regeneration frequency for each duty cycle. However, identifying specific in-use regeneration intervals per individual certification cycle (FTP, RMC or LLC) is complicated due to the generally wide-ranging duty cycles between regeneration intervals, e.g., if a vehicle runs 50 hours in city conditions and 50 hours in motorway conditions during a 100 hour regeneration interval, it is not possible to determine whether the data should be used in the overall calculation of the RMC, the FTP or the LLC frequency. Using back-to-back dynamometer emission cycles to determine regeneration intervals does not lead to representative in-use regeneration frequencies and durations. Customers are unlikely to drive the same or similar duty-cycles during their complete regeneration interval, which is the main factor that determines a regeneration frequency. Finally, effects of cold-starts and ambient conditions are not accurately simulated in back-to-back dyno cycles. EPA should therefore retain the option to determine a single regeneration frequency and duration that is used to calculate the IRAF for all emission cycles based on the average regeneration frequency of customer vehicles over all duty cycles. PACCAR respectfully submits that using average customer in-use data is a more appropriate method to determine regeneration frequencies and durations. [EPA-HQ-OAR-2019-0055-1346-A1, pp.50-51]

The Southwest Research Institute's ('SwRI's') system is the principal basis for the purported feasibility of the 0.020 g/bhp-hr NOx standard. CARB's assertion that the new low-NOx requirements are technically feasible is based on a system demonstrated by SwRI over accelerated laboratory aging. To support its low-NOx rulemaking, EPA also contracted with SwRI to perform an aged emissions demonstration with a technical solution very similar to the CARB 'Stage 3' technology package. [EPA-HQ-OAR-2019-0055-1346-A1, pp.4-5]

PACCAR concurs with EMA – which has been engaging with EPA and CARB on HDOH low-NOx rulemakings from the outset, including on the underlying SwRI demonstration projects – that the Omnibus/Option 1 low-NOx standards have not been demonstrated to be technically feasible, and are in fact infeasible, for the following reasons:

- a. The aged-engine 'Stage 3' NOx emissions results neither meet the proposed future 0.020 g/bhp-hr NOx standard across all required certification cycles, nor consistently meet the in-use NOx standards when laboratory tested on 'road cycles' that mimic real-world operation, which shows that the SwRI program was a demonstration of technical infeasibility. CARB and EPA have not considered real-world conditions and other factors that increase NOx emissions, or the accelerated aftertreatment deterioration that will occur in the field. Those real-world conditions and other factors, which were not 'in scope' in the SwRI demonstration program, will require significant additional development effort, and likely additional NOx and CO_2 emissions control hardware.

'Getting close' to meeting extremely stringent emissions requirements, as SwRI did, is inadequate and an unreasonable basis for setting the Option 1 emissions standards at issue, especially when the agencies have not considered critical and significant emissions-increasing factors.

- b. 'Packaging' requirements (i.e., fitting emission systems under the hood or cab) to 'close-couple' the new light-off SCR ('LO-SCR') to the turbocharger turbine exit will be extremely difficult, and/or will require cab retooling. Such retooling costs are expensive (on the order of $500 million) for low-volume products with potentially abbreviated amortization schedules, especially as those same vehicles transition to battery-electric and other 'zero-emissions' technologies driven, at least in part, by other regulations. [EPA-HQ-OAR-2019-0055-1346-A1, pp.5-6]

Diesel engine manufacturers often use the term 'margin' when talking about the headroom they must design into their emissions control strategies. Margin is the difference between the underlying emissions standard and the lower 'as-designed' emissions performance that diesel engine manufacturers target for their products. Manufacturers must design and calibrate to provide for sufficient margin to ensure robust compliance after accounting for the myriad factors that can compromise real-world emissions performance, thereby protecting themselves from recall and/or enforcement actions, fines, damaged reputations, etc. With this background, PACCAR explains its additional concerns regarding the demonstration testing and its inability to represent real-world, in-commerce applications:

- The demonstration testing on which EPA relies was conducted on a single engine with the calibration adjusted multiple times to perform in an optimal manner for a specific engine.
- Manufacturers must meet the proposed emission limits on tens of thousands of engines per year. These engines are mass-produced and have an inherent spread in emission performance due to natural variation between the mass-produced parts and because they must support multiple configurations, including for various vocational applications.
- In addition, although SwRI's aging protocol may represent the average aging of the emission control system, manufacturers must meet emission limits throughout each engine's useful life under all in-use conditions. Therefore, additional margin must be included to ensure that the emission limits are achieved under worst-case aging conditions.
- The SwRI data shows insufficient margin to be considered a demonstration of feasibility to the standard. [EPA-HQ-OAR-2019-0055-1346-A1, pp.6-7]

Moreover, while a close-coupled Selective Catalytic Reduction ('SCR') application (referred to as 'LO-SCR' or 'light-off SCR' by SwRI) is effective at demonstrating Low NOx in the laboratory, the LO-SCR system must be 'close-coupled' to the turbocharger turbine exit to actually be effective. This close-coupled configuration may not be possible for all current commercial vehicle applications due to packaging constraints and heat load impact on temperature sensitive components (such as the Engine Control Module ('ECM') and AC systems). In some cases, and especially with the smaller range of vehicles in the HD class, packaging constraints will be extremely difficult to overcome. Cab retooling will be necessary in certain instances, as efforts to adequately insulate long runs of exhaust piping will compromise the efficacy of the LO-SCR unit. And, as mentioned above, cab retooling costs can be very high (as much as $500 million), particularly for low-volume products with potentially abbreviated amortization schedules, since those same vehicles will be transitioning to battery-electric and other zero-emissions technologies. [EPA-HQ-OAR-2019-0055-1346-A1, p.7]

With the LO-SCR being larger than the traditional downpipe, additional heat shielding will be required to protect proximate components. That is particularly problematic since the proximate components include much of the Heating, Ventilation and Air Cooling ('HVAC') hardware, such as heater/evaporator coils, fan air intake, as well as electrical junctions, fuse panel, Powertrain Control Module ('PCM'), relays and other temperature sensitive components. Those thermal issues are exacerbated by the transition to low-GHG HVAC refrigerant HFO 1234yf, where there are additional flammability concerns. Adding length or height to the vehicle hood to 'make room' to mitigate the packaging challenges will compromise bumper-to-back-of-cab limitations, or will increase GHG emissions due to increased aerodynamic drag, or both. Reducing the substrate frontal area to improve packaging will increase backpressure and CO2 emissions. [EPA-HQ-OAR-2019-0055-1346-A1, pp.7-8]

Due to these constraints, some applications may require vehicle cab redesign to facilitate integration, and other applications may not be able to support this catalyst volume and would therefore be eliminated from commerce. The redesign expense is significant and not included in EPA's current economic impact analysis. A 'first-in-box' application modification or placing a portion of SCR first in a catalyst array currently located under the vehicle is more viable. However, this application results in additional heat loss and further delays the catalyst system's light off, leading to slightly higher emissions than the laboratory close coupled SCR configuration. [EPA-HQ-OAR-2019-0055-1346-A1, p.8]

In short, commercial vehicles are exposed to a number of variables that are not present in laboratory demonstrations that lead to intrinsic emissions variation and do not necessarily indicate a failed system. Any regulatory proposal must provide flexibility for this variation; if not, systems that have not failed but are simply demonstrating normal variation may be subject to unnecessary recalls, which would be untenable. [EPA-HQ-OAR-2019-0055-1346-A1, p.8] EPA has failed to address real-world, in-commerce variation in its feasibility demonstration efforts. [EPA-HQ-OAR-2019-0055-1346-A1, p.8]

A large number of real-world variables can affect Low NOx system performance, such as fuel sulfur (S), biodiesel metals, oil consumption differences, application variation that leads to aging variation, and sensor errors. Major improvements in NOx sensors accuracy are not foreseen in the proposed low-NOx standards timeframe. NOx sensors (three of which are used in the Stage 3 solutions) play a critical role in Diesel Exhaust Fluid ('DEF') dosing strategies and long-term trim functions. In addition, there are normal variations due to lab-to-lab differences and test-to-test variations. [EPA-HQ-OAR-2019-0055-1346-A1, p.9]

These data demonstrate that although a proposed emissions standard may be met in a laboratory-controlled environment under DF, there must be a 'variance allowance' for production engines tested from vehicles in commerce. This approach would establish a stringent emissions standard while providing a regulated Variance Allowance that enables compliance under real-world variation and would mitigate the unintended consequence of subjecting normally-functioning systems (i.e., those that have not failed) to recall actions by acknowledging the intrinsic variation of emissions due to real-world variables. Setting a tailpipe emissions standard for durability demonstration, and then providing an ‘in-commerce’ variability allowance, aligns with EPA’s proposed Option 1. In Preamble Section IV(K) titled ‘Other Flexibilities Under Consideration’, EPA acknowledges: ‘We understand that manufacturers generally aim to design and build vehicles not only with a sufficient margin to ensure the emissions control technology is meeting the applicable standards throughout the full useful life, but also an additional margin to reflect the fact that not every vehicle manufactured and every vehicle application will perform identically to the laboratory tests. This is particularly important, and challenging for manufacturers, when new technologies and test procedures are being implemented.’ 87 FR at 17564. [EPA-HQ-OAR-2019-0055-1346-A1, p.15]

PACCAR respectfully requests that EPA separate the variance allowance from the standard – based on observed standard deviation caused by real world variables – and then add that variance allowance to the standard for in-production performance. This could be accomplished, for example, using the proposed equation below:

In Production Standard = NOx FEL + VA

Where:

- NOx FEL = the standard, including any credit adjustments
- VA= variance allowance [EPA-HQ-OAR-2019-0055-1346-A1, pp.15-16]

In sum, PACCAR supports the regulatory levels of Option 2 as feasible under a laboratory controlled scenario, such as DF program durability demonstration, with the addition of a ‘variability allowance’ applied to in-commerce engine testing to account for real-world emission variations. PACCAR respectfully requests that EPA propose a FTP/RMC emission standard in alignment with Option 2 and a variance allowance of **30 mg** for in-commerce testing compliance. Because it is unclear how these variables would diminish over time, EPA should not propose phasing out the variance allowance. The variance allowance should be included for in-commerce engine testing including:

- SEA · Conformity Testing
- Verification of DF; and
- Heavy-Duty In-Use Testing (‘HDIUT’). [EPA-HQ-OAR-2019-0055-1346-A1, p.16]

Organization: *South Coast Air Quality Management District*

CARB staff has further indicated that the proposed MY 2024 standards are in fact feasible without requiring significant changes to the current engine and aftertreatment system architecture with thermal management strategies and improved aftertreatment systems, including advanced catalyst substrates and heated dosing.29 As an example, CARB notes that the SwRI Stage 1 program aftertreatment screening process has demonstrated 0.04 g/bhp-hr NOx on the FTP using a 2014 model conventional SCR system and heated dosing.30 CARB’s 2019 white paper provides further evidence of technological feasibility. By way of example, Stage 1 of SwRI's low NOx research program involved development work on both a 2012 MY 12-liter Cummins natural gas engine and 2014 MY 13-liter Volvo diesel engine with a target NOx emission rate of 0.02 g/bhp-hr on the FTP and RMC-SET test cycles.31 This phase achieved a 0.01 g/bhp-hr NOx over the FTP and a 0.001 g/bhp-hr NOx level over the RMC-SET on the Cummins natural gas engine.32 [EPA-HQ-OAR-2019-0055-1201-A1, p.8]

31 CARB, Assessment of the Technical Feasibility of Lower NOx Standards and Associated Test Procedure 2022 and Subsequent Model Year Medium-Duty and Heavy-Duty Diesel Engines, Staff White Paper (April 18, 2019), available at https://ww2.arb.ca.gov/sites/default/files/classic/msprog/hdlownox/white_paper_04182019a.pdf?_ga=2.68986130.2008336815.1651111319-1848774752.1595968774, pg. 11.

32 Id.

Additionally, a Volvo diesel engine achieved a 0.034 g/bhp-hr NOx level over the FTP and a 0.038 g/bhp-hr NOx level over the RMC-SET.33 [EPA-HQ-OAR-2019-0055-1201-A1, p.9]

33 Id.

Per EPA's own analysis, a nationwide Omnibus scenario in MY 2027 would bring significant NOx reductions over the baseline, similar to those that would be achieved via implementation of the Alternative Option.34 Numerous past and on-going studies also support the notion that a 0.02 g/bhp-hr standard for MY 2027 is feasible. For instance, as part of the CARB funded SwRI Stage 3 program, the final test results at the end of the useful life of 435,000 miles were 0.023 g/bhp-hr NOx on the composite FTP, 0.020 g/bhp-hr NOx on the RMC-SET, and 0.047 g/bhp-hr NOx on the LLC. While the results of CARB Stage 3 did not reach below 0.02 g/bhp-hr for FTP/RMC-SET, SwRI has identified a number of additional improvements that could ultimately reach the 0.02 level including new catalyst architecture, better DEF mixing, larger downstream catalyst volume, improvements to SCR formulation as well as trim/calibration improvements.35 With respect to the EPA funded SwRI Stage 3 'Rework' program, SwRI was able to incorporate what it learned from its Stage 3 program, changing the zone coated catalyzed soot filter with traditional DOC+DPF architecture and achieving 0.020 g/bhp-hr NOx on the composite FTP, 0.017 g/bhp-hr NOx on the RMC-SET, and 0.029 g/bhp-hr NOx on the LLC at 435,000 miles. [EPA-HQ-OAR-2019-0055-1201-A1, p.9]

35 FSOR at pg. 66.

Aside from the lab demonstration work, other work has shown the feasibility of 0.02 g/bhp-hr. In April 2022, Achates Power announced in-use NOx test results from the Heavy-Duty Diesel Demonstration program showing the opposed piston engine reaching 0.02 g/bhp-hr level in real world conditions, 50% below the proposed EPA in-use limit. To quote Achates, '[t]he engine showed a comfortable compliance margin to the NAAQS requirements on all cycles, even in the fully aged case.'36 Importantly, an Achates/FEV study concluded that Achates opposed-piston engine architecture complies with 2027 ultra-low NOx regulations and provides an 11% cost savings compared to a current production four-stroke, inline six cylinder engine and 6% savings excluding exhaust aftertreatment hardware.37 In summary, even though commercialized pathways to 0.02 g/bhp-hr have not yet been fully achieved at the time of this proposal, the past and ongoing work provides a fully convincing case that it can be done. The Clean Air Act does not require regulations to incorporate currently commercially available technology. What the Act requires are standards that reflect the greatest degree of reductions available with technology that will be available for the applicable model year.38 [EPA-HQ-OAR-2019-0055-1201-A1, p.9]

38 42 U.S.C. Section 7521(a)(3)(A)(i).

Organization: *Truck and Engine Manufacturers Association (EMA)*

Broadly speaking, EPA’s assumption that its proposed Option 1 standards and requirements are fully feasible is a fallacy. Moreover, that fallacy is premised on only one set of data — in some instances just one data point — from one still-evolving prototype engine used in one not-fully-successful experiment. That is the sum and substance of the basis for EPA’s incorrect assumption that manufacturers can design and build engine systems to meet a NOx standard starting at 0.02 g/bhp-hr, and ending at 0.04 g/bhp-hr at the 800,000 mile mark, without the need to replace any emissions-related components. As explained in great detail below, a rulemaking of this magnitude based on such scant data and such fallacious assumptions will not stand. Instead, an Option 2-like program will need to serve as the foundation for a sustainable final rule. [EPA-HQ-OAR-2019-0055-1203-A1, p. 16]

In order to ensure the adoption of fully achievable and cost-effective HDOH low-NOx regulations, and notwithstanding our broader agreement, the Agency should revise the proposed standards in the following manner:

(iii) Manufacturers will not produce Option 1-compliant products because the Option 1 standards are not feasible. Accordingly, the FTP/RMC certification standards for NOx must be set at Option 2-like levels, not 0.02 g/bhp-hr. Otherwise, the standards will fail to provide the requisite compliance margins, which will render them infeasible in practice, and will cause unacceptable compliance and recall risks for manufacturers. In addition, a program centered around Option 2-like levels will be more beneficial from an emissions-inventory perspective, once potential fleet turnover market responses, including pre-buy/no-buy responses, are taken into account. [EPA-HQ-OAR-2019-0055-1203-A1, p. 6]

EPA proposes to apply the GHG version of the RMC to the certification testing process for criteria emissions. The effective weighting factors at each steady-state data point for the GHG RMC were developed based on a robust dataset reflective of modern engines. The industry recognizes the importance of representativeness in the certification tests, and agrees it is illogical to make different assumptions about operational activity depending on the emissions constituents measured. EMA supports EPA's proposal to use this improved, more representative test for criteria emissions testing. [EPA-HQ-OAR-2019-0055-1203-A1, p. 115]

EMA supports that EPA proposes to allow a stop-start function to be active during the FTP and LLC cycles (§1036.501(f)). Stop-start could be an effective tool for reducing NOx, and having the ability to demonstrate NOx control over the LLC and RMC will be beneficial. More detail will be necessary, such as whether operator over-ride functions will influence whether stop-start can be active during certification testing. Also, there are concerns about deploying conventional starters to support restart, because the inertia of the dyno may cause unforeseen problems. EMA appreciates that EPA is providing for stop-start to be active in the certification tests, and is ready to work with EPA to iron out the details for the final rule. [EPA-HQ-OAR-2019-0055-1203-A1, p. 116]

Our conclusion is that the Omnibus/Option 1 low-NOx standards have not been demonstrated to be technically feasible, and are in fact infeasible, for the following reasons:

1) The aged-engine "Stage 3" NOx emissions results do not meet the proposed future 0.020 g/bhp-hr NOx standard across all required certification cycles, nor do they consistently meet the in-use NOx standards when laboratory tested using "road cycles" that mimic real world operation (which, practically speaking, makes the case that the SwRI program was a demonstration of technical infeasibility.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 18]
2) CARB and EPA have not considered the impacts of the real-world conditions and other factors that increase NOx emissions, or the accelerated aftertreatment deterioration that will occur in the field, all factors for which diesel engine manufacturers will be held accountable. Those real-world conditions and other factors, which were not "in scope" in the SwRI demonstration program, will require significant additional development effort, and likely additional NOx and CO2 emissions control hardware. "Getting close" to meeting extremely stringent emissions requirements, which is all that SwRI has done, is inadequate and unreasonable as a basis for setting the Option 1 emissions standards at issue,

especially when critical and significant emissions-increasing factors have not been considered. [EPA-HQ-OAR-2019-0055-1203-A1, p. 18]

3) The “Stage 3” technical solutions used as the basis for the EPA and CARB rulemakings include technologies such as individually-controlled cylinder deactivation systems that have never-before been used on HDOH production engines subject to the durability requirements of the medium heavy- (“MHD”) or heavy heavy-duty (“HHD”) diesel engine markets, and that also require an unknown scale of effort to address the “noise, vibration and harshness” (NVH) challenges that arise in the context of the multiple custom-tailored vehicle specifications of HD trucks. [EPA-HQ-OAR-2019-0055-1203-A1, p. 18]
4) “Packaging” requirements (i.e., fitting emission systems under the hood or cab) to “close couple” the new light-off SCR (“LO-SCR”) to the turbocharger turbine exit will be extremely difficult, and/or will require cab retooling. Such retooling costs come at a very high cost (on the order of $500M) for low-volume products with potentially abbreviated amortization schedules, especially as those same vehicles transition to battery-electric and other “zero-emissions” technologies driven, at least in part, by other regulations. EPA has done nothing to assess the feasibility of the multiple packaging challenges at issue. [EPA-HQ-OAR-2019-0055-1203-A1, p. 18]
5) Heavy-duty diesel engines also are regulated to control CO2 emissions. The “Stage 3” technical solutions for NOx have not been demonstrated in combination with the requisite improvements that will be needed to comply with the 2027 CO2 emissions standards. The Stage 3 engine does not even meet the 2021 or 2024 CO2 standards, for that matter. The well-established NOx/CO2 tradeoff that has challenged diesel engine manufacturers for decades has not been given adequate consideration in EPA’s Option 1 proposal. [EPA-HQ-OAR-2019-0055-1203-A1, p. 18]

As noted, the SwRI demonstration project is the source of the data behind EPA’s assumption that the low-NOx standards at issue are feasible for HDOH diesel engines. SwRI conducted baseline tests of a production configuration 15L Cummins HD diesel engine calibrated for certification to the US10 HDOH emission standards. SwRI outfitted the engine and its aftertreatment system with additional emissions control systems for the purpose of the demonstration project. Features of the “Stage 3” solution include cylinder deactivation (CDA) to increase light-load exhaust temperatures, and an EGR cooler bypass, as depicted below: [EPA-HQ-OAR-2019-0055-1203-A1, p. 19]

The aftertreatment system that CARB used in its low-NOx demonstration added several new components to the US10 DOC/DPF/SCR/ASC configuration, including a second SCR catalyst closely coupled to the turbocharger outlet (a light-off SCR, or “LO-SCR”) with its own independent heated DEF injector, a zone-coated soot filter (“zCSF”), and other refinements intended to improve DEF mixing in the downstream SCR. A third NOx sensor was added after the LO-SCR to calculate and activate DEF dosing rates for the downstream SCR, and an NH3 sensor was installed at the midpoint of the downstream SCR bricks to monitor and correct those dosing rates. Thermal management routines were structured to optimize cold-start and light load emissions control. A diagram of the CARB Stage 3 prototype aftertreatment system is included here: [EPA-HQ-OAR-2019-0055-1203-A1, pp. 19 - 20]

EPA is using the SwRI-developed Stage 3 solution as the backbone of its own technical feasibility demonstration, but with one primary modification. EPA's technical solution (which SwRI calls the Stage 3 Reworked system, or "Stage 3 RW") uses a conventional DOC/DPF rather than a zCSF to improve regeneration robustness and to sustain more consistent NO-NO2oxidation over time. The EPA Stage 3 RW system also includes minor sizing and control calibration differences compared to the CARB Stage 3 solution, but otherwise the technical packages are very similar. A schematic of the "RW" aftertreatment system is shown here: [EPA-HQ-OAR-2019-0055-1203-A1, p. 20]

In that regard, and as an initial matter, EPA's proposed Option 1 proposal is fundamentally infeasible because, among other things, EPA has not and cannot fully demonstrate the feasibility of the Option 1 NOx standards through testing with the "Stage 3" prototypes at SwRI, especially when adjustments for infrequent regeneration adjustment factors ("IRAFs") and other emission impacting factors are accounted for. In particular, EPA has failed to demonstrate the feasibility of maintaining compliance with the Option 1 NOx standards through the proposed extended useful life periods, and has not even completed the analysis of the Stage 3 protypes' emission results out to 800,000 miles. In addition, EPA has conducted no in-vehicle testing whatsoever, has not demonstrated that the Stage 3 prototype can meet the Option 1 NOx standards while also meeting the current Phase 2 GHG requirements, and has done no testing to show that the Stage 3 prototype is capable of meeting the 2027 MY GHG standards. Indeed, in some testing, the CO2 emissions from the Stage 3 prototype were up to 1.3% higher than the 2017 MY baseline engine. (87 FR at p. 17469) [EPA-HQ-OAR-2019-0055-1203-A1, p. 8]

Equally important, the ultra-low level of EPA's proposed standards (if set based on a 0.02 g/bhp-hr FTP/RMC NOx standard) would leave no room for any compliance margins that are necessary to account for production, fuel and emissions-testing variabilities, real-world operating conditions, or for the expected emissions deterioration over the proposed lengthened FULs of HDOH engines and vehicles. Simply stated, a program based on a 0.02 g/bhp-hr NOx standard, as opposed to Option 2-like requirements, will leave no room for manufacturers to ensure and certify full in-use emissions compliance over the proposed extended useful life periods, and so is fundamentally infeasible. As a result, manufacturers cannot commit to building Option 1 compliant diesel engines. Stated differently, if EPA finalizes Option 1, the Agency will, in effect, prohibit HDOH diesel engines as of 2027. That would have enormous ramifications for the economy and security of this country. [EPA-HQ-OAR-2019-0055-1203-A1, p. 9]

In light of those core infeasibility issues, the inconsequential incremental NOx emissions inventory differences between a 0.02 g/bhp-hr-centric program and an Option 2-like program do not outweigh the risks of not being able to implement the type of viable comprehensive HDOH low-NOx program that all stakeholders support. [EPA-HQ-OAR-2019-0055-1203-A1, p. 9]

Since the Agency's Option 1 proposal is not feasible, as detailed below, it necessarily follows that the more stringent "Alternative" concept is even more so. Accordingly, EMA fully agrees with the Agency that the Alternative alluded to in the NPRM is fundamentally unworkable and, as such, warrants no further discussion in these comments. Instead, EMA's comments will focus on the potentially implementable elements of Option 2, and, by comparison, the non-implementable elements of Option 1. [EPA-HQ-OAR-2019-0055-1203-A1, p. 9]

As noted above, a critical shortcoming of the Option 1 proposal, and to a certain extent the Option 2 proposal as well, is that the Agency has neither accounted nor provided for the compliance margins that manufacturers need to factor-in when designing and producing engine and aftertreatment systems capable of meeting the prescribed emission standards over the applicable useful life period. To the contrary, the "Stage 3" prototype systems that serve as the foundation for the NPRM just barely meet (or in some instances fail to meet) the new Option 1 NOx standards over the new test cycles without any margin at all. The lack of allowing for sufficient compliance margins is especially evident from the emissions-test results of the aged Stage 3 systems, and has been specifically noted by SwRI as an area of concern. The Agency's failure to provide for the needed compliance margins must be remedied in the final rule. [EPA-HQ-OAR-2019-0055-1203-A1, p. 9]

Significantly, EPA acknowledges the fundamental importance of this issue, notwithstanding the Agency's failure to account for it. For example, EPA notes that, "to account for variability in emission measurements, as well as production variability, manufacturers typically add margin between the DF and infrequent regeneration adjustment factor (IRAF)-adjusted test result, and the family emission limit (FEL)." (87 FR at p. 17460.) Similarly, the Agency states that "manufacturers design their engines to perform significantly better than the standards when first sold to ensure that the emissions are below the standard throughout useful life, even as the emissions controls deteriorate." (87 FR at p. 17467.) The NPRM also acknowledges that "manufacturer margins can range from less than 25 percent to 100 percent of the FEL." (Id.) Finally, the Agency summarizes this critical issue, as follows: We understand that manufacturers generally aim to design and build vehicles not only with a sufficient margin to ensure the emissions control technology is meeting the applicable standards throughout the full useful life, but also an additional margin to reflect the fact that not every vehicle manufactured and every vehicle application will perform identically to the laboratory tests. This is particularly important, and challenging for manufacturers, when new technologies and test procedures are being implemented. (87 FR at p. 17564.) [EPA-HQ-OAR-2019-0055-1203-A1, pp. 9 - 10]

Yet even with those express acknowledgements, the Agency did not attempt to quantify or provide for the compliance margins that manufacturers will need to meet NOx standards that are 90 percent lower than today's standards. As explained more fully below, that failure completely undermines the feasibility of the Option 1 proposal, and will require revisions to the Option 2 proposal to make it fully implementable. Accordingly, EMA appreciates the Agency's request for comments on whether "a margin between the demonstrated emissions performance and the proposed standards should be included, and, if so, what that value should be." (87 FR at p. 17471.) EMA's comments specifically respond to that request, and quantify the necessary margins at issue. [EPA-HQ-OAR-2019-0055-1203-A1, p. 10]

Given all the significant issues and concerns regarding EPA's Option 1 proposal, EMA appreciates that EPA is still "considering the degree to which there is uncertainty in how the [Stage 3] technologies deteriorate when the engine is installed in a wide variety of heavy-duty vehicle applications that exist in the marketplace, and how to address such uncertainty." (87 FR at p. 17563.) In that regard, EMA agrees that the feasibility issues and related uncertainties are significant, and we fully support the Agency's suggestion that higher interim NOx standards may be warranted, perhaps extending out for five or more MYs, to allow manufacturers "to gain experience with the additional [Stage 3] emission control technologies needed to meet the proposed NOx standards while these technologies are operating in the field." (Id.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 14]

Section 202 of the federal Clean Air Act ("CAA"), 42 U.S.C. §7521, governs the Agency's establishment of emission standards for new mobile sources, including HDOH engines and vehicles. CAA section 202(a)(3)(B) specifically governs the Agency's establishment of "revised standards for heavy-duty trucks." Unlike the general standard-setting provisions contained in section 202(a)(3)(A) – which call for the establishment of emission standards that "reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply" – section 202(a)(3)(B), the specific provision that applies here, simply states that the Administrator may set revised emissions standards "taking costs into account." [EPA-HQ-OAR-2019-0055-1203-A1, pp. 15 - 16]

Consequently, in assessing the details for the proposed revised low-NOx regulations at issue, costs, not the absolute limits of potential technological feasibility, are a paramount consideration. In this case, a full and fair consideration of costs and benefits leads to the conclusion that a low-NOx program centered around an Option 2-like program will yield an optimized final rule, while a program centered around the Option 1 proposal is simply not workable. [EPA-HQ-OAR-2019-0055-1203-A1, p. 16]

EMA has multiple concerns with the capabilities of the Stage 3 prototype systems to consistently achieve NOx results compliant with the Option 1 proposal. EMA similarly has concerns regarding manufacturers' ability to design, produce and deliver similar prototype engines and aftertreatment systems capable of meeting all of the Option 1 requirements over the extended useful life and emission warranty periods at issue. Indeed, the Option 1 standards are not feasible. [EPA-HQ-OAR-2019-0055-1203-A1, p. 16]

By way of background, it is important to understand the rigor of the current HDOH NOx standards. To comply with EPA and CARB's "US10" heavy-duty emissions standards, HDOH diesel engine manufacturers have deployed elaborate exhaust aftertreatment systems supported by complex control strategies downstream of advanced NOx-reducing exhaust gas recirculation ("EGR") systems, which were introduced earlier to meet the prior "US04" emissions-reduction step. Wall-flow diesel particulate filters ("DPF") were introduced in 2007 to meet the 0.01 g/bhphr particulate matter ("PM") standard. Those DPFs have required either a "7th" diesel fuel injector or in-cylinder dosing to periodically inject fuel into the exhaust stream over a diesel oxidation catalyst ("DOC"), elevating exhaust temperatures to oxidize soot that accumulates on the filter. By 2013, all major HDOH diesel engine manufacturers also had deployed Selective Catalytic Reduction ("SCR") systems with an ammonia slip catalyst ("ASC") downstream of the DPF to meet the fully-implemented US10 NOx standard of 0.20 g/bhp-hr. SCR systems require Diesel Exhaust Fluid ("DEF") stored on-board (and replenished at approximately every second refueling event), which is injected at carefully controlled rates, dynamically adjusted in response to operating parameters and ambient conditions. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 16 - 17]

Despite the fact that the NOx conversion efficiency of SCR varies with exhaust temperatures commonly encountered during HD diesel vehicle operation, comprehensive testing by West Virginia University ("WVU") of 100 HDOH diesel vehicles in various highway and vocational applications operating in Southern California has demonstrated that US10-compliant emissions-control systems reduce total NOx emissions from in-use vehicles at levels proportional to the change in the certification standards. DPFs are even more effective, reducing PM emissions to a fraction of the certification standard. Overall, NOx emissions from HD diesel vehicles compared to pre-regulation levels have been reduced by some 98%, and PM emissions by 99%. [EPA-HQ-OAR-2019-0055-1203-A1, p. 17]

One of the key enabling technologies in the Stage 3 prototype's suite of engine and aftertreatment solutions is cylinder deactivation ("CDA"). CDA permits an engine to selectively deactivate certain cylinders from the combustion process, thereby meeting the power demand with fewer cylinders in operation, which in turn elevates exhaust temperatures while decreasing CO2 emissions. [EPA-HQ-OAR-2019-0055-1203-A1, p. 21]

A critical challenge for manufacturers, however, is to implement CDA on a heavy-duty diesel engine, and have it deliver consistent, reliable, durable performance over 800,000 miles, without creating truck and cab "noise, vibration, and harshness" ("NVH") issues or driveline torsional problems. Implementing CDA with individual independent cylinder deactivation control has never been achieved before on MHD or HHD diesel engines,3 but this technology is a fundamental element of EPA's attempted technical feasibility demonstration, applicable to every HDOH diesel engine sold in the US from and after 2027. [EPA-HQ-OAR-2019-0055-1203-A1, p. 21]

> 3. One manufacturer of heavy heavy-duty engines has industrialized a system capable of deactivating all three front cylinders as a group (without individual cylinder control).

It is instructive first to consider the design aspects of CDA. CDA is not a bolt-on, one-size fits-all system that an OEM can purchase off-the-shelf from a component supplier. Each diesel HDOH engine valvetrain design will require a unique CDA design integration. CDA also will introduce new and potentially catastrophic failure modes, such as failures to open the exhaust valve on the exhaust stroke of a firing cylinder, and subsequent intake valve and valvetrain failures as the intake valve attempts to open under extremely high pressures. [EPA-HQ-OAR-2019-0055-1203-A1, p. 21]

In addition, CDA presents complex challenges for the multiple applicable HD OBD requirements, strategies and calibrations. OBD threshold diagnostic determinations become very difficult when CDA is factored-in, since multiple valves individually or in concert may experience either partial or complete failures. In such a case, separate failure modes would require separate diagnostic validation for each failure mode permutation. The OBD challenges would not be limited to diagnostics of the CDA system itself. CDA can significantly alter the required strategies and calibrations of multiple system diagnostics. For example, CDA greatly complicates the ability to diagnose misfire, a detection issue that already is among the more challenging under the HD OBD regulations. [EPA-HQ-OAR-2019-0055-1203-A1, p. 21]

Another major concern associated with CDA, as mentioned above, relates to NVH. The inline six-cylinder engine configuration that dominates the HDOH diesel engine market has inherent torsional balance advantages over other configurations. When individual cylinders are deactivated, that natural torsional and harmonic balance is disturbed, so the engine vibration levels are increased and torsionals in the engine and driveline systems are elevated. The result is increased noise levels and cab vibration levels that can be uncomfortable to the driver, and that can cause increased wear and stress on cranktrain and drivetrain components, and vibration levels throughout the vehicle that can cause performance and fatigue issues for on-board systems. [EPA-HQ-OAR-2019-0055-1203-A1, p. 21]

While SwRI performed some computer-based modeling to assess possible cylinder deactivation combination schemes to reduce simulated vibration as assessed in the test cell, there is a vast difference between vibration characteristics “as modeled” in an emissions laboratory, and those experienced in an actual HD vehicle on the road. That fact was duly noted by Neely, et al., of SwRI in their related SAE article, where they stated, “Acceptability standards to linear vibration (e.g. measured at the seat, steering wheel, foot pedal, frame rails, etc.) are better understood in a vehicle environment. The system driveline in a vehicle will differ from that in a dyno (test cell) as well, and it is recommended to evaluate driveline response in a typical vehicle setting.”4 EPA and SwRI have not done that. [EPA-HQ-OAR-2019-0055-1203-A1, p. 22]

> 4. Simultaneous NOx and CO2 Reduction for Meeting Future California Air Resources Board Standards Using a Heavy-Duty Diesel Cylinder Deactivation-NVH Strategy, Neely et al., Southwest Research Institute, SAE article 03-13-02-0014.

Indeed, one OEM’s experience with a prototype CDA system in a Class 8 vehicle has found that, at the lowest loads and speeds, drivers’ responses to the experienced NVH issues are not favorable, especially when the minimum number of cylinders are active. Depending on the extent of CDA at a given load and speed, NVH can vary from mildly perceptible to very significant and fatiguing. The concern for manufacturers and fleet operators then becomes whether CDA would adversely impact driver attentiveness, fatigue, and, ultimately, driver retention. While increasing the number of active cylinders and engine speed can result in a more positive driver response, that reduces the benefits derived from the elevated temperature of CDA. Passive or active engine mounts can help improve those negative responses, but there is insufficient data on the broad range of truck powertrain configurations to know whether those issues can be addressed in a sufficiently effective manner. [EPA-HQ-OAR-2019-0055-1203-A1, p. 22]

Manufacturers of Class 2b-3 vehicles (14,000 lbs. and less), where gasoline engines of smaller displacements have been fitted with CDA, are very familiar with the magnitude of the engineering challenges to overcome NVH issues. Each engine installation on each unique vehicle model is its own development project, requiring significant resources, multiple technical solutions, and substantial verification time. The technical solution, depending on the vehicle model, can include engine-mount tuning, active noise-cancellation systems, exhaust butterfly valves and pipe geometry modifications, active-tuned dampers, and high-torque-convertor slip settings. HDOH diesel vehicle and engine manufacturers do not have a sufficient body of knowledge regarding the range of heavy-duty truck powertrain configurations to know how effective those potential technical solutions might (or might not) be in larger engines and vehicles. Moreover, some of those solutions will have negative fuel efficiency impacts. [EPA-HQ-OAR-2019-0055-1203-A1, p. 22]

As noted, the CDA engineering challenge is multiplied in this case by the fact that each CDA installation requires an engineering investigation and a unique combination of solutions. Given the multiple significant differences among heavy-duty truck configurations and applications, the resultant number of those technical challenges could be insurmountable. When the level of customization that occurs with each customer’s purchase in the HD vehicle market is taken into account, the level of effort, resources and time it could take to implement CDA effectively could quickly become overwhelming. [EPA-HQ-OAR-2019-0055-1203-A1, p. 22]

The addition of a LO-SCR system is another key component of the Stage 3 RW aftertreatment control strategy, although one manufacturer evaluating its benefits is finding that the extra catalyst mass of the LO-SCR is increasing hot FTP results, to the point of increasing the composite FTP results. [EPA-HQ-OAR-2019-0055-1203-A1, p. 23]

A LO-SCR will be subjected not only to fuel-based contaminants such as metals commonly found in the biofuels promoted by EPA and CARB, but also oil poisoning will occur at a rate higher than experienced by today’s SCR systems (which benefit from the protection of an upstream DPF). Oil-derived contaminants are known to deposit heavily on the first catalyst brick encountered in the aftertreatment array, which acts to delay catalyst light-off under cold conditions and light load.5 Oil-derived poisonings are not reversible under any engine-based regeneration strategy, and they also can act to reduce the catalyst channel size. More desulfation activity will be required than today because the LO-SCR will not benefit from the elevated thermal conditions that now will be associated with downstream DPF regeneration events. Moreover, the interaction of DEF deposits with oil deposits is unknown (particularly under cold-start, and low-load operation), but may lead to a further reduction of the catalyst channel size, leading to increased backpressure and associated CO2 penalties.6 EMA is working with the Coordinating Research Council (CRC) to measure tailpipe emissions impacts when the Stage 3 system is run with a range of market-available fuels and biofuels. The results of that study should be considered before the Agency finalizes this rulemaking. [EPA-HQ-OAR-2019-0055-1203-A1, p. 23]

5. See A Case Study of a CuSSZ-13-SCR Catalyst Poisoned by Real-World High Sulfur Diesel Fuel, Yuanzhou Xi (Cummins) et al, SAE 2020-01-1319, April 14, 2020.

6. That poisoning effect would be exacerbated by the “thin wall, high-cell density” substrates proposed as a potential low-NOx technology solution by the Manufacturers of Emissions Controls Association (MECA). Oil poisoning is linear with exposure. In that regard, the accelerated catalyst aging demonstration performed at SwRI exposed the catalyst to only 1/3 of the expected “intermediate UL” (435k mile) oil quantities. No

consideration was given to the level of oil exposure expected under the proposed extended FUL of 800k miles (nearly double). That is an inadequate demonstration of the durability of the close-coupled SCR due to oil-derived poisoning.

Further complicating the issues associated with the LO-SCR system are packaging requirements. To be effective, the LO-SCR system must be "close-coupled" to the turbocharger turbine exit. In some cases, and especially with the smaller range of vehicles in the HD class, packaging constraints will be extremely difficult to overcome. Cab retooling will be necessary in some cases, as efforts to adequately insulate long runs of exhaust piping will compromise the efficacy of the LO-SCR unit. Cab retooling costs can be very high (as much as $500M), particularly for low-volume products with potentially abbreviated amortization schedules, since those same vehicles will be transitioning to battery-electric and other "zero-emissions" technologies due, at least in part, to additional anticipated GHG regulations and zero-emissions vehicle sales and purchase mandates. [EPA-HQ-OAR-2019-0055-1203-A1, p. 23]

An examination of packaging challenges on a single vehicle model as performed by one manufacturer has determined that the "hot side" of the engine compartment will require a complete redesign. With the LO-SCR being larger than the traditional downpipe, additional heat shielding will be required to protect proximate components. That is particularly problematic since the proximate components include much of the HVAC hardware, such as heater/evaporator coils, fan air intake and similar, as well as electrical junctions, fuse panel, PCM, relays and other temperature sensitive components. Those thermal issues are exacerbated by the transition to low-GHG HVAC refrigerant HFO 1234yf, where there are additional flammability concerns. Adding length or height to the vehicle hood to "make room" to mitigate the packaging challenges will compromise bumper-to-back of cab limitations, or will increase GHG emissions due to increased aerodynamic drag, or both. Reducing the substrate frontal area to improve packaging will increase backpressure and CO2 emissions. None of these challenges has an obvious solution. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 23 - 24]

Major improvements in the accuracy of NOx sensors are not foreseen in the timeframe of the proposed low-NOx standards. NOx sensors (three of them are used in the Stage 3 solutions) play a critical role in DEF dosing strategies and long-term trim functions. In addition, the NH3 sensor used to monitor ammonia levels for the mid-SCR catalyst bed is known to be highly inaccurate. EMA is working with SwRI to conduct tailpipe NOx sensitivity tests on the Stage 3 RW configuration in response to the installation of NOx and NH3 sensors with measurement bias representative of field-aged sensors. EMA is seeking to quantify with real data the tailpipe NOx impacts from those (and other) sensor inaccuracies. Significantly, however, that testing will reveal only a limited view of the production real-world variability that will be discussed later as part of EMA's "margin stackup" analysis. It is important to note that EPA has not addressed this issue at all in its feasibility-demonstration efforts. [EPA-HQ-OAR-2019-0055-1203-A1, p. 24]

The actual results from SwRI's testing of the Stage 3 prototype are not compliant with the proposed Option 1 low-NOx standards. This demonstrates that the Option 1 standards are not feasible. Focusing specifically on the results of the EPA Stage 3 RW system (which are slightly lower than the CARB Stage 3 engine results), set forth below are the lab-measured NOx emission data points at 435,000, 600,000 and 800,000 mile-equivalent aging, as reported by SwRI: [EPA-HQ-OAR-2019-0055-1203-A1, p. 24]

Stage 3 RW Tailpipe NO_x Emissions (*and proposed standard*) (g/bhp-hr)

Certification test cycle	**435k mile7**	**600k mile7**	**800k mile7**
Composite FTP (transient)	0.022 (*0.020*)	0.029 (*0.040*)	0.040 (*0.040*)
Ramped Modal Cycle (steady-state)	0.019 (*0.020*)	0.026 (*0.040*)	0.031 (*0.040*)
Low Load Cycle	0.034 (*0.050*)	0.038 (*0.100*)	0.037 (*0.100*)

7. Figures are mileage equivalents, achieved by aftertreatment bench-aging methods. The engine, however, including cylinder deactivation and EGR cooler bypass systems, was not aged to determine deterioration effects.

Recall that, for heavy heavy-duty engines, the interval from 435,000 miles to 800,000 miles will be held to a 0.040 g/bhp-hr FTP and RMC NOx standard under EPA's Option 1 proposal. As the test results above show, EPA's Stage 3 prototype does not meet the 0.020 g/bhp-hr NOx standard at 435,000 miles over the FTP certification cycle, and it generated results exactly equal to the "second stage" standard of 0.040 g/bhp-hr when tested to 800,000 miles. (The CARB Stage 3 engine generated a composite FTP result of 0.031 g/bhp-hr at just 290,000 miles equivalent aging before the engine was recalibrated mid-testing to reduce the tailpipe NOx to 0.023 g/bhp-hr at the expense of an almost 1% CO2 emissions penalty. CARB terminated its testing at 435,000 miles equivalent aging.) The emissions results reported by SwRI are, therefore, not fully compliant. Moreover, they are not even complete, since they only include the IRAFs that SwRI generated when the system was degreened, not when the system was aged. It is also clear that the SwRI results fail to account in any way for the necessary compliance margins. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 24 - 25]

Just as important, the Stage 3 RW CO2 emissions, as measured by SwRI, are 2.3% above the HHD 2027 FTP CO2 emissions standard for vocational engines, and 5.2% above the HHD 2027 RMC standard for tractor engines, an issue that EPA has attempted to downplay as immaterial to engine manufacturers' ability to comply with those future requirements, despite the well-established NOx/CO2 tradeoff that continues to challenge the diesel engine industry. More will be discussed on this significant point later. [EPA-HQ-OAR-2019-0055-1203-A1, p. 25]

There are two types of in-use real-world factors that need to be considered, since they can be detrimental to tailpipe NOx emissions over and above the Stage 3 demonstrated performance. The first set of factors includes those that cause temporary increases, or increased variability of NOx emissions, such as accumulated sulfur on aftertreatment systems (prior to a desulfation regeneration event), variable ambient conditions, and production variability. The second set of factors includes those that cause engine and aftertreatment systems to degrade to a greater degree than the "nominal" or "typical" degradation assessed through a test cell demonstration, whether that be a feasibility demonstration conducted on behalf of regulators, or a manufacturer's "deterioration factor" test run for certification purposes. Three examples are SCR poisoning due to fuel impurities, operation under more severe in-use duty-cycles, and inadequate maintenance practices. (A more comprehensive list of the various factors of concern will be provided later in these comments in the section related to EMA's efforts to quantify the additional NOx reductions needed relative to Stage 3 NOx emissions – i.e., the additional "margin" that is necessary to ensure robust emissions compliance in the field.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 26]

Those short-term and long-term emissions-impacting factors are risks that manufacturers will be held accountable for in designing their diesel engine products for robust emissions compliance, but which EPA has not considered in its "technical feasibility" demonstration. As explained below, the NOx increases in response to those factors are far from trivial. Yet EPA has not presented any kind of technical analysis that even attempts to quantify the emissions increases that can result from those in-use real-world impacts. Thus, while it may be good enough for EPA that the Stage 3 engine "came close" to complying with a 0.020 g/bhp-hr verification standard (recall that actual compliance was not achieved over the FTP test cycle or over the EU ISC in-use road cycle), that is in fact not good enough to sustain a rulemaking of this significance. [EPA-HQ-OAR-2019-0055-1203-A1, p. 26]

Diesel engine manufacturers often use the term "margin" when talking about the headroom they must design into their emissions control strategies. Margin is the difference between the underlying emissions standard and the lower "as-designed" emissions performance that diesel engine manufacturers target for their products. Manufacturers must design and calibrate to provide for sufficient margin to ensure robust compliance after accounting for the myriad factors that can compromise real-world emissions performance, and thereby to protect themselves from recall actions, fines, and damaged reputations. The next section details how NOx compliance margins have grown to become a larger and larger percentage of the emissions standards as those standards have been reduced, and what that could mean for the Agency's proposed low-NOx standards. [EPA-HQ-OAR-2019-0055-1203-A1, p. 26]

At a fundamental level, it appears that EPA has simply failed to take into account the inherent technical challenges that lean-burn engines present as compared to spark-ignited, stoichiometric burn engines, as well as the degree to which all of the real-world in-use variabilities impact NOx emissions from lean-burn engines. [EPA-HQ-OAR-2019-0055-1203-A1, p. 36]

Lean-burn engines are inherently more efficient than stoichiometric-burn engines, largely due to the "free-breathing" unthrottled air intake system, higher compression ratios, and the higher energy density of diesel fuel (15% higher than gasoline). This superior efficiency, and therefore more environmentally favorable CO2 emissions profile, coupled with exceptional durability, is what makes lean-burn diesel engines the powertrain of choice for the heavy-duty truck market. Lean-burn engines, and their low-CO2 emissions performance, however, do come with significant technical challenges when it comes to controlling emissions, especially with respect to aftertreatment controls. Those technical challenges, coupled with the sensitivity of aftertreatment to real-world factors, compel the manufacturers of these engines to certify their products with much higher compliance margins than their spark-ignited counterparts in order to ensure their continuing in-use emissions compliance. [EPA-HQ-OAR-2019-0055-1203-A1, p. 36]

In that regard, there are a number of inescapable physical and chemical differences between diesel and spark-ignition engines and their aftertreatment systems that result in the different requisite compliance margins at issue, including the following: [EPA-HQ-OAR-2019-0055-1203-A1, p. 36]

In that regard, there are a number of inescapable physical and chemical differences between diesel and spark-ignition engines and their aftertreatment systems that result in the different requisite compliance margins at issue, including the following: Part of what makes a lean-burn diesel engine more efficient is also what makes its real world in-use NOx emissions much more variable. More specifically, a diesel engine's unthrottled, variable air-to-fuel ratio combustion process leads to highly variable exhaust compositions and temperatures, which create many unique challenges for the engine's SCR-based NOx emissions aftertreatment system. In contrast, a stoichiometric natural gas (or gasoline or propane) spark-ignition engine's exhaust has a nearly constant composition and its temperature is stable under nearly all operating conditions after initial warmup. Spark-ignition engine exhaust is simply less variable, so it takes less effort to control those emissions. Diesel exhaust also experiences more extreme fluctuations between high temperature and low temperature operations where the catalyst is more susceptible to degradation. [EPA-HQ-OAR-2019-0055-1203-A1, p. 36]

In that regard, there are a number of inescapable physical and chemical differences between diesel and spark-ignition engines and their aftertreatment systems that result in the different requisite compliance margins at issue, including the following: Because of those inherent exhaust stream differences, a diesel engine requires a more complex diesel particulate filter and selective catalytic reduction aftertreatment system, which is comprised of at least four different temperature-sensitive catalysts. It also requires precise, real-time thermal management and dosing of ammonia-forming Diesel Exhaust Fluid ("DEF") into the exhaust. SCR requires sophisticated electronics and fast and accurate wide-range sensors to actively control the entire system. The particulate filter requires periodic high temperature regeneration to remove its accumulated soot, temporarily interrupting the SCR's NOx reduction performance. In sum, a diesel engine's emissions control system is much more complex than a spark-ignition engine's three-way catalyst(s) and single "on-off" (switching) oxygen-sensor-based control system. Unlike diesel engines, spark-ignition engines inherently maintain exhaust temperatures suitable for high efficiency catalyst performance over all operating conditions shortly after engine start. Diesel engine controls, however, must modulate DEF injection according to many factors, including variable exhaust temperatures to which NOx conversion efficiency is very sensitive. EPA acknowledges the complexity behind the DEF dosing-control function, which it described in the Agency's RIA, as follows: [EPA-HQ-OAR-2019-0055-1203-A1, pp. 36 - 37]

In that regard, there are a number of inescapable physical and chemical differences between diesel and spark-ignition engines and their aftertreatment systems that result in the different requisite compliance margins at issue, including the following: Small errors in dosing can lead to significant variability in tailpipe NOx. Underdosing causes inadequate NOx conversion, while overdosing causes ammonia slip which is converted to NOx in the ammonia slip catalyst. Either case increases tailpipe NOx. [EPA-HQ-OAR-2019-0055-1203-A1, p. 37] In that regard, there are a number of inescapable physical and chemical differences between diesel and spark-ignition engines and their aftertreatment systems that result in the different requisite compliance margins at issue, including the following: More generally, the number of emissions-related components used in diesel engines is significantly greater than for spark-ignited engines. That simple fact, coupled with the greater complexity of a diesel engine's aftertreatment system and related control algorithms, inevitably leads to greater emissions variability, especially under the broad range of real-world in-use operating conditions that heavy-duty diesel vehicles encounter. [EPA-HQ-OAR-2019-0055-1203-A1, p. 37]

In that regard, there are a number of inescapable physical and chemical differences between diesel and spark-ignition engines and their aftertreatment systems that result in the different requisite compliance margins at issue, including the following: As mentioned, diesel aftertreatment systems operate across a wide range of exhaust temperatures with associated variable NOx conversion efficiency, and lean-burn exhaust chemical compositions. Because of this, tailpipe emissions are sensitive to small reductions in catalytic activity caused by thermal and chemical aging effects. Spark-ignited applications with three-way catalysts, however, are more tolerant of thermal and chemical aging effects because the "starting point" (the degreened system) has more NOx compliance headroom. Moreover, the diesel fuel supply is more likely to contain contaminants than the gasoline supply, such as the metals commonly found in biodiesel blends. Long-term degradation of aftertreatment in compression-ignition diesel applications is further exacerbated by significantly longer useful life requirements than most spark-ignited applications and stoichiometric exhaust composition conditions. Of note, those already-longer useful life requirements are proposed to be extended even further – almost doubled - under EPA's proposed Option 1. [EPA-HQ-OAR-2019-0055-1203-A1, p. 38]

Spark-ignited gasoline engines have a strong advantage over diesel engines when it comes to the ability to robustly and consistently reduce engine-out NOx to near-zero tailpipe emissions, but that advantage does not extend to CO2 emissions. Forcing diesel products out of the market through the adoption of infeasible low-NOx emissions standards would force vehicle owners into higher CO2-emitting spark-ignited solutions, a highly counter-productive outcome. [EPA-HQ-OAR-2019-0055-1203-A1, p. 38]

The high-efficiency lean-burn engine's necessarily complex emissions control system, and the several other factors raised in this section, increase the in-use emissions-variability of diesel engines in ways that EPA has not accounted for. All of these factors necessitate compliance margins that make a 0.020 g/bhp-hr NOx standard inherently infeasible for HDOH diesel engines. [EPA-HQ-OAR-2019-0055-1203-A1, p. 38]

As noted, EPA has overlooked the gap between the proposed 0.020 g/bhp-hr HD NOx standard and the actual results of the Stage 3 and Stage 3 RW "feasibility demonstration" by claiming that manufacturers will continue to work on control strategy optimization and final calibration to overcome the exceedance (and one must assume, the required compliance margin). That claim, however, is simply not reasonable when assessed against the reality of what is, and what is not, technically feasible. [EPA-HQ-OAR-2019-0055-1203-A1, p. 38]

At the macro-level, there are three technology paths to consider for reducing tailpipe NOx emissions over and above that demonstrated by the Stage 3 solutions:

Reduce engine-out emissions: In theory, a reduction in engine-out NOx emissions could result in a reduction in tailpipe NOx. That could be achieved with higher EGR rates, adjustments to injection timing, or other strategies. However, those techniques necessarily would increase CO2 emissions, another regulated emission. The Stage 3 RW engine, as demonstrated, has 5.3% higher CO2 emissions than the 2027 HHD tractor CO2 emissions standard, and 2.3% higher than the vocational engine CO2 standard. In fact, the final SwRI calibration does not even meet the 2021 GHG standards, and has CO2 emissions slightly higher than the baseline Cummins X15 production configuration from which the Stage 3 RW system was developed. Overcoming an additional CO2 deficit caused by reducing engine-out NOx further to bring the Stage 3 RW system into compliance (with margin) will require additional CO2-reducing technology over and above what EPA has included in its feasibility demonstrations, rendering any related cost analysis inherently deficient. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 38 - 39]

Increasing exhaust temperatures: Increasing exhaust temperatures at light loads to improve SCR NOx conversion efficiency over a broader range of operating conditions would decrease tailpipe NOx emissions. That could be achieved through actions to decrease engine combustion efficiency, more frequent dosing of diesel fuel across the DOC, or by adding a spark-ignited burner system or electrically-heated catalyst upstream of one or both of the SCR units. Any of those actions also would increase CO2 emissions, thereby requiring additional CO2-control technology to comply with CO2 emissions standards that will be taking effect along with the future NOx standards. Such methods to overcome the Stage 3 system deficiencies will likewise require additional technology over and above what EPA has included in its feasibility demonstrations, again rendering any related cost analysis inherently deficient. [EPA-HQ-OAR-2019-0055-1203-A1, p. 39]

Improved SCR efficiency: If manufacturers were able to develop SCR NOx conversion efficiencies superior to the capability of the systems included in the Stage 3 demonstrations, that could be an effective means to overcome the deficiency of the Stage 3 solution. That is not a viable solution, however. The SCR conversion efficiencies observed with the Stage 3 RW engine are already unrealistically high when compared to manufacturers' experience with high mileage systems in the field. The Stage 3 RW engine at the 435,000 mile intermediate UL equivalent aging had a 99.3% overall conversion efficiency on the composite FTP transient test, and still produced a failing 0.022 g/bhp-hr result. The RMC barely passed at 0.019 g/bhp-hr despite having a 99.6% cycle SCR conversion efficiency. If a field sample were to degrade a mere 0.3% more, that RMC result would escalate to a badly failing 0.026 g/bhp-hr! While SCR manufacturers have made strides to improve the long-term durability of SCR catalysts, for example with the introduction of FeZe/CuZe "hybrid" catalysts, manufacturers with three or more years' experience with those systems in production have found that they offer only marginal improvements, at best, compared to their predecessor configurations The following graph compares test results from aged systems, comparing this new generation hybrid SCR (labeled "2027 SCR", though the manufacturer has had it in production for 3 years) to the former technical solution (labeled "current"). The manufacturer is reporting that the aging characteristics of the new hybrid SCR configurations are not proving to be superior to the old configuration. [EPA-HQ-OAR-2019-0055-1203-A1, p. 39]

The conversion efficiencies achieved in the laboratory aging process, while producing barely compliant or even non-compliant results, are unrealistic to expect consistently in the field. This issue is even further exacerbated by the growing prevalence of biofuels in the marketplace, with known aftertreatment degrading characteristics. Significant increases in aftertreatment sizing could be considered, but not without backpressure increases driving higher CO_2 emissions, increased heat demand from the same exhaust flow, and a significant increase in cost. Once again, overcoming those CO_2-increasing measures would require additional technology over and above what EPA has included in its feasibility demonstrations, rendering any related cost analysis for Option 1 inherently deficient. [EPA-HQ-OAR-2019-0055-1203-A1, p. 40]

In summary, while one might expect that additional work on system optimization may be available to achieve minor NOx reductions over and above the performance of the Stage 3 RW system, the levels of improvement required to comply with the Option 1 standards are simply not achievable without significant additional hardware and accompanying control strategies, including new CO_2-mitigation measures. Manufacturers are, in effect, "boxed in" by all of the constraints explained above. As with any development project to industrialize new emissions control concepts, there will be many other emissions-compromising technical challenges to overcome that have not yet even been imagined. Thus, the Agency's claim that manufacturers can simply calibrate the Stage 3 system into a robust compliance solution, given all that we know about aggravating factors and substantial margin requirements, is simply unreasonable. [EPA-HQ-OAR-2019-0055-1203-A1, p. 40]

Based on the foregoing analysis of margin requirements, and given the inherent technological constraints, the case could easily be made that it would be incumbent upon manufacturers to design for a compliance margin greater than 50%, and a margin as high as 75% could be necessary in the end. Under such assumptions, manufacturers would be forced to reduce Stage 3 RW FTP results by 55% to 75%, respectively. Reductions of that scale cannot be achieved with mere calibration efforts. The Agency's claim to the contrary has no sufficient basis in fact. [EPA-HQ-OAR-2019-0055-1203-A1, p. 40]

From all of the foregoing, it is clear that the Agency has failed to (and cannot) demonstrate the technical feasibility of a 0.020 g/bhp-hr FTP/RMC NOx standard for HDOH diesel engines. The proposed technology set, some components of which present serious technical risks to product reliability and durability, has proven incapable of achieving compliant results in dyno-based certification tests and when tested using in-use road-cycles replicated on the engine dynamometer. More than that, the variety of short-term and long-term NOx emissions-increasing factors that can impact field-sampled engines have been given no consideration in those attempted demonstrations. Recent trends of increasing compliance margins (when examined as percentage of prevailing standard) as represented in manufacturers' certification test results clearly demonstrate manufacturers' consistent need to over-comply in certification demonstrations, so that they can manage the additional and significant emissions-compromising influences under all real-world operating conditions. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 40 - 41]

Without a more robust demonstration that an improved technology package is capable of consistently complying with the proposed Option 1 standards, it is apparent that such standards, along with their related in-use emissions requirements, are not technically feasible. Accordingly, it would be manifestly unreasonable for the Agency to proceed with the adoption of Option 1. In fact, doing so likely would drive diesel engines from the HDOH market, which would significantly jeopardize the nation's economy and security. EPA is not authorized to do that. [EPA-HQ-OAR-2019-0055-1203-A1, p. 41]

SwRI presented the initial 800,000 mile aging results for PM from the Stage 3 prototype engine at the April 2022 SAE World Congress Exposition. Those results showed multiple RMC and LLC test results exceeding the proposed 0.005 g/bhp-hr PM standard when tested after ash cleaning of the DPF. SwRI reported that it took 10 to 15 hours of operation before the emissions was reduced from PM levels as high as 0.007 g/bhp-hr, 40% above the proposed standard. EPA has provided no exception for PM standard compliance for any period after ash cleaning. EPA therefore requires compliance over all certification test cycles under any conditions (with proper pre-conditioning). Here again, the demonstration that EPA is relying on actually demonstrates that the proposed emissions standard is not technologically feasible. The current PM standard of 0.01g/bhp-hr should therefore be retained in the final rule. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 43 - 44]

EPA also should consider the possibility that the proposed standards could compel new engine oil formulations. Engine lubricants perform critical functions, including reducing engine wear, enhancing fuel efficiency, and providing protection for the engine and its emissions control systems. The proposed low-NOx standards and extended useful life and warranty periods could have significant impacts on those functions. New oil formulations have been required in response to reduced emissions standards in the past. EPA should account for this possibility in its implementation schedule for the proposed regulations. [EPA-HQ-OAR-2019-0055-1203-A1, p. 143]

In the process of determining what emissions thresholds are achievable given the proposed substantial reductions in PM and NOx, EPA and industry may determine that the state of the art for monitoring key components such as catalytic converters, particulate filters, aftertreatment system sensors, or EGR components will require intrusive monitors. Intrusive monitors temporarily increase tailpipe criteria and GHG emissions when executed. EPA requires the average emissions impact of an intrusive monitor to be included in a manufacturer's certification results (much like IRAFs). As such, the applicable standards either will need to be adjusted even more to reflect those necessary temporary increases, or the OBD thresholds will have to be maintained at levels high enough to not require intrusive monitoring. Without such measures, the current OBD provisions would make the proposed standards even more stringent and infeasible. [EPA-HQ-OAR-2019-0055-1203-A1, p. 95]

EPA Summary and Response

Summary:

Additional comments on the FTP and SET NO_x standards stringency can be found in section 3.1.1 of this document, as well as EPA's summary of and responses to those comments. In general, some commentors stated that proposed Option 1 is feasible, some commenters stated that standards that are more stringent than Option 1 are feasible, and some commenters stated that only proposed Option 2 is feasible with changes to further account for the uncertainty of laboratory and in-use emissions levels. MECA commented that there are additional demos beyond the Stage 3 engine to support the ongoing process in the European Union of considering more stringent heavy-duty criteria emission standards. MECA referenced improvements to emissions control systems beyond what was used for the EPA demo and stated that they expect continued improvements to the emission control systems in the coming years. DTNA commented that there are no benefits to new catalyst designs compared to existing catalyst designs with respect to catalyst activity and durability. ATA commented that EPA hasn't demonstrated Option 1 is feasible.

A couple commenters stated that EPA has not demonstrated the feasibility of the proposed FTP and SET emission standards for NO_x, stating that EPA did not consider key design margins such as different configurations (ratings, exhaust length configurations, etc.), that demonstrated technologies are not commercially available, and that the EPA Stage 3 system doesn't meet GHG Phase 2 standards for MY 2027. DTNA commented that there are concerns with catalyst durability at the high miles and that effectively, EPA has tested the 'best-of-the-best' and declared it representative for all possible configurations. DTNA also commented that if EPA's proposed system were packaged to fit on a truck, the low temperature SCR catalyst effectiveness would be significantly reduced as it would operate at colder temperatures. DTNA stated that EPA made design compromises to minimize packaging impact on existing Class 8-day cab tractors because EPA is concerned that the Stage 3 system will not fit in a truck, and that the composite FTP test results are 0.038 g/hp-hr, which is just below the 0.040 g/hp-hr standard without IRAF. DTNA commented that EPA did not move forward with testing of its first candidate system as the system was determined to have unacceptable performance by SwRI due to high system backpressure, significant impact on RMC CO_2 emissions, and design limitations on turbomachinery, air-handling, and peak cylinder pressure limits.

DTNA commented that the EPA GHG Phase 2 vocational vehicle SI standard is 17% higher for CO_2 than the CI standard. They are concerned that the medium duty market could shift to SI engines that will significantly increase CO_2 emissions from the national fleet. They also commented that that the engine fails to comply with EPA's proposed PM standards and raises questions about N_2O compliance feasibility.

DTNA, ATA, and PACCAR also commented that current NO_x sensor technology is unable to adequately maintain control of SCR systems at the proposed standards. Some commenters stated that the proposed criteria pollutant standards could negatively impact GHG emissions and the ability to meet the GHG standards for the applicable MYs.

Some commenters stated that EPA must set standards that include margin to account for fuel contamination, production variability, measurement variability, packaging limitations, accumulation of sulfur, soot, and ash, maintenance variability, lower engine power ratings, and the impact of biodiesel. CARB commented that EPA should not set standards with margin. Allison recommended subcategory specific standards like those for HD GHG vehicle standards.

MFN commented that EPA's proposed stringency for LHDD and MHDD engines exceeds the feasibility demonstrated at SwRI by 75 percent on the FTP cycle (35 compared to 20 mg/bhp-hr), 106 percent on the SET cycle (35 compared to 17 mg/bhp-hr), and 210 percent on the LLC cycle

(90 compared to 29 mg/bhp-hr), negating any reasonable compliance margin, noting that the Agency has not explained the reason for such gross differences.

PACCAR commented that retooling costs are expensive (on the order of $500 million) for low-volume products with potentially abbreviated amortization schedules. They stated that close-coupled catalyst configurations may not be possible for all current commercial vehicle applications due to packaging constraints and heat load impact on temperature sensitive components, as the close coupled SCR catalyst is larger than the traditional downpipe requiring additional heat shielding. They commented that this is problematic as HVAC hardware, electrical junctions, fuse panels, Powertrain Control Module, relays and other temperature sensitive components could be affected. They commented that they also have flammability concerns with the transition to refrigerant HFO 1234yf. They also stated that cab redesign will compromise bumper-to-back-of-cab limitations or increase GHG emissions due to increased aerodynamic drag. They also commented that redesign expense is significant and not included in EPA's current economic impact analysis. They stated that under vehicle location for aftertreatment is more viable, but results in additional heat loss and further delays the catalyst system's light off. They requested a variance allowance of 30 mg/hp-hr for in-commerce testing compliance and that it include SEA, DF, and in-use testing.

Coach USA commented that interstate buses are subject, throughout the country, to heavily-enforced weight restrictions and any exceedance caused by SCR or derate-related equipment that causes a bus to be overweight would be unacceptable to sustaining interstate bus operations, as would any increased temperatures which could cause buses to be less reliable or otherwise potentially impair driver/passenger safety.

National Association of Chemical Distributors commented with concerns that the additional parts for the technologies needed to meet the standards could exacerbate current supply chain issues.

Multiple members of OIDA commented that standards should be set at a level that doesn't decrease the reliability of heavy-duty engines.

<u>Response:</u>

The final FTP and SET standards and test procedures, as well as the basis for those standards and test procedures, are explained in Section III of the preamble. As discussed in preamble Sections I.D and III.A, EPA is promulgating the new heavy-duty engine criteria pollutant standards under our authority in CAA section 202(a)(3)(A) and the final standards reflect the greatest degree of emission reduction achievable through the application of technology that we have determined will be available for MY 2027, giving appropriate consideration to the statutory factors. EPA's assessment of the statutory factors in CAA section 202(a)(3)(A) justify the final emission standards, and the final standards are appropriately based on further consideration of the data included in the proposed rule, as well as additional supporting data from our own test programs, and consideration of the extensive public input EPA received in response to the proposed rule. Preamble Sections III and IV, and RIA Chapter 3 include additional details on our assessment of the final standards, including our consideration of the technologies available to achieve the greatest degree of emission reduction in MY 2027, meeting the final standards over the useful life periods in the final rule, emission control performance over multiple test cycles, packaging constraints, impacts on CO_2 emissions, compliance margin, and lead time in the final rule. See also our responses to general comments on NO_x standards stringency in section 3.1.1 of this document. Our cost analysis of the final standards (i.e., cost of compliance for manufacturer associated with the application of such technology) is included in preamble Sections III and V, with additional detail in RIA Chapters 3 and 7 and section 18 of this document. In response to commenters who discuss the importance of fleet turnover for reducing emissions, we point to discussion in preamble Section X and section 25 of this Response to Comments document.

In setting the final standards, EPA in part considered the data, including the NOx and GHG emissions levels, from testing the Stage 3 demonstration engine with aftertreatment that was aged to the equivalent of 800,000 miles using today's commercially available NO_x sensors for aftertreatment control. Regarding comments on NO_x sensors, this demonstration supports that the final standards can be met with the current commercially available NO_x and NH_3 sensors. We have also considered all of the concerns and supporting information brought forward by the commentors that effect emission control system performance, as discussed in Section III of the preamble. The final standards, as summarized in Section III of the preamble, were demonstrated with margin and without increasing GHG emissions over the baseline engine. Regarding the comment about a portion of the test program that EPA did not move forward with, we note that the System B up front SCR catalyst diameter was too small and resulted in increased backpressure on the engine, as explained in RIA Chapter 3. Due to the inadequate size, we did not move forward with aging and testing this system, but that system does not impact our feasibility assessment based on the overall demonstration program. As discussed in RIA Chapter 3, the technologies we expect to be used to meet the final standards build upon the technologies used in today's light- and heavy-duty engines. Our final standards are based on our projection of the future performance improvements of the emission control technologies (e.g. cylinder deactivation, heated DEF dosers, dual-SCR aftertreatment, and NO_x sensors) like those applied in the Stage 3 engine for model year 2027, which in some cases are technologies that are currently available as prototypes but are not necessarily in production yet. MECA stated in their comments, and we agree based on the improvements we have seen in recent years, that it is reasonable to expect there will be additional improvements beyond what was demonstrated with the Stage 3 engine. For example, we have seen a reduction in catalyst volume over the last 10 years due to improvements in aftertreatment technology. Another example of this is the NO_x reduction improvements of EPA System A as compared to the CARB and EPA Stage 3 engine. As covered in RIA Chapter 3, the NO_x emissions from the EPA System A are lower than the CARB Stage 3 after degreening the aftertreatment. We acknowledge, however, that there are some uncertainties on the magnitude of possible additional improvement to aftertreatment beyond those included in the Stage 3 engine and we are finalizing standards that are higher than what was demonstrated to account for these uncertainties, as further detailed in Section III of the preamble. We project that the current state of development in conjunction with anticipated improvements make the final standards technologically feasible starting in MY 2027, consistent with our authority to set technology-forcing HD engine criteria pollutant standards under CAA section 202(a)(3)(A). Regarding comments on compliance margin, see also our response to comments in section 3.4 of this document regarding the interim in-use testing allowance for Medium HDE and Heavy HDE in the final rule.

Regarding the comment on meeting the Phase 2 GHG standards, the NO_X standards are incremental to the GHG standards, and the technology required to achieve both standards simultaneously can be independently applied to the engine. The Stage 3 engine was a MY 2017 engine that did not include the technology needed to meet the Phase 2 MY 2027 GHG standards. The demonstrated NO_x emissions were achieved without increasing GHG emissions from the base engine, and thus would have no adverse effect on GHG reductions achieved through the introduction of additional technology. See also discussion in preamble Section III. As explained above, EPA expects that the four-year lead time will provide sufficient time for all of the technologies for the final standards to become commercially available.

Regarding DTNA's comment regarding the medium duty market shifting to SI engines, to the extent this comment may be within the scope of this rulemaking, the commenter did not provide information to support their concern such that it would impact decisions in this final rule.

DTNA commented on the availability of heated DEF dosers and the evaluation of "noise, vibration, and harshness" (NVH) from CDA. EPA believes that setting the final standards with a least 4 years of lead time will allow enough time for suppliers to increase production of heated DEF dosers. The supplier of the heated DEF doser for the EPA Stage 3 system has provided EPA with dosers at various stages of their product development and their hardware is approaching production readiness. Regarding the comment on considering NVH when setting the standards, as outlined in RIA Chapter 3, we have conducted NVH testing with CDA active. EPA's assessment based on this testing is that there are several ways to reduce NVH to acceptable levels through design of the complete system, including, where CDA is used, engine mounts, cab mounts, and seat calibration. Based on consideration of this testing and the other data discussed in the RIA, we have determined that the final standards are achievable without increasing NVH outside of the acceptable range. EPA disagrees with DTNA's concern regarding N_2O compliance feasibility, as the N_2O emissions from the EPA and CARB Stage 3 engine were below the FTP N_2O standard, even after the aftertreatment was aged to the equivalent of 800,000 miles, which is beyond the final useful life for Heavy HDEs.

We received several comments on the FTP and SET test procedures. MECA provided data to support the current cold/hot start FTP weighting factors. DTNA commented that EPA should change the weighting factor for the FTP duty cycle and add 300 seconds of idle before the cold FTP. PACCAR commented that EPA should retain the option to determine a single IRAF based on the average regeneration frequency of customer vehicles over all duty cycles. See preamble Section III.B.2 for EPA's full response to comments requesting changes to the weighting factors for the FTP or adding 300 seconds to the beginning of the cold FTP. We neither proposed these changes nor requested comment on them in the NPRM, and for the reasons explained in preamble III.B.2 are not adopting the requested changes. We note that we requested comment on alteration to the FTP duty-cycle in the ANPR and only received comments in support of the current FTP duty-cycle, including weighting factors. DTNA analyzed the data from the EMA-WVU data set and stated that their analysis showed that the average idle period for a day-cab vehicle in California is 227 seconds. DTNA did not provide the data used in this analysis to EPA, so we are not able to independently verify the conclusions of their analysis or how broadly it applies to all heavy-duty engines. The current structure of the FTP duty-cycle with its weighting factors ensures that engine control strategies cover in-use operation where the vehicle is not idled for an extended period of time, thus the worst-case scenario is covered ensuring that quick catalyst light off strategies are employed.

Regarding the comment from PACCAR, 40 CFR 1065.680 states that “For engines subject to standards over more than one duty cycle, you must develop adjustment factors under this section for each separate duty cycle”. There is nothing in 40 CFR 1065.680 that prevents a manufacturer from developing a single IRAF that represents the average of, and can be applied to, all duty cycles. The IRAF determination procedure in 40 CFR 1065.680 provides flexibilities with respect to the method of IRAF determination.

Cummins commented that for PHEV testing, 40 CFR 1036.505 Figure 1 seems to indicate SET 5 cycle would be a cold cycle. This is not equivalent to engine SET where engine and aftertreatment are pre-conditioned before running the emission test. Cummins suggests skipping the cycle where engine starts for first time and use the following cycle to report criteria emissions. EPA disagrees with Cummins regarding 40 CFR 1036.505 Figure 1. We note that this is the same approach used for light duty PHEV testing, but in conjunction with the charge sustaining criteria for HD vehicles in SAE J2711. While it is true that the engine will start from a “cold” condition, the powertrain test procedure allows for powertrain operation over the duty-cycle utilizing hybrid propulsion where the ECU can activate heating of the aftertreatment prior to engine start. Thus, if aftertreatment heating is needed to ensure emission control under engine start, there is opportunity within the duty-cycle to achieve that heating. For example, this could be addressed with an electrically heated catalyst warming up the aftertreatment before the engine starts. The starting of the engine is representative of how the engine would start under this type of operation in-use. We would also like to point out that when determining the brake specific emission results from SET 5 in 40 CFR 1036.505 Figure 1, the emission results are determined using the work performed over the entire duty-cycle and not just the portion where the engine is operating. Thus, the emission results from SET 5 could be lower than the emission results from SET 6 where the engine is operating the entire time.

Cummins commented that potential test cell upgrades are needed to conduct PM testing to meet the requirements of the clean idle test in 40 CFR 1036.505(h) and 40 CFR 1036.510(g) and that there will be additional measurement uncertainty with the test procedure due to tailpipe emissions at a level similar to background. We discussed in Section III of the preamble and Section 3.5 of this document why we are not finalizing PM, HC, and CO standards for the clean idle duty cycle. Therefore, for the final rule, we are not including the PM, HC, and CO measurement requirements in 40 CFR 1036.505(h) and 40 CFR 1036.510(g) that would have required the measurement of PM during the idle portions of the FTP and SET under the proposed rule.

Regarding the comments on the selection of the engine rating for the Cummins X15 engine used for the EPA Stage 3 demonstration, we disagree that the rating is not representative since it is an available rating for the Cummins X15 engine. As explained further in the documents referenced in our response above regarding feasibility, the final NO_x standards include margin above the emissions levels demonstrated with the EPA Stage 3 engine to account for variability in emissions from engine ratings within the same engine family.

EPA agrees with EMA that clarifications are needed on how to restart the engine when stop-start systems are active on the engine due to dynamometer effects and additional specifics are needed on what type of stop-start systems can be considered for certification testing. EPA has updated 1036.501(d) to reflect that good engineering judgment should be used to restart the engine, including for example decoupling the dynamometer from the engine during the restart or using a bigger start motor. EPA has already considered the implications of user selectable stop-start systems for HD vehicles in 40 CFR 1037.660. We have made modifications to 40 CFR 1036.501(d) to provide clarification for what types of stop-start systems can be considered for use during engine certification. Specifically, we reference 40 CFR 1037.660 for limitations on its use during certification. In addition, we have added a new paragraph 40 CFR 1036.415(g) to address the use of stop-start during in-use testing. This new paragraph references 40 CFR 1037.601, linking the off-cycle testing stop-start requirements to the laboratory certification requirements.

We disagree with EMA's comment that the final standards will require a new lube oil, since the EPA Stage 3 demonstration was conducted with commercially available lube oil. To the extent that a new lube oil is developed, the final standards include four years of lead time for this development.

All commenters supported EPA promulgating lower than the current PM standards for the FTP and SET duty cycles. While many supported the proposed standard of 5 mg/hp-hr, some commenters stated that 7.5 mg/hp-hr would reflect the state of available technology today. See preamble Section III.B for further discussion of the basis of our final PM standards and our response to these comments. We note that most DPF equipped HD engines today emit PM at less than 1 mg/hp-hr. We also note that it has been shown that soot buildup in the DPF improves filtration efficiency and, as with ammonia storage on SCR catalysts, EPA allows for preconditioning prior to manufacturers carrying out their test of record for certification. This preconditioning not only establishes baseline ammonia storage on the SCR catalyst but reestablishes the DPF soot cake layer that was removed during the initial forced DPF regeneration that occurs prior to the preconditioning sequence.

Many commentors raised concerns regarding system packaging and its effect on emission performance, as well as weight and heat load as to effects on safety. In regard to system packaging, as described in preamble Section III, we have set final standards with margin to cover consideration of applications-specific design to meet the packaging requirements of those vehicles. In regard to weight, our assessment is that the addition of an upfront SCR catalyst to the aftertreatment system will not contribute significantly to the overall engine weight. See the FEV teardown study referenced in RIA Chapter 3 for details on our assessment of the increased mass of the aftertreatment system.[14] In regard to safety, the comments received have not provided any supporting data showing that there is a valid concern with increased heat load from the potential packaging constraints of the upfront SCR catalyst. Our assessment is that the upfront SCR catalyst can be packaged with proper heat shielding to mitigate any of the potential associated safety due to heat load concerns.

[14] Mamidanna, S. 2021. Heavy-Duty Vehicles Aftertreatment Systems Cost Assessment. Submitted to the Docket.

Regarding the comments from National Association of Chemical Distributors on standards potentially exacerbate supply issues, we do not have data supporting this conclusion. The final standards will go into effect for MY 2027 engines which is at least 4 years from now, which we believe will provide manufacturers enough time to supply the needed technologies to meet the standards. Additional, EPA hopes, as everyone does, that the current economic conditions – inflation, the pandemic, etc. – are alleviated by the time the final program is being implemented.

Regarding the comments on setting standards that don't decrease the reliability of heavy-duty engines, we believe that the standards will not reduce the reliability of heavy-duty engines. As discussed in RIA Chapter 3, the technologies we expect to be used to meet the final standards build upon the technologies used in today's light- and heavy-duty engines.

3.2.2 FTP and SET standards and testing for spark-ignition engines

Comments by Organizations

Organization: *American Automotive Policy Council (AAPC)*

EPA has proposed reductions in NOx and PM FTP emissions for gasoline spark-ignited emissions to the same level as diesel engines. In addition to the California Low NOx Regulation, the EPA also is proposing to reduce hydrocarbon (HC) emissions by 57-71% and Carbon Monoxide (CO) emissions by 58% versus the current standards. The proposed HC and CO emission standards are challenging and technology-forcing for spark-ignition engines, particularly when coupled with the new requirement to certify to a Supplemental Emissions Test (SET) standard. Given the stringency of the new standards and test procedures, we believe that an averaging, banking, and trading (ABT) requirement should also apply for HC and CO emissions. Having an HC and CO ABT program will allow additional compliance flexibility as manufacturer engineer new solutions for these stringent standards. [EPA-HQ-OAR-2019-0055-1293-A1, p. 3]

Organization: *California Air Resources Board (CARB)*

The proposed Option 1 NOx standards for MY 2031 SI engines on the FTP duty cycle are aligned with the corresponding Omnibus standards. However, they are less stringent than Omnibus for MY 2027 SI engines. U.S. EPA's own demonstration testing shows a 20 mg/hp-hr NOx on the FTP and SET duty cycles to be technically feasible for 2027 MY SI engines.118 Additionally, manufacturers are currently certifying SI engines to CARB's most stringent optional low NOx standard of 20 mg/hp-hr while also meeting the proposed Option 1 criteria pollutant standards for both FTP and SET (Appendix II) [Appendix II can be found at EPA-HQ-OAR-2019-0055-1186-A2, p.143-145]. Analysis of CARB optional low NOx engine certification data for MYs 2020 and 2021 shows that all of the 20 mg/hp-hr NOx certified engines meet the proposed Option 1 FTP standards for non-methane hydrocarbon (NMHC) and CO and 80 percent meet the proposed 5 mg/hp-hr FTP PM standard. In addition, the diesel-cycle derived SI engines certified to the optional 20 mg/hp-hr NOx standard also meet the proposed SET standards for NOx, PM, NMHC, and CO. Furthermore, the diesel cycle derived optional low NOx engines are subject to the CI engine certification procedures including durability demonstration and UL periods (e.g., 435,000 miles for heavy HDEs), again, indicating that SI engines can meet the 20 mg/hp-hr NOx for the proposed Option 1 UL periods.119,120 CARB staff urges U.S. EPA to align the proposed MY 2027 NOx standards for SI engines with the MY 2027 Omnibus standards. CARB staff supports the adoption of the proposed Option 1 standards for PM, HC, and CO. [EPA-HQ-OAR-2019-0055-1186-A2, p.48]

118 Tables III-25 and III-28 of NPRM (pages 17485-17486).

119 CARB certification webpage: New Vehicle and Engine Certification: Executive Orders for Compression-Ignition and Heavy-Duty Engines and Vehicles. Accessed 4/8/2022.

120 Appendix II: Model Years 2020 and 2021 Optional Low NOx Certified SI Engines

CARB staff also supports requiring SI engines to certify on the SET test procedures to ensure emissions are controlled under high load and speed conditions. [EPA-HQ-OAR-2019-0055-1186-A2, p.48]

Organization: *Cummins Inc. (Cummins)*

In Option 2, EPA proposes to lower the hydrocarbon (HC) emissions standard for all primary intended service classes from today's 140 mg/hp-hr level down to 40 mg/hp-hr, starting MY 2027. EPA cited the measured non-methane hydrocarbon (NMHC) test results from six MY 2019 gasoline engine certifications, ranging from 42 to 80 mg/hp-hr, as an indication of technological feasibility. However, all those NMHC values that EPA cited did not include the manufacturers' EPA-required deterioration factors (DFs) or the manufacturers' required compliance margins. EPA's online certification spreadsheet is incomplete with respect to those manufacturers' reported deterioration factors. However, for one of the certification engines for which EPA reported a 42 mg/hp-hr test result, that manufacturer reported a 1.9 multiplicative DF, which means that EPA prohibits that manufacturer from declaring a Family Emission Limit (FEL) below 80 mg/hp-hr. In any case, no manufacturer to date is shown in EPA's online certification spreadsheet to have declared a heavy-duty SI FEL below 140 mg/hp-hr. That is an indication that manufacturers are factoring in a compliance margin between the minimum FELs they are allowed by EPA to declare and the 140 mg/hp-hr standard. Otherwise, those manufacturers could have generated HC emissions credits by declaring FELs below the standard. [EPA-HQ-OAR-2019-0055-1325-A1, p. 6]

We urge EPA to carefully review its analysis of certification data, and we urge EPA to reach out to manufacturers to discuss HC deterioration factors—particularly at EPA's proposed longer useful life, and also discuss manufacturer-required compliance margins and minimum design targets (similar to our comments on NOx stringency). Additionally, EPA should consider a wider range of fuels. EPA appears only to have considered gasoline SI engines, not alternative-fuel SI engines, in setting the standard. A single-step standard of 80 mg/hr in MY 2027 could be more appropriate considering all these factors. Such a standard would still deliver over a 40% reduction, while ensuring a wide range of fuels could be used. [EPA-HQ-OAR-2019-0055-1325-A1, p. 6]

Furthermore, Cummins does not support EPA justifying the feasibility of a HC standard based on the projected availability of HC emissions credits. That approach to standard-setting could lead to competitive disruptions between manufacturers, based on the mix of technologies different manufacturers are able to sell into various market subsegments. [EPA-HQ-OAR-2019-0055-1325-A1, p. 6]

Organization: *Eaton Vehicle Group (Eaton)*

Agency Request / Topic: In addition, we are requesting input on several aspects of the proposed new LLC duty cycle for heavy-duty CI engines and applying the SET duty cycle to heavy-duty SI engines (see Section III) [EPA-HQ-OAR-2019-0055-1252-A1, p.7]

Eaton Comment Strategy / Materials: We also support adding the SET option for SI engines, especially as we prognosticate an increase in market share of such engines. [EPA-HQ-OAR-2019-0055-1252-A1, p.7]

Organization: *Ford Motor Company (Ford)*

Ford supports EPA's effort to increase the stringency of the heavy-duty emission and greenhouse gas standards, starting in 2027 model year. We believe that the Option 1 alternative, along with the recommendations outlined in our attached comments, represents the appropriate level of stringency. [EPA-HQ-OAR-2019-0055-1300-A1, p. 2]

Ford supports the criteria emission standards in Option 1. The standards proposed in Option 1 would reduce NOx and particulate matter (PM) standards to the same level as the California Low NOx regulation by 2031 MY. In addition, the EPA proposal would reduce hydrocarbon (HC) emissions by 71% and Carbon Monoxide (CO) emissions by 60% versus the current standards. [EPA-HQ-OAR-2019-0055-1300-A1, p. 3]

Ford believes that complying with the 2031 model year and later 20 mg/bhp-hr NOx standard will require the same robust and durable technological solutions as are needed to comply with the CARB requirements in 2027 model year. [EPA-HQ-OAR-2019-0055-1300-A1, p. 3]

Organization: *General Motors LLC (GM)*

GM supports EPA's effort to finalize more stringent criteria emissions regulations than today's standards for medium- and heavy-duty engines and vehicles, in 2027 and beyond. [EPA-HQ-OAR-2019-0055-1246-A1, p.2]

In Option 1, the EPA proposes to decrease NOx emissions from the current standard by 82.5% in 2027, and 90% In 2031. At the same time, the agency proposed to revise upwards the useful life and warranty of new equipment in 2027, and then again in 2031. Different technology packages may be necessary to achieve these different requirements.7 Proposed restrictions to averaging, banking, and trading credits decrease a manufacturer's ability to respond to these stepped changes. [EPA-HQ-OAR-2019-0055-1246-A1, p.4]

7 Engine hardware, emissions systems, on-board diagnostic software, electrification, etc.

GM encourages the agency to consider a one-step standard that considers technological feasibility, and the air quality goals of the standard. A program with a straightforward one-step structure, with full ABT, that includes ZEVs is preferred. [EPA-HQ-OAR-2019-0055-1246-A1, p.4]

Organization: *Motor & Equipment Manufacturers Association (MEMA)*

With regard to EPA's request for comments on several aspects of the proposed new LLC duty cycle for heavy-duty CI engines and applying the SET duty cycle to heavy-duty SI engines, much of the impact of this is on the engine certifier. MEMA would like to highlight the fact that accessory loads are very impactful to thermal management systems - especially during low load cycle conditions. New certification cycles should accurately quantify and reward contributions of technologies to fuel efficiency improvements and NOx emissions reductions. MEMA recommends that EPA develop unique considerations for vocational vehicles with regard to correct accessory loading to reflect real-world use. [EPA-HQ-OAR-2019-0055-1322-A1, p. 6] [Also included in Section 3.3 of this document]

Organization: *Moving Forward Network (MFN)*

Option 1 should immediately harmonize with state action in model year (MY) 2027. Instead of allowing a four-year delay in matching state-level stringency, Option 1 should immediately impose a NOx emission standard of 0.02 g/bhp-hr for spark ignition, light-, medium-, and heavy-duty engines through intermediate useful life and a 0.035 g/bhp-hr for heavy heavy-duty engines from intermediate useful life to full useful life. [EPA-HQ-OAR-2019-0055-1277-A1, p. 21]

EPA's data on HDO engines shows that the best-performing 2019 gasoline-powered engines are already certified below the proposed Option 1 standard, with significant room for improvement according to the agency itself.89 [EPA-HQ-OAR-2019-0055-1277-A1, p. 22]

89. Draft RIA, Tables 3-35 and 3-40 (Demonstration Program).

Organization: *National Propane Gas Association (NPGA) and Propane Education & Research Council (PERC)*

We suggest the following modifications to the Proposed Option 1:

- 2. **Supplemental Emission Test (SET):** We discourage the agency from implementing SET requirements for spark ignited engines.9 We believe these are being considered for spark ignited engines to alleviate concerns specifically pertaining to power enrichment and engine/aftertreatment protection. As an alternative, we suggest that EPA monitor in-use compliance of vehicles to identify the outliers and work with pertinent manufacturers directly rather than including unnecessary and onerous additional requirements, which would increase the cost of engineering, testing and hence the product. Further, the agency's proposal deviates from current practice in that SET certification is not required under CARB's 2027 Ultra-Low NOx standards for spark ignited engines.10 [EPA-HQ-OAR-2019-0055-1263-A1, p.3]

9 Id., at 17429.

10 Heavy-Duty Low NOx, California Air Resources Board, https://ww2.arb.ca.gov/our-work/programs/heavy-duty-low-nox

Organization: *Roush CleanTech (Roush)*

Roush is in favor of the Option 1 proposed FTP standards and useful life periods for SI engines as listed in Table III-22. We believe these standards are highly challenging to achieve on gasoline, but likely feasible when combined with the ABT and OBD threshold flexibilities proposed. We believe that the use of clean alternative fuels such as LPG and CNG will provide an attractive alternative path for compliance due to their proven advantages in heavy-duty NOx emissions, but that this is simply one of several technical approaches that could be adopted under the regulation. We believe that the proposed implementation dates of 2027 and 2031 are reasonable, although we are concerned that given the broad scope of questions and preliminary content included in the NPRM, it will be difficult to finalize the rule in time to achieve 2027MY implementation. We encourage EPA to focus on the core provisions relating to NOx, useful life, and warranty, with primary concern being achieving a single national program with ARB, even if that means some of the other areas under consideration may need to be delayed for a future program. We recognize that NOx FEL timeline may be different between EPA and ARB, and that EPA and ARB warranty provisions may vary, but we would hope these would be the only substantive difference between the programs. [EPA-HQ-OAR-2019-0055-1276-A1, p.2]

Organization: *Truck and Engine Manufacturers (EMA)*

EPA has requested comment on the proposed SET test cycle and standards for SI HDEs, and whether any modifications should be considered when adapting the current CI-based SET duty cycle to SI HDEs. Application of the SET test to gasoline SI engines will require significant engine and aftertreatment investments far beyond the scope of what EPA has considered in the NPRM. The higher-load operating points of the SET test are challenging for gasoline SI engines where engine and aftertreatment components can be damaged by the associated high exhaust temperatures. Fuel enrichment is commonly used to cool those components under high-load conditions. EPA's gasoline SI demonstration of SET compliance employed down-speeding to avoid fuel enrichment. While down-speeding could be used in these applications, there will be a significant loss in the engine performance that customers demand. EPA states in the preamble that down-speeding would have to be combined with enhanced emissions controls and improved catalyst formulations to meet the proposed standards. EMA believes the hardware and software changes required to comply with the proposed SET standard, while also maintaining the customer's performance requirements, would be far more extensive than that. Indeed, those applications would have to be transitioned to higher displacement engines, requiring potentially significant vehicle modifications to package both engine and aftertreatment systems. An undesired consequence of using higher displacement engines in those applications would be an increase to GHG emissions. Additionally, manufacturers would be required to achieve greater engineering margin to account for the multiple sources of variability present in real-world applications beyond that provided in EPA's test results. [EPA-HQ-OAR-2019-0055-1203-A1, p. 116 - 117]

Considering the foregoing, EMA recommends that the SET test requirement be delayed until MY 2031 to provide manufacturers of gasoline SI engines the time needed to develop and install the larger engines that would be required for those applications. Alternatively, the SET test could be introduced with MY 2027 as proposed, but with exclusions to criteria emissions requirements needed during fuel enrichment-supported operation under high-load. Those exclusions could be sunset in MY 2031. [EPA-HQ-OAR-2019-0055-1203-A1, p. 117]

EPA Summary and Response

The summary and response for this section includes a listing of the topics raised, then the comments are summarized by category and the responses follow each summary.

Comments relating to FTP and SET testing for spark-ignition engines fell into the following general categories:

- Broad support for or opposition to the proposed options
- Specific comments on the proposed duty cycles and standards
- Credits and flexibilities
- Analysis of alternative fuels

Broad support for or opposition to the proposed options

Ford commented with general support for EPA's proposed Option 1. CARB supported Option 1 for PM, HC, and CO, but recommended EPA align more closely with CARB's Omnibus program by pulling ahead the 20 mg/hp-hr NOx standard that was proposed for MY 2031 to apply in MY 2027. CARB provided certification data for SI engines currently certifying to their optional low NOx standard of 20 mg/hp-hr and noted that 100% of those certified engines met EPA's proposed HC and CO standards as well. Roush also commented in support of Option 1 and requested a "single national program with ARB" specifically for NOx standards, useful life, and warranty. MFN commented that they believed Option 1 was feasible to implement in MY 2027, citing EPA's demonstration program results and the compliance numbers for MY 2019 SI engines. GM commented in support for lowering the standards from today's levels, but recommended a "straightforward" single step program instead of proposed Option 1. Cummins requested that EPA adopt an HC standard of 80 mg/hp-hr that they believe more appropriately accounts for the deterioration factors and compliance margins that manufacturers are expected to use. Cummins also noted that EPA did not appropriately account for the DF values in the MY 2019 certification data used in justifying the standards.

Response:

We are finalizing new FTP standards and new SET standards for Spark-ignition HDE subject to the final 40 CFR part 1036, which includes all spark-ignition engines installed in vehicles above 14,000 lb GVWR and incomplete heavy-duty vehicles at or below 14,000 lb GVWR that are not subject to or otherwise certified under 40 CFR part 86, subpart S.

We acknowledge the support from Ford and Roush for the proposed Option 1 standards and from CARB and MFN for pulling ahead the proposed Option 1 standards to MY 2027. As described in section III of the preamble, we are finalizing standards of 35 mg/hp-hr NOx, 5 mg/hp-hr PM, 60 mg/hp-hr HC, and 6.0 g/hp-hr CO over the FTP duty cycle for MY 2027 and later engines. The NOx and HC standards match the MY 2027 step of proposed Option 1; the PM and CO standards match the MY 2031 step of Option 1. All of these standards were demonstrated to be technologically feasible in EPA's SI engine test program.

In response to Cummins, we clarify that we included the MY 2019 certification data as one indicator that the proposed emission standard levels were achievable by today's engines. The certification data was added as supporting information; our primary technical basis for the numeric levels of the standards was and continues to be the SI engine demonstration program. It is true that our proposed analysis of the supporting certification data presented test values that did not include the DF. In RIA Chapter 3, we have updated our analysis of this certification data to account for DF.

We thank CARB for sharing the certification data from their optional low NOx program. We agree that the data also support the proposed Option 1 NOx levels for some current engines, but most of the engines in the dataset are alternative-fueled engines, including the natural gas-fueled engines certified using the CI duty cycles. As discussed in preamble Section III.A.3 and section 3.10 of this document, while we have referenced a technology pathway for complying with our final heavy-duty engine criteria pollutant standards (Chapter 3 of the RIA), which is consistent with CAA section 202(a)(3), there are other technology pathways, including alternative-fueled engines, that manufacturers may choose in order to comply with the final performance-based standards.

We are not finalizing an HC standard of 80 mg/hp-hr as requested by Cummins. For Spark-ignition HDE over the FTP duty cycle, we are finalizing an HC standard of 60 mg/hp-hr (which matches the MY 2027 HC standards for proposed Option 1). As explained further in preamble Section III, we demonstrated HC levels below 40 mg/hp-hr over the FTP in EPA's SI engine testing program and for the reasons explained in the preamble we believe a 60 mg/hp-hr standard is the appropriate level for a HC standard starting in MY 2027.

We respond to comments regarding alignment with the CARB Omnibus program in the preamble for this rule and Section 3.1 of this document.

Specific comments on the proposed duty cycles and standards

CARB and Eaton specifically expressed support for EPA's proposal to include a new SET duty cycle and standards for Spark-ignition HDE. MEMA commented that the impact of the new duty cycle is largely on the engine certifier, but that EPA should ensure that accessory loads are well-represented in the duty cycle due to their impact on thermal management systems. NPGA/PERC opposed the new SET standards, indicating that the new test would increase costs and isn't in line with the CARB Omnibus program. NPGA/PERC suggested enrichment for SI engines was best addressed through in-use monitoring. EMA suggested EPA underestimated the investment and time needed for manufacturers to adapt their engines to comply with standards over the SET duty cycle. EMA commented that the high load points of the SET duty cycle will result in high exhaust temperatures for SI engines, and the high temperatures could damage aftertreatment systems if manufacturers needed to avoid engine protection enrichment strategies in order to meet the standards. EMA suggests that, while EPA demonstrated the standards could be met with downspeeding, a downsped engine may not meet the performance requirements of HD customers in the range of applications for SI engines. Additionally, EMA commented that utilizing increased displacement engines would have the unintended consequence of higher GHG emissions as well as necessitating increase engineering margins to account for multiple sources of variability. EMA requested that EPA delay the SET requirement until MY 2031 to provide manufacturers more lead time. Alternatively, EMA suggested EPA could provide additional lead time by introducing SET in MY 2027 with an exclusion that sunsets in MY 2031 for operation in the high load points that would currently require fuel enrichment.

Response:

We appreciate the support for new SET standards from CARB and Eaton. We also acknowledge the adverse comments from NPGA/PERC and EMA and agree that the new duty cycle would present some new challenges for the industry. We disagree with the suggestion from NPGA/PERC that EPA monitor in-use vehicles to address enrichment in lieu of establishing SET duty cycle standards. We prefer EPA's long-standing approach of requiring manufacturers to demonstrate that their engines meet standards to ensure engines are designed to achieve the lowest possible levels of emissions before they enter commerce.

While lead time is necessary for SET duty cycle standards for Spark-ignition HDE, we disagree with EMA's comment that additional lead time may be needed for manufacturers to reevaluate their engine protection enrichment strategies over the higher load conditions of a SET duty cycle due to higher exhaust temperatures. We also disagree with EMA's request for EPA to delay implementation of the SET or provide exclusions for high load operating points on the duty cycle to provide additional lead time. Instead, as explained in preamble Section III, we are finalizing new SET standards starting in MY 2027, which we demonstrated are feasible and appropriate starting in that MY. By applying SET standards that start in MY 2027, we can ensure manufacturers take the quickest action to address the high load operation and minimize enrichment for SI engines.

As explained further in preamble Section III, we are finalizing SET standards of 35 mg/hp-hr NOx, 5 mg/hp-hr PM, and 40 g/hp-hr HC. For CO, we are finalizing a SET standard of 14.4 g/hp-hr. As shown in our SI engine test program and described in the RIA for this rule, CO is the most challenging emission to control under enrichment conditions for gasoline-fueled engines, but we demonstrated our final CO standard is technically feasible. We believe an SET CO standard, at the level of today's FTP CO standard, will sufficiently ensure manufacturers are assessing the performance of their engines at high load conditions as soon possible, yet the final stringency would not require the flexibilities or additional lead time that was suggested by commenters. Since the SET cycle is not currently required, manufacturers are not currently held to any standards at sustained high load and we expect a standard of 14.4 g/hp-hr will significantly reduce emissions compared to levels emitted under that unregulated operation.

EMA's claim that meeting the CO standard of SI SET by downspeeding would result in deterioration of vehicle performance was not substantiated with data to indicate the magnitude of the anticipated performance deterioration. Our SI SET demonstration engine maintained performance that we believe is acceptable in the commercial vehicle sector. Furthermore, our performance-based standards do not require manufacturers to adopt a specific technology (e.g., downspeeding or larger displacement) and manufacturers are expected to adopt the technology that is most appropriate for their compliance strategies for the range of applicable standards. Finally, manufacturers have readily adopted increased engine displacement with downspeeding as their engineering solution to achieve the current GHG standards. Agency review of recent certified engines indicates a 10% or more increase the engine displacements of all new HD engine designs combined with a reduction in rated engine speed following the implementation of GHG emission standards.

We requested comment on modifications we should consider to adapt the current CI-based SET duty cycle to Spark-ignition HDEs. MEMA suggested that accessory loads were especially important to consider for vocational vehicles, but did not provide data or specific suggestions for accessory loads in vocational applications. We may consider amendments to the SET duty cycle in a future rulemaking as more information becomes available for testing Spark-ignition HDE over the SET.

Credits and flexibilities

Roush and AAPC commented that the proposed standards are challenging and noted the need for the flexibility of an ABT program. Specifically, AAPC requested that manufacturers be able to generate credits for HC and CO. GM requested "full ABT". Cummins recommended that EPA set the final HC standard without assuming manufacturers would use credits to comply, citing the potential for competitive disruptions.

Response:

The final standards are not based on the use of emissions credits for any pollutant and our analyses show that manufacturers can meet the final standards without the use of credits. See preamble Section III for the feasibility of the final standards and preamble Section IV for the final ABT program.

Consistent with the proposal for this rule, we are finalizing an ABT program for NOx credits only and are discontinuing the current options for manufacturers to generate HC and PM credits. We did not request comment on and are not finalizing an option for manufacturers to generate credits for CO. See Section IV of the preamble to this rule and section 12 of this document for a discussion of the final ABT provisions.

Analysis of alternative fuels

Roush noted that LPG and CNG are alternative fuel options that could achieve the proposed standards. Cummins commented that EPA did not appropriately consider the feasibility of the proposed standards for alternative-fueled vehicles.

Response:

We agree with Roush's comment that LPG and CNG fuels may be viable methods to achieve the proposed standards and we note that, consistent with our current heavy duty engine standards compliance program, manufacturers can pursue alternative fuels as a technology pathway to comply with the final standards. Regarding Cummins' comment, we have updated our feasibility analysis from proposal to include compliance data from alternative-fueled and gasoline-fueled engines in RIA Chapter 3.

3.3 Criteria pollutant standards for LLC testing

Comments by Organizations

Organization: *Alliance for Vehicle Efficiency (AVE)*

AVE supports additional modifications to Option 1 to provide the best opportunity for driving more rapid adoption of advanced engine and emission control technologies. These additional modifications include:

- Adoption of a lower limit of a Low Load Cycle (LLC) for engine certification.
- Considering a tighter than proposed in-use compliance standard to meet a lower LLC limit. [EPA-HQ-OAR-2019-0055-1280-A1, p 3]

Organization: *Allison Transmission, Inc. (Allison)*

- Allison supports EPA's proposal of a Low Load Cycle but believes that EPA should determine accessory loads in a manner that better represents real-world operations. [EPA-HQ-OAR-2019-0055-1231-A1, p.6]

EPA has proposed new test procedures for Low Load Cycle62 and proposed corresponding low load cycle emission standards.63 These standards are significantly higher than standards that apply for NOx and HC as measured under FTP and SET testing. Allison has reviewed the proposed Low Load Cycle and agrees that this cycle measures operations where aftertreatment thermal management strategy is a significant factor to maintaining emissions control. Therefore, we agree that Low Load Cycle would measure emissions across a broader range of engine operating conditions aligned with EPA's objectives in proposing the new requirements. [EPA-HQ-OAR-2019-0055-1231-A1, p.30]

62 Proposed 40 C.F.R. §1036.512.

63 Proposed 40 C.F.R. §1036.104(a)(3)

Allison notes that, as proposed, the Low Load Cycle would apply accessory loads of 1.5kw, 2.5kw, and 3.5kw for LHDEs, MHDEs, and HHDEs. Allison experience with eGen Flex hybrid system testing indicates accessory loads are a significant factor for thermal management, as hybrid systems moving from engine off all electric range operation to resumed engine operation exiting geofenced green zones, were able to more quickly recover thermal management compared to test vehicles run with lower accessory loads. This is a reason that hybrid technology with all electric range is a better fit for applications with higher accessory loads like transit bus. [EPA-HQ-OAR-2019-0055-1231-A1, p.30]

Based on these observations, Allison believes that EPA should determine accessory loads in a manner that better matches real-world operation and consider different assumptions for different vocations. Allison was unable to compile data to provide EPA within this comment period timeframe, but we will offer suggestions how EPA could consider accessory load assumptions or gather data via customer survey leading to final rule: [EPA-HQ-OAR-2019-0055-1231-A1, p.30]

- Allison would suggest EPA survey commercial vehicle customers (fleet and OEM) across segments of both tractor and vocational applications to gather this data because accessory loads are vehicle and application specific
- Allison would recommend EPA seek a range of worst case to best case accessory loads from customers because, for each vehicle or application type, accessory loads can vary seasonally based on ambient temperatures, particularly for applications that have more complex climate control (air conditioning/heating) systems like transit bus.
- Allison suggests EPA define different assumptions for accessory loads for tractor and vocational application because Allison would expect accessory loads to be higher on average for vocational applications compared to tractor applications. Any vehicle with complex accessories including climate control, air compressor loads, power-take-off is more likely to have higher accessory loads. For example, another application known to have higher-than-average accessory loads would be a reefer truck. [EPA-HQ-OAR-2019-0055-1231-A1, p.30]

Organization: *American Trucking Associations (ATA)*

While ATA cannot address every aspect of HD2027, we are supportive of the underlying environmental objectives and several of the elements being proposed. ATA's areas of support include: Low-load cycle NOx emissions standards are necessary to reduce overall NOx profiles from the trucking sector. [EPA-HQ-OAR-2019-0055-1326-A1, p. 3]

Organization: *California Air Resources Board (CARB)*

U.S. EPA's Stage 3 RW engine platform at 435,000 equivalent miles of accelerated aging resulted in tailpipe NOx emissions of 20, 17, and 29 mg/hp-hr respectively on the FTP, Ramped-modal cycle (RMC), and LLC duty cycles. Since the proposed useful lives for MY 2027 light and medium HDEs are much less than 435,000 miles, it can be concluded that, with application of emission control technologies similar to the Stage 3 RW, these engine classes could meet CARB staff recommended standards of 20 mg/hp-hr NOx on the FTP and SET and a 50 mg/hp-hr NOx on the LLC. [EPA-HQ-OAR-2019-0055-1186-A2, pp.40-41]

96 NPRM 17461

97 Sanchez, James. 'Test Results from EPA Diesel Demonstration'. Memorandum to Docket: EPA-HQ-OAR-2019-0055. February 10, 2022.

The Omnibus LLC standards for NOx were based on test data from the CARB Stage 3 engine, which used a zone-coated catalyzed soot filter (ZCSF) upstream of the downstream underfloor SCR system. Testing on the LLC of the CARB Stage 3 engine with ZCSF after accelerated aging to 435,000 miles was at 47 mg/hp-hr, and it provided the basis for CARB's Omnibus LLC standards of 50 mg/hp-hr through IUL. However, in the Stage 3 RW engine testing, the ZCSF was replaced with a separate diesel oxidation catalyst (DOC) and diesel particulate filter (DPF) aftertreatment system. These improvements resulted in lower NOx emissions on the FTP, SET, and LLC compared to corresponding NOx emissions from the CARB Stage 3 engine on which the Omnibus standards were based. In particular, LLC NOx emissions from the Stage 3 RW engine, which measured emissions at 435,000, 600,000, and 800,000 equivalent miles of accelerated aging, were significantly reduced and stable with no significant variations in the deterioration through the UL of 800,000 miles (see Figure 5-2 above). Thus, the technology and the demonstration results justify NOx standards on the LLC duty cycle that are more stringent than those in the proposed Option 1 or Omnibus. In fact, CARB's adopted 50 mg/hp-hr IUL standard for LLC could have been adopted for heavy HDE's at 600,000 and 800,000 mile UL. Adopting CARB's IUL LLC NOx standard of 50 mg/hp-hr out to full UL of 800,000 miles is feasible and would provide around a 50 percent compliance margin when looking at the Stage 3 RW test results at the equivalent mileage of 800,000 miles. CARB staff recommends that U.S. EPA adopt in its final rulemaking NOx standards that are more stringent than the proposed Option 1 or Omnibus LLC standards. [EPA-HQ-OAR-2019-0055-1186-A2, p.45]

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

Commenters support changes to duty cycle and in-use testing to curtail the extremely high emissions that occur when HDVs are idling or traveling at low speeds. Selective catalytic reduction (SCR)-based emissions control systems, typically used on diesel engines, work best when the engine's exhaust is at a high temperature, i.e., when trucks are traveling at higher speeds or when engines are working at 'higher load.' 87 Fed. Reg. at 17,418. This means that when trucks and buses are moving at lower speeds on congested highways through urban areas, on city streets, pulling into and out of logistics facilities and warehouses, or idling—the times when these vehicles are closest to pedestrians and cyclists and closest to people's homes, schools, and workplaces—they are emitting the highest levels of dangerous pollution.233 [EPA-HQ-OAR-2019-0055-1302-A1, p.55]

233 Huzeifa Badshah et al., Current State of NOx Emissions from In-Use Heavy-Duty Diesel Vehicles in the United States 17, ICCT (Nov. 2019), https://theicct.org/publication/current-state-of-nox-emissions-from-in-use-heavy-duty-diesel-vehicles-in-the-united-states/.

EPA proposes improving its duty cycle testing by adding a new low-load cycle to its current Federal Test Procedure (FTP) and Supplemental Emission Test (SET) duty cycles. 87 Fed. Reg. at 17,460. The new low-load cycle (LLC) would be identical to the Omnibus LLC, and would be subject to a different (higher) set of emissions limitations than the FTP and SET cycles. 87 Fed. Reg. at 17,463–64. Commenters support adoption of a low-load duty cycle to better limit the higher emissions that occur at low loads, though, as discussed below, we believe EPA should set more stringent emissions limits on this cycle. [EPA-HQ-OAR-2019-0055-1302-A1, p.56]

Organization: *Consumer Reports (CR)*

EPA is proposing to add a new low-load cycle (LLC) standard for CI engines. CR supports the addition of the LLC standard, and encourages EPA to extend this test to SI engines. The proposed LLC standard is needed to capture NOx emissions in urban areas where heavy duty vehicles operate in stop-and-start, and other low-load conditions. [EPA-HQ-OAR-2019-0055-1285-A1, p.7]

Studies by both CARB and ICCT show that NOx emissions in urban driving settings exceed emission rates certified by manufacturers.43 As the ICCT study states 'a disproportionate amount of NOx emissions from heavy-duty [diesel] vehicles is emitted during the low-speed operation characteristic of urban driving,' and that 'vehicle operation at speeds of less than 35 mph results in NOx emissions of more than five times the certification limit for the average heavy-duty vehicle in the study.'44 For this reason the LLC is necessary to ensure that NOx emission standards apply not only to driving conditions seen on highways, but also to emissions that occur during cold start warm-up, idling, low-load driving, and transient operations. Such a requirement is needed for both SI and CI engines. EPA must adopt the Option 1 LLC standards that reflect CARB's Heavy-Duty Omnibus Rule.45 Compared to Option 2, Option 1 reflects the greatest degree of emission reduction achievable, as required by the CAA. [EPA-HQ-OAR-2019-0055-1285-A1, p.7]

Organization: *Cummins Inc. (Cummins)*

1036.512(b)(3)

For LLC cycle, it was previously agreed to have slightly relaxed statistical criteria which was also adopted in the CARB Omnibus rule. See below for CARB criteria from 1065.514.A.3.(f)(4): [EPA-HQ-OAR-2019-0055-1325-A1, p. 25]

Organization: *District of Columbia Department of Energy and the Environment (DOEE)*

DOEE supports the inclusion of performance requirements to ensure achievement of emission standards across all duty cycles, including idle and low load in the final rule. [EPA-HQ-OAR-2019-0055-1299-A1, p. 5]

Due to the high level of heavy-duty engine NOx emissions that come from operation at low loads, we support EPA's proposal to adopt a low-load test that would provide a procedure for assessing emissions at low loads and allow for better control of NOx emissions in urban driving environments. For MY 2027-2030 engines, EPA has proposed a low-load cycle (LLC) standard of 90 mg/hp-hr, which is the same as that in the California Heavy-duty NOx Omnibus Regulation. However, several recent research initiatives – including EPA's Low NOx Stage 3 Research Program conducted by SwRI and a program conducted by Achates – provide clear evidence that a tighter standard is feasible. Based on this research, EPA should evaluate how much lower the LLC standard can be and improve the proposed standard in the final rule. [EPA-HQ-OAR-2019-0055-1299-A1, p. 5]

Organization: *Eaton Vehicle Group (Eaton)*

Agency Request / Topic: In addition, we are requesting input on several aspects of the proposed new LLC duty cycle for heavy-duty CI engines and applying the SET duty cycle to heavy-duty SI engines (see Section III) [EPA-HQ-OAR-2019-0055-1252-A1, p.7]

Eaton Comment Strategy / Materials: We believe the LLC cycle represents the real emissions in urban-like applications that currently generate significant NOx exactly where many people live and in environmentally disadvantaged communities. Furthermore, the technologies today already allow a significant compliance margin versus the proposed 50 mg standard. We believe the EPA should consider maintaining or possibly improving that limit. [EPA-HQ-OAR-2019-0055-1252-A1, p.7]

Organization: *International Council on Clean Transportation (ICCT)*

LLC compliance is also achieved with even larger margins. The LLC standard under EPA Option 1 calls for 90 mg/bhp-hr at 600k miles for MY2027-2030. The latest results from SwRI show 33 mg/bhp-hr or a 60% compliance margin. For MY 2031 and beyond the LLC Option 1 standard is listed as 50 mg/bhp-hr @ 435k miles and 100 mg/bhp-hr at 800k miles. SwRI results show LLC emissions at 30-40 mg/bhphr at 435k miles, at least a 20% margin, and 30mg/bh-hr

@800k miles, which provides a 70% compliance margin. [EPA-HQ-OAR-2019-0055-1211-A1, p. 10]

The industry has many years to improve the first-ever emission compliance design to reach the final level of emissions of the proposed Option 1 standards, and 8 years to assure its performance at 800k miles. These results also indicate that LLC standards can be tightened even further. [EPA-HQ-OAR-2019-0055-1211-A1, p. 10]

Organization: *Manufacturers of Emission Controls Association (MECA)*

MECA suggests that EPA consider tightening two categories of the Proposed Option 1 standards such that they are more stringent than those finalized in CARB's Omnibus. This recommendation is based on new, previously unavailable test results that have been released since the adoption of the Omnibus. Further testing on certification and real-world field cycles suggest that tighter standards are possible while retaining sufficient compliance margin that engine manufacturers need to account for manufacturing and field variability. We strongly encourage CARB to review this new test information and harmonize with EPA on more stringent standards. The two standards that can be tightened are the LLC standard and the idle standard. Similar to CARB's Omnibus, the idle standard should also be required for certification rather than an optional standard as currently proposed. There is significantly more data available from the SwRI demonstration program since CARB developed its Omnibus regulation. These data show that the LLC and idle standards finalized by CARB and proposed by EPA in Proposed Option 1 can be achieved with significant margin. The NOx level achieved over the LLC with systems fully aged to 800,000 equivalent miles is 0.037 g/bhp-hr, which includes the infrequent regeneration adjustment factor (IRAF) [6]. [EPA-HQ-OAR-2019-0055-1320-A1, p.5]

> [6] EPA, 'Test Results from EPA Diesel Engine Demonstration,' 10 May 2022. [Online]. Available: https://www.regulations.gov/document/EPA-HQ-OAR-2019-0055-1082.

MECA supports the inclusion of a low load cycle and standard to certification requirements that achieve low NOx emissions during low load operation. [EPA-HQ-OAR-2019-0055-1320-A1, p.17]

One challenge with diesel engine emission control is maintaining high NOx conversion during low load operation, due to insufficient temperature in the exhaust to support efficient catalyst conversion in the SCR. Diesel vehicles used in drayage, delivery operations, and other activities that result in high periods of idle, creep, and/or stop-and-go operation are examples of challenging duty-cycles. [EPA-HQ-OAR-2019-0055-1320-A1, p.17]

MECA supports EPA adopting, similar to CARB's Omnibus, revised regulatory requirements that aim to best control emissions at times of low load engine operation. During certification, the engines and aftertreatment systems would need to meet low emissions over the newly proposed low-load certification (LLC) cycle that targets average engine power of about 7%. MECA supports the addition of the LLC cycle in 2027 for engine certification. However, as stated in our comments on page 3-4 above, we believe the LLC standards at full useful life should be tightened for both MY 2027 and 2031. Testing at SwRI has shown that the Proposed Option 1

LLC standards can be achieved with significant margin at the proposed limits and may result in emissions backsliding over time in these operating modes that are the most critical to urban operation.[EPA-HQ-OAR-2019-0055-1320-A1, p.18]

Inclusion of the LLC is a very important part of this rule as it ensures that during certification, dynamometer testing evaluates the ability of technology to meet real-world emissions in an accurate test cell environment before they are deployed on the road. As discussed above, the cycle was derived from real truck data operated over actual duty cycles from many different truck vocations ranging from delivery to busses to line-haul tractors. The proposed LLC cycle is a robust approximation of all types of truck operation at low load. The approach used by NREL and SwRI to develop a real-world cycle stands as an example of how future certification cycles can be developed. MECA supports the inclusion of the proposed LLC cycle to give EPA the confidence, at time of certification, that the technology will be able to meet the requirements of the revised in-use compliance program proposed by staff based on a moving average window analysis. MECA members have developed and are offering a number of technology solutions (discussed previously) that can enable OEMs to meet the tighter-than-proposed LLC limits. Testing of the Stage 3 engine and aftertreatment systems have exceeded the proposed LLC emission limits with significant margin based on the same technology solutions that achieved ultra-low NOx emissions over the FTP, including over 98% conversion efficiency over the cold-start phase of the FTP. [EPA-HQ-OAR-2019-0055-1320-A1, p.19]

We support Proposed Option 1 slight increase to the emission standards at the final longer durability periods to account for possible deterioration beyond the current FUL of 435,000 equivalent miles. Results from the SwRI demonstration program support the NOx limits at the FUL requirements in Proposed Option 1. [EPA-HQ-OAR-2019-0055-1320-A1, p.20]

Organization: *Motor & Equipment Manufacturers Association (MEMA)*

With regard to EPA's request for comments on several aspects of the proposed new LLC duty cycle for heavy-duty CI engines and applying the SET duty cycle to heavy-duty SI engines, much of the impact of this is on the engine certifier. MEMA would like to highlight the fact that accessory loads are very impactful to thermal management systems - especially during low load cycle conditions. New certification cycles should accurately quantify and reward contributions of technologies to fuel efficiency improvements and NOx emissions reductions. MEMA recommends that EPA develop unique considerations for vocational vehicles with regard to correct accessory loading to reflect real-world use. [EPA-HQ-OAR-2019-0055-1322-A1, p. 6]

Organization: *National Association of Clean Air Agencies (NACAA)*

NACAA supports inclusion in the final rule of performance requirements to ensure achievement of emission standards across all duty cycles, including idle and low load. [EPA-HQ-OAR-2019-0055-1232-A1, p. 11.]

Due to the high level of heavy-duty engine NOx emissions that come from operation at low load we support EPA's proposal to adopt a low-load test that would provide a procedure for assessing emissions at low loads and allow for better control of NOx emissions in urban driving environments. For MY 2027-2030 engines, EPA has proposed a low-load cycle (LLC) standard of 90 mg/hp-hr, which is the same as that in the Omnibus. However, several recent research initiatives – including EPA's Low NOx Stage 3 Research Program conducted by SwRI29 and a program conducted by Achates – provide clear evidence that a tighter standard is feasible. Based on this research, EPA should evaluate how much lower the LLC standard can be and, in the final rule, improve upon the proposed standard. [EPA-HQ-OAR-2019-0055-1232-A1, p. 11]

29. https://www.regulations.gov/document/EPA-HQ-OAR-2019-0055-1082

Organization: National Waste & Recycling Association (NWRA)

NWRA commends EPA on beginning to break out short-haul and long-haul trucking as in terms of effective pollution controls. EPA's recognition that the start-stop and short distances traversed by short-haul drivers between stops potentially limits the ability of some pollution control devices to work effectively since they would not get to a high enough temperature. NWRA asks that EPA work with short-haul companies and manufacturers to find viable alternatives. [EPA-HQ-OAR-2019-0055-1242-A1, p. 2]

Organization: *Northeast States for Coordinated Air Use Management (NESCAUM)*

Should EPA instead promulgate Option 1, we urge the Agency to make the following changes to the proposed standards: We strongly support the establishment of EPA's proposed low load certification cycle and the inclusion of auxiliary load in the cycle. Test data collected by EPA, CARB, the International Council on Clean Transportation (ICCT), NESCAUM, and others demonstrate the substantial contribution to overall heavy-duty engine emissions from low load operation.27,28,29,30 In the Northeast and mid-Atlantic regions, recent data logging of on-road tractor trailers over 100 days of travel found that 10 percent to 40 percent of tractor trailer NOx was emitted at low load.31 Taken together, these studies strongly point to the need for additional NOx controls at low load cycles. Figure 6 shows the NOx mass emissions for idle (bin 1), low load (bin 2), and high load (bin 3) over 100 days of data logging of truck tractors in the NESCAUM study. The green bar shows the contribution of NOx emissions at low load as a fraction of total NOx emissions. [EPA-HQ-OAR-2019-0055-1249-A1, p. 10]

31 Ibid.

Even with this important contribution, the green bar understates total low load NOx emissions because the NOx sensors were not active at exhaust temperatures below 190 degrees Celsius. The right-hand graph in Figure 6 shows the percent of time the NOx sensor was active for each truck at low load conditions. On average, NOx sensors were inactive for 31 percent of the time. Not shown in the graph is NOx sensor activity at idle. NOx sensors were inactive for 67 percent of the time at idle. A proper accounting of NOx emissions when the NOx sensors were inactive would increase the amount of NOx emitted at low load and idle. It is important to note that these trucks are tractor trailers that spend a significant portion of the time at speeds above 60 miles per hour. For delivery trucks, buses, and other vocational vehicles, low load emissions comprise an even larger share of total emissions. [EPA-HQ-OAR-2019-0055-1249-A1, pp. 10 - 11]

Low load cycles and excess NOx emissions are of particular concern in Overburdened Communities located near busy truck routes and where trucks operate in stop and go conditions where exhaust temperatures are potentially too low to enable selective catalytic reduction (SCR) emissions control function. The truck data logging study found that for current engines, cold ambient temperatures reduce the amount of time NOx sensors are active, indicating potentially greater NOx emissions at low load in the wintertime. In addition to exacerbating localized heavy-duty truck emissions, lack of NOx sensor activity and SCR performance in cold weather are a concern for regional haze. [EPA-HQ-OAR-2019-0055-1249-A1, p. 11] [Also in Section 23 of this document]

While we support the low load certification test cycle proposed by EPA, we request that EPA finalize a more stringent low load NOx standard for model year 2027-2030 engines. The proposed standard in Option 1 of 90 milligrams/hp-hour is significantly higher than data show is achievable in 2027. For example, an upgraded Cummins engine with cylinder deactivation, improved engine calibration, and advanced aftertreatment had low load cycle (LLC) NOx emissions of 0.036 and 0.053 g/bhp-hr.[32,33] Results from EPA’s Heavy-duty Low NOx Stage 3 Research Program show the proposed Option 1 LLC standards are well above what the test data demonstrate are feasible at 435,000, 600,000, and 800,000 miles.[34,35] EPA’s test data indicate a 35 to 40 mg/bhp-hr standard is feasible in 2027. NESCAUM supports a more stringent low load certification standard beginning in model year 2027. Achieving the greatest technically feasible NOx reductions in 2027 and subsequent model year heavy-duty vehicles is essential to the Northeast to meet air quality requirements and to improve public health. [EPA-HQ-OAR-2019-0055-1249-A1, p. 11 - 12]

Low load cycles and excess NOx emissions are of particular concern in Overburdened Communities located near busy truck routes and where trucks operate in stop and go conditions. [EPA-HQ-OAR-2019-0055-1250-A1, p.14] [Also in Section 23 of this document]

While we support the certification test cycle proposed by EPA, we request that EPA finalize a more stringent low load NOx standard for model year 2027-2030 engines. The proposed standard in Option 1 of 90 milligrams/hp-hour is significantly higher than CARB and EPA data show is achievable for MY 2027. For example, an upgraded Cummins engine with cylinder deactivation, improved engine calibration, and advanced aftertreatment had LLC NOx emissions of 0.036 and 0.053 g/bhp-hr.33,34 Results from EPA's Heavy-duty Low NOx Stage 3 Research Program show the proposed Option 1 LLC standards are well above what the test data demonstrate are feasible at 435,000 miles, 600,000 miles, and 800,000 miles.35,36 EPA's test data indicate a 35 to 40 mg/bhp-hr standard is feasible in 2027. OTC supports a more stringent low load certification standard beginning in model year 2027. Given that 2027 to 2030 model year heavy-duty vehicles will be in service for many years to come, it is essential we realize the greatest NOx reductions possible with the implementation of new emissions standards. [EPA-HQ-OAR-2019-0055-1250-A1, p.14]

Organization: *PACCAR, Inc (PACCAR)*

Proposed 1036.522 addresses infrequently regenerating aftertreatment devices. As an initial matter, operation in the Low Load Cycle conditions may not trigger regeneration events under real-world conditions, especially in extreme low-load conditions. Manufacturers must therefore be afforded additional flexibility to address this issue, by, for example, being able to use FTP-derived IRAF values, or by omitting IRAF values if manufacturers can demonstrate that regenerations are unlikely to occur under real-world, low-load conditions. [EPA-HQ-OAR-2019-0055-1346-A1, p.50]

Organization: *Public Citizen and Healthy Port Communities Coalition (HPCC)*

The Proposal recommends three laboratory tests to better ensure that trucks meet emissions reduction criteria: (1) the Federal Test Procedure, (2) the Supplemental Emission Test, and (3) the Low-Load Cycle test. Both (1) and (2) are currently used to demonstrate emission control efficacy when a vehicle transitions from low to high loads or under a sustained load. But these tests fail to demonstrate emissions reduction efficiency under low load. The Proposal would add (3) as a way to ensure that engines retain the capacity for emissions reductions at lower speeds and operating temperatures. Controlling emissions over a broader range of conditions would be a welcome relief for communities adjacent to ports and freight corridors where currently even using the newest equipment cannot guarantee emissions reductions. [EPA-HQ-OAR-2019-0055-1417-A2, p. 2]

Organization: *Retail Industry Leaders Association (RILA)*

Large vehicles that use heavy-duty engines operate under a wide range of load conditions and speeds during day-to-day operation, including sustained low-load and idle. However, these load conditions are not currently included in the existing federal standards for criteria pollutant emissions, such as NO_x and PM. The absence of such standards has left these emissions largely unregulated during common low-load operations such as waiting at a traffic light or driving at low-speed. [EPA-HQ-OAR-2019-0055-1189-A2, p.3]

The medium- and heavy-duty trucks that use engines covered by this proposed rule are commonly used to transport freight and deliver goods to retailers. These trucks will often operate in low-load and idle modes during deliveries to retail facilities as they arrive, unload, and depart. Reductions to the pollution emitted by trucks during low-load operations will reduce exposure to pollutants experienced at these retail facilities by both employees that work near areas where trucks unload (e.g., around loading docks), as well as customers who might be exposed to the emissions of idling trucks when they enter or leave the facility. [EPA-HQ-OAR-2019-0055-1189-A2, p.3]

The inclusion of testing that covers low-load and idle operation in EPA's proposed rule is therefore seen as a logical update by RILA that can reduce exposure to criteria pollutant emissions faced by communities, including the retail community, across the country. [EPA-HQ-OAR-2019-0055-1189-A2, p.3]

Organization: *South Coast Air Quality Management District*

Additionally, there is no reason to believe a 0.05 g/bhp-hr LLC limit in MY 2027 is not possible. The Southwest Research Institute's (SwRI's) Stage 3 'Rework' system, funded by EPA itself, includes final test results on thermally aged development parts demonstrating 0.034 g/bhp-hr

NOx on the LLC at 800,000 miles, which is significantly lower than a proposed 0.05 g/bhp-hr standard.27 As CARB notes in its Initial Statement of Reasons for the Omnibus Regulation, a 0.05 g/bhp-hr standard on the LLC is feasible for MY 2027 and subsequent MY engines so long as manufacturers employ engine software and hardware technologies that accelerate catalyst light-off and keep the aftertreatment warm under sustained low load operations as well as remain neutral or provide GHG emission reductions.28 [EPA-HQ-OAR-2019-0055-1201-A1, pp.7-8]

Organization: *Truck and Engine Manufacturers Association (EMA)*

It is important to highlight from the outset that while there are various details of EPA's rulemaking proposal (particularly with respect to Option 1) that EMA and its members fundamentally disagree with, there are multiple major points of substantial agreement. In that regard, EMA agrees with EPA that:

(v) A new low-load cycle and related emission standards should apply to the certification of HDOH engines starting in MY 2027; [EPA-HQ-OAR-2019-0055-1203-A1, p. 5]

EPA also proposes to add a new low-load certification test cell cycle ("LLC") to the certification requirements for HDOH engines. The new LLC, first developed and applied to HD HDOH engine requirements by CARB, is a 92- minute test cycle that includes approximately 30 minutes of idle operation, a significant portion of high-to-low load operation with extreme airflow-induced cooling (i.e., downhill operation), and a significant portion of low-to-high load transient operation (i.e., drayage work). The selected LLC also has an average power that is approximately 6% of maximum power, and an average vehicle speed that is approximately 10 mph. It is an extreme cycle, especially as applied to every HDOH engine, regardless of the vehicle type and application in which the engine might be installed. [EPA-HQ-OAR-2019-0055-1203-A1, p. 115]

EMA has repeatedly questioned the analyses that CARB, SwRI, and NREL relied on to develop the LLC. One concern relates to the portion of the LLC that has been dubbed, "v11660_5." That portion's combination of engine, transmission, 6x4 axle configuration, and 4.20 axle ratio appears to be a heavy-haul configuration, which should mean heavier parts all around. However, the mass—after SwRI's mass reduction and after EMA subtracts a hypothetical 15,000-pound empty trailer—is 11,333 pounds for a GEM-simulated tractor. That tractor weight is not at all realistic. Even a heavy-haul single unit vehicle, like a dump truck, typically is heavier than 26,333 pounds (i.e., without subtracting an empty trailer). For reference, Navistar's regional-haul day-cab with a roof deflector and a 12-liter engine is about 15,000 pounds, and a Daimler Cascadia daycab with no roof deflector and a 13-liter engine is 16,300 lbs. Those day-cab configurations are among the lighter Class 8 vehicles, yet they are thousands of pounds heavier than the vehicle simulated to generate LLC portion "v11660_5." Thus, it would seem that the proposed LLC is not representative of the actual operation of any actual HDOH vehicle. EMA recommends that EPA work (with CARB) to modify the LLC to include only representative engine behavior drawn from representative vehicle operation. [EPA-HQ-OAR-2019-0055-1203-A1, p. 115 - 116]

Similarly unrepresentative is the LLC auxiliary load that EPA proposes to apply. EPA should increase the LLC auxiliary load for HHD engines from 3.5 kW to a value in the range of 5.0 to 5.5 kW, so that it is more representative of real-world auxiliary loads. [EPA-HQ-OAR-2019-0055-1203-A1, p. 116]

EMA supports that EPA proposes to allow a stop-start function to be active during the FTP and LLC cycles (§1036.501(f)). Stop-start could be an effective tool for reducing NOx, and having the ability to demonstrate NOx control over the LLC and RMC will be beneficial. More detail will be necessary, such as whether operator over-ride functions will influence whether stop-start can be active during certification testing. Also, there are concerns about deploying conventional starters to support restart, because the inertia of the dyno may cause unforeseen problems. EMA appreciates that EPA is providing for stop-start to be active in the certification tests, and is ready to work with EPA to iron out the details for the final rule. [EPA-HQ-OAR-2019-0055-1203-A1, p. 116]

EPA Summary and Response

Summary:

Multiple commenters provided perspectives on the proposed low-load cycle (LLC) standard and test procedure. Most commenters expressed general support for including the LLC. Stakeholders agree that the LLC would measure emissions across a broader range of engine operating conditions, and is aligned with EPA's objectives to reduce NO_X across different modes of operation and duty-cycles, including urban driving environments. One stakeholder provided data showing the need for additional NO_X emission controls at low load cycles. Several stakeholders emphasized that emission control under low-load operation is particularly important in overburdened communities located near busy truck routes and where trucks operate in stop and go conditions. One stakeholder also stated that emission control in low-load operation is also important to reduce exposure at retail facilities both for employees that work near areas where trucks unload (e.g., around loading docks), as well as customers who might be exposed to the emissions of idling trucks when they enter or leave the facility. One stakeholder encouraged EPA to work with CARB to revise the LLC such that it includes only representative engine behavior drawn from representative vehicle operation.

Several commenters provided additional input on the numeric level of the LLC. The majority of stakeholders urged EPA to lower the numeric level of LLC engine certification test standard. One commenter also urged EPA to lower the numeric level of the LLC standard for in-use compliance. In contrast, three stakeholders stated EPA needed to better account for accessory loads when setting the final LLC standard. Another stakeholder stated EPA should adopt relaxed statistical criteria which was also adopted in the CARB Omnibus rule. Finally, one stakeholder stated that manufacturers needed flexibilities for determining infrequent regeneration adjustment factors for the LLC (e.g., allow the use of FTP-derived IRAF values, or by omitting IRAF if the manufacturer can demonstrate regeneration is unlikely to occur during low-load operations in the real-world).

Several of the stakeholders who urged EPA to lower the LLC standard pointed to recent data from SwRI and Achates as providing clear evidence that a standard lower than 75 mg/hp-hr is feasible. One stakeholder suggested that EPA's test data indicate a 35 to 40 mg/bhp-hr standard is feasible in 2027. Another commenter stated that EPA should set the LLC to 50 mg/hp-hr for all engine classes. Finally, one stakeholder noted that not lowering the proposed numeric standard for the LLC could result in emissions backsliding over time in these operating modes.

Multiple stakeholders who stated that EPA should evaluate accessory loads when setting the LLC encouraged EPA to determine accessory loads in a manner that better matches real-world operation when finalizing the LLC standard. They further stated that EPA should consider different assumptions for different vocations and conduct a survey of fleets and vehicle manufacturers to gather data on accessory loads in tractor and vocational applications. They further stated that EPA should define different assumptions for accessory loads for tractor and vocational application because they expect accessory loads to be higher on average for vocational applications compared to tractor applications. One stakeholder stated EPA should increase the LLC auxiliary load for HHD engines from 3.5 kW to a value in the range of 5.0 to 5.5 kW, so that it is more representative of real-world auxiliary loads.

One commenter stated that the regression criteria should be relaxed for the LLC.

One commenter proposed to allow a stop-start function to be active during the FTP and LLC cycles (40 CFR 1036.501(f)).

Finally, three commenters stated that EPA should extend the LLC to SI engines.

Response:

EPA agrees with many of the commenters that the LLC is an important measure to accurately account for and control emissions across a broader range of engine operation, including urban driving conditions and other operation that could impact overburdened communities. As further detailed in preamble Section III, the final program includes new emission standards for the LLC duty cycle. The LLC duty cycle was developed by SwRI and NREL with average power and duration characteristics intended to test current diesel engine emission controls under three low-load operating conditions: transition from high- to low-load, sustained low-load, and transition from low- to high-load and its development, taking into account representative vehicle operation, and is fully described in Chapter 2.2.2 of the RIA. We disagree with the comment that the vehicle mass of 26,333 pounds used for profile v11660 is unrealistic, since 26,333 pounds is in the range of a class 8 tractor without a trailer. The operation included in profile v11660 was from a drayage tractor, which can spend a significant amount of time without a trailer connected. For the reasons described in this section and preamble Section III, we are finalizing the LLC test cycle as proposed.

Regarding the comment regarding flexibilities for IRAF determination, 40 CFR 1065.680 states that "For engines subject to standards over more than one duty cycle, you must develop adjustment factors under this section for each separate duty cycle." There is nothing in 40 CFR 1065.680 that prevents a manufacturer from developing a single IRAF that represents the average of, and can be applied to, all duty cycles. Nor does 40 CFR 1065.680 prevent you from determining that your IRAF is zero. The IRAF determination procedure in 40 CFR 1065.680 provides flexibilities with respect to the method of IRAF determination.

See preamble Section III for the basis for the final LLC standards. We agree with some commenters that data support a lower numeric value of the LLC standard than what we proposed for certain LLC standards in Option 1 (e.g. at the useful life value of 800,000 miles for Heavy HDE). We noted in the NPRM that the margin between the proposed Option 1 MY 2031 standards and the Stage 3 engine data is the largest on the LLC, suggesting that a lower numeric NO_X standard may be feasible than what we proposed. The final LLC numeric standard, as further discussed in preamble Section III, is the consistent with the most stringent proposed option, pulled forward to MY 2027.

The commenters who urged EPA to further consider accessory loads in finalizing the LLC did not provide data for accessory load, but EMA provided specific suggestions of 5.0 and 5.5 kW for tractor applications. They did not provide a basis for how they arrived at these specific loads. Based on data available, we considered accessory loads when setting the final numeric value of the LLC standard. Additional discussion on how we considered accessory loads is available in preamble Section III.

We did not propose and are not finalizing standards over the LLC to apply for Spark-ignition HDE. As we explained at proposal and as we describe in Section III.D.2 of the preamble, we are finalizing other provisions to ensure emissions are controlled under lower load operation for Spark-ignition HDE (see also section 3.6.1 of this document).

With respect to EMA's comment on stop-start technologies as it applies to the LLC, see EPA's response to a similar comment regarding the FTP in section 3.2.1 of this document.

With respect to National Waste & Recycling Association comment on working with engine and short-haul manufacturers to ensure emissions control technology works in stop-start operation, we have finalized standards with the new LLC to ensure that the emissions control technology performs under these conditions. In addition, we have evaluated technologies that enable emissions control under this operation (e.g., CDA and closed-couple SCRs).

We agree with the comment from Cummins that for gaseous-fueled engine testing with a single-point fuel injection system, the cycle regression criteria should be revised from the proposal in the final provision to address the slow response of the fuel system to changes in operator demand. As such we are finalizing the allowance for the use of the statistical criteria in 40 CFR 1036.540(d)(3) to validate the LLC for these engines.

3.4 Criteria pollutant interim in-use standards

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

U.S. EPA is soliciting comment on providing manufacturers with higher (numerical) standards for an interim period to gain experience with the additional emission control technologies needed to meet the proposed heavy HDE NOx standards. [EPA-HQ-OAR-2019-0055-1186-A2, p.54]

Verification testing of both new and in-use engines helps to ensure that production engines comply with applicable emissions standards when they are initially produced (i.e., as they leave the production lines) and as they are operated in-use. As U.S. EPA notes, it generally establishes in-use test standards that are equivalent to certification standards, but has occasionally established temporary higher in-use standards when it believes that manufacturers both need to utilize new technologies to comply with proposed standards, and need additional time to evaluate the capabilities of such new technologies to control emissions as engines and vehicles operate in-use, during the time period such new standards are first implemented. [EPA-HQ-OAR-2019-0055-1186-A2, p.54]

CARB staff strongly opposes the flexibilities that U.S. EPA is considering, which would allow temporary higher numerical values when regulatory agencies perform verification testing of new or in-use engines for MY 2027 through 2033 heavy HDEs, such as during confirmatory testing, Selective Enforcement Audit (SEA) testing, and in-use off-cycle testing. [EPA-HQ-OAR-2019-0055-1186-A2, p.54]

The interim in-use standards for new engines that U.S. EPA is considering are extremely high (i.e., loose), and further margin allowance would make the standards even higher and looser. These interim in-use standards lie somewhere between 1.4 to 2 times the certification standards for confirmatory and SEA testing, and 1.4 to 2 times the off-cycle standards for in-use testing. For off-cycle standards, this allowance is on top of the in-use thresholds which, depending on MY, are already 2 times or 1.5 times the certification standard and also include an additional proposed 10 percent measurement allowance. U.S. EPA's justification for providing these extremely high in-use standards is an asserted need to take into account '…the degree to which there is uncertainty in how the emissions control technologies deteriorate when the engine is installed in the wide variety of HD vehicle applications that exist in the marketplace and how to address such uncertainty.' [EPA-HQ-OAR-2019-0055-1186-A2, p.54]

However, the confirmatory and SEA tests are laboratory tests on certification duty cycles and not in field testing, and hence there is no reason why the test results should not be as close as possible to the certification levels the manufacturer submitted during certification. In fact, new engines tested under SEA should have no deterioration effects and should have lower emissions than their certification test results, similar to the zero-hour (de-green) test results in the Stage 3 and Stage 3 RW demonstration programs. [EPA-HQ-OAR-2019-0055-1186-A2, p.54]

U.S. EPA's rationale for the verification test standards for new engines is therefore inconsistent with the evidence, and U.S. EPA has also failed to articulate a rational connection between the facts and its proposal. State Farm, 463 U.S. at 43. [EPA-HQ-OAR-2019-0055-1186-A2, p.55]

CARB staff is especially concerned that U.S. EPA has not fully considered the adverse emissions consequences of this proposal. The proposed increased allowances will apparently at least double the allowable levels of pollutants emitted by heavy HDEs for a period of seven years, thereby effectively diluting the stringency of the Option 1 standards for heavy HDEs to Option 2 standards, which CARB has previously explained in Section 5 are impermissibly inconsistent with the statutory mandate of CAA section 202(a), and making it difficult for California and other states with air quality issues to meet their air quality goals. CARB staff strongly urges U.S. EPA not to include the interim in-use standard in its final rule. [EPA-HQ-OAR-2019-0055-1186-A2, p.55]

U.S. EPA's failure to analyze the scope and extent of the increased emissions resulting from this proposal, and their impacts on the public's health and welfare constitutes a failure to consider an important aspect of this proposal, State Farm, 463 U.S. at 43, and an impermissible abdication of U.S. EPA's duty to ensure affected heavy-duty engines and vehicles mandates of CAA section 202(a) to ensure heavy-duty vehicles and engines comply with applicable emissions standards throughout applicable useful lives. CAA sections 202(a)(1), 202(a)(3), Chevron, 467 U.S. at 842-843. (See CARB comment at Section 5.a, infra) [EPA-HQ-OAR-2019-0055-1186-A2, p.55]

CARB staff suggests that U.S. EPA consider how early reduction credits (i.e., producing lower FEL engines to generate credits) could provide any needed relief if manufacturers determine that they need to provide additional compliance margin during the introduction of compliant engines at a higher FEL (i.e., by producing credit consuming engines). Manufacturers will be producing cleaner FEL engines meeting the Omnibus more stringent standards starting with MY 2022, and those engines would produce significantly more credits under the federal HD program between 2022 through 2026 MYs. If manufacturers determine they need more margin, they can plan accordingly. By encouraging early action, this flexibility approach would also provide earlier emission reduction in our most vulnerable communities impacted by heavy HDE emissions. [EPA-HQ-OAR-2019-0055-1186-A2, p.56]

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

As part of Option 1, EPA proposes several changes to its laboratory-based duty cycle tests, in-use (sometimes called 'off-cycle') testing procedures, and verification testing. The current regulations must be revised to better regulate low load emissions and protect public health in communities overburdened by vehicle pollution. Commenters generally support making changes to close gaps in the current duty cycle and in-use testing procedures to reduce the amount of dangerous air pollution breathed by individuals living, working, and attending school in near-road communities. But Commenters oppose EPA's proposed 'flexibilities' that would weaken verification testing. [Comment also included in Chapter 11.6.1] [EPA-HQ-OAR-2019-0055-1302-A1, p.54]

Among the Option 1 'flexibilities' on which EPA requests comment is a drastic weakening of the standards' verification testing for Heavy Heavy-Duty Engines (HHDEs)—one that would permit emissions that vastly exceed EPA's proposed standards. The three types of verification testing include: confirmatory testing, in which EPA verifies a manufacturer's test results before an engine is certified; selective enforcement audit, in which EPA conducts testing of engines that come off the production line; and in-use testing of engines that have already entered commerce. 87 Fed. Reg. at 17,563. EPA's proposed 'interim in-use [NOx] standard[s]' for HHDEs would be based on purported 'uncertainty in how the emissions control technologies deteriorate.' 87 Fed. Reg. at 17,563–65. The proposed flexibility is discussed in terms that suggest that it would apply not just to in-use testing, but also to confirmatory and selective enforcement audits. But EPA's justification—the possibility of deterioration in control technologies' performance—has no bearing on confirmatory testing or selective enforcement audits, which apply to new engines that have not deteriorated. There is no basis for applying the proposed interim in-use standards during either confirmatory testing or selective enforcement audits. [EPA-HQ-OAR-2019-0055-1302-A1, pp.56-57]

As for in-use testing, EPA's standards already incorporate a margin for deterioration over time; providing an additional allowance for deterioration in EPA's in-use testing effectively double-counts that anticipated decrease in effectiveness. To the extent any further residual uncertainties remain, EPA's proposed rule—through its crediting and averaging provisions, as well as its generous scaling and measurement allowances—provides ample allowance for them. Id. at 17,467, 17,469, 17,474, 17,553. There is consequently no reasonable basis for the inflated testing standards—even at the low end of the suggested range of alternative standards, let alone the high end—for which EPA has requested comment. Id. at 17,564. Including the proposed interim in-use standards would establish a substantial incentive for manufacturers to design engines to the weaker standards, after certification, or to avoid the cost of long-lasting components that would ensure sustained emissions performance. See, e.g., Notices of Filing Consent Decrees, 63 Fed. Reg. 59,330–34 (Nov. 3, 1998) (describing enforcement actions against manufacturers over defeat-devices that relaxed emissions controls after certification testing). The record fully demonstrates the feasibility of meeting Option 1's standards without an additional allowance for deterioration. See DRIA at 108–30 (describing feasibility testing from Southwest Research Institute).238 [EPA-HQ-OAR-2019-0055-1302-A1, p.57]

> 238 See also Achates Power, Heavy-Duty Diesel Engine In-Use Testing (last accessed May 12, 2022), https://achatespower.com/wp-content/uploads/2022/04/Achates-Power-Heavy-Duty-Diesel-In-Use-Testing-Results.p df (testing of opposed-piston design, in fleet service with Walmart Corporation, achieving emissions well below Option 1 standards throughout life).

Organization: *Cummins Inc. (Cummins)*

EMA's comments and associated reports describe those issues and many others in detail, pointing to the need for continued work by both EPA and industry to evaluate improvements that should be implemented for the final rule, not just in the test and analysis protocols, but also with respect to compliance measures and stringency. As stated before, Option 1 is not feasible, including the proposed Option 1 off-cycle standards. For Option 2, a higher interim in-use conformity factor should be considered while manufacturers gain experience with new technologies and new 3B-MAW protocol. Also mentioned before, if EPA does finalize increases to today's useful life periods, it will need to account for additional uncertainty and variability in the deterioration of engines operated in the field by prescribing additional in-use margins to the off-cycle standards. [EPA-HQ-OAR-2019-0055-1325-A1, p. 13]

Organization: *International Council on Clean Transportation (ICCT)*

The technical concerns expressed by the manufacturers that the proposed standards cannot be met, in part due to a lack of compliance margin, are not warranted as the latest research by SwRI shows that with the remaining lead time the proposed emission standards can be met. [EPA-HQ-OAR-2019-0055-1211-A1, p. 9]

SwRI provides an example of compliance for both the traditional FTP cycle as well as the much-needed LLC, with ample compliance margin for an 800,000-mile useful life. The past manufacturer comments present an incomplete picture of the technical analysis performed by SwRI to evaluate the EPA proposal, specifically at the extended UL requirements. Manufacturers claim that the basis of the current evaluation was the previous research work for ARB's Low NOx omnibus rule, which included the technical package known as "Stage 3" aged to 435k miles. They claim that EPA contracted with SwRI to "perform an aged demonstration with a technical solution very similar to the CARB "Stage 3" technology package. Thus, the SwRI system is the principal basis for the purported feasibility of the 0.02 g/bhp-hr NOx standard". [EPA-HQ-OAR-2019-0055-1211-A1, p. 9]

What the manufacturer comments fail to mention is that aftertreatment aging was extended by SwRI to cover the 800,000 miles for the proposed UL. Moreover, the Stage 3 demonstration is only one potential pathway to meet the standards. European manufacturers are exploring other technology options (e.g., heated catalysts) to meet planned Euro VII standards. [EPA-HQ-OAR-2019-0055-1211-A1, p. 9]

The manufacturers claim that EPA has not demonstrated the technical feasibility of the standards, however, their claims are unfounded. [EPA-HQ-OAR-2019-0055-1211-A1, p. 10]

First, manufacturers claim that the Stage 3 aged-engine NOx emissions results do not demonstrate feasibility across all required certification cycles and extended UL. This is not up to date with the latest information. The latest SwRI update from April 2022 demonstrated composite FTP results of 27 mg/bhp-hr at 600k miles, which demonstrates feasibility for the 2027-2030 proposal with a margin of 23%; and 37 mg/bhp-hr at 800k, which demonstrates feasibility for the MY2031 and beyond with 8% margin.13 [EPA-HQ-OAR-2019-0055-1211-A1, p. 10]

13. Chris Sharpe et al. (2022). An Update on Continuing Progress Towards Heavy-Duty Low NOx and CO2 in 2027 and Beyond. Southwest Research institute. SAE World Congress Experience (April 5-6 2022).

Another consideration that supports the feasibility of the proposed NOx standards is that once the engine begins in-use operation, off-cycle, in-use compliance standards become numerically less stringent than the certification standards. The in-use standards provide extra margin to account for unexpected emission deterioration and engine-to-engine variability, compared to the certification standards. The proposed off-cycle in-use emission standards for non-idle Bins 2 and 3 are two times the certification standards for 2027-30, and 1.5 times the certification standards for 2031+. The 150 mg in-use standard for the 2031 LLC cycle for HHD engines between 435K and 800K miles is particularly generous, when compared to the projected SWRI data indicating less than 50 mg at full useful life (see EPA's Figure 3-17 from the TSD, reproduced above). These generous in-use standards support the feasibility of the proposed standards by reducing in the initial years the compliance risk that engines have higher emissions than anticipated. [EPA-HQ-OAR-2019-0055-1211-A1, p. 9]

Organization: *Motor & Equipment Manufacturers Association (MEMA)*

Most of the agency's laboratory work concentrated on aftertreatment aging rather than full engine aging. As a result, data regarding the impact of engine aging on components such as exhaust gas recirculation, camshafts, fuel injectors, turbochargers, piston rings, sensors, and electronics is lacking. [EPA-HQ-OAR-2019-0055-1322-A1, p. 4]

EPA also requested comment on whether they should finalize interim standards for testing used to verify that the engine meets the standards through its useful life. Unfortunately, significant additional testing is required. Much of SWRI's recent research focused on aftertreatment aging, and therefore was not as focused on full engine aging. As a result, not as much data is available on EGR aging, cam wear, fuel injection holes, turbochargers, oil control rings, etc. In addition, due to the variety and complexities of real-world use, many vocational cycles have very different demands resulting in an unknown statistical performance distribution. Estimating full commercial vehicle impacts based on this limited SWRI testing could be problematic – especially for vocational vehicles. Also, the industry does not have near as much data regarding 2nd and 3rd vehicle owner usage. As a result of these shortcomings, MEMA recommends that EPA include significantly more compliance margin for in-use testing standards. [EPA-HQ-OAR-2019-0055-1322-A1, pp. 6 - 7]

Organization: *National Association of Clean Air Agencies (NACAA)*

NACAA does not support finalizing any interim in-use emission standards. [EPA-HQ-OAR-2019-0055-1232-A1, p. 13]

EPA requests comment on a flexibility to provide manufacturers with higher numeric interim in-use standards for verification testing for heavy HD trucks. In particular, when in-use testing is conducted to verify that an in-use heavy HD truck meets applicable duty cycle or off-cycle emission standards throughout useful life, the vehicle would be held to a much less stringent standard from MY 2027 through MY 2033 (the "interim period"). According to the scenario on which EPA seeks comment, the interim in-use standard could be up to 100 percent of (or double) the actual standard. EPA says the reason for this provision would be to allow manufacturers time to gain experience with the emission control technologies while they are operating in the field. EPA also says that depending on what it observes as part of its engine demonstration study it may consider adopting even more lenient interim in-use standards in the final rule. [EPA-HQ-OAR-2019-0055-1232-A1, p. 13]

Under this scheme, it appears EPA would also forfeit its own authority to verify manufacturer-provided data as even EPA's testing of new Selective Enforcement Audit engines or the manufacturer's certification engine itself could not be held to the regular emissions standard. Beyond the likely emissions consequences of not pursuing corrective action on engines emitting at up to twice the standard, such so-called in-use standards set up a perverse motivation for manufacturers, who would be on notice that their certification submissions effectively could not be audited. This is not theoretical as there is a recent incident of fraudulent certification submissions by a heavy-duty engine manufacturer, resulting in loss of engine customers, truck and construction equipment manufacturing jobs and even permanent plant closure.30,31,32,33 [EPA-HQ-OAR-2019-0055-1232-A1, p. 13]

33 https://www.reuters.com/world/asia-pacific/japan-revoke-hinos-engine-certification-over-false-emissions-data-2022-03-18/

EPA should not finalize any interim in-use standards. Such "flexibility" is inappropriate and would weaken the rule's effectiveness in reducing emissions and protecting public health. Gaining experience with emission control technologies should be addressed by manufacturers during product development, not after vehicles are sold. [EPA-HQ-OAR-2019-0055-1232-A1, p. 14]

Organization: *Navistar, Inc. (Navistar)*

In setting higher interim in-use NOx standards in the final rule, EPA should take into account the inherent variability of in-use testing. For example, any factor that deviates from the original test cell environment and reference methods must be assumed to contribute to in service test variability including temperature, humidity, elevation, PEMS measurement allowance, test route, vehicle maintenance history, fuel temperature, and fuel usage history. These are all aspects of the in service fleet specific operation that are largely out of control of the OEM. The addition of the LLC test cycle, while designed to capture low load emissions, relies on engine broadcast load (torque), which does not provide the same level of precision and accuracy as the engine dyno reference method. As a result, we believe that EPA should provide a significant compliance margin initially to account for all of the various new requirements. Manufacturers need sufficient time to develop and validate a robust compliant calibration. Lessons learned from the 2010 emissions standard highlighted weaknesses in both the hardware and software strategy of every OEM. Early examples of SCR-equipped trucks experienced a range of technical issues as fleets and OEMs struggled to adapt to the new technology. By 2013, the design shortcomings were resolved and fleets learned how to operate and maintain the trucks properly. We believe that a similar or longer transition period, 3-5 years, may be necessary, given the simultaneous change in the standard, technology, testing, and customer acceptance. [EPA-HQ-OAR-2019-0055-1318-A1, p. 4]

Organization: *Northeast States for Coordinated Air Use Management (NESCAUM)*

Should EPA instead promulgate Option 1, we urge the Agency to make the following changes to the proposed standards: EPA is considering finalizing higher temporary in-use standards for all the proposed duty cycle and off-cycle heavy-duty engines and requests comment on whether the Agency should consider including in the final rule interim in-use standards to account for potential variabilities in performance during the early years of implementing new technology. Tables IV-16 and IV-17 of the preamble list potential low-end and high-end ranges for the proposed in-use standards. NESCAUM requests that EPA not finalize the proposed interim in-use standards, or if interim standards are finalized, that they be significantly more stringent than the ones proposed. With regard to the proposed low load interim in-use standards, test data show that NOx emissions of 0.036 to 0.053 g/bhp-hr on the CARB low load cycle are technically feasible. Manufacturers will have five years to prepare for commercial application of technologies to reduce low load emissions and finalizing NOx emissions standards in-use between 0.07 to 0.20 g/bhp-hr (70 mg/bhp-hr to 200 mg/bhp-hr) would substantially weaken the low load emissions requirements. Similarly, the FTP, SET, and idle interim in-use standards EPA is considering are significantly higher than what has already been demonstrated at intermediate and full useful life.[EPA-HQ-OAR-2019-0055-1249-A1, p. 14]

Organization: *Ozone Transport Commission (OTC) and Mid-Atlantic/Northeast Visibility Union (MANE-VU)*

Interim In-Use Standards: EPA is considering finalizing higher temporary in-use standards for all the proposed duty cycle and off-cycle heavy-duty engines and requested comment on whether the Agency should consider including in the final rule interim in-use standards to account for potential variabilities in performance during the early years of implementing new technology. Tables IV-16 and IV-17 of the preamble list potential low-end and high-end ranges for the potential in-use standards. OTC requests that EPA not finalize the proposed interim in-use standards, or if interim standards are finalized, that they be significantly more stringent than the ones proposed. With regard to the low load interim in-use standards proposed, test data show that NOx emissions of 0.036 to 0.053 g/bhp-hr on the CARB low load cycle are technically feasible. [EPA-HQ-OAR-2019-0055-1250-A1, p.15]

Manufacturers will have five years to prepare for commercial application of technologies to reduce low load emissions. Therefore, finalizing in-use NOx emissions standards between 0.07 to 0.20 g/bhp-hr (70 mg/bhp-hr to 200 mg/bhp-hr) would substantially weaken the low load emissions requirements. Similarly, the FTP, SET, and idle interim in-use standards EPA is considering are significantly higher than what has already been demonstrated at intermediate and full useful life. [EPA-HQ-OAR-2019-0055-1250-A1, p.15]

Organization: *PACCAR, Inc (PACCAR)*

In particular, PACCAR agrees with the following aspects of EMA's comments: A nationwide program centered around Option 2-like requirements, and including higher interim in-use standards, would be more cost-effective, and would reduce the prospects for further delaying fleet turnover or creating disruptive pre-buy/no-buy responses from the market. [EPA-HQ-OAR-2019-0055-1346-A1, p.2]

Organization: *States of California, et al. (The States)*

The States further recommend that EPA not adopt certain compliance flexibilities in the Proposed Rule, to the extent such flexibilities undermine the emission benefits of Option 1. Most notably, EPA should not adopt the proposed interim "in-use" standards—which are based on emissions from vehicles in operation – that are significantly less stringent than the certification standards that new engines must meet. [EPA-HQ-OAR-2019-0055-1255-A1, p. 3]

EPA should not adopt interim in-use emission standards less stringent than the standards to which manufacturers certify new engines. These proposed interim in-use standards permit 1.4 to 2 times more NOx emissions than the standards to which engines are certified under Option 1,72 effectively turning Option 1 standards into Option 2 standards immediately after certification. As EPA recognizes, this proposal departs from EPA's typical practice, which is to "set[] the same standards for certification testing and in-use testing."73 The industry concerns that EPA cites in support of this departure—"to give manufacturers time to gain experience with the new technology needed to meet the standards and [to] reflect uncertainties about potential variabilities in performance during the early years of implementing new technology"—do not justify such a dramatic relaxation of emission standards vital to protecting the health and welfare of our residents.74 The selective catalytic reduction (SCR) technologies at the heart of the NOx standards are not novel, but are refined technologies that have been used in the heavy-duty sector for more than a decade.75 Moreover, because CARB's Omnibus Rule takes effect three years in advance of model year 2027, the heavy-duty sector will have the benefit of several years of research, development, experimentation, and troubleshooting to ensure engines perform as expected.76 [EPA-HQ-OAR-2019-0055-1255-A1, pp. 17 - 18]

Reg. 5002, 5053 (Jan. 18, 2001) (discussing initial development of SCR technologies for NOx control within the heavy-duty fleet).

76. 87 Fed. Reg. at 14,434.

Furthermore, manufacturers already may protect against "uncertainties about potential variabilities in performance" of this technology through other strategies EPA acknowledges or proposes as flexibilities: most importantly, through (1) compliance margins built into engines by manufacturers; (2) the generous scaling factors and measurement allowances EPA builds into the proposed off-cycle standards; and (3) the use of NOx credits.77 Each of these measures is intended to or can be used to address unexpected performance deficiencies or similar discrepancies between certification standards and real-world performance. Thus, for example, if a manufacturer is concerned that its engines' aftertreatment components will deteriorate over time, and it cannot or chooses not to design its engines with an extra margin, the manufacturer can generate and bank credits in the lead-up to model year 2027 (for example, by introducing HD ZEV models into its fleet) to ensure it remains compliant. [EPA-HQ-OAR-2019-0055-1255-A1, p. 18]

77. Id. at 14,467, 14,469 (describing manufacturer-included margins for deterioration); id. at 17,474 (proposing off-cycle standards 1.5 to 2 times the certification standards and 10 percent allowance for measurement error); id. at 17,553 (discussing five-year credit life to "cover the transition to more stringent standards").

But the proposed interim in-use standards as proposed create a perverse incentive to manufacturers to design their engines to those looser in-use standards, as long as they can pass the certification tests initially. EPA and the States have too much enforcement experience with defeat devices to pretend this incentive will be universally resisted.78 Even a manufacturer not intending to defeat the standards will face cost incentives to use lower-quality components in aftertreatment systems that may degrade shortly after certification, with the same effect of noncompliance.79 In short, this proposal is likely to increase emissions well beyond Option 1 standards in practice. Therefore, EPA should reject this portion of the proposal and design its NOx standards to incentivize against engine component degradation and merely temporary compliance. [EPA-HQ-OAR-2019-0055-1255-A1, pp. 18 - 19]

78. See, e.g., Notices of Filing of Consent Decrees Under the Clean Air Act, 63 Fed. Reg. 59,330-34 (Nov. 3, 1998) (describing consent decrees against Caterpillar, Inc., Cummins Engine Co., Detroit Diesel Corp., Mack Trucks, Inc., Renault Vehicules Industriels, Navistar International Corp., and Volvo Truck Corp. to resolve enforcement actions by USDOJ and CARB over emission-control defeat devices installed by these companies in their heavy-duty diesel engines, which resulted in poorer performance of the engines' NOx control systems in use than in certification testing).

79. Cf. U.S. EPA, "EPA Announces Largest Voluntary Recall of Medium- and Heavy-Duty Trucks" (July 31, 2008) (describing 2018 recall of 500,000 model year 2010-2015 medium- and heavy-duty trucks due to SCR system components that degraded within a few years of operation), EPA-HQ-OAR-2019-0055-0146.

Organization: *Truck and Engine Manufacturers Association (EMA)*

In order to ensure the adoption of fully achievable and cost-effective HDOH low-NOx regulations, and notwithstanding our broader agreement, the Agency should revise the proposed standards in the following manner:

> (vii) As the Agency suggests in the NPRM, the final rule should include higher interim NOx standards for a sufficient number of years to allow manufacturers to gain in-field experience with the additional emission-control technologies that will be required, and to gather real-world data to assess how those systems perform and age under real world operating conditions out to the extended useful life periods. In that regard, higher interim NOx standards to facilitate the implementation of the new stringent low-NOx requirements (including, for example, through higher interim in-use multipliers) are distinct from the type of two-step progressively more stringent standards that EPA has included in Option 1. Those types of two-step emission standards raise fundamental feasibility and resource-constraint issues for manufacturers, including due to the potential need for additional engine hardware and software to comply with the second step, and ultimately would overlap and conflict with the Phase 3 GHG standards that EPA is beginning to develop. [EPA-HQ-OAR-2019-0055-1203-A1, p. 7]

Thus, and as detailed further below, EMA strongly agrees that the Agency should include in the final rule "interim in-use standards to account for uncertainties about potential variabilities in performance during the early years of implementing new technology." (87 FR at p. 17564.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 14]

As mentioned earlier in these comments, EPA and engine manufacturers need time to become familiar with the completely overhauled in-use test protocol and measurement processes, the capabilities and weaknesses of the ultra-low NOx emissions technology packages of the future, the impacts of a diverse and evolving market fuel-mix over newly-extended useful life requirements, and the numerous other factors that drive the uncertainty all stakeholders are faced with during the course of this rulemaking. Applying a conformity factor of 2.0 for the first 7 years following the effective date of these new standards will provide that prove-out time wihout undue risks of noncompliance. This aspect of EMA's proposal is addressed directly in Section 9 of these comments. Failing to provide adequately for a higher inteirm standard would unjustifiably and unnecessarily put engine manufacturers at risk of managing products in the field that were in a state of perpetual recall, simply because the requisite data was not available to set standards in line with the realistic capability of the available technology. [EPA-HQ-OAR-2019-0055-1203-A1, p. 81]

For all of the reasons discussed above, higher interim in-use standards for NOx (i.e., using a 2x conformity factor as opposed to a 1.5x conformity factor) are warranted for the first several model years after the new low-NOx standards take effect in MY 2027. EPA has implicitly conceded as much in "soliciting comment on providing engine manufacturers with higher (numerical) standards for an interim period to gain experience with the additional emissions control technologies needed to meet the proposed Heavy HDE standards (and their rates of deterioration) while those technologies are operating in the field." (87 FR at p. 17563.) EPA further explains the clear justification for higher interim standards, as follows: Manufacturers could use the interim period to collect data from field-aged engines in a range of applications to inform how the engines can be designed to meet the standards throughout useful life for all applications in which the engine is used. In setting the duration of an interim period, we would consider how long it would take manufacturers to collect field data from engines operating out to the full useful life mileage ultimately finalized in this rule. (Id.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 104]

EMA fully agrees with the Agency's assessment of the need for higher interim in-use NOx standards. The known and unknown risks of early model-year product non-compliance are too great without a reasonable phase-in of the final in-use low-NOx standards to allow for a robust assessment of how the new Stage 3-type systems will age and perform out to the new extended UL and warranty periods. To address those risks, EMA recommends setting the interim in-use NOx standards by applying a 2x in-use conformity factor for the first seven model years following the implementation of the new low-NOx standards (i.e., through and including MY 2033). Thereafter, the in-use conformity factor could drop to 1.5. [EPA-HQ-OAR-2019-0055-1203-A1, p. 104]

EPA maintains a publicly available database containing information and test results that manufacturers submit with their annual applications for Certificates of Conformity, a prerequisite to offering engine products for sale in the U.S. Among the data included in those databases are the manufacturers' emissions test results recorded on the engines for which EPA approvals are sought. "Deteriorated" emissions test results (actual test results modified to include emissions deterioration factors) were compared to the underlying standard (or Family Emissions Limit ("FEL") in cases where the manufacturer chose to certify the engine family to a level different from the applicable standard as permitted under credit "averaging, banking and trading" programs). The compliance margin that manufacturers are building-in can be readily determined from this analysis. EMA scanned all relevant data from a single model year for each of the previous four NOx emission reduction steps to calculate the average compliance margin in each case.8 The single model year was specifically selected to represent a "mature" view of the compliance margin to which manufacturers had "settled in" (that is, after compliant engines had been in production for a number of model years). The average FTP transient test margins are presented below in absolute and percent-of-standard terms: [EPA-HQ-OAR-2019-0055-1203-A1, p. 27]

Source	**Model Year**	**No. of Families**	**Standard (g/bhp-hr)**	**Margin (g/bhp-hr)**	**% Margin**
EPA database	2001	45	4.0	0.27	6.5%
EPA database	2006	52	2.5	0.17	6.9%
EPA database	2009	31	1.2	0.12	10.0%
EPA database	2021	26	0.20	0.074	37.1%

8. Certification test results from all heavy-duty diesel on-highway engine families included in the EPA database as manufactured by major manufacturers Cummins, DDC/Daimler, Volvo, Navistar, PACCAR, Hino and Isuzu were used (smaller

manufacturer submissions were excluded). For consistency, and to maintain a view of margin's relationship to the relevant standard, engine families were excluded if they were certified to an FEL less than or greater than 15% of the applicable NOx (or NOx + NMHC) standard. For the NOx "phase-in" period from 2007-2009 the relevant NOx standard was assumed to be the "equally-split family" FEL of 1.2 g/bhp-hr.

It is readily apparent that there has been a decreasing trend in the absolute (g/bhp-hr) margin (NOx standard minus deteriorated certification result) as NOx standards have decreased. That is, of course, necessary – the average margin of 0.27 g/bhphr for the US98 standard would be fundamentally unworkable with a US10 standard of 0.20 g/bhp-hr. More significantly, when examined as a percent of standard, the trend reveals a steadily increasing margin (orange line in graphic above) as NOx standards decrease (from right to left), with the most significant increase associated with the current US10 standard.9 The reason for this trend is simple – the level of variability in production diesel engine emissions control, and long-term degradation, has not decreased linearly with the NOx emissions standards themselves. Thus, the percentage of the standard reflected in those margins has gone up. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 27 - 28]

9. A similar examination shows steady-state cycle (or Ramped Modal Cycle) average US10 certification margins to have increased to 70% of the NOx standard.

This should, in fact, be expected. Today's aftertreatment-based emissions control systems are far more complex than the systems deployed to comply with US98 and US04, and therefore more sensitive to ambient and other external influences, as well as sensor inaccuracies and the expected range of production variability. Furthermore, tailpipe NOx emissions are very sensitive to SCR efficiency, and therefore the "high end" of long-term SCR degradation from fuel impurities, including metals in biofuel blends, or even severe service applications, can compromise NOx control to a significant degree. Additionally, more fundamental factors that influence margin requirements, such as laboratory or field emissions measurement system accuracy, have not improved at levels proportional to the reductions of the underlying standards over the years. All of those factors, and more, have required diesel engine manufacturers to increase the requisite margin relative to the standard to ensure robust post-production compliance. [EPA-HQ-OAR-2019-0055-1203-A1, p. 28]

Further evidence that manufacturers depend on significant compliance margins comes from the fact that, despite the current on-average 37% margins, not a single HD diesel engine manufacturer had certified an engine family to a level below the current 0.20 g/bhp-hr standard until a single manufacturer did so with MY 2022. Certifying engine families to an FEL below the standard would allow a manufacturer to earn emissions credits, which would be extremely valuable as part of a product development plan to transition toward future low-NOx standards. Yet even so, and after more than a decade of experience with the current US10 standards, and despite manufacturers' knowledge that a 75%-90% reduction in the NOx standard is being targeted (making credits that much more valuable), not a single HD highway diesel engine manufacturer had taken the risk to certify products with an FEL less than the current 0.20 g/bhp-hr standard through model year 2021. As noted, one manufacturer has recently submitted model year 2022 applications for FEL-generating families in California, but even in that case, the manufacturer's deteriorated certification test results are much less than 50% of the FEL, yielding a margin greater than 50%. This pervasive reluctance to certify with an FEL below the current 0.20 g/bhp-hr NOx standard, except in cases where unusually high margins can be provided for, highlights how essential significant compliance margins have become to ensure robust real-world emissions compliance. [EPA-HQ-OAR-2019-0055-1203-A1, p. 28]

EPA's failure to consider or provide for the necessary emissions-compliance margins is one of the key factors that establishes the fundamental infeasibility of Option 1. It also is a key factor in the assessment of how the Option 2 proposal will need to be modified. Indeed, without having conducted a careful examination of how the relevant real-world factors will contribute to the necessary margin requirements associated the proposed low-NOx standards, it is clear that EPA's assertions of technical feasibility are deficient and, at best, premature. [EPA-HQ-OAR-2019-0055-1203-A1, p. 28]

In quantifying this issue, the percent of margin is clearly a more compelling metric than the absolute margin. If we return to the graph of progressively increasing emissions margins, the shape of the orange curve indicates that it could be instructive to plot average manufacturer margin on a logarithmic scale. If we do so, and extrapolate the US04-to-US10 trend in a straight-line manner to a proposed 0.020 g/bhp-hr standard, the percent of margin required by this method would be just over 70%, which translates to an absolute margin of 0.014 g/bhp-hr, as depicted below: [EPA-HQ-OAR-2019-0055-1203-A1, pp. 28 - 29]

Including these calculated margin requirements on the original linear-scaled graph yields the following graphic: [EPA-HQ-OAR-2019-0055-1203-A1, p. 29]

The dramatic bend in the absolute margin curve (in blue) is very concerning. EPA's inherent assumption that less margin is needed than the calculated 0.014 g/bhp-hr shown, would only sharpen the bend in the curve, and be even more concerning. The bottom line is that assuming the percentage trends in margin requirements continue to hold – and there is no reason to assume otherwise – in order to meet an Option 1 0.020 g/bhp-hr NOx standard in a manner that could reasonably assure post-production compliance, diesel engine manufacturers would need to target an "as-designed" emissions performance level at or below 0.006 g/bhp-hr. There is no evidence – none – that such a zero-equivalent NOx level is feasible. Indeed, if one considers the trends in absolute margins, manufacturers would need to target negative emissions from their engines, which is, of course, irrational and impossible. Again, the relevant data demonstrate that Option 1 is not feasible and should be abandoned. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 29 - 30]

While EMA concedes that this extrapolation exercise does not provide a complete technical basis for understanding margin requirements in an era of ultra-low HDOH NOx standards, it is nonetheless worthy of consideration. All diesel engine manufacturers will have to determine the level of margin required to comply with future emissions standards based on the capabilities of their emissions control systems. EPA should not gloss over or ignore the significance of this point. Compliance margin is a factor that the regulators – not just manufacturers – should account for in assessing feasibility. Accordingly, EPA simply should not finalize this rulemaking until this issue has been fully and fairly accounted for. [EPA-HQ-OAR-2019-0055-1203-A1, p. 30]

EMA has started to examine in more detail the influence of individual external variables on the stability of tailpipe NOx emissions control. EMA's approach is to combine in a statistical manner the factors that can increase tailpipe NOx variability, while also including those factors that drive a mean offset to tailpipe emissions, in an attempt to calculate how much additional improvement manufacturers will have to achieve relative to the demonstrated performance of the Stage 3 RW solution. The analysis seeks to take into account all those factors for which diesel engine manufacturers will be held accountable for emissions compliance, but that so far have not been considered as part of the Stage 3 RW (or CARB Stage 3) testing to demonstrate "technical feasibility." [EPA-HQ-OAR-2019-0055-1203-A1, p. 30]

Recall that the Stage 3 RW achieved a 0.022 g/bhp-hr tailpipe FTP NOx emissions result at 435,000 miles. (Indeed, the CARB Stage 3 engine generated an FTP result of 0.031 g/bhp-hr at just 290,000 miles equivalent aging (purportedly to justify a 0.020 g/bhp-hr NOx standard), before the engine was recalibrated mid-testing to reduce the tailpipe NOx to 0.023 g/bhp-hr at the expense of an almost 1% CO2 emissions penalty.) EMA has identified multiple factors, not yet considered by EPA, that would increase that demonstrated result by varying amounts. In light of those multiple factors, it is obvious that manufacturers would be left to improve upon the Stage 3 demonstrated result, first to eliminate the 0.002 g/bhp-hr exceedance as measured by SwRI, and second to overcome the multiple real-world emissions-aggravating factors. [EPA-HQ-OAR-2019-0055-1203-A1, p. 30]

The mathematical method applied in this "margin-stackup" analysis is straightforward and typical of multiple variability-source analyses: [EPA-HQ-OAR-2019-0055-1203-A1, p. 30]

The various external sources of emissions-increasing variability and mean offset that EMA has identified have been captured in a spreadsheet set up to calculate the combined effects, as follows: [EPA-HQ-OAR-2019-0055-1203-A1, p. 31]

			Estimated Tailpipe NOx impact g/bhp-hr	
Applies to Dyno	Applies In-Use	Variation/offset driving margin requirement	mean offset	std dev σ_i
		Custom calibration (e.g. SwRI demo project)	reference	
X	X	Nominal result in production	0.0020	
X	X	Production variability		0.0060
	X	Packaging limitations (long exhaust piping to LOSCR)	0.0020	
	X	Without aftertreatment preconditioning	0.0039	
X	X	Sulfur + soot accumulation (N_2O make)	0.0030	
X	X	Ash Accumulation	0.0010	
X	X	Maintenance practices		0
	X	Cold ambient operation	0.0023	
	X	Operation at altitude	0	
X	X	Severe-service duty-cycles	0	
	X	Fuel Quality, DEF quality (short term emissions effects)	0.0020	
X	X	Field deterioration (metals in bio-fuels, etc.)		0.0050
X	X	Lab measurement variability		0.0060
	X	PEMS measurement variability rel to Lab (CARB only)		0.0000
		TOTAL MARGIN REQUIREMENT, DYNO	σ =	0.016
			2σ =	0.026
		TOTAL MARGIN REQUIREMENT, IN-USE	σ =	0.026
			2σ =	0.036

Margin of σ: Protects that 84% of population are below demo reference
Margin of 2σ: Protects that 97.7% of population are below demo reference

The analysis above is a snapshot of work in progress. EMA is striving to identify the most relevant available sources of data to inform the data entries for each line item, and, to that end, we have pulled data from a variety of available sources. Several factors have been “scaled” linearly from reference levels to be reflective of the proposed new low-NOx standards, which is unduly conservative for many of the reasons discussed earlier. For example, lab-to-lab NOx measurement variability does not conveniently decrease by 90% just because the standard (and actual NOx level) is reduced by 90%. A rigorous “round robin” measurement variability test program in which EPA participated demonstrates this point clearly. As depicted below, the coefficient of variability increased as the average measured NOx value decreased: [EPA-HQ-OAR-2019-0055-1203-A1, p. 32]

To give another example of how available data were used to populate the margin stack-up table, consider the item identified in the table as “Fuel quality, DEF quality.” For that element of the necessary variability allowance, EMA acquired information from an OEM reporting a 0.007 g/bhp-hr increase in NOx from a US10-compliant engine fueled with B20 when tested over certification cycles, compared to operation with certification-spec fuel. When those results are scaled down conservatively to the proposed NOx standard of 0.020 g/bhp-hr, the resultant fuel impact increase is 0.0014 g/bhp-hr. A second relevant data source is a 2021 CARB study where the impact of a 35% biofuel blend was assessed on “new technology diesel engines” (“NTDE”).10 In that study, NOx emissions increased over the FTP on a 2019 Cummins HDOH engine, and over the NRTC on a 2018 NTDE non-road Caterpillar engine. The (again, conservatively) scaled-down results from those tests would forecast a fuel-impact increase in NOx emissions of 0.0090 to 0.0178 g/bhp-hr from operation on biofuel. Several stakeholders have expressed concerns regarding the validity of the CARB study. Accordingly, in the margin stack-up table above, EMA has relied mainly on the much lower reported NOx increase from the OEM's fuel-impacts testing. In reality, however, we have no basis to assume the results would scale with the absolute tailpipe emissions, but EMA conservatively makes this preliminary estimate in the absence of other data. [EPA-HQ-OAR-2019-0055-1203-A1, p. 32]

> 10. CARB Low Emission Diesel Study (LED): Low Emission Diesel (LED) Study: Biodiesel and Renewable Diesel Emissions in Legacy and New Technology Diesel Engines - Final Report (ca.gov)

Based on all of this information, and without yet evaluating the NOx increases that may result from off-spec DEF, EMA included only a 0.0020 g/bhp-hr impact in the margin stack-up table. Importantly, the Coordinating Research Council will be evaluating the influences of several fuel formulations, including renewable fuels and biofuels, on tailpipe NOx emissions. That study, to be performed by SwRI on the EPA Stage 3 engine, should be completed by mid-year, and will be directly relevant to the margin analysis at issue. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 32 - 33]

Some factors in the stack-up analysis are more relevant to measurements in a test cell, while others are more relevant to field measurements — or "in-commerce" increments — using portable emissions measurement systems, or "PEMS". For example, cold ambient operation will impact tailpipe NOx emissions in the field, but will not be an issue impacting engine dyno tests in a lab. Several factors can play a role in both dyno-testing and in-use compliance testing. The spreadsheet is setup so that only those factors for which an "x" is entered in the appropriate columns to the left of the chart are included in the corresponding calculated results at the bottom of the chart. [EPA-HQ-OAR-2019-0055-1203-A1, p. 33]

One important aspect of this margin stack-up analysis relates to the first line item in the table, labeled "Custom calibration." This is considered the "starting point" or reference for the analysis, because the work attempts to determine how much better OEM products must be compared with the SwRI Stage 3 RW demonstration to ensure robust compliance in the field. In this case, it is important to recognize that the Stage 3 RW engine was calibrated for optimized emissions control on a single test article. If 1000 production engines were built from the same specifications and using the same controls and calibrations, we should expect the average emissions performance of those 1000 engines to be somewhat higher than the custom-calibrated engine. (Any one of those 1000 engines could then be "custom calibrated" to improve its emissions control, but such a process would not be practical for a production environment.) In the spreadsheet, this delta between the custom-calibrated result and the production average result (not to be confused with production variability), was estimated at 0.002 g/bhp-hr in the line item, "nominal result in production." [EPA-HQ-OAR-2019-0055-1203-A1, p. 33]

Another probable increase to tailpipe NOx emissions that has not yet been included in EMA's margin analysis stems from the fact that the SwRI Stage 3 engine is set up for a 500 HP rating.

That is a rating that would normally be among the higher power ratings within an engine family for an engine the size of the Stage 3 prototype. Lower horsepower ratings would, in general, produce less thermal energy over the certification (and road) cycles, which would trend toward reduced NOx conversion efficiencies from the SCR. A 400 HP rating, for example, would not be atypical for a manufacturer to provide for a Stage 3-like engine, and would likely have higher brake-specific tailpipe NOx emissions. Data showing this effect has been shared with EPA. That emissions-increasing variable is not included in EMA's margin stack-up. Nonetheless, the Agency will need to consider this point when setting the final standards, including sufficient variability allowances, relative to the emissions performance that the Stage 3 demonstration engine was able (and unable) to achieve. [EPA-HQ-OAR-2019-0055-1203-A1, p. 33]

To further illustrate the sensitivity of modern diesel engines and their emissions control systems to minor variability influences, one manufacturer conducted a Monte Carlo analysis to assess the influence of small perturbations in NOx, or NOx control variables on composite FTP results. The analysis involved simulating an array of small NOx concentration perturbations according to the uppermost graph below, coupled with minor exhaust flow measurement error sources. The range of influence to composite FTP results is shown in the graph at right. [EPA-HQ-OAR-2019-0055-1203-A1, p. 33]

This additional Monte Carlo analysis emphasizes the extreme sensitivity of tailpipe NOx emissions to small sources of variability, especially at low absolute tailpipe NOx levels. This is the concern that lies at the heart of the margin stack-up analysis, and the fundamental feasibility issues that necessarily stem from it. [EPA-HQ-OAR-2019-0055-1203-A1, p. 34]

Returning to the margin stack-up analysis, some have questioned the validity of combining several of these factors to quantify the impact on the real emissions development targets that manufacturers must establish, claiming it is unrealistic to expect all of them to occur in combination. The simple fact, however, is that as long as EPA expects manufacturers to design their products to ensure full in-use emissions compliance for all production engines and vehicles without allowing any special procedures to precondition aftertreatment systems — including under conditions just before regenerations are triggered, up to the point of the prescribed DPF ash cleaning maintenance, without regard to marginal maintenance practices, in cold ambient conditions and at high altitudes, regardless of the vehicle's application, and while operating on a wide range of market fuels (EPA's proposal would require compliance with "any commercially available biodiesel fuel blend that meets the specifications for ASTM D975 or ASTM D7467") – – then the combined effect of all of those emissions-impacting factors must be taken into account when establishing the tailpipe NOx design targets that define the requisite compliance margin. In other words, EPA must account for all of those factors when assessing what are and are not achievable standards, just as manufacturers are compelled to do. [EPA-HQ-OAR-2019-0055-1203-A1, p. 34]

Again, this "margin stack-up" analysis remains a work in progress, but the initial results are nonetheless quite striking and concerning. This evaluation, using conservative values in many cases by applying a linear scaling assumption to the proposed low-NOx standard levels, indicates that OEM products must perform 0.016 g/bhp-hr better than the Stage 3 RW engine if protecting for a 1σ compliance level (84% of production engines compliant), and 0.026 g/bhp-hr better if protecting for a 2σ compliance level (97.7% of production engine compliant). There is a clear irrationality from these results when assessed against a 0.020 g/bhp-hr standard. More specifically, the proposed standards are shown to be fundamentally infeasible, since the requisite compliance margin is larger than the standards. (Note that the analysis as shown does not account for the 0.002 g/bhp-hr by which the Stage 3 RW engine exceeded the proposed 0.020 g/bhp-hr proposed FTP transient standard, an exceedance that manufacturers will also have to make up for through improved designs.) [EPA-HQ-OAR-2019-0055-1203-A1, pp. 34 - 35]

Without making allowance for the various factors that contribute to manufacturers' necessary compliance margin requirements, EPA would be setting OEMs up for certain failure. The graph below shows the difference, in terms of NOx emissions distribution for a family population, between what manufacturers may be able to accomplish in a Stage 3 demonstration like laboratory setting (after the still-needed improvements to Stage 3 performance), and how that same engine family could perform in the field. The non-compliant zone in shaded grey, in essence, amounts to a "perpetual recall zone." In that zone, manufacturers would face a continuing series of recall actions, for which there would be no available improved technical solution to resolve the recall. Likely, the only available response from manufacturers would be to recover some level of NOx control by replacing the aftertreatment systems, which would mean that EPA would have failed to achieve one of the goals it set in this rulemaking. Alternatively, if the replacement of aftertreatment systems proved too costly or impractical, the remaining options for OEMs faced with Option 1-like standards would be perpetual recall, or exiting the market. [EPA-HQ-OAR-2019-0055-1203-A1, p. 35]

One way for EPA to account for the emission variabilities that inevitably result from real world operations, as detailed in the margin stack-up above, is to provide for a "variability allowance" that would be applied when assessing in-use emissions compliance of engines in (or from) the field. The variability allowance would be established based on best-available data, akin to that summarized in EMA's margin stack-up, and would be applied as an additive compliance margin during in-use testing, or when in-commerce engines pulled from a vehicle are dyno-tested over the certification cycles. Such an approach would avoid unfair and unwarranted compliance issues for OEMs stemming from variabilities well outside their control, while preserving the integrity of the Option 2-like standards that could be justified based on EPA's limited, and partially unsuccessful, feasibility demonstration. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 35 - 36]

Organization: *Volvo Group*

In response to the following EPA request, the Volvo Group establishes internal Compliance Margins at a fraction of the standard to account for issues such as production variability, maintenance, severe duty cycles, Fuel Quality, DEF quality, and measurement variability. At some level, the variability can exceed the standard itself. This approach is in alignment with the following EPA comment. "We understand that manufacturers generally aim to design and build vehicles not only with a sufficient margin to ensure the emissions control technology is meeting the applicable standards throughout the full useful life, but also an additional margin to reflect the fact that not every vehicle manufactured and every vehicle application will perform identically to the laboratory tests." (87 FR at p. 17564) [EPA-HQ-OAR-2019-0055-1324-A1, p. 7]

In conclusion, the Volvo Group believes the following principles must be reflected in the final regulation: a tailpipe NOx reduction which reasonably addresses in-use performance and expanded useful life requirements so fleets can have confidence in new technology and eschew purchase delays which could lead to devastating layoffs of our production workforce. [EPA-HQ-OAR-2019-0055-1324-A1, p. 10]

EPA Summary and Response

Summary:

In their comments CARB opposes interim in-use standards that would allow temporary numerically higher in-use standards. CARB states that other program elements will help reduce perceived uncertainty regarding deterioration of emissions control technologies, and additional information would be available to manufacturers due to the California Omnibus regulation's application in 2024. CARB states that, thus, there is a limited degree of uncertainty regarding deterioration of emissions control technologies, and no rationale for allowing higher interim standards. CARB further states that the increased temporary allowances would substantially increase allowable emissions, making it difficult for California and other states with air quality issues to meet their air quality goals. CARB suggests, as an alternative, that EPA consider early reduction credits to provide relief for manufacturers who believe they need additional compliance margin to meet MY 2027 and later standards. CARB states that EPA's inventory modeling didn't include the impacts of the interim in-use standard. CARB states that manufacturers will generate significant NO_x credits for engines that they build to meet the Omnibus MY 2024 standards.

With regard to general comments on higher in-use standards, CATF is concerned about additional allowances for deterioration. CATF states that these allowances double-count anticipated decreases in effectiveness and are not necessary because EPA's standards already incorporate a margin for deterioration. CATF states that including the interim in-use standard allows manufactures to design engines to less stringent limits and avoid the cost of more durable components. CATF states that, in addition, existing credit and averaging provisions, as well as scaling and measurement allowances, already address emission uncertainties. Finally, CATF indicates that Option 1 can be met without an additional allowance for deterioration.

Likewise, in their comments, NACAA states that the interim in-use standards are inappropriate and would weaken the rule, and thus should not be finalized. Also, in their comments, OTC/MANE-VU state that the interim standards should not be finalized, or if they are, they should be more stringent than the one proposed.

In their comments, EMA, Cummins, PACCAR, Volvo and Navistar supports higher interim in-use NOx standards in the final rule. These commenters state that manufacturers need time to develop a robust compliant calibration, given the inherent variability of in-use testing. Navistar comments that implementing the 2010 emissions standard highlighted weaknesses in both the hardware and software strategy of every OEM which required time to resolve. Navistar comments that the higher standards are needed for 3-5 years, while EMA states that higher standards should be in place for a sufficient number of years to allow manufacturers to gain in-field experience with the new technology. Navistar supports higher in-use standards to provide margin for temperature, humidity, elevation, PEMS measurement allowance, test route, vehicle maintenance history, fuel temperature, and fuel usage history. Cummins requests the higher standards be considered while manufacturers gain experience with new technologies and new 3B-MAW protocol. MEMA commented that much of SWRI's recent research focused on aftertreatment aging, and therefore was not as focused on full engine aging and not as much data is available on EGR aging, cam wear, fuel injection holes, turbochargers, oil control rings, etc.

EMA cites historic engine emission certification values to show that as the NOx standards have decreased over time, the compliance margin manufacturers have been certifying to have increased as a percentage of the standard. They use this, and the fact that up until MY 2022 no manufacturer has certified with an FEL below the 2010 NOx emission limit, to state that EPA has not considered or provided adequate compliance margin for the proposed Option 1.
After considering the comments and supporting information submitted, historical approaches by EPA to compliance margin in previous heavy-duty criteria pollutant standards rules, the implementation date of MY 2027, and the data collected from the EPA Stage 3 engine and other available data, as further explained in preamble Section III, EPA is finalizing an interim in-use testing allowance for compression ignition Medium and Heavy HDEs. In the preamble for the NPRM, we requested comment on if EPA should finalize higher in-use standards for Heavy HDE and other engine classes (i.e. Light and Medium HDE). Under the final rule, for any in-use testing of Medium and Heavy HDEs a 15 mg/hp-hr compliance allowance is added to the applicable standard, in consideration of the other sources of variability and deterioration of the aftertreatment that can occur once the engine enters the real world. The numeric values for the final emission standards and interim in-use testing allowance, along with how the standards and testing allowance were set, are discussed in Section III of preamble. As explained in Section III of the preamble, we are setting the standards at the level which reflects the greatest degree of emission reduction achievable that we have determined to be feasible starting in MY 2027, giving appropriate consideration to cost and other statutory factors. As discussed in Section III of the preamble, as more data becomes available in the future, we may propose a sunset date for the interim in-use testing allowance in a future rule.

Response:

With regards to comments from Navistar and Cummins on setting higher in-use standards with more margin, as discussed in preamble Section III, we are finalizing standards and test procedures that account for the factors listed. In addition, as detailed in preamble Section III, we are finalizing NOx standards as a function of ambient temperature, and we note that there is an existing NOx humidity correction to address humidity concerns, that an elevation exclusion is included in this final action in 40 CFR 1036.530, and that under the qualification criteria for the HDIUT program engines are required to be well maintained.

We disagree with comments that finalizing the interim in-use testing allowance is inappropriate and will incentivize manufacturers to develop engines that will be less durable. As explained in preamble Section III, in setting the final NO_x emission standards, EPA appropriately assessed the statutory factors specified in CAA section 202(a)(3)(A). As part of that assessment, we determined the numeric levels that are technically feasible starting in MY 2027 and included consideration of compliance margin in that assessment. Given the very long useful life mileages for Heavy HDE and greater amounts of certain aging mechanisms over the long useful life periods of Medium HDE, we determined that an interim in-use testing allowance approach was appropriate for the Medium HDE and Heavy HDE NO_x standards. The final emission standards and demonstration requirements at certification provide assurance at the time of certification that the engines will meet the standards through useful life. We also note that, as discussed further in Section III.B, for Heavy HDE we are also requiring the durability demonstration to show that the emission control system hardware is designed to comply with the NO_X standards out to 750,000 miles, as this demonstration in a controlled laboratory environment ensures that manufacturers are designing Heavy HDE to meet the final standards out to the regulatory useful life of 650,000 miles once the engine is in the real-world.

EPA appreciates the compliance margin analysis provided by EMA and has considered the data showing that the NOx compliance margin built in by manufacturers has increased with the historic increase in stringency of emission standards due to the variability of emission controls at lower NOx levels. EPA has taken this into consideration when setting the stringency for the NOx standards we are finalizing in this action, as described in preamble Section III.C.

See preamble Section III and Section 11 of the response to comments for how EPA is accounting for the portable emissions measurement systems (PEMS) measurement uncertainty.

With regard to CARB's comment on modeling the effects of the interim in-use standards, we note that we did not include higher in-use standards in the proposal but requested detailed comment on such an approach. In this final rule, we have modeled the impacts of the final interim in-use testing allowance on the NOx inventory for the final rule (see RIA Chapter 5 for the details of the emissions inventory modeling).

With regard to CARB's comment on more data being available in 2024, we acknowledge that this may be true, but we are finalizing this rule in 2022 based on the record before us.

With regard to CARB's comment on MY 2024 engines designed to meet CARB Omnibus standards generating credits to the federal NOx standards, see our response in preamble Section IV. With regard to CARB's comment on allowing manufacturers to generate NO_X emissions credits ahead of when they are required to comply with the new standards, rather than providing additional compliance margin, we point to the response in section 12 of this document and additional discussion in preamble Section IV. As described in section 12 of this document and preamble Section IV, we are finalizing a modified from proposal transitional credit program, which will allow manufacturers to generate NO_X emissions credits ahead of MY 2027; however, we are not finalizing the proposed early credit program. As further discussed in preamble Section III and IV, the final standards achieve the greatest emission reductions feasible starting in MY 2027, and do not require participation in an ABT program; the final ABT program is carefully calibrated to provide some flexibility to manufacturers to transition to meeting the final NOx standards while ensuring expected emission reductions of the program are achieved.

We acknowledge that the EPA Stage 3 demonstration conducted at SwRI was focused on the aftertreatment, however we determined that this program is appropriate and the data is relevant to feasibility based on the EMA deterioration study (which fully aged 3 engines and

aftertreatments through the current useful life of each engine) showing that the engine out emissions were relatively flat compared to the tailpipe emissions as the engines aged, see preamble Section IV.F.1. Our assessment is that properly designed engines would show similar emissions through the useful life values we are finalizing, making the aftertreatment demonstration the appropriate demonstration for feasibility of the emission standards.
We disagree with the comment from EMA that a conformity factor of 2.0 is needed for the first 7 years of these new standards. As discussed above, in Section 11 of this document, and in preamble Section III, we have determined that the final off-cycle standards are feasible and that they correspond to a conformity factor of 1.5 starting in MY 2027.

Finally, we are finalizing that the interim in-use testing allowance for Medium and Heavy HDEs only applies for in-use testing (i.e. testing of engines by EPA or the manufacturer that have entered commerce), not certification testing, selective enforcement audit testing or other production line testing prior to the engine entering commerce.

3.5 Criteria pollutant standards for idle testing

Comments by Organizations

Organization: *American Trucking Associations (ATA)*

While ATA cannot address every aspect of HD2027, we are supportive of the underlying environmental objectives and several of the elements being proposed. ATA's areas of support include: A national clean idle program developed as a nation-wide option which supports driver comfort while providing emissions reductions. [EPA-HQ-OAR-2019-0055-1326-A1, p. 3]

EPA proposes to allow engine manufacturers to voluntarily certify to the California Air Resources Board (CARB) clean idle standards by adding to EPA regulations an idle test procedure that is based on an existing CARB procedure. While having a single, uniform idling standard that can be recognized in every state is appealing, this proposal does not ensure that outcome. [EPA-HQ-OAR-2019-0055-1326-A1, p. 19]

Operators that seek to avoid the added expense of purchasing an APU and instead choose to idle their main truck engine for cab comfort in California must have a CARB Certified Clean Idle label on their vehicle. A handful of other states with idling restrictions provide this as a compliance option as well. Today, this label is only available by purchasing a truck with a CARB-certified engine with emissions levels, including emissions levels during idling, which are identical to a truck with an EPA-certified engine. So, while it appears appropriate to provide such an option on a nationwide basis, it is uncertain whether such an option would be recognized by California or other states with idling restrictions. [EPA-HQ-OAR-2019-0055-1326-A1, p. 19]

ATA supports EPA's proposed development of a national clean idle standard program. This program will need to balance the technical feasibility of the standard with the program's implementation and acceptance among the states. We are concerned that a federal idle standard that is recognized by 49 states or 45 states, for instance, will not meet the interstate uniformity needs of trucking companies. Therefore, we ask EPA to not only focus on setting a feasible idle standard but also work with states to recognize the program as an option which supports driver comfort while providing emissions reductions. [EPA-HQ-OAR-2019-0055-1326-A1, p. 19]

Organization: *California Air Resources Board (CARB)*

In the proposed Options 1 and 2, U.S. EPA is proposing that certifying to clean idle standards be voluntary, as currently certified federally today. For the proposed Option 1, the clean idle NOx standards and associated certification test procedures are identical to the Omnibus requirements. CARB staff strongly recommends that the proposed Option 1 clean idle NOx requirements be mandatory rather than optional. In discussions with engine manufacturers, CARB staff learned that most if not all manufacturers currently calibrate their HDEs sold nationally (CARB certified or not) to meet CARB’s optional idle NOx standards. However, vehicle manufacturers could not apply the clean idle sticker on the vehicles they sell unless it is CARB certified. In addition, many fleets have shown interest in having a clean idle sticker on the vehicles they purchase so that they can idle their engines in California and many other states that have adopted California’s idle restriction requirements. Thus, making the proposed Option 1 clean idle requirements mandatory for all HDEs used in vehicles with gross vehicle weight rating greater than 10,000 pounds sold nationally would align with CARB’s Omnibus requirements. Harmonized mandatory requirements in turn would provide significant emissions reductions nationally as well as eliminate the need for a clean idle sticker, thereby saving the customer money that would have been spent for the sticker, each of which is estimated to cost about $100. [EPA-HQ-OAR-2019-0055-1186-A2, pp.45-46]

As mentioned above, the proposed Option 1 voluntary clean idle NOx standards and associated certification test procedures are numerically identical to the mandatory Omnibus requirements. When CARB staff proposed the Omnibus requirements, idling test results from the CARB Stage 3 engine testing were not available and the idle standards in the Omnibus were based on EGR control only. As a result, CARB’s Omnibus idle NOx standards are significantly higher than what was eventually demonstrated from testing of the CARB Stage 3 engine. Testing of the CARB Stage 3 engine on CARB Idle Test Procedure showed significant idle NOx reductions of 0.1 g/hour NOx at low idle and 0.3 g/hour NOx at high idle (i.e., 1100 revolution per minute (rpm)), without impacts on GHG emissions.114 Additional extended 24-hour idle testing to mimic hoteling of sleeper cab tractors, conducted on the Stage 3 engine on behalf of U.S. EPA, also showed very low tailpipe idle NOx emissions of about 1 g/hour.115 These results are well below the 5 g/hour idle NOx standard adopted in the Omnibus or the proposed Option 1 for MY 2027. CARB staff strongly recommends U.S. EPA to evaluate available test data and adopt mandatory clean idle requirements that are at least as stringent as the Omnibus standards. [EPA-HQ-OAR-2019-0055-1186-A2, p.46]

114 Sharp, C. 'Further Development and Validation of Technologies to Lower Oxides of Nitrogen Emissions from Heavy-Duty Vehicles, Low NOx Demonstration Program – Stage 3,' Southwest Research Institute, ARB Contract 16MSC010, SwRI® Project Number 03.23379, Final Report, April 16, 2021. (page 135)

115 Sharp, C., Neely, G., Zavala, B., and Rao, S., 'CARB Low NOx Stage 3 Program - Final Results and Summary,' SAE Technical Paper 2021-01-0589, 2021, doi:10.4271/2021-01-0589.

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

While Commenters prefer the more stringent numerical emissions standards of Option 1 to the unjustifiably lax standards of Option 2, we urge EPA to further strengthen the standards in certain key areas: (1) duty cycle and in-use (off-cycle) standards, (2) idle standards, and (3) the FEL cap. EPA should also reject its proposed two-step approach for Option 1, finalizing the more stringent standards in MY 2027 instead of delaying their application until MY 2031. [EPA-HQ-OAR-2019-0055-1302-A1, p.57]

As one element of duty cycle testing changes included in Option 1, EPA proposes an optional NOx idle standard starting in MY 2023, which by MY 2027 would align with the Omnibus clean idle standard of 5.0 g/hr. 87 Fed. Reg. at 17,464. While manufacturers would not be required to certify compliance with the idle standard, 'once included the idle standard would become mandatory and full compliance would be required.' Id. EPA requests comment on whether the standard should instead be mandatory for MY 2027 and beyond. Id. [EPA-HQ-OAR-2019-0055-1302-A1, p.58]

Commenters support inclusion of a mandatory idle standard for model years 2027 onward, to better protect individuals from the higher emissions that occur during idling, such as when trucks are stopped at city streetlights. EPA should set a mandatory idle standard for MY 2027 onward that is at least as stringent as the 5.0 g/hr standard proposed in Option 1, and should consider setting it at a lower, more protective level. A 5.0 g/hr or lower standard is technologically feasible. Many HDE manufacturers are already planning to comply with a 5.0 g/hr standard in MY 2027 because of the CARB standard. The best-performing current engines are already achieving the 5.0 g/hr requirement, and some are achieving it with a wide compliance margin. See Comments of MFN, to be filed in Docket EPA-HQ-OAR-2019-005 on May 16, 2022. The Omnibus idle standard was proposed before results from CARB’s Stage 3 engine testing were available, and that testing showed NOx emissions far below the 5.0 g/hr adopted in the Omnibus and proposed by EPA as Option 1. See Comments of CARB, to be filed in Docket EPA-HQ-OAR-2019-0055 on May 16, 2022. [EPA-HQ-OAR-2019-0055-1302-A1, p.58]

Organization: *Consumer Reports (CR)*

EPA is also proposing to include a voluntary idle standard that aligns with CARB’s proposed idle certification standards. Although a number of states, including California, have laws that prevent trucks from idling for extended periods of time,46 no such rule exists at the federal level. Idling trucks emit an estimated 0.37 tons of NOx per year per vehicle,47 and increase public exposure to diesel particulate matter and other tailpipe emissions.48 For this reason, CR supports the inclusion of these standards in the final rule, and urges EPA to make this standard mandatory rather than voluntary. [EPA-HQ-OAR-2019-0055-1285-A1, p.7]

Organization: *Cummins Inc. (Cummins)*

Cummins supports EPA's proposal to finalize a nationwide voluntary Clean Idle NOx emissions standard. Cummins also supports EPA adopting CARB's existing two-mode idle NOx test procedure to which Cummins has been voluntarily certifying for many years. [EPA-HQ-OAR-2019-0055-1325-A1, p. 5]

For MY 2024 through 2026, Cummins recommends that EPA's optional Idle NOx standard align with CARB's current Clean Idle NOx level of 30 g/hr. For those model years, there is inadequate lead-time to develop, demonstrate, certify, produce, and integrate into vehicles new and reliable engine technologies to further control idle NOx emissions, while at the same time avoiding higher idle fuel consumption that increases GHG emissions. EPA's proposed 10 g/hr NOx idle standard is not feasible without active and efficient SCR. The SCR catalyst cannot be maintained at sufficient idle temperatures with 2024-2026 technologies without unduly increasing GHG and fuel consumption to a point that is fuel cost prohibitive for operators. [EPA-HQ-OAR-2019-0055-1325-A1, p. 5]

For MY 2027 and beyond, Cummins recommends that EPA's optional Idle NOx standard be set at a NOx level of 10 g/hr, with a 5 g/hr in-commerce variability allowance, primarily to account for idle exhaust flow measurement variability. EPA has evaluated idle measurement variabilities, as documented in a December 2019 SwRI report, "Measurement Variability Assessment of the GHG Phase 2 Fuel Mapping Procedure" (US EPA Contract No. EP-C-15-006, OMB Clearance Number 2031-2005, Work Assignments 2-08, 3-08, and 4-03). In the report, direct measurements showed up to 45% idle measurement variability between maximum and minimum measurements divided by the average. As long as EPA finalizes a 10 g/hr idle NOx standard with a 5 g/hr in-commerce variability allowance, Cummins projects that technologies that currently are being developed and on track for production starting in the 2027 model year could be used to achieve that lower level of idle NOx emissions, without the fuel and GHG penalties that would occur with 2024-2026 technologies at that level. [EPA-HQ-OAR-2019-0055-1325-A1, p. 5]

EPA requested comment on finalizing an approved vehicle label design, which would inform local enforcement personnel that a vehicle is equipped with an engine compliant to EPA's optional idle emissions standard and is allowed to idle. Cummins is certain that such a label will be necessary for operators to avoid shutting down engines when engine power is needed. Therefore, it is essential that EPA finalizes a label design. Otherwise, there is no incentive to certify to the voluntary standard, which could lead to NOx emissions increases caused by further fuel consumption optimization. [EPA-HQ-OAR-2019-0055-1325-A1, pp. 5 - 6]

EPA also must finalize with CARB an agreement that all vehicles with the federal Clean Idle label will be allowed to idle the same as vehicles with the CARB Clean Idle label. That will be essential not only in California, but also for CARB to continue to lead the other states and municipalities that currently recognize CARB's label. Because this is a nationwide MY 2024 issue, created when CARB lowered its voluntary Clean Idle standard for 2024, Cummins is willing and ready to work with both EPA and CARB now to achieve such an agreement in the near term. [EPA-HQ-OAR-2019-0055-1325-A1, p. 6]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

For manufacturers that certify their engines to EPA's proposed optional low NOx idle standards, Daimler Truck recommends that the Agency provide an EPA-specific clean idle sticker, sta1ting no later than MY 2024. [EPA-HQ-OAR-2019-0055-1168-A1, p.63]

Currently, only California provides an optional clean idle sticker, and the State only issues the sticker for vehicles with engines certified to all other California emission standards. If a customer would like a clean idle sticker, they are forced to purchase a vehicle that contains a California-certified engine, with the accompanying emissions controls, warranty requirements, OBD standards, and more. In this manner, a California Clean Idle sticker represents not just the engine's idle NOx emissions but rather its compliance with the full set of California emissions requirements. As California's standards continue to diverge from EPA's standards, this difference becomes even starker. Starting in MY 2024, customers will not be able to get clean idle stickers for their non-California certified vehicles, regardless of how low their idle emissions are. We expect that there will be significant splintering of the market between EPA and CARB-certified vehicles beginning in MY 2024, and some customers and applications will be left without a solution that enables obtaining a clean idle sticker due to technical and/or lead time constraints. [EPA-HQ-OAR-2019-0055-1168-A1, pp.63-64]

As the California Clean Idle sticker encompasses a growing suite of stringent requirements above and beyond merely clean idle status, the market still has a need for a clean idle sticker that reflects just that—low-NOx idle emissions. Many municipalities have passed laws allowing vehicles to idle only if they are equipped with clean idle stickers. While many of these municipalities specifically reference the California sticker, DTNA believes that most did not intend to force adoption of all of the other California requirements now required to equip a vehicle with a sticker. In fact, some locales specifically anticipate that an EPA sticker might exist. For example, Texas motor vehicle emissions regulations exempt heavy-duty vehicles from the State's anti-idling requirements if they are equipped with a 2008 or subsequent MY heavy-duty diesel (or liquefied or compressed natural gas) engine that has been certified by EPA or a state agency to emit no more than 30 g-hr NOx when idling.86 [EPA-HQ-OAR-2019-0055-1168-A1, p.64]

86 See 30 TAC 114.512(2).

Daimler Truck believes that the EPA should offer a voluntary clean idle certification, with an identifying sticker, similar in nature and location to the existing California sticker, to certify that vehicles emit no more than 30 g-hr NOx when idling. The specific threshold for certification could be adjusted according to the applicable MY NOx idle standards and the limits the engine is certified to. EPA should offer such a program no later than MY 2024. Customers are buying more expensive, California-certified trucks to receive this sticker today, even though their less expensive, EPA-only counterparts have the same low NOx idle emissions. [EPA-HQ-OAR-2019-0055-1168-A1, p.64]

Organization: *District of Columbia Department of Energy and the Environment (DOEE)*

EPA seeks comment on whether to include an idle standard. In the Heavy-duty NOx Omnibus Regulation, California adopted a mandatory idle standard of five grams/hour (g/hr). Since then, SwRI and Achates Power have demonstrated that heavy-duty trucks can achieve, and continuously sustain, significantly lower idle standards – all below one g/hr – over an indefinite period of time. This is an important development for heavy-duty trucks, which routinely idle for long periods of times. Achates, for example, has field data from actual truck operation in 40° F weather showing 0.15 g/hr average NOx at idle. EPA should finalize a mandatory idle NOx standard for MY 2027-2030 engines in the range of 0.5 to 1 g/hr. [EPA-HQ-OAR-2019-0055-1299-A1, p. 5]

Organization: *Edwin J. Ward*

Increased stringency of engine idling testing requirements
An important place to start in reducing heavy duty vehicle emissions is with vehicle idling. Section III(D)(IV) of the proposed rule explains EPA's intention to begin regulating engine idling. According to the proposed rule, engine idling over four minutes can lead to higher-than-expected emissions of criteria pollutants because the catalyst is allowed to cool below the "light-off temperature" of 350°C. I strongly support EPA's proposal to take into account idling emissions beyond four minutes and require a minimum light-off temperature of 350°C. [EPA-HQ-OAR-2019-0055-1050]

The emissions associated with heavy-duty vehicle idling are most pronounced in already-polluted, heavily urbanized areas where delivery vehicles make many stops and others are subjected to traffic-choked streets. In the Bronx, NY, the Hunts Point Cooperative Market is the largest food distribution center in the world, and supplies the majority of New York City's produce. Located in a majority Black and Puerto Rican neighborhood,6 the food market sees 13,000 heavy-duty trucks every single day.7 The sheer number of trucks per day in a 1.5 square mile neighborhood alone is enough to accentuate levels of criteria pollutants. But due to infrastructure constraints and a lack of refrigeration space, trucks must idle at all hours of the day to keep produce cold.8 This isn't a new problem for the residents of Hunts Point, who have witnessed nearly two decades of failed carrot and stick programs from local and state government, including a supposed "crackdown" on illegal idling9 and nearly $200 million previously allocated.8 Despite supposed state and local action, child asthma emergency room visits are 63% higher in Hunts Point than the rest of the city, and the neighborhood ranks seventh highest in adult asthma emergency room visits.8 [EPA-HQ-OAR-2019-0055-1050]

The Hunts Point neighborhood is a clear environmental justice community that has been and continues to be negatively impacted by air pollution caused by heavy-duty vehicle emissions from idling. Those impacts persist despite stringent local and state laws prohibiting idling, proving the importance of EPA finally taking action on this issue. By regulating heavy-duty vehicle idling, EPA can simultaneously reduce fuel costs for drivers and trucking companies, while also reducing the environmental burden on communities like Hunts Point, NY. [EPA-HQ-OAR-2019-0055-1050]

EPA's proposed rule further requests relevant data on idling reduction technologies like "start-stop." Having been widely deployed in light-duty vehicles in recent years, the technology must be studied further in diesel engines as it could have the paradoxical effect of allowing the catalyst to cool below light-off temperature and increasing emissions. Perhaps vehicle manufacturers could implement a start-stop feature that initiates only in park and after five minutes to ensure that the emissions saved from idling aren't outweighed by emissions in the subsequent engine warm-up period. [EPA-HQ-OAR-2019-0055-1050]

Ultimately, I urge EPA to move forward on increasing stringency of engine idling standards and testing requirements starting with requiring a minimum light-off temperature of 350°C during idling beyond four minutes. I also urge EPA to evaluate potential new technologies like "start-stop" while considering that these solutions alone may not achieve a significant emissions reduction. [EPA-HQ-OAR-2019-0055-1050]

[Conclusion] In the short term, EPA should adopt stringent engine idling standards and testing requirements starting with requiring a minimum light-off temperature of 350°C during idling beyond four minutes. This will create immediate air pollution benefits for environmental justice communities. EPA should also reject the proposed revision to Section 86.1823-08 to prevent any further erosion of emissions standards for light-duty trucks. [EPA-HQ-OAR-2019-0055-1050]

In addition to adopting the most rigorous engine NOx emissions standards, we urge EPA to adopt mandatory NOx idle emissions standards. Medium- and heavy-duty vehicles can spend 30-40 percent of their time at idle and NOx emissions at idle can represent up to 20 percent of an engine's total NOx emissions.100 California adopted 'clean idle' standards in 2008 that required new engines to equip a 5-minute non-programmable automatic engine shutdown system (AESS) or certify to a clean idle NOx standard of 30 grams per hour (g/hr).101 EPA's in-use data, presented by ICCT, shows that the majority of diesel engines across most manufacturers were already meeting the 30 g/hr threshold in 2019.102 In 2021, California adopted its Heavy-duty Engine and Vehicle Omnibus regulation that included updated NOx idling standards for all medium- and heavy-duty vehicles, including a 10 g/hr standard for MYs 2024-2026 and a 5 g/hr standard for MY 2027 and beyond. [EPA-HQ-OAR-2019-0055-1265-A1, p.24]

101 California Air Resources Board, 'Proposed Heavy-duty Engines and Vehicle Omnibus Regulation and Associated Amendments. Staff Report: Initial Statement of Reasons,' (June 23, 2020) ('ISOR'), page I-7.

102 Huzeifa Badshah, Francisco Posada, Rachel Muncrief. 2019. Current State of NOx Emissions from In-Use Heavy-duty Diesel Vehicles in the United States, ICCT, page 20, Figure 13.

EPA has proposed voluntary NOx idle emissions standards for medium- and heavy-duty vehicles beginning in MY2023 at 30 g/mi and ramping up to meet California's 5 g/mi standard for MYs 2027 and beyond. However, a voluntary standard misses the opportunity to make significant reductions in harmful diesel pollution that is often concentrated in urban areas where diesel emissions are already a serious burden on local communities. Accordingly, we urge EPA to finalize mandatory requirements to reduce idle emissions. [EPA-HQ-OAR-2019-0055-1265-A1, p.24]

The Air Resources Board (ARB) staff concluded in its Initial Statement of Reason (ISOR) for the Heavy-duty Omnibus regulation that the 10 g/hr NOx idle emission standard for the 2024-2026 MYs is feasible, based primarily on a Southwest Research Institute (SwRI) Low NOx testing program that evaluated the emission reductions achievable by changing calibrations during idle.103 SwRI demonstrated that reducing exhaust flow at idle can reduce NOx emissions during idle by almost 90 percent. In fact, with an auxiliary load, idle emissions were demonstrated as low as 1.6 g/hr, far below the 10 g/hr standard adopted for 2024 and the 5 g/hr standard adopted for MY2027 and beyond. ARB states that its 10 g/hr standard is indeed conservative. [EPA-HQ-OAR-2019-0055-1265-A1, p.24]

103 ISOR, page III-14.

It is critical that EPA adopt mandatory NOx idle emissions standards that are at least as protective as California's Omnibus regulation. According to ARB, in 2019, there were already a number of engines certified with idle emissions below 10 g/hr and a number of the best performing engines already achieved the 5 g/hr standard.104 Therefore, engines are already capable of the most protective standard a full 8 model years before it goes into effect.
A voluntary standard would do little to compel action to reduce harmful NOx emissions at idle.
A mandatory standard would cement the available emissions reductions experienced by California across the nation. [EPA-HQ-OAR-2019-0055-1265-A1, pp.24-25]

104 ISOR, page III-15.

EDF also recommends that EPA adopt a mandatory NOx idle standard for 2027 and beyond that goes beyond California's 5 g/mi standard. SwRI conducted additional testing since the adoption of the Omnibus regulation.105 Over a range of different duty cycles, SwRI demonstrates that, even at high mileage, engines can reduce NOx idle emissions to well below 1 g/mi. In fact, the highest idle emission rate they found was 1.4 g/mi. Engine manufacturers would still have a full 5 model years to achieve the more protective standards. [EPA-HQ-OAR-2019-0055-1265-A1, p.25]

105 Presentation by Christopher Sharp, SwRI, 'Update on Continuing Progress Towards 2027 Heavy-duty Low NOx Targets,' 32nd CRC Real World Emissions Workshop (March 14, 2022). Presentation by Christopher Sharp et. al., SwRI, 'An Update on Continuing Progress Towards Heavy-duty Low NOx and CO2 in 2027 and Beyond,' WCX (April 5-7, 2022).

It is critical that EPA utilize the most recent research and testing and the clear demonstration of success in California to adopt mandatory and protective NOx idle standards based on the greatest emissions reductions achievable by today's engines. [EPA-HQ-OAR-2019-0055-1265-A1, p.25]

ARB has determined that all medium- and heavy-duty vehicles are capable of meeting the mandatory idle emissions standards. California's 2008 clean idle standards exempted all medium-duty vehicles as well as buses and recreational vehicles because it was assumed that most manufacturers would meet the idle standards by installing an AESS, and that technology did not make sense for those particular vehicle segments at the time the rule was adopted.

However, all manufacturers have instead met the idle regulations by certifying to clean idle standards through the use of EGR and air-fuel ratios. Therefore, ARB determined in its 2020 ISOR that ‘EGR and air-fuel ratio controls are feasible for buses, recreational vehicles, medium-duty vehicles, armored vehicles, and workover rigs, just like for any heavy-duty vehicle, and so the rationale for exempting these vehicles that existed in 2005 no longer exists.’106 ARB also determined that other strategies for meeting the updated standards could include ‘raising the exhaust temperature to enable SCR operation using cylinder deactivation, mild hybrid systems, stop-start systems, or a combination of all of these strategies.’107 Therefore, it is clear that all medium- and heavy-duty engines must be subject to health-protecting NOx idle emissions standards that begin in MY 2024 and reflect the reductions [EPA-HQ-OAR-2019-0055-1265-A1, p.25]

107 ISOR, page III-15.

Organization: *Ford Motor Company (Ford)*

We support the adoption of optional Clean Idle test procedures and standards. These optional Clean Idle standards will be needed for non-50 state engine families and the owners and operators of vehicles equipped with them to comply with Clean Idle requirements outside of California. [EPA-HQ-OAR-2019-0055-1300-A1, p. 4]

Organization: *Maine Department of Environmental Protection (Department)*

Using the CARB Heavy-Duty Omnibus Regulation as a bellwether, the Department requests the following revisions to the federal proposal: [EPA-HQ-OAR-2019-0055-1288-A1, p.6]

- Idle standards. EPA should finalize a mandatory idle standard of 5 g/hr for model year 2027-2030 engines as CARB has finalized for the Heavy-Duty Omnibus Regulations, rather as an optional standard. Idling heavy-duty vehicles disproportionately impact populations and communities that are already overburdened by air pollution. Based on test results by the Southwest Research Institute,15 a 5gm/hr (or even less) idle standard is feasible through 800,000 miles of operation. Since heavy-duty vehicles may be operated at idle for as much as 33% of the time, 16 the Department suggests EPA make the idle standard mandatory and consider increasing the stringency of the standard in the final rule. [EPA-HQ-OAR-2019-0055-1288-A1, p.7]

Organization: *Moving Forward Network (MFN)*

Beginning in 2008, California required new trucks sold in the state to meet a "Clean Idle" standard. There are two means by which a truck can be certified to the standard, either by having an automatic shut-off that cuts the engine after five minutes of idling, or by meeting a 30 g/hr NOx idling standard. Rather than an increase in availability of stop-start and zero-emission technologies, which CARB's idle rule was meant to promote,138 all heavy-duty engines in 2020 comply with the standard by meeting the 30 g/hr requirement.139 Though this standard was implemented only in California, it has driven 50-state improvements, with EPA's in-use data showing that the vast majority of diesel engines meet the 30 g/hr threshold.140 [EPA-HQ-OAR-2019-0055-1277-A1, pp. 34 - 35]

> 140. Badshah, et al. 2019, Figure 13.

In-use data shows a higher fraction of idling than current test procedures,141 and it is well-established by EPA's data that idling is precisely the type of low-load operation where current emissions controls behave sub-optimally, a major rationale for the LLC. EPA's own in-use ("off-cycle") program bases the lowest level bin on idle test emissions, indicating both a heightened awareness of the problems these emissions hold and an understanding that it represents a significant share of general truck operations. [EPA-HQ-OAR-2019-0055-1277-A1, p. 35]

As EPA noted, CARB has lowered this standard to 10 g/hr for 2024, and to 5 g/hr for 2027 and beyond. This is not voluntary in California, and it should not be voluntary federally, either. The best-performing current engines can already achieve the 5 g/hr requirement.142 EPA's SwRI data shows that its Stage 3RW engine is also capable of meeting such a standard, with a wide compliance margin.143 And Achates Power's opposed-piston engine meets CARB's 5 g/hr requirement with even greater compliance margins.144 [EPA-HQ-OAR-2019-0055-1277-A1, p. 35]

> 142. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2020/hdomnibuslownox/isor.pdf, Figure III-3.
>
> 143. EPA-HQ-OAR-2019-0055-1082
>
> 144. Salvi et al. 2022

Given the importance of reducing idling emissions to communities near ports and warehouses and other heavily-trafficked areas, not only should EPA make its idling standards mandatory, but it should consider setting standards that fall well below CARB's current "Clean Idle" limits, which appear extremely conservative given the technical capacity of the next generation of diesel engines. [EPA-HQ-OAR-2019-0055-1277-A1, p. 35]

Organization: *National Association of Clean Air Agencies (NACAA)*

NACAA supports inclusion in the final rule of performance requirements to ensure achievement of emission standards across all duty cycles, including idle and low load. [EPA-HQ-OAR-2019-0055-1232-A1, p. 11.]

EPA seeks comment on whether to include an idle standard. In the Omnibus, California adopted a mandatory idle standard of 5 grams/hour (g/hr). Since then, SwRI and Achates Power have demonstrated that heavy-duty trucks can achieve and continuously sustain significantly lower idle standards – all below 1 g/hr – over an indefinite period of time. This is an important development for HD trucks, which routinely idle for long periods of times. Achates, for example, has field data from actual truck operation in 40° F weather showing 0.15 g/hr average NOx at idle. EPA should finalize a mandatory idle NOx standard for MY 2027-2030 engines in the range of 0.5 to 1 g/hr. [EPA-HQ-OAR-2019-0055-1232-A1, p. 11]

Organization: *Navistar, Inc. (Navistar)*

In particular, we support: The implementation of a national clean idle program in 2024, which is technically feasible, and does not create negative CO2 impacts. [EPA-HQ-OAR-2019-0055-1318-A1, p. 2]

Organization: *Northeast States for Coordinated Air Use Management (NESCAUM)*

Should EPA instead promulgate Option 1, we urge the Agency to make the following changes to the proposed standards: We request that EPA finalize a mandatory idle standard of 5 g/hr for model year 2027 and later engines consistent with CARB's finalized Omnibus regulation, rather than an optional standard. A Center for Environmental Research and Technology (CE-CERT) study found that vocational vehicles spend approximately 33% of the time at idle.36 Idling trucks emit pollution in crowded urban areas in communities already overburdened with air pollution.37 Southwest Research Institute's Stage 3 research program measured idle emissions at 435,000 miles in the range of 0.30 to 1.40 grams NOx per hour on five different duty cycles and 0.40 to 3.3 grams per hour at 800,000 miles.38 These values are well below the proposed standard and demonstrate the feasibility of NOx control at idle through 800,000 miles. Given these and other test results, we encourage EPA to make the idle standard mandatory and increase the stringency of the standard in the final rule. [EPA-HQ-OAR-2019-0055-1249-A1, p. 12]

Organization: *Ozone Transport Commission (OTC) and Mid-Atlantic/Northeast Visibility Union (MANE-VU)*

Idle Standard: We request that EPA finalize a mandatory idle standard of 5 g/hr for model year 2027 and subsequent model year engines, as CARB has finalized for its Omnibus regulation, rather than an optional standard. A Center for Environmental Research and Technology (CE-CERT) study found that vocational vehicles spend approximately 33% of the time at idle.37 Idling trucks emit pollution in crowded urban areas in communities already overburdened with air pollution.38 Southwest Research Institute’s Stage 3 research program found that idle emissions from 0.30 to 1.40 grams per hour at 435,000 miles on five different duty cycles and 0.40 to 3.3 grams NOx per hour at 800,000 miles are feasible.39 These values are well below the proposed standard and demonstrate the feasibility of NOx control at idle through 800,000 miles. Given these and other test results, we encourage EPA to make the idle standard mandatory and consider increasing the stringency of the standard in the final rule. [EPA-HQ-OAR-2019-0055-1250-A1, pp.14-15]

37 See footnote 35, at p. 75.

39 See footnote 24 (Sharp et al., Southwest Research Institute, April 5-7, 2022).

Organization: *PACCAR, Inc (PACCAR)*

PACCAR supports EPA’s proposal to include a voluntary ‘low NOx idle’ emissions standard. The specific proposed standards are a concern, however, because compliance to an idle-NOx standard is contingent upon the low-NOx technologies that will need to be deployed to meet the FTP, RMC and LLC standards, which will not be fully known until the NPRM is finalized. For MY 2024 to MY 2026 there are no significant nation-wide planned engine or aftertreatment upgrades currently anticipated, even though meeting the level proposed for MYs 2024 to 2026 (10.0 g/hr) would not be possible with today’s technology. Since there is no major planned change to technology until MY 2027, PACCAR does not support a decrease from the current level until MY 2027. PACCAR supports a standard that does not encourage backsliding and thus supports 30.0 g/hr through 2027. At the next step in the regulation to Low NOx in 2027, PACCAR would support a 10.0 g/hr standard with a 5.0 g/hr in-commerce variance allowance that is aligned with the anticipated technology to meet that regulated level. Although PACCAR generally supports the proposed 'Clean Idle test' provisions (see 40 C.F.R. 1036.514), PACCAR did not identify any corresponding Clean Idle label provisions. If EPA intends to promulgate Clean Idle testing provisions, it should also promulgate Clean Idle labeling provisions to enable local enforcement personnel to easily identify clean idle compliant vehicles. EPA should also secure agreement from CARB to accept the EPA clean idle provision, thereby allowing federally-compliant labeled Clean Idle vehicles to idle in California and other CARB-aligned jurisdictions. [EPA-HQ-OAR-2019-0055-1346-A1 pp.40-41]

Organization: *Southern Environmental Law Center (SELC)*

Under the current Option 1 proposal, however, idling standards and test procedures remain voluntary.37 Data indicates that NOx emitted during low load conditions and idling contributes between 15 and 60 percent of NOx emissions over duty cycles,38 and we encourage EPA to make idling standards and test procedures mandatory and consistent with California's Clean Idle NOx standard.39

Organization: *Truck and Engine Manufacturers Association (EMA)*

EMA supports EPA's proposal to include a voluntary "low NOx idle" emissions standard, and to base that standard on the CARB idle-NOx test procedure that has been in place since 2008. The specific proposed standards are a concern, however, because compliance to an idle-NOx standard is contingent upon the low-NOx technologies that will need to be deployed to meet the FTP, RMC and LLC standards, which will not be fully known until the rule is finalized. In addition, future developments related to the electrification of the HD fleet will offer new, more practical alternatives to reduce emissions from extended idling. [EPA-HQ-OAR-2019-0055-1203-A1, p. 41]

CARB created a two-speed idle emissions test procedure to support a voluntary idle-NOx standard as an alternative to a 5-minute non-programmable automated shutdown requirement. EPA is now proposing a voluntary idle-NOx standard of its own to reduce emissions during periods of extended idle, such as during loading and unloading operations, as well as during the extended idling to provide overnight hoteling loads. The Agency's proposed idle-NOx standard would be based on the same CARB test procedure, at a level matching CARB's low-NOx idle standard of 5g/hr, effective with MY 2027. The voluntary standard would initially become available in MY 2023 at 30g/hr, and then would be reduced to 10.0g/hr in 2024. [EPA-HQ-OAR-2019-0055-1203-A1, p. 41]

As an initial matter, there are no significant industry-wide planned engine or aftertreatment upgrades anticipated for model years 2024 through 2026. As manufacturers work to develop emissions control strategies to comply with the MY 2027 standards (while also evolving their product lines to zero-emissions solutions), there are minimal resources available to develop new technical solutions to achieve idle-NOx emissions controls superior to those offered today, and too little time to develop and verify the new hardware solutions that would be needed. For this reason, EMA recommends that the optional Idle-NOx standards remain at 30.0 g/hr for MY

2024-2026, and that EPA incorporate by reference CARB's test procedures and other clean-idle requirements for MYs 2024-2026, and that EPA incorporate by reference CARB's test procedures and other Clean Idle requirements for MY2024-2026. [EPA-HQ-OAR-2019-0055-1203-A1, p. 41]

EPA also proposes in §1036.104(b) that, "The mass emission rate of HC, CO, and PM in g/ hr during the Clean Idle test may not exceed the emission results from the idle modes of the SET duty cycle as described in §1036.505(h) or the idle segments of the FTP duty cycle as described in §1036.510(g)." That proposed requirement is unworkable. First, it is impractical to measure PM emissions over short durations of a cycle test. The PM demonstration requirement is also unnecessary, because today's HDOH PM standards require the use of DPFs to comply, which provides the maximum PM reduction technically achievable. The requirement to measure and demonstrate PM emissions levels relative to the optional idle-NOx-measured PM emissions should be eliminated. [EPA-HQ-OAR-2019-0055-1203-A1, p. 42]

Regarding HC and CO emissions during the optional idle demonstration test, the proposed requirement that those emissions not exceed the levels measured in the idle portions of the FTP and RMC is essentially a requirement that the optional idle performance be designed to decrease the HC and CO emissions relative to the FTP and RMC, including to overcome test-to-test variability and minor fluctuations with operating conditions. EMA questions the need for HC and CO controls to be in place during extended idle conditions, as there would be no perceived benefit to manufacturers to calibrate that mode of idle operations to include higher concentrations of HC or CO. As a result, there is no basis for the proposed requirement. If the Agency nonetheless decides to constrain HC and CO emissions through regulation, EMA recommends setting time specific standards under the clean-idle demonstration test for MY 2027 and beyond. Appropriate standards would have to be set following data review, especially from the Stage 3 engine or other engines similarly equipped. Another option, though not preferred, would be for EPA to require that the optional clean-idle results for HC and CO be no more than 30% higher than levels measured during idle portions of the FTP and RMC. EMA further recommends that §1036.104(b) state that EPA may approve alternative procedures with regard to controlling and demonstrating optional clean-idle NOx, and potentially HC and CO levels. [EPA-HQ-OAR-2019-0055-1203-A1, p. 42]

With respect to the proposed NOx standard starting with MY 2027, achieving an idle standard of 10.0 g/hr would require the use of CDA, elevated EGR rates, and/or additional load by way of an intake air throttle or similar technique. One or more of those strategies would be needed to increase aftertreatment temperature sufficiently to result in the enhanced SCR efficiencies required to achieve those levels. As discussed above, EMA has numerous concerns associated with the implementation of CDA on heavy heavy-duty applications. [EPA-HQ-OAR-2019-0055-1203-A1, p. 42]

NVH issues are the most significant concerns, with NVH being of particular relevance for hoteling needs during mandatory rest periods. The increased NVH with CDA could preclude maintaining the type of quiet, low-vibration environment that is critical to enabling proper driver rest during required service breaks. If alternating CDA control modes proves to be necessary to optimize the minimum SCR temperature/CO2 emissions trade-off, or for long-term durability reasons, mode switching could be particularly disruptive to drivers' needs for restful sleep. Given that, there is additional concern that drivers will attempt to defeat or work around the CDA functionality or diagnostic capabilities to avoid those disruptions. [EPA-HQ-OAR-2019-0055-1203-A1, p. 42]

Other methods to reduce idle emissions, such as increased EGR rates are known to increase the frequency and severity of EGR cooler fouling, increased soot formation, catalyst face plugging, and aftertreatment degradation. An alternative approach to increase exhaust temperatures would be to increase engine loads through a variety of methods. While effective, that approach adds complexity, diagnostic burden, and an increase in CO2 emissions and operating costs. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 42 - 43]

That said, starting in 2027, a 10.0 g/hr idle-NOx certification standard could be achievable, with an additional 5.0 g/h NOx variability allowance for any in-use testing. Anything lower than 10.0 g/hr would prove challenging to meet consistently across manufacturers' full product lines. For example, applications such as transit buses with high accessory loads may not be capable of meeting a standard less than 10.0 g/hr. Additionally, idle standards lower than 10.0 g/hr could disrupt product plans that involve the use of ABT provisions to bring the entire engine lineup into compliance with the new standards. Accordingly, EMA recommends that EPA finalize the rule with a 10.0 g/hr optional idle-NOx standard, and also provide a 5.0 g/hr NOx variability allowance for any in-use testing. [EPA-HQ-OAR-2019-0055-1203-A1, p. 43]

EPA has requested comment regarding whether an approved hood label should be provided for to inform local enforcement personnel that the vehicle is equipped with an engine compliant to the optional low-idle emissions standard. EMA believes it is imperative that such a label be specified and controlled in a manner similar to CARB's approach to its CLEAN IDLE hood label. Without such a federal label, there is no easy way for enforcement personnel to know that the vehicle's idle emissions are well controlled. [EPA-HQ-OAR-2019-0055-1203-A1, p. 43]

EPA also should secure agreement from CARB that the State of California will allow vehicles with the federal clean-idle label to idle for extended periods in California, including overnight idling, in the same way that the State acknowledges the CARB CLEAN IDLE hood label. This should be the case even if the federal idle standard is not as stringent as California's. The federal voluntary clean-idle standard, and its associated label, will be an important feature for various municipalities and states outside of California to allow for extended idle operation in locations currently requiring the CARB CLEAN IDLE label. Without those necessary label provisions, including authorization to idle for extended periods in California and elsewhere, there will be no incentive for manufacturers to develop clean-idle capability, or to certify their products to the optional clean-idle standard. [EPA-HQ-OAR-2019-0055-1203-A1, p. 43]

Organization: *Truck Renting and Leasing Association (TRALA)*

Finally, a true and workable national standard would allow the EPA to set a national clean idle standard for trucks in all states. As TRALA members are encouraging their customers to incorporate the latest safety and environmental technologies into their new trucks, a national clean idle standard would reduce confusion for drivers regarding which states they can utilize clean idle technology and would increase the adoption of the technology for new trucks. [EPA-HQ-OAR-2019-0055-1180-A1, p. 4]

Organization: *Volvo Group*

The Volvo Group supports a federal voluntary clean idle standard and its associated label. However, the Volvo Group believes a label must be specified and controlled in a manner similar to the California Air Resources Board (CARB)'s Clean Idle hood label approach. Without such a federal label, it is not easy for enforcement to know that the vehicle's idle emissions are well-controlled. For model years 2024-2026, the Volvo Group recommends a 30g NOx EPA Clean Idle level consistent with the current CARB Clean Idle level. [EPA-HQ-OAR-2019-0055-1324-A1, p. 5]

The criticality of this issue has already been seen due to the change in CARB's warranty requirements for MY2022 vehicles. The current lack of a federal voluntary clean idle standard with an associated label meant that fleets in all states that automatically opt-in to CARB's medium- and heavy-duty vehicle standards, as well as those municipalities or entities with existing clean idle ordinances, were required to pay over $2,000 more for their vehicles to pay for the CARB certification and its linked Clean Idle label, even though the additional warranty had no relevance to the idle technology, which was exactly the same as those vehicles without Clean Idle labels. The failure of EPA to develop a federal voluntary clean idle standard and label would lead to the forfeiture of federal rulemaking authority over vehicles for fleets seeking to comply with state or local ordinances requiring clean idle labels and impose the increased cost and technology risk that will be incurred under the California Omnibus NOx standard. [EPA-HQ-OAR-2019-0055-1324-A1, p. 5]

Organization: *Great Rivers Environmental Law Center and Dutchtown South Community Corporation (DSCC)*

The Proposed Regulation demonstrates that emissions from HD vehicles are particularly high when vehicles are idling or operated in stop and go traffic, likely because increases in exhaust temperature causes emissions restriction devices to be less effective or ineffective.14 Reports estimate that in some cases, NOx emissions from vehicles operated in such low-load engine conditions may be more than double that of emissions produced during normal operation.15 As a result, the undersigned believe that one of the most important ways in which EPA and MDNR can combat transportation-related pollution is to ensure that emissions are a low as possible during idling and low-load operation of HD vehicles. [EPA-HQ-OAR-2019-0055-1323-A1, p.4]

14 Proposed Regulation at p.17418.

15 Id.

Purportedly as a means of addressing the ozone problem in the St. Louis area, in 2009 MDNR enacted an anti-idling regulation applicable to the region. 10 CSR 10-5.385. This regulation prohibits heavy diesel commercial, public and institutional vehicles from idling for more than five minutes within any 60-minute period. This state regulation is incorporated into Missouri's

SIP in an attempt to reduce ozone levels in the area.16 However, Great Rivers has collected data demonstrating that this regulation is ineffective largely because of lack of enforcement. [EPA-HQ-OAR-2019-0055-1323-A1, p.4]

16 MDNR, Missouri State Implementation Plan Revision, Infrastructure Elements for the 2015 Ozone Standard at p.8 (Adopted March 28, 2019).

Great Rivers has collected data regarding the real-time use and effectiveness of anti-idling regulations as a means of reducing ozone pollution from traffic. This task was complicated by the fact that while MDNR enacted the anti-idling regulation and included it in the Missouri SIP, the actual implementation of the control requirement depends upon local enforcement, which is further complicated by the unique system of municipal governance and policing common to the St. Louis metropolitan area. Instead of one centralized local system of government, the area covered by Missouri DNR 10 CSR 10-5.385 is fractured into more than 120 different municipal governments, overlaid by four different county governments.17 Many of these local governments have their own police force and an independent system of ordinance enforcement. Despite the patchwork quilt of governmental structure in the St. Louis area, Great Rivers has been able to use records requests to individual municipal agencies to ascertain that none of the four county governments in the St. Louis metro area (Franklin, Jefferson, St. Charles and St. Louis County), nor the City of St. Louis, have records of enforcement of 10 CSR 10-5.385 within the last five years. Additionally, the 36 municipalities that have responded to Great Rivers' records requests to date have no records of enforcement of 10 CSR 10-5.385 within the same time period. Further, although St. Louis City and County have their own anti-idling ordinances, neither government has records of enforcement of those provisions within the last five years.18 Similarly, none of the municipalities located in St. Louis County responding to Great Rivers' records requests have issued tickets or other citations pursuant to St. Louis County's anti-idling ordinance. A similar lack of enforcement of anti-idling laws has been observed around the country.19 Given the lack of meaningful implementation and enforcement of these state and local anti-idling regulations, the stringency of the national idling standards for HD vehicles proposed by these regulations becomes even more important. [EPA-HQ-OAR-2019-0055-1323-A1, pp.4-5]

https://library.municode.com/mo/st._louis_county/codes/code_of_ordinances?nodeId=TITVIPUHEWE_CH612AIPOCO_612.340AIPONUPR (precluding idling for longer than 3 consecutive minutes).

19 Bloomberg, How to Win the War on Car Idling, (August 10, 2021), located at https://www.bloomberg.com/news/features/2021-08-10/can-cities-finally-win-the-war-on-vehicle-idling.

The undersigned support inclusion of the following requirements in the Final Regulation:

- Mandatory idling mode and low-load cycle testing of both CI and SI engines, conducted at certification and during in-use testing; [EPA-HQ-OAR-2019-0055-1323-A1, p.5]

EPA Summary and Response

Summary:

All commenters provided general support for EPA's proposal to set idle standards for heavy duty engines, with some qualifications. Some commentors supported making idle standards mandatory, while others commented that the idle standards should be optional. With regard to the level of the idle standard, there was support from many commenters that the standards should be set at the Proposed Option 1 level or lower, while several manufactures stated that 10 g/hr for certification and 15 g/hr in-commerce would be the lowest feasible standards for NOx. One manufacturer commented that EPA must set standards that do not increase CO_2 emissions. Another commenter said that NVH should be considered since many drivers idle the engine of the truck when sleeping in the truck.

Response:

EPA has considered these comments, along with the available data including the data from the EPA Stage 3 engine, and is finalizing voluntary idle NOx standards for MY 2024 - 2026 and MY 2027+ engines. The level of the standards, including EPA's analysis of the feasibility of the standards and response to some of these comments, are discussed in Section III of the preamble.

We are finalizing voluntary clean idle standards for two main reasons. The first is that the stringency of the final off-cycle standards will require that all engines have low NOx emissions when idling. This optional clean idle test will help further ensure that NOx emissions stay well controlled as aftertreatment temperatures are critical to controlling NOx, and this test will ensure control over a long period of extended idle time. Second, we believe an EPA clean idle label will facilitate the ability of state and local law enforcement officers to enforce certain state and local clean idle rules. The reason we believe that mandatory idle duty-cycle standards wouldn't alleviate the need for a clean idle label is because enforcement officers cannot tell from the outside of the vehicle what the model year the engine is. We have heard from stakeholders, including CARB, that this is important, so that enforcement officers don't have to wake up a sleeping driver to check if the engine meets the clean idle requirements.

Regarding the comment on considering NVH when setting the standards, as outlined in RIA Chapter 3, we have conducted NVH testing at idle with CDA active. EPA's assessment based on this testing is that there are several ways to reduce NVH to acceptable levels through design of the complete system, including, where CDA is used, engine mounts, cab mounts, and seat calibration. Based on consideration of this testing, we have determined that the final standards are achievable without increasing NVH outside of the acceptable range.

Some commenters stated that the proposed PM, HC, and CO standards are unworkable since the standards are set at the level the engine emits at during idle over the engine FTP and SET duty cycles and that variability in the emissions between the different tests could cause the engine to fail the idle PM, HC, and CO standards. EPA recognized this issue in the proposal and requested comment on if EPA should instead set PM, HC, and CO standards that are fixed and not based on the emissions from the engine during the FTP and SET. EPA has considered these comments and is not finalizing idle PM, HC, and CO standards for two main reasons. The first is that we agree that setting the standards right at the idle emissions level of the engine on the FTP and SET could cause false failures due to test-to-test variability. Second, we believe that the final off-cycle PM, HC, and CO standards, as discussed in Section III of the preamble, will ensure that PM, HC, and CO emissions will be controlled at idle, as this type of operation is covered by the FTP and LLC standards and control of these pollutants is less affected by changes in aftertreatment temperature.

Finally, EPA agrees with the comments from EDF that there should not be exemptions for buses and recreational vehicles, since the standards are voluntary and EPA's analysis shows that the standards are feasible.

3.6 Other proposed requirements for Spark-ignition HDE

3.6.1 Other requirements for Spark-ignition HDE

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

CARB staff supports the proposed idle control in 40 Code of Federal Regulation (CFR) 1036(j)(1) that requires the catalyst bed used in SI HDEs to maintain a minimum temperature of 350 °C to ensure emission are controlled during extended idling. CARB staff also supports the proposal to use modeled exhaust component temperatures to protect the catalyst instead of designing the engine to continuously monitor exhaust component temperatures, as specified in 40 CFR 1036(j)(2). [EPA-HQ-OAR-2019-0055-1186-A2, p.49]

The NPRM requests comments on the proposal to allow vehicle manufacturers the option to request approval to certify the OBD of the spark-ignited, engine-certified products using data from similar chassis-certified Class 2b and Class 3 vehicles that meet the provisions of 86.1806-17, provided they show that both products use the same engine and similar emission controls. CARB staff generally agrees with the proposal since CARB's HD OBD regulation includes similar allowances for spark-ignited engines. [EPA-HQ-OAR-2019-0055-1186-A2, p.66]

However, CARB staff has concerns regarding the language in 1036.110(a)(2), which seems to be the proposed regulation language that will cover this provision but does not include language requiring manufacturers to provide information showing the products use the same engine and similar emission controls. Further, the language indicates that HD spark-ignited engines for over 14,000 pounds GVWR may meet the requirements of 86.1806 if the engines ‘share essential design characteristics with engines that the engine manufacturer also installs in vehicles certified under 40 CFR part 86, subpart S.’ CARB staff believes the phrase ‘share essential design characteristics’ is vague and does not provide enough details about what design characteristics are considered or not considered by U.S. EPA in making this determination. CARB staff recommends that U.S. EPA make changes to the regulation language to provide more specifics. [EPA-HQ-OAR-2019-0055-1186-A2, p.66]

U.S. EPA states that they are proposing that spark-ignited engine manufacturers monitoring component temperatures to engage thermal protection modes make available the component temperature parameters (measured and modeled, if applicable) publicly available ‘as specified in a new c However, this regulation section does not exist in the version of 1036.110 provided. CARB staff is not sure if this was an oversight or if U.S. EPA was not going to propose such a requirement. If this was an oversight, CARB staff cannot comment on whether the proposal has issues or not since there is no regulation language to review. [EPA-HQ-OAR-2019-0055-1186-A2, p.78]

The requirements outlined §1036.205(b) for disclosing AECD at the time of certification are consistent with CARB guidance and the current requirements in 1039.205 (b). There is also a long-standing guidance form U.S. EPA and CARB that prohibits the use of component protection AECDs in the case of frail design of engines and aftertreatment components. VPCD-98-13 (x) states, "…whether an AECD is justified as necessary depends in part on considerations of currently available technology. For example, engine protection would not justify an AECD if the need for engine protection is the results of inadequate design of the engine, when viewed in comparison to currently available technology." And CCD-01-02 (v) states, "As set put in the 1998 guidance, U.S. EPA will not approve an AECD for a frail engine design where the need for engine protection is the result of inadequate design of the engine, when viewed in comparison to available technology." So, for the sake of consistency and a level playing field for the entire industry, CARB staff believes this prohibition against component protection AECDs used in the case of frail design should be codified in §1036.205(b)(11). This would be consistent with CARB and U.S. EPA position that any manufacturer who exercise poor or negligent engineering practices be held accountable for the impact to air quality and public health because of excess emissions from poorly designed products. [EPA-HQ-OAR-2019-0055-1186-A2, p.125]

Organization: *Cummins Inc. (Cummins)*

EPA proposes in §1036.115(j)(1) that manufacturers must design SI engines such that catalyst bed temperature does not fall below 350 °C during extended idle or may request an alternative strategy to keep emissions from increasing. It is not clear for what duration the temperature must be maintained, under what range of ambient conditions, what level of which pollutant is considered an emissions increase, or how a catalyst with a different light-off temperature or location would be addressed. In addition to providing clarifications to these questions, EPA could consider a more technology-neutral approach by referencing the target temperature generically as “light-off temperature” rather than 350 °C specifically. [EPA-HQ-OAR-2019-0055-1325-A1, p. 19]

EPA also proposes in §1036.115(j)(2) that for catalyst thermal protection, manufacturers can model exhaust component temperatures if they demonstrate at certification that modeled temperatures are within 5 °C of actual temperatures, rather than designing the engine to continuously monitor exhaust component temperatures. We are concerned that 5 °C is not achievable for accuracy of the model and request for EPA to share any data used to validate the 5 °C threshold. Also, EPA should clarify that engines not using enrichment for catalyst protection would not be subject to this provision. [EPA-HQ-OAR-2019-0055-1325-A1, p. 19]

Spark Ignited Scantool, 40 CFR 1036.110(b)(10)(i): Propose to clearly define air/fuel enrichment, either generic enough for the modes called out in this requirement, or in the context of the 3 modes (throttle, engine protect, catalyst protection) called out in the EPA regulations. [EPA-HQ-OAR-2019-0055-1325-A1, p. 30]

Organization: *Oshkosh Corporation*

Currently, heavy-duty certification requirements—and onboard diagnostic (OBD) requirements in particular—pose a substantial barrier to entry for these technologies due to high development and testing costs. This situation is further complicated by megatrends toward electrification in the transportation industry. We support the aspects of EPA’s proposal intended to provide flexibility in OBD compliance, including EPA’s proposal to allow, with the Agency’s approval, certain OBD test data from spark-ignition (SI) engine-certified products to be carried over to heavy-duty vehicle certification. See 87 Fed. Reg. at 17,483. Under this proposal, manufacturers would be able to certify the OBD of their engine-certified SI products using data from similar chassis-certified Class 2b and Class 3 vehicles meeting the provisions of 40 CFR 86.1806–17 upon showing that the engine- and chassis-certified products use the same engines and generally share similar emission controls (i.e., are “sister vehicles’”). Oshkosh requests that EPA finalize this flexibility with clarification that “sister vehicles” need not be produced by the same manufacturer; in other words, that OBD certification data shared between different manufacturers of record could be used to meet this compliance option, assuming the similarity requirement is met. [EPA-HQ-OAR-2019-0055-1226-A1, pp. 3 - 4]

Organization: *Roush CleanTech (Roush)*

Roush believes the 350ºC extended idle temperature standard, with compliance by manufacturer description as well as flexibility to use alternative methods, as proposed in 1036.115(j)(1) is reasonable. While we concur with EPA that reducing excess idling would be ideal, we appreciate the clear EPA guidance on reference expectations for balancing criteria emissions with CO2 and fuel consumption in this condition. [EPA-HQ-OAR-2019-0055-1276-A1, p.2]

Roush is concerned with EPA’s approach regarding spark ignited thermal modeling discussed in D.2.vi and proposed in 1036.115(j)(2). We believe that the OBD framework already provides a clear methodology for ensuring that inputs (whether physical or models) meet the requirements for emissions controls, and that industry is continually working with the agencies on items very similar to this (reference the performance-based demonstrations required for the thermal modeling used for thermostat monitor, cold start emissions reductions, etc.). We recommend that EPA not pursue this change as part of this regulation and pursue the concern with ARB and industry for implementation in future ARB OBD regulation if necessary. Some of our specific concerns and recommendations as follows:

- We are concerned about EPA's general assumption that temperature sensors are preferred to models, especially in the challenging measurement environments covered here. We believe that if EPA is concerned about the accuracy of information used for thermal protection AECD's, the requirements should be applicable to whatever combination of physical and virtual inputs are used. [EPA-HQ-OAR-2019-0055-1276-A1, p.2]
- The language of (j)(2) is confusing regarding scope of the requirement. The first sentence is specific to 'modeled exhaust component temperatures to protect the catalyst', but later in the paragraph requires 'all modeled and actual temperatures differ by 5ºC or less'. We recommend that EPA make it clear on whether the only accuracy requirement is for the specific modeled parameter used to initiate catalyst protection, or whether the accuracy requirement applies more broadly to include some or all modeled parameters associated with exhaust, even if larger errors in those parameters would not result in excessive activation of the AECD. [EPA-HQ-OAR-2019-0055-1276-A1, pp.2-3]
- We are concerned that EPA seems to be assuming that manufacturers would either utilize sensors or models ('You may use modeled exhaust component temperatures… instead of designing the engine to continuously monitor'); in practice we believe manufacturers almost always utilize models in addition to sensors due to the inherent limitations and failure modes of physical sensors. Specific to catalyst midbrick, in the interest of durability of both the sensors and the catalyst, we would almost certainly not attempt to measure the catalyst midbrick with a production sensor; we would measure gas temperatures at the catalyst inlet and outlet, and then use a model based largely on those temperatures to estimate the brick temperature. The regulation as written would still seem to consider this a 'modeled exhaust component temperature' (the catalyst midbrick temperature is modeled, not measured) and would still require it to meet the accuracy requirement. We don't believe this is what EPA was intending, and illustrates the issues associated with the 'sensor or model' approach. [EPA-HQ-OAR-2019-0055-1276-A1, p.3]
- We believe the requirement as specifically applied to spark-ignited engine catalyst temperatures over the FTP and SET cycles is largely redundant. The FTP emissions standards already ensure that manufacturers do not use enrichment during transient operation expected to be seen during urban vocational use, and the new SET requirement will ensure that enrichment is not triggered during sustained high-load operation as may be seen on heavier over-the-road usage. It is unclear what further air quality benefit would be associated with the additional model accuracy requirement, making it difficult to understand the justification for the increased cost to manufacturers and consumers (both for the initial cost of the additional sensor(s), wiring, and ECU content, the increase in testing costs, as well as the associated increased repair costs). There is offsetting reduction in engineering cost due to the use of sensors—a robust catalyst temperature model would still need to be developed and validated in order to protect the catalyst

during sensor failure conditions, to verify the sensors are accurate, etc.[EPA-HQ-OAR-2019-0055-1276-A1, p.3]

- We do not believe the proposed 5ºC accuracy value is reasonable, and is well beyond the standards even for laboratory equipment. For reference, 1065.307 allows up to 1% of Tmax variation for temperature measurement. For a catalyst midbed sensor capable of 2000ºF (1367K), this would be equivalent to 14ºC allowable error on a certification quality sensor and acquisition system. Clearly the production sensor or model cannot be expected to be anywhere near this accurate. We believe that correlation of the sensor or model of effectively twice the 1065.307 standard (linearity within 2% of Tmax) would be the bare minimum, but even this requirement seems excessive. Again, we don't believe models should be required to meet any requirements which don't apply equally to sensors. [EPA-HQ-OAR-2019-0055-1276-A1, p.3]
- At minimum, we believe EPA would need to develop a robust and complete test method, specifying at least the following:
  - Clarification of which components would be expected to be validated in the regulatory language, including thorough justification in the final rule. EPA language in the NPRM is inconsistent whether the intent is to require model accuracy verification for catalyst midbrick only, or whether such verifications would be required for any engine and/or aftertreatment component where enrichment could be utilized as part of the thermal protection strategy.
  - Clarification on whether EPA is allowing such instrumentation for certification testing, or whether separate tests would be required. Roush's current assumption is that instrumented catalysts and oxygen sensors cannot be used for certification (the instrumentation is intrusive and modifies out of the certified configuration) and therefore there would be additional test burden associated with the requirements in (j)(2).Specific design and accuracy of the reference temperature sensor for each of the component locations EPA would expect to be verified. Catalyst midbrick and oxygen sensors can be extremely challenging even for development purposes; we're interested in what measurement techniques EPA would propose that would meet the requirements for 1065.307.
  - Installation tolerances for the reference sensors (for instance, that the sensor must be located within a specified radial distance of the manufacturer specified modeled location). Obviously manufacturers will attempt to place the sensors as accurately as possible for our own testing, but since these requirements would be subject to agency or independent testing, it is crucial to ensure that the sensor location is well defined.
  - Methodology to account for the transient response characteristics of the reference sensor; models do not have the response delay associated with physical measurement. Filtering the model value based on the measured sensor system time response prior to performing the accuracy validation would seem to be appropriate, but we are open to other suggestions.
  - What condition the engine and/or aftertreatment system should be during testing—should this represent a stabilized (125-hour) condition, full useful life condition, OBD threshold condition, etc.
  - What compliance attestation is expected—are manufacturers considered compliant simply because they have evidence that one engine on day in one cell

> met the requirement, or is there an expectation that any engine on any day in any cell would pass? What level of in-use accuracy is expected, and how would surveillance testing be performed? [EPA-HQ-OAR-2019-0055-1276-A1, pp.3-4]

Organization: *Truck and Engine Manufacturers Association (EMA)*

Regarding idle requirements for SI engines, §1036.115(j)(1) requires that manufacturers maintain 350°C catalyst bed temperatures during extended idle. EMA supports the option to propose alternative strategies to prevent emissions from increasing during extended idling. [EPA-HQ-OAR-2019-0055-1203-A1, p. 43]

EPA Summary and Response

The summary and response for this section includes a summary of comments by category and the responses follow each summary.

EPA proposed two provisions for SI engines in a new 40 CFR 1036.115(j). Specifically, in paragraph (j)(1), we proposed that manufacturers would be required to show how they maintain a catalyst bed temperature of 350 °C in their application for certification or get approval for an alternative strategy that maintains low emissions during idle. In paragraph (j)(2), we proposed to require manufacturers to demonstrate that any thermal models used to initiate catalyst protection are accurate to within 5 °C.

CARB and Roush supported EPA's proposal that manufacturers ensure catalyst bed temperatures maintain a minimum of 350 °C and EMA supported the option for manufacturers to propose alternative strategies for preventing SI engine emissions during idle. Cummins requested that EPA clarify the duration and range of ambient conditions over which that temperature must be maintained, the emission level that would indicate an "increase" from a given pollutant, and whether a different temperature could be used if the catalyst has a different light-off temperature or location. Cummins suggested EPA could consider referencing a generic "light-off temperature" target rather than 350 °C.

<u>Response</u>:

- We disagree with Cummins' suggestion to replace the 350 °C target with "light-off temperature", because we prefer to rely on a specific numeric value, based on the industry-accepted light-off temperature for current catalyst systems, and provide flexibility for manufacturers to identify and obtain approval for a different value as needed. We recognize that the industry may develop new, advanced catalyst formulations or manufacturers may relocate catalysts to a position that would merit a different temperature specification. We are finalizing the 350 °C target, with the option to request approval for a different strategy, as proposed. If a manufacturer chooses such an alternative strategy, they would have to justify to EPA why their strategy is equivalent to maintaining catalyst temperature, including any conditions where emissions vary over time or under specific ambient conditions. We are revising our proposal to also allow manufacturers to request approval of a temperature lower than 350 °C; EPA review of a manufacturer's request would allow us to adjust the temperature specification to account for a different light-off temperature or catalyst location, which is consistent with Cummins' suggestion in the comment.

- We did not intend to limit the scope of the requirement to meet the exhaust temperature specification during extended idle and are therefore not adding specific conditions in response to Cummins' requests for clarification. Manufacturers should be able to demonstrate with engineering analysis and with testing that engines operating indefinitely at idle in any ambient conditions would be able to keep exhaust temperatures above the specified temperature setpoint.
- We intended for the new requirement to maintain exhaust temperatures to apply instead of adopting a defined procedure for measuring emission levels. Our approach of focusing on maintaining a sufficiently warm catalyst temperature, as indicated by our final temperature threshold, avoids the complexity and burden of compliance with a standard with a corresponding test procedure while nevertheless ensuring emissions will be controlled. As a result, there is no need to establish an allowable level of increased emissions.

CARB supported EPA's proposal in paragraph (j)(2) to allow manufacturers to use modeled exhaust component temperatures to protect the catalyst instead of designing the engine to continuously monitor exhaust component temperatures.

Response:

- We appreciate CARB's support for the proposed paragraph (j)(2), but CARB appears to have misinterpreted the proposal as a *new* option to allow manufacturers to model exhaust component temperatures. Manufacturers currently use modeled exhaust temperatures in lieu of continuously monitoring for many of their modern emission control systems for SI engines. Our proposal, which we are finalizing with some revisions noted in this section 3.6.1, was intended to be a new certification step for manufacturers to *validate* those temperature models.
- Manufacturers are already required to report AECDs as part of the certification process. We are updating the proposed regulatory language to clarify that the final validation requirement is specific to temperatures used in AECDs for catalyst protection. These AECDs, which are often activated in sustained high load operation, inherently result in changes in emissions levels in real world scenarios, but would not be observed in the FTP or SET duty cycles run in the laboratory. This validation step would ensure that SI engines relying on catalyst operation at stoichiometric ratios to certify in the laboratory are not excessively triggering enrichment with an AECD in the real world due to conservatively modeled component temperatures (i.e., catalysts, manifolds, exhaust valves, sensor, etc).

Roush and Cummins commented that they do not see the proposed 5 °C allowance as a reasonable delta between modeled and measured exhaust temperatures. Cummins requested that

EPA share data that validates the 5 °C threshold and suggested that engines that do not use enrichment for catalyst protection would not be subject to this requirement. Roush suggested that changes to requirements for thermal modeling are better addressed in a future OBD regulation with the California ARB. Roush expressed concern with EPA's assumption that temperature sensors are preferred, when it is impractical to apply a sensor for some components, such as the catalyst itself. Roush also suggested that a more "robust and complete test method" would be required, and included several clarifications to the proposal.

Response:

- We are revising our proposed provision to remove the specific accuracy demonstration requirement. We believe our revised approach will ensure EPA has the information needed to appropriately assess a manufacturer's AECD strategy, while avoiding Roush's concern over overlap with OBD requirements. We are revising the proposed paragraph (j)(2) as follows:
    - Clarifying that the new validation process is an additional requirement for any spark-ignition engine that includes an AECD for thermal protection in its application for certification.
    - Replacing the proposed 5 °C accuracy demonstration with a more general validation process that builds on the information requirements that we proposed and are finalizing for 40 CFR 1036.205(b). Manufacturers would describe why they rely on an AECD instead of other engine designs that can provide thermal protection, and describe the accuracy of any modeled or measured temperatures that would activate the AECD. Instead of requiring manufacturers to upfront submit second-by-second data to demonstrate a specific accuracy requirement is met, the final regulation gives EPA discretion to request the information at certification.
- In response to Cummins, we reiterate here and in the preamble for this final rule that this requirement would not apply to engines that manufacturers certify without an AECD for thermal protection.
- In response to Cummins request for data, the proposed 5 °C threshold was chosen based on EPA experience with manufacturer compliance data, but we are not including that proposed accuracy requirement in this final rule.
- In response to Roush's requests for a test method and additional clarification, we did not intend for this new requirement to include a defined test procedure. The more general validation process we are finalizing in this rule will not require additional testing to demonstrate a specific accuracy. Instead, we are requiring manufacturers to share more specific information to justify their AECD strategy during the certification process. Manufacturers are generally allowed to continue to use the modeled or measured temperatures that are most appropriate for their engines. We agree with Roush's suggestion that EPA should apply the same accuracy requirements to physical and virtual inputs used to AECD. The final provision includes a requirement to describe the accuracy of any AECD-triggering measured temperatures in addition to modeled temperatures.

EPA proposed a new 40 CFR 1036.110(b)(10) with two OBD provisions requiring new parameters to be available using a generic scan tool. For the first provision, Cummins requested EPA clarify the term "air/fuel enrichment" in proposed 40 CFR 1036.110(b)(10)(i), requesting a definition that is either generic enough for the modes called out in this requirement, or in the context of the 3 modes (throttle, engine protect, catalyst protection). CARB did not comment on the proposed 40 CFR 1036.110(b)(10), but did refer to the text for the second generic scan tool requirement that was in the preamble, noting that their staff could not locate the specific regulatory language.

Response:

- In response to Cummins request for clarification, we revised the proposed 40 CFR 1036.110(b)(10)(i) to include a description of the engine operation we consider in enrichment. Specifically, we are adding two sentences specifying that manufacturers include all time after engine warm-up when the engine is not operating at the air-fuel ratio designed for peak three-way catalyst efficiency and describing peak efficiency as typically involving closed-loop feedback control. As proposed, we are finalizing the requirement that the OBD system track enrichment based on throttle, engine protection, and catalyst protection. We intend this to mean that OBD parameter will indicate if the enrichment is due to 1) engine load, which includes inputs such as throttle, mass air flow, manifold pressure, 2) engine and engine component protection, and/or 3) protection of the catalyst or other exhaust emissions components.
- In response to CARB, we regret that the preamble text described the provision in proposed 40 CFR 1036.110(b)(10)(ii), but incorrectly referred to paragraph (c). We are not taking final action on this proposed provision to require modeled or measured component temperature parameters for heavy-duty spark-ignition engines at this time. We would like to clarify the type of information we would like the generic scan tool to include for component temperatures and believe it is better to solicit additional information in a future rule.

In a new 40 CFR 1036.110(a)(2), we proposed to allow vehicle manufacturers the option to request approval to certify the OBD of their spark-ignition, engine-certified products using data from similar chassis-certified Class 2b and Class 3 vehicles that meet the provisions of 40 CFR 86.1806-17. Oshkosh Corporation and CARB commented in support of the proposed OBD flexibility and CARB suggested some revisions to the proposed regulatory language. CARB suggested that the expression 'share essential design characteristics' was too vague, and requested EPA provide more specific information on what EPA will use to make their determination.

Response:

- We are revising our proposed regulatory language after considering CARB's request for more specific information. As described in the proposed rule, we want to encourage manufacturers to gain the advantage of more comprehensive monitoring by meeting chassis-based OBD requirements for vehicles that are closely related to Class 2b and 3 vehicles certified under 40 CFR 86.1806-17. Commenters shared only a general concern regarding the ambiguity of the proposed provisions rather than responding to the request in the proposed rule for comments suggesting regulatory changes that provide specific criteria to qualify candidate vehicles under this provision. This flexibility is approved through the certification process and the provision requires manufacturers to identify the design characteristics and justify their request. We are adjusting the wording of 40 CFR 1036.110(a)(2) to more carefully track the proposed preamble for describing how manufacturers qualify for this provision by installing the same engines into vehicles above and below 14,000 lb GVWR that share similar emission controls.

CARB staff commented that EPA should codify in 40 CFR 1036.205(b)(11) the prohibition against component protection AECDs used in frail design, as described in existing EPA guidance (VPCD-98-13 and CCD-01-02). CARB has published similar guidance. CARB stated that the guidance documents prohibit the use of component protection AECDs in the case of frail or inadequate design of engines and aftertreatment components. CARB further stated that any manufacturer exercising poor or negligent engineering practices should be held accountable for the impact to air quality and public health because of excess emissions from poorly designed products.

Response:

- The fundamental provision of the guidance related to “frail designs” is that EPA will not approve an AECD for a frail engine design where the need for engine protection is the result of inadequate design of the engine, when viewed in comparison to available technology. The proposed provisions related to engine and catalyst protection for spark-ignition engines were intended to accomplish that same purpose of relying on AECDs for protection only to the extent that other engine designs are not suitable to accomplish that protection. The final rule at 40 CFR 1036.115(j)(2) includes a requirement for manufacturers to justify their need for AECDs instead of other engine designs for thermal protection of catalyst or other emission-related components. We may consider revising 40 CFR 1036.205 in a future rulemaking to include additional elements from the guidance.

3.6.2 Off-cycle standards and low load cycle for Spark-ignition HDE

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

U.S. EPA requested comment on allowing manufacturers to attest to off-cycle emissions compliance. CARB staff suggests adding a compliance statement for SI HDE engines with off-cycle standards, similar to the requirements in the Omnibus regulation.134 A compliance statement would hold manufacturers accountable for the real-world emissions without the requirement that manufacturers need to conduct in-use testing. This would allow U.S. EPA the option of conducting off-cycle testing if it chooses to do so. SI HDEs do not have the same emission control challenges faced by CI engines. SI HDEs are capable of quick thermal management enabling early emission control during cold starts and do not have the same challenges to maintain emission control under extended low load operation. CARB staff recommends adopting the Omnibus off-cycle standards for SI HDEs as implemented by CARB's Omnibus program. [EPA-HQ-OAR-2019-0055-1186-A2, p.62]

134 https://ww2.arb.ca.gov/rulemaking/2020/hdomnibuslownox

U.S. EPA requested comment on allowing manufacturers to attest to off-cycle emissions compliance. CARB staff supports the addition of 1036.205(p) requiring a compliance statement stating the engines meet the off-cycle emissions standards when tested using the off-cycle test procedures. This is an important change with the new off-cycle emission standards and test procedures for newer engines. [EPA-HQ-OAR-2019-0055-1186-A2, pp.62-63]

Organization: *Great Rivers Environmental Law Center and Dutchtown South Community Corporation (DSCC)*

The undersigned support inclusion of the following requirements in the Final Regulation:

- Mandatory idling mode and low-load cycle testing of both CI and SI engines, conducted at certification and during in-use testing; [EPA-HQ-OAR-2019-0055-1323-A1, p.5]

Organization: *National Propane Gas Association (NPGA) and Propane Education & Research Council (PERC)*

We suggest the following modifications to the Proposed Option 1:

- 3. **Comments on Low Load Cycle (LLC)**: In response to the agency’s solicitation of feedback on the proposed requirements for LLC certification for spark ignited engines, we do not have significant concerns.11 However, stoichiometric spark ignited engines operating with propane do not undergo frequent catalyst deactivation; unlike diesel engines due to the higher exhaust temperatures and shorter time for catalyst reactivation during load changes. Therefore, the inclusion of LLC certification requirements would provide an opportunity for propane engines to compare more favorably to diesel engines. [EPA-HQ-OAR-2019-0055-1263-A1, p.3]

11 Supra note 1, at 17460.

Organization: *Truck and Engine Manufacturers Association (EMA)*

Regarding spark-ignited engines, EMA does not support the addition of the in-use MAW requirements for gasoline SI engines. EPA’s addition of the SET test for gasoline engines sufficiently covers real-world operation, especially with respect to high-load operation where gasoline engines are most challenged for tailpipe criteria emissions. Additionally, low-load operations should not be a concern, since gasoline SI engine inherently have much higher exhaust temperatures than diesel. [EPA-HQ-OAR-2019-0055-1203-A1, p. 85]

EPA Summary and Response

The summary and response for this section includes a listing of the topics raised, then the comments are summarized by category and the responses follow each summary.

CARB staff recommended EPA adopt off-cycle standards for SI HDEs as implemented by CARB's Omnibus program. CARB staff suggested adding a compliance statement for SI HDE engines with off-cycle standards would hold manufacturers accountable for the real-world emissions without the requirement that manufacturers perform in-use testing. CARB indicated that the compliance statement would allow EPA the option of off-cycle testing if it chooses. CARB staff recommends adopting the Omnibus off-cycle standards for SI HDEs as implemented by CARB's Omnibus program.

EMA does not support the addition of the in-use MAW requirements for gasoline SI engines, suggesting that the SET test for gasoline engines would cover the high-load operation where gasoline engines are most challenged for tailpipe criteria emissions in real world operation.

Response:

- We did not propose and are not finalizing separate off-cycle standards or in-use testing requirements for Spark-ignition HDE in this rule. This final rule includes several new requirements for manufacturers of Spark-ignition HDE that will ensure manufacturers are designing their engines to address emissions over a broader range of operating conditions that are not covered by the FTP duty cycle currently used for certification. We intend to evaluate certification data from the new SET duty cycle, in combination with the new idle and enrichment requirements we are finalizing in 40 CFR 1036.115(j), and may consider adopting off-cycle standards or in-use testing requirements for Spark-ignition HDE in a future rule.

- We disagree with CARB that off-cycle standards are needed for SI engines. EPA has the ability to do any amount of inspection or testing to inform our decision making about which engines to test for evaluating compliance with duty cycle standards. In-use and off-cycle test results, from EPA or others, can serve as a screening tool to help EPA identify the need for further duty cycle testing. As noted in section III of the preamble, we are expanding the engine operation covered by heavy-duty SI duty cycle testing by setting new standards over the SET duty cycle to apply for those engines. We believe the combination of the SET and FTP duty cycles represent most of operation of heavy-duty SI engines and will capture most real-world emissions from those engines. Furthermore, EPA's current approach of reviewing designs for defeat devices will further ensure that manufacturers will control emissions over the full range of engine operation, which can achieve a similar result as manufacturers attesting to off-cycle emissions compliance.

Great Rivers et al. and NPGA/PERC commented in support of the LLC for SI engines. Neither organization provided data or additional information. Great Rivers et al. also supported mandatory idling mode to apply at certification and in-use. EMA stated that low-load operations should not be a concern, since gasoline SI engine inherently have much higher exhaust temperatures than diesel.

Response:

- We did not propose and are not finalizing LLC to apply for heavy-duty SI engines at this time. We did not include LLC as part of our SI engine demonstration program to inform feasibility of LLC standards. We recognize that, at this time, we are primarily addressing high-load and idle operation with the new SET duty cycle standards, enrichment requirements, and idle requirements we are finalizing in this rule. We note that our prioritization for this rule does not mean we agree with EMA that low-load operations "should not be a concern"; we intend to evaluate certification data from the new SET duty cycle, in combination with the new idle and enrichment requirements we are finalizing in 40 CFR 1036.115(j). We may consider adopting low-load requirements for Spark-ignition HDE in a future rule.
- We did not propose and are not finalizing mandatory idle testing for heavy-duty SI engines. We are finalizing a requirement to ensure that SI engine catalysts maintain a temperature of 350 °C during extended idle and we continue to believe, as noted in the NPRM, that the catalyst temperature control provision we are finalizing would effectively address idle emissions for heavy-duty SI engines in the lab and in the real world. See Section III.D of the preamble to this final rule and section 3.6.1 of this document.

3.6.3 ORVR for Spark-ignition HDE

Comments by Organizations

Organization: *Truck and Engine Manufacturers Association (EMA)*

The Agency's proposal includes new evaporative emissions control requirements during refueling. Those requirements, new to HD gasoline vehicles, will require Onboard Refueling Vapor Recovery (ORVR) systems to comply. EPA has requested comment on the proposed ORVR standard level, test procedures, canister conditioning and fuel-rig testing. [EPA-HQ-OAR-2019-0055-1203-A1, p. 120]

Although similar light-duty ORVR hardware could be deployed on heavy-duty incomplete vehicles to meet the new refueling evaporative emissions limits, the large fuel tank and canister sizes of those vehicles present a unique challenge to industry in balancing ORVR and canister BETP emissions. They will also require complete fuel system redesigns on many heavy-duty vehicles. Large scale use of these larger canisters to ORVR and canister BETP requirements has not been demonstrated by industry. Due to the uncertainty regarding the use of the new canister designs, EMA is requesting longer test schedule drive sequences and a heavy-duty ORVR compliance three-year phase-in of 30%, 60% and 100%. [EPA-HQ-OAR-2019-0055-1203-A1, p. 120]

EPA acknowledges that the real-world operating conditions of heavy-duty vehicles are more challenging than for light-duty vehicles (87 FR at p. 17491), and requests comments on possible adjustments to the ORVR test procedure. EMA recommends that an additional FTP-75 drive schedule be added to the 3-Day, 2-Day, canister BETP and ORVR test procedures following the canister load and prior to the drive schedule. That procedure would align with existing approved drive schedules utilized for certification by heavy-duty vehicle manufacturers. [EPA-HQ-OAR-2019-0055-1203-A1, p. 121]

EPA also requested comment on potential adjustments to the canister-load procedure. Manufacturers have several decades of testing experience with canisters loaded to a saturated condition and are uncertain as to any appropriate adjustments regarding the canister-load procedure. To propose an alternate canister-loading condition, extensive testing would be required to determine the correct condition and resulting impact on the emission test results. Due to that uncertainty, EMA proposes that EPA adjust the drive schedules, as proposed above, to better reflect heavy-duty vehicle real-world operating conditions rather than consider adjustments to the canister-load condition. [EPA-HQ-OAR-2019-0055-1203-A1, p. 121]

Also due to the uncertainty of the execution of these new canister designs to meet the ORVR requirements, EMA requests a heavy-duty ORVR three-year compliance phase-in of 30%, 60% and 100%, starting with MY 2027. EPA should also consider an alternative OBD2-style ORVR phase-in schedule, which would incentivize OEMs to certify products to the heavy-duty ORVR requirements as early as possible, and may encourage OEMs to certify 8,501 to 14,000 lb. GVWR incomplete vehicles to the heavy-duty ORVR requirements. CARB provided for an optional phase-in period to comply with the LEV III evaporative and refueling requirements. OEMs found the phase-in to be useful and necessary in transitioning their product lines to the new requirements, and therefore EMA recommends a similar option for HD vehicles. [EPA-HQ-OAR-2019-0055-1203-A1, p. 121]

For fuel system rigs and vehicles that can fit into the existing ORVR SHEDs, the light-duty test procedures with the proposed revised drive schedules, or a bench purge of the canister for rig testing as outlined in the CARB section 12.5.2 BETP test procedure, could be conducted. [EPA-HQ-OAR-2019-0055-1203-A1, p. 121]

Due to the steady-state temperature condition and short duration of the ORVR test, nonfuel-based background emissions do not have an impact on the ORVR test results. Overall vehicle contribution to the ORVR HC mass observed in the SHED is negligible. For example, consider the case of a 1-hour hot soak during the 2-day evaporative test, where the vehicle may emit 0.05g/60min, while also assuming a 50-gallon fuel tank undergoing a refueling test at 9.8 gal/min (assuming a 10% prefill and 1 minute dwell time after nozzle shutoff). Such a case would result in 0.0001 g/gal HC dispensed, less than 0.05% of the ORVR standard. The outcome of this analysis under reasonable assumptions indicates that an adjustment to the ORVR standard is not required to account for the extremely small differences in rig tests and vehicle tests. [EPA-HQ-OAR-2019-0055-1203-A1, p. 121]

Testing heavy-duty vehicles and rigs can present unique test procedure challenges compared to those involved in light-duty vehicle testing. There are situations where a heavy-duty refueling test must be stopped and restarted (e.g., dual fuel tanks with separate filler tubes or fuel dispensing constraints). For testing those systems, EMA recommends following the ORVR light-duty vehicle test procedures with the proposed drive schedules, but further recommends treating the actual refueling portion of the test as two separate fueling actions. More specifically, EMA recommends the following provision: Measure the hydrocarbon increase in the SHED for each refueling action. Sum the two hydrocarbon increases and divide by the total amount of fuel dispensed for both ORVR refueling events. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 121 - 122]

The revisions to the test procedures and the ORVR phase-in schedules proposed by EMA should be taken into consideration by EPA for future rulemakings that are applicable to 8,501 to 14,000 lb. GVWR incomplete heavy-duty vehicles. EMA also recommends that EPA clarify that the ORVR requirements would be applicable to vehicles that operate on volatile fuels, but exclude diesel-fueled vehicles. [EPA-HQ-OAR-2019-0055-1203-A1, p. 122]

EPA is proposing to use engineering analysis for heavy-duty ORVR compliance in lieu of demonstration testing (87 FR at p. 17491). EMA supports that proposal, which is reflective of existing practice in the current HD regulations. EMA also supports EPA's proposal to align heavy-duty ORVR useful life requirements with the existing evaporative useful life requirement of 15 years or 150,00 miles (87 FR at p. 17490). Such alignment reduces certification and database burden. [EPA-HQ-OAR-2019-0055-1203-A1, p. 122]

EPA has requested comment on the appropriate ORVR SHED mixing time for heavy-duty vehicle testing (see 87 FR at pp. 17491 and 17495). Modifications to the mixing time are not required on existing ORVR SHEDs. If existing ORVR SHEDs and/or the rig approach are used, SHED mixing time modifications are not required as the longer fuel-fill events for large fuel tank refills address this concern, where canister emissions must be controlled during the ORVR fill. The graph below presents an example of an ORVR test on a large fuel tank product, where the FID reading is stable within the current mixing time of 60 seconds. [EPA-HQ-OAR-2019-0055-1203-A1, p. 122]

EMA recommends that the vehicle volume used for fuel rig testing should be the same volume used for PZEV rig testing (5 cubic feet as specified in CARB MAC 2001-03, November 2001). Manufacturer testing of large fuel tank fuel rigs indicates that the current mixing time is appropriate, and the 5 cubic feet vehicle volume value as specified in CARB MAC 2001-03 is appropriate for heavy-duty ORVR testing. [EPA-HQ-OAR-2019-0055-1203-A1, p. 122]

EPA's proposal provides that in cases where there is a secondary manufacturer, the ORVR certification and fuel system installation instructions will be controlled by the original OEM (87 FR at pp. 17491-17492). EMA supports the EPA proposal, as it is consistent with current practice related to heavy-duty spitback compliance regulations. [EPA-HQ-OAR-2019-0055-1203-A1, p. 123]

Updates and corrections are required to the proposed evaporative SHED calculations outlined in proposed §86.117-96. EPA's proposed equation in §86.117-96(d) for Methanol mass contains a typographical error. The temperature of the sample withdrawn (TE) is only multiplied by the concentration from the 1st Impinger. TEf and TEi need to move outside of the parenthesis so it applies to the sample from both impingers. [EPA-HQ-OAR-2019-0055-1203-A1, p. 123]

Additionally, for consistency, EPA should align the Methanol mass equation in §86.143-96(b)(1)(i) with the Methanol mass equation in §86.117-96(d), as proposed in the NPRM. [EPA-HQ-OAR-2019-0055-1203-A1, p. 123]

Also related to the proposed calculations, updates and corrections are required to the SHED evaporative calculations to be consistent with other areas of the CFR and to reflect the latest available standard practices for evaporative calculations. For example, the THC density referenced for the THCE equation in §86.143-96(c) is incorrect. The THC density referenced in §1066.1005(f) is based on a hydrogen-to-carbon ratio of 1.85. As defined 86.143-96(b)(ii), for evaporative emissions, the THC mass assumes a hydrogen to carbon ratio of 2.3. EMA recommends using a density of THC with an H/C ratio of 2.3 in §1066.1005(f), and that EPA update the reference in §86.143-96(c) accordingly. [EPA-HQ-OAR-2019-0055-1203-A1, p. 123]

EMA also has concerns about how the test fuel is specified for ORVR testing. Having a singular test fuel reduces regulatory burden and streamlines the laboratory testing process. The general testing fuel outlined in §1065.710 aligns with the other testing requirements specified in the EPA Tier 3 regulations. Both conventional and flex-fuel vehicles use the same commercial E10 fuel during refueling. Accordingly, the test fuel specified for both should be the same. EMA recommends that EPA specify that the heavy-duty ORVR test fuel should meet the fuel requirements outlined in §1065.710 for general testing for both conventional and flex-fuel vehicles. [EPA-HQ-OAR-2019-0055-1203-A1, p. 123 - 124]

Finally, EMA recommends that EPA revise the ORVR fuel-dispensing rate specification. Having a uniform dispensing rate reduces regulatory burden and streamlines the laboratory testing process. Providing for a 9.8 gpm fuel rate would align with the global ORVR fuel-dispensing rate requirements. For fleet customers it is desirable to maximize fill rate (e.g., minimize refueling time) to minimize vehicle down-time. EMA therefore recommends that EPA specify the ORVR fuel dispensing rate as a uniform regulated rate of 9.8 gpm. [EPA-HQ-OAR-2019-0055-1203-A1, p. 124]

With the above recommended modifications to the final rule, EMA believes that the refueling evaporative emissions requirements would be workable and achievable. EMA is ready to work with the Agency on these detailed recommendations. [EPA-HQ-OAR-2019-0055-1203-A1, p. 124]

Organization: *Alliance for Vehicle Efficiency (AVE)*

AVE supports EPA's proposal to expand Onboard Refueling Vapor Recovery (ORVR) to incomplete heavy-duty vehicles rated over 14,000 lbs. [EPA-HQ-OAR-2019-0055-1280-A1, p. 6]

AVE recommends EPA expand ORVR to incomplete heavy-duty vehicles rated over 14,000 pounds Gross Vehicle Weight Rating, with a refueling emission standard of 0.20 grams hydrocarbon per gallon of liquid fuel dispensed, applicable for a useful life of 15 years or 150,000 miles. [EPA-HQ-OAR-2019-0055-1280-A1, p. 6]

With regulatory developments since ORVR was first introduced in 1994, primary and secondary manufacturers have gained significant experience with ORVR technology on all categories of gasoline vehicles, including complete heavy-duty gasoline vehicles (HDGVs) and even incomplete light-heavy-duty gasoline vehicles (LHDGVs). [EPA-HQ-OAR-2019-0055-1280-A1, p. 6]

Cost-effective ORVR technology is available to control refueling emissions, supported by the EPA's draft regulatory impact analysis for this proposed rule. ORVR is a proven technology to significantly reduce evaporative and refueling emissions, resulting in meaningful emission reductions of volatile organic compounds that lead to the formation of ozone and secondary particulate matter (PM2.5), as well as emissions of hazardous air pollutants. [EPA-HQ-OAR-2019-0055-1280-A1, p. 7]

Organization: *Ingevity Corporation (Ingevity)*

Ingevity supports EPA's proposal to expand ORVR to incomplete heavy-duty gasoline vehicles (HDGVs) rated over 14,000 lbs. GVWR, including the proposed refueling emission standard of 0.20 grams hydrocarbon per gallon of liquid fuel dispensed applicable for a useful life of 15 years or 150,000 miles. ORVR is a proven technology to significantly reduce evaporative and refueling emissions, resulting in emission reductions of volatile organic compounds that lead to the formation of ozone and secondary particulate matter (PM2.5), as well as emissions of hazardous air pollutants. [EPA-HQ-OAR-2019-0055-1213-A1, p. 2]

EPA should pursue ORVR for incomplete vehicles above 14,000 lb. GVWR (hereinafter referred to as HHDGVs)2, as this is the only remaining class of gasoline motor vehicles without refueling control. With regulatory developments since ORVR was adopted in 1994, manufacturers have gained significant experience with ORVR technology on all categories of gasoline vehicles, including complete heavy-duty gasoline vehicles (HDGVs) and even incomplete light-heavy-duty gasoline vehicles (LHDGVs). Cost-effective technology is available to control refueling emissions and there should no longer be implementation concerns. [EPA-HQ-OAR-2019-0055-1213-A1, p. 3]

> 2. Within this document LHDGV: means an HDGV with a GVWR between 8,501 and 14,000 lbs. GVWR. ORVR test procedures within 40 CFR 86 Subpart B apply to complete and incomplete LHDGVs. HHDGV means an incomplete HDGV with a GVWR more than 14,000 lbs.

OEMs and secondary manufacturers now have 35 model years of experience in working together on measures to ensure that any actions taken by the secondary manufacturer to complete the vehicle do not violate the certificate of conformity or create in-use issues for on-vehicle fuel vapor control systems. In addition, there are now several regulatory provisions which provide structure to how OEMs and secondary manufacturers may work together (40 CFR §§1037.130,621, 622) under EPA's certification programs. This long experience together with the very recent regulatory provisions suggest that any concerns have been addressed and there is no need for added regulatory measures. [EPA-HQ-OAR-2019-0055-1213-A1, p. 3]

In the feasibility analysis for ORVR of the NPRM10, EPA includes a discussion on the activated carbon working capacity assumptions for sizing a canister. Ingevity believes a clarification to this text is needed for the use of the terms and values for "efficiency" and "canister loading efficiency". The original text and a proposed change for clarification are provided below. [EPA-HQ-OAR-2019-0055-1213-A1, p. 4]

10. 87 FR 17493, (March 28, 2022).

Original text: "During the diurnal test, the canister is loaded with hydrocarbons over two or three days, allowing the hydrocarbons to load a conventional carbon canister (1500 GWC, gasoline working capacity) at a 70 percent efficiency. In contrast, a refueling event takes place over a few minutes, and the ORVR directs the vapor from the gas tank onto the carbon in the canister at a canister loading efficiency of 50 percent. For our analysis, we added a design safety margin of 10 percent extra carbon to our ORVR systems." [EPA-HQ-OAR-2019-0055-1213-A1, pp. 4 - 5]

Proposed change for clarification: During a diurnal test, the carbon canister is loaded with hydrocarbons from the fuel tank over the course of two or three days. Under these very slow loading conditions, a Tier 3 baseline canister filled with 15 BWC carbon11 will exhibit a gasoline working capacity (GWC) of around 70 g/L of carbon. In contrast, during a refueling event, hydrocarbons are being directed from the fuel tank to the ORVR canister within only a few minutes. This faster loading rate results in a reduction of the GWC to approximately 50 g/L. For this analysis, a design safety margin of 10 percent was added to the minimum ORVR carbon volume. [EPA-HQ-OAR-2019-0055-1213-A1, p. 5]

11. 15 BWC = butane working capacity as defined by ASTM D5228

Approaches to adapt the current test procedures used by lower GVWR vehicles for vehicles above 14,000 lb. GVWR and appropriate conditioning procedure for these larger vehicles [EPA-HQ-OAR-2019-0055-1213-A1, p. 5]

In the NPRM, EPA requests comment on appropriate mixing times and approaches for calculating SHED displacement for larger SHED enclosures. In EPA's final rule, "Control of Air Pollution From New Motor Vehicles and New Motor Vehicle Engines; Evaporative Emission Regulation and Test Procedure for 1985 and Later Model Year Gasoline-Fueled Heavy-Duty Vehicles"12, EPA included a mixing rate of 500-750 cfm/1000ft3 of SHED volume and default vehicle volume of 100 ft3. Ingevity agrees that requiring the concentration in the SHED to stabilize before the final concentration measurement would be an appropriate approach. [EPA-HQ-OAR-2019-0055-1213-A1, p. 5]

12. 48 FR 1465 (Jan 12, 1983)

EPA asked for comment on specific canister conditioning cycle or adjustments to the current conditioning cycle to better represent real-world heavy-duty vehicles during a refueling event.

Current evaporative emission test procedures which apply to all HDGVs and refueling emission test procedures which apply to LHDGVs and complete HHDGVs are based on the procedures and drive cycles specified in 40 CFR §86 Subpart B. In the past there were HDGV specific drive cycles under 40 CFR §86 Subpart M.13 Even in the earlier HDGV evaporative emission test procedures, manufacturers had the opportunity to use light-duty procedures in lieu of those specific to HDGVs. In the Tier 3 final rule, the HDGV specific procedures were dropped and replaced completely with those in 40 CFR §86 Subpart B and the provisions of 40 CFR §1037.103(c) were applied to all HDGVs over 14,000 lbs. GVWR as an option for evaporative and refueling emissions certification. [EPA-HQ-OAR-2019-0055-1213-A1, p. 5]

13. See §86.1245 (Subpart M) within "Evaporative Emission Regulation and Test Procedure for 1985 and Later Model Year Gasoline-Fueled Heavy-Duty Vehicles," 48 FR 1465, Jan 12, 1983.

Given that evaporative and refueling emission control systems depend on the same purge systems and canisters for effective control, it would not be possible to substitute different preconditioning drive cycles for HHDGV ORVR without also changing those for HHDGV evaporative emission control. Beyond this, since much of the premise for certification under 40 CFR §1037.103(c) depends on LHDGV certification data developed under 40 CFR §86 Subpart B, the current construct of the HHDGV evaporative and refueling emission regulations would have to be reproposed. Nevertheless, EPA retains the authority and flexibility provided under 40 CFR §1066.10. [EPA-HQ-OAR-2019-0055-1213-A1, p. 5]

Other testing options EPA should consider for manufacturers to demonstrate the effectiveness of their ORVR systems on incomplete vehicles above 14,000 lb. GVWR. [EPA-HQ-OAR-2019-0055-1213-A1, p. 6]

In our comments on the ANPRM, Ingevity suggested that HHDGV ORVR certification be based primarily on 40 CFR §86 Subpart B test procedures, with engineering analysis only applicable when SHED based procedures are not practical. After reviewing the language in the NPRM, Ingevity supports a two-prong approach to the certification provisions. The refueling emission standard (0.20 g/gal of dispensed gasoline) is a performance standard and we believe it is essential that EPA adopt specific laboratory test procedures such as the SHED based procedures in 40 CFR §86 Subpart B for demonstrating compliance. These test procedures already apply to LDVs, LDTs, and LHDGVs, and with appropriate modifications, can and should be applied to all HHDGVs. Nonetheless, there are technical and practical reasons why the current language in 40 CFR §1037.103(c) provides manufacturers of HHDGVs the option to certify evaporative and refueling emissions using an engineering analysis approach in addition to the 40 CFR §86 Subpart B test procedures.14 We support providing the manufacturers the option to use 40 CFR §1037.103(c) for refueling emission certification for both complete and incomplete HHDGVs. [EPA-HQ-OAR-2019-0055-1213-A1, p. 6]

14. See p. 23508 of "Control of Air Pollution from Motor Vehicles: Tier 3 Motor Vehicle Emission and Fuel Standards," 79 FR 23414, April 28, 2014.

EPA also sought comment on two other approaches for certification. The first is a bench test where a fuel/evaporative/refueling emission control system mock-up is installed in a light-duty SHED instead of on an HDGV chassis. The second is the evaluation of a component, subassembly, and/or a full assembly in a light-duty SHED or a mini-SHED. EPA did not specify how information from these evaluations could be used as a basis for certification. Component/subassembly/assembly evaluations conducted by vendors and vehicle manufacturers are valuable tools in the development and prove out of hardware and system designs and indeed may be useful in assessments related to establishing designs, assessing some elements of performance, functional durability, and diagnosing problems. Such information could be useful in certification under 40 CFR §1037.103(c). A good example of this might be where an element of design is used in an HHDGV configuration, but a similar element of design is not found in an LHDGV system (e.g., mechanical fill pipe seal). However, information from these types of tests alone would not provide conclusive evidence of full system performance for certification purposes. [EPA-HQ-OAR-2019-0055-1213-A1, p. 6]

The NPRM does not specifically state that the ORVR requirement would apply to new HHDGVs sold in all 50 states. While it is possible that CARB will move to adopt HHDGV ORVR requirements within their mobile source emission standards program, we recommend that EPA affirmatively state in the final rule that the requirements are nationwide such as was done in the preamble to the original ORVR final rule.15 [EPA-HQ-OAR-2019-0055-1213-A1, p. 6]

> 15. See p. 16266, ”Control of Air Pollution From New Motor Vehicles and New Motor Vehicle Engines; Refueling Emission Regulations for Light-Duty Vehicles and Light-Duty Trucks,” 59 FR 16262, April 6, 1994.

The family criteria for evaporative and refueling emissions certification are codified in 40 CFR §86.1821-01. These criteria are quite general and leave much to the manufacturers use of good engineering judgment. It is recommended that these provisions be clarified to address that they apply to LDVs, LDTs, and HDGVs. Furthermore, for refueling emissions, EPA should address whether LHDGVs certified using Subpart B test procedures can be grouped with HHDGVs certified using the Compliance Demonstration provisions in 40 CFR §1037.103(c) or if they should be kept separate. Also, to help inform the manufacturers use of good engineering judgment under §86.1821-01 and 40 CFR §1037.103(c) it would be helpful to add criteria related to fuel tank volume, total canister adsorptive capacity, and purge in certification guidance. Finally, to facilitate certification and reduce testing burdens for HHDGVs, the evaporative and refueling family criteria should be clarified and optimized as needed to allow for maximum application of certification data across LHDGVs and HHDGVs, consistent with good engineering practice and in other regulations. [EPA-HQ-OAR-2019-0055-1213-A1, p. 7]

EPA has proposed that HHDGVs meet the refueling emission standards for a useful life of 15-years/150,000 miles, consistent with their requirements for evaporative emission standards. We support this requirement. EPA is seeking comment on other useful life periods for HDGE exhaust emission standards for model years later than the 2027 model year implementation proposed for ORVR implementation. In no case should future useful life requirements for evaporative/refueling emissions be longer than for the exhaust emission standards, and since EPA did not explicitly propose that evaporative and refueling emission standards be included in the potential longer useful life periods on which EPA is seeking comment for exhaust emission standards, we recommended that the useful life for evaporative/refueling emission standards not be extended beyond 15-years/150,000 miles in this rule, even if it is for HDGE exhaust emissions. [EPA-HQ-OAR-2019-0055-1213-A1, pp. 7 - 8]

Evaporative/refueling emission standard durability assessment provisions are covered in 40 CFR §§86.1824-08 and 86.1825-08. EPA is proposing a set of changes for exhaust emissions, but no changes or new provisions were proposed for evaporative or refueling emissions. We recommend that the current provisions for evaporative and refueling emissions be retained. [EPA-HQ-OAR-2019-0055-1213-A1, p. 8]

The NPRM included a brief discussion regarding the use of mechanical fill pipe seals which in our view provided an incomplete picture of the potential for their use in HHDGVs. While EPA did not oppose or preclude the use of mechanical fill pipe seals, previous EPA regulatory analyses for ORVR systems were based mostly on the use of liquid fill pipe seals (dynamic and submerged). There were several reasons for this approach. The first, as expressed by EPA in the NPRM, was component durability and related to this the potential for adverse impacts of worn nozzle spouts. Second, most if not all LDVs, LDTs, MDPVs, and LHDGVs covered by ORVR had enough fill height for a liquid seal to work effectively, even with the system backpressure. However, EPA also favored liquid seals because overall hardware costs were less and the viability of such designs was demonstrated by the fact that several vehicle models already had fill neck and fill pipe geometries which effectively functioned as a liquid fill pipe seal and included one of several types of anti-spit back valves (sometimes referred to as a fuel filler tube check valve) needed to address spillage at nozzle automatic shut-off. In discussing liquid versus mechanical seals, it was noted that limited data indicates that refueling vapor generation is 20-25% less in a mechanical seal versus liquid seal design.16 This could be an advantage for some vehicle models. [EPA-HQ-OAR-2019-0055-1213-A1, p. 8]

> 16. S.R. Reddy, "Mathematical Models for Predicting Vehicle Refueling Vapor Generation," SAE 2010-01-1279, April 2010.

Over the past 10-15 years there have been two changed circumstances related to mechanical seals. First, there have been improvements in the materials used in the seals which at least directionally improves durability in areas such as tolerance to alcohols and temperature extremes. Second, powertrains and fuel system designs have evolved, and these changes have led some manufacturers to use mechanical seals to reduce refueling vapor generation. This has mostly occurred in vehicles such as PHEV models (many with NIRCOS) which tend to have powertrain designs which provide less canister purge. These vehicles now have a 15-year/150,000-mile useful life requirement and are subject to IUVP. Thus far, EPA has not reported issues with the durability or performance of these seals nor has CARB or EPA ever discussed adding an OBD requirement for this technology. [EPA-HQ-OAR-2019-0055-1213-A1, p. 8]

A few HHDGV models without adequate fill height (e.g., metal tanks mounted on the outside of the chassis frame rail which fill through a bung-type opening) may need to use a mechanical seal and depending on the fuel/ evaporative/refueling system configuration some dual tank vehicles may elect to do so as well. The rule is expected to include adequate lead time for engineering to further optimize the design of a mechanical seal assembly and for its integration into the fuel system and to comply with other applicable Federal regulations. [EPA-HQ-OAR-2019-0055-1213-A1, p. 8]

Organization: *Eaton Vehicle Group (Eaton)*

Agency Request / Topic: For SI engines, we request comment on our proposed refueling HC emission standard for incomplete vehicles above 14,000 lb GVWR, including requests for comment and data to inform test procedure updates we should consider to measure HC emissions from these larger fuel systems and vehicles. [EPA-HQ-OAR-2019-0055-1252-A1, p.8]

Eaton Comment Strategy / Materials:Eaton supports ORVR extension to HD vehicles that use SI engines, as this technology is cost-effective and traps evaporative emissions. As the alternative is to retrofit fuel pumps, ORVR remains the overall cost-effective solution. We believe the procedures outlined in the NPRM are feasible and incomplete vehicles can be managed through delegated authority as is established for GHG certification. [EPA-HQ-OAR-2019-0055-1252-A1, p.8]

Organization: *Manufacturers of Emission Controls Association (MECA)*

EPA's regulatory framework offers the most comprehensive evaporative/refueling control program in the world for chassis certified vehicles. Onboard Refueling Vapor Recovery (ORVR) has been successfully implemented in the U.S. and Canada for over 25 years. Within EPA's IUVP program, there have been over 4500 tests conducted on in-use vehicles equipped with ORVR with an average reduction efficiency of 98% [24]. The odometer readings on a large fraction of these vehicles exceeded 100,000 miles. U.S. Tier 2 or California LEV II have reduced evaporative emissions by 90%, and U.S. Tier 3 or California LEV III are 98% effective in reducing evaporative VOC emissions. [EPA-HQ-OAR-2019-0055-1320-A1, pp.21-22]

> [24] G. Passavant, 'Summary and Analysis of 2000-2015 Model Year IUVP Evaporative and Refueling Emission Data,' 2017.

Heavy-duty gasoline vehicles (HDGVs) fall into two categories. The first category, light HDGVs (LHDGVs) (GVWR < 14,000 lb.) are usually chassis certified and have been required to meet refueling emission standards since the 2018 model year. The second category, heavy HDGVs (HHDGVs) (> 14,000 lb. GVWR) usually are classified as incomplete vehicles since the engine is tested on a dynamometer for exhaust emissions and during production the engines are installed on a chassis where the chassis is completed by a secondary manufacturer [25] [26]. While Tier 3 evaporative requirements apply to HHDGVs, refueling emission standards do not yet apply to this subcategory of HDGVs. MECA estimates that HHDGV refueling emissions are equivalent to about 0.37 g/mile (based on 4.1 g/gallon emission rate and average fuel efficiency of 11 mpg). Control of refueling emissions with ORVR is a significant opportunity to reduce VOC emissions (ozone and PM2.5 precursors and air toxic emissions) from these HDGVs. [EPA-HQ-OAR-2019-0055-1320-A1, p.22]

[25] EPA, ‘Tier 3 Motor Vehicle Emission and Fuel Standards,’ 28 April 2014. [Online]. Available: https://www.govinfo.gov/content/pkg/FR-2014-04-28/pdf/2014-06954.pdf.

[26] 40 CFR 85.020.

Specific to EPA’s proposal, MECA supports extending ORVR requirements to HHDGVs at a refueling emission standard of 0.20 grams hydrocarbon per gallon of liquid fuel dispensed as now applies to LDVs, LDTs, MDPVs, LHDGVs, and complete HHDGVs. The OEMs have twenty-five model years of experience with the design and certification of ORVR systems, which together with the EPA IUVP data mentioned above, clearly demonstrate the feasibility. Very recently, a complete HHDGV with a fuel tank of one hundred gallons was certified to ORVR for the 2022 model year [27]. [EPA-HQ-OAR-2019-0055-1320-A1, p.22]

[27] PRWeb, ‘ROUSH CleanTech and Blue Bird First to Achieve Certification to 2022 Heavy Duty Refueling Standard,’ 2 May 2022. [Online]. Available: https://www.prweb.com/releases/roush_cleantech_and_blue_bird_first_to_achieve_certification_to_2022_heavy_duty_refueling_standard/prweb18651222.htm.

Consistent with the current requirements for evaporative emission and refueling emission controls for all lighter weight vehicles, MECA supports EPA’s proposal to apply a useful life of 15 years/150,000 miles to the HHDGV refueling emission standard. The Tier 3 evaporative emission standard useful life for all HDGVs is currently 15 years/150,000 miles. Given that integrated ORVR/evaporative control system designs share hardware such as the activated carbon canister and purge valve and functions such as vapor transport and canister purge, a common requirement for evaporative and refueling emission standard useful life is logical and necessary. [EPA-HQ-OAR-2019-0055-1320-A1, p.22]

MECA believes the implementation of ORVR is feasible and practical for primary and secondary manufacturers. Since the first HDGV evaporative emission standards were implemented in the 1985 model year, OEMs and secondary manufacturers now have thirty-five model years of experience in working together on measures to ensure that any actions taken by the secondary manufacturer to complete the vehicle do not violate the certificate of conformity or create in-use issues for on-vehicle fuel vapor control systems. In addition, there are now several regulatory provisions within 40 CFR1037 which provide guidelines on how OEMs and secondary manufacturers may work together under EPA’s certification programs [28]. This extensive experience together with these recent regulatory provisions suggest that any concerns have been addressed and there is no need for added regulatory measures. Regarding testing for refueling emissions certification, the ORVR test procedures promulgated in 1994 are fully fit for purpose and, perhaps with minor changes or clarifications, should be applied to HHDGVs using the driving cycles and SHED-test procedures currently specified in Subpart B. MECA supports a compliance demonstration through a full vehicle emission testing and certification as contained in Subpart B plus continuation of the manufacturers’ certification option using the compliance demonstration flexibility provided in 40 CFR1037.103(c). [EPA-HQ-OAR-2019-0055-1320-A1, pp.22-23]

[28] 40 CFR Part 1037.130, 1037.621, 1037.622.

Organization: *Motor & Equipment Manufacturers Association (MEMA)*

For SI engines, EPA requests comment on their proposed refueling HC emission standard for incomplete vehicles above 14,000 lb GVWR, including requests for comment and data to inform test procedure updates. EPA should consider measuring HC emissions from these larger fuel systems and vehicles. MEMA also recommends avoiding “break points” in the standards that could result in intentionally shifting a vehicle to a higher GVWR class to reduce emissions compliance equipment. In essence developing a continuum of standards and technology applications rather than a sharp break or jump. MEMA also recommends that on-board vapor recovery technology be required. SI engines should have the best available evaporative emissions control technologies. In addition, higher truck classes should use all available lower truck class technologies. [EPA-HQ-OAR-2019-0055-1322-A1, p. 6]

Organization: *Oshkosh Corporation*

EPA requests comments regarding options for sealed housing evaporative determination (SHED) testing for heavy-duty vehicles related to evaporative and refueling emissions. See Proposed Rule, 87 Fed. Reg. at 17,491. Oshkosh generally opposes the expansion of these requirements based upon the same concerns raised above related to OBD test and certification burdens, as well as the limited availability of SHED facilities sufficiently sized to accommodate larger heavy-duty vehicles, which EPA acknowledges in the Proposed Rule. See id. at 17,490-91. Specifically, Oshkosh notes that there are few if any existing SHED testing facilities available to accommodate vehicles such as a fire truck or concrete mixer. These logistical concerns should be accommodated in the final rule. Oshkosh thus supports EPA’s proposal to continue to allow manufacturers to demonstrate compliance with applicable evaporative and refueling emission standards by using an engineering analysis rather than requiring SHED testing data. The Company also supports EPA’s proposal to allow manufacturers to demonstrate compliance by testing refueling components only, separate and apart from the vehicle body and chassis. See id. at 17,491. A final alternative would be for manufacturers to demonstrate compliance by use of “sister vehicle” data, similar to EPA’s proposal for demonstrating OBD compliance. Under this approach, EPA could allow manufacturers to rely upon test data from vehicles with similar fuel system characteristics (e.g., a comparable fuel tank and carbon cannister) to show compliance with the applicable evaporative and refueling emission standards. [EPA-HQ-OAR-2019-0055-1226-A1, pp. 4 - 5]

Organization: *Roush CleanTech (Roush)*

Roush is fully in support of the heavy-duty refueling emissions requirements for incomplete spark ignited vehicles. As we have demonstrated in our 2022MY complete vehicle certification, compliance to the standards is feasible, with significant air quality benefits. We do have a few specific suggestions:

- We fully agree with the continued allowance for compliance by attestation for heavy-duty vehicles. As noted, it is extremely difficult to perform the light-duty evaporative cycles on heavy-duty vehicles, and for incomplete vehicles it is extremely difficult to determine what a representative completed vehicle would even be. Specific to the refueling tests, use of rigs should be explicitly permitted as the basis for compliance judgement; this permits the use of existing light-duty ORVR test facilities and procedures, and provides a fully representative result as the non-refueling emissions are negligible given the short sampling time involved.

- We recommend allowing additional drive time as part of the test sequences. In our experience, the requirements of the refueling and BETP standards particularly are in conflict, although different manufacturers may experience difference constraints based on their specific designs. The existing drive cycles are all based on light-duty consumer usage, and were never intended to be reflective of heavy-duty commercial vehicle use. We believe that providing manufacturers the option to conduct a second series of drive cycles for the two-diurnal, BETP, and refueling tests without need for any additional justification is entirely reasonable. The running loss / 3-diurnal test sequence is more complex due to the need for fuel tank heating; we would suggest simply providing flexibility for manufacturers to request additional preconditioning for this procedure. [EPA-HQ-OAR-2019-0055-1276-A1, pp.4-5]

EPA Summary and Response

The summary and response for this section includes a listing of the topics raised, then the comments are summarized by category and the responses follow each summary.

EPA proposed a 0.20 g HC/ gal liquid fuel refueling emissions standard for incomplete vehicles above 14,000 lb GVWR and ORVR test procedures. Comments relating to the proposed refueling emission standards fell into the following general categories:

- Support or opposition for the refueling standards or ORVR requirements in general
- Test procedure recommendations based on EPA requests for comment
- Corrections and clarifications of the test procedure
- Unsolicited recommendations for updates

Support or opposition for the refueling standards or ORVR requirements in general

Several commenters expressed explicit support for the refueling standards, useful life and/or ORVR requirements in general, including: Truck and Engine Manufacturers Association (EMA), Alliance for Vehicle Efficiency (AVE), Ingevity Corporation, Eaton Vehicle Group, Manufacturers of Emission Controls Association (MECA), Motor & Equipment Manufacturers Association (MEMA), and Roush CleanTech. Except for one comment regarding a request for a phase-in of the ORVR standard, we received no comments opposing the refueling emission standard for incomplete vehicles above 14,000 lb GVWR. EMA commented that EPA underestimated the challenge of implementing ORVR technology on the larger vehicles with larger fuel tanks. To address uncertainties for those vehicles, they requested a three-year phase in of 30%, 60%, and 100% starting in MY2027, including an option that can encourage OEMs to certify 8,501 to 14,000 lb GVWR incomplete vehicles. Commenters did also express concern with some of the test procedure options EPA was considering in the proposal, discussed further below.

Response:

- We thank the commenters for their support. As explained in preamble Section III.E and further justified in RIA Chapter 3, we are finalizing the refueling emission standard of 0.2 g HC/gal liquid fuel as proposed, with a final regulatory useful life of 15 years or 150,000 miles (whichever occurs first).
- We disagree with EMA that a phase-in is necessary to comply with the new refueling emission standard. We are finalizing the implementation starting in MY 2027 for the reasons shared in preamble Section III.E.
- However, we considered that an optional phase-in that encompasses incomplete 8,501 – 14,000 GVWR vehicles may encourage OEMs to certify those additional incomplete vehicles to the new heavy-duty refueling emission standard while also providing some flexibility to manufacturers in meeting the new refueling emission standard.
- As detailed in preamble Section III.E of the final rule, manufacturers will have the option of certifying all incomplete vehicles above 14,000 pounds GVWR to the refueling standard in model year 2027, or in the alternative, manufacturers can opt into the alternate phase-in that applies for all incomplete heavy-duty vehicles, regardless of GVWR.

Test procedure recommendations based on EPA requests for comment

Ingevity and MECA commented in support of the full vehicle test. Ingevity indicated that a bench test and component/subassembly/assembly evaluations would not provide conclusive evidence of full system performance, but noted that an engineering analysis may be appropriate when a full SHED test is "not practical". EMA, MECA, Oshkosh, and Roush also supported EPA's proposal to allow engineering analysis as an option to demonstrate compliance with the refueling standard.

Response:

- We thank commenters for their support of our proposed testing approaches. We proposed and are finalizing that refueling emissions would be measured over the same test procedures that currently apply for complete vehicles in 40 CFR 1037.103, including a full-vehicle SHED test as the primary compliance demonstration pathway with
- the option for manufacturers to perform an engineering analysis in 40 CFR 1037.103(c) for demonstrating they meet the new refueling emissions standard.
- See the comments that follow for specific revisions to our test procedures after considering comments, and our responses to approaches raised in comments that would be relevant to the engineering analysis. While we have not revised 40 CFR 1037.103(c) to include reference to good engineering judgment, we note here that 40 CFR 1068.5 continues to apply for all sectors covered by 40 CFR part 1068, including highway heavy-duty engines and vehicles.

EPA requested comment on the updates to the conditioning procedure to account for larger vehicles. EMA recommended adding an additional FTP-75 drive schedule to the 3-day, 2-day, canister BETP, and ORVR test procedures following the canister load and prior to the drive schedule. EMA noted that an additional FTP-75 would align with existing approved drive schedules utilized for certification by heavy-duty vehicle manufacturers now and would be preferred over updating the canister loading procedure, which would require "extensive testing" to validate. Roush also commented on a need for additional drive time after the canister load. Roush suggested providing manufacturers the option to conduct a second series of drive cycles for the two-day and BETP. They also suggested that the 3-day test may require additional conditioning.

Response:

- We thank EMA and Roush for their comments, insight, and observations regarding conditioning procedures that occur between the canister load and drive schedule. As noted in preamble Section III.E, we are revising the 2-day diurnal and BETP tests to include a second FTP duty cycle for vehicles with fuel tank capacity above 50 gallons, which have the greatest need for additional conditioning.
- We agree with EMA that updating the canister loading procedure would require additional validation and we are not revising that procedure in this rule. We disagree with EMA that the additional FTP-75 is also needed for the 3-day diurnal procedure; we believe the existing 3-day diurnal procedure is already appropriate for larger fuel tanks since it has two additional UDDS (Urban Dynamometer Driving Schedule) and two additional NYCC (New York City Cycle) as compared to the existing 2-day diurnal procedure.

Several commenters recommended analyses or testing in response to EPA's request for comment on approaches to consider for adapting the current 40 CFR part 86, subpart S, test procedures used by lower-GVWR vehicles for vehicles above 14,000 lb. GVWR. We address specific commenters' recommendations for analysis or testing below. We are not finalizing the prescriptive test procedure changes requested at this time, but in most cases, the approaches raised in comments would be relevant to the engineering analysis option as noted in the responses below.

Response:

- EMA indicated that the full vehicle light-duty test procedures would work if the HD vehicle could fit in the existing SHED, but reiterated their request for revised drive schedules (i.e., an additional FTP-75). If a manufacturer was performing a fuel system rig test, EMA recommended a bench purge of the canister using CARB's BETP procedure as a reference. EMA commented, with example calculations, that the vehicle contribution of HC mass is negligible, so the rig test and full vehicle test should be similar. For vehicle volume, EMA recommended the fuel rig testing should be the same volume (5 cubic feet) used for partial zero-emission vehicle (PZEV) rig testing (CARB MAC 2001-03, November 2001).

  - We acknowledge EMA's agreement that the light-duty test procedures we are finalizing are appropriate for HD vehicles that can fit in existing SHED enclosures. As noted previously, we are finalizing an additional FTP-75 for 2-day diurnal and the BETP cycles for fuel tanks with greater than 50 gallons capacity.
  - As noted in the NPRM, we recognize there is limited availability of SHEDs that can fit certain heavy-duty vehicles and a manufacturer can request approval of a rig test as their engineering analysis for those vehicles. Manufacturer engineering analysis of the HC mass contribution from the vehicle, as well as their recommendation to use CARB's bench purge and the PZEV-based vehicle volume, would be appropriate information to share with EPA to demonstrate the use of good engineering judgment in a supporting compliance demonstration.
- Ingevity stated that a bench test of a fuel/evaporative/refueling emission control system mock-up and component/subassembly/assembly evaluations would not, by itself, provide conclusive evidence of full system performance.
  - EPA agrees that the bench test would not by itself, prove conclusive. Rather, the bench test will be part of a larger collection of evidence, both data and engineering analysis, to demonstrate compliance.
- Oshkosh expressed support for EPA's proposal to allow manufacturers to demonstrate compliance by testing refueling components only, separate and apart from the vehicle body and chassis. Roush commented that, "Specific to the refueling tests, use of rigs should be explicitly permitted as the basis for compliance judgement; this permits the use of existing light-duty ORVR test facilities and procedures, and provides a fully representative result as the non-refueling emissions are negligible given the short sampling time involved."
  - EPA agrees that component and system data, like that generated with a SHED or mini-SHED, when applied with good engineering judgement as part of an engineering analysis, may appropriately demonstrate compliance. Manufacturers will need to present compelling evidence, such as component and full SHED data that shows comparable results. We note that we are not finalizing a specific component- or system-based procedure at this time.
- Oshkosh also requested a final alternative where manufacturers could demonstrate compliance by use of "sister vehicle" data, similar to EPA's proposal for demonstrating OBD compliance.
  - EPA agrees that a manufacturer may apply good engineering judgement to use data from similar vehicles in an engineering analysis to demonstrate compliance with the refueling standard. We would expect such an engineering analysis to include fuel system detail, vehicle design information, and vehicle expected use information along with any other relevant information.

Corrections and clarifications of the test procedure

For dual fuel tanks with separate filler tubes, EMA recommended: "Measure the hydrocarbon increase in the SHED for each refueling action. Sum the two hydrocarbon increases and divide by the total amount of fuel dispensed for both ORVR refueling events."

Response:

- We generally agree with EMA's recommendation for assessing refueling emissions from dual-tank vehicles. Since other assessment methods may also be valid, we are not finalizing a prescriptive approach for these vehicles; instead, as noted in the preamble section III.E, we are finalizing a revision to 40 CFR 86.154-98 that directs manufacturers to use good engineering judgment for dual tank configurations.

EMA agreed with EPA's assessment in the NPRM that in cases where a secondary manufacturer finishes an incomplete vehicle subject to the new refueling standards, the ORVR certification and fuel system installation instructions will be controlled by the original OEM as it is consistent with HD spitback compliance regulations.

Response:

- We thank EMA for confirming our assessment from the proposal. We continue to expect, as stated in the proposal, that the addition of any ORVR hardware and all ORVR-related aspects of the certified configuration would continue to be managed and controlled by the chassis manufacturer that holds the vehicle certificate. Accordingly, we do not expect that addition of the ORVR hardware would result in any appreciable change in a secondary manufacturer's obligations or require secondary builders to perform significant modifications to their products.

EMA identified a typographical error in the methanol mass equation as well as an opportunity for driving consistency in related equations.

Response:

- This correction and an update to make equations consistent are in the final regulations.

EMA also shared fuels information regarding hydrogen to carbon (H/C) ratio and the resulting fuel density.

Response:

- This topic is responded to in section 32.2 of this document.

Ingevity noted that the NPRM does not specifically state that the ORVR requirement would apply to new heavy heavy-duty gas vehicles (HHDGVs) sold in all 50 states. They recommend that EPA affirmatively state in the final rule that the requirements are nationwide such as was done in the preamble to the original ORVR final rule.

Response:

- CAA section 203 and our regulations prohibit the sale or introduction into commerce of new heavy-duty engines subject to EPA emission standards unless they are covered by a valid certificate of conformity complying with EPA emission standards and regulations for that model year. Thus, our federal standards apply to all new heavy-duty engines. Under CAA section 209, there are circumstances under which manufacturers' compliance with state standards shall be treated as compliance with applicable federal standards. We intend to work with CARB and manufacturers to answer compliance questions as they arise in a given model year.

Ingevity noted that the family criteria for evaporative and refueling emissions certification (40 CFR 86.1821-01) are quite general and leave much to the manufacturers use of good engineering judgment. They recommended that these provisions be clarified to address that they apply to LDVs, LDTs, and HDGVs. Ingevity also requests clarity on whether LHDGVs certified using Subpart B test procedures can be grouped with HHDGVs

Response:

- The FRM includes edits in 40 CFR 86.1821 to state that the engine-family provisions apply for all sizes of vehicles subject to evaporative or ORVR standards. The FRM also includes edits in 40 CFR 86.1821 to clarify that manufacturers must certify HDV greater than 14,000 lb GVWR in families that are separate from HDV at or below 14,000 lb GVWR that are certified based on testing.

Unsolicited recommendations for updates

Ingevity noted that the feasibility analysis uses the term "percent efficiency" when discussing carbon canister loading and that "g/L" may be more precise for gasoline working capacity (GWC).

Response:

- We thank Ingevity for their thorough review and proposal on wording related to canister efficacy. In this feasibility discussion, the term "g/L" is more precise than "%". We have made this change. However, it is important to note that in the feasibility table and calculations, g/L is shown and properly applied. The calculations, analysis, and feasibility do not change.

Ingevity shared that, “it would be helpful to add criteria related to fuel tank volume, total canister adsorptive capacity, and purge in certification guidance”.

Response:

- We did not propose to specify fuel tank and purge design criteria and are not including any such criteria in this final rule.

EMA suggested we specify E10 for the ORVR testing (in place of E0). EMA requested EPA streamline the laboratory test process by focusing the fuel flow rate on 9.8 gpm fuel-dispensing rate as opposed to the current regulations in 40 CFR 86.154(e) that require proven function at 9.8 gpm and allows verification down to 4.0 gpm. EMA recommended that EPA clarify that the ORVR requirements apply to vehicles operating on volatile fuels but exclude diesel fueled vehicles.

Response:

- We did not expressly request comment on certain aspects of the existing evaporative and refueling emission standards test procedures such as the test fuel(s) or fuel-dispensing rate that we proposed to make applicable to incomplete HD vehicles greater than 14,000 lb GVWR.
- We did not propose changes to the testing fuel type and are not including any changes to the testing fuel type in the final rule. We may consider such a change in a future rulemaking.
- We also did not propose changes for fuel dispensing rate and are not including any such changes in this final rule. We may consider such a change in a future rulemaking.
- The existing regulations in 40 CFR 1037.103(a) provide the clarity requested by one commenter regarding applicability of ORVR standards, and consistent with the proposal will be applicable to the new refueling standard for incomplete HD vehicles greater than 14,000 lb GVWR under the final rule. The existing provision specifies that evaporative and refueling emission standards specified in 40 CFR 1037.103 apply for HD vehicles above 14,000 lb GVWR fueled by “volatile liquid fuels (such as gasoline or ethanol) or gaseous fuels (such as natural gas or LPG).”

3.7 Certifying hybrid electric vehicles

Comments by Organizations

Organization: *Allison Transmission, Inc. (Allison)*

- EPA should additionally simplify powertrain certification requirements for GHGs. EPA should consider methods involving the testing of standalone components and/or a further build-out of the Greenhouse Gas Emissions Model (“GEM”) as an alternative to the proposed requirements and should not mandate powertrain testing for hybrid vehicles [EPA-HQ-OAR-2019-0055-1231-A1, p.6]

EPA has requested comments whether using powertrain testing to certify heavy-duty hybrids should be mandatory for all hybrid engine and powertrain combinations.58 Allison believes that powertrain testing/certification should remain an option in addition to standalone certification and chassis dynamometer testing/certification. There are two major concerns: [EPA-HQ-OAR-2019-0055-1231-A1, p.28]

58 87 Fed. Reg. at 17,457.

- If EPA were to mandate powertrain testing, this result would not only increase the direct cost of regulation (e.g., through additional testing burdens) but also create substantial logistical difficulties between hybrid powertrain vendors and OEMs responsible for final assembly of the vehicles. All these expenses would be incurred in what has been a traditionally low volume market, meaning that per vehicle costs would be proportionally higher since they could not be allocated to high-volume vehicles. Although some measure of empirical value might be obtained through the generation of powertrain testing data, the per-vehicle cost increases would make it more difficult for this technology to further expand in the commercial market sector. Requiring mandatory powertrain criteria pollutant certification for hybrid technology is expected to drive additional logistics and/or capital expense to certification process of a low volume market. Added cost and logistics contributes to regulatory overhead, and this makes the technology more difficult to apply at a reasonable cost to customers with lower volume applications that could benefit from hybrid emissions reduction. [EPA-HQ-OAR-2019-0055-1231-A1, p.28]

- Powertrain certification testing cycles are also not reflective of real-world applications where hybrid technology works well, such as transit bus operation. Powertrain certification duty cycles contain sustained high load operation (under SET) and SS55MPH/SS65MPH operation. These type of duty cycles do not reflect the typical applications that benefit from hybrid technology and which the market will preferentially select. Allison recommends that in lieu of the duty cycles proposed, EPA should utilize duty cycles related to metro transit authority routes that would better represent real world operation of hybrid transit bus operations with lower average speed and a greater number of stops. A few metro transit duty cycles that could be considered include Manhattan Cycle and OCTA. See Appendix 3.[EPA-HQ-OAR-2019-0055-1231-A1, p.28]

Organization: *Cummins Inc. (Cummins)*

EPA proposes to allow manufacturers the option to certify hybrid engines and powertrains to engine criteria pollutant emissions standards using a powertrain test procedure starting in MY 2023, including the ability to participate in the engine NOx ABT program. (EPA had previously finalized a similar powertrain test option for certifying to engine GHG standards.) Cummins supports adding this option which provides a path for manufacturers to better demonstrate the emissions reductions that can be achieved with hybrids. EPA requested comment on whether they should require powertrain testing for hybrids rather than offering it as an option. Cummins supports keeping it optional in addition to the existing process of engine-only certification for hybrids. [EPA-HQ-OAR-2019-0055-1325-A1, p. 19]

Plug-in hybrid electric vehicles (PHEV) can serve as a bridge to zero emissions operation in applications where BEV or FCEV are not yet technically or commercially viable. As discussed above, manufacturers may use the optional powertrain test procedure to certify PHEV to engine criteria pollutant and GHG standards, which Cummins supports. However, improvements in certification and compliance processes are needed to recognize more fully the real-world NOx reductions that can be achieved by PHEV and to reduce complexity. [EPA-HQ-OAR-2019-0055-1325-A1, p. 19]

Zero emissions (ZE) mode is a critical part of the operation of a PHEV, delivering significant NOx and GHG reductions to the environment. EPA's proposed procedure captures the GHG benefit of PHEV ZE mode through use of a utility factor (UF) to weight emissions from charge-depleting (CD) and charge-sustaining (CS) operation. However, manufacturers are required to meet criteria pollutant standards under the worst-case condition from CD or CS operation. ZE mode is not factored into the emissions result. Cummins recommends allowing manufacturers to use a UF-based calculation (i.e., Equation §1036.505- 10) for criteria pollutant emissions including NOx, in order to account for the criteria pollutant reductions demonstrated by PHEV in ZE mode. [EPA-HQ-OAR-2019-0055-1325-A1, p. 19]

As proposed, the 3B-MAW approach for in-use testing also does not account for ZE mode emissions properly. When the engine is off for purposes of optimizing CO2 and criteria pollutants, the data will be excluded per §1036.515(c)(2) even though powertrain work is non-zero. Another critical mode of operation for PHEV is when the battery/motor assists the engine. While the hybrid certification process captures the impact of this mode, 3B-MAW will not appropriately identify bins per the overall powertrain work which would be different from engine-only work measured from CO2. These concerns also apply to non-plug-in hybrids. The applicability of the proposed 3B-MAW calculation method should be modified to align with PHEV and HEV real world operation. Updates are needed in §1036.515 to address these issues. [EPA-HQ-OAR-2019-0055-1325-A1, p. 20]

A series hybrid system can be integrated with multiple types of traction systems based on application requirements. The proposed certification procedure would require testing of the complete system including the traction system. However, traction systems such as hub motor, in-wheel motor, and e-axle (6x4) configurations introduce test cell complexity. Cummins suggests that EPA allow an option to use a generic traction system model in a hardware-in-the-loop (HIL) simulation, analogous to the use of a generic transmission model in powertrain testing, to reduce certification complexity. [EPA-HQ-OAR-2019-0055-1325-A1, p. 20] See Appendix B for additional test procedure comments. Cummins would like to work with EPA on continued improvements to hybrid-related procedures. [EPA-HQ-OAR-2019-0055-1325-A1, p. 20]

1036.514

Hybrid functions enable reduction in idle fuel consumption and emission management. Clarification is requested why hybrid functions needs to be disabled only for plug-in hybrids. Cummins suggests hybrid functionality should be enabled for both plug-in and non-plug-in hybrids. [EPA-HQ-OAR-2019-0055-1325-A1, p. 25]

1036.527(e)

Clarification is requested for definition of Psys for series hybrids which have different types of electric traction systems. See figures below: [EPA-HQ-OAR-2019-0055-1325-A1, p. 26]

Organization: *Ford Motor Company (Ford)*

We support the added regulatory flexibility to test hybrid and plug-in hybrid vehicles on either an engine dynamometer or a powertrain dynamometer. We believe that the powertrain dynamometer test procedures produce emission results that are more representative of on-road operation than engine-only testing. [EPA-HQ-OAR-2019-0055-1300-A1, p. 5]

Organization: *Hyliion, Inc.*

The heavy-duty trucking industry is one that is steeped in tradition and reliability. However, it is an industry that is both innovative and flexible when addressing decarbonization and clean air goals. [EPA-HQ-OAR-2019-0055-1238-A1, p. 3]

As the EPA recognizes: “NOx exposures over short periods can aggravate respiratory diseases, particularly asthma, leading to respiratory symptoms (such as coughing, wheezing or difficulty breathing), hospital admissions and visits to emergency rooms. Longer exposures to elevated concentrations of NO2 may contribute to the development of asthma and potentially increase susceptibility to respiratory infections. People with asthma, as well as children and the elderly are generally at greater risk for the health effects of NO2.”1 [EPA-HQ-OAR-2019-0055-1238-A1, p. 3]

1. https://www.epa.gov/no2-pollution/basic-information-about-no2

We at Hyliion recognized the negative effects of air pollutions particularly in the communities that are most vulnerable. Through utilizing our All-Electric Range solution, we are able to provide a zero-emission solution in ports, city centers, and environmental justice communities where limited emissions are most critical. However, while addressing this urgent problem, we encourage the EPA embrace a multi-technology approach. We agree that EVs are an excellent option for many business models in the trucking industry, particularly in shorter distance hauls. However, neglecting the real and nonnegotiable aspects of long-haul heavy-duty trucks is not in the best interests of our global goals and certainly not for our communities who consistently bear the burden and negative health implications of air pollution. [EPA-HQ-OAR-2019-0055-1238-A1, p. 3]

BEVs available today for this space are simply too heavy to accomplish the goals we require from this industry. A full BEV is impractical for long haul because the batteries compete with payload and diminish the ability of the truck to generate revenue. With this in mind, the ERX utilizes smaller batteries that remain constantly charged by an onboard generator allowing for drivers to maintain a cost-effective payload. [EPA-HQ-OAR-2019-0055-1238-A1, pp. 3 - 4]

As a hybrid technology, we have a unique challenge to identify appropriate in use testing and certification pathways that correctly and accurately demonstrate our ability to both perform and be compliant with necessary standards. Regulators sometimes are challenged to understand and integrate the hybrid duty cycle with their existing testing and certification parameters. We urge EPA to work closely with CARB to coordinate a common approach to hybrid testing and certification and that allows for various pathways to certification that best fit the needs of both the manufacturers who are developing clean, advanced engine and powertrain technology and the regulatory agencies seeking to reduce the impact of air pollution on U.S. cities. [EPA-HQ-OAR-2019-0055-1238-A1, p. 5]

Organization: *Motor & Equipment Manufacturers Association (MEMA)*

EPA also requests comment on the proposed clarification in 40 CFR 1036.101(b) that gives manufacturers the option to test the hybrid engine and powertrain together, rather than testing the engine alone. Specifically, the agency has asked for feedback on whether EPA should require all hybrid engines and powertrains to be certified together, rather than making it optional. MEMA agrees that an engine-only test does not show the benefits of hybrid technology, so this is a good additional option. However, this option should not preclude engine-only or powertrain-only testing and certification. [EPA-HQ-OAR-2019-0055-1322-A1, p. 5]

Test cycles should be modified to be more reflective of real-world conditions including transient, steady state, and high-speed steady state. This is especially true in the areas of lower speed, transient, and stop and go conditions where hybrids can provide the most significant benefit. MEMA supports EPA requiring an idle cycle for all powertrains with accountability for hybridized systems. Any idle certification cycle should encourage available technologies like start-stop and engine off coasting, also known as sailing. [EPA-HQ-OAR-2019-0055-1322-A1, p. 6]

Organization: *Natural Gas Vehicles for America (NGVAmerica)*

Hybrid powertrains present some unique testing challenges and, as such, we urge EPA to provide sufficient flexibility in the certification and testing of hybrid natural gas/electric power-trains; [EPA-HQ-OAR-2019-0055-1330-A1, p.13]

Organization: *Oshkosh Corporation*

As a vehicle manufacturer actively engaged in the development of battery-electric vehicles (BEVs), Oshkosh is pleased to provide comments intended to support EPA's efforts to reduce regulatory barriers and to facilitate market launch of these vehicles. Vocational vehicle duty cycles in particular present unique challenges for power supply that may be solved with hybrid or other range-extending solutions, and we encourage EPA to consider how the Agency can facilitate the development of such solutions in this rulemaking. In the same way that hybrid technologies have served as a bridge between internal combustion engine (ICE) and electric vehicle (EV) technologies in other sectors of transportation (i.e., passenger cars), hybrid and range-extending technologies have an important role to play in bridging the transition for the heavy-duty sector as well. [EPA-HQ-OAR-2019-0055-1226-A1, p. 3]

Organization: *Valero Energy Corporation*

EPA also proposes to establish provisions to quantify NOx emissions from hybrid electric vehicles (HEVs) in order to allow HEVs to generate NOx emission credits. [EPA-HQ-OAR-2019-0055-1328-A2, p.6]

7 40 CFR 86.016-1(d)(4)

Both CARB and EU have recently raised concerns about emissions from HEVs, which can experience multiple high-power cold-start events over a single trip. The EU has determined that under its current certification test procedure, plug-in hybrids register only 25% of the emissions measured under real world driving conditions.9 An analysis of REV found that they consume more energy and may have as much as four times more emissions than attributed to them in the certification procedure. Given concerns about the true emissions from HEV and the ability of current test procedures to capture those emissions, it is not appropriate for EPA to allow NOx emission credits to be generated from HEVs. [EPA-HQ-OAR-2019-0055-1328-A2, p.6]

<u>EPA Summary and Response</u>

Preamble Section III.A provides a high-level overview of comments received and EPA responses to comments on the proposed updates and clarifications to regulatory language, as well the proposed test procedures for hybrid engines and hybrid powertrains. In this Section 3.7 of the Response to Comments document, we provide additional detail summarizing comments received and our responses to those comments.

<u>Summary</u>:

Some commenters generally highlight that different technology solutions may be better suited for different use cases or duty-cycles, and urge EPA to consider multiple technologies, including hybrid or range extending technologies, in the development of the final rulemaking.

As discussed in preamble Section III.A, commenters generally support the proposed option to conduct powertrain testing to certify a hybrid engine or hybrid powertrain. Commenters who stated that powertrain testing for certification should remain an option, but not be required, noted that powertrain dynamometer test procedures produce emission results that are more representative of hybrid engine or powertrain on-road operation than engine-only testing; however, they state that requiring powertrain testing, rather than engine dynamometer testing, would add regulatory costs to hybrid vehicles, and result in logistical difficulties between hybrid powertrain vendors and manufacturers for final vehicle assembly. They further stated the per-vehicle cost increases would make it more difficult for hybrid technology to further expand in the commercial market sector. Once commenter urged EPA to work closely with CARB to coordinate a common approach to hybrid testing and certification that allows for various certification pathways.

Commenters who stated that the proposed test cycles are not reflective of hybrid operations, recommend that EPA utilize duty cycles related to metro transit authority routes (e.g., Manhattan Cycle and OCTA); they stated the metro transit authority routes would better represent real world operation of hybrid transit bus operations with lower average speed and a greater number of stops. Another commenter recommended EPA allow manufacturers to use a utility factor (UF)-based calculation (i.e., Equation §1036.505- 10) for criteria pollutant emissions including NOx, in order to account for the criteria pollutant reductions demonstrated by hybrids. In contrast, one commenter pointed to data collected from light-duty hybrid electric vehicles in Europe that the commenter stated shows hybrid electric vehicles emit at higher levels than demonstrated in current certification test procedures; based on those data the commenter stated that EPA should not allow HEVs to generate NOx emissions credits.

Another commenter stated that, in addition to the defined duty cycles, the 3B-MAW off-cycle test procedure does not properly account for emissions reductions from hybrid systems; the commenter stated that EPA should modify the 3B-MAW calculation method to align with hybrid operations in the real world.

One commenter also requested EPA allow an option to use a generic traction system model in a hardware-in-the-loop (HIL) simulation, analogous to the use of a generic transmission model in powertrain testing, to reduce certification complexity for certifying series hybrids. This commenter provided additional requests for clarification of two specific aspects of the proposed hybrid test procedures. Another commenter stated that EPA should require an idle cycle for all powertrains with accountability for hybridized systems.

In addition, one commenter urged EPA to simplify powertrain certification requirements for GHGs.

Response:

EPA agrees with a multi-technology approach to reduce emissions as the heavy-duty industry increasingly moves towards application of zero emissions technologies. As commenters point out, we proposed and are finalizing test procedures for manufacturers to optionally use hybrid engines or hybrid powertrains to demonstrate NOx emissions performance. Manufacturers and customers can therefore select the technology that best fits the needs of their duty-cycle. If testing the hybrid engine and hybrid powertrain together results in NO_X emissions that are below the final standards, then manufacturers can choose to certify to a FEL below the standard and participate in the NOx ABT program in the final rule.[15] See Preamble Section III.A for more discussion on our decision to finalize as proposed the allowance for manufacturers to use powertrain or engine dynamometer testing to certify hybrid engines or hybrid powertrains.

EPA disagrees that metro transit authority routes or other similar test cycles would be more representative of hybrid operations. While transit authority routes would be representative of hybrid bus operations, they would not represent the duty cycles of other hybrid vehicle types. We expect to continue working with manufacturers to identify data or other information that would support updates to the test procedures for certifying hybrid systems; we may consider this information in the development of future rules relevant to heavy-duty highway hybrid systems. Section III of the preamble includes additional details on the certification and off-cycle test requirements we are finalizing for hybrid systems, including clarifications on the use of HIL simulation where appropriate. As discussed in preamble Section III, we are finalizing that the applicable criteria pollutant standards must be met under the worst-case conditions, which is achieved by testing and evaluating emissions from plug-in hybrids (PHEVs) under both charge-depleting (CD) and charge-sustaining (CS) operation. This approach ensures that criteria pollutant emissions are controlled under all conditions, which would include under conditions where the PHEV is not charged and is only operated in charge sustaining-operation, rather than allow the use of a utility factor curve to weight CD and CS emissions as suggested by one commenter. [16,17] We note that by not assuming a zero-emissions tailpipe performance of all hybrid engines and hybrid powertrains (PHEV and non-plug-in hybrids) in the final rule, we are ensuring that hybrid engines and hybrid powertrains only generate NO_X emissions credits that are reflective of their emissions performance over the required test procedures. Further, the updates to our duty-cycle and off-cycle test procedures ensure that a broader range of operations are captured. The combination of updates to our test procedures and requiring manufacturers to meet the final criteria pollutant standards under the worst-case conditions addresses the concern that one commenter raised about allowing hybrid electric vehicles to generate NO_X emission credits if hybrid electric vehicles emit at higher levels than demonstrated in certification test procedures.[18] Section III of the preamble also includes details on the optional idle test that we are

[15] We note that our approach to NO_X emissions credits for hybrid engine and hybrid powertrain differs from our approach to NO_X emissions credits for ZEV in the final rule based on our consideration of several factors; see Section 12.6 of this Response to Comment document for discussion on this topic.

[16] We acknowledge that the draft RIA for the proposed rule also included discussion on the potential for higher NO_X emissions under some heavy-duty hybrid operating conditions. As discussed in this section of the Response to Comments document, the test procedures we are finalizing address NOx emissions under all operations, and thus will ensure that the applicable criteria pollutant standards are met under all conditions, including worse-case conditions.

[17] Testing under worst-case conditions is consistent with the Agency's longstanding approach of requiring engines and vehicles to meet emissions standards under all conditions. As discussed in preamble Section III.B, we are allowing a UF curve for certifying PHEVs to GHG emissions standards; we believe this difference in approach is warranted because of differences in the spatial scale of GHG versus criteria pollutant impacts and the relative accuracy of a UF curve when representing emissions on average versus the specific emissions of a particular engine or powertrain configuration. Specifically, the UF approach is appropriate for capturing the average GHG emissions from a PHEV, which is appropriate for GHG emission impacts; however, the UF approach cannot fully capture the specific criteria pollutant emissions from a particular PHEV configuration, which is important for the local nature of criteria pollutant emission impacts.

[18] We note that the referenced data relate to CO_2 emissions from light-duty hybrid electric vehicles, rather than NO_X emissions from heavy-duty hybrid electric vehicles. While we're finalizing limited changes to heavy-duty test

finalizing; EPA continues to believe it is appropriate for the idle test to be voluntary for all powertrains, including hybrid systems, since the off-cycle standards will capture emissions performance during idle operations.

As discussed in preamble Section III.B, we are finalizing updates to further clarify how to carry out the test procedure for plug-in hybrids to measure GHG pollutants; however, substantive changes to the powertrain certification requirements for GHGs are outside the scope of this rulemaking.

3.8 Regulatory useful life

Comments by Organizations

Organization: *Alliance for Vehicle Efficiency (AVE)*

AVE supports EPA's proposed Option 1 standard, with a modification of the proposed full useful life timelines and warranty requirements, as the best option for driving more rapid adoption of advanced engine and emission control technologies. [EPA-HQ-OAR-2019-0055-1280-A1, p. 2.]

AVE asks EPA to modify the proposed full useful life timelines and warranty requirements. [EPA-HQ-OAR-2019-0055-1280-A1, p. 2.]

Currently, suppliers are not provided the necessary data (and certain data may not exist) nor information to design for a reasonable warranty and to determine if the proposed full useful life (FUL) timelines are feasible. Suppliers lack the data necessary, beyond the current goals to extended distance, time-in-service and beyond the first owner/user of vehicle, to make accurate assessments about the durability of many products. More research on engine wear and use patterns that result in degradation is needed before proposing longer warranties and extending FUL timelines. As such, AVE recommends several changes to EPA's proposed warranty requirements and FUL timelines: [EPA-HQ-OAR-2019-0055-1280-A1, p. 2.]

- Consider re-evaluating the FUL timeline once more engine test data is available. [EPA-HQ-OAR-2019-0055-1280-A1, p. 2.

AVE supports additional modifications to Option 1 to provide the best opportunity for driving more rapid adoption of advanced engine and emission control technologies. These additional modifications include:

procedures for hybrid engines and hybrid powertrains, we do not consider the data submitted by the commenter to be directly relevant to the test procedure changes we are finalizing since the data are not relevant to NOx (i.e., CO_2 emissions were measured in the referenced studies) and further are not relevant to heavy-duty vehicles since the data reflect the behavior of light-duty passenger car drivers, not heavy-duty commercial vehicle drivers. Further, any changes to light-duty vehicle test procedures based on the data submitted are outside the scope of this rule.

- Alignment of the EPA proposed standard with California's Omnibus rule by adding an intermediate useful life standard for MY2027 to 2030 engines up to 435,000 miles. [EPA-HQ-OAR-2019-0055-1280-A1, p. 3]
- ...

Organization: *Allison Transmission, Inc. (Allison)*

- EPA should also not finalize the Intermediate Useful Life ("IUL") standards that have been proposed. This additional certification requirement would add to the overall costs that customers will experience during the transition period to lower NOx standards and such cost is of dubious value for vocational vehicles that may have a low likelihood to exceed mileage or hours thresholds. [EPA-HQ-OAR-2019-0055-1231-A1, p.6]

Option 2 standards are also the preferable option for the final rule due to the inherent challenges and lead-time required for the validation of new emission control technologies. In this regard, EPA is concurrently proposing to extend useful life periods for both spark-ignition and compression ignition HDVs. Like the stringency of required NOx emission levels, useful life periods are more aggressive under Option 1 than Option 2 when fully phased-in by MY 2031, although the first phase of Option 1 is somewhat less aggressive than Option 2 as applied to MY 2027 and later MY vehicles.8 Whatever useful life periods are contained in the final rule, however, the longer useful life periods will impose substantial upfront engineering and materials costs. As EPA is aware, systems will need to be designed and built to ensure sufficient "head room" for compliance over many years, which in the case of EPA's proposed standards, may be up to 15 years. Companies that supply original equipment manufacturers ("OEMs") with various systems, like Allison, will need to ensure that the lengthy proposed mileage/time periods can be accommodated. Because EPA intends to move this regulation forward to completion in 2022, there will be only four years (perhaps less) time from the finalization of the regulation to the time where fully-engineered vehicle systems will need to be developed, produced, and sold to ultimate purchasers. This means that interim dates for design, testing, validation, production, and distribution will be challenging even under the least stringent options being considered by EPA. [EPA-HQ-OAR-2019-0055-1231-A1, p.8]

> 8 Table 1 – Proposed Options 1 and 2 Emission Standards for Heavy-Duty CI and SI Engines on Specific Duty Cycles, Id. at 17,422.

Within Option 1, EPA has proposed to utilize intermediate useful life ("IUL") standards of 435,000 miles that incorporate additional emission levels that must be met at such mileage thresholds in order to ensure that the emissions performance of an engine or vehicle does not degrade so as to threaten the ability to comply at the end of their applicable full useful life periods. Compliance with IUL would be determined through the use of deterioration factors as specified in proposed 40 C.F.R. §1036.245. [EPA-HQ-OAR-2019-0055-1231-A1, 10]

While EPA recognizes that heavy duty highway vehicles include vocational vehicles (which represent a "diverse array of vehicles . . . categorized into weight classes based on gross vehicle weight ratings (GVWR) that span Class 2b trucks and vans greater than 8,500 lbs. GVWR through Class 8 long-haul tractors and other commercial vehicles that exceed 33,000

GVWR"16) the proposed IUL standards do not take into account this extremely varied utilization. For MYs 2031 and later, the only variation to IUL standards occurs with respect to whether a vehicle is spark ignition or compression ignition and regarding its broad weight class. IUL standards are varied with respect to the three duty cycles, but all vehicles within the heavy-duty weight class are treated the same. This regulatory structure fails to account for numerous heavy-duty vehicles which have unique operating profiles for which the same IUL standard may be inappropriate.[EPA-HQ-OAR-2019-0055-1231-A1, 10]

16 87 Fed. Reg. at 17,417.

Allison would therefore first argue that EPA should not utilize IUL standards. EPA's basic rationale for such standards is that IUL standards are needed to ensure overcompliance with emission standards. Specifically, EPA is "proposing intermediate useful life standards that engines do not degrade in performance down to the duty cycle and off-cycle standards too quickly and allow for an intermediate check on emissions performance deterioration over the useful life."18 This rationale has two logical faults. First, EPA standards are the legal measure of compliance; if an in-use engine continues to meet the standards it was certified to during the applicable regulatory period, it is compliant. An engine that is closer to or further away from the required emission standards is still compliant. Second, intermediate useful life standards do not allow for a "check on emissions performance." That role is served by in-use standards and EPA is already proposing to require longer regulatory useful life and emission-related warranty requirements as well as a "low-load test cycle and off-cycle test procedure for CI engines [to] help ensure that the reductions in tailpipe emissions are achieved in-use, not only under high-speed, on-highway conditions, but also under low-load and idle conditions."19 [EPA-HQ-OAR-2019-0055-1231-A1, 11]

18 87 Fed. Reg. at 17467.

19 Id. at 17,427.

The IUL standards amount to an additional certification requirement which adds additional cost and is of dubious value for vocational vehicles that may have a low likelihood to exceed mileage or hours thresholds. EPA's justification that "it could be many years after engines are on the road before EPA could verify that the engines meet the standards our to useful life"20 does not account for the fact that such assurance is also provided by longer regulatory useful life and emission-related warranty requirements. Manufacturers are directly incentivized by such provisions to ensure that engines will meet requirements over many years -- at the very real risk a substantial, future compliance costs related to potential recalls/remedial actions. EPA has proposed to at least double currently applicable emission related warranty periods based on mileage and impose new hours requirements.21 The IUL standards amount to an additional regulatory layer that is unvalidated in many vocational vehicle applications. [EPA-HQ-OAR-2019-0055-1231-A1, 11]

20 Id. at 17,461.

21 Table 4 – Proposed Options 1 and 2 Emission-Related Warranty Periods for Heavy-Duty CI and SI Engines Criteria Pollutant Standards, 87 Fed. Reg. at 17,425.

Although as stated above, Allison does not recommend that EPA finalize the proposed IUL requirements, if EPA determines to include IUL standards in the final rule, EPA must at minimum align such requirements with the California Air Resources Board ("CARB") Omnibus Regulation which is limited to an eight, versus ten year period.22 Given the broad categories of vehicles involved, there would appear to be no rationale for not harmonizing this element of EPA's heavy-duty vehicle program with the current California program. [EPA-HQ-OAR-2019-0055-1231-A1, 11]

22 13 C.C.R. 1956.8(j)(11).

In the proposed rule, EPA states that it will give "full consideration" to the useful life and warranty periods that it has proposed for Options 1 and 2, including "the full range of options between them."23 For the reasons stated below, Allison believes that EPA should finalize Option 2 regulatory periods. In our analysis, Option 2 more appropriately balances the costs and benefits of extended useful life and warranty periods and better takes into consideration the real-life dynamics concerning these periods and customer behavior. [EPA-HQ-OAR-2019-0055-1231-A1, p.12]

23 87 Fed. Reg. at 17,421.

It seems clear that EPA intends this proposed rule to incentivize the deployment of new emissions technology as well as deliver substantial public health and environmental benefits. But if useful life and warranty periods are extended too far into the future, these regulatory requirements will tend to inhibit, rather than incentivize, the development of new emissions control technology given that the longer periods will inherently favor the deployment of emission controls systems which can best be verified in the near-term. EPA should also consider that it has the legal ability to revisit useful life and warranty issues in a future rulemaking; it should therefore avoid the conclusion that it must finalize each and every component of the proposed rule at the high end of stringency in order to obtain intended benefits. Rather, EPA could move to finalize Option 2 useful life and warranty provisions now and assess at a later date how these provisions worked, or did not, work in practice and whether these periods should be extended in future years. Having the benefit of seeing how Option 2 requirements are actually complied with could only help to inform EPA's analysis of the proper length and extent of the useful life and warranty provisions. [EPA-HQ-OAR-2019-0055-1231-A1, pp.13-14]

Organization: *American Lung Association et al.*

To realize the maximum health benefits, US EPA recognizes the need to establish standards that look beyond the stringency levels and proposes updated test procedures, truck 'useful life' requirements and warranty provisions to support achieving pollution reductions across real-world driving conditions throughout the useful life of the truck. We believe that Option 1 provides a strong foundation, and offer the following recommendations to protect public health: [EPA-HQ-OAR-2019-0055-1271-A1, p.2]

Strengthen full useful life to 1 million miles. We appreciate that Option 1 would require emission controls to operate as intended over a more realistic useful life of the truck. By extending the mileage through which the control systems must operate correctly, the proposal recognizes that emissions can rise as engines age. We appreciate that Option 1 proposes to cover <u>more</u> of a vehicle's estimated full useful life than both existing rules and what would be covered by Option 2, but we believe that the mileage requirements for heavy-duty vehicles must be set to 1 million miles in order to capture all of the operational life of the vehicle, which EPA considers to be over 900,000 miles.4 [EPA-HQ-OAR-2019-0055-1271-A1, p.2]

> 4 US EPA. Overview Briefing of the Proposal at page 11. April 2022. https://www.epa.gov/system/files/documents/2022-04/hd-2027-stds-nprmoverview-2022-04.pdf

Organization: *American Truck Dealers (ATD)*

EPA claims that longer useful life periods will result in more durable emission control related components that, combined with longer warranty periods, could reduce repair costs for new CMV purchasers. EPA also suggests that these combined effects may increase new CMV sales (or more likely reduce the decline in sales discussed above).13 ATD disagrees and instead concurs with the position taken by EMA that the higher costs associated with unreasonably longer useful life mandates would undermine the technological feasibility of a revised NOx rule. [EPA-HQ-OAR-2019-0055-1321-A1, p. 6]

> 13. 87 Fed. Reg. 17414, 17590.

Organization: *American Trucking Associations (ATA)*

While ATA cannot address every aspect of HD2027, we are supportive of the underlying environmental objectives and several of the elements being proposed. ATA's areas of support include: [EPA-HQ-OAR-2019-0055-1326-A1, p. 3]

- Further reduction of NOx emissions over a broader range of operating conditions and maintaining emissions control over a greater portion of an engine's operational life are warranted. [EPA-HQ-OAR-2019-0055-1326-A1, p. 3]
- Current emission warranty and useful life periods for heavy-duty engines and vehicles should be revised from the current requirements to increase the durability and efficacy of in-use emissions compliance. [EPA-HQ-OAR-2019-0055-1326-A1, p. 3.]

Fleets desire durable products yet durability is a direct function of increased cost. Products age and deteriorate and as such, they are either replaced or repaired. Proposed useful life periods up to 800,000 miles should be reduced sufficiently so that manufacturers are not required to sell excessively expensive extended warranty packages to fleets that factor in multiple replacements of emission control systems and additional margins. Vehicles outside warranties but still within useful life periods may also be subject to costly recalls and vehicle downtime. At the end of the day one fact remains consistent – fleets will incur every cost associated with their equipment one way or another. In the trucking industry, every penny counts. [EPA-HQ-OAR-2019-0055-1326-A1, p. 7]

Organization: *Alliance for Vehicle Efficiency (AVE)*

AVE recommends EPA expand ORVR to incomplete heavy-duty vehicles rated over 14,000 pounds Gross Vehicle Weight Rating, with a refueling emission standard of 0.20 grams hydrocarbon per gallon of liquid fuel dispensed, applicable for a useful life of 15 years or 150,000 miles. [EPA-HQ-OAR-2019-0055-1280-A1, p. 6]

Organization: *BorgWarner*

1. BorgWarner is in favor of forward progress to consistently reduce NOx, CO2 and other emissions, but we have concerns with the proposal's full useful life (FUL) and emissions warranty provisions. [EPA-HQ-OAR-2019-0055-1234-A1, p. 1.]

BorgWarner recommends EPA include a specific engine-based component life and degradation assessment in its consideration of the final rules. The proposed FUL extension is based only on the accelerated testing of the aftertreatment components and systems, with no regard for engine degradation either due to mileage or time-based limits. It is impossible to design a system for the long durations proposed with no data from current technology to this time in service nor data on how the secondary, tertiary and other users might operate the vehicles. [EPA-HQ-OAR-2019-0055-1234-A1, p. 2]

Much of the analysis has considered the single use case of class 8 long haul and overlooks any vocational applications in classes 2B through 8. It is critical to understand how the engine system is used for all use profiles over the life, in order to translate that into correct design specifications for function and durability over the full life anticipated. [EPA-HQ-OAR-2019-0055-1234-A1, p. 2]

Organization: *California Air Resources Board (CARB)*

For MY 2031 heavy HDEs, U.S. EPA has proposed 20 mg/hp-hr NOx standard on both the FTP and SET duty cycles and a 50 mg/hp-hr on the LLC duty cycle at the IUL of 435,000 miles (Figure 5-1). [EPA-HQ-OAR-2019-0055-1186-A2, p.41]

U.S. EPA's justification for this proposal is that the longer UL of 800,000 miles for heavy HDEs warrants IUL NOx standards to '…ensure that the emissions from the engine are as low as feasible for the entire UL and provide an intermediate check on emission performance deterioration over the UL.'96 CARB staff agrees with the justification. However, considering the proposed UL of 600,000 miles for MY 2027 heavy HDEs, the same justification should also be used for the need of IUL NOx standard for MY 2027 heavy HDEs. As demonstrated in the Stage 3 RW, a 20 mg/hp-hr NOx on the FTP and SET and a 50 mg/hp-hr on the LLC at 435,000 miles is technically feasible 97 (See also Figure 5-2 for test results from the Stage 3 RW engine). There is enough lead time between now and 2027 to further develop technologies to achieve lower emissions levels than currently demonstrated by CARB and U.S. EPA. It is important to note that, because Omnibus was adopted in December 2021 with a 20 mg/hp-hr IUL NOx standard for model year 2027, manufacturers have additional lead time beyond what the CTP proposal provides. [EPA-HQ-OAR-2019-0055-1186-A2, pp.41-42]

96 NPRM 17461

97 Sanchez, James. 'Test Results from EPA Diesel Demonstration'. Memorandum to Docket: EPA-HQ-OAR-2019-0055. February 10, 2022.

Adoption of an IUL NOx standard by U.S. EPA for MY 2027 would also provide much-needed harmonization of standards with CARB's Omnibus, thereby allowing manufacturers to reduce complexity and cost by producing a single engine design nationally. [EPA-HQ-OAR-2019-0055-1186-A2, p.44]

UL periods in the Omnibus and included in U.S. EPA's proposed Option 1 were derived based on information from engine rebuild and replacement data reflective of real-world vehicle usage, as well as information from engine and aftertreatment system manufacturers. In both cases, the UL periods were chosen to roughly correspond to the age when engines get either rebuilt or replaced.121,122 In addition, the feasibility of the standards for the Omnibus UL periods (which are included in U.S. EPA's proposed Option 1) was demonstrated in the Stage 3 RW demonstration program. 123 [EPA-HQ-OAR-2019-0055-1186-A2, pp.49-50]

121 CARB Heavy-Duty Engine and Vehicle Omnibus Regulation and Associated Amendments. Staff Report. June 23, 2020 (pages III-57-III-60)
122 NPRM, 17497-17594
123 'An Update on Continuing Progress Towards Heavy-Duty Low NOx and CO2 in 2027 and Beyond'. Sharp, Christopher, B. Zavala, G. Neely, S. Rao. Southwest Research Institute. Presentation to the SAE 2022 WCX™ World Congress Experience. April 5-7. Detroit, Michigan.

CARB staff strongly suggests U.S. EPA adopt the proposed Option 1 UL periods for both CI and SI HDEs. In addition, CARB staff recommends that U.S. EPA adopt an IUL period of 435,000 miles for MY 2027 heavy HDEs. As mentioned above, an IUL period together with CARB recommended IUL NOx standards on all duty cycles for MY 2027 heavy HDEs would serve as an intermediate check to ensure emissions remain low during the earlier part of the UL. [EPA-HQ-OAR-2019-0055-1186-A2, p.50]

Organization: *Clean Air Board of Central Pennsylvania*

EPA is proposing two regulatory options for NOx. We support Option 1, which will implement stronger NOx standards in two steps. The first improvement would be required in 2027 with a second more stringent standard 2031 (a NOx standard that would be 90% lower than today's standards). We support Option 1 with longer useful life and warranty periods. Ensuring that the warranty and useful life requirements meet 100% of the expected life of these vehicles will ensure health benefits throughout the life of the vehicles. [EPA-HQ-OAR-2019-0055-1305-A1, p.1]

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

Option 1’s useful life and warranty periods align with those of the Omnibus, compelling manufacturers to make critical durability improvements that are still eminently feasible. 87 Fed. Reg. at 17,500, 17,508. Option 2, on the other hand, shaves off years and tens of thousands of miles from Option 1’s useful life periods without even attempting to provide a technological feasibility rationale. EPA even acknowledges that, according to its data, ‘most of the proposed standards are achievable well beyond the proposed Option 2 mileage’ for spark-ignition engines. 87 Fed. Reg. at 17,501 (emphasis added). Option 2 repeats the same mistake with its proposed warranty periods. 87 Fed. Reg. at 17,508. In light of Congress’s clear intent that EPA set technology-forcing standards, it would be unreasonable for the Agency to adopt useful life and warranty periods that are significantly weaker than what manufacturers can attain (and which are already required by the Omnibus). [EPA-HQ-OAR-2019-0055-1302-A1, p.50]

To further ensure that emissions will be properly controlled over a greater portion of an engine’s operational life, Commenters also support lengthening warranty and in-use periods. Emissions controls, like other components of engines, typically work less efficiently and become more likely to malfunction as they age. The Clean Air Act specifies that emissions standards under Section 202(a) ‘shall be applicable to such vehicles and engines for their useful life (as determined under [42 U.S.C. 7521(d)]…) whether such vehicles and engines are designed as complete systems or incorporate devices to prevent or control such pollution.’ 42 U.S.C. 7521(a)(1). EPA’s standards therefore include a durability requirement: a requirement that manufacturers demonstrate their engines will meet the standards throughout the regulatorily defined ‘useful life’ of the engine.241 The Clean Air Act also requires EPA to specify a warranty period within which manufacturers are responsible for the cost of repairing or replacing emissions control components that fail. 42 U.S.C. 7541(a)(1). [EPA-HQ-OAR-2019-0055-1302-A1, pp.59-60]

241 40 C.F.R. 86.004-26(c)-(d) and 86.004-28(c)-(d). 40 C.F.R. 86.004-2.

EPA is correct to note that, ‘practically, any difference between the regulatory useful life and the generally longer operational life of in-use engines represents miles and years of operation without an assurance that emission standards will continue to be met.’ 87 Fed. Reg. at 17,495. In a 2013 report, EPA found that in the real world, many HDEs did not reach the end of their operational life (their first rebuild) until they had been driven more than twice the current useful life mileages for those classes of engines. 87 Fed. Reg. at 17,498. In other words, many HDEs are driven hundreds of thousands of miles beyond the point to which manufacturers must currently show emissions controls can last. [EPA-HQ-OAR-2019-0055-1302-A1, p.60]

Commenters support increasing the useful life mileage values for HDEs and extending the warranty period to cover a larger portion of the engines’ operational lives. Because the current useful life and warranty periods cover only a fraction of the real-world operational life of trucks, older trucks on the road are very likely emitting higher levels of NOx, and neither truck operators nor manufacturers have the proper incentives to ensure that emissions controls on those older trucks are functioning properly. Useful life and warranty periods covering a greater fraction of HDEs' expected operational life will help to protect people from dangerous NOx, ozone, and particulate matter pollution, and will shift more of the costs and risks of designing functional pollution control equipment to engine manufacturers, who have control over design, rather than effectively requiring operators to bear those costs. [EPA-HQ-OAR-2019-0055-1302-A1, p.60]

Specifically, we urge EPA to adopt useful life and warranty periods at least as long as those proposed in Option 1. EPA notes that it 'could justify proposing useful life requirements equivalent to the operational life data presented in Section IV.A.2 [of the Proposal], but [is] proposing somewhat shorter (less stringent) values in proposed Option 1 considering the effect of useful life on the feasibility of meeting the proposed Option 1 standards.' 87 Fed. Reg. at 17,500. As the Proposal also notes, the Option 1 useful life periods generally align with those in the Omnibus. Id. EPA proposes in Option 1 to adopt warranty periods covering close to 80% of useful life, which would align with the MY 2027 and MY 2031 warranty periods adopted by CARB. 87 Fed. Reg. at 17,508. The fact that many manufacturers must comply with the Omnibus standards when they take effect supports the technological feasibility of setting useful life and warranty periods at a level approximately as stringent as the Omnibus. Given the Clean Air Act's command that EPA set regulations reflecting the 'greatest degree of emission reduction achievable,' 42 U.S.C. 7521(a)(3)(A)(i), and EPA's statement that it could justify even longer useful life periods equal to operational life, we urge EPA to consider setting useful life periods more stringent than those proposed in Option 1 if the Agency determines that longer periods would be feasible in combination with the emissions standards it finalizes. Additionally, we urge EPA to adopt new warranty and useful life values in a single step, finalizing its proposed Option MY 2031 values as standards applicable to MY 2027 in order to achieve the emissions reductions from these changes as swiftly as possible. [EPA-HQ-OAR-2019-0055-1302-A1, p.61]

Organization: *Clean Fuels Alliance America (Clean Fuels)*

Longer full useful life requirements will create value and overall reduced costs for U.S. customers that use diesel fuel, biodiesel, or renewable diesel. [EPA-HQ-OAR-2019-0055-1248-A1, p.3]

Organization: *Consumer Reports (CR)*

Under the CAA, manufacturers must only certify emission standards for 'useful life' of the vehicle and engine.49 The CAA also directs the EPA to prescribe warranty periods for heavy-duty engines, and requires manufacturers to provide an emissions warranty.50 The current designated useful life for all trucks is only 10 years and between 110,000 and 435,000 miles, depending on class. Warranties cover only 5 years of the vehicle's life. In contrast, most trucks remain on the road between 20 and 30 years and between 550,000 and 1.2 million miles, depending on class.51 As a result, many trucks spend more than a decade on the road while not meeting emission standards. [EPA-HQ-OAR-2019-0055-1285-A1, p.8]

50 42 U.S.C 7541(a).

51 Id.

EPA is proposing to increase the useful life of heavy-duty vehicles. Under Option 1 for light heavy-duty engines, EPA is proposing to increase the useful life from 10 years or 110,000 miles to 15 years or 250,000 miles. For medium heavy-duty engines EPA is proposing to increase the useful life from 10 years or 185,000 to 15 years or 325,000 miles. For heavy heavy-duty engines, EPA is proposing to increase the useful life from 10 years or 435,000 miles to 13 years or 800,000 miles. Under option 2, EPA is not proposing to extend the useful life years for any class of engine, and is proposing lower mileage increases. [EPA-HQ-OAR-2019-0055-1285-A1, p.8]

The proposed extended useful life and warranty periods are necessary to ensure that heavy-duty certified emissions levels are achieved in real-world settings. EPA must adopt the proposed Option 1 useful life and warranty periods. Option 2 does not go far enough to capture the real-world longevity of heavy-duty vehicles. [EPA-HQ-OAR-2019-0055-1285-A1, p.8]

Organization: *Cummins Inc. (Cummins)*

EPA proposes to significantly lengthen emissions useful life periods for all primary intended service classes starting in MY 2027. As discussed above, EPA's Option 1 proposal, including its associated two-step extended useful life periods, is not feasible. EPA's Option 2 proposals for longer useful life periods, although only one step, are still significant increases. For example, in EPA's Option 2 proposal, the mileage period for Heavy Heavy-Duty Engines (HDE) would increase from 435,000 miles today to 650,000 miles—a nearly 50% increase in miles. Useful life mileages would increase for all other primary intended service classes as well, with as much as a 2.3x increase in one class (Light HDE). Cummins does not support increases in emissions useful life periods. Such changes will increase the initial purchase price of the vehicle as manufacturers seek to re-coup the costs of paying for component replacements or other measures needed to comply with the longer requirements. Significantly increasing the useful life at the same time as introducing new technology will increase prices beyond just the added technology costs and likely impact the customer adoption of new engines with those technologies. If EPA does finalize increases to today's useful life periods, it will need to account for additional uncertainty and variability in the deterioration of engines operated in the field by allowing additional in use margin to the duty-cycle and off-cycle standards when those engines are tested for compliance. For those same reasons, EPA requested comment on such margins in Option 1, but those same uncertainties and variabilities also exist for Option 2's proposed longer useful life. [EPA-HQ-OAR-2019-0055-1325-A1, p. 7]

EPA proposes to continue the practice of including hours in the regulated useful life period for the Heavy HDE class to account for engines "that operated frequently, but accumulated relatively few miles due to lower vehicle speeds" (87 FR 17501), based on a 20 mile per hour speed threshold consistent with today's Heavy HDE useful life criteria of 435,000 miles and 22,000 hrs. EPA requests comment on the need for a useful life hours criterion for Heavy HDE and whether they should include one for other primary intended service classes. Cummins supports continuing to include useful life hours for Heavy HDE as well as adding useful life hours for the other primary service classes of Medium HDE, Light HDE, and SI HDE. Just as in Heavy HDE, and perhaps even more so, there are applications within the other classes that accumulate relatively few miles due to lower vehicle speeds. It is also appropriate to use an average speed of 20 miles per hour, the same threshold EPA is already proposing for warranty in those service classes, for determining hours for the other classes. Cummins has submitted average vehicle speed data and run hours to EPA for numerous vehicles and applications operating in-use, which supports adding hours limits based on the 20 mph speed threshold. [EPA-HQ-OAR-2019-0055-1325-A1, p. 7]

EPA proposes not to migrate the provision for an alternate useful life period assigned by the Administrator in paragraph (5) of the existing useful life definition in §86.004-2. That provision has been used in the past and should be migrated to Part 1036 for possible future use. [EPA-HQ-OAR-2019-0055-1325-A1, p. 7]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

EPA should change useful life and emissions warranty periods to be more reasonable, specifically: 95

- Class: Heavy HDEs
    - Useful Life Period: 10 years/500,000 miles
    - Emissions Warranty Period: 5 years/350,000 miles
- Class: Medium HDEs
    - Useful Life Period: 10 years/250,000 miles
    - Emissions Warranty Period: 5 years/175,000 miles [EPA-HQ-OAR-2019-0055-1168-A1, p.71]

95 Daimler Truck also supports adding appropriate equivalent standards for the number of hours of engine operation

A significant portion of the infeasibility, cost, uncertainty, and risk in the Proposed Rule derives from EPA's proposed extensions of the useful life and emissions warranty programs. It is cost prohibitive and impractical for manufacturers to adequately design components and be certain of their reliability for these extended periods, especially since EPA's rule proposals drive the development of new technology with only four years of lead-time and three years of stability between programs. 96 [EPA-HQ-OAR-2019-0055-1168-A1, p.71]

96 While Daimler Truck's comments in this section focus primarily on increased technology costs and compliance burdens associated with EPA's useful life and emission warranty period proposals, we also note that EPA's proposals will mean significantly increased info1mation collection costs and burdens on manufacturers, which are relevant to OMB's review of the Proposed Rule under the Pape1work Reduction Act, see 44 U.S.C. 3501 et seq. Increased useful life times, for example, will translate to increased durability testing, which will add burden to manufacturers in terms of costs and man hours. We anticipate that the incremental burden increase for collecting aging data alone (as compared to current useful life periods) would amount to thousands of hours.

Failure rates are likely to increase exponentially in the periods EPA considers, especially as these periods further tax manufacturers' ability to validate before production, and as engines typically experience increasing rates of ‘wear-out.’ Additionally, EPA underestimates the impact of new technology on warranty rates; new technology will always experience a period of increased failure rates as manufacturers’ experience in the field leads to more robust and mature technology. [EPA-HQ-OAR-2019-0055-1168-A1, pp.71-72]

Many manufacturers expect that, to meet the most stringent emission standards in the Proposed Rule at the extended useful life periods that EPA proposes, proactive replacement of catalysts will be necessary. This will be required to protect against aging and fuel-poisoning concerns that EPA fails to adequately recognize in the standard-setting parts of the Proposed Rule. Manufacturers will likely pay these replacement costs as warranty costs during useful life, which will translate to increased purchase prices for customers. After useful life, operators will have to keep replacing these components according to the same maintenance intervals (as with Diesel Particulate Filters today), likely at significant cost in perpetuity. [EPA-HQ-OAR-2019-0055-1168-A1, p.72]

EPA’s proposed standards are so tight that manufacturers will be required to replace aftertreatment components that lose very little relative effectiveness. An SCR that loses 1% total effectiveness over useful life will not reach EPA’s proposed emission standards over useful life, and manufacturers will be forced to replace them proactively, at significant cost. This represents a phenomenal cost for a very modest improvement in emissions as a vehicle ages. EPA has not considered these costs at all in the Proposed Rule. [EPA-HQ-OAR-2019-0055-1168-A1, p.72]

EPA can limit these exorbitant warranty costs by limiting the extended useful life to reasonable values so that manufacturers can realistically design and validate their products. By setting the useful life to 500,000 miles for a HHD truck, and 250,000 miles for a MHD truck, EPA can avoid costly replacement of aftertreatment components (which would have extremely limited emissions benefit and significant uncertainty. [EPA-HQ-OAR-2019-0055-1168-A1, p.72]

The approach that Daimler Truck proposes not only supports improved emissions outcomes, but also reduces uncertainties for manufacturers by:

- reducing the chances that a vehicle will be evaluated for in-use emissions performance in a failed state (after the warranty period, but before full useful life), since operators are incentivized by the warranty to repair their products
- providing validation timelines are more manageable for manufacturers than the extremely long timeframes that EPA has proposed;
- ensuring that deterioration factor (DF) validation and certification data can be compiled and completed in a timely manner; and
- potentially avoiding replacement of the SCR system during useful life. [EPA-HQ-OAR-2019-0055-1168-A1, pp.72-73]

98 Proposed Rule, 87 Fed. Reg. at 17,508.

The Company's proposed approach would also reduce manufacturer and customer cost uncertainty, since the true cost of maintaining emissions compliance through useful life will be calculated and priced in at the point of sale. [EPA-HQ-OAR-2019-0055-1168-A1, p.73]

Organization: *Eaton Vehicle Group (Eaton)*

Agency Request / Topic: We are requesting stakeholder input on our proposed useful life and warranty periods, as well as the range of options covered by the proposed Options 1 and 2, or other alternatives outside of that range [EPA-HQ-OAR-2019-0055-1252-A1, p.8]

Eaton Comment Strategy / Materials: We can only speak to the critical components we provide such as CDA hardware, power management devices for electrical and fuel heaters, and EGR pumps. We design all of these components for the life of the truck, which typically exceeds FUL. Eaton cannot speak to the rest of the system, namely the Aftertreatment catalysts and DEF dosers, their degradation, and potential warrantee exposure. [EPA-HQ-OAR-2019-0055-1252-A1, pp.8-9]

Organization: *Ingevity Corporation (Ingevity)*

Ingevity supports EPA's proposal to expand ORVR to incomplete heavy-duty gasoline vehicles (HDGVs) rated over 14,000 lbs. GVWR, including the proposed refueling emission standard of 0.20 grams hydrocarbon per gallon of liquid fuel dispensed applicable for a useful life of 15 years or 150,000 miles. ORVR is a proven technology to significantly reduce evaporative and refueling emissions, resulting in emission reductions of volatile organic compounds that lead to the formation of ozone and secondary particulate matter (PM2.5), as well as emissions of hazardous air pollutants. [EPA-HQ-OAR-2019-0055-1213-A1, p. 2]

Organization: *Great Rivers Environmental Law Center and Dutchtown South Community Corporation (DSCC)*

The undersigned support inclusion of the following requirements in the Final Regulation:

- Mandatory longer useful engine life requirements to ensure engines will meet applicable emissions standards throughout their useful life [EPA-HQ-OAR-2019-0055-1323-A1, p.6]

Organization: *Manufacturers of Emission Controls Association (MECA)*

We understand EPA's need to ensure that heavy-duty vehicles are meeting emission standards while in operation, which requires that emission critical components are durable and repaired quickly if a malfunction occurs. Based on several stakeholder meetings between EPA, CARB, and industry, we believe that EPA's Proposed Option 1 warranty and durability provisions have struck a suitable balance between stringency and phase-in time to allow suppliers to work with their customers to fill current information gaps and complete additional R&D to ensure future trucks continue to be durable and meet emissions warranty requirements. The phase-in approach will allow component suppliers to better understand the economic impact of longer warranty periods on their business as well as time to design longer durability into components. MECA supports hourly limits for vocational vehicles that may operate for thousands of hours at low speed or idle prior to reaching the mileage or year warranty clock threshold. We support Proposed Option 1 slight increase to the emission standards at the final longer durability periods to account for possible deterioration beyond the current FUL of 435,000 equivalent miles. Results from the SwRI demonstration program support the NOx limits at the FUL requirements in Proposed Option 1. [EPA-HQ-OAR-2019-0055-1320-A1, p.20]

One area of misalignment between EPA's Proposed Option 1 and CARB's Omnibus is the lack of an intermediate useful life standard for MY 2027-2030 engines in Proposed Option 1. MECA suggests that EPA add an intermediate standard for these model years that must be met for the first 435,000 miles of an engine's useful life. We believe that an intermediate standard will result in two major benefits compared to Proposed Option 1. First, it will lead to more robust emission control systems being installed on trucks and keep marginal systems off the roads. Second, this approach has precedence and better aligns with a single national program. In addition to the CARB and EPA engine and aftertreatment configurations being tested at SwRI, several other technologies and system configurations were also tested on technologies that were outside the scope of the agency work plans. Results from these parallel demonstration programs prove that there are further options to meeting the 0.02 g/bhp-hr standard at 435,000 miles. Three recent papers presented at the 2021 and 2022 SAE WCX meetings highlight the application of cylinder deactivation, supplemental heat and advanced aftertreatment to achieving down to 0.012 g/bhp-hr, which provides margin to the 0.02 g/bhp-hr proposed standard. The supplemental heat can be via a fuel burner [3] [4]or an electric heater [5]. A pre-publication paper that will be available later this year will summarize several engine and aftertreatment technology combinations along with calibration and dosing strategies that show great promise in achieving the Proposed Option 1 standards as well as an intermediate useful life standard of 0.02 g/bhp-hr at 435,000 miles. [EPA-HQ-OAR-2019-0055-1320-A1, pp.4-5]

New aftertreatment architectures, that employ a close-coupled selective catalytic reduction (SCR) catalyst before the diesel oxidation catalyst (DOC) and diesel particulate filter (DPF) in a twin SCR system arrangement with dual urea dosing, can meet future FTP/RMC NOx limits of 0.02 g/bhp-hr after 435,000 miles by 2027. Several potential future aftertreatment layouts have been demonstrated in the SwRI test program. MECA has published two white papers that outline the technologies and models used to design catalyst, substrate and architectures to meet ultra-low NOx levels [16] [15]. Over the past 8 years of demonstration work at SwRI, testing has confirmed MECA's modeled results while also showing the need for modest enhancement of emissions control durability to provide margin for the FTP and RMC cycles over extended useful life. Over the next five years, industry will embrace any remaining challenges as suppliers continue to optimize their components and engine manufacturers hone their calibrations to exceed what has been demonstrated to date. This continued improvement work is why MECA believes that an intermediate limit of 0.02 g/bhp-hr is a technologically achievable up to 435,000 miles for a national program by 2027. [EPA-HQ-OAR-2019-0055-1320-A1, p.10]

> [16] MECA, 'Technology Feasibility for Model Year 2024 Heavy-Duty Diesel Vehicles in Meeting Lower NOx Standards,' 2019. Online at https://www.meca.org/wp-content/uploads/resources/MECA_MY_2024_HD_Low_NOx_Report_061019.pdf.

EPA has used intermediate standards previously in the Tier 2 passenger car regulation to keep marginally designed emission control systems out of the market so only the most robust designs remain on the roads for their useful life. This is particularly important in trucks that can last 20 to 30 years with multiple owners and duty cycles. [EPA-HQ-OAR-2019-0055-1320-A1, p.10]

Finally, we encourage continued collaboration and discussion between EPA and CARB to study impacts of proposed warranty and durability requirements as the rule is implemented, given the lack of information on warranty and failure modes past today's FUL of 435,000 miles. Such efforts could be designed by working with truck fleets to survey field aged parts on in-use trucks to examine real-world deterioration from a representative cross-section of vehicle age, state of repair and ownership status. This would provide useful information to OEMs and suppliers working to meet Omnibus warranty and durability requirements and lead to emission controls with higher durability, lower warranty claims, and ultimately reduced emissions. A recent CARB-funded project where CE-CERT conducted testing to inform a future heavy-duty I/M program could serve as a model for a research program that identifies field aged parts in various conditions for retrieval and analysis. [EPA-HQ-OAR-2019-0055-1320-A1, pp.20-21]

As we previously commented, there is considerable uncertainty about the state of vehicles during the time of operation beyond today's 100,000 mile warranty. Much of the data on warranty claims and repairs as well as vehicle use characteristics originate from the time when the first owner operates a vehicle while data from repairs made by second and third owners is very limited. Many suppliers do not have data on the durability, replacement or diagnostics of their parts past the warranty because the dealer network is not required to share that information. This lack of information leads to challenges for suppliers who are trying to design parts that will meet the extended durability requirements out to 800,000 miles. Without warranty claim information beyond 100,000 miles, it is difficult for suppliers to estimate the cost impact of the proposed extended 2031 warranty and challenges suppliers trying to design to the much longer 2031 durability periods. The lack of data also challenges suppliers trying to design to longer durability periods. MECA members manufacture durable parts according to the specifications demanded by their customers, the OEMs, as part of individual business agreements. The individual component specifications provided to the supplier may not include a correlation between the specification and how that relates to mileage durability on the vehicle. Finally, besides the engineering design time needed to design components to longer durability requirements, the testing out to the long mileage durability requirements (such as 800,000 miles for class 8 engines), especially for on-engine components whose aging cannot be accelerated, takes months to years on dynamometers. [EPA-HQ-OAR-2019-0055-1320-A1, p.21]

Aftertreatment parts deterioration can be accelerated through well-known means such as engine exhaust exposure at higher temperature and higher oil consumption to represent longer hours of operation as described in the DAAAC protocol developed under a consortium at SwRI. As noted above, wear of on-engine emission critical parts such as EGR, turbochargers, fuel injectors or CDA is not able to be accelerated and must be run for the full duration of the useful life period. Understanding the wear mechanism is also more challenging because parts are rarely returned in their used state, but only after failure when it may be difficult to assess how deterioration progressed over the life of the part. Furthermore, there is no way to properly account for and/or accelerate the years of useful life, as this may be reached in many different types of duty cycles and environments. [EPA-HQ-OAR-2019-0055-1320-A1, p.21]

Consistent with the current requirements for evaporative emission and refueling emission controls for all lighter weight vehicles, MECA supports EPA's proposal to apply a useful life of 15 years/150,000 miles to the HHDGV refueling emission standard. The Tier 3 evaporative emission standard useful life for all HDGVs is currently 15 years/150,000 miles. Given that integrated ORVR/evaporative control system designs share hardware such as the activated carbon canister and purge valve and functions such as vapor transport and canister purge, a common requirement for evaporative and refueling emission standard useful life is logical and necessary. [EPA-HQ-OAR-2019-0055-1320-A1, p.22]

Organization: *Motor & Equipment Manufacturers Association (MEMA)*

MEMA urges EPA to reduce the proposed warranty requirements and the full useful life timelines for all vehicles. The warranty increases of a factor of four or more are based on specific and limited laboratory testing that does not reflect complex, real-world use. Additionally, more data and analysis of second and third vehicle owner usage should be conducted before proposing significantly longer warranties and FUL timelines. [EPA-HQ-OAR-2019-0055-1322-A1, pp. 3 - 4.]

MEMA Supports Option 1 with Modifications to Warranty Time Period/Mileage, Covered Warranty Parts, and FUL [EPA-HQ-OAR-2019-0055-1322-A1, p. 5.]

MEMA urges EPA to reduce the proposed warranty requirements and the full useful life timelines for all vehicles. The warranty increases of a factor of four or more are based on specific and limited laboratory testing that does not reflect complex, real-world use. Additionally, more data and analysis of second and third vehicle owner usage should be conducted before proposing significantly longer warranties and FUL timelines. [EPA-HQ-OAR-2019-0055-1322-A1, p. 5.]

In addition, MEMA recommends an hours limit on all implemented standards in addition to mileage. [EPA-HQ-OAR-2019-0055-1322-A1, p. 7]

MEMA urges EPA to reduce the proposed factor of four increase in warranty requirements and the full useful life timelines for all vehicles until more data is available to justify such a substantial increase. More testing and validation of assumptions is necessary before increasing the FUL and this is especially true for vocational vehicles. [EPA-HQ-OAR-2019-0055-1322-A1, p. 9.]

Organization: *Moving Forward Network (MFN)*

Heavy-duty engines can last up to 1.2 million miles before a rebuild, yet the current warranty extends to just 100,000 miles, and the useful-life period is only 435,000 miles. The proposed changes to the warranty and useful-life periods for heavy-duty vehicles more closely mirrors the real-world operation of these engines and would help maintain working emissions controls while diminishing any costs incurred by the operators. [EPA-HQ-OAR-2019-0055-1277-A1, p. 27]

The useful life is critical to ensure adequate testing such that emissions controls are functional for the life of the engine. The warranty period, however, is more important to minimize tampering or disrepair, and shifts the cost of failures onto the manufacturer rather than the driver. Currently, the market allows manufacturers to profit from producing less durable products– increasing warranty requirements thus helps shift the responsibility for creating more durable emissions controls back to the entity with design control. [EPA-HQ-OAR-2019-0055-1277-A1, p. 27]

EPA's two-step approach to useful life and warranty matches that of the Omnibus rule. However, the Omnibus approach was limited, in part, to uncertainty in the research at SwRI, which forced CARB to linearly extrapolate data on reduced aging of the emissions control system.116 Since then, the SwRI research has continued, and the most recent data shows that the emissions controls at the 2031 FUL of 800,000 indeed perform as expected, with compliance margin—in fact, for the LLC and RMC cycles, the Stage 3RW shows quite wide compliance margins of 60 percent and 22 percent, respectively, eliminating any question of uncertainty in the longevity and durability of the system.117 Given the increased data on the viability of the technology and the need to ensure robust emissions reductions as quickly as possible from the largest swath of vehicles, EPA cannot justify delayed requirements on useful life and warranty, and must pull forward its proposed 2031 Option 1 values to 2027. [EPA-HQ-OAR-2019-0055-1277-A1, p. 28]

116. https://ww2.arb.ca.gov/sites/default/files/barcu/board/rulemaking/hdomnibuslownox/fsor.pdf, pp. 163-4.

117. EPA-HQ-OAR-2019-0055-1082.

Organization: *National Propane Gas Association (NPGA) and Propane Education & Research Council (PERC)*

We suggest the following modifications to the Proposed Option 1:

1. **Useful Life:** The Useful Life specifications that are included in the rulemaking under Proposed Option 1 (155,000 miles/12 years for MY2027-2030 and 200,000 miles/ 15 years for MY2031 and later) over the FTP duty cycle are in line with CARB's 2027 Ultra-Low NOx standards (Heavy-Duty Engine and Vehicle Omnibus Regulation) for Otto cycle engines with a Gross Vehicle Weight Rating (GVWR) greater than 14,000 pounds.8 This would increase the complexity and cost of the product for propane industry manufacturing partners, which will be ultimately passed on to vehicle fleets. This may also limit the agency's goal to achieve desired emissions levels from these engines.
   As such, we recommend that EPA modify the Useful Life requirements to 10 years/150,000 miles. This modification would align with engines in the Class 2b/3 applications, and is consistent with typical usage of these vehicles. [EPA-HQ-OAR-2019-0055-1263-A1, pp.2-3]

8 Supra note 1, at 17424.

Organization: *PACCAR, Inc (PACCAR)*

PACCAR supports extending regulatory Useful Life (UL) to more accurately represent Heavy Duty Commercial vehicle operations. However, EPA must ensure that its UL proposal is cost effective, technically feasible, and that it does not require aftertreatment component replacement. [EPA-HQ-OAR-2019-0055-1346-A1, pp.16-17]

PACCAR supports a 600,000 miles UL standard as technically achievable in commerce. The UL and the emissions standard will dictate whether OEMs will need to replace the aftertreatment system during an engine's UL to maintain compliance. Emission system drift and variation will increase as the useful life extends, making it increasingly difficult to comply with increasingly stringent emissions standards. If replacing aftertreatment components is the only way to ensure compliance with these stringent emissions standards over the course of the proposed extended useful life, unreasonable cost increases for new HDOH engines and vehicles are inevitable. The stringency of EPA's proposed Option 1 standard, coupled with (i) the significant uncertainties regarding durability and in-field performance of the new Stage 3 emission-system componentry over the extended useful life periods (up to 700,000 miles) and (2) the strict liability risks under the under the new pass criteria for in use testing, make it likely that OEMs would need an aftertreatment component replacement strategy to maintain compliance. Simply put, the risk of recalls – perhaps multiple recalls – and the significant associated costs, would be too great for OEMs not to have the option to have an aftertreatment component replacement strategy. [EPA-HQ-OAR-2019-0055-1346-A1, p.17]

PACCAR provides for EPA's awareness the following additional observations that influence OEMs' ability to meet extended useful life requirements:

- The SwRI demonstration tested emissions on a nominal demonstration engine in a test lab with an artificial aging procedure. In reality, however, vehicles likely will encounter conditions that lead to higher aging than was demonstrated during the SwRI test, such as specific vehicle duty cycles that lead to higher regeneration frequencies, additional aging due to use of lower quality fuels, and specific engines that have higher oil consumption, etc.
- OEMs must certify their nominal demonstration engines far below the legal limit to have sufficient margin for part-to-part, lab-to-lab and aging variation.
- The SwRI program shows that the available aftertreatment technology is not capable of controlling drift in emission performance sufficiently to a full useful life of 800,000 miles.
- Either the full useful life should be limited to a value well below 800,000 miles, or the emission limit must be increased to have sufficient margin between the SwRI demonstration testing and the regulated limit. [EPA-HQ-OAR-2019-0055-1346-A1, pp.17-18]

PACCAR supports an extended UL demonstration in the lab to ensure aftertreatment system robustness, combined with other flexibilities to reduce the liability of UL in commerce. A viable UL approach should include the following elements:

- Demonstration Standard: laboratory demo (DF) out to 700,000 miles
- Verification of DF: out to 600,000 mile (in-use)
- In-commerce Liability for Recall: less than or equal to 600,000 miles [EPA-HQ-OAR-2019-0055-1346-A1, p.18]

Under this scenario, an OEM would be subject to recall up to 600,000 miles UL. Between 600,000 miles and certification demonstration at 800,000 miles, OEMs would be responsible for: · SEA and · Confirmatory; · But not in commerce. [EPA-HQ-OAR-2019-0055-1346-A1, pp.18-19]

PACCAR does not support the proposed intermediate useful life (IUL) standard. Adding a separate IUL emission limit would add a significant burden because it would double the pass requirements for two separate emission limits. This limits strategies designed to meet UL that may not result in linear degradation of performance but are fully capable of maintaining compliance. [EPA-HQ-OAR-2019-0055-1346-A1, p.19]

The proposed regulation defines IUL in MY 2031 as 435,000 miles / 10 years / 22,000 hours. However, CARB reduced the 10 years to eight years based on 435,000 miles being 72.5% of the 600,000 miles final useful life and eight years being 72.5% of the 11 years final useful life. Consequently, EPA's standard would be more stringent than CARB's already non-feasible standard if EPA adopts the IUL as proposed. [EPA-HQ-OAR-2019-0055-1346-A1, p.19]

In sum, PACCAR supports a single step useful life standard at 600,000 miles for in-commerce vehicles and DF validation at MY 2027 and does not support an IUL standard. [EPA-HQ-OAR-2019-0055-1346-A1, p.19]

PACCAR summarizes below the major issues that EPA should take into account as it moves forward with this rulemaking:

- PACCAR supports an extended UL demonstration in the lab, combined with other flexibilities to reduce the UL liability in commerce and proposes the following elements:
    - Demonstration Standard: laboratory demonstration (DF) out to 700,000 miles using accelerated aging methods
    - Verification of DF: in commerce out to 600,000 miles
    - In-Commerce Liability for Recall: less than or equal to 600,000 miles [EPA-HQ-OAR-2019-0055-1346-A1, p.59]

Organization: *Retail Industry Leaders Association (RILA)*

RILA is broadly supportive of EPA's proposed changes to the regulatory useful life and emissions-warranty requirements but urges EPA to build a stronger consensus with market participants around the cost elements involved in this area to avoid any excessive cost-increases. EPA should work with manufacturers and other relevant stakeholders to support a clearer understanding of the various factors included in EPA's regulatory impact analysis (e.g., technology costs, warranty costs, and truck maintenance costs) that may not be immediately apparent to market participants. [EPA-HQ-OAR-2019-0055-1189-A2, p.3]

The technologies used to reduce emissions from heavy-duty engines are expected to deteriorate in effectiveness over each engine's full operating life. To ensure a reasonable longevity of the emissions controls, EPA's existing regulations should include minimum useful life periods over which these technologies are required to operate adequately. Such regulations around regulatory useful life are vital to ensure that the initial standards persist across a reasonable duration and provide the intended environmental and societal benefits. [EPA-HQ-OAR-2019-0055-1189-A2, p.3]

In this context, EPA's proposal to extend the regulatory useful life of heavy-duty engines has the potential to ensure that the emissions controls within these engines continue to protect communities from pollution are designed for longer into its operational life. [EPA-HQ-OAR-2019-0055-1189-A2, p.3]

However, improvements to emission controls longevity and extended warranty periods are likely to carry additional costs to be passed on to purchasers of vehicles that use these engines. Even though the proposed increase to emissions warranty period and regulatory useful life could potentially lead to reduced operating costs over an engine's operating life, any increase to a vehicle's up-front cost could function as a barrier to adoption of new vehicles using engines covered in the scope of this proposed rule. Such a barrier may have unintended consequences that run counter to the intended aims of this proposed rule, as it might keep older and more-polluting vehicles in service for longer than they otherwise might be. [EPA-HQ-OAR-2019-0055-1189-A2, p.4]

Organization: *Truck and Engine Manufacturers Association (EMA)*

It is important to highlight from the outset that while there are various details of EPA's rulemaking proposal (particularly with respect to Option 1) that EMA and its members fundamentally disagree with, there are multiple major points of substantial agreement. In that regard, EMA agrees with EPA that:

> (iii) The current emission warranty and useful life periods for HDOH engines and vehicles should be revised to increase the durability and efficacy of in-use emissions compliance; [EPA-HQ-OAR-2019-0055-1203-A1, p. 5]

In order to ensure the adoption of fully achievable and cost-effective HDOH low-NOx regulations, and notwithstanding our broader agreement, the Agency should revise the proposed standards in the following manner: The proposed extended useful life ("UL") requirements should be reduced sufficiently to ensure that manufacturers are not required to assume that they will need to replace aftertreatment systems during the extended UL periods, which necessary replacements would result in substantial and unreasonable cost increases for new HDOH engines and vehicles starting in the MY 2027. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 6 - 7]

On top of that, the almost doubling of the FUL period over which compliance with the already infeasible NOx standard would be required could force OEMs to include the cost of aftertreatment replacement as an assumed component of regular maintenance, while also leading to undue and unreasonable risks and costs stemming from potentially increased recall liability. [EPA-HQ-OAR-2019-0055-1203-A1, p. 12]

The Agency asserts, without support, that the "proposed useful life periods are feasible and would not require manufacturers to adopt component replacement as a part of their critical emissions-related maintenance strategies." (87 FR at p. 17496.) We disagree. As an initial matter, EPA does not yet have the final analysis of the Stage 3 RW emission results at the 800,000 mile benchmark; nor has EPA shown that all of the Option 1 certification standards and Bin 3 standards are even feasible. [EPA-HQ-OAR-2019-0055-1203-A1, p. 12]

As a consequence, and given (i) the significant uncertainties regarding the durability and in-field performance of all of the new Stage 3 emission-system componentry over the extended useful life periods (up to 800,000 miles), (ii) the lack of the Stage 3 prototype's fully demonstrated compliance with the Option 1 standards, and (iii) the strict liability risks under the new 3B-MAW protocols, manufacturers likely will need to adopt aftertreatment component replacement strategies. The risks and costs of recalls, perhaps multiple recalls, would be too great for manufacturers to do otherwise. [EPA-HQ-OAR-2019-0055-1203-A1, p. 12]

EPA proposes to significantly extend the emissions useful life periods for all primary intended service classes starting in MY 2027. For example, EPA proposes to almost double the UL requirement for HHDE (435,000 miles today, increased to 800,000 miles by 2031) and to require a 2.5x increase for LHDE (110,000 miles today, increased to 270,000 miles by 2031). [EPA-HQ-OAR-2019-0055-1203-A1, p. 44]

EMA does not support EPA's proposal to extend the useful life periods. The proposed changes will force manufacturers to adopt new emissions-related maintenance recommendations to replace aftertreatment systems rather than accept the significant risk of a non-compliance determination and the expense of one or multiple recalls late in the useful life. Because EPA will require manufacturers to pay for the aftertreatment replacement, manufacturers will necessarily recoup those significant costs at the only available opportunity, the point of purchase. Extending the useful life as proposed also will compel manufacturers to enhance the design of many emissions-related components, imposing even more costs on the buyer. The result would be a substantial increase to the initial purchase price of heavy-duty vehicles. (See Section 16 for more details about the cost implications of EPA's proposal.) The expected cost increases invariably will lead to deferred purchases, delaying the adoption of the latest, cleanest vehicles. EMA stands ready to work with EPA to finalize more appropriate useful life requirements in the final rule. [EPA-HQ-OAR-2019-0055-1203-A1, p. 44]

EPA proposes to continue the practice of including hours in the regulated useful life period for the heavy heavy-duty engine (HDE) class to account for engines "that operated frequently, but accumulated relatively few miles due to lower vehicle speeds" (87 FR 17501), based on a 20 mile per hour speed threshold consistent with today's heavy HDE useful life criteria of 435,000 miles and 22,000 hrs. EPA has requested comment on the need for a useful life hours criterion for all heavy HDE, and whether they should include hours criterion for the other primary intended service classes. EMA supports continuing to include useful life hours for Heavy HDE as well as adding useful life hours for the other primary service classes of Medium HDE, Light HDE, and SI HDE. Just as in Heavy HDE, and perhaps even more so, there are applications within the other classes that accumulate relatively few miles due to lower vehicle speeds. It is also appropriate to use an average speed of 20 miles per hour in determining useful life hours for those other classes. [EPA-HQ-OAR-2019-0055-1203-A1, p. 44]

The Agency is proposing this suite of new technical requirements while also proposing to nearly double the mileage over which compliance will be required. In that regard, the extended Useful Life requirements will very likely compel replacement of major emissions control systems costing well over $10,000 within the required compliance period. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 170 - 171]

EPA Summary and Response

The summary and response for this section includes a listing of the topics raised, then the comments are summarized by category and the responses follow each summary.

Comments relating to useful life fell into the following general categories

- Support or opposition
    - General support for or opposition to lengthening useful life
    - Support for proposed Option 1 or Option 2
    - Support for useful life periods longer or shorter than proposed
- Need for more information
- Increased purchase price, delayed effectiveness of the rule, and aftertreatment replacement

- Projected operating costs
- Intermediate useful life
- Hours-based useful life periods
- Useful life for refueling standards
- Alternate useful life periods

Support or opposition

Several commenters expressed general support for or opposition to EPA's proposal to lengthen useful life periods, without addressing numeric values. Clean Fuels, GREL/DSCC, and RILA commented with general support for longer useful life periods but did not specifically support a proposed option. EMA expressed support for revising the useful life periods, but did not support EPA's proposed useful life values. EMA suggested EPA reduce the proposed useful life requirements to avoid aftertreatment replacement and the associated "substantial and unreasonable cost increases". Cummins did not support EPA's proposal to increase useful life periods, commenting that even proposed Option 2 included significant increases in useful life that would increase the purchase price of vehicles. Cummins noted that either option's increase in useful life in conjunction with new standards will further add costs and add to uncertainty and variability in the field that would require additional compliance margin for all standards. While MEMA supported proposed Option 1 generally, they suggested EPA reduce the useful life periods citing a need for more data. Similarly, AVE expressed support for proposed Option 1 standards with modified useful life timelines.

Some organizations expressed support for the proposed options. Commenters supporting Option 1 included CARB and Consumer Reports. CARB cited the analysis they used to justify the same useful life periods adopted in their Omnibus rulemaking and EPA's CI engine test program that evaluated the engine's performance to 800,000 miles. Consumer Reports supported the useful life periods of proposed Option 1, suggesting that Option 2 did not capture enough of the operational life of the engines. Allison supported the useful life periods of proposed Option 2 and suggested that opting for the less stringent of EPA's proposed options does not prevent the agency from revisiting useful life periods in a future rule after observing the implementation of the Option 2 periods.

Four organizations suggested EPA adopt useful life periods longer than the proposed options. American Lung Association et al. requested that EPA extend the useful life period beyond proposed Option 1 to 1 million miles in order to capture the full operational life of the vehicle. Clean Air Task Force et al. requested that EPA adopt useful life periods at least as stringent as proposed Option 1 noting EPA's statutory obligations and their preference that EPA align with CARB's Omnibus program. They noted EPA's rebuild data that indicated some engines may be driving on the road more than twice the mileage of today's useful life and that manufacturers have little incentive to ensure emission controls function properly when useful life only covers a fraction of the operational life of the engine. Clean Air Task Force et al. recommended EPA consider useful life periods longer than proposed Option 1 if feasible with the final standards. MFN requested that EPA pull forward the useful life periods of the MY 2031 step of proposed Option 1 to begin in 2027. MFN noted the long operational life of the engines and the SwRI CI technology demonstration program as reasons EPA cannot delay the longest proposed useful life periods to MY 2031. Clean Air Board of Central Pennsylvania suggested that the useful life should cover the full life of the vehicle.

Several organizations suggested specific useful life periods shorter than the proposed options. DTNA requested useful life periods of 10 years/500,000 miles for Heavy HDE and 10 years/250,000 miles for Medium HDE with equivalent hours criterion. DTNA noted that EPA's proposed options are "cost prohibitive and impractical" to design their engines with certainty, especially when new technology will be required to meet the standards. NPGA/PERC recommended EPA adopt a useful life of 10 years/150,000 miles for Spark-ignition HDE to match the useful life periods of Class 2b/3 vehicles. They indicated that the proposed Option 1 useful life periods would add complexity and cost to propane products and those costs would be passed to the purchasers. PACCAR supported a 600,000 mile useful life, indicating that stringent standards will be increasingly difficult to meet at longer useful life periods due to "emission system drift and variation". PACCAR proposed that useful life vary for certification and in-use, with a DF demonstration out to 700,000 miles at certification in the laboratory, DF verification out to 600,000 in the field, and recall liability limited to 600,000 miles.

Response:

- We appreciate the expressed support from certain commenters for our proposal to lengthen useful life periods and acknowledge the concerns raised by other commenters.
- A key objective of our proposal was to adopt useful life periods that cover a larger portion of the operational life of the engine. We retain that original objective, and are modifying our proposal to finalize useful life periods that cover a significant portion of the engine's operational life while also giving appropriate consideration to the relationship between the useful life and the stringency of the final numeric standards and considering comments and additional information on uncertainties and potential corresponding costs.
- As explained in the preamble for this rule, we are finalizing a single-step program for the new useful life periods to begin in Model Year 2027. For Spark-ignition HDE, Light HDE, and Medium HDE, we are finalizing useful life mileages that match the MY 2031 step of proposed Option 1. For the heaviest engine class (Heavy HDE), the final useful life mileage matches proposed Option 2. See preamble section IV.A for a discussion of the basis of our final useful life periods.
- We disagree with commenters recommending that we finalize useful life periods below the mileages of the less stringent proposed Option 2, since we specifically indicated that Option 2 represented the lower bound of the range of mileages we would consider finalizing for each engine class and the EPA test programs demonstrated that low emission levels can be maintained at mileages at least as long as Option 2 for all engine classes.
- We did not propose and do not believe it is appropriate at this time to finalize useful life periods beyond proposed Option 1 as requested by American Lung Association et al., Clean Air Task Force et al., and Clean Air Board of Central Pennsylvania. As noted in the NPRM, proposed Option 1 represented the upper bound of the range of mileages we would consider finalizing for each engine class due to the effect of useful life on the

feasibility of meeting the standards and lack of data on emission performance at mileages approaching the rebuild and replacement mileages. Chapter 2 of the final RIA presents the rebuild and replacement mileages for CI and SI engines, respectively, that were used to estimate the average operational life of each engine class and inform our proposed useful life mileages.

- EPA's analysis and test programs demonstrated it is appropriate and feasible for the smaller engine classes to maintain emission control at the final emissions standards over useful life periods matching proposed Option 1 for those engines. We are less certain on the feasibility of finalizing proposed Option 1 at the national level for Heavy HDE at this time. Commenters listed uncertainties at the distinctly higher mileages proposed for the largest engines, provided additional information on costs, and expressed concern over potential economic impacts (we respond to comments related to costs in Section 18 and related to economic impacts in Sections 25 and 26 of this document). As noted in responses below, we considered comments, additional analysis, and all of our engine demonstration data in setting the final useful life values in this rule.
- Our combined final useful life of 650,000 miles and lengthened durability demonstration to an equivalent of 750,000 miles for Heavy HDE addresses many of the concerns behind PACCAR's suggested useful life approach. See section III.B of the preamble for more information.

Need for more information

Several organizations commented on suppliers' ability to develop technologies to meet the proposed useful life periods. Allison commented that even proposed Option 2 would be challenging for suppliers to design, test, validate, produce, and distribute in the four year lead time. Allison also commented that either proposed option would result in higher upfront engineering and material costs and that EPA should consider that manufacturers need "head room" to ensure compliance. Eaton commented that the components they produce (CDA hardware, power management devices for electrical and fuel heaters, and EGR pumps) are designed to last the life of the vehicle, which typically exceeds the useful life of the engine. AVE commented that in order for many technology suppliers to assess the durability of their products at the proposed useful life periods, they need more information related to extended distances, time in-service, and use patterns (including beyond the first owner). AVE recommended re-evaluating the full useful life timeline when more engine test data is available. BorgWarner commented that "it is impossible to design a system" to meet the proposed useful life periods because EPA's CI engine test program, which used accelerated aging of the aftertreatment system, did not demonstrate the degradation of the engine components over the extended useful life periods or account for use patterns of multiple owners or vocational applications that these HD engines may experience. MECA encouraged EPA to continue to work with CARB to study the impacts of the rule's implementation of the warranty and useful life updates in this rule and to gather more information on the deterioration of field-aged parts. MECA noted that while the durability of aftertreatment systems can be evaluated using accelerated aging tests, some technologies, such as CDA, are not able to be aged and must tested over the full useful life period to understand its deterioration. MEMA indicated that additional data and analysis on use (relating to 2nd and 3rd owners and vocational vehicle applications) is needed before proposing longer useful life and warranty periods.

Response:

- While we appreciate Eaton's comment that their technologies are designed to last beyond the useful life periods of current engines, we recognize the concern from other technology suppliers that stated it would be a challenge to design components for very high mileages since there is limited durability data available at mileages beyond today's warranty periods and even less beyond today's useful life periods. As noted by Allison, and discussed in Section III of the preamble to this final rule, we have taken into consideration manufacturer "head room" in the final standards by considering compliance margin within the context of this final program.
- We recognize the concerns expressed by the four technology suppliers that they need more information on component failures and use patterns of the range of vehicles that use these HD engines. We understand that there is limited engine and aftertreatment data at 800,000 miles, which could make it costly to adequately design components to maintain the emissions levels proposed for Heavy HDE at the useful life mileages in the MY 2031 step of Option 1. As noted in section IV.A of the preamble, we are finalizing a useful life mileage for Heavy HDE of 650,000 miles, which is within the range of manufacturers' extended warranty offerings for those engines. We expect manufacturers will share data relating to component failures and use from warranty claims at their extended mileages as they work with their suppliers to develop engine configurations to meet the new useful life mileages (e.g. 650,000 miles for Heavy HDE).
- We are not planning to conduct any formal programs to collect durability data in the near-term, as requested by MECA, but will continue to monitor test results from certification and in-use and expect to coordinate with CARB to evaluate any new information.

Increased purchase price, delayed effectiveness of the rule, and aftertreatment replacement

Many commenters noted that longer useful life will increase purchase price and several indicated that the higher purchase price may delay effectiveness of the rule. ATA cautioned that, while fleets want durable products that may result from longer useful life periods, that durability comes at a cost to the fleets that purchase the vehicles. RILA requested EPA work with manufacturers and other stakeholders to clarify and "build a stronger consensus" on the costs outlined in the RIA. RILA also notes that costs of improved durability, even if they reduce operating costs, can lead to up-front costs that may unintentionally keep older, more-polluting vehicles in service.

Several organizations specifically expressed concern over aftertreatment replacement. ATA noted that useful life periods as long as 800,000 miles may lead manufacturers to sell their vehicles with warranty packages that cover expensive component replacements within the useful life, which is another cost incurred by the fleets. DTNA commented that the combination of the proposed useful life periods and standards will require an aftertreatment efficiency that may lead many manufacturers to replace catalysts under warranty to ensure emission control is maintained, and that the cost of that component replacement would be added to the purchase price of the vehicle. PACCAR stated that stringent standards, uncertainty on durability, and liability risks for in-use testing, make it likely that some manufacturers would replace aftertreatment components within the useful life to ensure compliance, which would cause "unreasonable cost increases". EMA suggested that manufacturers would likely adopt aftertreatment component replacement due to the risks and costs of recalls considering durability and in-field performance uncertainties, EPA's incomplete demonstration out to 800,000 miles at the time of the comment, and liability risks under the proposed updates to the in-use test procedures. Since aftertreatment replacements are required to be covered by the manufacturer under this rule, the costs (that they estimate would be over $10,000) would necessarily increase the purchase price even more than the increases due to the new technologies added to meet the standards. EMA suggested that the increased purchase prices would cause customers to defer purchases and delay adoption of cleaner vehicles.

Response:

- We recognize that manufacturers will need to make investments in the durability of their emission control components in order to meet the longer useful life periods we are finalizing. We also acknowledge that some of those costs will be passed on to customers as an increased purchase price and that increase in purchase price has the potential to have sales impacts. Our final cost analysis in Chapter 7 of the RIA uses the final useful life periods to calculate updated indirect R&D costs to manufacturers. The cost updates reflect our consideration of comments from manufacturers and others, and include a clearer description of the factors we analyzed as requested by RILA. The updated cost analysis informed our updated economic analysis. As outlined in chapter 10 of the RIA and section 25 of this document, our updated economic analysis projects that sales effects due to increased costs would be minimal and short-lived.
- Our current regulations require that manufacturers cover the cost of any scheduled replacement of catalysts, and we note that the requirement to cover costs would not be restricted to catalyst replacements scheduled within a warranty period. We agree with commenters that any manufacturers opting to schedule catalyst replacement would likely recoup those costs by increasing the purchase price of their vehicles. We also recognize the general risk expressed by commenters that a significant increase in purchase price may prevent some customers from purchasing new vehicles with the latest technologies, delay fleet turnover, and reduce the effectiveness of the rule. However, as noted above, our updated economic analysis projects that sales effects due to increased costs of this final rule would be minimal and short lived.
- In section IV.A of the preamble, we describe how the uncertainties expressed by commenters informed our final useful life mileages. As explained in the preamble, we also project that the final standards and corresponding useful life periods will not require manufacturers to plan for the replacement of the entire catalyst system as a part of their compliance strategy and we have not included a catalyst system replacement in our cost analysis.

Projected operating costs

The proposed cost analysis included operating costs and the proposal projected that the longer useful life and warranty would reduce owner costs over the life of the vehicles. ATD disagreed with EPA's cost analysis that projects reduced repair costs due to the longer useful life and warranty periods, and instead suggests that higher costs of "unreasonably longer useful life mandates" would undermine feasibility of the rule. Clean Fuels agreed that a longer useful life would reduce costs to customers. Clean Air Task Force et al. commented that a longer useful life will shift the costs and risks of designing emission controls to be borne by the manufacturers instead of the operators.

Response:

- In the cost analysis for this final rule, we updated operating costs for owners and operators, including updated repair costs, based on the final standards and useful life periods. For more information on the methodology and results, see our updated assessment of costs RIA Chapter 7.

Intermediate useful life

Several organizations commented on EPA's proposed intermediate useful life. CARB and MECA supported EPA adopting an intermediate useful life at 435,000, as proposed in Option 1. MECA cited three publications achieving NOx levels below 0.02 g/hp-hr using CDA, supplemental heat, or advanced aftertreatment and noted that passenger vehicle regulations have included intermediate useful life standards. CARB further recommended that EPA adopt an intermediate useful life for 2027 as well, using the same numeric values at 435,000 miles as proposed for 2031, indicating that CARB's early adoption of an intermediate useful life as part of the Omnibus requirements for MY 2027 provided additional lead time for the industry. In Section 3.1, several other organizations expressed support for alignment with CARB's Omnibus program, including an intermediate useful life standard in MY 2027.

Allison did not support intermediate useful life due to added certification costs that would be shared by all customers, regardless of whether the vehicle they purchase would reach that 435,000-mile threshold, such as vocational vehicle applications. Allison disagreed with the need for an "intermediate check on emissions performance deterioration" noting that the full useful life standard should be the measure of compliance and in-use standards are the more appropriate check. Allison further noted that the full useful life and warranty requirements are direct incentives to meet the requirements and the intermediate useful life is an added regulatory layer and cost. PACCAR also did not support an intermediate useful life standard due to the burden of separate standards and the fact that some systems may not have the linear degradation but would maintain compliance with a single standard. PACCAR notes that the 10-year intermediate useful life age value proposed by EPA does not match 8-year value finalized for CARB's intermediate useful life.

Response:

- We proposed to include an intermediate useful life for Heavy HDE in the MY 2031 step of proposed Option 1. While our CI test program did achieve a 20 mg/hp-hr NOx level at the 435,000-mile point of the test, we proposed to allow more lead time for manufacturers to achieve the 20 mg/hp-hr standard and we did not include an intermediate useful life for the proposed MY 2027 step. We also note, in response to CARB's comment on additional lead time, that the CAA section 202(a)(3)(C) minimum lead time requirement for an EPA criteria pollutant standard under CAA section 202(a)(3) is based on the date of promulgation of such standard.
- We are not finalizing intermediate useful life standards at this time. We are finalizing a single-step program, in part, to limit complexity. We do not believe the additional complexity of separate standards at an intermediate useful life for Heavy HDE is appropriate at this time. Our final standards, in combination with the final durability and in-use testing requirements, will ensure engine manufacturers design systems compliant for the full useful life.
- While some commenters indicated support for requiring manufacturers to meet lower standards early in an engine's operational life, our primary focus with this final rule is to establish feasible standards at full useful life for all engine service classes. Results from the EPA technology demonstration program did not show a drastic increase in deterioration after 435,000 miles that would support the need for an intermediate standard. In addition, while we have tested catalyst and engine strategies to demonstrate the feasibility of the standards finalized in this action, EPA standards are performance-based and we do not wish to restrict or hamper a manufacturer's use of technologies that may use different deterioration or calibration strategies to achieve the full useful life standards. We acknowledge PACCAR's concern that an intermediate useful life may unnecessarily limit manufacturers' compliance strategies.

Hours-based useful life periods

Three commenters supported the proposal to include hours-based useful life periods. MEMA supports adding an hours limit for useful life. Cummins and EMA supported continued use of the hours criterion for Heavy HDE useful life periods and requested that EPA add hours to the useful life periods for other engine classes. Cummins specifically noted that smaller classes are often used in low speed applications where an hours-based useful life may apply. Cummins and EMA also supported the proposed 20-mph conversion factor to calculate the hours-based useful life values for all engine classes.

<u>Response</u>:

- We received no adverse comments for hours-based useful life periods and are finalizing hours as a useful life criteria for all engine classes. As described in Section IV.A of the preamble to this final rule, we are applying a 20-mph conversion factor, as proposed, to calculate the hours values from the final mileage values.

Useful life for refueling standards

AVE, Ingevity, and MECA supported the proposal to apply a useful life of 15 years or 150,000 miles for the proposed refueling emission standard for incomplete vehicles greater than 14,000 lb GVWR.

Response:

- We are finalizing the refueling emission standard to apply for a useful life of 15 years or 150,000 miles, as proposed.

Alternate useful life periods

Cummins requested that EPA allow an alternate useful life period as specified in the current 40 CFR 86.004-2.

Response:

- Our proposed migration did not include the portion of the useful life definition in 40 CFR 86.004-2 that allows manufacturers to request an alternative useful life period. Manufacturers have not used this provision in recent years and we believe the addition of new hours-based useful life values for all engine classes will cover the range of applications for which manufacturers may consider requesting an alternative useful life. Our final updated useful life provisions in 40 CFR 1036.104(c) will not include an allowance for manufacturer to request an alternative useful life periods.

3.9 Closed Crankcase

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

Closing crankcase emissions is important in controlling significant PM emissions as well as unaccounted methane emissions emitted with the blowby gases. CARB staff supports the proposed requirements to close crankcase ventilation system for all CI HDEs to prevent crankcase emissions from being emitted directly to the atmosphere starting with MY 2027 engines. [EPA-HQ-OAR-2019-0055-1186-A2, p.47]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

The current open crankcase breather system has allowed turbocharger and engine manufacturers to invest continuously in turbocharger technology and manufacturing precision over the years, to maintain high compressor efficiency over the lifetime of an engine. This has proven to be very successful in ensuring the fuel efficiency of today's HD diesel engines. Such efficiencies are achieved only by maintaining a clean and contamination-free air inlet system to the turbocharger for engine combustion. [EPA-HQ-OAR-2019-0055-1168-A1, p.94]

EPA's proposal to require a closed crankcase ventilation system will have numerous adverse impacts on engine performance and efficiency. With the addition of an engine closed crankcase breather, the combustion vapors are made up of oil particles that are drawn into the turbocharger compressor housing and that attach to the hot internal surfaces of the turbocharger. This condition leads to an oil build-up that effects airflow and thereby reduces compressor housing efficiency. As illustrated in Figure 36 below, this loss of compressor efficiency along with the reduced width of the compressor efficiency map leads to reduced engine performance, surge margin, and engine braking performance. [EPA-HQ-OAR-2019-0055-1168-A1, p.94]

Figure 36 (green lines) shows the compressor efficiency of a new baseline turbocharger with 0 hours on a turbocharger Hot Gas Test Stand (HGTS). Daimler Truck introduced a close crank case ventilation (CCV) system on this turbocharger using a mule engine on a durability test bench for 144 hours. The test cycle used is a representative alternating load cycle, typical of a line haul vehicle, alternating between 1050 rpm and 1450 rpm sweeping the full load points. After 144 hours, the turbocharger was taken off from the durability engine test stand and tested on the turbocharger gas stand for compressor efficiency. The results are shown in the blue lines of Figure 36; compressor efficiency decreased by 4.5% at rated torque. The turbocharger was further placed on the durability mule engine and test continued for 200 hours with the same cycle listed above. The turbocharger was taken out from the durability mule engine and tested on a turbocharger gas stand; the results were a loss of 8.2 % compressor efficiency at rated torque as shown in red lines of Figure 36. [EPA-HQ-OAR-2019-0055-1168-A1, p. 95]

Based upon this test, we concluded that with the current closed breather system installed on a heavy duty engine running at a customer representative high duty cycle, up to 7-8% compressor efficiency can be expected to be lost in as little as 200 hours of high load operation. Since 7-8% compressor efficiency loss was significant, further testing was not performed on this system. Figure 37 below shows a picture of the compressor housing after 200 test hours.
Severe compressor coking was observed, leading to this compressor efficiency loss. During the 200 hours run, data in Figure 38 also shows decreasing compressor pressure outlet (CPO), i.e., the engine boost deterioration, which is in line with the compressor coking as observed in the compressor photo: [EPA-HQ-OAR-2019-0055-1168-A1, pp.95-96]

Daimler Truck also performed this testing on improved crankcase breather technology (such as an electrically driven crankcase breather, with HEPA filtration), which produces less oil fouling and reduces compressor efficiency losses. Figure 39 shows the impact on compressor efficiency loss with this advanced crankcase filtration system. This results in a slight improvement, but compressor fouling or coking was still observed with a compressor efficiency drop of up to 4% in as little as 200 hours. The test was further continued to 400 hours and observed further degradation in compressor efficiency of up to 6% as shown in the red color lines of Figure 39. [EPA-HQ-OAR-2019-0055-1168-A1, pp.96-97]

Significant design and engineering efforts have been invested to reduce the coking of the oil mist in the compressor housing by reducing internal surface temperatures at the compressor housing with the addition of water cooled compressor stage. The reduced wall temperatures to below 160 degrees Celsius is expected to provide some reduction in the rate of contamination in the compressor stage. Daimler Truck has further performed testing on reduced wall temperatures to below 160 degrees Celsius and the results (discussed later in this section) shows that even with reduced compressor inlet wall temperature, a reduction can be expected, but is unlikely to completely eliminate the oil coking build-up. [EPA-HQ-OAR-2019-0055-1168-A1, p.97]

Daimler Truck has investigated several approaches to improve crankcase separation performance, including using an electric drive system to reduce oil content. The new improved electric drive systems work on the basic principle of removing or reducing the mass of the oil droplets in the crankcase vapor before the vapor is sent to the turbocharger inlet. The new innovative electric drive systems have approximately 2 to 3% improved oil particle separation efficiency over the current oil pressure driven system. Even with increased efficiency of removing the mass of the oil droplets (mainly larger sizes > 0.3 μm), the oil contamination affecting the turbocharger compressor efficiency loss can still be measured within 200 hours on an engine dyno durability test. The results are slight improvement in a reduction of compressor coking, but even with the new electric drive technologies, the compressor efficiency loss of 5-6% is still obse1ved in the data (shown later in Figure 42). Figure 40 shows the ove1view of various current and upcoming future new crank case ventilation technologies evaluated in the test program. The results for these new technologies will be discussed later in this section. [EPA-HQ-OAR-2019-0055-1168-A1, pp.97-98]

Research studies 118 have shown that removing the larger oil droplets can have a significant reduction in total oil mass and effect the rate of coking buildup . However, the smaller oil particles below 0.5 μm (Figure 41a) that are not removed are still present contributing to the coking buildup and compressor efficiency loss, as shown in the research studies of Sumi N. et al. 119 (Figure 4 1). [EPA-HQ-OAR-2019-0055-1168-A1, p.98]

Daimler Truck further conducted a study of various current and future closed crankcase breather technologies on a 15 liter heavy duty on highway engine running a customer representative duty cycle. The various technologies investigated as shown in Figure 42 are: (42a.) current Alfdex production system, (42b.) electric eAlfdex system, 3nine with HEPA filters (42c.), breather discharge into the vehicle air filter (42d.). The durability cycle ran was described previously in this section and the periodic examination of the compressor housing was done every 24 to 50 hrs. The baseline turbocharger with zero hours compressor efficiency test was performed on Hot Gas test Stand (HGTS). After 200 hours of durability cycle, the turbocharger assembly was tested again on the HGTS and also examined for the soot build up. The results of this study are shown in Figure 42 with the soot build up and the compressor efficiency losses. [EPA-HQ-OAR-2019-0055-1168-A1, p.99]

Daimler Truck concluded that current and future crankcase breather technologies are not sufficient to eliminate oil contamination in the compressor housing. This contamination leads to a significant rate of fouling, affecting compressor efficiency loss, even with the best available technology. [EPA-HQ-OAR-2019-0055-1168-A1, p.99]

With the closed breather system, the engine air induction system can be contaminated by introducing crankcase gases into the engine filtered air induction system. This can produce a significant contamination of the entire engine air system including the vehicle charge air cooler. [EPA-HQ-OAR-2019-0055-1168-A1, p.100]

Within hours of on engine testing, Daimler Truck results show the effects of engine pe1fonnance; such effects can also be detected with measurement and visual inspection of the entire air system. These effects include fouling of the charge air cooler, engine induction system including intake manifold, cylinder head intake runner, intake valves, valve seats and critical port areas that can reduce port volume and disrupt critical port flow. The long term effects of the oil contaminated air and combustion deposits within the combustion chamber are still unknown. Downstream of the exhaust ports and exhaust manifold are also of concern with EGR cooler effects on cooler fouling and afte1treatment contamination. [EPA-HQ-OAR-2019-0055-1168-A1, p.100]

Daimler Truck conducted a further study in a test cell using a DD 15 Gen 5 current production engine over the FTP, RMC, fuel maps and the engine brake performance of a clean turbocharger (as a baseline) and a back-to-back study with a turbocharger that has undergone 200 hours of closed crank case ventilation system (as shown in Figure 42a for mechanical oil pressure driven system). A DD15 durability engine was used to age the turbocharger using a closed crank case ventilation system in the same manner described above. The turbocharger was removed from the mule engine after 200 hours and placed on the test cell engine for this back-to-back study. The effects on fuel consumption of a closed crank case turbocharger over the baseline turbocharger (using open crank case ventilation) are shown in Table 14 below. The fuel consumption results show that with a closed crank case system, there is an increase in fuel consumption of 1.13% over composite FTP cycle, an increase of 0.9% over the RMC cycle with up to a 1.5 % increase over the entire 10x10 Fuel map. This fuel economy loss with only 200 hours of closed crank case ventilation is substantial. [EPA-HQ-OAR-2019-0055-1168-A1, pp.100-101]

Daimler Truck also ran an engine braking torque evaluation of the turbocharger and the results are shown in Figure 43. A 7% to 10% loss in engine brake power is documented. This is a substantial loss of engine braking power after only 200 hours of aging. This potentially has safety implications, requiring the need to increase vehicle mechanical braking power to maintain adequate braking performance. [EPA-HQ-OAR-2019-0055-1168-A1, p.101]

The impact to fuel economy for an electrical oil pressure driven system (as shown in Figure 44) can be estimated based on the significant compressor efficiency loss recorded over 200 engine hours. As shown in Figure 43, at the 200 hours test point, the future electric closed crankcase breather compressor efficiency loss is 4%. Engine fuel economy degradation based on compressor efficiency loss of 4% is estimated to be 0.7%. Apa1t from 0.7% fuel efficiency loss, the closed crank case system has other adverse impacts on the engine pe1f01mance, including increased particulate emissions leading to a shortened filter regeneration interval (i.e., more

IRAF), as well as increased aftertreatment aging and poisoning, which further increases the likelihood of increased tailpipe emissions. The reduced compressor efficiency leads to lower boost, increasing the potential for low boost OBD monitor codes, and the need to replace emissions relevant parts as they degrade from exposure to oil mist. [EPA-HQ-OAR-2019-0055-1168-A1, p.102]

Significant progress has been made over the years to improve compressor efficiency, resulting in a direct improvement in fuel economy and reduced CO2 emissions. As shown in Figure 44, the testing shows that intake air contaminated with crankcase breather gases even at reduced levels can decrease overall engine fuel economy. [EPA-HQ-OAR-2019-0055-1168-A1, p.102]

As shown the above two sets of tests, fuel efficiency loss is significant since OEMs would have to introduce more and more engine efficient technologies to offset this GHG loss to meet GHG Phase 2, 2027 step which EPA did not consider during the Phase 2 rule making. Apart from this, the need to compensate for increased GHG emissions caused by close crank case ventilation, will lead to increased engine out NOx. More info1mation on NOx/GHG emission tradeoffs that could occur under the Proposed Rule is provided in Section II.B.3 of these comments. [EPA-HQ-OAR-2019-0055-1168-A1, p.102]

Daimler Truck also conducted a visual inspection of intake side components after 1600 hours with active closed crank case ventilation systems on a DD 15 Gen 5 engine test. The impact of the intake side components is shown in Figure 45 and include the following:

- **Charge air cooler outlet:** Oil at the bottom and also top flange (picture #1 below). The oil was seeping through the joint.
- **Charge air cooler outlet to the intake boost pipe:** The hose connection before boost pipe shows evidence of liquid oil (picture #2).
- **Intake air inlet pipe to the engine:** Inlet sludge/ wet accumulation observed as shown in (picture #3). [EPA-HQ-OAR-2019-0055-1168-A1, pp.102-103]

Introduction of crankcase breather gases into the induction air upstream of the compressor housing of the turbocharger will potentially increase warranty liability and introduce risk in meeting the compliance targets for full useful life. As highlighted in the previous sections, the first component to be affected in performance, fuel economy, and eventually in service replacement is the turbocharger. A turbocharger is a non-serviceable component, therefore, any degradation of performance will need to be corrected with a complete replacement. Other vehicle and engine parts that could suffer the same fate are vehicle charge air coolers, intake and exhaust components including EGR coolers and aftertreatment systems. [EPA-HQ-OAR-2019-0055-1168-A1, pp.103-104]

With the routing of crankcase gases directly into the turbocharger inlet, the risk of increased secondary damage to engine components is high. Any engine condition that causes increased blowby gases with increased debris contamination—including soot and material debris—will end up overloading the crankcase breather and passing into the intake system of the engine. This increased contamination of the entire engine intake system will need to be serviced during the engine repair and increases the service cost, service time, customer downtime, and OEM warranty cost. The increased contamination will also lead to the entire turbocharger replacement. [EPA-HQ-OAR-2019-0055-1168-A1, p.104]

Introducing a closed breather into the induction system airstream will negatively impact engine warranty, service, as well as both the OEM and customer costs of the final product. Service costs in downtime and material will also be significant. [EPA-HQ-OAR-2019-0055-1168-A1, p.104]

More efficient crankcase breather technology will add to the cost of the engine and, most significantly, the costs of other components to mitigate oil contamination to the turbocharger, such as a water-cooled turbocharger compressor. This will have a significant impact by increasing the complexity of the crossover coolant tube on the turbocharger, specifically by requiring a dedicated compressor housing for each vehicle application due to compressor outlet angle and orientation. The inevitable results will be significantly increases cost and manufacturing complexity along with customer and service complexity. [EPA-HQ-OAR-2019-0055-1168-A1, p.104]

Cold weather condensation and ice formation risk to the turbocharger compressor wheel is also a concern and could impede crankcase breather function for the engine, as well as create the potential for added contamination and failure to the compressor stage of the turbocharger. [EPA-HQ-OAR-2019-0055-1168-A1, p.104]

Daimler Truck has some experience with cold weather operation using the closed crank case breather. There was evidence of condensation and ice formation at the breather outlet/inlet to the airstream to the turbocharger. This has devastating results to the compressor inlet blades and function of the crankcase breather system. With the introduction of ice particles, the risk of compressor wheel damage is extremely high as shown in Figure 46.[EPA-HQ-OAR-2019-0055-1168-A1, p.104]

Potential solutions to this would be heated systems, which adds significant additional cost and electrical system demand from an already high demand for engine accessory electrical power (i.e. grid heater). [EPA-HQ-OAR-2019-0055-1168-A1, p.104]

Without the advantage of a throttle-controlled induction system, the safety risk of a runaway engine increases with the addition of closed crankcase breather system. In certain failed conditions, the breather can deliver fuel in the form of diesel fuel or motor oil to the inlet of the turbocharger. This fuel delivery is uncontrolled, and can result in unintended acceleration events. The nature of diesel combustion cycles limit an engine manufacturer's ability to control these events. Since diesel engines are 'fuel-controlled' (as opposed to 'air-controlled' for gasoline engines), an uncontrolled fueling event will lead to rapid, runaway engine acceleration with no possibility for control systems to prevent such a condition. One typical example of such a condition might be engine oil overfilling. If enough oil is added to the crankcase, it can be drawn through the crankcase ventilation system, introduced into the combustion air, and lead to an uncontrolled safety-relevant condition of a runaway engine in the field, and/or hydro-locking of the engine as liquid oil is introduced into the cylinders. Such risks are not present on systems with closed crankcase ventilation systems. [EPA-HQ-OAR-2019-0055-1168-A1, p.105]

As shown in the above sections, the 200 hour coking testing above was performed with new oil for consistent test-to-test oil condition. Therefore, oil degradation in customer usage and extended oil changes lead to increased oxidation leading to increased tendency of coking. Testing and analysis will need to be performed to determine the closed breather impact to oil quality and coking behavior. [EPA-HQ-OAR-2019-0055-1168-A1, p.105]

Closed crankcase breather systems for HD engines would be technically challenging and unduly demanding for the transportation industry. As detailed in this section, current breather technology cannot achieve the level of oil separation and filtration required to maintain peak engine performance throughout the required emission compliance mileage. A closed crank case breather system is expected to cause compressor efficiency loss, reduced fuel economy, reduced engine brake performance, increased CO2 emissions, increased service routines including turbocharger replacement, and unscheduled truck downtime. EPA’s proposal would also increase customer dissatisfaction and cost increases for manufacturers and customers, in addition to the increased safety risk presented by the possibility of an oil-fueled engine runaway condition. [EPA-HQ-OAR-2019-0055-1168-A1, pp.105-106]

These challenges are present with all engines – but are especially problematic for heavy duty engines, which have much longer service lives in which these effects will accumulate, and are more likely to experience duty cycles which will exacerbate these challenges. [EPA-HQ-OAR-2019-0055-1168-A1, p.106]

Based on our investigation, future electrically-controlled breather technology can significantly improve discharged oil mass and is preferable to a closed breather system. When compared to today’s engine oil pressure driven units, the discharged emissions from the future open crank case electric breather technologies will be reduced, while continuing to maintain a high efficient charge air circuit. [EPA-HQ-OAR-2019-0055-1168-A1, p.106]

Daimler Truck thus recommends that EPA continue to allow open crankcase ventilation with robust diagnostics. We recommend that, at least for heavy-heavy duty engines, EPA set a performance-based requirement rather than prescribing what it believes it appropriate technology for manufactures to use. Manufactures are capable of designing highly effective open crank case ventilation systems and demonstrating their continued emission control through deterioration testing and in-use emissions validation. Additionally, manufacturers could be required to diagnose the degradation in filtration efficiency and or system disconnections and leaks. In fact, EPA’s proposal to adopt CARB’s latest OBD regulations would incorporate such diagnostics requirements in the federal regulations automatically starting in MY 2024 (see CA 13 CCR 1971.1 (g)(2)). [EPA-HQ-OAR-2019-0055-1168-A1, p.106]

Organization: *Truck and Engine Manufacturers Association (EMA)*

Open crankcase ventilation systems have evolved over the years, now incorporating very effective vapor separation systems. EPA is proposing to require manufacturers to close those crankcase systems. (§1036.115(a)). EMA believes this is an unnecessary development expense to add to this already tremendously challenging and costly regulation, and in fact, could be harmful to engine and aftertreatment durability, contrary to EPA’s goal to extend useful life requirements. [EPA-HQ-OAR-2019-0055-1203-A1, p. 118]

Closed crankcase ventilation ("CCV") systems can foul turbochargers, leading to degraded performance and turbo efficiency (increasing CO_2 emissions), as well as potential secondary damage including fouled intercoolers and, as boost is reduced, increased engine-out PM. Increased engine-out PM has multiple undesirable consequences, including increased CO_2 and other emissions levels due to increased regeneration frequencies, as well as accelerated aging of aftertreatment systems. EPA acknowledges many of these potential impacts in the preamble to the NPRM. [EPA-HQ-OAR-2019-0055-1203-A1, p. 118]

The types of failures that can be experienced with CCV systems are more severe than those that can occur with open crankcase systems. Consider a failure of the system that filters the blowby gas. With an open ventilation system, a failure results in a MIL and/or puddling oil on the ground, which both will lead to relatively rapid repair, with no significant impact to emissions before the repair is performed. If, however, the filtration system fails with a CCV system, it can damage the turbocharger, intercooler, and downstream components (if vented to the compressor inlet) or the aftertreatment system (if vented to the exhaust, as EPA suggests). This can turn one relatively simple failure into several more significant and expensive ones, that can directly impact emissions. In fact, the core issue at hand may not even be noticeable or detectable until more serious collateral damage has occurred. [EPA-HQ-OAR-2019-0055-1203-A1, p. 118 - 119]

Compressor coking can occur in diesel CCV applications. Coking is most likely to develop with high compressor outlet temperatures under high load. Although CCVs are common in lighter duty engines, including diesels, heavy-duty engines, especially heavy heavy-duty engines, are much more likely to experience these conditions than passenger cars. Experience with lighter-duty products does not amount to a sufficient feasibility demonstration for heavy-duty engines. The images below show examples of downstream damage to the turbocharger, and the resultant impact to engine boost: [EPA-HQ-OAR-2019-0055-1203-A1, p. 119]

There also is a slight safety risk for closed crankcase systems that cannot be adequately controlled. Creating a path from the crankcase to the engine intake risks introduction of a potentially uncontrolled fuel source, potentially leading to an engine runaway condition. [EPA-HQ-OAR-2019-0055-1203-A1, p. 120]

More generally, today's open crankcase systems have very little emissions impact. Some manufacturers have evaluated end of useful-life crankcase emissions and found no material impacts. Manufacturers are required to include crankcase emissions in their certification results (either by measuring separately and adding to tailpipe emissions, or plumbing the crankcase ventilation into the exhaust upstream of emissions measurement sampling). The fact that these emissions are measured and accounted for renders any theoretical environmental benefits moot, which means an obligation to close the crankcase introduces only risk, with potential emissions increases as already noted. There is, then, no sound basis for EMA [*sic*] to propose this design-based (not performance-based) requirement. [EPA-HQ-OAR-2019-0055-1203-A1, p. 120]

The arguments in the Preamble supporting the requirement for closed crankcase systems include concerns about CH_4 emissions from natural gas engines. EPA directly acknowledges that this is only a concern for natural gas engines, a small fraction of the HD market. Increasing the risks described earlier on all HD engines to reduce CH4 emissions from a small fraction of heavy-duty engines is not practical or reasonable. [EPA-HQ-OAR-2019-0055-1203-A1, p. 120]

EPA should continue the practice of setting performance-based standards, and this is no less true with respect to crankcase ventilation systems. The emissions contribution at issue is fully accounted for, including FUL impacts through the DF testing process. Robust diagnostics could also be implemented to ensure ventilation system efficiency in-use, consistent with the CARB OBD requirements effective with MY 2024. [EPA-HQ-OAR-2019-0055-1203-A1, p. 120]

In sum, EPA should eliminate the requirements to implement closed crankcase systems on HD diesel engines in the final rule. EPA is effectively proposing to implement a solution to a problem that does not exist, at the risk of creating new emissions-elevating problems. There are no effective emissions benefits, simply unwarranted risks, introduced by this proposed requirement. [EPA-HQ-OAR-2019-0055-1203-A1, p. 120]

Organization: *Moving Forward Network (MFN)*

Because of the progress made on tailpipe particulate matter emissions, PM emissions from open crankcases have become a dominant source of the remaining operating PM emissions from heavy-duty trucks. Manufacturers of emissions controls estimated that "crankcase PM can represent over 60 percent of the total PM footprint of a 2007 DPF equipped truck."147 EPA appropriately notes that a substantial share of the market has already adopted closed crankcases, indicating the technological feasibility of this new requirement. Suppliers support this requirement, noting that "closed crankcase technology is readily available."148 [EPA-HQ-OAR-2019-0055-1277-A1, p. 36]

147. MECA 2020, https://www.regulations.gov/comment/EPA-HQ-OAR-2019-0055-0365, p. 17.

148. MEMA 2020, https://www.regulations.gov/comment/EPA-HQ-OAR-2019-0055-0462, p. 6.

As a significant source of harmful particulate emissions, crankcase blowby gases pose an obvious health risk to all communities in which heavy-duty trucks operate. However, crankcase emissions can also provide an acute problem to the truck drivers most directly and repeatedly exposed to such emissions.149 It is no wonder that both industry and regulators support containing such harmful emissions.150 [EPA-HQ-OAR-2019-0055-1277-A1, p. 36]

149. EPA-HQ-OAR-2019-0055-0987

150. MECA 2020, MEMA 2020, and ODEQ 2020 (https://www.regulations.gov/comment/EPA-HQ-OAR-2019-0055-0464).

Given the wide availability of the technology and the broad harm that these emissions cause, we support EPA's proposal to require closed crankcases on all heavy-duty vehicles, for all fuels. [EPA-HQ-OAR-2019-0055-1277-A1, p. 36]

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

Finally, regardless of which option it ultimately selects, EPA should revise the proposed durability demonstration, strengthen the proposed anti-tampering and inducement provisions, reject exemptions for vocational vehicles, and finalize the proposed PM standard and closed crankcase requirements. [EPA-HQ-OAR-2019-0055-1302-A1, p.49]

Finally, Commenters support EPA's proposals to adopt a revised PM standard and to require closed crankcase ventilation systems for compression-ignition engines, both of which will achieve important reductions in PM pollution. 87 Fed. Reg. at 17,461–62, 17,466–67. The proposed PM standard of 5 mg/hp-hr is unquestionably feasible (even allowing for measurement variability), as manufacturers are already certifying engines well below this level. Id. at 17,462. Finalizing a PM standard at least that low will preserve these gains by preventing backsliding in the future. Similarly, given that a sizable portion of the market has already embraced closed crankcases, see id. at 17,466, EPA should require this eminently feasible technology on all compression-ignition engines. Crankcase emissions comprise a significant portion of the direct PM (and other pollutant) emissions from HDVs,245 exposing communities and vehicle operators to unnecessary health risks. EPA must carry out its duty to protect public health and welfare by requiring manufacturers to eliminate these harmful emissions by adopting this readily available and affordable technology. See DRIA at 139 (estimating initial technology cost of $37 per engine). [EPA-HQ-OAR-2019-0055-1302-A1, p.64]

EPA Summary and Response

Summary:

The California Air Resources Board (CARB, Moving Forward Network (MFN), Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association and Sierra Club all support closed crankcase ventilation systems for compression-ignition engines as originally proposed. MFN commented that such technology is readily available (referencing MECA and MEMA in their comment), and these commenters suggest that technology is affordable for manufacturers. They also commented that the proposed PM standard of 5 mg/hp-hr is feasible and would support public health by reducing harmful PM emissions and currently unaccounted for methane gas.

Daimler Truck North America LLC (DTNA) and Engine Manufacturers Association (EMA) oppose EPA requiring closed crankcases and support a performance-based standard with a method of compliance that allows leaving the crankcase open with additional robust diagnostics.

DTNA conducted various studies to assess impacts of coking of the oil mist in the compressor housing using various closed crankcase technologies. On a closed crankcase ventilation system with a new baseline turbocharger, DTNA tested a cycle that was typical of a line haul vehicle with results showing compressor efficiency loss up to 7-8% in as little as 200 hours. Compressor efficiency loss can lead to reduced engine and engine braking performance. Another test DTNA ran was on the same cycle but with electrically driven crankcase breather technology. Results improved but compressor efficiency loss was still seen up to 4% in 200 hours. For another test, DTNA added a water-cooled compressor stage to reduce internal surface temperatures at the compressor housing, which reduced coking but did not eliminate it. Finally, a new electric drive system that removes mass of the oil in the crankcase vapor before sending it to the turbocharger inlet was investigated by DTNA but an efficiency loss of 5-6% was still observed. DTNA concluded that crankcase breather technologies do not eliminate oil contamination. Fouling of the charge air cooler and engine induction system components were observed within hours of testing in DTNA's tests. DTNA voiced concern that the long term effects of oil contaminated air and combustion deposits are unknown.

Additionally, further studies by DTNA done over the FTP, RMC, fuel maps and engine brake performance with a clean turbocharger compared with a turbocharger that has undergone 200 hours with a closed crankcase, resulted in increased fuel consumption across all cycles. DTNA conducted an engine braking torque evaluation of the turbocharger resulting in 7-10% engine brake power loss, which DTNA stated poses a potential safety risk. Estimations on the impact to fuel economy for an electrical oil pressure system were provided by DTNA. Approximately 4% compressor efficiency loss and 0.7% engine fuel economy degradation were estimated by DTNA. DTNA stated that this could lead to increased particulate emissions, increased aftertreatment aging and lower boost. After 1600 hours, a visual inspection was done by DTNA on an active closed crankcase ventilation system and oil and sludge accumulation were observed. Other concerns DTNA noted based on these studies include the difficulty of achieving warranty and useful life compliance due to the addition of crankcase breather gases into the induction air upstream of the compressor housing of the turbocharger, secondary damage to engine components, increased service cost, increased service and customer downtime, OEM warranty costs, potential damage to the compressor wheel due to cold weather condensation and runaway engine risk.

DTNA commented that EPA did not consider the complexity of adding closed crankcase technologies for OEMs during the Phase 2 rulemaking or how compensating for increased GHG emissions caused by closed crankcases will lead to increased NOx.

DTNA recommends EPA include an allowance of leaving the crankcase open with additional deterioration determination and in-use emissions validation of the open crankcase ventilation system.

EMA lists similar concerns of closing the crankcase as DTNA, including coking, degraded performance and turbo efficiencies leading to increased CO_2 emissions, secondary damage to components, increased engine-out PM, and risk of engine runaway condition. EMA commented that due to closing the crankcase, severe damage can occur if the filtration system fails which would not be the case if the crankcase is left open. EMA stated that open crankcases have very little emissions impact and recommend allowing the crankcase to remain open with additional robust diagnostics, consistent with CARB OBD requirements.

Response:

After consideration of these comments, EPA is finalizing a standard that is technology neutral with respect to closing the crankcase or keeping it open, which manufacturers may comply with through either closing the crankcase or meeting certain measurement requirements and including accounting for emissions from an open crankcase in demonstrating compliance with the standards in 40 CFR 1036.104 (see Preamble section III Crankcase Emissions for further details).. EPA conducted a HD Chassis Crankcase test on an open crankcase that showed THC and CO crankcase emissions to be a significant fraction of total emissions from recent model year heavy-duty diesel trucks. As EPA explained in the proposed rule, closing the crankcase would prevent crankcase emissions from being vented directly to the atmosphere by routing the emissions back into the intake air system or routing them upstream of the aftertreatment in the exhaust.

After consideration of DTNA's and EMA's concerns, we are providing an additional method of compliance as an alternative option to a closed crankcase. While we understand the safety concerns that DTNA and EMA have raised, we do not believe that those concerns are unresolvable, nor do we believe that they should serve as the sole barrier to the introduction and use of closed crankcase systems. We believe that both closed and open crankcase systems are comparably effective at emissions reductions as both pathways require the manufacturer to meet the same emission standard. Using an open crankcase is an appropriate way for manufacturers to meet the overall purpose of the proposed closed crankcase requirements if they have durability and safety concerns with impacts of future closed crankcase technologies. Manufacturers that elect to follow this method of compliance may have an open crankcase, but those manufacturers must account for the contribution of crankcase emissions to the total tailpipe emissions from the engine at the time of certification and throughout the engine's useful life. Determination of deteriorated crankcase emissions and accounting for any crankcase emissions during manufacturer run in-use testing will be included in overall engine compliance (see Preamble Section III.B regarding crankcase emissions for further details).

3.10 Additional technology pathways to meet proposed criteria pollutant standards

Comments by Organizations

Organization: *Achates Power, Inc.*

Achates Power developed and demonstrated a 10.6L heavy duty opposed-piston (OP) diesel engine in a project supported by the California Air Resources Board, the South Coast Air Quality Management District, the San Joaquin Valley Air Pollution Control District and other organizations1. [EPA-HQ-OAR-2019-0055-1216-A1, p. 1]

1. https://achatespower.com/wp-content/uploads/2021/04/Achates-Power-HD-Demo-Technical-Review-1.pdf

Achates Power tested the heavy-duty OP engine against the established (Federal Test Procedure, Supplement Emissions Test) and new (low-load, idle) dynamometer test protocols. The engine demonstrated the ability to comply with the most stringent CARB (2027) NOx regulations. These tests used engine measurements with full-aged (450,000) aftertreatment system models from BASF. [EPA-HQ-OAR-2019-0055-1216-A1, p. 1]

Even at the fully aged point, the engine had a compliance margin of 30% or more against all cycles2. [EPA-HQ-OAR-2019-0055-1216-A1, p. 2]

> 2. Salvi, A., Redon, F., Youngren, D., and Fromm, L., "Low CO2, Ultralow NOx Heavy Duty Diesel Engine: Experimental Results," SAE Technical Paper 2022-01-0426, 2022, https://doi.org/10.4271/2022-01-0426. https://achatespower.com/wp-content/uploads/2021/06/Achates-Power-Ultralow-NOx-at-Low-Loads-and-Idle.pdf [[See table on p.2 of EPA-HQ-OAR-2019-0055-1216-A1]]

Achates Power continues to test and develop the engine. It is the process of testing tailpipe emissions with an aftertreatment system aged to 800,000 miles by Southwest Research Institute's Exhaust Composition Transient Operation Laboratory using the Diesel Accelerate Aging Cycles3 to confirm emissions compliance with a fully aged aftertreatment system. These results will be reported later this year. [EPA-HQ-OAR-2019-0055-1216-A1, p. 2]

> 3. https://www.swri.org/press-release/ecto-lab-epa-cleaner-trucks-initiative-emissions

One of the engines was installed in a Peterbilt 579 truck and operated in service by a major retailer. In-use tailpipe emissions were measured by researchers at the University of California Riverside (UCR) using a Portable Emissions Measurement System. While the demonstration is continuing, an initial set of tailpipe measurements met the most stringent in-use NOx limits from CARB and proposed by EPA (2031) with a compliance margin of 52% or greater to the most stringent proposed EPA limit4. Kent Johnson, the Principal Investigator for UCR said "The Achates Power 10.6L heavy duty opposed-piston engine demonstrated NOx emissions control far better than other diesel engines we have tested. This first round of measurements…showed between a 99% and 50% margin to the most stringent EPA 2031+ in-use NOx proposed Regulations, which is outstanding." [EPA-HQ-OAR-2019-0055-1216-A1, p. 2]

> 4. https://achatespower.com/wp-content/uploads/2022/04/Achates-Power-Heavy-Duty-Diesel-In-Use-Testing-Results.pdf

Importantly, all these tailpipe measurements only included conventional underfloor aftertreatment systems. The latest results use a one-box DOC/DPF/SCR/ASC system currently used by one of the Class 8 tractor market leaders. No additional emissions control technology is utilized or is required for the opposed piston engine to meet ultralow NOx levels over an extended full useful life. [EPA-HQ-OAR-2019-0055-1216-A1, p. 2]

The heavy-duty diesel OP engine also demonstrated the ability to meet the fully phased (2027) EPA Green House Gas II regulations, with a margin of 4% or more5. [EPA-HQ-OAR-2019-0055-1216-A1, p. 3]

> 5. https://achatespower.com/wp-content/uploads/2020/12/Achates-Power-Opposed-Piston-Heavy-Duty-Diesel-Engine-Demonstration-Performance-Results-Ultralow-NOx-without-additional-hardware.pdf [[See table on p.3 of EPA-HQ-OAR-0055-1216-A1]]

Moreover, the fleet operator measured a 10%+ fuel economy advantage of the Peterbilt truck with the heavy duty OP engine vs. a model year 2021 reference truck operating the same routes with similar loads6. [EPA-HQ-OAR-2019-0055-1216-A1, p. 3]

> 6. https://achatespower.com/wp-content/uploads/2022/04/Achates-Power-Heavy-Duty-Diesel-In-Use-Testing-Results.pdf

We commissioned FEV, a leading independent engineering firm and expert in this field, to prepare an independent, detailed cost analysis of a commercial vehicle OP engine vs. a conventional engine of the same power and torque. FEV’s conclusion is that with everything else being equal – volume, sourcing strategy, machining rates, overhead rates – that the OP engine costs 7% less than the conventional engine considering the base engine only7. And since – as discussed above – the aftertreatment system does not to grow in cost or complexity – the ultralow emissions OP engine will cost less than current conventional engines. [EPA-HQ-OAR-2019-0055-1216-A1, p. 3]

> 7. https://achatespower.com/wp-content/uploads/2020/03/Achates-Power-Cost-Study-White-Paper_March-2020.pdf

Achates Power is confident a heavy-duty diesel opposed piston engine can be in volume production by 20298, following a normal 6-year industrialization cycle. One path to market is with established engine companies/OEMs as they manufacture, distribute, and service engines under license from us, as we do on other projects, like the Advanced Combat Engine for the U.S. Army developed by Cummins and Achates Power. Another path to market is for Achates Power to work with a series of established partners to manufacture, distribution, and service the engine. There is ample capacity and capital at all levels. [EPA-HQ-OAR-2019-0055-1216-A1, p. 3]

> 8. https://achatespower.com/wp-content/uploads/2022/05/Achates-Power-Opposed-Piston-Engine-Commercialization-Pathway.pdf

Beyond diesel fuel, the opposed-piston engine can operate cleanly and efficiently on renewable diesel, and Achates Power is developing hydrogen combustion capability on the engine platform. A common engine platform can operate in a near-zero manner with diesel and renewable diesel in the short term; and with renewable and zero carbon fuels in the long-term. [EPA-HQ-OAR-2019-0055-1216-A1, pp. 3 - 4]

Organization: *Alliance for Vehicle Efficiency (AVE)*

AVE asks EPA to consider the proven capabilities of the cost-effective technologies that exist today to meet EPA's proposed Option 1 and the most stringent standards. [EPA-HQ-OAR-2019-0055-1280-A1, p. 3]

More than two-years ago, EPA began extensive research to analyze the performance of available technologies to meet more stringent emission standards. Since then, ongoing, and recently published data confirms that a 0.02 g/bhp-hr NOx standard can be met by manufacturers. Examples of available technologies include: Advanced Engine Architecture: The10.6L heavy-duty opposed piston diesel engine has been tested in a demonstration project supported by the California Air Resources Board, the South Coast Air Quality Management District, the San Joaquin Valley Air Pollution Control District, and other organizations.2 [EPA-HQ-OAR-2019-0055-1280-A1, p. 3]

2. https://achatespower.com/wp-content/uploads/2021/04/Achates-Power-HD-Demo-Technical-Review-1.pdf

More than two-years ago, EPA began extensive research to analyze the performance of available technologies to meet more stringent emission standards. Since then, ongoing, and recently published data confirms that a 0.02 g/bhp-hr NOx standard can be met by manufacturers. Examples of available technologies include: Advanced Aftertreatment: Since 2010, emission control systems have advanced greatly. Today's applications are significantly smaller, lighter, and less expensive. By 2027, further improvements in aftertreatment technologies, engine calibration and thermal management are expected to help meet the 0.02 g/bhp-hr NOx standard over the FTP and also meet the NOx standards for the Low-Load Cycle.3 [EPA-HQ-OAR-2019-0055-1280-A1, p. 3]

3. MECA Technology Feasibility for Heavy-Duty Diesel Trucks in Achieving 90% Lower NOx Standards in 2027

More than two-years ago, EPA began extensive research to analyze the performance of available technologies to meet more stringent emission standards. Since then, ongoing, and recently published data confirms that a 0.02 g/bhp-hr NOx standard can be met by manufacturers. Examples of available technologies include: Active thermal management: To assist with cold-start emissions, active thermal management technologies such as fuel burner and electric heaters have been developed and can be deployed to further help meet the 2027 standards.[EPA-HQ-OAR-2019-0055-1280-A1, p. 3]

More than two-years ago, EPA began extensive research to analyze the performance of available technologies to meet more stringent emission standards. Since then, ongoing, and recently published data confirms that a 0.02 g/bhp-hr NOx standard can be met by manufacturers. Examples of available technologies include: Cylinder Deactivation: Data shows cylinder deactivation is a technology able to reduce fuel consumption and increase exhaust temperature to facilitate improved NOx conversion. Combined with close-coupled selective catalytic reduction, this will further help with low-NOx compliance.4 [EPA-HQ-OAR-2019-0055-1280-A1, p. 3]

4. Matheaus, A., Neely, G., Sharp, C., Hopkins, J. et al., "Fast Diesel Aftertreatment Heat-up Using CDA and an Electrical Heater," SAE Technical Paper 2021-01-0211, 2021, doi:10.4271/2021-01-0211.

More than two-years ago, EPA began extensive research to analyze the performance of available technologies to meet more stringent emission standards. Since then, ongoing, and recently published data confirms that a 0.02 g/bhp-hr NOx standard can be met by manufacturers. Examples of available technologies include: Particulate Filters: Existing diesel applications which use diesel particulate filters (DPFs) provide sufficient margin for meeting the lowered PM limit. [EPA-HQ-OAR-2019-0055-1280-A1, p .3]

Numerous pathways exist to meet stringent standards: Supporting all pathways gives the U.S. an opportunity to reach its environmental goals faster while supporting the automotive industry. The chart below outlines available technologies to greatly reduce NOx and PM emissions from HD trucks. [EPA-HQ-OAR-2019-0055-1280-A1, p. 4]

Organization: *Allison Transmission, Inc.*

EPA should keep in mind several additional perspectives when determining the final standards to apply to MY 2027 and later HDVs:

- EPA should adopt a regulatory pathway that will allow for the use of emerging low-carbon fuels, such as hydrogen. As EPA recognizes, there are certain uses where it is currently difficult to fully electrify all product offerings. Renewable liquid fuels may be effectively required for certain vehicles for the foreseeable future. Compliance flexibility will therefore be necessary to allow manufacturers to both meet the new NOx standards as well as the need to make longer-term investments in low-carbon fuels. Apart from hydrogen, other low-carbon intensity fuels such as natural gas and propane may be used as well as higher octane gasoline in certain HDV commercial applications. While EPA has considered these fuels to some degree in its supporting analysis, EPA should not foreclose their further development and potential use by adopting standards that would effectively restrict the ability of the market to pursue different fueling options for the medium-duty and heavy-duty sectors. [EPA-HQ-OAR-2019-0055-1231-A1 pp.9-10]

Organization: *California Association of Sanitation Agencies (CASA)*

Of utmost concern is that an electrification-only approach will take significantly longer to implement than an approach that allows NZEVs. Also, renewable non-fossil biogas produced at publicly owned treatment works (POTWs) will need a long-term home in the national effort to decarbonize the economy, which is not addressed in this proposed rulemaking. [EPA-HQ-OAR-2019-0055-1301-A1, pp.1-2]

Essential public services must operate at all times to protect public health and the environment. As essential public service providers and fellow dedicated environmental stewards, CASA members provide reliable wastewater treatment to protect public health and the environment. CASA members are public, local agencies responsible for providing wastewater conveyance and treatment to over 90 percent of the sewered population across California. While our primary objective is to reliably convey and treat wastewater and residual biosolids to state and regional standards, CASA's members also support the state and nation's clean air goals, which rely heavily on clean vehicles. To support these goals, many of our members produce renewable wastewater biogas as an inherent component of wastewater treatment, and via co-digestion, that can be used as a low carbon transportation fuel (reducing GHGs, NOx, and PM relative to diesel options), which can also support specialty vehicles that must be deployed to meet increasingly frequent mutual aid and critical response demands due to natural disasters (e.g., wildfires, extreme weather events, etc.) and other types of emergencies and routine functions.[EPA-HQ-OAR-2019-0055-1301-A1, p.2]

CASA members operate medium-and heavy-duty vocational trucks that perform maintenance and repair operations. On any given day they are required to travel long distances (to maintain over 110,000 miles of public sewers and facilities), overcome rough terrain, and provide extended operation of auxiliary equipment via power-take off (PTO) devices at project sites. It is critical to consider the high level of energy and hours of operation required while at worksites and the need for certain trucks to be outfitted with equipment driven by PTO devices. Vehicles are often called upon to tow equipment such as generators or pumps, perform welding operations, power onboard pumps, vacuums, welding machines and air compressors, and other tasks that require long duty cycles. We also utilize heavy duty vehicles to transport biosolids to agricultural fields for beneficial recycling via land application. At this point in time, there are no ZEV options available that provide the level of service required to maintain reliable service to protect public health and the environment, as well as remain in compliance with existing State Water Board and Regional Water Board regulations and permit requirements, while providing critical and timely response services. CASA strongly supports EPA's approach, to balance ZEV and NZEV development to ensure we meet existing air quality standards, while also providing vehicle options that can support critical response needs of our communities and our core functions. [EPA-HQ-OAR-2019-0055-1301-A1, p.2]

NZEVs are not only critical for supporting community resilience, but also reducing NOx emissions to remain in compliance with the Clean Air Act.
Our members have already begun purchasing ultra-low emission natural gas powered on-road heavyduty vehicles (supported by Cummins-Westport engines) to comply with restrictive local air quality regulations (e.g., SCAQMD Rule 1196). These vehicles are immediately available and emit 90 percent fewer NOx emissions relative to current standards for heavy-duty vehicles – comparable to emissions from an equivalent all-electric heavy-duty vehicle when the emissions associated with the electricity production are taken into account. Under CAA section 202(a)(3)(A), standards for emissions of NOx, PM, HC, and CO emissions from heavy-duty vehicles and engines are to ''reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology.'' When fueled by renewable biogas, the Cummins-Westport ISX12N engine can provide even greater GHG emissions reductions than ZEVs by also reducing the emissions from renewable waste sources (i.e., fugitive methane emissions from landfills). Some of our members have recently invested significant capital into co-digestion and biogas conditioning infrastructure, as well as compressed natural gas (CNG)

vehicles – all in support of California mandates for achieving GHG emission reductions by 2030 and carbon neutrality, as well as complying with local regulations. Additionally, specialty and critical response vehicles must be able to travel long ranges that include the individual service territory as well as assisting with regional and remote disaster efforts and other types of emergencies. CASA strongly supports including the use of NZEVs fueled by non-fossil, renewable biogas, especially where ZEVs are not feasible or available, allowing for immediate emissions reductions while meeting critical demands reliably across large regions. [EPA-HQ-OAR-2019-0055-1301-A1, pp.2-3]

Wastewater biogas is a non-fossil, renewable, low carbon transportation fuel that should continue to be used to support community resilience and critical response – not wasted!
Regulations under California's Senate Bill 1383 began implementation in 2022 (requiring diversion of organic waste from landfills to achieve methane reduction) and significantly more renewable biogas will be produced at POTWs through the co-digestion of wastewater sludge with methane producing organic waste diverted from landfills. Co-digestion is a proven approach of economically producing renewable energy/fuel, as well as a soil amendment (biosolids) to improve California's soil ecosystem. In fact, more than 90 percent of California's wastewater flow is treated through anaerobic digestion, generating biogas and will continue to do so. As quantified in the SWRCB's Co-Digestion Capacity Analysis (released by the Governor's office in August 2020), POTWs can utilize available existing infrastructure in the form of anaerobic digestion to receive and co-digest all of the divertible food waste across the state thereby removing a major source of fugitive methane from landfills (which account for about 20 percent of the state's methane inventory). Co-digestion also further advances two initiatives undertaken at USEPA - the joint challenge with the Department of Energy to expand renewable resources at POTWs and the "Winning with Food Waste" initiative to divert food waste away from landfills. Both initiatives favor codigestion of food waste at wastewater treatment plants. Utilizing co-digestion, California's POTWs can significantly increase biogas production to provide, among other benefits, a source of low carbon fuel, on- and/or off-site renewable energy production, and biosolids which help mitigate climate change when land applied. [EPA-HQ-OAR-2019-0055-1301-A1, p.3]

Accordingly, CASA strongly supports:
-EPA's approach, to balance ZEV and NZEV development to ensure we meet existing air quality standards, while also providing vehicle options that can support critical response needs of our communities.
-Continued beneficial use of wastewater-derived biogas for the production of a low carbon fuel.
-The use of NZEVs fueled by non-fossil, renewable wastewater biogas, especially where ZEVs are not feasible or available, allowing for immediate emissions reductions to comply with federal standards for ozone while meeting critical demands reliably across large regions. [EPA-HQ-OAR-2019-0055-1301-A1, p.3]

Organization: *CALSTART*

Manufacturers should be given flexibility in meeting NOx emission targets through accelerated deployments of battery and fuel cell technologies. [EPA-HQ-OAR-2019-0055-1313-A1, p.26]

Organization: *Clean Energy (CE)*

Near-zero engines can be powered by RNG thereby achieving both significant NOx reductions and net-negative carbon emissions. What truly sets near-zero trucks apart from other alternatives is they have similar power, range, and refueling times as their diesel counterparts. Thus, further technological development is not needed for these engines to perform the duty-cycles required by America's trucking and bus fleets as evidenced by Amazon, United Parcel Service (UPS), Waste Management and LA Metro's large-scale deployments. [EPA-HQ-OAR-2019-0055-1350-A1, pp.1-2]

We urge EPA to amend the greenhouse gas regulations to incorporate the benefits of renewable natural gas as part of the medium and heavy-duty engine and vehicle certification regulations. Under California's Low Carbon Fuel Standard, RNG is the lowest carbon intensity fuel available based on the weighted average. EPA should reinstate the 0.15 factor for calculating GHG emissions for natural gas vehicles to reflect RNGs increasing utilization. RNG is now the dominant fuel used in on-road natural gas vehicles throughout the country. In 2021, RNG made up 64 percent (up from 53 percent in 2020) of the fuel used in natural gas vehicles in the United States.12 We see no reason why the GHG reduction benefits of NGVs should be excluded given the surge in RNG production and use and the GHG benefits of electric trucks recently being questioned. An ATRI study released in May of 2022 '*found that while electric trucks have no direct tailpipe emissions, CO2 production associated with vehicle, battery and electricity production would only result in a 30 percent decrease in CO2 emissions when compared to a standard diesel truck.*'13 According to ATRI, '*the marginal environmental benefits of electric trucks are due, in large part, to lithium-ion battery production – which generates more than six times the carbon of diesel truck production.*' [EPA-HQ-OAR-2019-0055-1350-A1, p.4]

12 https://ngvamerica.org/wp-content/uploads/2022/05/NGV-RNG-Decarbonize-2022-5.2.22.pdf

13 https://truckingresearch.org/2022/05/03/understanding-the-co2-impacts-of-zero-emission-trucks/

EPA's regulatory programs should be designed to accelerate the production of trucks and engines that reduce carbon emissions – they should not be designed to favor or support one technology over others. EPA has indicated that electric vehicles are a game changer and therefore warrant treatment that other technologies do not. But near-zero engines that are capable of achieving carbon net-negative emissions right now are also a game changer, and they too should be encouraged. [EPA-HQ-OAR-2019-0055-1350-A1, pp.5]

Organization: *Clean Energy Ventures et al.*

We also believe that the Agency needs to embrace an innovation-driven, data-driven, 'all-of-the-above' approach to achieve rapid decarbonization this decade. We are very concerned that EPA is proposing to provide technology-specific incentives to only two of the many technologies that are being developed to decarbonize the nation's trucks and buses, rather than continuing the fuel-neutral, technology-neutral, performance-based approach that has proven to be so successful for more than five decades of Clean Air Act mobile source regulations. [EPA-HQ-OAR-2019-0055-2339-A2, p.2]

Instead of providing incentives that are limited to specific technologies, we urge EPA to establish fuel-neutral, technology-neutral, performance-based standards and incentives that will allow all effective technologies to be recognized for their contributions and that does not stifle innovation by companies that are developing non-BEV or non-FCEV technology solutions or biofuels-based decarbonization strategies. [EPA-HQ-OAR-2019-0055-2339-A2, p.2]

Organization: *Clean Fuels Alliance America (Clean Fuels)*

The biodiesel and renewable diesel industry is on a path to sustainably double the market to 6 billion gallons annually by 2030, eliminating at least 35 million metric tons of CO2 equivalent greenhouse gas emissions annually. With advancements in feedstock, use will reach 15 billion gallons by 2050 or sooner. These fuels are among the cleanest and lowest-carbon fuels available today to help tackle the climate challenge. Biodiesel and renewable diesel are helping companies drive decarbonization in their supply chains and should continue to be viewed as a primary tool of the Administration to reduce greenhouse gas (GHG) emissions now and to meet President Biden's near- and long-term climate goals, particularly in hard to decarbonize sectors. 2 [EPA-HQ-OAR-2019-0055-1248-A1, p.1]

> 2 Executive Office of the President. Executive Order 14008: Tackling the Climate Crisis at Home and Abroad, 86 FR 7619 (February 1, 2021), available at https://www.federalregister.gov/d/2021-02177

We would like to first thank you for recognizing the progress in fuel quality made by the biomass-based diesel industry and its producers. With advancements in production technology, a greater understanding of fuel performance issues, and the BQ-9000 quality management system, we believe that the industry is now a leading example of how biofuels can offer performance benefits beyond just the reduction in GHG emissions. [EPA-HQ-OAR-2019-0055-1248-A1, pp.1-2]

In addition to reducing greenhouse gas emissions, advanced biofuels also reduce particulate matter emissions. This benefits all populations including minority, low-income, and indigenous populations. For every 100 million gallons of U.S. biodiesel used today in place of petroleum, particulate matter is cut by approximately 252 tons. According to EPA and the California Air Resources Board, biodiesel and renewable diesel significantly reduce criteria pollutants from diesel transportation and heating oil. [EPA-HQ-OAR-2019-0055-1248-A1, p.4]

Last year, the National Biodiesel Board, now Clean Fuels Alliance America, launched a report prepared by Trinity Consultants that quantifies the health benefits and corresponding economic savings from converting petroleum-based diesel to B100.10 The report estimated that displacing diesel with biodiesel in communities with high diesel emissions rates could result in significantly improved health outcomes for the local population. In the 13 sites analyzed throughout the country, Trinity estimated that a switch from diesel to 100 percent biodiesel would avoid or lessen 240,000 asthma attacks, recover 46,000 lost workdays, and avert 1,100 cases of cancer –

among other key benefits – generating a societal value of $3 billion dollars a year.11 [EPA-HQ-OAR-2019-0055-1248-A1, p.4]

10 Trinity Consultants. (March 2021). Assessment of Health Benefits from Using Biodiesel as Residential Heating Oil. https://www.biodiesel.org/news-resources/health-benefits-study.

11 Id.

In the transportation sector, benefits included a potential 44 percent reduction in cancer risk when heavy-duty trucks such as semis use B100, resulting in 203,000 fewer or lessened asthma attacks for the communities studied. When biodiesel is used for home heating oil, the study found an 86 percent reduced cancer risk and 17,000 fewer lung problems for the communities studied. [EPA-HQ-OAR-2019-0055-1248-A1, p.4]

The American Lung Association has found that major trucking corridors, warehouse distribution centers and other diesel hot spots can inflict serious harms to human health and often highlight disparities in the impacts of transportation pollution.12 Biodiesel can make a difference now in reducing harmful tailpipe emissions that have this adverse impact. Biodiesel is one the simplest sustainability solutions available right now. Continuing to use cleaner, better fuels today can lower health impacts and costs for cities and transportation corridors into the future. [EPA-HQ-OAR-2019-0055-1248-A1, p.5]

12 American Lung Association. (2020). The Road to Clean Air.

The immediacy of these potential health benefits is even more critical when one considers the years, possibly decades, it will take for states to pursue electrification and other deep decarbonization strategies. Further, the economic impact of utilizing biomass-based diesel in today's diesel technologies is more achievable with current fleet financial constraints and limited access to other immature technologies. [EPA-HQ-OAR-2019-0055-1248-A1, p.5]

Original Equipment Manufacturers (OEM)
In addition to recognition from the EPA and other regulatory agencies, Clean Fuels is also discussing higher blend approvals and support from several engine manufacturers. We realize that not every Original Equipment Manufacturer (OEM) supports biodiesel at higher levels, but those that do support higher blends of biodiesel recognize its ability to support their fleet customers and users and their commitments towards climate change and immediate decarbonization when compared to longer term solutions. [EPA-HQ-OAR-2019-0055-1248-A1, p.2]

For example, New Holland recognizes the importance of biodiesel as an alternative source of energy and the opportunities that it brings to their customers. They were the first agricultural equipment brand to fully embrace the potential of biodiesel and support their customer's fuel choices. As a result, New Holland provides products with the flexibility to confidently run on everything from petroleum diesel to 100% biodiesel.5 [EPA-HQ-OAR-2019-0055-1248-A1, p.2]

5 https://www.newholland.com/Pages/splash.html

These new proposed Heavy-Duty Engine and Vehicle Standards are an important part of our country's continued push for cleaner air and a cleaner environment. The new Ultra-Low Emissions Diesel Engines (ULEDEs) produced under these regulations will be substantially cleaner than New Technology Diesel Engines (NTDE) in the market today and will approach near-zero regulated emissions of PM, NOx, unburned hydrocarbons, and carbon monoxide. [EPA-HQ-OAR-2019-0055-1248-A1, p.3]

Utilization of increasing volumes of ultra-low carbon liquid fuels like biodiesel and renewable diesel will provide the one important environmental aspect that these new regulations do not directly address—reduction of GHG emissions from the existing fuel supply. [EPA-HQ-OAR-2019-0055-1248-A1, p.3]

Biodiesel is a solution that reduces carbon now. Specifically, when compared to electric vehicles (EVs), utilizing biomass-based diesel now will allow the United States to meet our carbon reduction goals earlier than if we were to rely on EVs alone. It has been shown that the immediate investment in a mature, currently commercialized biomass-based diesel fuel yields higher annual greenhouse gas emissions reductions than waiting for a technology that is still considered immature, such as EVs.7 The benefits of using and increasing the use of biomass-based diesel now will not only provide immediate greenhouse gas reductions, but also will have a positive impact on health in disadvantaged communities. [EPA-HQ-OAR-2019-0055-1248-A1, p.3]

7 Frank, Jenny & Brown, Tristan & Haverly, Martin & Slade, Dave & Malmsheimer, Robert. (2020). Quantifying the comparative value of carbon abatement scenarios over different investment timing scenarios.

When considering options to help reduce greenhouse gas emissions from vehicles and equipment, there are two essential elements to consider: the amount of the reduction and when it happens. This is because carbon emissions are persistent and accumulate. The resulting increased levels of GHGs in the atmosphere contribute to global warming now and for decades to come. A reduction in GHG emissions now can avoid decades of associated heating, thus having significantly more value than carbon reductions made in the future. The time value of carbon is key, and the next decade is critical.8 [EPA-HQ-OAR-2019-0055-1248-A1, pp.3-4]

8 National Biodiesel Board. Biodiesel.org. (2021). Cutting Carbon: Comparing Biomass-Based Diesel & Electrification for Commercial Fleet Use.

The immediate reductions achieved by biodiesel and renewable diesel are crucial to reach our near- and long-term carbon reduction goals. The importance of increasing biomass-based diesel and reducing carbon cannot be understated as the Intergovernmental Panel on Climate Change (IPCC) clearly reaffirmed in their Sixth Assessment Report: Carbon reductions today are more important than carbon reductions in the future.9 [EPA-HQ-OAR-2019-0055-1248-A1, p.4]

9 Intergovernmental Panel on Climate Change. (2021) Climate Change 2021: The Physical Science Basis. Contribution of Working Group I to the Sixth Assessment Report of the Intergovernmental Panel on Climate Change.

The most recent update to the Greenhouse Gases, Regulated Emissions, and Energy Use in Technologies (GREET) model published in October of 2021 estimates that the *average* gallon of biodiesel and renewable diesel reduces emissions by approximately 74%, considering the U.S. biodiesel feedstock mix published by EIA. Additionally, since 2010, use of these fuels has avoided 143.8 million metric tons of carbon. [EPA-HQ-OAR-2019-0055-1248-A1, p.4]

In addition to reducing greenhouse gas emissions, advanced biofuels also reduce particulate matter emissions. This benefits all populations including minority, low-income, and indigenous populations. For every 100 million gallons of U.S. biodiesel used today in place of petroleum, particulate matter is cut by approximately 252 tons. According to EPA and the California Air Resources Board, biodiesel and renewable diesel significantly reduce criteria pollutants from diesel transportation and heating oil. [EPA-HQ-OAR-2019-0055-1248-A1, p.4]

Last year, the National Biodiesel Board, now Clean Fuels Alliance America, launched a report prepared by Trinity Consultants that quantifies the health benefits and corresponding economic savings from converting petroleum-based diesel to B100.10 The report estimated that displacing diesel with biodiesel in communities with high diesel emissions rates could result in significantly improved health outcomes for the local population. In the 13 sites analyzed throughout the country, Trinity estimated that a switch from diesel to 100 percent biodiesel would avoid or lessen 240,000 asthma attacks, recover 46,000 lost workdays, and avert 1,100 cases of cancer – among other key benefits – generating a societal value of $3 billion dollars a year.11 [EPA-HQ-OAR-2019-0055-1248-A1, p.4]

10 Trinity Consultants. (March 2021). Assessment of Health Benefits from Using Biodiesel as Residential Heating Oil. https://www.biodiesel.org/news-resources/health-benefits-study.

11 Id.

In the transportation sector, benefits included a potential 44 percent reduction in cancer risk when heavy-duty trucks such as semis use B100, resulting in 203,000 fewer or lessened asthma attacks for the communities studied. When biodiesel is used for home heating oil, the study found an 86 percent reduced cancer risk and 17,000 fewer lung problems for the communities studied. [EPA-HQ-OAR-2019-0055-1248-A1, p.4]

The American Lung Association has found that major trucking corridors, warehouse distribution centers and other diesel hot spots can inflict serious harms to human health and often highlight disparities in the impacts of transportation pollution.12 Biodiesel can make a difference now in reducing harmful tailpipe emissions that have this adverse impact. Biodiesel is one the simplest sustainability solutions available right now. Continuing to use cleaner, better fuels today can lower health impacts and costs for cities and transportation corridors into the future.[EPA-HQ-OAR-2019-0055-1248-A1, p.5]

12 American Lung Association. (2020). The Road to Clean Air.

The immediacy of these potential health benefits is even more critical when one considers the years, possibly decades, it will take for states to pursue electrification and other deep decarbonization strategies. Further, the economic impact of utilizing biomass-based diesel in today's diesel technologies is more achievable with current fleet financial constraints and limited access to other immature technologies. [EPA-HQ-OAR-2019-0055-1248-A1, p.5]

Organization: *CleanAirNow (CANKC)*

CANKC does NOT support the false solutions that come from non-renewable and heavy polluting sources like natural gas and biomass in the Heavy Duty Truck Rule and other emission standards. Our communities do not need the false promises of 'cleaner trucks,' we need zero emissions. [EPA-HQ-OAR-2019-0055-1239-A1, p.2]

CANKC supports the following recommendations from the Moving Forward Network:

- The Heavy Duty Truck Rule **must not include false solutions like natural gas**, which only further environmental and public health harms for EJ communities [EPA-HQ-OAR-2019-0055-1239-A1, p.2]

Organization: *ClearFlame Engine Technologies (ClearFlame), Remora, and SixWheel*

As you update the Agency's Phase 2 GHG standards for certain heavy-duty vehicles and as you develop EPA's expected proposal for new Phase 3 GHG standards that will apply to all heavy-duty engines and vehicles, we strongly urge you to adapt EPA's successful fuel-neutral, technology-neutral "systems approach" to reducing greenhouse gas (GHG) emissions from all of the nation's heavy-duty engines and vehicles. [EPA-HQ-OAR-2019-0055-1261-A1, p. 3]

An innovation-driven, all-of-the-above approach will lead to more rapid carbon mitigation than pre-selecting particular technologies. The current Proposal includes provisions that reward BEVs and FCEVs that are not available to other technologies, including but not limited to ours. This approach will delay –and ultimately reduce – the overall GHG benefits of the program, an unintended consequence with real-world climate impacts. [EPA-HQ-OAR-2019-0055-1261-A1, p. 3]

We strongly urge EPA to revise these provisions in its final rule to enable all technologies to qualify under these provisions, thereby sending a market signal that encourages all innovations that may achieve the same – or even greater – emissions benefits when upstream and other indirect emissions are considered, at greater speed, scale, and/or cost-effectiveness. [EPA-HQ-OAR-2019-0055-1261-A1, p. 3]

We strongly urge EPA to revise its definition of "Fuel" and other provisions that will be necessary to ensure that a ClearFlame engine can be certified and operate using any high-blend ethanol or biofuel, including E85 and E98. [EPA-HQ-OAR-2019-0055-1261-A1, p. 3]

The Proposal lists ethanol only as a blend option for gasoline. It is critical that EPA sends the right market signal here – that an ethanol-fueled compression-ignition engine can receive the appropriate EPA certification and any incentives that it qualifies for, by virtue of its emissions performance. [EPA-HQ-OAR-2019-0055-1261-A1, p. 3]

EPA Should Maintain its Historic Fuel-Neutral, Technology-Agnostic Performance-Based Approach in the Proposal's Final Rule and Next Year's Expected Phase 3 GHG Proposal.

For the reasons outlined above, a fuel-neutral, technology-neutral, "systems approach" is still critically necessary – both for this Proposal and for next year's expected proposal to reduce GHGs from all heavy-duty engines and vehicles. [EPA-HQ-OAR-2019-0055-1261-A1, p. 4]

Here are just a few reasons why: [EPA-HQ-OAR-2019-0055-1261-A1, p. 4]

First, diesel engines will continue to emit a significant portion of the transportation sector's NOx and GHG emissions inventories in 2050. Even in states that have adopted California's Advanced Clean Truck Rule, up to 60% of the truck tractor sales market will still be diesel in 2035.5 These engines are likely to remain on the roads for decades thereafter. In other words, diesel engines that are sold in 2035 will still be in use deep into mid-century. [EPA-HQ-OAR-2019-0055-1261-A1, p. 4]

> 5. California's Advanced Clean Truck Rule, which has been adopted by New York and other states, requires 55% of Class 2b-3 truck sales, 75% of Class 4 – 8 straight truck sales, and 40% of truck tractor sales to be zero-emission by 2035.

Second, EPA's Heavy-Duty Highway Engine and Vehicle Rule of 20016 (the "2001 Diesel Rule") showed that a fuel-neutral, technology-neutral, performance-based "systems approach" reduced emissions and related health harms at scale, faster and most cost-effectively that any approach that picked specific technology winners. Indeed, when the 2001 Diesel Rule was finalized, it was widely anticipated that NOx adsorbers would be the "technology winner" that would enable diesel engines to meet the NOx standard in that rule. A competing technology, Selective Catalytic Reduction (SCR), was considered impractical and unlikely to succeed, due to the logistical hurdles posed by the need for SCR-equipped engines to use urea to operate cleanly. By 2010, SCR had become the industry standard, and NOx adsorbers never reached widespread use in the heavy-duty truck market. The lesson from that rule is clear: despite pressure to anoint NOx adsorbers as the technology "winner," the final Rule was drafted in a fuel-neutral, technology-neutral, performance-based manner, which enabled the market to innovate and then shift quickly to a technology solution that enabled implementation at scale, in the most cost-effective and fastest way possible, within a decade. [EPA-HQ-OAR-2019-0055-1261-A1, p. 5]

> 6. EPA, Heavy-Duty Engine and Vehicle Standards and Highway Diesel Fuel Sulfur Control Requirements, Regulatory Announcement, accessed on May 15, 2002 at https://nepis.epa.gov/Exe/ZyPDF.cgi/P1001CXZ.PDF?Dockey=P1001CXZ.PDF.

We encourage the EPA to establish objective and transparent emissions-based criteria that qualify a technology as zero or near-zero emissions. Any and all technologies that demonstrate proper emissions reductions should be able to qualify. It is essential for market fairness and to send the appropriate market signal to technology developers. [EPA-HQ-OAR-2019-0055-1329-A2, p. 4]

In sum, we strongly urge EPA to adopt a final NOx and GHG program that is open to all demonstrated, cost-effective emissions-reduction solutions. Doing so is critical to achieve near-term and long-term goals. [EPA-HQ-OAR-2019-0055-1329-A2, p. 4]

It is important to avoid unnecessarily limiting innovation at this stage of decarbonization. Encouraging and rewarding innovation will be necessary to reduce emissions in hard-to-decarbonize sectors like heavy-duty transportation. Such an open approach should also yield technology development benefits that pay dividends later when EPA seeks to decarbonize the non-road diesel sector. [EPA-HQ-OAR-2019-0055-1329-A2, p. 4]

Ever since the first federal vehicle emission standards for heavy-duty engines were adopted, EPA has correctly assumed that compression-ignition engines would be fueled by diesel fuel. This assumption predates those first emission standards, and has been appropriate for more than a century. Indeed, most people simply call these engines “diesel engines,” and most people probably have never even heard the phrase “compression-ignition.” For most engines over this time, the diesel fuel powering these engines was a petroleum product; in recent years, biodiesel and renewable diesel has entered the fuel market, and those fuels have been integrated into EPA’s fuel and vehicle emissions regulatory architecture. [EPA-HQ-OAR-2019-0055-1261-A1, p. 8]

Similarly, EPA has historically assumed that ethanol would only be used in spark-ignition engines. Again, this has been the correct assumption for decades. Even within this Proposal, EPA considers the impacts of ethanol blends on the cost of emission control aftertreatment devices used in spark-ignition engines10 and discusses ethanol only in the context of current and proposed test procedures for spark-ignition engines.11 [EPA-HQ-OAR-2019-0055-1261-A1, p. 8]

10 See Proposal, at 17488.

11 See, e.g., Proposal at 17490, 17491, 17631, 17703, 17849, and 17866.

It is now time to update these assumptions, and to integrate the use of ethanol in a compression-ignition engine into the policy architecture that will govern future heavy-duty engines and vehicles. Thus, ClearFlame strongly urges EPA to finalize this Proposal in a way that explicitly anticipates that future compression-ignition engines may operate on high-blend ethanol fuels (e.g., E85 or E98). [EPA-HQ-OAR-2019-0055-1261-A1, p. 9]

As we have stated above, ethanol can play a major role in decarbonizing the hard-to-electrify segments of the highway and nonroad diesel engine and vehicle markets. In order for this to happen, EPA must remove any uncertainty surrounding whether or not ethanol can be used to certify future compression-ignition engines or whether this fuel must be used thereafter throughout the useful life of such future engines. [EPA-HQ-OAR-2019-0055-1261-A1, p. 9]

Organization: *Coalition for Renewable Natural Gas (RNG Coalition)*

As EPA recognizes, '[h]eavy-duty vehicles and engines are important contributors to concentrations of ozone and particulate matter and their resulting threat to public health, which includes premature death, respiratory illness (including childhood asthma), cardiovascular problems, and other adverse health impacts.' 87 Fed. Reg. at 17,414. In the proposal, EPA seeks to reduce emissions of nitrogen oxides ('NOx') and other pollutants, as well as proposing further greenhouse gas ('GHG') emissions starting for model year 2027. RNG submits these comments because, while it appears EPA considered natural gas vehicles ('NGVs') technologies in developing the proposed standards, see, e.g., id. at 17,430, it does not appear to have considered the benefits of using RNG. RNG is increasingly being used in NGVs and also can be used in the production of hydrogen. We believe this is a lost opportunity for EPA to achieve greater emissions reductions, including GHG emissions, from the heavy-duty sector. [EPA-HQ-OAR-2019-0055-1204-A1, p.1]

RNG is biogas-derived fuel that has been captured from organic waste streams—including agricultural wastes, municipal wastewater, and municipal solid waste in landfills—and upgraded to achieve quality standards necessary to blend with or substitute for geologic natural gas. Every community in America produces waste. As that waste breaks down, it emits methane, which is a naturally occurring, but potent and harmful GHG. RNG projects capture this methane from existing food waste, animal manure, wastewater sludge and garbage, and redirect it away from the environment, repurposing it as a clean, green energy source. As such, RNG can produce carbon-negative results when fueling on-road vehicles like short- and long-haul trucks, transit buses, and refuse and recycling collection vehicles.1 [EPA-HQ-OAR-2019-0055-1204-A1, pp.1-2]

> 1 Decomposition of wastes in landfills was identified by EPA as a major source of methane emissions in the United States. See EPA, Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2020, at ES-7 (2022), available at https://www.epa.gov/ghgemissions/inventory-us-greenhouse-gas-emissions-and-sinks-1990-2020.

RNG can be used in the same applications as conventional natural gas, including in transportation, industrial, and heating/electricity applications. RNG is currently sold in the transportation fuel market as renewable compressed natural gas ('CNG') and renewable liquefied natural gas ('LNG'), and RNG makes up over 95 percent of our nation's cellulosic biofuel production under the Renewable Fuel Standard ('RFS') program. During power outages, RNG can also be tapped to provide reliable, sustainable energy. This dependability is also why it is already being used to power essential services for food storage, airports, universities, hospitals, and other important facilities. [EPA-HQ-OAR-2019-0055-1204-A1 ,p.2]

Heavy-duty vehicles are the fastest growing segment of U.S. transportation in terms of energy use and emissions.2 Ultra-low NOx, medium- and heavy-duty natural, gas-powered trucks and buses are on the road today and perform at levels that are 95 percent below the current NOx standard and 98 percent below the particulate matter standard.3 They provide cost-effective emissions reductions in the heavy-duty sector compared to electric options still in development.4 [EPA-HQ-OAR-2019-0055-1204-A1, p.2]

3 NGVAmerica, A First, California Fleets Fueled with Bio-CNG Achieve Carbon-Negativity, June 2, 2021, https://ngvamerica.org/2021/06/02/a-first-california-fleets-fueled-with-bio-cng-achieve-carbon-negativity/; see also 87 Fed. Reg. at 17,433 (noting that only natural gas and liquified petroleum gas engines have been certified to meet California's more stringent, optional standards).

4 NGVAmerica, Breathe Cleaner Air Right Now, https://ngvamerica.org/environment/?msclkid=787e309ece7411ecacf726e33f83661d (last visited May 13, 2022).

According to EPA's GHG Inventory, the largest source of carbon dioxide ('CO2'), and of overall GHG emissions, is fossil fuel combustion primarily from transportation and power generation.5 RNG is key to reducing these emissions and meeting this Administration's climate change goals. In 2021, 64 percent of all on-road fuel used in NGVs was RNG.6 Using California Air Resources Board data, the average carbon intensity value of RNG in its Low Carbon Fuel Standard program was carbon negative at -44.41 gCO2e/MJ for calendar year 2021. Based on this data, RNG use in transportation fuel displaced 3.8 million metric tons of CO2 equivalent in 2021, which is equivalent to removing CO2 emissions from more than 427 million gallons of gasoline consumed. [EPA-HQ-OAR-2019-0055-1204-A1, p.2]

5 See EPA, Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2020, at ES-7 (2022), available at https://www.epa.gov/ghgemissions/inventory-us-greenhouse-gas-emissions-and-sinks-1990-2020.

6 NGVAmerica and RNG Coalition, Decarbonize Transportation with Renewable Natural Gas, May 2022, available at https://ngvamerica.org/resource-center/.

Importantly, RNG use can provide significant GHG emissions reductions today. NGVAmerica reports that 74 percent of heavy-duty trucks are not certified to the latest NOx emission standard.7 Fleet turnover is important to ensuring the emissions reductions being sought are actually achieved. 'Technological and commercial maturity of medium- and heavy-duty natural gas vehicles have encouraged adoption of natural gas for commercial vehicle fleets, with reported reductions in the total cost of ownership through fuel cost savings and reduced maintenance, in addition to substantial emission reductions.'8 'RNG availability enhances the economic value of converting trucking and municipal fleets from diesel to natural gas, which in turn supports investments in supply infrastructure, increasing the value and viability of further conversions.'9 EPA's proposal should ensure that it is supporting these conversions and increased use of RNG in the transportation fuel sector. A large part of EPA's focus, however, appears to be to transition to electric vehicles, which is much more difficult to accomplish in the heavy-duty sector and is likely on a much longer time frame. [EPA-HQ-OAR-2019-0055-1204-A1, p.3]

7 NGVAmerica, Breathe Cleaner Air Right Now, https://ngvamerica.org/environment/?msclkid=787e309ece7411ecacf726e33f83661d (last visited May 13, 2022).

9 Id. at 3.

EPA recognizes that development of electric vehicles and hydrogen fuel cell heavy-duty vehicles, while considered to be zero emissions, may be more challenging. 87 Fed. Reg. at 17,562. While we believe EPA should recognize all the available technologies to reduce emissions and ensure that NGVs are equally supported (not just electric vehicles),10 it should be noted that RNG can be used to produce renewable hydrogen. Renewable hydrogen at scale could significantly reduce carbon emissions from the heavy-duty transportation sector where electrification is difficult or impossible, such as in the heavy-duty transportation sector. When renewable hydrogen production is paired with carbon capture and sequestration, the RNG process is ultimately carbon-negative. Therefore, the material used for RNG today can be deployed as renewable hydrogen, providing another avenue for zero-carbon and carbon-negative renewable gas in the energy, transportation, and industrial sectors. [EPA-HQ-OAR-2019-0055-1204-A1, p.3]

10 Nonetheless, we agree that EPA should not provide multipliers for electric vehicles to meet the NOx emissions standards. See, e.g., 87 Fed. Reg. at 17,426. In light of the numerous benefits of NGVs today and the incentives already included for electric vehicles, it is unclear why electric vehicles should receive additional incentives to meet any of the standards being proposed, particularly where NGVs provide similar emissions profiles, and, when using RNG, can provide even better lifecycle GHG emissions reductions. Because of the various sources of biogas, RNG can be an available (and abundant) fuel across the entire country. Nonetheless, much of the use in the transportation fuel sector is concentrated in California due to that state’s low-carbon fuel standard, and NGVs similarly could benefit from incentives for increased investment in infrastructure, such as fueling stations, nationally.

In short, this Administration’s decarbonization and clean air goals will only be achieved by focusing on a multi-technology approach. RNG provides a cost-effective, carbon-negative solution, that can provide carbon reductions right away. EPA’s proposal should take this into account and, as appropriate, support continued production and expansion of NGVs and hydrogen fuel cell vehicles, not just electric vehicles. [EPA-HQ-OAR-2019-0055-1204-A1, p.3]

Organization: *Cummins Inc. (Cummins)*

Internal combustion engines fueled by hydrogen (H2 ICE) are under development at Cummins (see Hydrogen Engines). H2 ICE offers the potential for significant near-term emissions reductions because it is an affordable zero carbon, low NOx technology that can be produced at scale at existing manufacturing facilities. However, more regulatory clarity is needed for manufacturers to certify such engines to applicable criteria pollutant and GHG emissions standards. Regulation updates may be needed to address emissions measurement and testing, OBD, DF testing, etc., to recognize this advanced technology. In addition, regulatory incentives that would recognize H2 ICE as a ZEV-like zero carbon technology would help drive demand for H2 ICE, which in turn would accelerate the development of the hydrogen refueling infrastructure that will be needed to support the future implementation of hydrogen fuel cell vehicles. Cummins would like to work with EPA as this rule is finalized and during the Phase 3 GHG rulemaking to address specific needs. [EPA-HQ-OAR-2019-0055-1325-A1, p. 20]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

Hydrogen-Fueled Internal Combustion Engines (H2-ICEs) provide an important pathway to rapid penetration of vehicles with effectively zero CO2 emissions and near-zero NOx emissions. This rulemaking presents an opportunity for EPA to encourage innovation in alternate fuel engine development generally, and H2-ICEs specifically. Currently H2-ICE new technology is in the primitive proof-of-concept stage of innovation, and regulatory pathways are needed to bring this new near-zero CO2 and NOx technology to the market. Such technology could bring carbon neutral transportation to sectors that are not currently ripe for battery or fuel-cell applications, given the current state of technology development. It could also create a use-case for widespread hydrogen fueling, which could spur the development of hydrogen infrastructure and lay the groundwork for future fuel cell vehicles, which would rely on the same infrastructure. We also believe that H2-ICE is a favorable technology, even in the long term, for vehicles with high power demands and high daily mileage requirements (which BEVs and FCEVs may not serve well). Daimler Truck's vision for H2-ICE applicability in a zero-emissions future is illustrated in Figure 47 below: [EPA-HQ-OAR-2019-0055-1168-A1, p.125]

Importantly, this technology can be implemented rapidly, using existing products, processes, and technical expertise. In concept, H2-ICEs are very similar to existing combustion engines and can leverage the extensive technical expertise manufacturers have developed with existing products—in many cases, using the same components for many key systems. Similarly, these products can be built on the same assembly lines, by the same workers and with existing supply chains already in place, preventing costly plant retooling and American manufacturing job losses. H2-ICEs thus have an important role to play in facilitating the ZEV transition with minimal supply chain and economic disruptions. [EPA-HQ-OAR-2019-0055-1168-A1, p.126]

Although H2-ICE technology is promising, it is in an infant state, and near-term penetration potential is relatively low. By developing a regulatory framework that facilitates H2-ICE development, EPA could speed the adoption of such technology and help revolutionize certain applications in the HD transportation sector that are otherwise difficult to decarbonize. This could be achieved by eliminating regulatory obstacles to market introduction of H2-ICEs.

Specifically, EPA should use the opportunity presented in this rulemaking to create a favorable regulatory environment for these engines by providing relief in areas such as DF testing, GHG certification and testing requirements (under Parts 1036 and 1037), and expensive diagnostic requirements. [EPA-HQ-OAR-2019-0055-1168-A1, p.126]

Daimler Truck has performed a concept study of H2-ICE by converting a diesel engine to adapt all the relevant hardware components to accommodate H2 combustion. The results are shown in Figure 48. Along with effectively zero CO2 emissions, near-zero NOx emissions are also possible with H2-ICE innovative technology. Engine-out NOx levels are extremely low when compared to diesel emissions, and the temperatures created are extremely favourable for adapting existing SCR aftertreatment technologies—leading to further NOx reductions. [EPA-HQ-OAR-2019-0055-1168-A1, p.126]

Similarly, when measured at the tailpipe, CO2 emissions from these vehicles are extremely low—two orders of magnitude lower than a conventionally-fueled heavy duty engine. Figure 49 below shows a typical breakdown of CO2 emissions as measured at the tailpipe of an H2-ICE. Most of these emissions are ambient in nature (e.g., from the ambient air, or from the carbon content of urea) and do not represent a net increase of CO2 to the environment. EPA already allows the removal of background CO2 from emissions calculations; in these conditions, H2-ICE engines are as close as practical to zero, and are competitive with BEVs and FCEVs from a total carbon lifecycle perspective. [EPA-HQ-OAR-2019-0055-1168-A1, pp.126-127]

As manufacturers move aggressively towards decarbonization, global consistency in the regulatory approach to ZEVs is essential to provide the certainty and predictability necessary to spur investment, especially in markets that are likely to adopt such technologies first. European Union (EU) regulators have already recognized the advantages of H2-ICE engines, and the EU framework provides a path for these engines to be certified as ‘zero-emission heavy-duty vehicles’ by defining such vehicles as follows: ‘Zero-emission heavy-duty vehicle’ means a heavy-duty vehicle without an internal combustion engine, or with an internal combustion engine that emits less than 1 g CO 2 /kWh as determined in accordance with Regulation (EC) No 595/2009 and its implementing measures, or which emits less than 1 g CO 2 /km as determined in accordance with Regulation (EC) No 715/2007 of the European Parliament and of the Council and its implementing measures.138 [EPA-HQ-OAR-2019-0055-1168-A1, p.127]

138 See Regulation (EU) 2019/1242, Art. 3(11) (June 20, 2019).

It is also expected that the EU regulations will be further updated to more explicitly recognize these engines as a zero-emission technology. Such recognition provides significant benefits for manufacturers by reducing regulatory burdens, as well as development and certification costs, and by otherwise incentivizing commercialization. [EPA-HQ-OAR-2019-0055-1168-A1, p.128]

Similarly, CARB ZEV standards for passenger cars and light-duty trucks already recognize extremely low-emissions from H2-ICEs, providing a mechanism for manufacturers to generate credits for producing such vehicles that can be applied towards their ZEV sales obligations: (E) Credit for Hydrogen Internal Combustion Engine Vehicles. A hydrogen internal combustion engine vehicle that meets the requirements of subdivision 1962.2(c)(2) and has a total range of at least 250 UDDS miles will earn an allowance of 0.75, which may be in addition to allowances earned in subdivision 1962.2(c)(3)(A), and subject to an overall credit cap of 1.25.139 [EPA-HQ-OAR-2019-0055-1168-A1, p.128]

139 See 13 CCR 1962.2(c)(3)(E).

We recommend that EPA recognize, as CARB and the EU have, the potential of H2-ICE engines to play an important role in the zero-emission transition, and to take steps to reduce regulatory burden and incentivize manufacturers to introduce this technology. As a global manufacturer with deep roots in U.S. and European market, Daimler Truck recommends global alignment in recognizing H2-ICE as a zero-emission technology. [EPA-HQ-OAR-2019-0055-1168-A1, p.128]

EPA could reduce manufacturer burden, and thereby accelerate the penetration of zero-CO2 technologies in the commercial truck sector, by regulating HDVs with H2-ICEs as ZEVs, or, at a minimum, by removing the most costly and onerous engine certification requirements. [EPA-HQ-OAR-2019-0055-1168-A1, p.128]

Currently the market for H2-ICE technology, especially in the near-term, is limited. Since H2 infrastructure does not exist in any significant quantity, it is expected that manufacturers will face difficulties recouping their H2-ICE investment costs, and a high regulatory burden may prevent manufacturers from bringing these technologies to market. [EPA-HQ-OAR-2019-0055-1168-A1, p.128]

By making several changes to how H2-ICE vehicles are certified, EPA could regulatory burdens in a manner that would help to ensure the success of these new technologies, enabling immediate carbon reductions at low cost and with few lost jobs. [EPA-HQ-OAR-2019-0055-1168-A1, p.128]

First, we recommend that EPA recognize vehicles powered by H2-ICEs as effectively zero emission, placing them in a category similar to BEVs and FCEVs, which do not require costly certification, demonstration, diagnostic, and compliance requirements. We do not believe such compliance obligations have any value with respect to H2-ICE emissions performance, since the engines already emit effectively no CO2, NOx, PM, and other constituent pollutants of concern— even in degraded or failed states, based on the fundamental physics governing this combustion cycle and fuel. ZEV recognition for these products would significantly incentivize their production, as they would qualify for emissions credits and advanced credit multipliers in the same manner as BEVs and FCEVs. [EPA-HQ-OAR-2019-0055-1168-A1, p.128]

Alternatively, if EPA decides to continue to require H2-ICEs to be certified under its program for traditional combustion engines, we recommend that EPA significantly reduce the certification burden by making the following modifications to its certification requirements:

- ***Reduced DF validation burden and Durability requirements***.
    - DF validation is extremely expensive and burdensome, and carries a several-year lead-time to complete for new technologies.

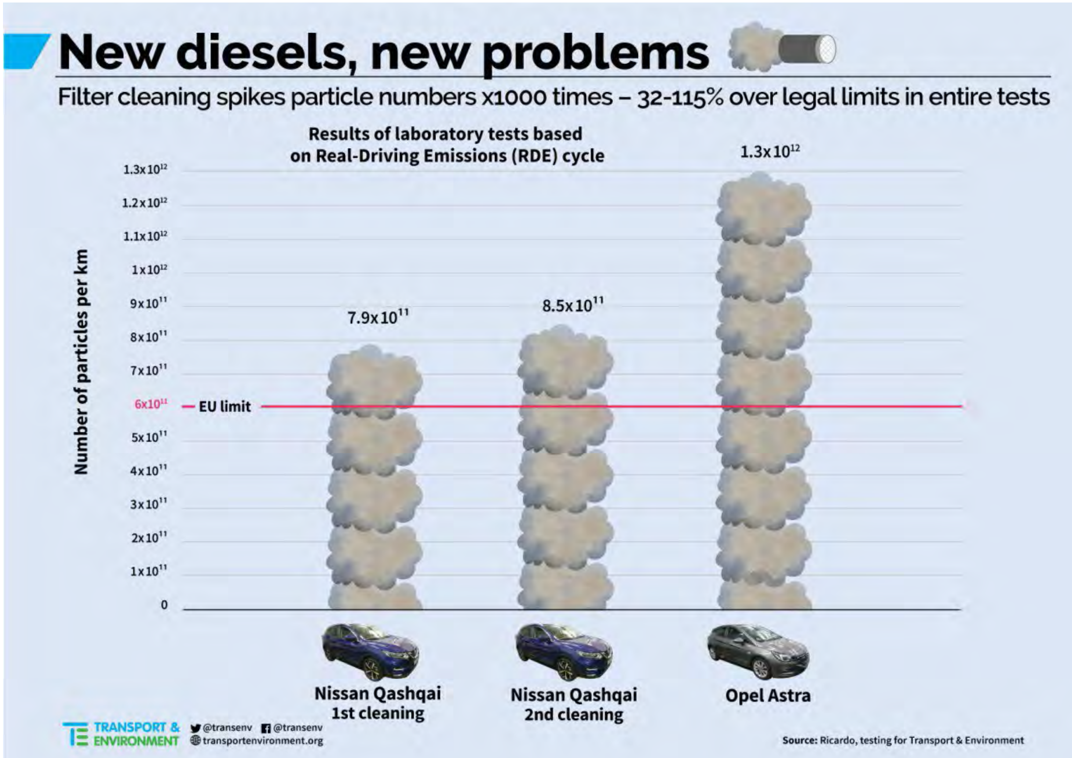
- EPA could allow manufacturers to attest to durability and useful life requirements (as proposed for ZEV durability and useful life requirements in the NPRM).
- EPA could consider a reduced Useful Life standard for H2-ICE in the HHD category - consistent with how SI engines in the LHD and MHD categories are treated.

- ***Simplified OBD regulation***.
  - The development and demonstration of an OBD system, as required in EPA's proposed Section 1036.110, is extremely time consuming, expensive, and risky for manufacturers.
  - It also drives significant material cost to the engine, as sensors are added purely for the purpose of diagnostic requirements.
  - The combustion mechanisms of an H2-ICE mean that, even in a failed condition, increased emission potential is extremely limited. CO_2, PM, and hydrocarbon emissions are effectively zero in any combustion regime with H_2 fuel, and even in the case of a failed catalyst, engine-out NO_x emissions are extremely low with this technology. The value of an OBD system in an H2-ICE-powered vehicle is extremely limited—especially when considered in light of its cost.
  - EPA could reduce this burden by requiring the OBD system only to detect circuit faults—which make up the vast majority of real world failures—and avoid requirements for threshold diagnostics and rationality checks which add cost and complexity and are onerous to develop and demonstrate.
- ***Simplified GHG regulation and certification.***
  - Current certification procedures and demonstration requirements are not necessary for the demonstration of an engine that does not use carbon as a fuel.
  - EPA could declare such engines to emit zero CO_2 for the purposes of GEM inputs for vehicle certification under 40 C.F.R. Part 1037 and allow a default FCL/FEL of zero g/hp-hr for engine GHG certification under 40 C.F.R. Part 1036. [EPA-HQ-OAR-2019-0055-1168-A1, p.129]

EPA has an important opportunity in this rulemaking to encourage the development of technologies with effectively zero CO_2 emissions today, in applications that would not otherwise be ripe for ZEV penetration in the foreseeable future. Daimler Truck recommends that EPA work with manufacturers to determine the best path to enable these technologies. [EPA-HQ-OAR-2019-0055-1168-A1, p.129]

Organization: *David Pedersen*

Furthermore, as the Federal Register document for this proposed rule explains, the existing emissions controls – most notably the DPF (a euphemistic term which conceals the true name PTOX, or particulate-trapping oxidizer) and SCR systems – are known to cause not only downtime and in-use de-rating problems[2]; they are also emissions sources in their own sense. When regenerating, DPFs emit 1000 times the legal soot limit for up to 15 kilometres (ca. 9.3 miles) or more[3], often in populated areas where soot accumulates more rapidly due to lower engine RPMs and thus cooler combustion:



https://www.transportenvironment.org/wp-content/uploads/2021/07/New-diesels-new-problems-filters.png

This essentially deletes (no pun intended) the purpose of the DPF, which is to trap and neutralize diesel particulate matter before it escapes into the ambient air where it poses a risk to all living things in the vicinity. SCR also suffers from a similar issue, in which raw ammonia is released from the exhaust due to the inherent inefficiencies in the thermal decomposition of the urea and subsequent reaction between the ammonia and exhaust-stream NOx. Such a problem can be life-threatening, as was tragically demonstrated by the death of the worker at the arena in Fernie British Columbia. I will point out here that diesel soot is also a climate issue, as the IPCC has repeatedly noted that soot – a short-lived climate forcer – must be significantly reduced in order to meet the Paris Accord's target of keeping the global average temperature anomaly (increase) to below 1.5 degrees Celsius (2.7 degrees Fahrenheit).[4] As such, it is clear that continuing to try to clean up diesel emissions is futile and dangerous, and that expedited electrification is the clear winner and a necessity in order for America to meet its public-health obligations (both legally and morally). [EPA-HQ-OAR-2019-0055-1059]

It is bad enough that truck and non-road machinery owners and operators are forced to endure the problems associated with and caused by DPFs and SCR – technologies that I believe should never have been mandated, which the science increasingly agrees with me on. However, it is also inexcusable that so many people are forced to breathe diesel exhaust (and its constituent components) against their will, as it is clearly a violation of their constitutional rights (including the rights to life, liberty, and security of the person). [EPA-HQ-OAR-2019-0055-1059]

There is also a golden opportunity for mandating electric vehicles; the technology is advancing so rapidly that there will easily be all-electric trucks and buses, and off-road vehicles and machinery, available and market-ready by as early as 2025, so the Agency can and should take a hard look at where things stand and set the *earliest* date for the phase-out of sales of new diesel vehicles and machinery. The sooner such a mandate is implemented, the sooner the suffering will stop. [EPA-HQ-OAR-2019-0055-1059]

In summary, I urge the Agency to abandon its proposed rulemaking unless it is willing to mandate electric trucks as soon as possible AND eliminate the need for DPFs and SCR to decrease the burden on owners and operators and increase the safety of the public. [EPA-HQ-OAR-2019-0055-1059]

Organization: *Eaton Vehicle Group (Eaton)*

2. **The regulations need to be based on data that evaluates recent technologies developed to address the NOx challenges, accounting for major improvements achieved since the data used in the NPRM was created.** The EPA evaluations of Aftertreatment-focused technologies recently published show marginal feasibility of Option 1. However, Eaton and other suppliers have developed an array of technologies, 6 years ahead of the new regulations, that show in a certification test environment that CARB limits are achievable through <u>multiple pathways</u>, with <u>compliance margins well in excess of 40%</u>, with <u>less fuel consumed (CO2 neutral or better)</u>,

based on conventional, robust and very cost-effective components. [EPA-HQ-OAR-2019-0055-1252-A1, p.2]

Eaton and other suppliers, in collaboration with Southwest Research Institute (SwRI), have tested a significant array of NOx reduction technologies using the same certification-oriented test rig as the work in support of developing both the Omnibus and EPA standards. The data from these investigations showed in 2021 that the Omnibus 2027 NOx levels are achievable with margins in excess of 40%, while contributing to lower CO2 emissions, at reasonable cost increments that are offset by fuel savings, and with robust technologies designed for the life of the truck. We have recently supplied the relevant data to the EPA for consideration. Below are a few salient examples: [EPA-HQ-OAR-2019-0055-1252-A1, p.2]

- In a recent memo1, the EPA showed results of an advanced Aftertreatment system that achieved 20mg NOx on the Composite FTP cycle at 435,000 miles, which is the exact limit of the Omnibus and Option 1 proposed limit in 2027. Eaton added Cylinder Deactivation (CDA) as an active thermal management technology, and in the new configuration, we demonstrated 18 mg in 20192 with a 0.5% CO2 improvement, and then further improved to 15 mg NOx in 20203, while maintain lower CO2 emissions. On the LLC cycle, the EPA measured 29mg, well within the Omnibus and Option 1 limit of 50mg. The addition of CDA technology, further reduced the LLC emissions to 24mg. Thus, the addition of the CDA technology enables achieving the most stringent targets of the Omnibus rule and Option 1 with a 25% margin on the FTP cycle and 50% margin on the LLC cycle seven years ahead of actual implementation using a technology that has been used in gasoline engines for over two decades. [EPA-HQ-OAR-2019-0055-1252-A1, p.2]

  1 Test Results from EPA Diesel Engine Demonstration, May 3rd 2022, Docket EPA-HQ-OAR-2019 0055

  2 Neely, G., Sharp, C., Pieczko, M., and McCarthy, J. Jr., 'Simultaneous NOx and CO2 Reduction for Meeting Future CARB Standards Using a Heavy-Duty Diesel CDA-NVH Strategy,' SAE Int. J. Engines 13(2):2020, https://www.sae.org/publications/technical-papers/content/03-13-02-0014/, first published online Dec. 10, 2019

  3 Matheaus, A., Neely, G. A., Sharp, C. A., Hopkins, J. and McCarthy, J. Jr., 'Fast Diesel Aftertreatment Heat-up Using CDA and an Electrical Heater,' SAE 2021-01-0211, April 6, 2021.

- In addition, Eaton and other suppliers examined the effects of using alternative active heating, implemented through either electrical heaters or fuel burners. The addition of the electrical heater achieved 16 mg on the Composite FTP cycle (and 0.9% CO2 improvement) and 12mg on the LLC cycle (with an additional 1.8% CO2 savings). Further refinements in calibrations4 achieved 12mg on the FTP cycle, while saving 1.5% CO2. Together these configurations show that the compliance margins are significant: 40% on FTP and 50%-75% on LLC (while also improving CO2 by 2.9%). Noteworthy is that tests of the Beverage cycle produced 1 mg/hp-hr NOx, which would be considered near-zero and less than 10% of the LLC certification value. [EPA-HQ-OAR-2019-0055-1252-A1, p.3]

4 Zavala, B., McCarthy Jr., J., Matheaus and Sharp, C. A., 'Fast Diesel Aftertreatment Heat-up Using CDA and an Electrical Heater between 1.2 and 5.0 kW,' Accepted in Frontiers In Mechanical Engineering, April 11, 2022

- Eaton and other suppliers also evaluated active heating using a fuel burner5. Together with the advanced Aftertreatment system aged at 435,000 miles and CDA, the NOx emissions achieved were 12 mg on the Composite FTP and under 10 mg on the LLC cycle, demonstrating 40% and 80% compliance margin to Option 1 and Omnibus levels. [EPA-HQ-OAR-2019-0055-1252-A1, p.3]

5 Thomas Harris, James McCarthy, Jr., Chris Sharp, Bryan Zavala and Andrew Matheaus, Meeting Future NOx Emissions Limits with Improved Total Fuel Efficiency, ATZ live: Heavy-Duty, On- and Off-Highway Engines 2021, Heavy-Duty_2021_Paper_14, 12/1/21

- The results above led us to explore eliminating the need of the Light-Off Catalyst and achieve the emissions using a conventional Aftertreatment architecture and active heating. In this configuration (CDA engine, heater and conventional Aftertreatment), we achieved 6mg on the LLC cycle (an 88% compliance margin) and near-zero (1 mg) on realistic drive cycles (beverage truck cycle)6. Updated calibrations recently achieved 11 mg on the LLC and 20mg on the Composite FTP. These results are not yet optimized but are encouraging as they achieve the Omnibus and Option 1 levels for the FTP and an 80% margin on the LLC. Further optimization of calibrations is expected to recover margin on the FTP cycle as well. However, these results are significant because they achieve the NOx targets using conventional Aftertreatment, while the additional technologies (CDA and burners) are designed for the life of the truck and not subject to the high initial cost and degradation of the catalysts when using a Light-Off SCR. [EPA-HQ-OAR-2019-0055-1252-A1, p.3]

6 McCarthy, J. Jr., Matheaus, A., Zavala, B., Sharp, C. and Harris, T., 'Meeting Future NOx Emissions Over Various Cycles Using a Fuel Burner and Conventional Aftertreatment System, SAE 2022-01-0539, 3/29/2022

- A different approach to achieving low NOx is afforded by the Exhaust Gas Recirculation (EGR) pump, which in conjunction with advanced turbomachinery, helps achieve a 4% reduction in CO27. However, the EGR pump also is capable of reducing the engine-out NOx by 40-60% while raising exhaust temperature at low load and idle. Using a similar approach, Achates Power (on a different engine architecture but using the same physics principles) also demonstrated better than 50% compliance margin with Option 1 and the Omnibus limits. While the EGR pump is a new technology, it relies on conventional Roots rotor technology that Eaton has manufactured for over 50 years. [EPA-HQ-OAR-2019-0055-1252-A1, p.3]

7 Nilesh Bagal, Chris Bitsis, Analytical and Experimental Evaluation of Next Generation High Efficiency Powertrains with 48V EGR Pump, Vienna Engine Symposium, 2022

The key results to date (5 years ahead of proposed implementations) based on Aftertreatment systems aged at 435,000 miles, can be summarized as follows: [EPA-HQ-OAR-2019-0055-1252-A1, p.3]

In conclusion, we recommend the Agency adopts a modification of Option 1 that aligns with the CARB Omnibus limits because:

- This approach achieves a single national standard that includes the needs of states with non-attainment issues, hence it is a long-term solution that provides stability and incentives to invest.
- The limits are in fact achievable with significant compliance margin, with multiple technology pathways, based technologies that are robust (in fact modifications of existing technologies) and designed for the life of the truck.
- The incremental costs of these technologies are minimal (approximately 3% of the truck or less) and many options also reduce CO2 (and thus also achieve fuel savings), as illustrated in the surveys by National Renewable Energy Lab, CARB, and Manufacturers of Emissions Controls Association (representing the suppliers that actually design, produce and sell the technologies above). [EPA-HQ-OAR-2019-0055-1252-A1, p.4]

4. **The regulations should drive simultaneous NOx and CO2 reduction**. There are multiple pathways for internal combustion-based powertrains to achieve stringent NOx levels, together with 5-10% CO2 reduction. [EPA-HQ-OAR-2019-0055-1252-A1, p.5]

As shown above, there are several technology pathways to achieve the low NOx limits proposed in the Omnibus rule and Option 1. Some of these also reduce CO2, and thus have value in both achieving the 2027 GHG limits as well as real fuel efficiency benefits that translate in transportation fuel cost reductions, which further helps reduce the modest incremental costs of the additional technologies. To illustrate this point we submit the following examples: [EPA-HQ-OAR-2019-0055-1252-A1, p.5]

- CDA has an immediate CO2 benefit at low load (5-20%, but also 1% on GHG cycles). However, the CDA function is a significant part of high efficiency engine braking, thus its incremental costs are in fact small and they enable higher power engine brakes as well.
- Electric heaters typically require 48V power. Once installed on the vehicle, this is the basis of micro- and mild-hybridization, with benefits in the range of 2-3% (micro) and 5-8% (mild).
- Furthermore, the additional electrical power has non-emission benefits such as power for advanced computing needed for ADAS applications or power for electrical HVAC that improves driver comfort through faster cabin cooling.
- Heavy Duty electrical diesel hybrids have potential as vocational powertrains with 15%-25% CO2 reduction, while providing full heater capability for the Aftertreatment function

- EGR pumps enable better breathing and efficient turbo machinery with a 4% CO_2 benefit but also 40%-60% engine-out NOx, and up to 90C temperature increase that reduces the load on the Aftertreatment system. [EPA-HQ-OAR-2019-0055-1252-A1, p.5]

We recommend the following:

- The Agency should take into consideration the system-level effects of combining the low NOx and low CO_2 technologies when calculating the impact and cost of compliance. [EPA-HQ-OAR-2019-0055-1252-A1, p.5]

Organization: *Environmental Defense Fund (EDF) (1265 and 2855)*

Current zero-emission technologies are capable of dramatically reducing NOx emissions. In fact, the White Paper EDF has submitted along with these comments finds that ZEV deployment in the 2027-2029 timeframe can deliver 840,000 tons of NOx reductions beyond EPA's proposed option 1 through 2050 and 2.2 million tons of NOx reductions beyond a 2026 baseline through 2050. Accordingly, in both these and future standards, we prefer that EPA adopt multipollutant standards that achieve reductions in both criteria and climate pollution and drive zero-emitting technologies. A multipollutant approach is firmly grounded in EPA's authorities under 202(a)(1), discussed above, and 202(a)(3), which, directs the Administrator to establish standards for NOx and particulate matter reflecting the 'greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology.' [EPA-HQ-OAR-2019-0055-1265-A1, p.22]

Setting standards in this manner would allow both a heavy-duty NOx engine standard and a heavy-duty GHG standard to be set in a way that incorporates the dual criteria and climate benefits of zero-emission vehicles and ensure there are not pollution trade-offs between two different sets of standards and between ICE vehicles and ZEVs. As addressed in more detail in our comments on EPA's proposed adjustments to the Phase 2 GHG standards, it is clear that a rapid increase in the market share of zero emission vehicles has begun and will continue in the coming years. Neither EPA's proposed NOx nor GHG standard adequately account for this market shift. While EPA has estimated that ZEVs will comprise 1.5 percent of the fleet during the period of these standards, analysis conducted by ERM projects ZEV sales of up to 34 percent in 2027-29.99 [EPA-HQ-OAR-2019-0055-1265-A1, p.22]

99 See supra fn 72.

Organization: *Fuel Cell and Hydrogen Energy Association (FCHEA)*

Hydrogen has significant potential to promote environmental justice. Using hydrogen as a fuel or energy source in combination with fuel cells produces no NOx, SOX, and particulate matter that directly affect corridor adjacent communities. For example, replacing heavy-duty trucks, port equipment, buses, vans, and other vehicles with zero-emission fuel cell electric options would significantly reduce harmful pollutants and noise in these communities, improving local air quality and public health. These medium– and heavy-duty vehicles are especially important from an environmental justice standpoint as our nation's highways often cut through disadvantaged and minority communities. [EPA-HQ-OAR-2019-0055-1187-A2, p. 2]

Organization: *International Council on Clean Transportation (ICCT)*

Major suppliers continue to develop and test technologies that can be used to simultaneously achieve lower NOx emissions and reduced CO2/fuel consumption. An example is the Eaton Corp development of a 48- volt electric heater to increase catalyst inlet temperatures at low loads. The heater combined with cylinder deactivation cut low load NOx emissions in half compared to cylinder deactivation alone, while reducing CO2 and fuel consumption by nearly 2 percent. FTP CO2/fuel consumption was reduced by slightly less than 1 percent.10 Another example is use of an EGR pump to optimize turbocharger and EGR flow. Testing at SwRI indicates a fuel consumption reduction of approximately 3 percent on the hot FTP.11 [EPA-HQ-OAR-2019-0055-1211-A1, pp. 8 - 9]

10. SAE paper 2021-01-0211, Tables 8 and 17a, April 6, 2021.

11. Int'l Vienna Engine Symposium 2022 – Session: Latest results in engine and component development

Another promising option for compliance with the proposed Option 1 standards is the opposed piston diesel engine being developed by Achates Power in San Diego, CA. On the dynamometer the demonstration engine met the proposed 2031 NOx standards using a current, conventional aftertreatment system. More importantly, this 400 hp, 10.6-liter diesel engine has been installed in a Peterbilt class 8 tractor and placed into fleet service by Walmart. Recent PEMS testing of this truck performed by UC Riverside demonstrated NOx emissions over 50 percent below the proposed in-use limits. Walmart also compared fuel consumption of the Achates/Peterbilt truck to a comparable truck with a Detroit Diesel 15-liter engine. The Achates-powered truck had 10 percent better fuel economy. An independent study showed the cost of volume production of the opposed piston engine including compliance with the proposed standards will cost no more and possibly less than current diesel engines.12 This technology provides a second feasible pathway for engine manufacturers to meet the proposed standards. [EPA-HQ-OAR-2019-0055-1211-A1, p. 9]

Organization: *Loren Marz*

There should be some provision for use of renewable/synthetic diesel fuels in any future regulatory action regarding GHG emissions. In some scenarios, these non-fossil diesel fuels are more effective in reducing overall GHG emissions than electrification. See, e.g., https://pubs.acs.org/doi/10.1021/acs.est.0c05893, https://www.velocys.com/2019/10/10/negative-emission-fuel-agreement/. [EPA-HQ-OAR-2019-0055-1394]

Organization: *Mass Comment Campaign sponsored by Climate Action Campaign (22,659)*

- Cleaner trucks are not only available and ready now, they also are projected to deliver critical cost savings for operators and drivers. [EPA-HQ-OAR-2019-0055-1193, p.1]

- Across nearly every vehicle class, zero-emission electric trucks and buses are projected to be cheaper to own and operate than their combustion engine counterparts within five years. [EPA-HQ-OAR-2019-0055-1193, p.1]

Organization: *Mass Comment Campaign sponsored by Union of Concerned Scientists - 2 (959)*

Lastly, in addition to phasing out diesel engines, the rule should make clear that natural gas-powered engines are not the solution. Studies have shown that trucks running on methane can be as polluting as diesel, and we need to be driving investments in cleaner energy sources, not deploying more fossil fuel infrastructure.4 [EPA-HQ-OAR-2019-0055-1608-A1, p.1]

> 4 https://theicct.org/publication/a-comparison-of-nitrogen-oxide-nox-emissions-from-heavy-duty-diesel-natural-gas-and-electric-vehicles/

Organization: *Manufacturers of Emission Controls Association (MECA)*

In addition to on engine and aftertreatment technology innovation over the course of the demonstration program, a new engine architecture has been developed and tested. The engine has been commercialized by Achates Power and is a 400 hp, 10.6L opposed-piston configuration. Besides being tested on an engine dynamometer, the engine has been installed in a Peterbilt 579 tractor that is current in fleet service with Walmart. The results from the test program show that the opposed piston engine combined with current commercially available aftertreatment systems can achieve NOx emissions of 0.007 g/bhp-hr on the FTP cycle, 0.014 g/bhp-hr on the SET, 0.02 g/hr on the clean idle cycle and 0.021 g/bhp-hr on the LLC after 435,000 equivalent aging. These values offer substantial margin (30-65%) relative to the 2031 limit of the Proposed Option 1 standards with greater than 50% margin under all operating modes [14]. [EPA-HQ-OAR-2019-0055-1320-A1, p.8]

> [14] A. Salvi, F. Redon, D. Youngren and L. Fromm, 'Low CO2, Ultralow NOx Heavy Duty Diesel Engine: Experimental Results (SAE 2022-01-0426),' SAE WCX, April 2022.

Another promising technology that is being explored to both reduce the NOx and GHG footprint of heavy-duty vehicles is the hydrogen internal combustion engine (H2ICE). These engines, when coupled with advanced NOx aftertreatment, have the potential to meet the proposed NOx limits while emitting zero tailpipe carbon emissions when operated on any hydrogen fuel and zero lifecycle carbon emissions when operated on renewable green hydrogen. There is broad industry support for internal combustion engines fueled with clean hydrogen, including most engine manufacturers and component suppliers conducting significant development work and on-road demonstration in trucks. H2ICE are attractive options in commercial trucking where challenges exist in applying current BEV technology, with one of the main benefits being the opportunity to leverage existing investments in manufacturing capacity in engines and aftertreatment while growing the market for on-board hydrogen storage technology and infrastructure. [EPA-HQ-OAR-2019-0055-1320-A1, pp.8-9]

H2ICE vehicles share many components with today's diesel and natural gas powered vehicle fleet, including the base engine, installation parts, powertrain components and aftertreatment system architectures. Furthermore, H2ICE can borrow technology from currently available natural gas engines, such as cylinder heads, ignition systems, fuel injection, turbochargers, cooled exhaust gas recirculation (EGR), and engine control unit/software, among others. Nearly all on-road and off-road engine OEMs, along with their suppliers, are developing H2ICE for commercial introduction in the MY 2025-2027 time frame. [EPA-HQ-OAR-2019-0055-1320-A1, p.9]

Engines and aftertreatment systems can be designed and optimized for simultaneous reductions in NOx and CO2 emissions. [EPA-HQ-OAR-2019-0055-1320-A1, p.10]

The penetration of fuel-saving technologies into the heavy-duty fleet has been spurred by U.S. EPA's Heavy-Duty Greenhouse Gas Phase 1 and Phase 2 Standards. At the same time, research undertaken by multiple teams as part of the Department of Energy's SuperTruck I program has demonstrated how these technologies can be combined to achieve a 16% boost in fuel economy and improved freight efficiency. Participants in the SuperTruck II program have been demonstrating even greater gains in fuel and freight efficiency, with engines achieving 55% brake thermal efficiency through the use of technologies like waste heat recovery. Last year DOE awarded five OEMs funding to develop electric powertrains in SuperTruck III. [EPA-HQ-OAR-2019-0055-1320-A1, pp.10-11]

Component suppliers have continued to innovate, and many technologies that were not even considered as compliance options in the Phase 2 rule are now likely to be deployed on limited engine families in 2024 and more broadly in 2027. Furthermore, engine efficiency technologies – such as cylinder deactivation, advanced turbochargers, and hybridization – have also been demonstrated in combination with advanced aftertreatment technologies on heavy-duty diesel engines. Testing has shown the ability of several advanced engine technologies to be optimized to improve fuel efficiency while increasing exhaust temperature in diesel engine exhaust, which improves SCR NOx reduction performance. [EPA-HQ-OAR-2019-0055-1320-A1, p.11]

The calibration of internal combustion engines is a delicate balance that has to deal with trade-offs to optimize performance and emissions. For example, there is an inverse relationship between PM and NOx emissions that engine manufacturers applied to meet emission standards up through the 2006 heavy-duty highway regulations. In 2007, the requirement to reduce both PM and NOx emissions caused OEMs to install DPFs on diesel vehicles, which allowed engine calibrators to optimize the combustion in the engine to meet lower NOx emissions while relying on the DPF to remediate the resulting higher PM emissions. This example of effective emission regulations provided a technology solution to overcome the traditional barriers of engine thermodynamics. In 2010, SCR systems were installed on most trucks in response to a further tightening of NOx limits. SCR allowed calibrators to not only reduce the soot load on DPFs (and in turn provide a better NOx-to-soot ratio to promote passive soot regeneration) as a way of improving fuel efficiency but also to take advantage of another well-known trade-off in combustion thermodynamics between fuel consumption (or CO2 emissions) and NOx emissions from the engine. [EPA-HQ-OAR-2019-0055-1320-A1, p.11]

Since 2010 the predominant technologies to reduce tailpipe NOx from diesel engines have been EGR from the engine and SCR in the exhaust, and every generation of SCR system has led to improvements in catalyst conversion efficiency. In 2011, U.S. EPA adopted federal GHG standards for heavy-duty trucks that were implemented in 2014 through 2020. The Phase 2 regulation was adopted in 2016 to cover trucks from 2021 through 2027. Engine manufacturers quickly recognized SCR as a very effective technology option that has allowed them to meet the first phase of heavy-duty GHG standards while still achieving NOx and PM reduction targets from the engine. OEMs have accomplished this by calibrating new engines to burn less fuel and rely on the SCR system to remediate the additional NOx emissions that result from such calibration. [EPA-HQ-OAR-2019-0055-1320-A1, p.11]

The portfolio of technology options available to reduce GHG emissions from heavy-duty trucks and engines is continually growing in response to federal GHG standards. In fact, a review of heavy-duty engine certifications from 2002 to 2019 shows that once emission control and efficiency improving technologies were required on engines in 2010-2011, the inverse relationship between CO2 and NOx emissions at the tailpipe was overcome and both were reduced simultaneously (see Figure 1). Several engines certified since 2010 have shown the ability to achieve 0.1 g/bhp-hr or lower NOx emissions over the composite FTP certification cycle, which is 50% below the current standard. Of those engines, several have demonstrated the ability to meet future Phase 2 GHG regulation limits for vocational engines that go into effect in 2021, 2024 and 2027. Setting stringent emission targets for both CO2 and NOx through realistic regulations has caused engine calibrators to expand their toolbox from the engine to the powertrain to enable simultaneous NOx reductions and engine efficiency improvements. [EPA-HQ-OAR-2019-0055-1320-A1, pp.11-12]

Advances in thermal management, air handling and electrification technologies enable high catalyst performance required to reduce NOx to meet the proposed emission standards. [EPA-HQ-OAR-2019-0055-1320-A1, p.12]

Thermal management of the SCR system is critical to achieving low NOx emissions during low load operation. Traditionally, under colder exhaust operating conditions, engines would be calibrated to run hotter via higher idle speeds, late fuel injection into cylinders or by injecting fuel over the DOC to keep aftertreatment hot, both of which result in additional fuel consumption and CO2 emissions. Recent emission control packaging architectures have included innovations in materials and designs to minimize thermal losses from the exhaust system. Double-walled exhaust pipes and canning designs with either air gaps or ceramic fiber insulation – as well as packaging exhaust components close together in a compact space, referred to as a 'one-box system' – help retain exhaust heat over long periods. [EPA-HQ-OAR-2019-0055-1320-A1, p.12]

In addition to passive ways to retain heat in the exhaust system, technologies can be installed on engines that deliver exhaust heat when needed. It is possible to use bypass hardware to minimize heat loss in turbochargers or EGR coolers, upstream of the exhaust system. All modern diesel engines include turbochargers to provide boost and increased fuel economy and EGR systems to control NOx emissions. These can both contribute to lower exhaust temperatures by either converting the heat into useful boosting work or reducing the combustion temperature for in-cylinder NOx control, which results in lower heat energy in the exhaust stream through their operation. During low-speed operation and low exhaust flow, a turbocharger offers limited boost. Therefore, in the future, engines may employ turbocharger and EGR bypass valves that can be activated at times when it is more desirable to deliver hot exhaust to downstream catalysts for warm-up and stay-warm operation. Transient response challenges that may result from bypass systems can be resolved with electric assist motors built into the turbocharger or by the addition of an electric or mechanically driven boost compressor. [EPA-HQ-OAR-2019-0055-1320-A1, p.13]

At low load, a bypass alone may not yield enough heat using standard diesel engine combustion techniques. Several advanced thermal management strategies will provide options for engine manufacturers to calibrate engines to simultaneously heat up exhaust and save fuel, which can offset the costs of the technologies to their customers. Technologies such as fuel burners and electric heaters in combination with cylinder deactivation and advanced aftertreatment systems have been demonstrated to achieve ultra-low NOx levels without increasing CO2 emissions [3] [4] [5]. The reason for this is due to their efficiency in generating heat compared to traditional methods of late post-injection of fuel across a DOC. In fact, these technologies have been tested across several drive cycles in conjunction with the systems in the SwRI demonstration program. Results for the FTP show the ability to meet 0.012 g/bhp-hr with a 1.6% reduction in CO2. Depending on the actual calibration and control of the heat source, the system can be optimized to reduce both NOx and CO2 or favor one of these for greater reductions while holding the other neutral. [EPA-HQ-OAR-2019-0055-1320-A1, p.13]

[5] A. Matheaus, G. Neely, C. Sharp, J. Hopkins and J. McCarthy, Jr., ‘Fast Diesel Aftertreatment Heat-up Using CDA and an Electric Heater (SAE 2021-01-0211),’ SAE WCX, April 2021.

Cylinder deactivation (CDA) is an established technology on light-duty vehicles, with the primary objective of reducing fuel consumption and CO2 emissions. This technology combines hardware and software computing power to, in effect, 'shut down' some of an engine’s cylinders, based on the power demand, and keep the effective cylinder load in an efficient portion of the engine map without burning more fuel. Based on decades of experience with CDA on passenger cars and trucks, CDA is now being adapted to heavy-duty diesel engines. On a diesel engine, CDA is programmed to operate differently than on gasoline engines, with the goal of the diesel engine running hotter in low load situations by having the pistons that are firing do more work. This programming is particularly important for vehicles that spend a lot of time in creep and idle operation modes. During low load operation, CDA has resulted in exhaust temperatures increasing by 50°C to 100°C when it is most needed to maintain effective conversion of NOx in the SCR. In some demonstrations, CDA has been combined with a 48V mild hybrid motor with launch and sailing capability to extend the range of CDA operation over the engine, and this may deliver multiplicative CO2 reductions from these synergistic technologies [15]. [EPA-HQ-OAR-2019-0055-1320-A1, p.13]

[15] MECA, 'Technology Feasibility for Heavy-Duty Diesel Trucks in Achieving 90% Lower NOx Standards in 2027,' 2020. Online at https://www.meca.org/wp-content/uploads/resources/MECA_2027_Low_NOx_White_Paper_FINAL.pdf.

The use of variable valve actuation (VVA) is another approach for active thermal management. VVA approaches include: early exhaust valve opening (EEVO), early intake valve closing (EIVC) or late intake valve closing (LIVC), all considered active thermal management strategies. Both EIVC and LIVC reduce the amount of air trapped at valve closing. Both methods reduce the effective compression ratio and volumetric efficiency, resulting in lower NOx emissions and reduced air-fuel ratio, and in turn, hotter exhaust temperature. EEVO results in hotter exhaust gas to heat-up aftertreatment; however, more fueling is needed to maintain brake power output. This results in a CO2 emissions penalty that must be accounted for in calibrating for better fuel economy and higher engine-out NOx during hot operation when the SCR can be used to remediate NOx emissions. VVA offers some potential cost savings and is therefore used in some medium-duty applications as a fast heat-up strategy. OEMs will have multiple pathways at varying costs to achieve their thermal management objectives and achieve ultra-low NOx emissions in low-load and low-speed operation. [EPA-HQ-OAR-2019-0055-1320-A1, p.14]

Modern turbochargers have a variety of available design options enabling lower CO2 emissions by improving thermal management capability, such as: i.) state of the art aerodynamics, ii) electrically-actuated wastegates that allow exhaust gases to by-pass the turbocharger to increase the temperature in the aftertreatment, and iii.) advanced ball bearings to improve transient boost response. These and other technologies are available to support further reductions in CO2 and emissions. More advanced turbochargers are designed with a variable nozzle that adjusts with exhaust flow to provide more control of intake pressure and optimization of the air-to-fuel ratio for improved performance (e.g., improved torque at lower speeds) and fuel economy. These variable geometry turbochargers (VGT), also known as variable nozzle turbines (VNT) and variable turbine geometry (VTG), also enable lower CO2 emissions through improved thermal management capability to enhance aftertreatment light-off. Finally, modern turbochargers have enabled engine and vehicle manufacturers the ability to downsize engines, resulting in fuel savings without sacrificing power and/or performance. The latest high-efficiency turbochargers are one of the more effective tools demonstrated in the DOE SuperTruck program [17]. In addition to affecting the power density of the engine, turbochargers play a significant role in NOx and CO2 regulations compliance. Continuous improvement in turbocharger technology is making it possible to run very lean combustion (high air/fuel ratios), which is efficient. This improvement allows for very low particulate generation and even low engine-out NOx. [EPA-HQ-OAR-2019-0055-1320-A1, p.14]

> [17] Navistar, 'Final Scientific/Technical Report for SuperTruck Project: Development and Demonstration of a Fuel-Efficient, Class 8 Tractor & Trailer Engine System,' 2016.

Turbo-compounding is a variant of turbocharger technology that allows for the mechanical energy from the exhaust gas to be extracted and added to the engine crankshaft through a transmission. Mechanical turbo-compounding has been employed on some commercial diesel engines, and EPA estimated penetration to reach 10% in the U.S. by the time the Phase 2 GHG Regulation is fully implemented in 2027 [18]. An early 2014 version of a turbo-compound-equipped engine was used during the first stage of testing at SwRI under the CARB HD Low NOx Test Program, and the results from this engine with advanced aftertreatment have been summarized in several SAE technical papers [10, 8, 9]. While turbo-compounding has the potential to reduce fuel consumption, it can result in lower exhaust temperatures that can challenge aftertreatment performance. Therefore, it is important to consider turbo-compound designs that incorporate bypass systems during cold start and low load operation or electrically driven turbo-compounding systems where the unit can be placed after the aftertreatment system. Driven turbochargers can be used to control the speed of the turbomachinery independently of the engine's exhaust flow and vary the relative ratio between engine speed and turbo speed. Driven turbochargers may be utilized for several reasons, including performance, efficiency, and emissions. Considered an 'on-demand' air device, a driven turbocharger also receives transient power from its turbine. During transient operation, a driven turbocharger will behave like a supercharger and consume mechanical or electrical energy to accelerate the turbomachinery for improved engine response. At high-speed operation, the driven turbocharger will return mechanical or electrical power to the engine in the form of turbo-compounding, which recovers excess exhaust power to improve efficiency. This cumulative effect lets a driven turbocharger perform all the functions of a supercharger, turbocharger, and turbo-compounder. NOx emission control uniquely benefits from the application of driven turbochargers in several ways, including the ability to decouple EGR from boost pressure, reduce transient engine-out NOx, and improve aftertreatment temperatures during cold start and low load operation. Bypassing a driven turbine can provide quick temperature rises for the aftertreatment while still delivering the necessary boost pressure to the engine through supercharging, which also increases the gross load on the engine to help increase exhaust temperature [19]. Testing has shown that routing engine exhaust to the aftertreatment by bypassing a turbocharger is one of the most effective methods to heat up the aftertreatment [15]. [EPA-HQ-OAR-2019-0055-1320-A1, p.15]

> [19] J. Brin, J. Keim, E. Christensen, S. Holman and T. Waldron, 'Applying a Driven Turbocharger to Improve Diesel NOx Conversion,' in SAE WCX, Detroit, MI, 2022.

48-volt mild hybrid electrical systems and components are expected to make their way onto heavy-duty vehicles in the near future. These 48-volt systems can be found on many light-duty vehicle models (primarily in Europe) from Mercedes, Audi, VW, Renault and PSA. In the U.S., FCA is offering a 48-volt system on the RAM 1500 pick-up and the Jeep Wrangler under the eTorque trademark. Because the safe voltage threshold is 60 volts, which is especially important when technicians perform maintenance on the electrical system, 48-volt systems are advantageous from an implementation standpoint. From a cost perspective, 48-volt systems include smaller starter and wire gauge requirements, offering cost savings from a high voltage architecture of a full hybrid. The U.S. Department of Energy's SuperTruck II program teams employed 48-volt technologies on their vehicles to demonstrate trucks with greater than 55% brake thermal efficiency. A recent study demonstrated through model-based simulations that a 48-volt technology package combined with advanced aftertreatment can achieve a composite FTP emission level of 0.015 g/bhp-hr [20]. [EPA-HQ-OAR-2019-0055-1320-A1, p.15]

> [20] F. Dhanraj, M. Dahodwala, S. Joshi, E. Koehler, M. Franke and D. Tomazic, 'Evaluation of 48V Technologies to Meet Future CO2 and Low NOx Emission Regulations for Medium Heavy-Duty Diesel Engines (2022-01-0555),' in SAE WCX, Detroit, MI, 2022.

Similar to the passenger car fleet, truck OEMs are considering replacing traditionally mechanically-driven components with electric versions to gain efficiency. Running accessories off of 48-volt electricity rather than 12-volts is more efficient due to reduced electrical losses and because components that draw more power, such as pumps and fans, have increased efficiency when operating at higher voltages. The types of components that may be electrified include, electric turbos, electronic EGR pumps, AC compressors, electrically heated catalysts, electric cooling fans, oil pumps and coolant pumps, among others. Another technology that 48-volt systems could enable is electric power take-offs rather than using an engine powered auxiliary power unit or idling the main engine during hoteling while drivers rest. MECA members supplying commercial 48V components for commercial vehicles believe that the technology may be feasible to apply to a limited number of engine families by 2024, and it is likely to see greater penetration by 2027, especially on Class 8 line-haul where full hybridization is less practical. [EPA-HQ-OAR-2019-0055-1320-A1, pp.15-16]

Mild hybridization covers a range of configurations, but a promising one includes an electric motor/generator, regenerative braking, electric boost and advanced batteries. Stop/start deployment also provides a thermal management benefit to the aftertreatment by preventing cooling airflow through the aftertreatment during hot idle conditions. In this way, 48-volt mild hybridization is complementary technology to CDA and start-stop capability, allowing the combination of multiple technologies on a vehicle to yield synergistic benefits and justify the cost. By shutting off the engine at idle or motoring using start/stop, micro hybrid technology can help to maintain aftertreatment temperature by avoiding the pumping of cold air through the exhaust. Capturing braking energy and storing it in a small battery for running auxiliary components when the engine is off offers another CO2 reducing strategy for OEMs to deploy. [EPA-HQ-OAR-2019-0055-1320-A1, p.16]

In lighter medium-duty applications, advanced start-stop systems have been developed that use an induction motor in a 48-volt belt-driven starter-generator (BSG). When the engine is running, the motor, acting as a generator, will charge a separate battery. When the engine needs to be started, the motor then applies its torque via the accessory belt and cranks the engine instead of using the starter motor. The separate battery can also be recharged via a regenerative braking system. In addition to the start-stop function, a BSG system can enhance fuel economy even during highway driving by cutting off the fuel supply when cruising or decelerating. Such systems can also be designed to deliver a short power boost to the drivetrain. This boost is typically 10 to 20 kW and is limited by the capacity of the 48V battery and accessory belt linking the motor to the crankshaft. New designs are linking the BSG directly to the crankshaft and allowing additional power boost of up to 30kW to be delivered, giving greater benefits to light and medium commercial vehicles [15]. [EPA-HQ-OAR-2019-0055-1320-A1, p.16]

> [15] MECA, ‘Technology Feasibility for Heavy-Duty Diesel Trucks in Achieving 90% Lower NOx Standards in 2027,’ 2020. Online at https://www.meca.org/wp-content/uploads/resources/MECA_2027_Low_NOx_White_Paper_FINAL.pdf.

Full hybrid configurations are currently found on several models of light-duty passenger cars and light trucks in the U.S. and a limited number of medium-duty trucks. These include models that can also be plugged-in to enable some all-electric operation, usually described as all-electric range (AER). A full hybrid can enable electrification of many of the components described above for mild hybrid vehicles, but the higher voltages allow for more parts to be electrified and to a larger degree. Full hybrids implement larger electric motors and batteries, which support greater acceleration capability and regenerative braking power. Mild hybridization is well-suited to heavy-duty vehicles used for long-haul transportation because of the limited fuel economy of a full hybrid at highway speeds. Full hybridization and electrification are more practical for small heavy-duty vehicles (e.g., Class 4-6) that do not travel long distances or operate for long periods without returning to a central location. Full hybrid vehicles have made the highest penetration into parcel delivery, beverage delivery and food distribution vehicles because they can take advantage of regenerative braking in urban driving [21]. We expect to see some application of strong hybrids combined with a low NOx engine to reduce CO2 emissions in several vocational applications. Integrated electric drivetrain systems, consisting of a fully qualified transmission, motor and power electronics controller, are now commercially available. With power levels of over 160kW and the ability to meet high torque requirements, these systems enable electrification of medium-duty commercial vehicles. There is also an increasing number of electric drivetrain solutions up to 300kW that are suitable for Class 8 vehicles that can be used with either battery or fuel cell power sources [15]. [EPA-HQ-OAR-2019-0055-1320-A1, pp.16-17]

> [15] MECA, 'Technology Feasibility for Heavy-Duty Diesel Trucks in Achieving 90% Lower NOx Standards in 2027,' 2020. Online at https://www.meca.org/wp-content/uploads/resources/MECA_2027_Low_NOx_White_Paper_FINAL.pdf.
>
> [21] CARB, 'Draft Technology Assessment: Heavy-Duty Hybrid Vehicles,' 2015.

As noted above, the types of technologies that enable electrified heavy-duty vehicles are already commercially available with more anticipated by 2027. MECA supports EPA's proposal to revise the Phase 2 vehicle GHG limits for MY 2027 based on EPA's analysis in this rule of the projected penetration of heavy-duty electric vehicles. Some barriers that remain, such as infrastructure needs, should be addressed through state and national efforts. MECA supports EPA revisiting projections of heavy-duty electric vehicle penetration, as challenges to electrification of the heavy-duty sector are overcome. [EPA-HQ-OAR-2019-0055-1320-A1, p.17]

Organization: *Motor & Equipment Manufacturers Association (MEMA)*

MEMA strongly discourages any technology mandates (i.e., avoid ZEV mandates). [EPA-HQ-OAR-2019-0055-1322-A1, p. 8]

Organization: *Moving Forward Network (MFN)*

EPA's rule stringencies do not fully reflect the technological capability to reduce emissions of nitrogen oxides from conventionally powered vehicles in the timeframe of this rule. The co-proposed options considered by EPA (Options 1 and 2) are not reflective of the full range of emissions reductions technology potential for diesel engines. Below, we outline ways in which the proposal must be strengthened to reflect the best available evidence. [EPA-HQ-OAR-2019-0055-1277-A1, p. 23]

Mild hybridization is an emissions reduction strategy that is synergistic with the VVA strategy mentioned previously. Mild hybridization can offer a lower cost opportunity for emissions reductions than strong hybrids, particularly with increasing movement towards 48V electrification. Higher voltage allows for more efficient power distribution, and shifting the number of hydraulically or mechanically-driven accessories to electric operation has benefits not just for efficiency but also packaging of the engine compartment. A 48V mild hybrid system simply builds upon these already existing rationale for moving to a 48V electric system and uses it for better regenerative braking and more responsive stop-start. [EPA-HQ-OAR-2019-0055-1277-A1, p. 25]

Many strategies would benefit from 48V mild hybridization—for example, a 48V electrical system is an enabler for devices like an electrically driven turbocharger,103 an electrically heated catalyst,104 or an electrified EGR pump.105 Recent analysis shows such a system deployed in a medium-duty application is capable of simultaneously meeting both a 20 mg/bhp-hr standard on the FTP cycle and its 2027 GHG target.106 A recent study by Eaton at SwRI showed that an electric heater connected to a 48V system worked synergistically with CDA, further reducing fuel use while improving NOx reduction at low-load conditions.107 According to the paper, this system, too, is broadly applicable to a range of heavy-duty classes and operating conditions. [EPA-HQ-OAR-2019-0055-1277-A1, p. 25]

105. McCarthy 2019b

106. Dhanraj et al. 2022

107. Matheaus et al. 2021

The cost-competitiveness of these 48V systems is well established. One analysis projected that 48V systems in line-haul operation would cost less than $7,000 for up to 4 percent fuel savings in 2025.108 A recent report by the National Academies estimated 2022 costs for a 48V mild hybrid system to range from $4,584- 5,010 (Class 4) up to $10,080-11,700 (Class 8 vocational), noting that “costs will likely come down in the 2022 and 2030 timeframes,” with fuel savings ranging from 16-22 percent depending on the duty cycle.109 These costs are substantially reduced compared to those previously used by EPA.110 [EPA-HQ-OAR-2019-0055-1277-A1, p. 25]

110. Compare to EPA-420-R-16-900, p. 2-175.

EPA noted the potential for opposed-piston engines to play a significant role in emissions reductions:

“Opposed-piston engine technology has not yet been proven feasible in Class 8 on-highway applications, but if feasibility is shown, then the technology could provide another pathway to ultralow NOx, high efficiency engine technology for heavy-duty vehicle fleets. If the demonstration project cited above is successful, then it may lead to early-commercial deployment of opposed piston diesel engines for heavy-duty on-highway applications in the near-term. As such, it may be reasonable to anticipate commercialization of heavy-duty opposed-piston diesel engine technology by model year 2027.” (EPA Draft RIA, p. 22) [EPA-HQ-OAR-2019-0055-1277-A1, p. 26]

Recent data from Achates Power confirms the success of the cited demonstration program, with wide margins for compliance. Lab test results confirm that this engine design is capable of meeting simultaneously EPA’s greenhouse gas engine emissions requirements for 2027 and the Omnibus rule, “in a cost-effective and robust manner.”111 [EPA-HQ-OAR-2019-0055-1277-A1, p. 26]

111. Salvi, A., Redon, F., Youngren, D., and Fromm, L., “Low CO2, Ultralow NOx Heavy Duty Diesel Engine: Experimental Results,” SAE Technical Paper 2022-01-0426, 2022, doi:10.4271/2022-01-0426.

Not only has this novel design been confirmed in the lab, but this engine is now being deployed in real world operation, pulling freight for Wal-Mart. Early test results indicate compliance with EPA’s proposed in-use requirements.112 [EPA-HQ-OAR-2019-0055-1277-A1, p. 26]

112. https://achatespower.com/wp-content/uploads/2022/04/Achates-Power-In-Use-Emissions-Measurements.pdf

It is vital that EPA avoid incentivizing natural gas vehicles, which perpetuate reliance on fossil fuels whose production and use—from drilling to transporting to refining to storage—is rife with emissions that adversely impact communities, public health, and the environment.175 Moreover, supporting combustion technologies, particularly where additional fueling infrastructure is required, locks in long-term fossil fuel investments that risk becoming stranded assets. [EPA-HQ-OAR-2019-0055-1277-A1, p. 44]

175 https://envhealthcenters.usc.edu/infographics/infographic-natural-gas

Beyond the financial and stranded cost risks, there is also risk that natural gas vehicles will not achieve their claimed emission levels. Preliminary results from an on-going study of 200 medium- and heavy-duty vehicles show that natural gas vehicles emit well above their certification when tested in the real world.176 Thirty natural gas vehicles certified at the current NOx standard of 0.2 grams per brake horsepower hour (g/bhp-hr) and 15 natural gas vehicles certified at the optional low NOx standard of 0.02 g/bhp-hr were tested using a Portable

Emission Measurement System (PEMS). The results were alarming, with 0.2- certfied vehicles emitting, on average, roughly double their certification rate, and the 0.02-certified vehicles emitting roughly triple (Figure 7). [EPA-HQ-OAR-2019-0055-1277-A1, pp. 44 - 45]

> 176 https://ww2.arb.ca.gov/sites/default/files/2021-04/Natural_Gas_HD_Engines_Fact_Sheet.pdf

The study also found that “[a]s vehicles age and accumulate mileage, emission control systems can deteriorate as a result of natural degradation or mal-maintenance, which can lead to emissions that are often much higher than their certification standard.” A related study comparing technology specific emission control system deterioration found that as natural gas vehicles age, they can and do pollute more than their diesel counterparts and, by extension, exponentially more than EVs.177 [EPA-HQ-OAR-2019-0055-1277-A1, p. 45]

> 177 Marc Besch et al., In-use emissions and chassis dynamometer emissions rates of heavy-duty diesel and alternative fueled vehicles operating in Southern California, 30th CRC Real World Emissions Workshop (Mar. 2021) [hereinafter “30th CRC Real World Emissions Presentation”].

Organization: *National Association of Clean Water Agencies (NACWA)*

NACWA asks that EPA include NZEVs that are fueled by biogas produced by POTWs. Utilities across the country are expanding their efforts to recover the resources available from wastewater, including biogas that is produced from the anaerobic digestion of biosolids. Biogas production can be increased through co-digestion of biosolids and food waste, which is becoming more common as communities and states encourage or require the diversion of food waste from landfills. Since the disposal of food waste in landfills increases the fugitive methane emissions from landfills, co-digestion and use of biogas as a vehicle fuel can result in significant greenhouse gas emission reductions. EPA should therefore provide incentives for renewable biogas – whether produced from anaerobic digestion of biosolids alone or co-digestion with food waste – to be used as a vehicle fuel for NZEVs. [EPA-HQ-OAR-2019-0055-1343-A1, p.2]

Organization: *National Center for Health Research (NCHR)*

Lastly, in addition to phasing out diesel engines, the rule should make clear that natural gas-powered engines are not the solution. Research has shown that trucks running on methane can be as polluting as diesel, and any future investments should ensure cleaner energy sources, rather than incentivize the extraction, transportation or use of fossil fuels. [4] [EPA-HQ-OAR-2019-0055-1227-A1, p.1]

Organization: *National Propane Gas Association (NPGA) and Propane Education & Research Council (PERC)*

The current propane vehicle market as well as the evolution of renewable propane are evidence of the industry's abilities to meet the environmental goals of the agency. Renewable propane has entered the U.S. and European markets, unveiling new opportunities to transition from conventional fuel and equipment to renewable fuel produced from vegetable oil, used cooking oil, animal tallow and biomass waste. 14 Renewable propane maintains all the advantages of conventional propane, but with even greater reductions in lifecycle carbon dioxide emissions.15 One domestic operation based in Louisiana produces approximately 75 million gallons/year of renewable fuels including renewable propane.16 Starting this year, a new biorefinery in California is slated to produce 13 million gallons/year of renewable propane.17 The produced renewable propane is currently utilized in the propane market throughout the U.S. with a carbon intensity of 20.5 – 43.5 gCO2e/MJ.18 Further, renewable propane is identical in chemical composition to conventional propane, which means that it is a drop-in replacement for conventional propane applications and engines and equipment do not require add-ons or modification to utilize renewable propane or a blend of renewable and conventional propane, in contrast to diesel and electric alternatives. [EPA-HQ-OAR-2019-0055-1263-A1, pp.3-4]

We ask the agency to consider the modifications and advantages shared through this comment in order to present the most beneficial landscape for all alternative fuels. We recognize the value of uniform nationwide standards to relieve burdens for our manufacturing partners. Under Option 1 of the proposal, the propane industry is best positioned to assist the agency in reaching its environmental goals. We encourage the agency to revise the maximum butanes standard to yield further benefits. Also, we emphasize the innovation of the propane industry in the research, development, and deployment of renewable propane to progress the advantages the industry offers. [EPA-HQ-OAR-2019-0055-1263-A1, p.4]

Organization: *Natural Gas Vehicles for America (NGVAmerica)*

Ultra-low NOx medium- and heavy-duty natural gas-powered trucks and buses are on the road today and perform at levels that are 95 percent below the current federal NOx standard and 98 percent below the federal particulate matter standard. When fueled by renewable natural gas (RNG) recovered from landfills, wastewater treatment facilities, and food and agricultural waste digesters, these trucks and buses produce greenhouse gas emissions that are up to 331 percent lower than diesel powered vehicles and deliver carbon neutral or carbon negative emissions in even the most specialized real-world applications. [EPA-HQ-OAR-2019-0055-1330-A1, p.1]

The latest data from California's Low Carbon Fuel Standard program demonstrates how clean and low carbon RNG fueled heavy-duty vehicles truly are. The most recent data (Q4, 2021) confirms that the average carbon intensity (CI) value of California's bio-CNG mix is -62.3 gCO2e/MJ and has had a negative CI value for the last six reporting quarters. California fleets that fueled with bio-CNG in 2020 achieved carbon negativity for the first time ever, with an annual average CI score of -5.85 gCO2e/MJ. The 2021 annual average CI was -44.41 gCO2e/MJ as a result of more, lower-carbon fuel coming into the mix.1 [EPA-HQ-OAR-2019-0055-1330-A1, p.2]

1https://ww2.arb.ca.gov/resources/documents/low-carbon-fuel-standard-reporting-tool-quarterly-summaries

Based on data available from 2021, NGVAmerica and the Coalition for Renewable Natural Gas calculate that domestically produced, low-carbon, renewable natural gas now accounts for 64 percent of natural gas used in on-road transportation.2 This important milestone is made possible by the U.S. EPA's implementation of the Renewable Fuel Standard, and other important regulatory programs that encourage the production of low-carbon fuels and the deployment of advanced clean technology vehicles. [EPA-HQ-OAR-2019-0055-1330-A1, p.2]

2 https://ngvamerica.org/wp-content/uploads/2022/05/NGV-RNG-Decarbonize-2022-5.2.22.pdf

We fervently believe that the Administration's decarbonization and clean air goals will only be achieved by focusing on a multi-technology approach that includes cost-effective carbon-negative solutions like RNG trucks that can begin accruing and compounding significant clean air and carbon reductions right away. We, therefore, respectfully request that EPA build on the incentives it has proposed in this rulemaking to included additional incentives for natural gas vehicles and engines. [EPA-HQ-OAR-2019-0055-1330-A1, p.2]

Many state and local authorities have requested that EPA adopt a new limit of 0.02 grams per brake-horsepower-hour (0.02 g/bhp-hr), a level that is 90 percent more demanding than the current federal limit of 0.20 g/bhp-hr. California state authorities have adopted new engine standards that require moving to the 0.02 NOx level beginning in 2027. [EPA-HQ-OAR-2019-0055-1330-A1, p.3]

Engine manufacturers that produce EPA and California Air Resources Board (CARB) certified natural gas-powered engines already meet the 0.02 NOx standard, and more, even cleaner natural gas engines are on the way as a result of research and development programs that include additional development of lower-polluting engines and also hybridization of natural gas platforms. Businesses that produce lower polluting natural gas engines and vehicles can deliver the benefits this rulemaking seeks without waiting for new developments or the statutory lead time requirements imposed on EPA. Natural gas-powered vehicles also provide significant reductions of greenhouse gas emissions due to the fact that an increasingly larger percentage of natural gas used in the on-road transportation market is renewable natural gas, sourced from renewable feedstock. [EPA-HQ-OAR-2019-0055-1330-A1, p.3]

In this rulemaking, EPA can lead the way for new, cleaner emission standards; but EPA also could have a more immediate impact on emissions if it accelerates efforts to turn over the legacy fleet of older, more polluting vehicles, and ensures that natural gas vehicles and other cleaner fueled vehicles are given full consideration. The Bipartisan Infrastructure Law provides billions in new funding to accelerate use of low- and zero-emission technologies. To ensure that the benefit of this funding is maximized, it is critical that policy makers give full consideration of all available options and evaluate technologies based on cost-effectiveness as opposed to trying to ensure that one technology is selected. [EPA-HQ-OAR-2019-0055-1330-A1, p.3]

There is no reason to wait to act until new standards are developed and implemented since vehicles and engines powered by natural gas are already available today, delivering significant emission reductions across every on-road application. In the near term, EPA could have a significant impact on the market for commercially available, natural gas vehicles by leveling the playing field in incentives and ensuring fair regulatory treatment relative to other technologies. EPA’s notice is extremely frank about the reasons that it has provided significant regulatory credits for electric vehicles. Pertinent parts of that discussion are provided here:

As stated in the HD GHG Phase 2 rulemaking, our intention with these multipliers was to create a meaningful incentive to those considering adopting these qualifying advanced technologies into their vehicles. The multipliers are consistent with values recommended by California Air Resources Board (CARB) in their supplemental HD GHG Phase 2 comments.802 CARB’s values were based on a cost analysis that compared the costs of these technologies to costs of other conventional GHG-reducing technologies. Their cost analysis showed that multipliers in the range we ultimately promulgated would make these technologies more competitive with the conventional technologies and could allow manufacturers to more easily generate a viable business case to develop these technologies for heavy-duty vehicles and bring them to market at a competitive price. As we stated in the 2016 HD GHG Phase 2 final rule preamble, we determined that it was appropriate to provide such large multipliers for these advanced technologies at least in the short term, because they have the potential to provide very large reductions in GHG emissions and fuel consumption and advance technology development substantially in the long term. However, because the credit multipliers are so large, we also stated that we should not necessarily allow them to continue indefinitely. Therefore, they were included in the HD GHG Phase 2 final rule as an interim program continuing only through MY 2027. [EPA-HQ-OAR-2019-0055-1330-A1, pp.3-4]

The above restated passages appear on pages 17594 and 17595 of the Federal Register notice. It is noteworthy that the credits are not based on current emission benefits. The credits are based on cost with the intent on making electric vehicles 'more competitive' with conventional technologies. We are mindful that EPA has sought to balance the use of credits with other safeguards, but it is also important to note that these incentives are anti-competitive when it comes to natural gas vehicles because they create an unlevel playing field. Natural gas vehicles involve significant cost (like hydrogen fueled vehicles) due to their low-volume and the cost of the storage vessels and systems. Like electric vehicles operating on a renewable grid,3 natural gas vehicles when powered by RNG have the potential to deliver significant greenhouse emission reductions and therefore should be similarly encouraged. Thus, EPA has every reason to treat natural gas vehicles like electric vehicles when providing regulatory incentives – moreover, since natural gas has largely not qualified for these incentives, it is reasonable to extend similar size incentives for natural gas technology at least for a period of time to allow natural gas trucks to increase in market share. [EPA-HQ-OAR-2019-0055-1330-A1, p.4]

> 3 According to the U.S. Energy Information Administration, in 2020 renewable energy sources accounted for about 12.6% of total U.S. energy consumption and about 19.8% of electricity generation.

It is important to note that these Ultra-Low NOx natural gas engines – commercially available, scalable and supported by a mature infrastructure of fuelers and suppliers today – perform at or below certification standards during a full range of duty cycles. A report by the University of California Riverside's College of Engineering – Center for Environmental Research and Technology found that while natural gas technology was cleaner than certified standards across duty cycles, its heavy-duty diesel counterparts emitted higher levels of NOx than their certification standards in the same duty cycle.4 [EPA-HQ-OAR-2019-0055-1330-A1, pp.4-5]

> 4 'Ultra-Low NOx Natural Gas Vehicle Evaluation,' University of California Riverside, CE-CERT, November 2016. Available at: https://cngvc.org/wp/wp-content/uploads/2017/03/UCR-UltraLow-NOx_NGV-Evaluation_Final-Report.pdf.

Further, a November 2019 study by the International Council on Clean Transportation found that a disproportionate amount of NOx emissions from heavy-duty diesel vehicles is emitted during low-speed operation characteristic of urban driving.5 By contrast, natural gas engines thrive in such operational environments. [EPA-HQ-OAR-2019-0055-1330-A1, p.5]

> 5 'Current state of NOx emissions from in-use heavy-duty diesel vehicles in the United States,' International Council on Clean Transportation, November 2019. Available at: https://theicct.org/publications/nox-emissions-us-hdv-diesel-vehicles.

Natural gas vehicles also offer significant climate change benefits. Compared to diesel, natural gas engines fueled with geologic natural gas provide marginal greenhouse gas emission reductions, that like diesel fueled vehicles will be reduced by improvements in engine efficiency and power-train efficiencies. When fueled with renewable natural gas (RNG or biomethane) captured from agricultural, food, landfill or wastewater, even greater CO_2 and greenhouse gas benefits are achieved, up to 331 percent lower than diesel.6 Renewable natural gas supplies can be delivered to customers for direct use or blended with supplies of conventional natural gas either as CNG or LNG as needed to provide low emissions. [EPA-HQ-OAR-2019-0055-1330-A1, p.5]

6 Dependent upon RNG source. Reductions of 45% up to 331% compared to diesel; values based on CARB LCFS program data under CA-GREET 3.0.

RNG currently accounts for an estimated 64 percent of the fuel used in on-road vehicles, and many fuelers are committed to ensuring much higher levels in the near future. The latest data from California's Low Carbon Fuel Standard program demonstrates how clean and low carbon these heavy-duty, high fuel use vehicles truly are. The most recent data (Q4, 2021) confirms that the average carbon intensity (CI) value of California's bio-CNG is below zero at -62.3 gCO2e/MJ and has had a negative CI value for last six reporting quarters. California fleets that fueled with bio-CNG in 2020 achieved carbon negativity for the first time ever, with an annual average CI score of -5.845 gCO2e/MJ. 2021's annual average CI was -44.41 gCO2e/MJ as a result of increased supplies of dairy gas.7 [EPA-HQ-OAR-2019-0055-1330-A1, p.5]

7 https://ww2.arb.ca.gov/resources/documents/low-carbon-fuel-standard-reporting-tool-quarterly-summaries

RNG benefits the whole country. Based on a review of California and U.S. EPA data, it appears that current allocation of RNG across the country is roughly split with 50 percent in California and the remainder outside California. It is expected that, as more states move to incentivize RNG production either through low-carbon fuel standards or clean-fuel standards, the uptake of RNG outside California will continue to increase. In addition, we currently anticipate that RNG will replace most if not all conventional natural gas in the on-road market. Last year, NGVAmerica members committed that 80 percent of natural gas motor fuel dispensed through their operations will be from renewable sources by 2030. Given accelerating production, we now project that our industry will meet that goal by 2025. This projection is based on recent annual growth and the desire of large transit agencies and trucking fleets to maximize the environmental benefit of using natural gas vehicles. [EPA-HQ-OAR-2019-0055-1330-A1, pp.5-6]

Investments in Ultra Low-NOx and Near Zero emission natural gas vehicle technologies can greatly benefit communities, especially the underserved and marginalized communities in metropolitan and industrial areas. With vehicle costs closer to that of diesel than other competing technologies, and fuel price differentials of up to $1.50 (more in recent months as diesel prices continue to spike) less than diesel fuel per diesel gallon equivalent, natural gas transportation provides the largest and most cost-effective reductions in transportation-related pollutants than other powertrain options commercially available today or near-term.8 Based on our estimates, natural gas is at least twice as cost-effective as electric power-trains in offsetting NOx emissions. [EPA-HQ-OAR-2019-0055-1330-A1, p.6]

8 https://www.ngvamerica.org/environment/.

Natural gas is a viable transportation fuel for a variety of applications from medium- and heavy-duty on-road vehicles, including short-haul and regional trucking, refuse trucks, school buses, utility and other work trucks, and transit buses of all types. With the advent of the Cummins 15-liter9 and Westport's HPDI10 technology, natural gas is well poised to tackle the largest of Class 8 trucks including trucks that operate in the most demanding conditions. Hyliion's hybrid and hyper truck offer significant emission reductions, uncompromised 1,000-mile range, and power, and in the case of the hyper truck, an all-electric range of up to 75 miles.11 For these reasons, natural gas as a transportation fuel provides the most significant near-term and long-term opportunity to deliver meaningful and cost-effective emission reductions for fleets and communities. Despite these advantages, regulatory treatment and the lack of incentives for natural gas vehicles continues to limit the market penetration of new natural gas vehicles. [EPA-HQ-OAR-2019-0055-1330-A1, p.6]

As recognized in the Biden Administration's 'Long Term Strategy,' released during the COP26 policy discussions, achieving net-zero emissions will require focusing on a variety of strategies beyond just electrification. The plan states that the Administration will 'prioritize clean fuels like carbon-free hydrogen and sustainable biofuels where electrification is challenged.' The plan elsewhere specifically calls attention to the limitations of electrification and the need to expand efforts to promote the use of low-carbon biofuels and hydrogen: 'Accelerated research, development, demonstration, and deployment of lower-carbon fuels, such as clean hydrogen and sustainable biofuels, will contribute to the decarbonization of applications that may be more difficult to electrify including aviation and *marine transportation and some medium- and heavy-duty trucking segments*.' (emphasis added).12 [EPA-HQ-OAR-2019-0055-1330-A1, pp.6-7]

> 12 https://www.whitehouse.gov/wp-content/uploads/2021/10/US-Long-Term-Strategy.pdf

In comments to the previous administration, NGVAmerica has consistently advocated that renewable natural gas should be a key part of any inclusive mix of technologies and fuels. Today, renewable natural gas is the dominant fuel used in on-road natural gas vehicles. In 2021, RNG made up 64 percent (up from 53 percent in 2020) of the fuel used in natural gas vehicles in the United States.21 In California with its Low Carbon Fuel Standard Program, 92 percent of natural gas motor fuel consumed in 2020 was produced from renewable sources.22 Based on recently released data from CARB, we believe that RNG will make up about 98 percent of fuel consumed in NGVs in California in 2021. Renewable natural gas is already helping to achieve significant reductions in carbon emissions. As noted earlier, bio-CNG sold in California now has an average carbon intensity that is negative. [EPA-HQ-OAR-2019-0055-1330-A1, pp.9-10]

> 21 https://ngvamerica.org/wp-content/uploads/2022/05/NGV-RNG-Decarbonize-2022-5.2.22.pdf

22 NGVAmerica and Coalition for Renewable Natural Gas. Available at: https://ngvamerica.org/wp-content/uploads/2021/05/NGV-RNG-CA-Decarbonize-2020-FINAL-6.2.21.pdf.

In the coming years, the carbon intensity of renewable natural gas is expected to be even lower as greater amounts of extremely, low-carbon biomethane is produced and used in natural gas vehicles. A recent analysis estimates that by 2024, the average carbon intensity of renewable natural gas in California will be -101.74.23 Our industry fully expects and is committed to ensuring that renewable natural gas use will continue to increase in the coming years. NGVAmerica's members recently endorsed a commitment that by 2030, 80 percent of natural gas on-road motor fuel in the United States will be derived from renewable sources, rising to 100 percent by 2050.24 [EPA-HQ-OAR-2019-0055-1330-A1, p.10]

24 NGVAmerica Statement on Climate Change, July 29, 2021. Available at: https://ngvamerica.org/wp-content/uploads/2021/08/NGVAmerica-Climate-Change-Statement-FINAL-7.29.21.pdf.

NGVAmerica agrees that climate change is cumulative; the longer we wait, the harder it gets to solve. We also believe that there is no single perfect, affordable, and immediate solution to addressing transportation related climate change emissions. Some of us are old enough to remember the promises of the past: methanol will be the dominant alternative fuel, soon everyone will drive a car that gets 65 miles to the gallon (Al Gore's PNGV Program), MTBE in gasoline, an 18-year-old born today will drive a hydrogen fueled vehicle (George Bush 2002). Today, the big promise is electrification of everything. But as former Energy Secretary Ernest Moniz recently opined, 'full electrification of the economy is simply not an achievable goal.'25 He went on to remark that hard to decarbonize sectors of the economy will require a fuel source, such as low-carbon fuels and carbon negative fuels. [EPA-HQ-OAR-2019-0055-1330-A1, p.10]

25 https://www.spglobal.com/platts/en/market-insights/latest-news/oil/091521-moniz-wants-to-turn-more-focus-to-clean-alternative-fuels-negative-emissions

We support electrification where it makes sense and even anticipate that in the near future an increasing larger share of heavy-duty natural gas vehicles will employ hybrid electric powertrains.26 Significant investments are being made to bring natural gas/hybrid powertrains to market. Light-duty natural gas fueled vehicles could someday employ similar hybrid-electric powertrains as hybrid vehicles become more prolific. [EPA-HQ-OAR-2019-0055-1330-A1, p.10]

26 https://www.truckinginfo.com/10150691/hyliion-launches-improved-hybrid-truck-powertrain-all-electric-hypertruck-erx

EPA's motor vehicle certification standards should be used to support vehicles that operate on low-carbon fuels. If there are no vehicle incentives, technologies with higher upfront costs will continue to struggle. They will struggle even more if other more expensive technologies are given generous incentives or are mandated. We ask that EPA provide NGVs with the same level of support and incentive as it does electric vehicles in order to encourage manufacturers to ramp up production and achieve economies-of-scale. [EPA-HQ-OAR-2019-0055-1330-A1, p.11]

Such incentives are needed to encourage the commercialization of a greater variety of vehicle models and technologies in the US market and stimulate competition. For example, the Westport HPDI technology has now been successfully deployed for heavy-duty trucks in Europe for about five years, providing significant GHG emission reductions thanks to its diesel-like performance, but is currently not commercialized in North America. The availability of both compressed and liquefied natural gas vehicles (CNG and LNG), using either spark ignition or compression ignition engine technologies, together with the continuous deployment of CNG and LNG refueling infrastructure27 and increasing share of biomethane28, are all important factors that encourage fleets to invest in CNG and LNG trucks29. As a result, over 10,000 CNG and LNG trucks have been registered in Europe in 2021, accounting for 3.6 percent of all new trucks registered in 2021 and representing over 40 percent increase compared with 2020.30 [EPA-HQ-OAR-2019-0055-1330-A1, p.11]

For greenhouse gas emissions, we previously have requested that EPA use the 0.15 factor for greenhouse gas emissions as a way to reward manufacturers for RNG use and to create an efficient method of calculating the benefit of renewable natural gas until EPA moves to adopt a well-to-wheels regulatory approach for all fuels, or until EPA is prepared to come up with a detailed assessment and emission factor specific to RNG use. A benefit of the 0.15 factor is that it is consistent with the fuel efficiency credits and has been used in the past in EPA's regulations. Importantly such factors must be in place for sufficient number of years to allow automakers to incorporate them into their production plans, which typically require 2 – 3 years lead-time. [EPA-HQ-OAR-2019-0055-1330-A1, pp.11-12]

The concept of adjusting the regulatory framework to encourage low-carbon fuels is explained in much greater detail in a recent NGVA Europe study, which we urge EPA to review.31 [EPA-HQ-OAR-2019-0055-1330-A1, p.12]

> 31 https://www.ngva.eu/wp-content/uploads/2021/04/Frontier-Economics-Study-for-NGVA-Carbon-abatement-costs-260421-stc.pdf

EPA's regulatory programs should be designed to accelerate the production of trucks and engines that reduce carbon emissions – they should not be designed to favor or support one technology over others. EPA famously indicated that electric vehicles are a game changer and therefore warrant treatment that other technologies do not. But low-carbon fuels that achieve carbon neutrality or carbon negative emissions right now are also a game changer, and they too should be encouraged. [EPA-HQ-OAR-2019-0055-1330-A1, p.12]

There is no reason not to provide an incentive for natural gas trucks operating on low-carbon biofuel, when the alternative is that fleets will continue to rely on petroleum fueled vehicles if not provided a cleaner alternative. [EPA-HQ-OAR-2019-0055-1330-A1, p.12]

Organization: *Neste US, Inc*

Renewable diesel is a safe, proven, and affordable solution that is ready to play a larger role in the country's energy mix to address climate change. Neste's renewable diesel is fully compatible with all diesel engines and, because it has similar chemical composition to fossil diesel, can be used as a drop-in replacement fuel. Unlike fossil diesel, however, Neste's renewable diesel contains near-zero aromatics or impurities, has a high cetane number to ensure efficient and clean combustion, and can significantly reduce life-cycle greenhouse gas (GHG) emissions. [EPA-HQ-OAR-2019-0055-1225-A1, p.1]

EPA should acknowledge Renewable Diesel's role in climate policy

PA should acknowledge the utility of renewable diesel and encourage its use in heavy-duty vehicles as a method of GHG emissions without relying on EVs. While electrifying heavy-duty vehicle fleets may eventually significantly reduce GHG emissions across the country, by overlooking the use of renewable diesel in favor of full electrification, EPA is missing a quicker and similarly effective way to reduce such emissions. [EPA-HQ-OAR-2019-0055-1225-A1, p.4]

The Renewable Fuel Standard is the cornerstone of the U.S. climate policy

Neste is concerned by other commenters urging the Agency 'to establish standards requiring 100 percent of all new heavy-duty vehicles be zero-emission no later than 2035.3 While EPA has stated this rulemaking is not considering that action, it is worth noting that any EV mandate is inconsistent with the statutory mandate of the Renewable Fuel Standards (RFS), which incorporates the congressional assumption that de-carbonization of liquid fuel will remain a cornerstone of the United States' climate policy for the foreseeable future.4 Because Congress directed EPA to implement the RFS program, EPA cannot promote the substantial or exclusive use of another technology that will frustrate Congress’ RFS goals. [EPA-HQ-OAR-2019-0055-1225-A1, p.4]

3 Id. at 17420.

4 Americans for Clean Energy v. EPA, 864 F.3d 691, 697 (D.C. Cir. 2017) (quoting the Energy Independence and Security Act, Pub. L. No. 110-140, 121 Stat. 1492 (2007) (noting that Congress enacted requirements in the Renewable Fuels Program in order to 'move the United States toward greater energy independence and security, [and] to increase the production of clean renewable fuels').

The majority of heavy-duty vehicles run on diesel. As noted above, Neste’s renewable diesel, because it has the same chemical composition of fossil fuel, can be used as a one-to-one replacement in vehicles already built to run on diesel. Renewable diesel is significantly cleaner than fossil fuel and today can reduce GHG emissions by up to 75% over the fuel’s life cycle today, with the potential to improve as producers reduce GHG emissions from their own operations and additional lower carbon intensity feedstock are developed. In fact, in California, the use of renewable diesel in the transportation sector accounted for 30% of the state’s GHG emissions reductions.5

Organization: *Northwest Alliance for Clean Transportation*

[*From Hearing Testimony, April 12, 2022; Alex Schay*] I take this opportunity to point out that renewable natural gas engine technology, or RNG technology, is currently the only technology that, A, meets the 0.02 grams per braking horsepower NOx requirement, the requirement that is proposed as the 90-percent reduction via this draft rule; and, B, RNG technology is the only currently commercially-available technology that enables payloads of 105,000 pounds with a range of 600 to 700 miles, thereby meeting most duty cycles for nearly all trucking fleets. With that context in mind, I suggest to those on the call and those taking testimony that RNG technology is the most appropriate technology at present both for reducing NOx emissions and for making significant near-term reductions in greenhouse gas emissions. With that backdrop in mind, I would ask the EPA to consider providing incentives that enable fleet owners to cover the additional vehicle costs and the additional costs associated with setting up a fueling station that can fuel RNG vehicles and/or provide incentives for making alterations to maintenance bays that enable safe maintenance of vehicles that use a gaseous fuel rather than a liquid fuel. If you should have additional questions about the Northwest Alliance For Clean Transportation, please feel free to visit us at www.nwalliance.net, and with that, I yield my time. [EPA-HQ-OAR-2019-0055-2867]

Organization: *Odyne Systems, LLC (Odyne)*

Methods to eliminate or abate high NOx emissions during PTO operation: There are various methods to provide zero emissions PTO operation. The PTO receives power from the traction engine of a medium or heavy-duty vehicle to typically power equipment mounted to the vehicle. [EPA-HQ-OAR-2019-0055-1264-A1, p.7]

Manufactures of powertrains can use known methods that reduce NOx such as cylinder deactivation (CDA), dual-SCR aftertreatment configuration and heated diesel exhaust fluid (DEF) dosing during PTO operation. [EPA-HQ-OAR-2019-0055-1264-A1, p.7]

Electrification is a different method that can be used to eliminate NOx and GHG emissions during PTO operation, by enabling the engine to be turned off. A plug-in electric Power Take-Off system (ePTO) is recharged by the grid and then operated in a charge depleting mode of operation when equipment requires power typically provided through a PTO by the chassis engine. Since the battery is recharged by the grid, the emissions during PTO operation are zero if the battery has sufficient capacity to provide all the energy required to operate the truck mounted equipment. [EPA-HQ-OAR-2019-0055-1264-A1, p.7]

Sometimes an ePTO battery system is not of sufficient capacity to provide the needed energy to keep the truck engine off until the battery can be recharged by the grid. In those situations, such as during double shift operations, mutual assistance during emergencies, or if the grid is unavailable or down, the engine can be used in a hybrid ePTO mode of operation to prevent the high emissions associated with a conventional PTO. Such a hybrid ePTO mode operates the engine under a higher load that quickly recharges the batteries using the engine while continuing to power equipment. Once the batteries are recharged to a predetermined levels with the engine, the engine is then turned off, eliminating the low load mode of PTO operation that produces high NOx. [EPA-HQ-OAR-2019-0055-1264-A1, p.8]

NREL tested the ePTO in a charge sustaining mode (hybrid ePTO mode) rather than a charge depleting mode to measure a worst-case scenario. The hybrid ePTO mode begins with a certain battery state of charge (SOC), then as truck equipment requires power, depletes the battery, and then the ePTO system uses the chassis engine to recharge the battery while continuing to power the PTO load, resulting in a net-zero change in the battery SOC. During recharging of the battery, the engine is under a higher load, resulting in much better NOx abatement than an engine running continuously to supply power to a PTO. See Page 54: Text and graph from the published report 75782. https://www.nrel.gov/docs/fy20osti/75782.pdf [EPA-HQ-OAR-2019-0055-1264-A1, p.8]

A previously published report by SCAQMD using measured field data showed that more than half of an average workday is composed of a combination of idling and PTO based on a large sample of trucks operating at worksites, resulting in high emissions. [EPA-HQ-OAR-2019-0055-1264-A1, p.8]

Page 48: text from NREL report ’Results indicate that the hybrid vehicle produces roughly an order of magnitude less NOx exhaust emissions and consumes 4~5 times less fuel than the conventional vehicle while operating a PTO work cycle.' [EPA-HQ-OAR-2019-0055-1264-A1, pp.8-9]

NREL report Page 54: text from the published report 'This is calculated by assuming all the energy used by the electric PTO system will be recharged back to the batteries via the vehicle engine, so no plug-in capabilities were considered here (e.g. if the vehicle PTO used 1kW-hr of energy then 1kW-hr of energy would be put back on the battery packs by engine recharging mode operation). The vehicle is a plug-in hybrid so in reality vehicle out emissions for this scenario could effectively go down even lower. Also, emissions during charging of the batteries could potentially be optimized to have lower NOx emissions as shown in the engine mapping section discussed previously. Figure 54 demonstrates that the Odyne electric PTO system can have a dramatic impact of an order of magnitude on NOx emissions from utility vehicles when performing stationary PTO work. [EPA-HQ-OAR-2019-0055-1264-A1, p.9]

NREL report page 57, figure 56, shows much lower total NOx output with ePTO in hybrid mode in comparison to a conventional PTO in which the engine is on continuously during PTO worksite operation. [EPA-HQ-OAR-2019-0055-1264-A1, p.9]

There are PTO electrification systems (ePTOs) in production for a wide range of heavy-duty truck PTO applications that eliminate NOx emissions for typical duty cycles and are capable of reducing NOx by up to 90% and GHGs by 80% even if not grid recharged, per testing performed by NREL and paid for by CARB. [EPA-HQ-OAR-2019-0055-1264-A1, p.10]

Organization: *Renewable Energy Group*

[*From Hearing Testimony, April 13, 2022, Ezra Finkin*] I'm the senior manager for corporate affairs and development with Renewable Energy Group. Renewable Energy Group operates 11 bio refineries in the U.S. and Europe. Last year, REG produced 480 million gallons of cleaner fuel including biodiesel, enabling 4.1 million metric tons of carbon reduction. I would like to state our support for EPA in its finding included in this proposed rule that the pool of biodiesel available to fleets across the country is of very high quality and that biodiesel blends about 5 percent, or B5, are expected to operate in future catalysts and filters developed to meet this proposed standard. Through this proposed rule, future emission control technologies are expected to generate closer to zero tailpipe emissions, to deliver cleaner air benefits to communities in need of cleaner air. When fueled with high blends of biodiesel, we can expect significant climate benefits alongside expected clean air benefits from the heavy-duty vehicles equipped with these next-generation emission control technologies. Today, biomass-based diesel, including biodiesel, plays a large role in decarbonizing the heavy-duty on and offroad fleets. Just over 3 billion gallons of biomass-based diesel were supplied to the U.S. market last year and, according to the Energy Information Administration, substantial growth is expected this year and next. EPA's proposed renewable volume obligation for 2022 recognizes the availability of feedstock and production capacity to expand volumes of biomass-based diesel this year. Three billion gallons of biomass-based diesel equates to about 21 million tons of greenhouse gas emission reductions. In a single year the benefits of the switch to biomass-based diesel represents the emissions generated from nearly 4.5 million passenger vehicles or switching them overnight to a truly zero-emission option, according to EPA's greenhouse gas equivalencies calculator. We recognize that the climate crisis is a code red emergency, to use President Biden's own words. A crisis requires immediate action and with growing volumes of biomass-based diesel we have a ready to go option to reduce emissions today from the heavy-duty fleet. Analysis included in this proposed rule provides evidence for the need to support the use of higher biodiesel plans by engine manufacturers. Many engine makers already approve the use of 20 percent biodiesel, or B20, and those that currently do not approve B20 should consider evidence presented in this proposal to do so. We encourage other engine manufacturers to consider support for higher blends above 20 percent, or B20. Widespread access to high-quality biodiesel across the country, the use of higher blends of biodiesel may contribute significantly to immediate term greenhouse gas emission reductions while also allowing next-generation emission control technologies to function properly to deliver air quality benefits to those communities most in need of cleaner air. Thank you very much for the opportunity to present our views and suggestions at this public hearing. REG will also be submitting written topics. [EPA-HQ-OAR-2019-0055-2867]

[*From Hearing Testimony, April 13, 2022, Martin Haverly*] I'm the senior manager of research and development and innovation with Renewable Energy Group. As you've already heard from my colleague earlier, Renewable Energy Group is an industry leader delivering high-quality low-carbon biodiesel and renewable diesel fuel to markets in the U.S. and abroad. I would like to reiterate our support for the EPA and its finding that the pool of biodiesel available to vehicle and equipment operators across the country is of very high quality while biodiesel blends above 5 percent, or B5, are not expected to impede the performance of next-generation after treatment, devices developed to meet this proposed new tailpipe standard. According to findings, including the proposed rulemaking, EPA reports that the presence of metals and other quality metrics has greatly improved. These findings are derived from a robust fuel sampling survey conducted by the agency, the California Air Resources Board, and the National Renewable Energy Laboratory. The vast majority of fuel samples show the presence of impurities far below specified and allowable levels. We support EPA in its proposal to require engine manufacturers to provide detailed evidence to document claims of off-spec biodiesel when seeking an exemption of test results as part of an end-use compliance. Decades ago, REG developed processes to produce and deliver to the marketplace the highest quality biodiesel. As the industry leader, we are encouraged to know that our competitors have also stepped up to develop and deliver high-quality low-carbon bio-based diesel fuel including biodiesel, and that plays a disproportionate role in reducing transportation sources of greenhouse gas emissions. Evidence in this proposed rule demonstrates that access to high-quality biodiesel is prevalent and that higher blends of biodiesel are not expected to impede the performance of after treatment devices. Through the renewable fuel standard, the EPA has proposed growth in bio-based diesel volumes in 2022 and we believe that even more fuel may be delivered to the market this year and beyond. Blends of 20 percent biodiesel, or B20, should be the norm and we encourage engine manufacturers to work alongside fuel producers like Renewable Energy Group to support blends above B20. The diesel commercial trucks of the future can deliver cleaner air through the next-generation after treatment devices while delivering even greater climate benefits when operating using higher blends of low-carbon bio-based diesel fuels. Thank you very much for this opportunity to present our views and suggestions at this public hearing. As already noted, Renewable Energy Group will also be submitting written comments and we look forward to supporting the EPA as you continue your important mission to fight global warming and increase investment in renewable fuels while improving air quality and reducing emissions. [EPA-HQ-OAR-2019-0055-2867]

Organization: *State Soybean Associations (SSA)*

While we appreciate EPA's efforts to reduce nitrogen oxide ('NOx') and greenhouse gas ('GHG') emissions from heavy-duty vehicles, we are concerned with EPA's reliance on electric vehicles ('EVs') to justify more stringent emission standards from such vehicles, while failing to fully recognize the emissions reductions that renewable fuels provide. In terms of GHG reductions, the rule also understates the greenhouse gas lifecycle analysis from EVs and gives short shrift to the potential role that renewable fuels play in advancing the administration's climate change objectives. [EPA-HQ-OAR-2019-0055-2035-A1, p.1]

The State Soybean Associations urge EPA to better reflect the importance of biodiesel and renewable diesel in reducing tailpipe emissions from heavy-duty vehicles. While EVs are a valuable tool for emissions reduction, they require replacing full fleets, which is costly and could take decades, especially in the heavy-duty vehicle industry. Biodiesel and renewable diesel, on the other hand, can be used immediately in place of traditional diesel in existing vehicles while producing a significantly reduced level of emissions. [EPA-HQ-OAR-2019-0055-2035-A1, p.1]

Increased EV penetration into the heavy-duty market is not required for emissions reduction. Where more stringent standards need to be justified or met, increased use of biodiesel and renewable diesel, which can be used immediately and is compatible with current fleets, can help EPA achieve those goals. [EPA-HQ-OAR-2019-0055-2035-A1, p.2]

EV mandates also are inconsistent with the statutory mandate of the Renewable Fuel Standard ('RFS'), which employees a market-forcing approach to creating annual standards. This is true for the partial EV mandate in the proposal and would be increasingly true for higher EV penetration rates, if adopted. Indeed, in the Proposed Rule EPA notes that it has received comments requesting that the agency 'establish standards requiring 100 percent of all new heavy-duty vehicles be zero-emission no later than 2035.'2 EPA cannot meet Congressional intent behind the RFS to increase the volume of renewable fuels in the transportation sector while implicitly mandating vehicles that do not run on any type of liquid fuel. When Congress enacted the RFS, it signaled that the decarbonization of liquid fuel should and would remain a cornerstone of the United States' climate policy. EPA cannot promote the exclusive use of a technology that will frustrate these Congressional mandates. [EPA-HQ-OAR-2019-0055-2035-A1, p.2]

2 Id. at 17420.

Moreover, EPA fails to acknowledge that electrification is not the most economically or technologically feasible option for achieving its desired emission reductions. As CARB has recognized in its 2022 Draft Scoping Plan Update, which recognizes the importance of continued use of liquid fuels, the 'transition to complete ZEV technology will not happen overnight. ICE vehicles from legacy fleets will remain on the road for some time, even after all new vehicle sales have transitioned to ZEV technology.'3 For that reason, CARB concluded that, '[i]n addition to building the production and distribution infrastructure for zero-carbon fuels, the state must continue to support low-carbon liquid fuels during this period of transition….'4 [EPA-HQ-OAR-2019-0055-2035-A1, p.3]

3 Cal. Air Resources Bd., '2022 Draft Scoping Plan Update' (May 10, 2022), at 152.

4 Id.

Given the significant benefits associated with renewable fuels and the uncertainties regarding the benefits of EVs, EPA should not favor EVs over other vehicles that can run on renewable fuels in planning for the decarbonization of the U.S. transportation sector. [EPA-HQ-OAR-2019-0055-2035-A1, p.3]

Organization: *Tenneco*

In this white paper, Tenneco highlights the feasibility of meeting that level of NOx emission standards with a burner as a "drop-in addition" to existing ATS. Additionally, the Tenneco recommended solution promotes DPF durability and the data demonstrates "CO2 neutrality" can be achieved.[EPA-HQ-OAR-2019-0055-1284-A1 p.1]

In Stage 3 of the CARB Low-NOx Demonstration, one technology package was shown to be feasible for meeting the NOx limit of 0.02 g/hph on the FTP [1-3]. This package included a market available 15-liter engine, otherwise known as the Stage 3 engine, up-fitted with cylinder de-activation (CDA) and recalibrated to provide hotter exhaust during a cold start, as well as a dual-dosing aftertreatment system that included advanced catalyst formulations. [EPA-HQ-OAR-2019-0055-1284-A1 p.1]

1. Zavala, B., Sharp, C., Neely, G., and Rao, S., "CARB Low NOx Stage 3 Program - Aftertreatment Evaluation and Down Selection", SAE Technical Paper 2020-01-1402, 2020.

2. Neely, G., Sharp, C., Pieczko, M., and McCarthy, J. Jr., "Simultaneous NOx and CO2 Reduction for Meeting Future CARB Standards Using a Heavy-Duty Diesel CDA-NVH Strategy," SAE Int. J. Engines 13(2):2020.

3. Sharp, C., Neely, G., Zavala, B., and Rao, S., "CARB Low NOx Stage 3 Program - Final Results and Summary," SAE Technical Paper 2021-01-0589, 2021.

Tenneco is developing an exhaust burner for an alternative technology package that offers several advantages relative to the "Stage 3 system". A cut-away image of the burner and an illustration of the complete technology package are provided below. The package utilizes the "classic" heavy-duty aftertreatment system (ATS) in production today, which includes a diesel oxidation catalyst (DOC), a diesel particulate filter (DPF), a selective catalytic reduction (SCR) catalyst, and an ammonia slip catalyst (ASC). The exhaust burner is located upstream of the DOC; it is relatively small (not to scale in the figure) and thus can be located within the engine compartment, adjacent to the turbocharger outlet.[EPA-HQ-OAR-2019-0055-1284-A1 p.1]

To demonstrate the technical feasibility of the burner-based technology package, Tenneco and Eaton (supplier of a Roots blower that provides combustion air to the burner) funded testing at SwRI [4,5]. This testing utilized a production market available 15-liter engine (i.e. not up-fitted with CDA) running on its production calibration. The ATS utilized was of the classic architecture (illustrated above) and included catalyst formulations similar to those in the Stage 3 system, in the hydrothermally-aged state. The exhaust burner was located immediately downstream of the turbocharger. The downpipe between the burner and DOC was insulated. [EPA-HQ-OAR-2019-0055-1284-A1, p.2]

4. Harris, T., McCarthy Jr., J., Sharp, C., Zavala, B., Matheaus, A., "Meeting Future NOx Emissions Limits with Improved Total Fuel Efficiency", presented at the ATZ Heavy-Duty, On- and Off-Highway Engines 2021 Conference, Rostock, Germany, December 1, 2021.

5. McCarthy, Jr., J., Matheaus, A., Zavala, B., Sharp, C. et al., "Meeting Future NOx Emissions Over Various Cycles Using a Fuel Burner and Conventional Aftertreatment System," SAE Technical Paper 2022-01-0539, 2022.

NOx and CO2 results from several FTP tests (Federal Test Protocol – for heavy duty engines) carried out during this testing campaign are shown in the table below [4]. The "burner on" cases differed in terms of the burner control strategy, specifically with respect to an "on/off switch" associated with the DPFout temperature. The best NOx result obtained, 0.023 g/hph, does not quite meet the standard of 0.02 g/hph, but it is worth emphasizing that this result was obtained without any modification of the engine's calibration; co-optimization of the engine and aftertreatment calibrations should enable the 0.02 g/hph NOx emissions limit to be achieved. [EPA-HQ-OAR-2019-0055-1284-A1, p.2]

4. Harris, T., McCarthy Jr., J., Sharp, C., Zavala, B., Matheaus, A., "Meeting Future NOx Emissions Limits with Improved Total Fuel Efficiency", presented at the ATZ Heavy-Duty, On- and Off-Highway Engines 2021 Conference, Rostock, Germany, December 1, 2021.

It can be noted in the table that "CO2 neutrality" was also achieved in the test with the lowest NOx. This surprising result was realized because a) the burner took over some of the responsibility for exhaust thermal management from the engine, and b) the burner is more efficient than the engine at converting fuel energy into exhaust heat. Data collected during this study provided clues to the engine's behavior, indicating that the engine transitioned from thermal management mode (extra exhaust heat-producing) to fuel economy mode much sooner when the burner operated (see illustration below). Therefore, the engine consumed less fuel over the cycle, and this amount of fuel saved was almost equal to that consumed by the burner. In addition, an energy balance analysis conducted on the data indicated that the efficiency of the burner at converting fuel into exhaust heat is ~85%, with a majority of the ~15% inefficiency associated with heating up the combustion air utilized by the burner. In comparison, the efficiency of current engine measures for converting fuel into extra exhaust heat is ~60% [6]. [EPA-HQ-OAR-2019-0055-1284-A1, p.2]

6. Kovacs, D., Rauch, H., Rezaei, R., Huang, Y. et al., “Modeling Heavy-Duty Engine Thermal Management Technologies to Meet Future Cold Start Requirements”, SAE Technical Paper 2019-01- 0731, 2019.

The burner testing at SwRI also included vocational and low-load engine test cycles [5]. On the beverage cycle, tailpipe NOx was reduced from 2.15 g/hph to near zero (0.001 g/hph), while an additional 13.5% CO2 was emitted. On the new low-load cycle (LLC) compliance test, tailpipe NOx was reduced from 0.918 to 0.006 g/hph, while CO2 increased by 9.0%. Once again, these results were obtained with a prototype burner and controls along with a production engine and calibration, so better results can be expected from continuing development. [EPA-HQ-OAR-2019-0055-1284-A1, pp.2-3]

5. McCarthy, Jr., J., Matheaus, A., Zavala, B., Sharp, C. et al., “Meeting Future NOx Emissions Over Various Cycles Using a Fuel Burner and Conventional Aftertreatment System,” SAE Technical Paper 2022-01-0539, 2022

It is worthwhile to compare these results with those from the Stage 3 technology package also tested at SwRI [2, 3]. As noted above, this package included a market available 15L engine up-fitted with cylinder de-activation (CDA), and a dual-dosing ATS (i.e. an ATS similar to that employed in the Tenneco-Eaton study, but that also included a light-off SCR). On the LLC, the burner system achieved much lower NOx (0.006 g/hphr) compared to the Stage 3 package (0.024 g/hphr), but produced an additional 8.4% CO2. It can be concluded that while the burner is more efficient than a conventional engine at converting fuel energy into exhaust heat, it is not as efficient as an engine equipped with CDA. [EPA-HQ-OAR-2019-0055-1284-A1, p.3]

2. Neely, G., Sharp, C., Pieczko, M., and McCarthy, J. Jr., "Simultaneous NOx and CO2 Reduction for Meeting Future CARB Standards Using a Heavy-Duty Diesel CDA-NVH Strategy," SAE Int. J. Engines 13(2):2020.

3. Sharp, C., Neely, G., Zavala, B., and Rao, S., “CARB Low NOx Stage 3 Program - Final Results and Summary,” SAE Technical Paper 2021-01-0589, 2021.

The test results detailed above identify two remaining challenges for the burner technology package. First, on the FTP cycle, engineering margin is required for the NOx emissions value; even 0.020 g/hph is not sufficient, but 0.016 g/hph might be acceptable. Second, on the LLC, the burner is consuming too much additional fuel. The testing and simulation studies described below address both of these issues. [EPA-HQ-OAR-2019-0055-1284-A1, p.3]

One means of providing NOx margin on the FTP is to use the burner to pre-heat the ATS before the engine is started. Pre-heating was investigated in a separate testing study conducted at Tenneco [7]. This study used the same burner as in the SwRI testing, a 13L engine, and a classic ATS with substrates similarly sized to those used in the SwRI testing described above. Important learning from this study included:

- Using lean combustion conditions for pre-heating results in low CO, HC and NOx emissions, and rapid warming and activation of the DOC drives the CO and HC to zero after only a few seconds.
- An air flow rate greater than that required to sustain combustion within the burner enables it to be operated at a higher power without over-heating the DOC (in the figure below, the DOC-in temperature is being limited to ~500°C by the burner's controls); this means that a higher-capacity air pump will be required if pre-heating is desired.
- Most of the heat produced by the burner during pre-heating is stored in the DOC and DPF, but this heat is rapidly transferred to the SCR once the engine is turned on and begins to produce exhaust (see DPF-out temperature plot below).
- Pre-heating for 300s enabled the DPF-out temperature to exceed the 300°C before 60s of the cold FTP cycle has elapsed; pre-heating for 180s was nearly as effective. Once the engine has been turned on, the burner can be operated at higher average power to compensate for a shorter preheating period (this strategy was employed in the 3-min pre-heating case).[EPA-HQ-OAR-2019-0055-1284-A1, p.3]

7. Harris, T., Bellard, R., Muhleck, M., and Palmer, G., "Pre-Heating the Aftertreatment System with a Burner," SAE Technical Paper 2022-01-0554, 2022.

To connect these results to the Tenneco-Eaton-SwRI test results described above, a "1D" model of the SwRI test system was developed using the software GT-POWER. This model included nearly all of the relevant physics and chemistry needed to predict accurately the NOx emissions at the tailpipe. Data from the cold FTP tests (with and without the burner operating) run at SwRI were used to calibrate the model; it validated well against LLC test results (see plots below). [EPA-HQ-OAR-2019-0055-1284-A1, p.4]

This model was used first used to investigate the effect of pre-heating on NOx emissions. The simulation results presented below correspond to cases for 3, 1, and 0 minutes of pre-heating. It can be seen that even 1 minute of pre-heating can significantly increase the DPF-out temperature at 100s into the cold-start FTP cycle relative to operating the burner only when the engine is running. More importantly, this temperature increase translates into lower NOx emissions at the tailpipe (TP); the 1-min pre-heating provided a 20% reduction in NOx relative to the no-pre-heating case. A similar improvement was observed on the hot-start FTP as well. Collectively, a 20% reduction in NOx on both the cold and hot cycles would enable the 0.023 g/hph NOx emissions test result noted above to be reduced to 0.019 g/hph. [EPA-HQ-OAR-2019-0055-1284-A1, p.4]

Next, the model was used to consider substituting an SCR-on-DPF (SCRF) for the DPF in the classic ATS. An SCRF is simply a DPF with higher porosity walls that can be coated with some amount of SCR catalyst. With an SCR-on-DPF, some of the SCR catalyst will warm up and become active for NOx reduction much sooner in the FTP test, because that material does not have to wait for the DPF substrate itself to be heated by the burner. In the plot below, simply deleting the DPF from the ATS is shown as the limiting case. Substituting an SCRF for the DPF does not provide NOx emissions as low as that limiting case, but the impact is still positive. The positive effect is strongly dependent on the "loading" of SCR catalyst on the SCRF (i.e. the number of catalytic sites), as well as on the amount of ammonia (NH_3) stored on the catalyst at the beginning of the FTP. [EPA-HQ-OAR-2019-0055-1284-A1, p.5]

Finally, the model was used to consider the burner's fuel consumption by the burner during the LLC. The on/off control of the burner that was utilized in the Tenneco-Eaton-SwRI testing produced a large oscillation in the DPF-out temperature (apparent in the simulation results below). A new control strategy was developed that provided much tighter control of that temperature. More importantly, this new strategy provided a 35% reduction in fuel consumed by the burner for an equivalent level of NOx at the tailpipe. In addition, this control strategy only requires the calibration of a single parameter to achieve the desired trade-off between NOx emissions and fuel consumed (this parameter is being varied in the plot on the right).[EPA-HQ-OAR-2019-0055-1284-A1, p.5]

In conclusion, we believe that the alternative technology package considered here (i.e. burner plus classic ATS) optimizes the lowest NOx emissions performance without compromising CO_2 emissions and eases the integration into the vehicle. The test results from SwRI supports the conclusion; the additional test and simulation results presented above indicate that the remaining challenges can be overcome. Furthermore, this package provides some clear advantages relative to the Stage 3 technology package:

- The burner is a "drop-in addition" to existing ATS, with the potential to minimize re-design and revalidation of the ATS itself.
- The burner (as well as the electrically-powered air pump) readily fits within the existing engine compartment space; this means that re-arranging components on the engine, or re-designing the hood, will not be necessary.
- The burner promotes DPF durability in two different ways. First, it reduces DPF active regeneration frequency by enhancing passive regeneration, building upon the reasonable amount of passive regeneration afforded by the classic ATS as a result of its action to raise the exhaust temperature when the engine is experiencing low-load conditions. Second, the burner can improve DOC temperature control when the DOC is receiving fuel to produce heat for active regeneration of the DPF.
- The burner, along with the DEF dosing system, can be operated to "post-load" NH_3 onto SCR after the engine has been turned off. This additional amount of NH_3 on the catalyst will facilitate NOx conversion during the next cold start, and will eliminate the need for extraordinary hardware (e.g. a heated DEF doser, or electrically heated mixer) that would enable DEF dosing to begin sooner during that start.[EPA-HQ-OAR-2019-0055-1284-A1, pp.5-6]

Organization: *Westport Fuels Systems (WFS)*

Long-haul road freight is recognized as one of the most challenging transport sectors to decarbonize due to the demanding use profiles, and the pressures of cost competitiveness. [EPA-HQ-OAR-2019-0055-1278-A1, p.1]

There is considerable expectation that Battery Electric and Hydrogen Fuel Cell technologies can provide the solutions to a future sustainable road freight sector, and the trajectory of many proposed rulemaking initiatives is presumptive of these technologies being ubiquitous across the freight fleet. [EPA-HQ-OAR-2019-0055-1278-A1, p.1]

While battery electric and fuel cell technologies can play a role, this commentary highlights why the options to decarbonizing freight must also include cost-effective approaches that include a central role for Internal Combustion Engines (ICEs), fueled by renewable natural gas and/or hydrogen (H2). [EPA-HQ-OAR-2019-0055-1278-A1, p.1]

ICE solutions using the WFS HPDI™ fuel system can significantly reduce emissions both at the tailpipe and across the lifecycle. As such, changes to policy frameworks that recognize more than the singular metric of zero tailpipe emissions will enable a greater diversity of solutions. This approach will better suit the diverse needs of the freight sector, and deliver faster, larger, CO2 reductions, at the lowest cost. [EPA-HQ-OAR-2019-0055-1278-A1, p.1]

As policymakers create frameworks to both encourage and support the deployment of new technologies, RNG and Hydrogen ICEs should be given equal footing to Fuel Cell Electric Trucks and battery electric trucks. [EPA-HQ-OAR-2019-0055-1278-A1, p.1]

Some policy considerations laid out in the EPA rulemaking docket referenced above prioritize battery electric and fuel cell trucks (ZEV). These technologies can certainly play a key role in transitioning to a sustainable, decarbonized heavy-duty road freight sector, but limiting the spectrum of options means missing an opportunity to accumulate reductions faster, particularly in the next 10-15 years. A holistic perspective of technology, environmental metrics and economics show that a broader range of solutions is not only required but is equally compelling and necessary if we are to reach CO2 reductions targets in a timely manner. [EPA-HQ-OAR-2019-0055-1278-A1, p.2]

Advances in ICE technology have already led to growing market adoption of ICEs using ultra low carbon biomethane. Increasing attention is being focused on the potential of Hydrogen ICE for heavy-duty vehicles. Many vehicle manufacturers, Tier 1 automotive suppliers, consultancies and academic institutes have disclosed R&D programs centered on hydrogen ICEs for heavy-duty, including Cummins, Deutz, Scania, Ricardo, AVL, Mahle, to name a few. These programs largely examine Spark Ignition ICE technology. Westport's HPDI Fuel System has been successfully integrated in commercial heavy-duty LNG trucks which in turn have been adapted for use with Hydrogen or 'H2 HPDI'. Engines optimized with H2 HPDI overcome many of the challenges of either spark ignited ICEs, or fuel cell and battery electric options, to deliver the attributes needed for sustainable freight operations: highest power density, highest efficiency, manufacturability and cost-effective CO2 abatement. [EPA-HQ-OAR-2019-0055-1278-A1, pp.2-3]

EPA's motor vehicle standards should be used to support vehicles that operate on low-carbon fuels. If there are no vehicle incentives, technologies with higher upfront costs will continue to struggle. They will struggle even more if other more expensive technologies are given generous incentives. We ask that EPA provide NGVs with the same level of support and incentive as it does electric vehicles in order to encourage manufacturers to ramp up production and achieve economies-of-scale. [EPA-HQ-OAR-2019-0055-1278-A1, p.2]

Such incentives are needed to encourage the commercialization of a greater variety of vehicle models and technologies in the US market and stimulate competition. For example, the Westport HPDI technology has now been successfully deployed for heavy duty trucks in Europe for about five years, providing significant GHG emission reductions thanks to its diesel-like performance, but is currently not commercialized in North America. The availability of both compressed and liquefied natural gas vehicles (CNG and LNG), using either spark ignition or compression ignition engine technologies, together with the continuous deployment of CNG and LNG refueling infrastructure1 and increasing share of biomethane2, are all important factors that encourage fleets to invest in CNG and LNG trucks3. As a result, over 10,000 CNG and LNG trucks have been registered in Europe in 2021, accounting for 3.6% of all new trucks registered in 2021 and representing over 40% increase compared with 20204. [EPA-HQ-OAR-2019-0055-1278-A1, p.2]

Frontier Economics in their study 'CO2 Emission Abatement Costs of Gas Mobility and Other Road Transport Options'5 considered a 2030 timeframe, and examined ICEs using liquefied natural gas (LNG) and liquefied biomethane (LBM), and fuel cell electric vehicles (FCEV). The target vehicle segment is Heavy Duty Vehicles (HDV), with 40-tonne gross vehicle weight capability, for use in long haul operation. [EPA-HQ-OAR-2019-0055-1278-A1, p.3]

5 https://www.frontier-economics.com/media/4643/carbon-abatement-costs.pdf

Compared to a reference diesel heavy-duty truck, analysis of purely tailpipe CO2 (Tank-To-Wheel, TTW) yields the expected 100% reduction via FCEV. The H2 HPDI ICE exhibits very high tailpipe CO2 reductions (97%) but falls short of the zero tailpipe CO2 metric due to the use of small quantities of diesel for ignition, the use of which is fundamental to the high efficiency and power density of H2 HPDI compared to H2 spark ignition ICE. On a Tank-to-Wheel basis the HPDI Liquified Biomethane (LBM) options produce ~20% CO2 reductions since they use fuel containing elemental carbon; the large benefits of biomethane are derived from the Well-To-Tank portion. [EPA-HQ-OAR-2019-0055-1278-A1, p.3]

On a Well-to-Wheel (WTW) basis, including vehicle manufacturing emissions, it is evident that there is a far greater range of CO2 reductions, and clearly the relationship between tailpipe CO2 and total CO2 reductions is not directly correlated to a simple tailpipe only perspective. [EPA-HQ-OAR-2019-0055-1278-A1, p.3]

Due to the high efficiency of HPDI, H2 HPDI can deliver equivalent CO2 reductions as fuel cell vehicles, though even with green hydrogen neither technology results in zero CO2. Indeed, the 40% biomethane option delivers similar CO2 reductions as the hydrogen pathways. Only the 100% biomethane pathway achieves zero WTW CO2. [EPA-HQ-OAR-2019-0055-1278-A1, p.3]

Acknowledging that most, if not all, decarbonization strategies represent added cost, the cost of CO2 abatement is a critical differentiating factor between technologies and should be carefully considered in any rulemaking, especially where there is broad parity in environmental performance. [EPA-HQ-OAR-2019-0055-1278-A1, p.3]

Both biomethane and hydrogen ICEs are strongly advantaged in this aspect due to their commonality with high volume diesel powertrains, resulting in lower capital cost estimates. Consequently, they result in far more cost-effective abatement strategies than fuel cell only strategies. Such is the economic advantage of HPDI that it is more cost effective to deploy H2 HPDI with 100% green hydrogen than it is to deploy fuel cell with the lower cost option of blue hydrogen. [EPA-HQ-OAR-2019-0055-1278-A1, p.3]

What is also evident is that while it is disadvantaged by a proposed policy focus on tailpipe CO2 emissions, the HPDI fuel system with biomethane is the most cost-effective pathway, offering the greatest overall CO2 reductions. This simply cannot be overlooked and must be strongly supported in any balanced road freight decarbonization strategy. [EPA-HQ-OAR-2019-0055-1278-A1, p.3]

The cost-effectiveness of the HPDI approach translates into far greater CO2 reductions for every dollar of public and private investment. [EPA-HQ-OAR-2019-0055-1278-A1, p.3]

One of the dimensions of sustainability laid out at the beginning of this commentary is energy efficiency. Efficiency translates into operating economics due to fuel costs and is increasingly important when considering the need to maximize the supply capacity of precious low-carbon renewable energy sources. [EPA-HQ-OAR-2019-0055-1278-A1, p.4]

It is acknowledged that full battery electric powertrains are the most energy efficient options available, and where they are suited to the operational demands of road freight they represent a valuable solution to decarbonization. However, concerns over their cost, weight, range and charging requirements mean there is considerable uncertainty about their suitability to long-haul, heavy-duty trucking. [EPA-HQ-OAR-2019-0055-1278-A1, p.4]

Given that 'grey hydrogen' should not be used in transport (produces no CO2 reduction, or even increases total CO2), hydrogen fueled options are reliant on blue or green hydrogen, that is not readily available at scale and is subject to competing demands for other industrial sectors. To this end, comparing energy efficiency remains an important aspect of comparing hydrogen vehicle options. [EPA-HQ-OAR-2019-0055-1278-A1, p.4]

The analysis presented so far demonstrates that while fuel cell solutions for heavy-duty trucks do provide 100% reduction in tailpipe CO2, this is a very narrow and misleading perspective. On a Well-To-Wheels basis, fuel cells produce no incremental CO2 reductions, no discernible increase in energy efficiency, and are a far more cost intensive approach to decarbonization compared with hydrogen internal combustion engines. [EPA-HQ-OAR-2019-0055-1278-A1, p.4]

Fuel cell solutions do offer an advantage over ICE – the absence of tailpipe sources of air pollutants (disregarding water vapor, and other vehicle pollutant sources such as tire and brake wear). [EPA-HQ-OAR-2019-0055-1278-A1, p.4]

To illustrate, consider the marginal cost-benefit analysis of the NOx abatement of fuel cell compared to hydrogen ICE with HPDI in the European Union context. For simplicity, we used illustrative NOx emissions of Euro VI trucks as the baseline6, recognizing that future Euro VII NOx levels are likely to be lower. [EPA-HQ-OAR-2019-0055-1278-A1, p.4]

6 TNO 2019 R10193

The most common technical approach to H2 ICE is spark ignition (SI), lean burn or stoichiometric. SI solutions are typically burdened with challenges surrounding lower compression ratio (knock limited) and high wall heat transfer losses, that impact both power density and efficiency. [EPA-HQ-OAR-2019-0055-1278-A1, p.4]

The HPDI fuel system is a unique ICE approach, successfully deployed in natural gas heavy-duty trucks. When adapted to hydrogen, the HPDI technology delivers significant performance advantages compared to spark ignition H2 ICE namely: higher BMEP and power density, and increased thermal efficiency. [EPA-HQ-OAR-2019-0055-1278-A1, p.4]

H2 HPDI has shown an ability to exceed the efficiency and power density of current diesel engines with recent simulations showing 52.5% BTE. High efficiency HPDI leads to lower WTT emissions than Spark Ignition and lower cost of CO2 abatement [EPA-HQ-OAR-2019-0055-1278-A1, p.4]

An important consideration for differentiating between different hydrogen technology options is fuel quality sensitivity. Because of the highly sensitive catalysts used in FCEVs, the hydrogen they use must be extremely pure or they risk permanently damaging/disabling the vehicle. FCEVs require hydrogen of purity 99.97% and furthermore contaminants at volumes as low as <0.00000004% sulphur or <0.0002% CH4 can destroy the catalyst. [EPA-HQ-OAR-2019-0055-1278-A1, p.4]

Transitioning heavy road freight to a sustainable, decarbonized, future is a clear societal need. It is also well understood to be a very challenging prospect. A number of potential powertrain / fuel / energy solutions exist, including battery electric, fuel cell electric, hydrogen ICEs and biomethane fueled ICEs. There is a large array of attributes that defines sustainable freight, and there are equally numerous trade-offs between different solutions; trade-offs that in all likelihood have different optima when seen from the differing perspectives of policy and end user. [EPA-HQ-OAR-2019-0055-1278-A1, p.5]

Westport Fuel Systems believes that an optimal pathway to sustainable road freight requires keeping all these options available, recognizing that different technical pathways are at different stages of technical and commercial viability, and that there will be segments of the road freight sector where, for example, battery electric may prove to be an ideal solution, but for heavier vehicles, in long haul operation, hydrogen and biomethane have a stronger set of attributes. [EPA-HQ-OAR-2019-0055-1278-A1, p.5]

Vehicle CO2 regulation should take account of carbon intensity of fuel/energy production. The extremely strict definition of HDZEV (from a CO2 perspective) as referenced in many sections of the EPA proposal rulemaking should be restated to encompass ICE options that are near-zero tailpipe CO2 and deliver equivalent or greater WTW CO2 reductions. Other pieces of legislation should encourage investment in all options that deliver urgently needed CO2 reductions while moving away from fossil fuels. As well, regulatory instruments used in the certification and type approval of vehicles should accommodate both spark ignition and dual-fuel HPDI hydrogen ICEs. [EPA-HQ-OAR-2019-0055-1278-A1, p.5]

Hydrogen fuel approved for use in transport should not be restricted to the same, extremely high purity, grades required for fuel cells. Hydrogen ICEs are much more tolerant to lower specification hydrogen, making them more robust in the marketplace, increasing compatibility with distribution systems, and eliminating some of the cost components of fuel cell grade hydrogen. [EPA-HQ-OAR-2019-0055-1278-A1, p.5]

US policy, regulation, investment and R&D funds/incentives should consider the highly competitive, cost-effective option of hydrogen and biomethane fueled ICEs among the suite of options to decarbonize the heavy-duty freight sector in the U.S. [EPA-HQ-OAR-2019-0055-1278-A1, p.5]

Key WFS commentary/observation highlights include:

- Internal Combustion Engine (ICE) powertrains fueled with hydrogen or biomethane (RNG) can achieve equal (or greater) CO2 reductions to fuel cells. [EPA-HQ-OAR-2019-0055-1278-A1, p.6]
- Hydrogen ICEs with the HPDI fuel system can be as energy efficient as fuel cell pathways. [EPA-HQ-OAR-2019-0055-1278-A1, p.6]
- While fuel cells will produce zero tailpipe NOx emissions, the marginal cost of NOx abatement is extremely high, and will only be further exacerbated by the future North American emissions standards. [EPA-HQ-OAR-2019-0055-1278-A1, p.6]
- Hydrogen ICEs are far less sensitive to fuel quality than fuel cells and can offtake hydrogen from diverse sources. [EPA-HQ-OAR-2019-0055-1278-A1, p.6]

Organization: *William F. Limpert*

EPA should also consider increased use of “green” hydrogen for transportation needs. This is hydrogen that is produced only with renewable energy. EPA should not consider hydrogen that is produced by the combustion of fossil fuels, or any other method that emits greenhouse gases. The green hydrogen should be produced as locally as possible to avoid long transmission pipes that create environmental damage, take away property rights, have an extreme explosion potential, and are vulnerable to terrorist acts. [EPA-HQ-OAR-2019-0055-1190]

Organization: *Valero Energy Corporation*

Neither the structure of the rule nor EPA's assessment of benefits and impacts should arbitrarily favor a single technology or fuel source. Just as we noted in comments on EPA's proposal for Revised 2023 and Later Model Year Light-Duty Vehicle GHG Emission Standards, EPA should not favor one technology over all others in designing standards to reduce air pollution particularly when doing so EPA disregards the pollution and other adverse impacts of that favored technology. Valero incorporates those comments as part of these comments and asks that EPA take those comments into consideration for this proposed rule. The comments are attached to these comments as Attachment A. [EPA-HQ-OAR-2019-0055-1328-A2, pp.6-7]

EPA Summary and Response

Summary:

Several commenters urge the EPA to establish standards that support neutrality and flexibility in fuel and technology options such that the standards do not limit innovation. One commenter specifically lists concerns regarding EPA providing incentives that are limited to specific technologies, and states that they would like all effective technologies to be recognized for emissions improvement contributions. Another commenter states that they would like EPA to revise the definition of “fuel” and other provisions to encourage all innovations that may achieve the same, or greater, emissions benefits beyond BEVs and FCEVs. These commenters suggest that for market fairness, any and all technologies that demonstrate proper emissions reductions should be able to qualify as zero or near-zero emissions.

Many commenters also discuss alternative fuel options. For example, several of commenters state their support for using hydrogen fuel in heavy-duty internal combustion engines (H2ICE). They state that EPA standards should support vehicles that operate on low-carbon fuels, and H2ICEs should be given equal consideration as fuel cell and battery electric trucks. One commenter states that their HPDI Fuel System has been adapted for use with hydrogen and has been integrated in commercial heavy-duty trucks; they further state that these trucks deliver sustainable freight options that are cost effective and achieve CO_2 reduction. Another commenter also suggests that there is wide industry support for hydrogen fuel in meeting NO_X limits while emitting zero tailpipe carbon emissions.

In addition, a subset of commenters further expressed their support for the widespread use of low carbon fuels. Some commenters urge the EPA to send what they characterize as “the right signal" by allowing certification of an ethanol-fueled compression ignition engine based on its emissions performance. Other commenters discussed the benefits of renewable natural gas and urge EPA to amend the greenhouse gas regulations to incorporate these benefits. One commenter also requested that EPA incentivize renewable natural gas. A subset of these commenters stated their support for renewable biogas produced at publicly owned treatment works (POTWs). They support near-zero emissions vehicles that are fueled by renewable biogas when ZEVs are not feasible as a way to comply with federal ozone standards. Still other commenters provided information on what they characterize as the benefits of biodiesel and renewable diesel. They state that these fuels will provide immediate greenhouse gas reductions. One commenter suggests EPA should acknowledge renewable diesel in their climate policy and any EV mandate is inconsistent with the Renewable Fuel Standards (RFS). Another commenter is concerned that the focus on EVs takes away from the emissions reductions renewable fuels provide. Finally, other commenters discussed renewable propane and the CO_2 emissions reductions from this fuel. They state that under proposed Option 1, the propane industry is best positioned to help the EPA achieve its environmental goals. In contrast, other commenters do not support the use of natural gas as an emissions solution; they mention studies that show that methane can be as polluting as diesel.

Still other commenters provided perspectives on other types of engine technologies, in addition to or in lieu of discussion on specific fuel types. For instance, some commenters stated their support for the opposed-piston (OP) diesel engine technology. One commenter described tests they have conducted on an OP engine; they state that the test results demonstrate that OP engine technology can be used to comply with the proposed standards. The commenter also discussed how the engine can operate on renewable diesel.

Several commenters also discuss thermal management technologies, such as fuel burners and electric heaters. They comment that these technologies can assist with cold start emissions. One commenter demonstrated CO_2 improvement with the use of alternative active heating. They mention the regulations should simultaneously drive NO_X and CO_2 reductions. Another commenter submitted comments on the feasibility of meeting NO_X emissions standards with a burner as a drop-in addition to existing aftertreatment technology; they stated that they are currently working on a technology package including this burner component.

Two commenters stated their support of variable valve actuation (VVA) for heavy-duty vehicles. They go into detail on early exhaust valve opening (EEVO), early intake valve closing (EIVC) and late intake valve closing (LIVC) as examples of strategies to utilize VVA. Cylinder deactivation (CDA) is another strategy listed to address low-load emissions and fuel consumption. One of these commenters also discusses how mild hybridization is an emissions reduction strategy that is synergistic with VVA and is low cost but still creates movement towards 48V electrification.

Finally, one commenter provided information on a plug-in electric power take-off system (ePTO) and how this system can be used to eliminate NO_X and greenhouse gases due to the engine being turned off. They stated there are currently ePTO systems in production for a wide range of heavy-duty truck applications.

Response:

EPA appreciates the comments and supporting information regarding alternative technology pathways for complying with heavy-duty engine emissions standards. Several commenters stated that EPA should not rely on electrification to achieve the standards and should instead consider the emissions reductions achievable from alternative fuels. Other commenters stated that for many vehicle applications, ZEV technologies are projected to be cheaper to own and operate within five years. Several other commentors stated their support for biogas, RNG, RNP, and other low-carbon fuels, while other commentors expressed concerns with the use of these fuels. Finally, other commenters urged the EPA to establish standards that support neutrality and flexibility in fuel and technology options that do not limit innovation.

As discussed in preamble Section III.A.3, while we have referenced a technology pathway for complying with our final heavy duty engine criteria pollutant standards (Chapter 3 of the RIA), which is consistent with CAA section 202(a)(3), there are other technology pathways that manufacturers may choose in order to comply with the final performance-based standards. We did not rely on alternative technology pathways in our assessment of the feasibility of the final standards, however, manufacturers may choose from any number of technology pathways to comply with the final standards (e.g., alternative fuels, including biodiesel, renewable diesel, renewable natural gas, renewable propane, or hydrogen in combination with relevant emissions aftertreatment technologies, and electrification, including plug-in hybrid electric vehicles, battery-electric or fuel cell electric vehicles). We acknowledge that in some cases such alternative technology pathways may further address manufacturers' concerns regarding compliance margin and/or offer a lower cost alternative, or other advantages such as simultaneous reductions in GHG emissions, and as such offer additional pathways to feasibly meet the final standards. See also our responses to general comments regarding the level and feasibility of the final standards in section 3.1.1 of this document.

In response to comments on providing incentives for alternative technology pathways, or treating certain technology pathways as near-zero or zero emissions technologies, we note that we are not finalizing the proposed allowance for manufacturers to generate NO_X emissions credits from heavy-duty ZEVs, or any credit multipliers that were included in the proposed NO_X ABT program (see preamble Section IV.G and section 12 of this Response to Comments document for additional details). In response to comments related to GHG emissions standards and the use of alternative technology pathways to meet GHG emissions standards, EPA is not taking final action at this time on the portion of the HD 2027 NPRM regarding proposed changes to HD GHG Phase 2 standards. EPA intends to undertake a separate rulemaking regarding more stringent HD GHG standards in the future (i.e., HD GHG Phase 3 standards). Section 28 of this Response to Comments document details the comments we received specific to the proposed revisions to the GHG Phase 2 standards. Finally, in response to comments related to criteria or GHG emissions that occur upstream of a vehicle (e.g., from production of fuel or energy), we point to section 19.3 of this document.

In response to comments requesting regulatory relief (e.g., DF testing, GHG certification and testing requirements, diagnostic requirements) for H2ICE or other technology pathways, we did not propose or request comment on such revisions and are not including them in the final rule.

As discussed immediately above in this response, manufacturers may choose from any number of technology pathways to comply with the final standards, including H2ICE. Should manufacturers or other stakeholders continue to want regulatory relief for H2ICE products, or other technology pathways, then EPA encourages manufacturers to continue working with EPA on these matters separate from this final rulemaking process.

3.11 Other comments on criteria pollutant standards

Comments by Organizations

Organization: *Allison Transmission, Inc. (Allison)*

Allison supplies transmissions for many vocational vehicle applications which are utilized in a variety of different applications; many of these vocational vehicles accumulate mileage much more slowly than long-haul freight vehicles. Apart from mileage, vocational vehicles may also have vastly different utilization, from school buses with regular routes to beverage delivery trucks, utility vehicles, refuse trucks, construction and/or specialized agricultural or silvicultural vehicles. Applying the same broad standard for criteria pollutants, like NOx, for these vehicles varies from the treatment of such vehicles pursuant to the Phase 2 GHG rule wherein vocational vehicles have 18 different separate subcategories.17 EPA has not provided a rationale why similar subcategorization of these vehicles with regard to “criteria” air pollutant standards like NOx should not apply. [EPA-HQ-OAR-2019-0055-1231-A1, pp.10-11]

17 81 Fed. Reg. at 74,242-3 (Oct. 26, 2016).

Organization: *American Bus Association (ABA) (1070 and 1308)*

As EPA points out, the Clean Air Act (CAA) framework has provided significant advances in improving air quality, through cleaner burning fuels and emission control standards – and this is not to suggest additional improvements cannot be made. As stated by the Truck and Engine Manufacturers Association (EMA) in 2018, “Over the past 20 years EMA manufacturers have innovated and implemented advanced clean technologies to reduce NOx emissions by over 90% and particulate emissions by over 98%.” But there needs to be a balance, accounting for all of the actual costs and benefits associated with the motorcoach industry and the impact of the emissions control program on these businesses and weighing what is truly feasible and makes sense over a reasonable time horizon. It does not serve to increase the stringency of the emission control standards and testing, if the result is fewer motorcoaches on the road due to an excessive increase in cost to purchase a new vehicle, the weight of the new vehicle exceeding federal limits, or the new emission control system on the engine further degrading the reliability of the vehicle. EPA must consider all heavy-duty vehicles users, including bus and motorcoach operators, and take into account the unique challenges and federal laws beyond the environmental arena, when considering this rule. Further, the proposed rule leaves major open questions about its impact on engine size and weight. Any significant increase in either the size or weight of engines could counter-productively serve to potentially reduce the number of passengers that could be transported on a motorcoach. For example, both under federal and state laws buses are subject to strict weight limits (23 USC 127). However, the proposed rule contains no useful analysis of its bus weight implications. Vehicle redesign costs to accommodate any increased weight to the engine or emissions control system components should have also been considered in the Regulatory Impact Analysis. [EPA-HQ-OAR-2019-0055-1308-A1, p.4]

The Proposal, in its current form, and in particular Option 1, raises several concerns for ABA. Most notably, ABA is concerned about the feasibility, weight, cost and resulting reliability of implementing the proposed stringent emission control standards and testing protocols, along with the extension of the engine useful life and engine manufacturer warranty. If EPA proceeds with the Proposal, ABA strongly advocates for pursuing Option 2, under the proposed standards and test procedures. ABA also notes that EPA could alleviate a number of concerns raised by the motorcoach industry by expanding the Relief Measures provided to engine manufacturers in 2012, that allow for modifications to emission control systems to prevent reducing engine performance, to engines manufactured for use in motorcoaches. Based on EPA's current time schedule for this rulemaking, if no relief from the proposed requirements is provided, EPA does not appear to be interested in ensuring the motorcoach industry remains a viable option of travel. Under the Proposal the motorcoach industry will face increased safety risks and exorbitant increases in costs to operate. In turn, those communities most reliant on motorcoach services, including disadvantaged and rural communities, emergency responders and the military, will all note a reduction in service capacity across the national transportation network. As previously noted, ABA will supplement these comments as appropriate.[EPA-HQ-OAR-2019-0055-1308-A1,p.12]

Organization: *RV Industry Association (RVIA)*

RVIA supports EPA's objective of reducing the negative health effects associated with the pollution from motor vehicles and we recognize that the proposed regulation will have benefits relating to improved air quality. These benefits, however, are directly correlated to vehicle miles traveled and the benefits to those in disadvantaged communities are tied to vehicles that tend to operate in those communities. As detailed in our Oct. 1, 2015 comments to EPA's Phase 2 GHG NPRM8, annual VMT for motorhomes has been determined to be 4,290 miles9. This is about 1/3 the VMT of a typical delivery truck10 and about 1/16 the VMT of a typical Class 8 truck11. This means that benefits linked to motorhomes will be about 1/3 those of the typical delivery truck and 1/16 of Class 8 truck benefits. In urban communities most negatively affected by truck pollution, the relative benefit tied to motorhomes will be even less, given that motorhomes are generally not operating in these communities. [EPA-HQ-OAR-2019-0055-1270-A1, p. 4]

- 8. Letter from Dianne Farrell to EPA Docket No. EPA-HQ-OAR-2014-0827, Oct. 1, 2015, page 6.
- 9. This figure is based on a survey of odometer readings taken from 987 three-year old motorhomes sold in calendar years 2012-2014.
- 10. Average annual vehicle miles traveled for a delivery truck is 10,309 miles. Averagewww.afdc.energy.gov/data/10309
- 11. Average annual vehicle miles traveled for Class 8 truck is 62,751 miles. Averagewww.afdc.energy.gov/data/10309

The cost benefit relationship described above necessitates EPA doing more than simply putting in place 'one-size fits all' standards applicable to all categories of vehicles covered by the regulation. [EPA-HQ-OAR-2019-0055-1270-A1, p. 4]

Unlike most vehicles subject to this rulemaking, motorhomes are not generally used for commercial purposes and are not providing the end user a source of revenue. Motorhome owners do not benefit financially from motorhome ownership. This reality makes the cost/benefit ratio seen for commercial trucks even further from reality for motorhomes. [EPA-HQ-OAR-2019-0055-1270-A1, p. 4]

For motorhomes, the cost/benefit ratio is magnitudes of order worse than it is for the commercial trucks that are responsible for the overwhelming majority of the pollution for which this regulation seeks to curtail. [EPA-HQ-OAR-2019-0055-1270-A1, p. 4]

Organization: *Motor & Equipment Manufacturers Association (MEMA)*

MEMA is also concerned about the lack of data regarding vocational applications and the difficulties that this will cause. Vocational applications could also be regulated as a separate category. [EPA-HQ-OAR-2019-0055-1322-A1, p. 5]

EPA Summary and Response

Summary:

Some commenters urged EPA not to finalize 'one-size fits all' standards applicable to all categories of vehicles covered by the regulation, but rather consider setting separate standards or requirements for different vehicles types. EPA recognizes the concerns raised by commenters, but consistent with the current criteria pollutant standards, we are not finalizing vehicle-specific standards in this rulemaking. Rather, we are finalizing standards specific to the heavy-duty engine categories used in the existing criteria pollutant standards (i.e., Heavy HDE, Medium HDE, Light HDE, SI). We think the current categorization is a reasonable exercise of our discretion, that sufficiently accounts for differences in vehicle type and emissions performance.

Response:

Preamble Section III.A.2 includes additional discussion on the factors we considered when setting the final standards; as discussed in preamble Section III and RIA Chapter 3, our technical assessment demonstrated feasibility of the final standards over several different duty-cycles, which reflect real world operations of a variety of different vehicle types. In setting the final emission standards, EPA appropriately assessed the statutory factors specified in CAA section 202(a)(3)(A), including giving appropriate consideration to the cost associated with the application of technology EPA determined will be available for the model year the final standards apply (i.e., cost of compliance for the manufacturer associated with the application of such technology). EPA’s assessment of the relevant statutory factors in CAA section 202(a)(3)(A) justify the final emission standards. We also evaluated additional factors, including factors to comply with E.O. 12866; our assessment of these factors lend further support to the final rule. See also our response to similar comments in section 18.9 of this document. We note that the final provisions for engine derating, or inducements, which one commenter notes, are discussed in preamble Section IV.D, with additional information included in section 8 of this Response to Comments document.

4 Warranty

Comments by Organizations

Organization: *Alliance for Vehicle Efficiency (AVE)*

AVE supports EPA's proposed Option 1 standard, with a modification of the proposed full useful life timelines and warranty requirements, as the best option for driving more rapid adoption of advanced engine and emission control technologies. [EPA-HQ-OAR-2019-0055-1280-A1, p. 2.]

AVE asks EPA to modify the proposed full useful life timelines and warranty requirements.

Currently, suppliers are not provided the necessary data (and certain data may not exist) nor information to design for a reasonable warranty and to determine if the proposed full useful life (FUL) timelines are feasible. Suppliers lack the data necessary, beyond the current goals to extended distance, time-in-service and beyond the first owner/user of vehicle, to make accurate assessments about the durability of many products. More research on engine wear and use patterns that result in degradation is needed before proposing longer warranties and extending FUL timelines. As such, AVE recommends several changes to EPA's proposed warranty requirements and FUL timelines: [EPA-HQ-OAR-2019-0055-1280-A1, p. 2.]

- Engine-related warranty regulations apply only when a vehicle has full maintenance records of required servicing and shows no sign of abusive use;
- Exclude from a longer warranty standard parts that will be replaced by routine maintenance and identify which vehicle systems and/or specific parts should be covered by longer warranties; and
- ...

The proposed longer warranties for new vehicles are intended to protect consumers and ensure emission systems work properly throughout the life of new heavy-duty trucks. Due to unknown risks to suppliers and manufacturers, these extended warranties, as proposed, will add extensive, unknown costs to vehicles. This added cost could disincentivize new vehicle purchases, thereby undermining the goals of the Proposal. [EPA-HQ-OAR-2019-0055-1280-A1, p. 2.]

Organization: *Allison Transmission, Inc. (Allison)*

- Overly aggressive extension of emissions warranties associated with Option 1 will also drive up cost of technology, exacerbating difficulties for individual vehicle sectors in meeting the standards and exacerbating the difficulty in turning over fleets reliant on old technology. This is another reason that Allison believes a single-phase approach, as in Option 2, is a better long-term strategy. The focus on mileage in repair cost analysis associated with tractor application underestimates the cost of seven-to-ten-year warranty structures, particularly with respect to demanding vocational vehicle applications. Allison's own data (see Table 1) shows that vocational vehicle usage differs substantially from tractor usage, meaning that hours of operation may be the operative factor with respect to the extent of warranty coverage. EPA data utilized to develop warranty periods does not adequately take these very real differences in utilization into account. EPA should therefore consider alternative warranty concepts that it first advanced last year in the 2021 Advance Notice of Proposed Rulemaking ("ANPR").4 [EPA-HQ-OAR-2019-0055-1231-A1, pp.5-6]

4 Control of Air Pollution From New Motor Vehicles: Heavy-Duty Engine Standards, 85 Fed. Reg. 3,306 (Jan. 21,2021).

- Neither Option 1 or Option 2 reflects concepts EPA introduced in the 2021 ANPR to tailor emissions warranties by component and vocation. We would like to encourage EPA to reconsider those concepts given one size does not fit all for diverse uses and unique customer needs in commercial vehicle. [EPA-HQ-OAR-2019-0055-1231-A1, p.6]

In the proposed rule, EPA states that it will give "full consideration" to the useful life and warranty periods that it has proposed for Options 1 and 2, including "the full range of options between them."23 For the reasons stated below, Allison believes that EPA should finalize Option 2 regulatory periods. In our analysis, Option 2 more appropriately balances the costs and benefits of extended useful life and warranty periods and better takes into consideration the real-life dynamics concerning these periods and customer behavior. [EPA-HQ-OAR-2019-0055-1231-A1, p.12]

23 87 Fed. Reg. at 17,421.

As a vendor to vehicle OEMs, Allison recognizes that longer warranty periods required of a vehicle manufacturer will inevitably filter into contract negotiations affecting the cost of components which will need to be designed for longer periods and may require increased material costs. OEMs will need to additionally project the costs of future repairs under warranty, even while its testing of vehicle systems may not be conclusive of future issues. This tends to result in companies making conservative estimates going forward to reduce risk of large-scale and unanticipated financial exposure; these estimates in turn directly impact pricing to the ultimate purchaser. [EPA-HQ-OAR-2019-0055-1231-A1, p.12]

Balanced against these cost increases, EPA makes several projections and assumptions: EPA believes longer emissions warranty coverage will reduce the overall costs of heavy-duty commercial vehicles over the long-term.25 This is based on forecasting that longer emissions warranty coverage encompassing a greater percentage of a vehicle's extended useful life period will result in the most efficient behavior across the manufacturing process. This, in turn, will result in lower lifetime costs attributable to the servicing and maintenance of vehicles in-use. EPA's theory appears to be that because more of future repair costs would be covered by the manufacturer, rather than operator, manufacturers will have the incentive to design covered parts and systems in a manner that will result in lower repair costs. [EPA-HQ-OAR-2019-0055-1231-A1, p.12]

25 87 Fed. Reg. at 17,428.

While Allison appreciates the logic of this argument, there are several issues that serve to challenge EPA's conclusions. Specifically, while component and system validation can serve to identify issues that may occur in the future, testing has limited ability to accurately predict how frequently such conditions will be experienced in real world operation. This is particularly true with respect to durability issues given the range of operations involved for different vehicle types as well as the actual behavior of customers in their use and maintenance of vehicles and equipment over time. In addition: [EPA-HQ-OAR-2019-0055-1231-A1, pp.12-13]

- Testing limitations mean that manufacturers have limited data available to inform how prices may be set to fully account for lengthened useful life and warranty periods. This situation will tend to cause companies to set prices conservatively (in this context, higher) to address the inherent risk involved in accounting for extended warranties and increased periods for potential liability. It may take several years of experience addressing longer useful life/warranty periods before more accurate projections can have a lower or more realistic price impact.
- At the same time, under EPA's proposed emission warranty periods, which distinguish between vehicles solely on the basis of whether they are spark-ignition or light, medium or heavy heavy-duty engines (”HDEs”),26 the supply chain structure of the North American Heavy-Duty manufacturing sector will tend to limit individualized pricing. That is, the broad categories utilized by EPA will tend to drive similar pricing of components for all vehicles in each of the four different intended service classes. A component supplier may or may not know the precise end use for which a component will be used, leading to a natural inclination to default to assumptions based on end uses with potentially high exposure to emissions warranty claims. Again, this would not produce the most efficient result in obtaining EPA's expressed policy goals.
- Due to all these factors, the initial price of longer warranties when combined with the initial price of new emissions control technology will tend to increase incentives for customers to engage in "pre-buy" activities. This, in turn, will directionally delay projected emissions benefits and increase incentives for fleet owners and others to keep older, repaired and rebuilt technology vehicles on the road. In the context of this rulemaking, EPA should at minimum, examine this issue as part of its planned analysis of pre-buy and low-buy activities which is not yet complete.27 [EPA-HQ-OAR-2019-0055-1231-A1, p.13] 27 Id. at 17,590-1.

26 Table IV-9, 87 Fed. Reg. at 17,508.

Allison appreciates EPA's objectives in proposing to extend both the useful life and warranty periods and the policy goals that have been articulated: promotion of better engine maintenance, less tampering and maintaining emission performance over time.28Allison also does not contest that other indirect results could occur, e.g., that longer useful life and warranty periods could lead manufacturers to "simplify repair processes and make [manufacturers] more aware of system defects that would be tracked and reported to EPA over a longer period of time."29 These are valid policy goals. EPA, however, should be reticent to push out such periods too far even while it seeks to harmonize standards with California programs. [EPA-HQ-OAR-2019-0055-1231-A1, p.13]

28 See, e.g., 87 Fed. Reg. at 17,497, 17,505.

29 Id.at 17,424, 17,505-6.

It seems clear that EPA intends this proposed rule to incentivize the deployment of new emissions technology as well as deliver substantial public health and environmental benefits. But if useful life and warranty periods are extended too far into the future, these regulatory requirements will tend to inhibit, rather than incentivize, the development of new emissions control technology given that the longer periods will inherently favor the deployment of emission controls systems which can best be verified in the near-term. EPA should also consider that it has the legal ability to revisit useful life and warranty issues in a future rulemaking; it should therefore avoid the conclusion that it must finalize each and every component of the proposed rule at the high end of stringency in order to obtain intended benefits. Rather, EPA could move to finalize Option 2 useful life and warranty provisions now and assess at a later date how these provisions worked, or did not, work in practice and whether these periods should be extended in future years. Having the benefit of seeing how Option 2 requirements are actually complied with could only help to inform EPA's analysis of the proper length and extent of the useful life and warranty provisions. [EPA-HQ-OAR-2019-0055-1231-A1, pp.13-14]

When EPA solicited comments on the Clean Truck Initiative in early 2020, Allison indicated that the Agency should explore mechanisms which would "vary the length of warranty coverage across different types of components."37 As Allison commented at the time, it may not be possible in all cases to design, or cost-effectively design, every emission related component to reach the same useful life period required with respect to a new engine. Both EPA and CARB have explored different concepts to, among other options, prorate parts and labor through more limited coverage, or to limit warranty to include only the most expensive components.38 [EPA-HQ-OAR-2019-0055-1231-A1, p.17]

37 85 Fed. Reg. 3,306, 3,325 (Jan. 21, 2020).

38 CARB Post-September 26 [2019] Workshop presentation at 7.

Allison recognizes that EPA has articulated somewhat different goals in connection with this proposed rule. In broad brush, EPA appears to have adopted the view that more expansive useful life and longer warranty periods are an unmitigated good. While it has refrained from proposing the longest theoretical periods based on data that it reviewed regarding rebuilds,39 EPA has not sought to further explore any of the concepts contained in the ANPRM. Rather, EPA is proposing useful life periods from 10 to 15 years that incrementally vary only with respect to whether a vehicle is spark ignition, or in the case of compression-ignition, only with respect to weight. Alternative standards that are proposed only vary with respect to increased mileage. [EPA-HQ-OAR-2019-0055-1231-A1, p.17]

39 See, e.g., mileage for Class 8, out-of-frame rebuild periods. 87 Fed. Reg. at 17,498, Table IV-1.

Similarly, under the Proposed Rule, warranty periods may be subject to exponential extension in terms of mileage and will be subject to a concurrent hours of operation limitation, but are not further segmented as between different vehicle types or different portions of emissions-related equipment.40 Hours limitations are based on the use of a static 20 mile per hour average vehicle speed across all vehicle service classes.41 EPA has requested comment on whether the existing regulatory list of emission-related components should be expanded to include additional more specific components or systems,42 but not whether useful life and/or warranty periods might be differentiated as between such specific components or systems. This approach contrasts with EPA's 2021 ANPRM which sought comment on alternative warranty approaches.43 [EPA-HQ-OAR-2019-0055-1231-A1, p.17]

40 Table IV-9, Id. at 17,508.

41 Id. at 17,508.

42 Id.

43 85 Fed. Reg. at 3,325.

In addition to the proposed alternatives, EPA should consider the following options:

- EPA should consider taking a targeted approach to emission warranties that focuses on components with the highest emissions impact or known degradation concerns. While EPA is taking comment on expanding the current list of warrantable parts, it should, as part of that analysis, consider the incremental value of adding any new systems as well as the incremental value of focusing on parts that more directly impact emissions. Blanket approaches, such as "anything that lights the MIL" should be avoided. Focusing on the most essential components could have multiple benefits, including ensuring that issues with large emission impacts are promptly identified and, in the end, recalled and/or repaired. More is not necessarily better if compliance efforts are spread among numerous subsystems with only incremental emissions impact.
- EPA should also consider tailoring emissions warranties to different vehicle classes and vocations, rather than just relying on the type of engine involved and weight class. Vocational markets tend to value warranties based on years and hours of use -- whereas freight and tractor trailers tend to value warranties that cover more mileage. While EPA has proposed both mileage and hours as parameters, the Agency could utilize a finer-targeted system that prioritizes miles in some sectors such as long-haul freight, while prioritizing time/hours in vocational segments. A more focused and tailored approach to emissions warranties obviously will have the downside of increased complexity and additional reliance on warranty tracking systems. But at the same time, the costs of extended warranty periods could be better contained through a targeted approach. Allison has included Table 3 below so that EPA may review the 2022 vocational models Allison uses to differentiate warranty terms and pricing to meet customer needs based on

different customer usage. Within the vocational market applications vary in use and how end- users value different coverage terms beyond base warranty [EPA-HQ-OAR-2019-0055-1231-A1, pp.17-18]

Organization: *American Lung Association et al.*

To realize the maximum health benefits, US EPA recognizes the need to establish standards that look beyond the stringency levels and proposes updated test procedures, truck 'useful life' requirements and warranty provisions to support achieving pollution reductions across real-world driving conditions throughout the useful life of the truck. We believe that Option 1 provides a strong foundation, and offer the following recommendations to protect public health: [EPA-HQ-OAR-2019-0055-1271-A1, p.2]

Strengthen warranty provisions to match full useful life. Again, we appreciate that Option 1 proposes strengthening the emissions control warranty provisions to cover a greater period of a truck’s operational life, but recommend full warranty coverage for emissions controls to ensure repair and replacement throughout the life of the vehicle. Warranty coverage provides a level of certainty to the owner of a new or used truck that the vehicle emission controls will function properly or be repaired by the manufacturer, therefore restoring emission benefits in the event of failure. US EPA also notes that warranty coverage reduces the likelihood of tampering or delayed maintenance of emission controls, which must remain the case in the later stages of vehicle life. [EPA-HQ-OAR-2019-0055-1271-A1, p.3]

Organization: *American Truck Dealers (ATD)*

ATD supports reasonable revisions to existing HDE/CMV emissions warranty periods. The proposal acknowledges that longer emission warranty periods are likely to increase the purchase price of new CMVs.14 By definition, an emission warranty is included in the price a first purchaser pays when buying a new CMV. However, given that CMV and HDE OEMs must “pass on” the costs associated with emission warranty (and useful life) mandates, the practical result will be an increase above the prices first purchasers would otherwise pay for the new CMVs and HDEs they buy. ATD also is concerned that new CMV purchasers with short trade cycles will not value and want to “pay for” the incremental cost of lengthy emissions warranties. [EPA-HQ-OAR-2019-0055-1321-A1, p. 6]

14. Id.

Organization: *American Trucking Associations (ATA)*

While ATA cannot address every aspect of HD2027, we are supportive of the underlying environmental objectives and several of the elements being proposed. ATA’s areas of support include:

Current emission warranty and useful life periods for heavy-duty engines and vehicles should be revised from the current requirements to increase the durability and efficacy of in-use emissions compliance. [EPA-HQ-OAR-2019-0055-1326-A1, p. 3.]

Requiring the purchase of costly extended warranties does not prevent tampering or the purchase of illicit emission defeat devices. Enforcement of emission standards under the Clean Air Act ("CAA") does. [EPA-HQ-OAR-2019-0055-1326-A1, p. 15]

The CAA prohibits tampering with emissions controls, as well as manufacturing, selling, and installing aftermarket devices intended to defeat those controls. EPA's National Compliance Initiative began in FY 2020 and focused on stopping the manufacture, sale, and installation of defeat devices on vehicles and engines used on public roads as well as on nonroad vehicles and engines. In FY 2021 alone, EPA settled 40 civil enforcement cases, the greatest number of resolutions for tampering and aftermarket defeat devices for any one year in the agency's history – thereby stopping the manufacture or sale of devices intended to defeat required emissions controls on vehicles and engines used on public roads. [EPA-HQ-OAR-2019-0055-1326-A1, p. 15]

Enforcement Alerts, such as the December 2020 EPA "Aftermarket Defeat Devices and Tampering are Illegal and Undermine Vehicle Emissions Controls," are widely distributed by trade associations representing truck dealers and fleets.11 While rates of tampering with emission control systems and the installation of illicit emissions defeat devices have plummeted, nothing can prevent rogue trucking operations from circumventing the law better than enforcement and the detection of devices which enable such behaviors. Longer, more expensive warranty packages are not justified to curtail unscrupulous activities on the part of some. [EPA-HQ-OAR-2019-0055-1326-A1, p. 15]

11. EPA Enforcement Alert, "Aftermarket Defeat Devices and Tampering are Illegal and Undermine Vehicle Emissions Controls", EPA 300-F-20001, December 2020.

Organization: *BBU Environmental Services*

As small trucking business owner I can state that the def systems are not reliable. I not only loose money to repair costs i also lose productive time of the unit. I think these systems should be warrantied by the manufacturer for life of the unit and there should be a penalty for down time while they are being worked on. [EPA-HQ-OAR-2019-0055-1020, p. 1]

Organization: *BorgWarner*

1. BorgWarner is in favor of forward progress to consistently reduce NOx, CO2 and other emissions, but we have concerns with the proposal's full useful life (FUL) and emissions warranty provisions. [EPA-HQ-OAR-2019-0055-1234-A1, p. 1.

To help mitigate unknown and unquantified risks that would be placed on suppliers, the EPA could consider identifying specific parts and systems that should carry longer warranties and ensure that evidence is collected to demonstrate that any life limits are feasible. Due to vehicle ownership patterns, automotive suppliers have neither visibility nor access to the information and data required to design for an appropriate warranty for the mileage and temporal limits being proposed. [EPA-HQ-OAR-2019-0055-1234-A1, p. 1]

BorgWarner recommends adjusting engine-related warranty regulations such that they apply only when the vehicle has full maintenance records according to service schedules and there is no evidence of abuse leading to failures. Owner/Operator maintenance and repair can have a significant impact on engine and emission systems' performance and life. [EPA-HQ-OAR-2019-0055-1234-A1, p. 2]

When truck components or systems experience failure, the root cause needs correct diagnosis as failure can be the result of mechanical failure elsewhere within the engine system. Inadequate or incomplete service diagnostic routines might incorrectly identify faults in the wrong components. Therefore, it is important that poor or incomplete protocols in the service shops do not manifest themselves with replacement of good parts, repeat symptoms and inflated costs. [EPA-HQ-OAR-2019-0055-1234-A1, p. 2]

Some components and systems require routine maintenance or replacement during the service life of a vehicle. It is important to correctly determine these intervals and define these by component. A manufacturer's warranty exposure can be limited by having a FUL definition for each system component. [EPA-HQ-OAR-2019-0055-1234-A1, p. 2]

Organization: *California Air Resources Board (CARB)*

The NPRM requested comments on the proposed warranty mileage values.

CARB staff strongly supports Option 1, which is consistent with the Omnibus Regulation's warranty periods. It is important that warranty periods be uniform throughout the nation. As discussed in the proposed rule, the longer warranty periods are critical in encouraging vehicle owners to repair their vehicles and providing incentives to manufacturers to improve their products to minimize the repair costs to reduce emissions. During the Omnibus Regulation rulemaking process, industry stakeholders raised concerns regarding the potential cost impact of warranty requirements. In response, the Board directed CARB staff to engage with affected stakeholders to conduct a warranty cost study. Accordingly, CARB staff convened an industry stakeholder work group to analyze and study the various differences in the cost estimate methodologies used for estimating warranty costs. The work group met a total of 16 times over a period of nine months. The details of the study are available in the final report.172 Based on what was learned from the workgroup process and study, CARB staff believes that our methodology provides reasonable and defensible estimates of the average incremental warranty cost ($1,104 for a heavy heavy-duty diesel engine with a 600,000 mile, 10 year, 30,000 hours warranty for 0.02 g/bhp-hr at 435,000 miles and 0.04 g/bhp-hr at 800,000 miles) that affected parties will face under the Omnibus Regulation. Although U.S. EPA's warranty cost estimation method is significantly different than the CARB staff methodology and we comment on the warranty cost estimation method in comment b of this section, U.S. EPA's estimated per-engine warranty costs of Option 1 are reasonable and comparable to those of Omnibus Regulation. [EPA-HQ-OAR-2019-0055-1186-A2, p.109]

172 California Air Resources Board Staff Report on the Warranty Cost Study for 2022 and Subsequent Model Year Heavy-Duty Diesel Engines, December 2021, https://ww2.arb.ca.gov/sites/default/files/2022-01/warranty_cost_study_final_report.pdf

U.S. EPA requested comment on applying a different conversion speed for all classes or a unique speed to each engine class to calculate the hours-based periods. CARB staff supports the use of a consistent 20 miles per hour conversion factor, which is consistent with the approach taken by CARB's Omnibus Regulation. [EPA-HQ-OAR-2019-0055-1186-A2, p.112]

The 20-mph average speed was derived from a 2017 CARB-funded study conducted by the Bourns College of Engineering, Center for Environmental Research & Technology175 that collected in-use activity data for 90 on-road HD diesel vehicles. The different types of vehicles that were included in the study spanned several vocational areas, such as shuttle buses, refuse haulers, utility repair vehicles, etc. The average speed derived from the study inherently takes into account the different environmental factors and engine loads experienced by vocational vehicles and is a reasonable value to use to determine the operational hours period for the proposal. Assigning a unique speed to each engine class would require additional data. [EPA-HQ-OAR-2019-0055-1186-A2, p.112]

175 Collection of Activity Data from On-Road Heavy-Duty Diesel Vehicles, ARB Agreement No. 13-301, May 2017, https://ww2.arb.ca.gov/sites/default/files/classic//research/apr/past/13-301.pdf

CARB staff have significant concerns regarding the proposed components covered by emission warranty. U.S. EPA requested comment on whether it is appropriate to expand the list of components covered by emission warranty to include any component whose failure causes the vehicle's OBD MIL to illuminate, as adopted by CARB. The proposed rule states, 'If we were to finalize a link between warranty and OBD MILs, we expect the cost of expanding the list of warrantable components to include all components that may trigger an OBD MIL, regardless of their direct impact on emissions, would be unreasonable.' CARB staff disagree with this statement and suggest linking the warranty to OBD MILs as adopted by CARB Omnibus. [EPA-HQ-OAR-2019-0055-1186-A2, p.112]

Emission-related components are monitored by OBD because they provide necessary input for the monitoring of other components and systems, which can directly affect emissions (e.g., engine misfire monitoring, fuel system monitoring, SCR, etc.), and because they can be used to enable AECD operations. These components shown in Table 10-1 from the CARB staff report 176 can contribute to severe emissions increases due to the improper monitoring of components and systems. [EPA-HQ-OAR-2019-0055-1186-A2, pp.112-113]

176 Appendix C, Economic Impact Analysis / Assessment, page C-15, https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2018/hdwarranty18/appc.pdf?_ga=2.100296222.1089019171.1648488649-859068364.1628622434

In CARB staff's analysis, the additional cost due to linking warranty to OBD was small. For example, for HHDD, CARB staff estimated that the additional OBD-related repair cost would only be $7.33 per engine (in 2017$) as shown in Table 10-1. U.S. EPA staff should carefully consider and publicly share their estimates of associated cost increase estimate before concluding the additional cost would be unwarranted and unreasonable. [EPA-HQ-OAR-2019-0055-1186-A2, p.113]

Furthermore, the proposed 1068.120(c) states that '*The emission-related warranty covers **all components whose failure would increase an engine's emissions of any regulated pollutant,** including components listed in 40 CFR part 1068, appendix A, …'* Therefore, even if a certain component is not directly related to emission control, if the failure indirectly increases the emission, it should be covered by the emission-related warranty. Since OBD monitors emission-related engine systems or components, it is illogical not to link warranty and OBD MILs because defects in such components contribute to increases of emissions. [EPA-HQ-OAR-2019-0055-1186-A2, pp.113-114]

CARB staff is providing data regarding the following request for comment: *'… on the extent to which emissions warranty period is an important aspect of purchasers' business decisions, and the specific impacts purchasers anticipate for the range of emissions warranty periods we are considering in this rule. For instance, we are interested in how a longer regulatory emissions warranty may impact the timing of an engine or truck purchase, how long an engine or vehicle is kept, and/or how well an engine is maintained.'* [EPA-HQ-OAR-2019-0055-1186-A2, p.114]

Relevant data is available in Section V (Goal #2) of CARB staff's final report of the recently conducted HD warranty cost study.177 As the regulatory warranty periods are lengthened in California through the Step 1 (equivalent to Option 2) warranty and Omnibus Regulation, it is likely that more vehicles produced under these newer warranty requirements will be later re-sold in the secondary market as used vehicles with a portion of the lengthened warranty period coverage remaining (i.e., residual warranties). To better understand the secondary market value of such residual warranties, CARB staff conducted an online survey in April 2021 as part of Goal #2, and collected 694 responses from fleets and owner/operators and from five dealers. The survey results indicate that the remaining residual warranties do in fact add value to vehicles sold in the secondary market, with the value increase averaging approximately $2,000 for a 2 years/200,000 miles period of residual warranties, and $4,000 for a 4 years/400,000 miles residual period. The survey did not evaluate the impact of different year-to-mile ratios (e.g., 6 months/200,000 miles, etc.) because it would have added complexity to the survey process. [EPA-HQ-OAR-2019-0055-1186-A2, p.114]

> 177 California Air Resources Board Staff Report on the Warranty Cost Study for 2022 and Subsequent Model Year Heavy-Duty Diesel Engines, December 2021, Section V, https://ww2.arb.ca.gov/sites/default/files/2022-01/warranty_cost_study_final_report.pdf

These results suggest that higher initial vehicle purchase prices which offset later repair costs will likely be passed on with their attendant benefits to the subsequent vehicle owners to some extent, which potentially will reduce the cost impact that the Omnibus Regulation warranty amendments may have on first owners as seen in the increased value recognized by subsequent vehicle owners. CARB staff expects the same impact would occur with lengthened warranty requirements finalized nationally by U.S. EPA. [EPA-HQ-OAR-2019-0055-1186-A2, pp.114-115]

CARB staff have significant concerns regarding the effectiveness of graduated warranties being considered (not proposed). U.S. EPA asked for comments related to graduated warranties on page 17512:

'We are not proposing and did not analyze a graduated warranty approach for this proposal. However, we may consider a graduated warranty as a viable alternative to our proposed warranty periods if we receive additional information that would support such an approach. A graduated warranty approach could extend beyond our proposed warranty periods in mileage, hours, and years, to cover more of the operational life of the engine, but it could be based on different phases of varying coverage. These could include, for example:

- *Phase 1: Full parts and labor coverage for all emission-related components,*
- *Phase 2: Parts and labor coverage for limited emission-related components, and*
- *Phase 3: Parts-only coverage for limited emission-related components.'* [EPA-HQ-OAR-2019-0055-1186-A2, p.115]

CARB staff do not believe graduated warranties are necessary. CARB staff believes that the warranty period should remain applicable to the entire engine and its emissions control systems, and not vary by component. If the warranty period were to vary by component, this could be confusing for vehicle owners and manufacturers. Instead, CARB staff recommends linking OBD to warranty, which in turn would avoid the needing to rely on separate parts lists and would simplify the process. The full parts and labor coverage for all emission-related components of Option 1 provides the greatest emission benefit, and its cost is reasonable and defensible (as discussed above in comment 10.a of this section). [EPA-HQ-OAR-2019-0055-1186-A2, p.115]

Organization: *Clean Air Board of Central Pennsylvania*

EPA is proposing two regulatory options for NOx. We support Option 1, which will implement stronger NOx standards in two steps. The first improvement would be required in 2027 with a second more stringent standard 2031 (a NOx standard that would be 90% lower than today's standards). We support Option 1 with longer useful life and warranty periods. Ensuring that the warranty and useful life requirements meet 100% of the expected life of these vehicles will ensure health benefits throughout the life of the vehicles. [EPA-HQ-OAR-2019-0055-1305-A1, p.1]

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

The warranty period is the period during which the Clean Air Act requires a manufacturer to warrant to the purchaser that an engine will conform with applicable Section 202 regulations. 42 U.S.C. 7541(a)(1); 40 C.F.R. 1068.115. As the Proposal notes, warranty periods have remained the same since 1983, even as useful life has increased, so that today the emissions warranty periods range from 22–54% of regulatory useful life. 87 Fed. Reg. at 17,505. With EPA's proposed changes to lengthen the useful life, this gap would grow even larger if warranty periods are not correspondingly increased. [EPA-HQ-OAR-2019-0055-1302-A1, p.60]

As the Proposal notes, extending the warranty period to cover a greater fraction of an engine's regulatory useful life and operational life provides important incentives for behaviors and actions that lead to reduced NOx emissions. Because a warranty is voided if operators do not properly maintain the engine, an increased warranty period would incentivize proper maintenance for a longer period of time. 87 Fed. Reg. at 17,505. Owners similarly would be incentivized not to install emissions control defeat devices that would void the engine warranty. Id. Manufacturers would be incentivized to simplify repair processes and better train technicians if they are responsible for the costs of repairs for a longer period. Id. Because manufacturers investigate possible defects whenever warranty claims are submitted, 40 C.F.R. 1068.501(b), a longer warranty period would provide more information and greater opportunity to identify defective parts, 87 Fed. Reg. at 17,506. [EPA-HQ-OAR-2019-0055-1302-A1, p.60]

Commenters support increasing the useful life mileage values for HDEs and extending the warranty period to cover a larger portion of the engines' operational lives. Because the current useful life and warranty periods cover only a fraction of the real-world operational life of trucks, older trucks on the road are very likely emitting higher levels of NOx, and neither truck operators nor manufacturers have the proper incentives to ensure that emissions controls on those older trucks are functioning properly. Useful life and warranty periods covering a greater fraction of HDEs' expected operational life will help to protect people from dangerous NOx, ozone, and particulate matter pollution, and will shift more of the costs and risks of designing functional pollution control equipment to engine manufacturers, who have control over design, rather than effectively requiring operators to bear those costs. [EPA-HQ-OAR-2019-0055-1302-A1, p.60]

Specifically, we urge EPA to adopt useful life and warranty periods at least as long as those proposed in Option 1. EPA notes that it 'could justify proposing useful life requirements equivalent to the operational life data presented in Section IV.A.2 [of the Proposal], but [is] proposing somewhat shorter (less stringent) values in proposed Option 1 considering the effect of useful life on the feasibility of meeting the proposed Option 1 standards.' 87 Fed. Reg. at 17,500. As the Proposal also notes, the Option 1 useful life periods generally align with those in the Omnibus. Id. EPA proposes in Option 1 to adopt warranty periods covering close to 80% of useful life, which would align with the MY 2027 and MY 2031 warranty periods adopted by CARB. 87 Fed. Reg. at 17,508. The fact that many manufacturers must comply with the Omnibus standards when they take effect supports the technological feasibility of setting useful life and warranty periods at a level approximately as stringent as the Omnibus. Given the Clean Air Act's command that EPA set regulations reflecting the 'greatest degree of emission reduction achievable,' 42 U.S.C. 7521(a)(3)(A)(i), and EPA's statement that it could justify even longer useful life periods equal to operational life, we urge EPA to consider setting useful life periods more stringent than those proposed in Option 1 if the Agency determines that longer periods would be feasible in combination with the emissions standards it finalizes. Additionally, we urge EPA to adopt new warranty and useful life values in a single step, finalizing its proposed Option MY 2031 values as standards applicable to MY 2027 in order to achieve the emissions reductions from these changes as swiftly as possible. [EPA-HQ-OAR-2019-0055-1302-A1, p.61]

Organization: *Cummins Inc. (Cummins)*

As shown in the table in Section I of Cummins' comments, EPA proposes to significantly lengthen emission warranty periods across all primary intended service classes. The two-step emission warranty periods proposed in Option 1 would drive excessive increases to the initial purchase price of the vehicle, as manufacturers would need to build in additional cost to cover longer warranty and therefore should not be finalized. Even Option 2, the generally less stringent of EPA's two options, will result in significant increases to the initial purchase price of the vehicle. EPA's proposed Option 2 aligns with the warranty periods finalized by CARB for MY 2022-2026 diesel engines, also known as CARB Step 1 warranty. The price increases associated with CARB's Step 1 longer warranty periods are known for current technologies because manufacturers are selling those products this year. Cummins provided our engine pricing for CARB's Step 1 warranty to EPA in May 2021 as CBI. That information shows that EPA has underestimated the cost impact of lengthening emission warranty and should reconsider its proposals. [EPA-HQ-OAR-2019-0055-1325-A1, p. 6]

EPA requests comment on whether it is appropriate to expand the list of components covered by emission warranty to include any component whose failure causes the vehicle's OBD MIL to illuminate, as adopted by CARB. EPA has not proposed this expansion, citing "concerns that not all OBD MILs are tied directly to an emission-related component" and "the cost of expanding the list of warrantable components to include all components that may trigger an OBD MIL, regardless of their direct impact on emissions, would be unreasonable" (87 FR 17509). Cummins agrees with EPA's reasoning and supports EPA's proposal not to expand the list of covered components. [EPA-HQ-OAR-2019-0055-1325-A1, p. 8]

EPA proposes to add hours-based warranty periods based on a 20 mile per hour average vehicle speed threshold to convert from the proposed mileage values. EPA requests comment on applying a different conversion speed for all classes or a unique speed to each engine class to calculate the hours-based periods. Cummins supports the addition of hours to warranty periods across all engine classes (SI HDE, Light HDE, Medium HDE, Heavy HDE) in recognition that some applications within those classes accumulate relatively few miles due to lower vehicle speeds. Similar to useful life periods, Cummins again supports using an average speed of 20 mph for determining the hours limit across all engine classes. As mentioned above, Cummins has submitted average vehicle speed data and run hours to EPA for numerous vehicles and applications operating in-use, which supports hours limits based on the 20- mph speed threshold. [EPA-HQ-OAR-2019-0055-1325-A1, p. 8]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

EPA should change useful life and emissions warranty periods to be more reasonable, specifically: 95

- Class: Heavy HDEs
  - Useful Life Period: 10 years/500,000 miles
  - Emissions Warranty Period: 5 years/350,000 miles
- Class: Medium HDEs
  - Useful Life Period: 10 years/250,000 miles
  - Emissions Warranty Period: 5 years/175,000 miles [EPA-HQ-OAR-2019-0055-1168-A1, p.71]

95 Daimler Truck also supports adding appropriate equivalent standards for the number of hours of engine operation.

A significant portion of the infeasibility, cost, uncertainty, and risk in the Proposed Rule derives from EPA's proposed extensions of the useful life and emissions warranty programs. It is cost prohibitive and impractical for manufacturers to adequately design components and be certain of their reliability for these extended periods, especially since EPA's rule proposals drive the development of new technology with only four years of lead-time and three years of stability between programs. 96 [EPA-HQ-OAR-2019-0055-1168-A1, p.71]

> 96 While Daimler Truck's comments in this section focus primarily on increased technology costs and compliance burdens associated with EPA's useful life and emission warranty period proposals, we also note that EPA's proposals will mean significantly increased information collection costs and burdens on manufacturers, which are relevant to OMB's review of the Proposed Rule under the Paperwork Reduction Act, see 44 U.S.C. 3501 et seq. Increased useful life times, for example, will translate to increased durability testing, which will add burden to manufacturers in terms of costs and man hours. We anticipate that the incremental burden increase for collecting aging data alone (as compared to current useful life periods) would amount to thousands of hours.

In Section 11.B. l of these comments, Daimler Truck explains why EPA's cost estimates for the Proposed Rule are inaccurate. Much of that inaccuracy comes from EPA's insistence that warranty costs will only increase slightly, and linearly. Several independent studies suggest that such assumptions are grossly incorrect, as we note in Sections 11.B. l and II.B.3 of these comments. [EPA-HQ-OAR-2019-0055-1168-A1, p.71]

Failure rates are likely to increase exponentially in the periods EPA considers, especially as these periods further tax manufacturers' ability to validate before production, and as engines typically experience increasing rates of ‘wear-out.’ Additionally, EPA underestimates the impact of new technology on warranty rates; new technology will always experience a period of increased failure rates as manufacturers’ experience in the field leads to more robust and mature technology. [EPA-HQ-OAR-2019-0055-1168-A1, pp.71-72]

EPA can limit these exorbitant warranty costs by limiting the extended useful life to reasonable values so that manufacturers can realistically design and validate their products. By setting the useful life to 500,000 miles for a HHD truck, and 250,000 miles for a MHD truck, EPA can avoid costly replacement of aftertreatment components (which would have extremely limited emissions benefit and significant uncertainty. [EPA-HQ-OAR-2019-0055-1168-A1, p.72]

Daimler Truck’s proposed useful life and emissions warranty periods (set forth above) would still achieve EPA’s objective of ensuring that warranty mileage would cover ‘at least half’98 of the useful life mileage for Heavy and Medium HDEs, as Daimler Truck’s proposed warranty mileages would be 70% of the useful life mileage for Heavy HDEs and 87.5% of the useful life mileage for Medium HDEs. Thus, the Company’s proposal would help to ensure that all of EPA’s envisioned emissions benefits are realized during useful life and that customers are incentivized to replace failed components because they will be covered by warranty.

> 98 Proposed Rule, 87 Fed. Reg. at 17,508.

Finally, Daimler Truck supports EPA's position that the emissions warranty coverage should not extend to all components which illuminate the malfunction indicator light (MIL). The Company agrees that many components that illuminate the MIL have no impact on emissions. Such examples include fuel level sensors, vehicle speed sensors, real-time clocks, and any number of other components that have an input to the diagnostics system (and are thereby required to light the MIL) but do not have any input to any emissions controls. Daimler Truck does not believe that these components should be considered emissions control components, and therefore should not be covered by the emissions warranty. [EPA-HQ-OAR-2019-0055-1168-A1, p.73]

Organization: *Great Rivers Environmental Law Center and Dutchtown South Community Corporation (DSCC)*

The undersigned support inclusion of the following requirements in the Final Regulation:

- Mandatory extended emissions warranties to improve engine maintenance and to help defeat tampering [EPA-HQ-OAR-2019-0055-1323-A1, p.6]

Organization: *Hyliion, Inc.*

Although it is understandable that EPA would seek extended emissions and useful life warranties, it is important to recognize the downsides of such enhanced performance guarantees. Extended warranties require OEMs to guarantee the performance of their products for longer times and more miles and are not without significant cost. It is like purchasing insurance for the engine. These costs will inevitably be passed through to the customer and thus are likely to dampen demand as both the cost of the warranty and the cost of the new, cleaner technology are included in the price of the engine. EPA must take this into account when considering the implementation of its draft rule. [EPA-HQ-OAR-2019-0055-1238-A1, p. 4]

Longer warranties put unknown and potentially massive risks on the motor vehicle parts manufacturing industry, which could result in significant price increases on vehicles. Increasing costs could impede momentum toward the replacement of the legacy fleet with desire for low emissions vehicles. [EPA-HQ-OAR-2019-0055-1238-A1, p. 4]

With this in mind, Hyliion supports Option 2 as it would match CARB's Step 1 warranty periods that will already be in effect beginning in Model Year 2022 for engines sold in California. We believe a consistent and uniform approach will provide the industry with greater predictability and thus increases the odds that OEMs will be able to rein in costs. [EPA-HQ-OAR-2019-0055-1238-A1, p. 4]

Organization: *Manufacturers of Emission Controls Association (MECA)*

We understand EPA's need to ensure that heavy-duty vehicles are meeting emission standards while in operation, which requires that emission critical components are durable and repaired quickly if a malfunction occurs. Based on several stakeholder meetings between EPA, CARB, and industry, we believe that EPA's Proposed Option 1 warranty and durability provisions have struck a suitable balance between stringency and phase-in time to allow suppliers to work with their customers to fill current information gaps and complete additional R&D to ensure future trucks continue to be durable and meet emissions warranty requirements. The phase-in approach will allow component suppliers to better understand the economic impact of longer warranty periods on their business as well as time to design longer durability into components. MECA supports hourly limits for vocational vehicles that may operate for thousands of hours at low speed or idle prior to reaching the mileage or year warranty clock threshold. [EPA-HQ-OAR-2019-0055-1320-A1, p.20]

As we previously commented, there is considerable uncertainty about the state of vehicles during the time of operation beyond today's 100,000 mile warranty. Much of the data on warranty claims and repairs as well as vehicle use characteristics originate from the time when the first owner operates a vehicle while data from repairs made by second and third owners is very limited. Many suppliers do not have data on the durability, replacement or diagnostics of their parts past the warranty because the dealer network is not required to share that information. This lack of information leads to challenges for suppliers who are trying to design parts that will meet the extended durability requirements out to 800,000 miles. Without warranty claim information beyond 100,000 miles, it is difficult for suppliers to estimate the cost impact of the proposed extended 2031 warranty and challenges suppliers trying to design to the much longer 2031 durability periods. The lack of data also challenges suppliers trying to design to longer durability periods. MECA members manufacture durable parts according to the specifications demanded by their customers, the OEMs, as part of individual business agreements. The individual component specifications provided to the supplier may not include a correlation between the specification and how that relates to mileage durability on the vehicle. Finally, besides the engineering design time needed to design components to longer durability requirements, the testing out to the long mileage durability requirements (such as 800,000 miles for class 8 engines), especially for on-engine components whose aging cannot be accelerated, takes months to years on dynamometers. [EPA-HQ-OAR-2019-0055-1320-A1, p.21]

Organization: *Motor & Equipment Manufacturers Association (MEMA)*

EPA's proposed Option 1 should be modified to include a significant reduction of the proposed the warranty time periods and mileage requirements, a special consideration for vocational vehicles, and an exclusion of normal maintenance and wear parts from the warranty. Each of these modifications is described in further detail below. [EPA-HQ-OAR-2019-0055-1322-A1, p. 3]

These modifications are necessary because Option 1 significantly increases the Warranty period and Full Useful Life (FUL) for HD engines based on minimal testing. While we understand the desire to ensure that vehicles maintain their lower NOx performance throughout the FUL, the costs of implementing such long warranties are relatively unknown and will therefore increase the financial risk to component suppliers as OEMs push the longer warranty requirements on the supply base. In addition, many emissions components that have a shorter life and are routinely replaced due to wear should not be covered under by the warranty requirements. [EPA-HQ-OAR-2019-0055-1322-A1, p. 3]

MEMA urges EPA to reduce the proposed warranty requirements and the full useful life timelines for all vehicles. The warranty increases of a factor of four or more are based on specific and limited laboratory testing that does not reflect complex, real-world use. Additionally, more data and analysis of second and third vehicle owner usage should be conducted before proposing significantly longer warranties and FUL timelines. [EPA-HQ-OAR-2019-0055-1322-A1, pp. 3 - 4.]

Longer warranties on criteria emissions systems put unknown and potentially massive risks on the motor vehicle parts manufacturing industry, which could result in significant price increases on vehicles. [EPA-HQ-OAR-2019-0055-1322-A1, p. 4]

EPA's envisioned increases in warranties and full useful life requirements on vocational vehicles are less validated than other commercial vehicles, with little to no testing and verification conducted on these uses. The real-world uses for heavy-duty vocational vehicles are different and extremely complex because of the vast range of duty cycles, load configurations, and application demands. Thus, more testing and validation of assumptions is necessary before greatly increasing the warranty time periods/mileage and FUL on vocational vehicles. [EPA-HQ-OAR-2019-0055-1322-A1, p. 4.]

MEMA urges EPA to not require warranty coverage on parts that have a shorter life and are routinely replaced due to wear, such as sensors, injectors, rings, filters, and valves. Instead, such parts and components should be defined as standard maintenance or replacement items. We urge EPA to work with industry stakeholders, including suppliers, to develop a list of wear parts and components with these criteria in mind. [EPA-HQ-OAR-2019-0055-1322-A1, p. 4]

MEMA urges EPA to reduce the proposed warranty requirements and the full useful life timelines for all vehicles. The warranty increases of a factor of four or more are based on specific and limited laboratory testing that does not reflect complex, real-world use. Additionally, more data and analysis of second and third vehicle owner usage should be conducted before proposing significantly longer warranties and FUL timelines. [EPA-HQ-OAR-2019-0055-1322-A1, p. 5.]

MEMA is also concerned about the lack of data regarding vocational applications and the difficulties that this will cause. Vocational applications could also be regulated as a separate category. [EPA-HQ-OAR-2019-0055-1322-A1, p. 5]

EPA is essentially asking industry to design parts without clear functional requirements - well past their current state-of-the-art design life. Frequency of failure past the design life is relatively unknown and therefore, the costs are also unknown. MEMA recommends EPA not require warranty coverage on parts that have a shorter life and are routinely replaced due to wear, such as sensors, injectors, rings, filters, and valves. Instead, such parts and components should be defined as standard maintenance or replacement items. We urge EPA to work with industry stakeholders, including suppliers, to develop a list of wear parts and components with these criteria in mind. [EPA-HQ-OAR-2019-0055-1322-A1, p. 5]

MEMA members have concerns about the uncertainty regarding 7- and 10-year emissions warranties. MEMA strongly supports a phased-in approach as this helps address suppliers' need for adequate lead-time to understand and improve component durability. Suppliers would take on significant cost implications early in the timeline. They currently do not have access to the necessary data to assess and make improvements. EPA should provide data on HD vehicles on the road today including higher quality data on usage patterns. [EPA-HQ-OAR-2019-0055-1322-A1, p. 7]

In addition, suppliers also require drive and duty cycle data from second and third truck owners as well as vocational vehicles to more fully understand those use cases and successfully design components to meet them. However, MEMA does support incremental changes in the warranty time periods/mileage including a series of step changes based on additional data and with the assumption that normally replaceable emissions components would be left out of the warranty coverage. The lack of data on 2nd and 3rd truck users is especially concerning in terms of warranty coverage. Many older trucks that are repurposed into specialized vocational applications, like dedicated snowplow trucks, may sit for months before the next use. MEMA is concerned about using a one-size-fits-all approach to a very complex set of use cases. [EPA-HQ-OAR-2019-0055-1322-A1, p. 7]

MEMA is supportive of the EPA’s suggestion that their proposed provisions will increase the likelihood that emission controls will be properly diagnosed and maintained through more of the service life of heavy-duty engines as this seems logical. See comments above about designating more parts as service parts versus warranty parts. [EPA-HQ-OAR-2019-0055-1322-A1, p. 7]

MEMA urges EPA to reduce the proposed factor of four increase in warranty requirements and the full useful life timelines for all vehicles until more data is available to justify such a substantial increase. More testing and validation of assumptions is necessary before increasing the FUL and this is especially true for vocational vehicles. [EPA-HQ-OAR-2019-0055-1322-A1, p. 9.]

Wear items should be defined as standard maintenance or replacement items and therefore not covered by a warranty. We urge EPA to work with industry stakeholders, including suppliers, to develop a list of wear parts and components with these criteria in mind. [EPA-HQ-OAR-2019-0055-1322-A1, p. 9]

Organization: *Moving Forward Network (MFN)*

Heavy-duty diesel engines last well beyond the current useful lifetime, with 90 percent of engines lasting nearly double the current regulatory requirement, and 50 percent of Class 8 engines nearly triple (Figure 3). As a result, the regulatory 100,000-mile warranty requirement is only a very small fraction of the expected lifetime of the engine and is well behind typical warranties and extended warranties of 250,000 and 500,000 miles.113 [EPA-HQ-OAR-2019-0055-1277-A1, p. 26]

Heavy-duty engines can last up to 1.2 million miles before a rebuild, yet the current warranty extends to just 100,000 miles, and the useful-life period is only 435,000 miles. The proposed changes to the warranty and useful-life periods for heavy-duty vehicles more closely mirrors the real-world operation of these engines and would help maintain working emissions controls while diminishing any costs incurred by the operators. [EPA-HQ-OAR-2019-0055-1277-A1, p. 27]

The useful life is critical to ensure adequate testing such that emissions controls are functional for the life of the engine. The warranty period, however, is more important to minimize tampering or disrepair, and shifts the cost of failures onto the manufacturer rather than the driver. Currently, the market allows manufacturers to profit from producing less durable products– increasing warranty requirements thus helps shift the responsibility for creating more durable emissions controls back to the entity with design control. [EPA-HQ-OAR-2019-0055-1277-A1, p. 27]

Repair costs and downtime can be a significant burden for drivers, and survey data has shown that there is a significant interest in coverage that better reflects the operational lifetime of the vehicle.114 Nearly one-quarter of respondents in that study already opt for an extended warranty, with a substantial share of those respondents' choosing warranties that exceed the current useful-life requirements of the engine. A majority of owner-operators suggested future warranty coverage should meet or exceed 500,000 miles, well above the current minimum. This is borne out in more recent analysis of the market, which shows that 85 percent of the market already opts for an extended warranty, with just about half of those users opting for warranty coverage of at least 500,000 miles.115 [EPA-HQ-OAR-2019-0055-1277-A1, p. 27]

114. Kerschner, B., and D. Barker. 2017. Survey and analysis of heavy-duty vehicle warranties in California (15MSC009). Prepared by the Institute for Social Research for the California Air Resources Board, December 2017. Online at https://ww3.arb.ca.gov/regact/2018/hdwarranty18/apph.pdf.

115. https://ww2.arb.ca.gov/sites/default/files/2022-01/warranty_cost_study_final_report.pdf

Organization: *National Association of Chemical Distributors (NACD)*

Also, option 1's increased requirements on warranties will invariably increase the costs of new trucks more than option 2's lower standards. With longer term warranties, truck manufacturers will be forced to factor the costs of parts and labor that are covered by the warranties into the cost of a new truck. This forces fleet owners to pay a higher upfront cost when purchasing vehicles instead of allowing them to pay the cost farther down the line when maintenance is needed. With most fleet owners managing small operations, as according to the American Trucking Association over 97% of carriers operate fewer than 20 trucks, these increased upfront costs will not be something that all owners can cover.3 These increased warranties also dissuade fleet owners from purchasing newer trucks in the long term, resulting in older vehicles on the road. [EPA-HQ-OAR-2019-0055-1279-A1, p. 4]

3. American Trucking Association, 'Economics and Industry Data,' Trucking.org, ATA, https://www.trucking.org/economics-and-industry-data

Organization: *National Association of Small Trucking Companies (NASTC)*

Improved warranty coverage so more of emission system and parts failures' costs of servicing are borne by OEMs instead of truckers and carriers. We agree that enhanced, improved warranty coverage would help reduce truck owners' costs of servicing emission system-related problems. Also, explicit statements that manufacturers may not deny warranty claims based on the use of commonly available DEF would clarify responsibilities and balance the equities of manufacturers and commercial product owners and users. [EPA-HQ-OAR-2019-0055-1130-A1, p. 3]

Organization: *National Waste & Recycling Association (NWRA)*

NWRA member companies have a unique perspective in that the association represents the manufacturers of heavy-duty trucks and the haulers such as WM, Republic, GFL, and Waste Connections, along with over 700 other members. This enables NWRA to understand the impact that new air pollution regulations would have particularly on the short-haul trucking industry. Our drivers start and stop hundreds of times a day, averaging as low as 9 to 12 MPH throughout the day, equating to a run time of 4,500 hours over two years, instead of the 4,500-hour run time for one year used in the proposed regulation. NWRA asks that EPA consider using the maximum number of hours a driver could drive in a year based on FMCSA's hours of service regulations to calculate the warranty hours that are being proposed. [EPA-HQ-OAR-2019-0055-1242-A1, p. 1 - 2]

Organization: *Natural Gas Vehicles for America (NGVAmerica)*

NGVAmerica and its members submit the following recommendations for policies and programs that the EPA and other federal agencies can advance to encourage the use of cleaner trucks.

4) Address longer life vehicles and required warranties for vehicles and emission systems equally across all vehicle technologies as EPA has proposed; but, we express concern that the costs of providing new longer warranties will be passed along to suppliers and customers and could create an unintended barrier to entry to new and innovative technologies by increasing costs associated with those technologies and needed components. NGVAmerica believes that the proposed warranty provisions in Option 2 represent a more balanced approach that is likely to achieve much of what EPA intends without negative consequences placed upon suppliers and ultimate customers and on the acquisition and deployment of cleaner trucks; [EPA-HQ-OAR-2019-0055-1330-A1, p.13]

Organization: *Owner-Operator Independent Drivers Association (OOIDA)*

We also welcome improvements to vehicle warranties and believe all of these provisions must be included in any final rulemaking. [EPA-HQ-OAR-2019-0055-1266-A1, p.6]

OOIDA supports the NPRM's restructuring of current warranty offers. Given drivers' concerns about emissions technologies, sensible warranty programs are critical for encouraging investment and implementation. While the proposed warranty options would be an improvement over some current coverage policies, OOIDA recommends 500,000 miles as opposed to the 450,000 miles under option 1 or the 350,000 miles for option 2. 500,000 would be more aligned with fair-market warranty values. Additionally, OOIDA favors alternative programs that would offer longer, prorated warranties that provide different levels of coverage based on a vehicle's age or mileage. The warranty could be limited to include only certain parts after a certain amount of time, and/or not include labor for some, or even all, of the duration of coverage. [EPA-HQ-OAR-2019-0055-1266-A1, p.7]

Organization: *PACCAR, Inc (PACCAR)*

As discussed above, PACCAR supports EPA’s initiative to extend Heavy-Duty engine warranty periods to cover a greater portion of UL. We specifically support a single step in MY 2027, which is aligned with CARB Step 1 Warranty period, and EPA’s proposed Option 2 of 350,000 miles. This step would increase the UL warranty coverage from 22% to 58% of useful life based on a 600,000 commercial useful life. PACCAR also supports other approaches to ensure long-term in commerce-emissions performance and initiatives that work to incentivize fleet turn over to facilitate the adoption of the new low NOx technology. However, we have concerns about certain aspects of EPA’s proposal that addresses warranty and allowable maintenance. [EPA-HQ-OAR-2019-0055-1346-A1, p.52]

Proposed section 1036.120(c) addresses’[c]omponents covered’ and provides that ‘the emission-related warranty covers all components whose failure would increase an engine’s emissions of any regulated pollutant, including components listed in 40 CFR part 1068, appendix A, and components from any other system you develop to control emissions. The emission-related warranty covers *these components even if another company produces the component*.’ (emphasis added). This broadly worded section needs to revised. Manufacturers have invested billions of dollars developing their products to ensure and maintain emission systems compliance, while keeping pace with increasingly stringent emissions standards. However, as proposed, EPA’s provision conceivably could make OEMs liable for customers installing non- original manufacturer-produced components. OEMs are incapable of validating third-party produced components to ensure they comply with respect to emissions performance and durability as the original manufacturer’s components. OEMs accordingly should not be potentially liable for components produced by another company. [EPA-HQ-OAR-2019-0055-1346-A1, pp.52-53]

PACCAR summarizes below the major issues that EPA should take into account as it moves forward with this rulemaking: PACCAR supports EPA’s initiative to increase warranty to cover a greater percentage of useful life (currently at 22% of UL). PACCAR supports EPA’s proposal to extend the warranty period of at least 50% of Useful life, and would recommend EPA align with the CARB Step 1 warranty period of 350,000 miles (which is 58% of the proposed in-commerce useful life of 600,000 miles). [EPA-HQ-OAR-2019-0055-1346-A1, p. 60]

Organization: *Retail Industry Leaders Association (RILA)*

Additionally, EPA's separate proposal to extend the emissions-related warranty period for heavy-duty engines will likely lead to improved engine maintenance over each engine's lifetime and may even induce the development of simplified repair processes. [EPA-HQ-OAR-2019-0055-1189-A2, p.3]

Organization: *Truck and Engine Manufacturers Association (EMA)*

It is important to highlight from the outset that while there are various details of EPA's rulemaking proposal (particularly with respect to Option 1) that EMA and its members fundamentally disagree with, there are multiple major points of substantial agreement. In that regard, EMA agrees with EPA that:

> (iii) The current emission warranty and useful life periods for HDOH engines and vehicles should be revised to increase the durability and efficacy of in-use emissions compliance; [EPA-HQ-OAR-2019-0055-1203-A1, p. 5]
> (vi) The increase in manufacturers' costs to cover the proposed extended warranty requirements will be substantial, and necessarily will be passed on to purchasers at the point of sale. [EPA-HQ-OAR-2019-0055-1203-A1, p. 5]

Those elements of the low-NOx regulations will result in much higher warranty claims, maintenance costs, and recall liability, at least until the multiple new low-NOx technology systems are proven-out over a multi-year period following the implementation of the 2027 MY standards and compliance programs. More specifically, the substantially extended warranty periods will at least triple the cost of coverage on existing emissions-related components, while also adding warranty costs to cover the new emissions-related components that manufacturers will need to utilize to meet the new standards. [EPA-HQ-OAR-2019-0055-1203-A1, p. 12]

The proposed warranty provisions under §1036.120(c) require that, "The emission-related warranty covers all components whose failure would increase an engine's emissions of any regulated pollutant, including components listed in 40 CFR part 1068, appendix A, and components from any other system you develop to control emissions." That proposed expansion of warranty is overly broad. Current provisions allow that an emissions-related components' is one that has a "primary purpose to reduce emissions or whose failure would commonly increase emissions without significantly degrading engine/equipment performance." (See item IV in the referenced Part 1068 Appendix I, and definition of Critical Emissions-Related Component proposed in §1068.30.) EPA should not expand the universe of components to be covered under the emissions warranty provisions to include those components whose only relation to emissions control is that a failure would increase emissions. EMA agrees with EPA's assessment that, "the cost of expanding the list of warrantable components to include all components that may trigger an OBD MIL, regardless of their direct impact on emissions, would be unreasonable." (87 FR at p. 17509) EMA recommends that this aspect of §1036.120(c) be eliminated in the final rule. [EPA-HQ-OAR-2019-0055-1203-A1, p. 128]

Also of concern is the proposed requirement under §1036.120(b) that the emissions-related warranty should not be shorter in duration than any published warranty a manufacturer "offers with or without charge." EMA believes the use of the word "offers" could be misleading, as it does not directly reflect the warranty actually provided as part of a vehicle sale, whether with or without charge. EPA should clarify this language. [EPA-HQ-OAR-2019-0055-1203-A1, p. 128]

EPA Summary and Response

The summary and response for this section includes a listing of the topics raised, then the comments are summarized by category and the responses follow each summary.

Comments relating to emissions warranty fell into the following general categories

- Support or opposition
  - General support for or opposition to lengthening warranty periods
  - Support for proposed Option 1 or Option 2 warranty periods
  - Support for warranty periods longer or shorter than proposed
- Need for more information
- Potential costs and economic impacts of extending the warranty period
- Reactions to EPA's stated advantages of longer warranty periods
- Hours- and years-based warranty periods
- Components covered by emissions warranty
- Recommended changes to the structure of the emissions warranty program
- Miscellaneous regulatory changes

Support or opposition

ATD, ATA, Great Rivers, and RILA generally supported EPA taking action on lengthening emission-related warranty periods without addressing numeric values. ATD commented in support of "reasonable" revisions. EMA agreed that EPA should revise emissions warranty periods to increase the efficacy of in-use emissions compliance, but did not explicitly support or oppose the warranty periods of either proposed option.

ALA, CARB, and MECA supported the warranty periods of proposed Option 1. MECA and MEMA both supported a phase-in. AVE expressed support for proposed Option 1 standards with modified warranty requirements to limit coverage. Allison, Hyliion, NGVAmerica, and PACCAR supported the single-step proposed Option 2. Allison commented that Option 2 more appropriately balances the costs and benefits and takes into consideration the real-life dynamics and customer behavior. Allison also suggested that EPA could adopt Option 2 now and reevaluate warranty periods in a future rule. Hyliion commented that Option 2 matches CARB's Step 1 warranty, which would provide greater predictability that may limit costs. Cummins recommended that EPA not finalize Option 1 and noted that even Option 2 would result in significant cost increases.

Several organizations recommended warranty periods that differed from the proposed options. Clean Air Task Force et al and MFN suggested that EPA finalize a single-step program that pulls ahead the MY 2031 warranty periods of proposed Option 1 to start in MY 2027. BBU Environmental Services and Clean Air Board of Central Pennsylvania suggested that warranty period should cover the full life of the vehicle. OOIDA recommended a 500,000-mile warranty citing the preferences their members expressed in a recent owner-operator survey. DTNA suggested alternate warranty periods for two engine classes: 5 years/350,000 miles for Heavy HDE and 5 years/175,000 miles for Medium HDE.

Response:

- We appreciate the expressed support from certain commenters for our proposal to lengthen emission-related warranty periods and acknowledge the concerns raised by other commenters.
- We did not propose and do not believe it is appropriate at this time for the warranty periods to cover the full life of the engine, but we retain our proposed objectives to lengthen warranty periods to cover a larger portion of the operational lives and to be more consistent with the final useful life periods. See preamble section IV.B.1 for a discussion of the basis of our final warranty periods, including our consideration of comments on the advantages of longer warranty periods and concerns for the highest mileages in our proposal.
- As explained in section IV.B.1 of the preamble, we are finalizing a single-step program for the new warranty periods to begin in Model Year 2027. Clean Air Task Force, et al. and MFN recommended we pull ahead the proposed MY 2031 warranty periods from Option 1 to start in MY 2027. We agree on that approach for the smaller engine classes and our final warranty mileages match the MY 2031 step of proposed Option 1 for Spark-ignition HDE, Light HDE, and Medium HDE. We disagree on applying that approach for Heavy HDE and we are not pulling ahead the MY 2031 step (600,000 miles) for the Heavy HDE warranty mileage. Similar to our approach for useful life, we are finalizing a warranty mileage that matches the longest mileage proposed for MY 2027, which matches the mileage proposed for Option 2 (450,000 miles). See preamble section IV.B.1 for a discussion of the basis of our final warranty periods, including our consideration of comments on the advantages of longer warranty periods and concerns for the highest mileages in our proposal.
- Allison suggested that we could adopt Option 2 in this rulemaking and reevaluate warranty in a future rule; however, we believe warranty periods that are longer than Option 2 are justified in this rule, starting in MY 2027. A delay in implementing the longest warranty periods will delay the extra miles, years, or hours of coverage for owners and delay the extended emissions control assurance due to proper maintenance and repair for more of the life of heavy-duty engines.
- MECA and MEMA indicated that a phase-in would help suppliers prepare for the longer warranty periods. As we noted in the preamble section IV.B.1, we do not believe a phase-in is needed for suppliers to address data needs at the warranty mileages we are finalizing.

Need for more information

Several organizations commented on suppliers' ability to develop technologies to meet the proposed warranty periods. AVE commented that more research on engine wear and use patterns is needed. BorgWarner indicated that suppliers do not currently have access to data required to design to the proposed warranty provisions. MEMA suggested that EPA's proposal is asking industry to design parts without clear functional requirements and the rule needs more testing and validation specific to vocational vehicle applications and more data and analysis of subsequent owners' usage. MEMA specifically cautioned against applying a one-size-fits-all approach for warranty periods and recommended a separate category for engines intended for vocational applications. Allison also noted real world operational data is best and that validation testing in the design process may not accurately predict the frequency of failures, due to varying vehicle types, operations, maintenance, and use. Allison further commented that suppliers may not know the end-use of their components/systems, causing them to inefficiently design and price their components based on a worst-case assumption. DTNA commented that it is cost prohibitive to design components and be assured of their reliability, given 4 years lead time and 3 years of stability

Response:

- For Heavy HDE, where the highest mileage data is currently most limited, the final warranty mileage of 450,000 is similar to the current useful life mileage for those engines and we expect suppliers are currently designing to that mileage. We expect that suppliers and engine manufacturers will continue to collect additional warranty information, beyond today's federal requirements, from extended warranty packages available for current engines. We also note that the CARB Step 1 warranty may be an additional data resource.[19,20]
- We agree with MEMA that it is not appropriate to establish warranty periods that are one-size-fits-all. As noted in response to other comments in this section and preamble IV.B.1, we are finalizing three warranty thresholds (i.e., mileages, years, and hours) for each heavy-duty engine class, which we believe will lead to more appropriate warranty obligations across the range of possible vehicle applications for which a heavy-duty engine may be used. At this time we do not have sufficient information to establish application-based categories for engines beyond the primary intended service classes that currently apply.

Potential costs and economic impacts of extending the warranty period

Several organizations commented on the costs of lengthened warranty periods and potential economic impacts. CARB commented that EPA's costs are reasonable and comparable to the costs presented in their Omnibus program. CARB also indicated that the higher initial cost will be offset by lower repair costs and that they expect resale value of warranty will be maintained as first owners sell to subsequent owners. AVE commented that extended warranties as proposed will add extensive unknown costs to vehicles. ATD (and, similarly, ATA in section 18.3 of this document) expressed concern about cost impacts on first purchasers, with a specific mention of

[19] For more information on the California Air Resources Board HD Warranty 2018 rule see, "Proposed Amendments to California Emission Control System Warranty Regulations and Maintenance Provisions for 2022 and Subsequent Model Year On-Road Heavy- Duty Diesel Vehicles with Gross Vehicle weight Ratings Greater Than 14,000 Pounds and Heavy-Duty Diesel Engines in such Vehicles," June 18, 2019. Available online: https://ww2.arb.ca.gov/rulemaking/2018/hd-warranty-2018. Last accessed September 21, 2022.

[20] EPA is reviewing a waiver request under CAA section 209(b) from California for the Step 1 Warranty rule. See "California State Motor Vehicle Pollution Control Standards; Heavy-Duty Vehicle and Engine Emission Warranty and Maintenance Provisions; Request for Waiver of Preemption; Opportunity for Public Hearing and Public Comment" at 87 FR 35760 (June 13, 2022).

purchases whose current business model includes short trade cycles and would not keep their vehicles/engines through the longer warranty period to get the full value of the higher purchase price. Cummins noted that even the less stringent proposed Option 2 would significantly increase the initial purchase price, as indicated by the price increases due to CARB's Step 1 warranty program starting in MY 2022. Hyliion suggested that longer warranties would put unknown and potential massive risks on parts manufacturing industry that can lead to additional price increases. Allison, EMA, and DTNA noted the likelihood of high failure rates and warranty claims for new technology, especially in the early years of implementation. Allison commented that OEMs will likely be conservative in estimating costs of future repairs to reduce risks; those increased warranty projections will be passed to customers in the purchase price.

Many commenters indicated that purchase price increases due to the longer warranty periods may delay effectiveness of the rule. Allison suggested that "overly aggressive" warranties will drive up costs, incentivize pre-buy, and reduce turnover of old technology which would delay emissions benefits of the rule. Hyliion, NACD, and NGVAmerica also commented that the cost of extended warranties will be passed on to the customer and decrease demand for new trucks.

Allison, DTNA, EMA and several other organizations suggested EPA's cost analysis was inaccurate. Allison stated that EPA's repair cost analysis, which focused on tractor mileage-based repair cost, is not representative of vocational vehicle repair costs. EMA claimed that extended warranty will triple the cost of coverage on existing emissions-related components while also adding warranty costs to cover the new emissions-related components. DTNA also commented that a longer useful life would impact a manufacturer's decision to schedule maintenance to replace catalysts and the manufacturer may consider the catalyst replacement costs as warranty costs.

<u>Response</u>:

- We acknowledge comments highlighting increased purchase prices due to the lengthened warranty periods and note that, in the proposal for this rule, we described an expectation that manufacturers would continue their current practices of estimating warranty repair costs actuarially and adding the costs to the purchase price of the engine or vehicle. We received no comments that would change that expectation for the final rule.
- We also acknowledge comments indicating a risk of pre-buy and low-buy with increased purchases prices.
- In response to ATD's specific concern relating to purchasers with short trade cycles, we expect, to the extent that fleets currently base their short trade cycles on the time at which today's warranty periods expire, that these companies would consider adjusting their current business model to accommodate the longer warranties in this final rule.
- As explained in section 3.8 of this Response to Comments document and in preamble IV.A, we project the final standards and useful life periods will not require manufacturers to plan for the replacement of the entire catalyst system as a part of their compliance strategy, as DNTA suggests may occur. Since DTNA connected an extended useful life and potential aftertreatment replacement to "exorbitant warranty costs", we are clarifying here that the current and final requirement to pay for any replacement of catalyst beds or particulate filters as part of scheduled maintenance is independent of whether the

scheduled replacement interval falls within the warranty period. A manufacturer that opts to schedule replacement outside of the warranty period, but within useful life, would also be required to pay the cost of the replacement. We agree that, to the extent a manufacturer opts to schedule replacement of their aftertreatment system, they would likely add the cost to their purchase price whether is labeled a "warranty" or "maintenance" replacement. Again, as noted in preamble section IV.A, such replacement is not expected under the final rule.

- See section 18.3 of this document for a complete list of organizations that commented with additional information specific to our analysis of warranty costs. That section provides our responses, including our response to Allison's concern relating to our use of the tractor mileage-based repair cost, and a summary of updates we made for the final analysis.
- We updated our cost and economic impact analyses to reflect the final warranty periods. For more information, see our complete assessments of costs in Chapter 7 and economic impacts in Chapter 10 of the Regulatory Impact Analysis for this final rule.

Reactions to EPA's stated advantages of longer warranty periods

We discussed four potential beneficial outcomes of longer warranty periods in the proposal (see Section IV.B.1 of the NPRM preamble). Many commenters agreed that longer warranties would incentivize owners to maintain their engines over more of the life of the vehicle. Allison expressed support for our expectation that longer warranties may promote better maintenance, reduce tampering, maintain emission performance over time, improve awareness of defects, and encourage manufacturers to simplify repair processes. NASTC agreed that longer warranty would reduce owner costs of servicing emission-related problems. MFN agreed that the warranty period is important to minimize tampering or disrepair, and noted that warranty periods shift the cost of failures onto the manufacturer rather than the driver. Allison disagreed that manufacturers would be motivated to improve their component designs to reduce repair costs due to longer warranty periods. ATA noted that requiring all owners to pay for longer warranties would not prevent tampering, since there will always be "rogue" operations willing to tamper; instead, ATA indicates that enforcement of the CAA is a better tool for reducing tampering.

Response:

- We appreciate the expressed agreement from certain commenters on the possible beneficial outcomes of lengthened emission-related warranty periods and acknowledge the disagreement raised by other commenters.
- In response to NASTC, we clarify that, while repair costs will be covered by the manufacturer over a larger portion of the operational life of the engine and we believe a longer warranty period may incentivize manufacturers to reduce the costs of servicing their emission-related components, at least some of the repair costs will be paid upfront by the first purchaser of the engine. Similarly, in response to MFN, while the emission-related warranty does ensure manufacturers take responsibility for the repair of component failures, we expect they will continue to estimate the cost to address future

repairs under warranty and add that cost to the purchase price such that owners pay for the repairs upfront instead of throughout the life of the engine.

- We agree with ATA that enforcement is an effective deterrent for tampering and that longer warranty periods will not *eliminate* tampering. We disagree that a longer warranty would be ineffective, since we expect even "rogue" trucking operations would, at minimum, delay their tampering until the longer warranty period has ended to continue having repair costs covered by not voiding their warranty, thus providing many additional miles of ensured emission control.

Hours- and years-based warranty periods

Several organizations commented on the proposed years or hours criteria for useful life. MEMA stated that members had concerns with the proposed 7 and 10 year limits, but did not provide specific information. Allison noted that data collected at the higher mileages may not accurately predict the use of vocational vehicles that are more limited by hours of operation. Allison suggested EPA should "utilize a finer-targeted system" and further differentiate warranties by vehicles classes and vocations. NWRA suggested EPA consider hours-of-service regulations as the basis of our warranty hours. Cummins and CARB supported applying an hours-based warranty period for all engine classes to cover lower-speed applications and the 20-mph conversion factor that we proposed.

Response:

- While MEMA indicated concern for the proposed Option 1 years values, they did not provide specific information to update our proposed years. To account for engines that are less frequently used (e.g., seasonal vehicles such as motorhomes or snowplows), we are continuing to apply year-based warranty periods and the final years values are increased from 5 years to 10 years for all engine classes, which matches the MY 2031 step of proposed Option 1. See preamble IV.B.1.
- We agree with Allison that vocational vehicles have distinct use patterns; however, we did not propose and are not finalizing warranty periods at the vehicle level. See preamble IV.B.1.
- Regarding NWRA's suggestion, it is our understanding that the hours-of-service regulations would not be appropriate for determining hours, because those regulations target drivers operating high speed vehicles that travel many miles per year. High mileage vehicles would likely reach the warranty mileage criteria first and do not represent the vehicles that would be hours-limited. The hours criterion is intended to limit an engine manufacturer's warranty obligation for lower-speed vehicles, such as refuse trucks, that may not accumulate many miles, but operate frequently in modes that can stress the engine.
- We appreciate Cummins and CARB support for hours-based warranty periods. We received no adverse comments on this issue and are adding hours-based warranty periods for all engine classes in the final rule. Consistent with our final hours-based useful life periods, we are calculating the final hours-based warranty periods by scaling the final mileages using a 20-mph conversion factor.

Components covered by emissions warranty

The NPRM included a request for comment on expanding the list of components covered under warranty to include any component that triggers an OBD MIL. CARB recommended EPA adopt the provision to align with their program, referring to proposed 40 CFR 1036.120(c) to suggest that the phrase "covers all components whose failure would increase an engine's emissions of any regulated pollutant" logically connects warranty to the OBD system, since it monitors for emissions increases and would indicate that a failed component has led to an emissions increase. Allision, Cummins, DTNA, and EMA opposed expanding the list of components. DTNA provided examples of components (e.g., fuel level sensors, vehicle speed sensors, real-time clocks) that provide an input to the OBD system and could trigger a MIL. EMA suggested we update the regulatory text describing the components covered by warranty to be consistent with the proposed 1068.30 definition of "critical emission-related component" and paragraph (IV) of 1068, appendix A. Specifically, they requested that warranty to be limited to components whose "primary purpose to reduce emissions or whose failure would commonly increase emissions without significantly degrading engine/equipment performance."

<u>Response</u>:

- While we did not directly propose to use a component's connection to a MIL as an indicator that it should be covered under warranty, EMA and CARB seemingly interpreted our proposed regulatory text in 40 CFR 1036.120(c) as expanding the list of components covered.
- We agree with CARB that OBD is an effective tool to identify components that fail and lead to emissions increases. However, we retain our proposed position and disagree that <u>all</u> components that trigger a MIL should be covered under warranty. Since a failure of some components would not directly increase emissions, we would not consider them a component covered under emissions-related warranty.
- We are revising proposed 40 CFR 1036.120(c) to refer directly to appendix A of 1068 as the list of components covered under warranty. This revision is consistent with the original intent of the list of emission-related components in 1068, appendix A, which states that "This appendix specifies emission-related components that we refer to for describing such things as emission-related warranty or requirements related to rebuilding engines." By removing the proposed phrase "covers all components whose failure would increase an engine's emissions of any regulated pollutant" in 40 CFR 1036.120(c), we clarify that we are not expanding the list of components beyond what is currently covered under emissions-related warranty.
- We note here and in our maintenance discussion in preamble IV.B.2 that we are also replacing the current text of paragraph IV of 40 CFR 1068, appendix A, with a reference to the new part 1068 definition of critical emission-related components. This revision avoids having similar text in the appendix and definition. We expect that these updates, along with the revised 40 CFR 1036.120(c) reference to the 1068 appendix, will address EMA's recommendation since their recommended text is consistent with the new definition of critical emission-related components.

- We note that the warranty provisions for other sectors continue to use the language proposed for 40 CFR 1036.120(c) and we may consider addressing any potential inconsistency in a future rulemaking.

Two manufacturers requested that EPA clarify the regulatory text in proposed 40 CFR 1036.120(b) and 1036.120(c). EMA commented that the phrase “offers with or without charge” in 1036.120(b) is misleading. PACCAR expressed concern that, under the proposed 1036.120(c), OEMs would be liable for third-party components added to their engine.

Response:

- We are revising the proposed 40 CFR 1036.120(b) to remove “with or” in the final provision, which was added in error. The phrase “offers without charge” is consistent with the corresponding provision in other sectors (e.g., 40 CFR 1039.120(b)) and with the current definition of warranty in 40 CFR 86.004-2 that refers to a “basic mechanical warranty” that would be offered without charge.
- We are revising proposed 40 CFR 1036.120(c) to clarify one aspect of the components covered by warranty. Since manufacturers rely on many suppliers to create the emission-related components on the engine they are certifying, we continue to believe it is appropriate for an emission-related warranty to cover any components, regardless of the company that produced them, that are the original components or the same design as components from the certified configuration, We note that we are adding the same clarification to the corresponding vehicle provision in 40 CFR 1037.120(c). We also note that we proposed no changes and are finalizing no changes to the existing 40 CFR 1068.115, which specifies when manufacturers may or may not deny warranty claims. See also section 6.3 of this document for our description of the relationship between warranty and scheduled maintenance under the final rule.

Recommended changes to the structure of the emissions warranty program

In the ANPR and NPRM for this rule, we requested comment on alternative approaches we should consider for emissions-related warranties. Allison and OOIDA expressed support for the graduated warranty approach that included options for pro-rating certain components over time. Similarly, Allison, AVE, and BorgWarner recommended that EPA identify certain components to be covered by the longest warranties.

Response:

- While we recognize that there could potentially be value in these approaches, we did not propose and do not have sufficient data at this time to develop a graduated warranty program or determine appropriate warranty periods for specific components. We may consider those approaches in a future rule.

AVE, BorgWarner, and MEMA noted that many components require routine maintenance and that those components should not be covered under warranty. MEMA suggested that, instead, such parts and components should be defined as standard maintenance or replacement items. BBU Environmental Services requested that DEF systems be covered by manufacturer warranty for the full life of the vehicle.

Response:

- In our updated maintenance provisions (see Section 6 of this document and section IV.B.2 of the preamble), we are retaining the current structure that allows manufacturers to specify maintenance intervals for components that require regular adjustment, cleaning, and/or replacement within the useful life. We are updating the minimum maintenance intervals to reduce the frequency at which manufacturers can require this scheduled maintenance.
- In general, scheduled maintenance specified by the manufacturer is proactive maintenance covered by the owner, which is distinct from a manufacturer's responsibility to cover a failed component under warranty.
- In response to BBU, DEF systems are emissions-related components and will be covered under warranty for a larger portion of the operational life of the vehicle under this final rule. We are not finalizing a unique extended warranty for DEF systems. While we believe manufacturers will be able to design their aftertreatment systems to be durable enough to last the useful life of the engine (see preamble section IV.A), they continue to have the option to schedule replacement of those systems as long as they pay for the catalyst bed, the most expensive part of a DEF system. See our updates to the proposed maintenance provisions and corresponding responses to comments in Section 6 of this document.

Miscellaneous regulatory changes

AVE and BorgWarner requested that owners should have to supply maintenance records and show no sign of abuse or manufacturers should be allowed to deny a warranty claim. BorgWarner expressed concern over current practices in shops that use inadequate or incomplete diagnostic routines to identify failures. BorgWarner also suggested that having a useful life definition for each system component would limit a manufacturer's warranty exposure.

Response:

- Our current regulations under 40 CFR 1068.115(a) specify that a manufacturer can deny a warranty claim for "improper maintenance or use." We are making no changes to that provision in this final rule.
- In section 5 of this document and section IV.B.3 of the preamble, we describe the serviceability improvements we are finalizing. Some of the new serviceability requirements are targeted at improving access to repair and servicing information that may address some of the concerns expressed by BorgWarner.

- In section 6 of this document and section IV.B.2 of the preamble, we describe our update to 40 CFR 1036.125(h)(2) to clarify the information we require that manufacturers include in their owner’s manual if they expect specific maintenance record be kept by owners.
- While BorgWarner suggests a unique useful life for each emission-related component, we note that regulatory useful life applies for the entire certified engine configuration and is distinct from a manufacturer’s requirement to warrant emission-related components. We do not have sufficient information to set warranty periods for individual components at this time.

In response to EPA’s request for comment in the NPRM for this rule, NASTC commented in support of EPA explicitly stating in the warranty regulations that manufacturers may not deny warranty based on use of commonly available DEF.

<u>Response</u>:

- We did not propose and are not finalizing any explicit regulatory text to note the use of commonly available DEF at this time. We may consider this in a future rule where we expect we would propose to apply it broadly to all sectors covered under 1068.

5 Serviceability

5.1 Repair and servicing information in owner’s manual

<u>Comments by Organizations</u>

Organization: *American Truck Dealers (ATD)*

Regarding “serviceability,” ATD specifically objects to any EPA requirement that:

1. Emissions-related service information be published in owners’ manuals given that professional technicians have ready access to such information elsewhere. [EPA-HQ-OAR-2019-0055-1321-A1, p. 7]

2. OEMs prominently “advertise” to CMV owners their right to have emissions-related repairs performed at so-called “independent” repair facilities using third-party components of their choosing. To the contrary, OEMs are and should be free to encourage CMV operators to use original equipment parts and components, and to seek out franchised dealership service departments when in need of emission-related service, thereby helping to protect air quality by

both ensuring the proper service and repair of emissions-critical systems, and avoiding emissions tampering. [EPA-HQ-OAR-2019-0055-1321-A1, p. 7]

Organization: *California Air Resources Board (CARB)*

U.S. EPA has recognized that defective designs and tampering can contribute to increase in-use emissions. Mal-maintenance can also result in increased emissions. Many commenters on U.S. EPA's ANPRM stated that they were frustrated with the emission control system reliability, misdiagnosis with improper repair by professional service facilities and limited access to maintenance information that would facilitate the owner's ability to properly repair their vehicles themselves. To help address these concerns, U.S. EPA has proposed that important maintenance information be available in the owner's manual starting voluntarily before 2027 and be required in 2027 and subsequent model years. U.S. EPA has asked comment about making this proposal mandatory as soon as 2024 MY and what other information should be included in the owner's manual. [EPA-HQ-OAR-2019-0055-1186-A2, p.117]

CARB staff fully supports U.S. EPA making serviceability requirements mandatory as early as 2024 MY. Manufacturers already have this information and provide it to their authorized repair facilities (usually for a fee). Although there will be additional printing costs to include the information requested by U.S. EPA, this cost should be negligible. Furthermore, it can be argued that accurate information on how an owner can properly repair and service an engine available readily in the owner's manual would pay for itself by potential avoided warranty costs by the manufacturer. Therefore, CARB staff believes this requirement should be made mandatory and should not be delayed for another 3 years. Better accessibility to repair information will help owners to address repairs as soon as possible with accurate information and help avoid having their truck taken out of service. [EPA-HQ-OAR-2019-0055-1186-A2, p.118]

CARB staff supports that the manufacturer provide in the owner's manual more detailed information on how to clean their DPF. DPF is a critical emission control component designed to control toxic/carcinogenic diesel particulate matter. Failure to properly remove accumulated ash at regular intervals will result in DPF cracking and/or uncontrolled thermal events that could cause sintering or platinum group metal migration for catalyzed DPFs. CARB staff agrees that it is important to have owner's manual information on how to remove the DPF for cleaning, the criteria for determining if the ash was properly removed, such as using the clean or 'birth' weight of the DPF, DPF inlet and outlet pressures are available with a generic scan tool and any other information on how to properly maintain and prevent damage to the DPF. In addition to these items listed in the NPRM, CARB staff has assembled an internal workgroup to provide more specific criteria what needs to be in the owner's manual for DPF cleaning. This working group is also intended to provide criteria for manufacturer 'swapping' programs where an owner can turn in their DPF at an authorized repair facility for cleaning and get installed a different DPF that has been 'cleaned'. This is to ensure that damaged DPFs are not returned into service and no used DPFs are offered for sale. This more recent effort was based on experiences gained in implementing CARB's diesel retrofit program. When CARB staff have developed a more finalized version of DPF cleaning, we will share that with U.S. EPA staff for possible guidance and/or adoption. [EPA-HQ-OAR-2019-0055-1186-A2, p.118]

Other information that should be included in the owner's manual are inducement warnings, inducement derate schedules, and when a vehicle will go into final inducement. Also, as mentioned above, CARB staff believes it is important to have detailed DPF cleaning information and the criteria for when a filter is deemed 'clean' in the owner's manual. [EPA-HQ-OAR-2019-0055-1186-A2, p.118]

Organization: *Cummins Inc. (Cummins)*

In §1036.125(h)(3)-(11), EPA proposes to require manufacturers to include eight types of information in their engines' owner's manuals: how the owner can use OBD information, how the emission control systems operate, flow path diagrams, exploded-view drawings with part numbers and assembly requirements, basic wiring diagrams for aftertreatment-related components, where to find emission recall and repair information for free from NHTSA, troubleshooting guide for DEF and DPF warning signals, and DPF cleaning instructions including filter weights and inlet/outlet pressures. Much of this information is currently readily available to owners of Cummins engines, accessible online for free after specifying their engine serial number or engine model. For example, see https://quickserve.cummins.com/ and https://parts.cummins.com/. Additionally, some of the same information is already required by regulation and is made available per EPA's and CARB's service information requirements (SIR). [EPA-HQ-OAR-2019-0055-1325-A1, p. 17]

Much of the additional information EPA proposes to require manufacturers to include in the owner's manual resides in numerous sources today, such as operation and maintenance manuals, service manuals, troubleshooting and repair manuals, wiring diagrams, parts databases, temporary repair practices, technical service bulletins, etc. Each source is organized and tailored according to the intended audience and type of information it needs to convey. Requiring manufacturers to add such information to the owner's manual, which is the source intended to describe normal operation of the engine, is redundant and could cause unnecessary confusion. EPA should allow manufacturers to determine the best approach for communicating the information owners need to know and should not prescribe where that information resides or how it is delivered. [EPA-HQ-OAR-2019-0055-1325-A1, p. 17]

EPA should not finalize the proposed additions to owner's manuals in §1036.125(h)(3)-(11), nor the proposed requirement of §1036.135(c)(10) to link to that information from a QR code on the emission control information label. (If EPA does finalize the requirement for a mandatory QR code on the engine label, it should take effect no earlier than MY 2027.) [EPA-HQ-OAR-2019-0055-1325-A1, p. 17.].

Cummins would like to work with EPA to explore alternatives for ensuring owners have the information they need to keep their engines' emission control systems functioning properly.[EPA-HQ-OAR-2019-0055-1325-A1, p. 17]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

The complexity of modern emissions control systems requires expert evaluation to determine the appropriate cause of any given failure, and the correct procedure to replace failed components.

Such determinations and service actions should only be performed by trained professionals operating with detailed information about the particular system at hand. Manufacturers are already required to provide access to their service tools and information at a reasonable price, and professional repair facilities and fleets already make use of this information. [EPA-HQ-OAR-2019-0055-1168-A1, p.76]

EPA proposes to require OEMs to provide additional maintenance information in the owner's manual. This proposal is intended 'as a way to improve factors that may contribute to mal-maintenance, resulting in better service experiences for independent repair technicians, specialized repair technicians, owners who repair their own equipment, and possibly vehicle inspection and maintenance technicians.'120 The proposal is unnecessary, however, as most of the information that EPA would require is already readily available to technicians and fleets, and manufacturers are already required to provide access to detailed service procedures, manuals, etc.121 [EPA-HQ-OAR-2019-0055-1168-A1, p.106]

120 Proposed Rule, 87 Fed. Reg. at 17,516.

121 For example, the public is able to purchase service information for Detroit Diesel engines readily at https://dtnacontent-dtna.prd.freightliner.com/content/public/DDCSN/Literature/chassis-engine-service-informationsubscription.html. Similarly, our service and diagnostic tools are available to the public,

Detailed service information is necessary so that trained technicians can properly maintain the engine and its emissions control systems. Daimler Truck provides detailed information intended to keep the service technician safe and to ensure the continued proper functioning of the system. For example, the Company provides safety-critical information including how to properly remove and service an aftertreatment system (including to clean the DPF), or how to service the fuel system, with safety-critical specifications for torque, identified one-time-use components, and more information necessary to guard against the risk of fire and other safety issues. [EPA-HQ-OAR-2019-0055-1168-A1, pp.106-107]

The operator's manual is not sufficient (in terms of length, scope, or detail) to provide this information. EPA nonetheless proposes to require manufacturers to provide technical information in the owner's manual about how to repair the engine, how to diagnose and troubleshoot problems, exploded-view diagrams with part numbers and basic assembly requirements with 'enough detail to allow a mechanic to replace any of those components.'122 [EPA-HQ-OAR-2019-0055-1168-A1, p.107]

122 Proposed Rule, 87 Fed. Reg. at 17,516.

Daimler Truck is extremely concerned that providing the required information in the owner's manual could lead owners to believe that the detailed service information in the troubleshooting and service manuals is not necessary, and could lead operators and mechanics to attempt to diagnose, troubleshoot, repair, or maintain the system without adequate information. This, in turn, would likely lead to improper maintenance of the emissions control system, but more importantly, could also lead to *significant safety concerns* as untrained, ill-informed technicians may miss critical maintenance and repair operations. [EPA-HQ-OAR-2019-0055-1168-A1, p.107]

123 Id.

It is not feasible, practical, or effective to include all necessary service information in the operator's manual. For comparison, the operator's manual provided with Detroit engines is less than 100 pages; but the service information (which Detroit makes available at a reasonable cost) is an online resource with *thousands of pages* of detailed troubleshooting information, diagrams, troubleshooting procedures, and most importantly, *safety critical procedures* to protect the operator and/or technician. It also includes exploded diagrams and assembly instructions for all components, including the most up-to-date part number information. The troubleshooting, repair, and part number information is all updated constantly with the most recent procedures and parts. [EPA-HQ-OAR-2019-0055-1168-A1, p.107]

Daimler Truck is similarly concerned by EPA's proposal to require manufacturers to provide in the operator's manual a troubleshooting guide to address DEF dosing-and DPF regeneration-related warning signals, including a description of the fault condition, potential causes, including a list of all codes that cause derate or inducement.123 This information is already provided in the existing service information that manufacturers provide at a reasonable price. For instance, the troubleshooting manual for any given Detroit engine is roughly one thousand pages of detailed service information and cannot be reasonably condensed into an operator's manual format. [EPA-HQ-OAR-2019-0055-1168-A1, p.107]

Indeed, several printed pages of information included in an engine operator's manual are not sufficient to enable adequate troubleshooting, diagnosis, repair, or maintenance. Further, given the limitations of the print manual format, any information included in the engine operator's manual will be out of date before it can be used. Including such information in the manual only serves to encourage untrained, ill-informed service work, which is detrimental to emissions performance and will cause a variety of safety risks. [EPA-HQ-OAR-2019-0055-1168-A1, p.107]

While EPA has received comments that many fleets would like this information, the fact remains that this information is already available. Fleets and service facilities can access all of this information, with significantly more detail than could be included in the operator's manual. [EPA-HQ-OAR-2019-0055-1168-A1, p.108]

Modern diesel engines are complicated equipment that must be serviced by a trained and informed professional. The full repair and diagnostic information needed to perform this work competently cannot be included in an operator's manual. Daimler Truck recommends that instead of mandating enhanced service information in an operator's manual, EPA should focus on enforcing current requirements to make service tools and information available to trained technicians—and specifically, that the Agency focus on ensuring that the information provided by manufacturers is sufficient, accurate, and accessible. [EPA-HQ-OAR-2019-0055-1168-A1, p.108]

Daimler Truck acknowledges EPA's goals of trying to increase owner understanding of emission control systems and improve repair experiences. However, in setting what information must be included in the operator's manual for proper service and maintenance, the Agency makes some assumptions about these procedures that are not borne out in reality. The most specific example, and the most problematic, is EPA's proposal to require the inclusion of instructions for servicing the DPF. [EPA-HQ-OAR-2019-0055-1168-A1, p.108]

EPA assumes that manufacturers could provide relatively simple instructions that would enable them to easily clean their own DPFs. For Detroit engines, Daimler Truck does not currently provide an in-shop DPF cleaning procedure in any service literature, including to our branded dealer network, due to the complex, sensitive nature of DPF cleaning. We do not believe an in-shop DPF cleaning procedure would stand up to the performance equivalency requirements demanded today by EPA and CARB. Our validated and EPA-approved DPF cleaning process requires a core exchange, where filters are cleaned in a controlled facility with specialized equipment. Daimler Truck cannot provide simple instructions for how an operator can perform this procedure, since it cannot be performed without special training, equipment, and instructions. [EPA-HQ-OAR-2019-0055-1168-A1, p.108]

Failure to perform DPF cleaning or improperly cleaning a DPF may result in negative outcomes that significantly affect the health of the emissions control system, including: DPF soot leakage; DPF coating degradation; DPF overtemp, which can result in DPF cracking or SCR damage due to PGM migration; and SCR overtemp. [EPA-HQ-OAR-2019-0055-1168-A1, p.108]

EPA proposes to specify, in a new Section 1036.125(h), the information manufacturers must provide to help an operator to determine that DPF maintenance is necessary, or that it has been sufficient. The information required in the Proposed Rule is insufficient, and is in fact inadequate for these purposes. OEMs should have the ability to determine the best way to notify an operator of approaching DPF maintenance requirement. Below are examples of specific pieces of information that EPA proposes to require in Section 1036.125(h) that would in fact be counterproductive to the goal of ensuring optimal DPF service and cleaning: [EPA-HQ-OAR-2019-0055-1168-A1, p.108]

First, system backpressure is not necessarily a primary or reliable metric for determining DPF state. Backpressure is a function of mass flow, temperature, soot, and ash load. Displaying DPF backpressure is not useful or meaningful unless done in a controlled way (i.e., during a specific service routine). The sensitivity of backpressure measurements to external factors may result in false negative/positive for indicating DPF maintenance is required. Backpressure is also influenced by other factors in the system, for example, solidified DEF deposits, DOC face-plugging with hydrocarbons and soot. If an operator uses backpressure as a DPF diagnostic with other influencing variables, they may interpret a false positive or negative for DPF maintenance. Isolating backpressure to the DPF component level requires sensors located at DPF in and DPF out. Manufacturers may not measure pressure directly across the DPF today. [EPA-HQ-OAR-2019-0055-1168-A1, pp.108-109]

Second, clean filter weight & preinstalled filter weight are inappropriate as 'clean filter' criteria. Due to a stack up of production tolerances on the particulate filter, mat, and can weights, a generic clean filter weight band lacks the granularity required to determine weight gain due to ash. Weights by serial number are required. Further, using pre-installed filter weight as a metric requires the filter to be measured before installation into the assembly. This weight must be recorded and tracked from the canning/housing supplier to the truck plant, then manually flashed into the calibration. This tracking is a significant undertaking for a method that has additional error and other issues. [EPA-HQ-OAR-2019-0055-1168-A1, p.109]

Our experience with weighing DPFs has found a number of challenges for capturing an accurate ash weight over lifetime. DPF assembly weights may fluctuate with residual gasket material stuck to the flange, due to dirt road grime improperly cleaned from the can, and even influences of can oxidation/rust. DPFs must be weighed hot both pre-and post-installation to eliminate the effect of condensation due to ambient and exhaust conditions. This requires an oven for weights at the canner and increases cost and complexity of manufacturing. A repair shop must either purchase an oven to check DPF weights, or a technician removes the filter from the vehicle at a controlled, high temperature. In our experience, this violates safety protocols and safe handling DPF removal guidelines for many shops and technicians. A filter weighed at different conditions can have different measured weights. Manufacturers carefully control for this during testing to determine accurate filter weights, which is not feasible or controllable in a service environment. Moisture trapped in the DPF can significantly influence the weight of DPFs, which may obscure any information about the amount of ash or particulate matter in the DPF. [EPA-HQ-OAR-2019-0055-1168-A1, p.109]

Third, pressure drop and weight are also inappropriate as 'clean filter' criteria. EPA's proposed wording of Section 1036.125(h)(11)(ii) implies that 'clean filter criteria' must include pressure drop and weight. For the reasons described above, we do not believe these criteria are appropriate for determining whether a filter has been adequately cleaned or not. [EPA-HQ-OAR-2019-0055-1168-A1, p.109]

Daimler Truck invests significant research and development resources into developing its proprietary filter cleaning process. This process requires specialized equipment for an effective multi-step cleaning process, as well as thorough multi-step quality checks after cleaning. The Company does not use system backpressure or filter weight in this process as a metric to indicate a DPF has been successfully cleaned. The metrics used and validated as part of this cleaning process cannot be measured or reported in the vehicle, and rely on off-board measurement equipment. Furthermore, in order to gain approval for offering this process to the field, the Company has demonstrated equivalency between a new and remanufactured cleaned DPF with EPA and CARB. [EPA-HQ-OAR-2019-0055-1168-A1, p.109]

EPA's proposal to require certain DPF cleaning information in operator manuals will encourage less precise, less complete DPF cleanings, which could lead to premature DPF failures and increased PM emissions. EPA should allow manufacturers significant leeway with regards to such critical maintenance of emissions critical components. DPF cleaning is not a simple operation, and cannot be treated as such. [EPA-HQ-OAR-2019-0055-1168-A1, pp.109-110]

Because of the sensitivity of the emission control system to proper DPF maintenance and the scrutiny that regulatory oversight agencies apply to the OEM cleaning procedures, it is unreasonable for EPA to require an OEM to publish criteria for DPF cleaning. This would amount to a tacit endorsement of third-party cleaning methods that have not been validated for effectiveness or risk to the system. [EPA-HQ-OAR-2019-0055-1168-A1, p.110]

As an alternative approach for ensuring adequate DPF maintenance and cleaning, Daimler Truck recommends that EPA:

- Allow OEMs flexibility in the metrics used to display DPF service life to the operator. For example, an indicator of DPF ash full % or estimated mileage to cleaning can be provided in J1939 or in a dash maintenance menu, rather than a specified parameter (such as pressure drop) which may not be adequately indicative of remaining filter life.
- Allow OEMs sole discretion to determine whether and how to release DPF cleaning methods, given the sensitivity of the component and its direct impacts to emissions, as well as potential risks for long-term compliance and warranty obligations. Further, EPA should not require the publication of in-shop cleaning procedures if the OEM has deemed them insufficient. [EPA-HQ-OAR-2019-0055-1168-A1, p.110]

Organization: *Ford Motor Company (Ford)*

We recommend that EPA remove the requirement to include extensive service information for critical emission-related components in the owner’s manual (e.g., OBD information, flow path for intake air and exhaust gas, engine coolant flow path, emission-related part numbers, etc.) . This type of information is already available in Ford service manuals. Including this type of information in the owner’s manual will require significant quantities of new data to be added to the owner’s manual and will likely provide little benefit to customers. Ford would be willing to support a requirement that instruction on how to access manufacturer service information resources (web site addresses, etc.) be included in the Owner’s Manual. [EPA-HQ-OAR-2019-0055-1300-A1, p. 6]

Organization: *Lubrizol Corporation (Lubrizol)*

2) Lubrizol supports provisions to require lubricant-related maintenance information to be provided to owners and operators in the owner’s manual. Lubrizol supports EPA’s proposal to require important maintenance information to be made available in the owner's manual.3 As EPA knows, the owner's manual relied upon by heavy-duty vehicle owners or operators to describe appropriate engine maintenance, applicable warranties, and any other information related to operating or maintaining the engine or vehicle. By requiring additional maintenance information in the owner's manual, EPA will be taking an important step towards reducing mal-maintenance, better service experiences for independent repair technicians, specialized repair technicians, owners who repair their own equipment, and possibly vehicle inspection and maintenance technicians. Most important, we believe that this step will provide greater assurance of long-term in-use emission reductions by reducing likelihood of occurrences of tampering. [EPA-HQ-OAR-2019-0055-1304-A1, p.3]

3 See Proposal, p. 17515.

The owner's manual and engine label should also include an internet link that would enable owners or operators to obtain this information online. [EPA-HQ-OAR-2019-0055-1304-A1, p.3]

We support making these changes mandatory, starting with MY 2024. Given the importance and complexity of emission control systems and the impact to drivers for failing to maintain such systems, Lubrizol urges EPA to require that OEMs provide this additional information in the owner's manual as soon as possible. [EPA-HQ-OAR-2019-0055-1304-A1, p.3]

Organization: *National Association of Small Trucking Companies (NASTC)*

Nevertheless, NASTC first and foremost appreciates that, with this proposed rule, the agency has carefully considered our sector's input from the 2020 advanced notice of proposed rulemaking, as seen from this NPRM's modernization of inducement and serviceability provisions. Specifically, NASTC applauds separate inducement schedules for high- and low-speed vehicles — making it easier for truckers to make repairs while on the road, using generic scan tools, and providing more, specific information like diagnostic codes — and better warranty coverage of emission system and parts failures so as to keep trucks that remain in service performing emissions reduction while reducing truckers' costs of servicing the systems for the actual life of a vehicle. [EPA-HQ-OAR-2019-0055-1130-A1, p. 2.

Requiring that systems provide more, specific information, including diagnostic codes. Having cab displays that name the condition that triggered the pending or active derate and a countdown timer of the estimated time or distance before the next stage of derating (even if overridden) would give truckers more and better information about inducements as they happen, help them make informed decisions about trip management, repairs, etc., and make the inducement system more tolerable. Coupled with generic scan tools and new capabilities to diagnose and repair emission system problems, this empowers drivers with better information, better tools, and better options. Drivers are more likely to take action when enabled in the ways and by the means proposed. They would know not only the problem, but how to fix it, while better able to manage trip plans and commercial obligations. Moreover, NASTC supports the proposed additional information in owner's manuals, including how to use the OBD system to troubleshoot problems. [EPA-HQ-OAR-2019-0055-1130-A1, p. 3] (these comments are also in 7.4)

In addition to rectifying the overly aggressive inducement and imbalanced serviceability rules that presently affect commercial motor carriers, there are other important reasons to enact the above and most of the other proposed regulatory reforms in these areas. As NASTC members and other transportation industry commenters in the ANPRM made clear, the present rules, including those relating to inducement and serviceability, cause extensive unpredictability, uncontrollability, and unduly burdensome and economically harmful effects, such as unreasonable costs and delays for truckers and supply chain disruptions for businesses and consumers. [EPA-HQ-OAR-2019-0055-1130-A1, p. 3]

The reason for far too many of the consequences suffered under present inducement and serviceability rules is the underlying emissions standards and the highly complex, expensive equipment created in response to the mandates on newer model diesel engines and heavy-duty vehicles. As welcome as regulatory relief from the status quo is regarding these respects, the underlying proposed NOx and GHG emissions reduction standards in this NPRM will certainly result in OEMs introducing even more complex, expensive diesel engines and associated systems. The mandates on OEMs will surely result in unpredicted, adverse spillover effects on commercial vehicle owners—including even more equipment unreliability, unpredictability, additional uncontrollable expenses, delays keeping truckers from productive use of time and resources, lost business, and sweeping adversity and deprivation visited upon businesses and consumers across the nation. [EPA-HQ-OAR-2019-0055-1130-A1, p. 4]

Organization: *Owner-Operator Independent Drivers Association (OOIDA)*

More repair and servicing information in owner's manuals such as descriptions, diagrams, instructions, troubleshooting guides, and QR codes will make self-maintenance more understandable and more commonplace. [EPA-HQ-OAR-2019-0055-1266-A1, p.7]

Organization: *PACCAR, Inc (PACCAR)*

Finally, as proposed, section 1036.125(h)(6) states that manufacturers should 'Include exploded-view drawings to allow the owner to identify the part numbers and basic assembly requirements for turbochargers, aftercoolers, and all components required for proper functioning of EGR and aftertreatment devices. Include enough detail to allow a mechanic to replace any of those components.' (emphasis added). As parts are improved and updated, part numbers will change and be superseded. Therefore, EPA should revise its Proposed Rule to allow industry to identify these parts by name instead of number. [EPA-HQ-OAR-2019-0055-1346-A1, pp.53-54]

Organization: *Truck and Engine Manufacturers Association (EMA)*

As also noted below in our specific comments on the proposed regulations, EMA does not support EPA's proposal to include additional maintenance information in the owners' manual. Many of the proposed service information items go beyond the scope of general information necessary for all users, and could create significant unintended consequences. Most of the service-related information that EPA is proposing to now provide in the owners' manual is already available and provided by manufacturers today, but through specific service databases, guides and other documentation, where different types of information are made available according to specific user skill-sets, warranties, maintenance needs, etc. Further, much of the information at issue is already provided for at a "fair and reasonable cost" (as required by the service information regulations of 40 CFR part 86). Given that this information is already available, we do not understand the need to provide duplicate information in the owners' manual, especially when any such information likely will go beyond the maintenance capabilities of the target audience for vehicle owners' manuals. The proposed inclusion of maintenance and emission controls information along with general vehicle information would give the false impression that more substantive repairs are similar in nature to the general use information otherwise provided in an owners' manual. Further, including service information in the owners' manual would greatly increase the size of the manual – it would result in a manual that is prohibitively large, and would not fit in a typical vehicle glove box or elsewhere in the vehicle without taking up a significant amount of space. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 97 - 98]

In sum, it is unclear why information that is otherwise available, and tailored to the appropriate audiences, should also be included in a general vehicle owners' manual. While we do not support the proposal to provide such information in the owners' manual, we would not be opposed to providing information in the owners' manual regarding where service information can be found. [EPA-HQ-OAR-2019-0055-1203-A1, p. 98]

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. §1036.125(h): "(h) Owners manual. Include the following information in the owners manual to clarify maintenance instructions and the owner's responsibilities:" As noted above, we do not support the proposed addition of the items listed in paragraphs (h)(1) through (11) to owners' manuals. These items go beyond the scope of general information provided to all users, and more detailed service-related information is available via other manufacturer-provided manuals and tools. We note that manufacturers are already obliged by the service information regulations of 40 CFR 86.010-38 to make such information available, thus manufacturers are already providing this information publicly. While we do not support the proposal to also provide such information in the owners' manual, we would not be opposed to providing information in the owners' manual regarding where service information can be found. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 103 - 104]

EMA opposes the proposed requirement to describe the emissions control system and OBD trouble codes (§§1036.125(h)(4) through (8)) in such detail as to give owners the sense that they could apply "backyard mechanic" skills to repair complex emissions control systems, despite a complete lack of training, and without the correct tools to make quality repairs to restore emissions control. Just the opposite could happen, where the actions of the owner could lead to other component issues and potentially more severe emissions exceedances. Today's technicians connect to the emissions control system with qualified tools to perform diagnostic routes, and to reset parameters when new sensors are installed. This level of rigor is required to take appropriate corrective action on today's complex emissions control systems. [EPA-HQ-OAR-2019-0055-1203-A1, p. 128]

EPA should abandon the proposal to compel manufacturers to educate owners on repair processes through the owner's manual. The proposed requirements of §§1036.125(h)(3) through (11) should be deleted in the final rule. Current service information requirements offer qualified repair technicians the tools, information and supporting training they need to effect quality repairs. This should be the preferred path owners take when they are alerted to component issues by way of the OBD MIL lamp. [EPA-HQ-OAR-2019-0055-1203-A1, p. 128]

EPA Summary and Response

Summary:

EPA received comments from users indicating the need to adopt the proposed serviceability provisions. NASTC commented that the proposals to improve serviceability are important for two main reasons: 1) to address existing imbalanced serviceability rules that presently affect commercial motor carriers, 2) to prepare and assist with serviceability of more complex, expensive diesel engines and emission systems resulting from the revised emission standards. NASTC also commented that they support EPA's new serviceability requirements in the owner's manual including how to use the OBD system to troubleshoot problems and that these provisions will make it more likely that drivers will take action. OOIDA commented that EPA must finalize all provisions in the proposal regarding serviceability, inducements, and self-diagnostic tools that will help drivers better assess and maintain their emissions equipment. Individual operators reinforced the concern that current systems are very complex and cannot be serviced by individual owners, which increases operating costs and downtime. Lubrizol, a supplier of lubricants to the heavy-duty industry also commented in support of the serviceability provisions in the rule and indicated that the owner's manual is heavily relied upon by owners and operators.

CARB commented that their staff fully supports EPA making serviceability requirements mandatory as early as MY 2024. CARB noted that manufacturers already have this information and provide it to their authorized repair facilities, and although there will be additional printing costs to include the information requested by EPA, this cost should be negligible. Furthermore, CARB stated it can be argued that accurate information on how an owner can properly repair and service an engine available readily in the owner's manual would pay for itself by potential avoided warranty costs by the manufacturer. Therefore, CARB staff stated they believe this requirement should be made mandatory and should not be delayed for another 3 years as better accessibility to repair information will help owners to address repairs as soon as possible with accurate information and help avoid having their truck taken out of service.

EPA received comments from service providers that EPA should not require emission-related service information to be published in owner's manuals, given that professional technicians have ready access to such information elsewhere. EMA and manufacturers such as DTNA, Ford, Cummins and PACCAR commented that this information is available elsewhere. Specifically, Cummins said much of this information is available to their owners online for free after specifying ESN or engine model. Daimler stated that manufacturers already provide troubleshooting information at a reasonable price and that this information is too extensive to be reasonably condensed into an owner's manual. Finally, EMA and manufacturers such as DTNA and PACCAR expressed concerns that providing this information would only serve to encourage untrained, ill-informed service work by owners who may think they can apply "backyard mechanic" skills to perform certain repairs and that modern engines are complicated and must be serviced by trained and informed professionals. Cummins added that the owner's manual is intended to describe normal engine operation, and that adding this information to the owner's manual could cause confusion because they provide the additional service information in other ways. DTNA stated that additional information in the owner's manual could lead operators and mechanics to perform diagnosis and repair without adequate safety information, because they might believe the detailed information in the troubleshooting and service manuals is not necessary.

Response:

See Section IV.B.3 of the preamble for details on the requirements we are finalizing and our supporting rationale. It is clear from the comments EPA received that operators believe there is a lack of information available to perform proper and prompt maintenance and avoid derates. EPA also received comments confirming that in the real-world repairs and maintenance are not always done by professional mechanics. See, for example, the OOIDA comments stating that their members have the resources and means to maintain their trucks, and prefer doing this work themselves.[21] EPA's final rule includes requirements to improve availability of serviceability information to facilitate proper maintenance throughout the life of the vehicle. This information is especially helpful for older vehicles to help operators maintain long-term compliance that will improve real-world environmental outcomes. EPA agrees with commenters that there is a particular need to improve access to serviceability information related to engine derating.

EPA agrees with CARB's comments that any additional printing costs in the owner's manual would be negligible if there are any at all. OEMs today already provide some of this information, for example, DTNA and PACCAR include some assembly drawings of parts in their manuals,[22] Many manufacturers also include some diagrams that can be slightly improved to meet these new requirements (e.g., adding exhaust flow indicators or DEF flow indicators). EPA also disagrees that owner's manuals are intended only to describe normal engine functions, which is why today they contain information on warning lights and emergency procedures (like emergency jump starting, etc.)

EPA appreciates the comments that operators should not see the owner's manual as a substitute for any service or troubleshooting guides and has added a requirement that manufacturers identify a web site for the service information we require under 40 CFR 86.010-38(j).

Manufacturers commented that this information is available elsewhere, and therefore should not be put into the owner's manual. EPA disagrees with this rationale, as this is true for nearly all the information already in an owner's manual. For example, information on how to check belts, fluids, air filter components would also be expected in other technical documents, but is also in the owner's manual because having prompt access to this information is essential for proper maintenance. Regarding DTNA's comments expressing concern that additional information in an owner's manual may lack safety information or sufficient detail, EPA disagrees that the final serviceability requirements present such risk. First, we note that we have modified the final regulations from those proposed to not take final action at this time to require certain additional information, in particular information proposed about assembly like the requirement to include "enough detail to allow a mechanic to replace any of those components." See preamble Section IV.B.3 for further details. Second, we have included a requirement for manufacturers to include information in the owner's manual on where operators can access or purchase more detailed serviceability and safety information, like the service manual DTNA mentioned in their comment.

EPA received comment from CARB and Lubrizol that it is both feasible and beneficial to adopt these provisions early; however, to ensure manufacturers have enough time to implement these changes within the context of this overall final rule, we are finalizing as proposed that the final serviceability requirements apply starting in MY 2027. Manufacturers may optionally meet these requirements before MY 2027.

---

[21] Comments from the Owner Operator Independent Driver Association, EPA-HQ-OAR-2019-0055-1266.
[22] https://dtnacontent-dtna.prd.freightliner.com/content/dam/public/dtna-servicelit/ddc/pdfs/OperatorsManual/DDPlatform/DDC-SVC-MAN-0189_2022.pdf#page=140&zoom=100,0,529, https://www.peterbilt.com/download/file/6031

EPA recognizes that part numbers are updated as designs change and as manufacturers address problems. EPA is not requiring that an owner's manual would need to be updated for a given model year to reflect changes in part numbers. We have added language to reflect this expectation. We have also limited the part number requirement to just SCR-related sensors and filters. The critical information path for locating correct replacement parts is to have data to start with and work with parts counter specialists to find updated part numbers. EPA expects that, just like owner's would be able to identify updated replacement parts based on the part numbers of outdated failed parts installed on their vehicle, the same is possible with outdated part numbers on drawings.

EPA understands the concerns of some commenters regarding the potential breadth of requirements as proposed to include a troubleshooting guide for DEF-dosing and DPF-regeneration. EPA did not intend the proposal to result in the equivalent of service manuals being published in the owner's manual. Today, there is little if any information available in owner's manuals regarding vehicles that have been induced to 5 mph. For example, the word "derate" only appears three to five times in some heavy-duty engine owner manuals (out of 100-200 pages total) and only in connection to a trouble light turning on. Derating engines because of SCR-related issues without providing information to understand the cause of the derate is counter-productive to the intended effect of inducing the owner/operator to quickly address the cause of the condition, and such timely response would more likely occur with proper information. For example, if an operator unknowingly puts in contaminated DEF which will result in inducement, there should be information in the available through the owner's manual on how to promptly address this issue and avoid inducement. After consideration of comments,

EPA is finalizing a more specific set of requirements in 40 CFR 1036.125(h)(8) to describe what troubleshooting information needs to be included that will provide operators with proper maintenance information.

EPA received comments on our proposed requirement to include DPF cleaning information in the owner's manual, including information from CARB that CARB has an ongoing effort related to the aim of this proposed requirement. After consideration of comments, EPA is not taking final action at this time on this aspect of the proposal and may consider this in a future rulemaking.

Finally, EPA agrees with CARB that we should also require inclusion of information regarding inducement warnings and derate schedules in the owner's manual and has accordingly updated the requirements from proposal in the final rule.

5.2 QR Code on engine label with link to owner's manual

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

CARB staff supports the standardization of sensor labeling and the QR code on the engine label. These are common sense requirements that give truckers and repair facilities repair information quickly and would better assist in making correct engines repairs. [EPA-HQ-OAR-2019-0055-1186-A2, p.118]
