EPA should not finalize the proposed additions to owner's manuals in §1036.125(h)(3)-(11), nor the proposed requirement of §1036.135(c)(10) to link to that information from a QR code on the emission control information label. (If EPA does finalize the requirement for a mandatory QR code on the engine label, it should take effect no earlier than MY 2027.) [EPA-HQ-OAR-2019-0055-1325-A1, p. 17.].

Organization: *Ford Motor Company (Ford)*

We recommend that the engine label requirements be modified to remove the requirement that manufacturers host the IT system that is linked to the QR Code on the engine label. We support making engine information and owner's manuals available electronically, but we believe that it would be appropriate for EPA to host such an IT system; as is the case with fueleconomy.gov. Having EPA host this type of information will ensure that the data linked to the QR Codes is presented in a consistent manner for all engine manufacturers and the data provided will link directly to data submitted to EPA during engine certification. [EPA-HQ-OAR-2019-0055-1300-A1, p. 6]

Organization: *Lubrizol Corporation (Lubrizol)*

3) Lubrizol supports requiring OEMs to provide lubricant and oil information in an engine label. In addition to requiring manufacturers to provide more information in their owner's manuals, Lubrizol urges EPA to require that lubricant information should also be provided on a label that is placed at the appropriate place in the engine compartment. As EPA notes in the Proposal,4 the agency has had similar requirements in the past, such as when EPA required vacuum hose diagrams to be included on the emission labels. The engine label should include an internet link that would enable owners or operators to obtain this information online. [EPA-HQ-OAR-2019-0055-1304-A1, p.4]

4 See Proposal, p. 17516.

4) Lubrizol supports requiring OEMs to include a QR Code to help ensure that the appropriate engine oil or lubricant is used throughout useful life. Lubrizol supports EPA's proposal,5 in 40 CFR 1036.135(c), that manufacturers include a Quick Response Code or 'QR Code' on the emission label that would direct repair technicians, owners, and inspection and maintenance facilities to a website which provides critical emissions systems information at no cost. This information should include engine-specific lubricant requirements, including the recommended lubricant, service intervals, and other relevant information that is necessary to ensure that the correct high-performing lubricant is used throughout the engine's useful life. Providing this information will help ensure that the engine and emissions control systems are adequately protected during all modes of operation throughout their useful lives. [EPA-HQ-OAR-2019-0055-1304-A1,p.4]

5 See Proposal, p. 17516.

Organization: *Truck and Engine Manufacturers Association (EMA)*

EMA has concerns related to the proposed QR code included in the labeling requirements of §1036.135(c)(10). EMA is generally supportive of the concept of electronic labeling, and has been working to develop specific features of electronic labeling for some time. We do, however, have concerns about the QR code requirements EPA proposes. [EPA-HQ-OAR-2019-0055-1203-A1, p. 128]

As an initial matter, EMA views electronic labeling as an alternative to conventional emissions label requirements. EPA's proposal, however, is to add a QR code to the existing emissions label. EPA should make the QR code-based label available as an alternative to the existing physical label mounted on the engine. [EPA-HQ-OAR-2019-0055-1203-A1, p. 129]

If EPA does not finalize the rule with the option to use electronic labeling as an alternative to conventional labeling requirements, EMA recommends that manufacturers be given the option to add a second label featuring the QR code EPA describes, as an alternative to adding the QR code to the existing label. A manufacturer should also be given the option to make a readable QR code accessible by means other than labeling. For instance, the QR code could be readable as a physical impression on a component surface accessible to users. [EPA-HQ-OAR-2019-0055-1203-A1, p. 129]

EMA does not think it is appropriate that owner's manuals be accessible from the QR code required. Manufacturers already have various means to make owner's manuals available to users. To make them available via the QR code is redundant and unnecessary. This requirement should be eliminated in the final rule. [EPA-HQ-OAR-2019-0055-1203-A1, p. 129]

The other information proposed to be accessible through the QR code link requires clarification. For example, it is unclear what EPA means in §1036.135(c)(10)(i) by, "as long as the appropriate information is available for each engine." It is unclear what "appropriate" information is intended to be covered, and how it must be associated with the engine from which the QR code was read. In (ii), it is unclear if EPA is requiring the same list of emissions control systems that manufacturers are required to include on the emissions control label. If that is the case, EMA recommends removing that redundant requirement. In (iii), EMA is uncertain what type of fuel and lubricants requirements EPA is proposing to include. It is also a risk to exclude fuel sulfur level requirements when providing fuel requirements; that element of the provision should be removed in the final rule. EMA stands ready to work with the Agency to finalize §1036.135 in a more reasonable manner. [EPA-HQ-OAR-2019-0055-1203-A1, p. 129]

EMA recommends that EPA make available an option that EPA host the QR-code accessed information proposed under §1036.135(c)(10) on an EPA-supported website. Although individual manufacturers could host this information, it would be preferrable for some users accessing this information for EPA to do so. EPA could design a website, similar to Fueleconomy.gov, which would provide data to the public in a consistent format for all engine manufacturers. [EPA-HQ-OAR-2019-0055-1203-A1, p. 129]

EPA Summary and Response

Summary:

EPA received comment from CARB and Lubrizol supportive of the proposed requirement to add a QR code on the engine label with a link to an electronic version of the owner's manual for the engine. Lubrizol added that they recognize the benefit of greater access to repair information and instructions for proper oil and lubricants. EMA commented that they support efforts to create an electronic label, but they objected to the proposed requirement to add a QR code as redundant and unnecessary because owner's manuals are already available to users. EMA recommended that EPA allow electronic labeling as an alternative to conventional labels, rather than adding electronic labeling requirements as a supplement to the conventional label. EMA recommended that EPA at least allow manufacturers to create a second label with a QR code, and to make QR codes accessible separate from labeling. EMA requested clarification of various information items described in the proposed rule, and they suggested that EPA design an EPA-supported website to provide relevant engine information to the public (like fueleconomy.gov).

Ford recommended that we modify the proposed requirement for QR codes by instead arranging for EPA to maintain the linked information on an EPA-supported website (like fueleconomy.gov). Cummins recommended that EPA not finalize the proposed requirement for QR codes, but also stated that EPA should not require QR codes before model year 2027 in any case.

Response:

We are not taking final action at this time on the proposed requirement to include QR codes on the emission control information label. EPA recognizes the potential for electronic labels with QR codes or similar technology to provide useful information for operators, inspectors, and others. Manufacturers are actively pursuing alternative electronic labeling. After reviewing submitted comments, we think we should engage in further analysis before moving forward with adopting electronic labeling requirements.

We note that consistent with existing regulations, which are not reopened or changed by this rulemaking, manufacturers must continue to meet requirements for applying physical labels to their engines. Manufacturers may also include a QR code or other electronic labeling information that goes beyond what is required under our regulations for physical labels. We note that the prohibition in 40 CFR 1068.101(b)(7)(iii) against applying false information labels also applies for information that is available electronically. We recommend that manufacturers communicate any such plans with EPA's Compliance Division, and note that such information could help inform a potential future rulemaking in this area. Further, we are including a final requirement that manufacturers include information on where to obtain more service information in the owner's manual to ensure that owners are properly informed on how to find such information, which should ensure users have information regarding where to access the same information that was proposed to be available using the QR code.

5.3 Improved serviceability of electric vehicles

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

CARB staff appreciates U.S. EPA's acknowledgement of the work to develop the ZEP Certification procedures for medium and HD vehicles. In response to U.S. EPA's request for comments on maintenance and operational information for improved serviceability of BEVs and FCEVs, CARB staff recommends that the U.S. EPA proposal include, at minimum, all elements in ZEP Certification related to the access to service information and diagnostics. CARB staff agrees that with U.S. EPA's assertion 'that the maintenance and operational information described in the NPRM could help potential BEV and FCEV purchasers to understand the possible operational impacts of these technologies on their businesses, as well as ensure the vehicles are supported during their use in the field.' These provisions would result in vehicles that can be easily serviced and repaired outside of warranty periods and support secondary markets. [EPA-HQ-OAR-2019-0055-1186-A2, p.24]

CARB staff is providing several references50,51,52,53 to similar efforts under the Advanced Clean Cars II rule making development proposals to require robust warranties, service information, and recycling labels for light-duty vehicles. [EPA-HQ-OAR-2019-0055-1186-A2, p. 25]

Organization: *Lion Electric Co. USA Inc. (Lion)*

We support the EPA's proposal that battery-electric vehicle (BEV) manufacturers take responsibility towards educating fleets on how to properly maintain their vehicles. Lion provides detailed training for drivers and mechanics through our Customer Success Team as part of vehicle delivery, to ensure that all parties are comfortable with and prepared to utilize their new electric truck or bus. While a battery-electric vehicle comes with fewer parts to maintain, it is important that owners adhere to regularly scheduled maintenance to get the most out of their vehicle. Lion makes that transition as accessible as possible. For maintenance that requires a Lion technician to perform, we have Experience Centers across the United States that are equipped to address any service needs. [EPA-HQ-OAR-2019-0055-1151-A2, p. 3]

We believe that the service and diagnostic monitoring applications as listed under Request for Comments on Maintenance and Operational Information for Improved Serviceability for Electric Vehicles should be included on all BEVs and that OEMs should strive to make electric vehicles that are accessible to their customers. Adopting the California Air Resources Board (CARB) Zero-Emission Powertrain Certification (ZEPCert) program would provide nationwide direction to OEMs and encourage manufacturer accountability. This is the best way to promote widespread ZEV adoption and create an ecosystem of vehicles that supports fleet industries with easy-to-use controls and data points. [EPA-HQ-OAR-2019-0055-1151-A2, p. 3]

We also support BEV manufacturers providing purchaser guidance and powertrain monitoring as part of their vehicle configuration. Lion electric buses and trucks already come standard with onboard touchscreens that provide detailed monitoring data that can be understood by a trained technician (this is part of the training Lion offers upon delivery of our vehicles). LionBeat, our telematics fleet management software, can provide charging power, range, energy use, and even data on the time spent idling versus driving per trip. These metrics can help fleet owners assess the efficiency of their routes and the health of their vehicles, minimizing downtime. In addition, the onboard diagnostics can provide maintenance history and reminders to keep servicing on schedule. These tools give fleet owners more control over their vehicles and operations. They also provide a sense a security, removing uncertainty that might otherwise prevent business growth by generating dependable, accessible data for vehicle servicing and optimal usage. Having this type of flexibility and knowledge will allow fleets to operate confidently, facilitating a smoother transition into zero-emission technology. [EPA-HQ-OAR-2019-0055-1151-A2, p. 3]

Organization: *Retail Industry Leaders Association (RILA)*

- EPA's rulemaking notes the accelerated rate of adoption for HD ZEVs within the market. RILA suggests that this shift presents a significant opportunity for EPA to provide guidance on HD ZEV battery's 'second life', recycling, or disposal. [EPA-HQ-OAR-2019-0055-1189-A2, p.8]

- RILA requests that EPA consider new requirements for original equipment manufacturers (OEMs) to provide standard repair time (SRT) recommendations for HD ZEVs. [EPA-HQ-OAR-2019-0055-1189-A2, p.8]
- RILA supports EPA's proposal to require manufacturers to include a Quick Response Code or 'QR code' on HD ZEV labels linking to a website that would direct repair technicians, owners, or inspection and maintenance facilities to a website with information. There is considerable value in allowing users to connect quickly to safety procedures, first responder guides, and information regarding maintenance intervals. RILA suggests that there are other areas of information that could be included, such towing requirements and clearly identified lift points that are specific to HD ZEVs since such vehicles need to be towed from rear axle or have axle shafts disconnected. [EPA-HQ-OAR-2019-0055-1189-A2, p.8]

Organization: *Tesla, Inc. (Tesla)*

EPA also proposes an update to communication protocols and data access for medium- and heavy duty BEVs that would require a standardized connector that is compatible with automotive scan tools.151 The agency should ensure that any such requirement is future proofed and inclusive of new technologies that can provide service repair information in easier and more cost-effective ways. [EPA-HQ-OAR-2019-0055-1219-A1, p.19]

151 87 Fed. Reg. at 17518.

In BEVs OBD-CAN is archaic and it should not be the only way manufacturers can be compliant. EPA should allow for additional connector options. CARB has taken such an approach in its standards for new heavy-duty zero-emission powertrains.152 CARB's standards allow manufacturers to choose how to best provide relevant diagnostic information to the vehicle operator. This ensures the vehicle purchasers and operators will have the necessary operating information for repairability while maintaining product design flexibility and more optimal customer experience, which is critical to driving product innovation and adoption.153 [EPA-HQ-OAR-2019-0055-1219-A1, p.19]

> 152 California Air Resources Board, California Standards and Test Procedures for New 2021 And Subsequent Model Heavy-Duty Zero-Emission Powertrains (June 27, 2019) at C.3.1. ('A manufacturer must have installed a connector meeting the requirements in subsection (h)(2) of title 13, CCR, section 1971.1, with a vehicle controller area network communications protocol that is capable of connection and communication with scan tools that meet the requirements in subsection (h)(3) of title 13, CCR, section 1971.1 or have a device permanently installed on the vehicle capable of displaying the information required in section 3.2 without the need for additional diagnostic tools.')(emphasis added).
>
> 153 See, Tesla Comments to CARB (Feb 15, 2019). Tesla incorporates by reference these comments.

More specifically, EPA should provide the flexibility to utilized diagnostic over IP (DoIP) capabilities. Allowing for DoIP communication supports future designs and will promote greater access to diagnostic information. To that end, Tesla recommends EPA also allow other devices to be installed in a BEV, including, but not limited to, a RJ45 connector or wireless connection option. Allowing for DoIP supports wireless diagnosis and is a more futureproof solution to communicate onboard diagnostic data, software updates, and vehicle data. Tesla vehicle advances such as software updates need higher data throughput (software updates, drivers assistance, navigation maps, large software games, etc.). Many components within a Tesla vehicle, and increasingly other OEMs, do not necessarily communicate over CAN. Newer technology and autonomous driving features have high data throughput needs (for example, camera images or transferring a 4-dimensional rendering of the environment around the vehicle during the process of troubleshooting) that are not compatible with the CAN system. Allowing for RJ45, wireless, and other manners of connection will allow for proper and fulsome communication of such data. [EPA-HQ-OAR-2019-0055-1219-A1, pp.19-20]

Further, as to the agency asking about which (if any) vehicle signals should be standardized and made available for repair and service technicians,154 Tesla suggest that EPA follow the recommendations that CARB is proposing in the Advance Clean Car II rulemaking and align with them where applicable.155 [EPA-HQ-OAR-2019-0055-1219-A1, p.20]

154 87 Fed. Reg. 17526-17529.

155 See, CARB, Proposed Advanced Clean Cars II (ACC II) Regulations

Organization: *Walmart*

The proposed rule requests input on several system needs that can improve the performance and maintenance of BEVs/FCEVs. As a large fleet, these reflect valuable improvements that can better ensure that a smooth integration of BEV/FCEVs into our operation and better meet the distribution and logistics expectations we hold as a business. In particular: [EPA-HQ-OAR-2019-0055-1191-A2, p. 3]

We agree with the labelling recommendations requiring original equipment manufacturers (OEMs) to install QR codes on alternative fuel vehicles with links to the operators/service manuals, safety procedures, first responder guides as well as maintenance intervals. [EPA-HQ-OAR-2019-0055-1191-A2, p .3]

We believe OEMs should provide standard repair time (SRT) recommendations guidance for BEV/FCEV to fleet owners and operators for expected operational life of vehicle. [EPA-HQ-OAR-2019-0055-1191-A2, p. 3]

We believe BEVs/FCEVs specific towing requirements and lift points need to be clearly displayed on vehicles (for example, EVs need to be towed from rear axle or have axle shafts disconnected). [EPA-HQ-OAR-2019-0055-1191-A2, p. 4]

We request that OEMs be encouraged to consider alignment of BEV/FCEV maintenance intervals and diagnostic equipment/connectors with compression ignition. [EPA-HQ-OAR-2019-0055-1191-A2, p. 4]

We support EPA's effort to provide future guidance on battery second life, recycling, or disposal. [EPA-HQ-OAR-2019-0055-1191-A2, p. 4]

We recommend OEMs include in onboard diagnostics and signals like a distance to empty (DTE) display for alternative energy powered vehicles that are commonly found in both ICE and passenger EVs today. [EPA-HQ-OAR-2019-0055-1191-A2, p. 4]

EPA Summary and Response

Summary:

Several commenters provided perspectives on EPA's request for comment to improve serviceability of electric vehicles. Commenters were generally supportive of the concepts that EPA requested comment on; several commenters also suggested additional ideas to consider (e.g., new requirements for original equipment manufacturers (OEMs) to provide standard repair time (SRT)).

Response:

EPA is not taking final action at this time on this topic EPA requested comment on in the proposal. We may consider the comments provided on improved serviceability of HD electric vehicles in a future rulemaking relevant to HD electric vehicles.

5.4 Improved service information through education and voluntary incentives

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

U.S. EPA is seeking comment on whether educational programs and voluntary incentives could lead to better maintenance and real-world emission benefits. CARB staff fully supports such educational programs and in fact has experience with requiring manufacturers of diesel particulate retrofit filters provide training to end users and installers on how to properly assess an engine prior to retrofit installation, how to properly clean their retrofit DPF, what the warning lights mean, and other important information for the successful operation of their retrofit. The training could be provided either online or in person. This regulatory driven education requirement helped avoid many problems with retrofits that were seen in the early years of implementation. [EPA-HQ-OAR-2019-0055-1186-A2, p.119]

A similar approach can be extended to manufacturers of HDEs. Manufacturers should be required to provide online or in-person training sessions to drivers and repair technicians to better understand the engine's emission control system, dashboard warnings, inducements, maintenance, etc. This will help minimize manufacturer warranty costs, unhappy operators, and avoid unplanned downtime, thus resulting in a more successful HDE program. [EPA-HQ-OAR-2019-0055-1186-A2, p.119]

Organization: *Lubrizol Corporation (Lubrizol)*

5) Lubrizol supports providing increased education and information about the benefits of using the appropriate high-performing lubricant throughout useful life. [EPA-HQ-OAR-2019-0055-1304-A1, p.4]

Lubrizol supports providing increased education and information about the benefits of using the appropriate high-performing lubricants and oils throughout their useful life.6 Lubrizol has worked closely with SmartWay staff and others in the Office of Transportation and Air Quality to ensure that vehicle owners or operators can easily access the most up-to-date information regarding the benefits of using the appropriate engine oils and lubricants throughout useful life. We believe that the SmartWay program can provide a necessary complement to the information that should be distributed in owner's manuals, engine labels, and QR Codes by providing additional information about the cost savings, emissions reductions, maintenance benefits, and other benefits of using the appropriate engine oils and lubricants throughout useful life. Education should be directed to service and maintenance facilities and technicians, as well as owners and operators of the vehicles. [EPA-HQ-OAR-2019-0055-1304-A1, p.5]

6 See Proposal, p. 17519.

In designing its education and outreach programs, Lubrizol encourages EPA to consider strategies to ensure that communications reach service and maintenance facilities and technicians, as well as owners and operators of the vehicles. [EPA-HQ-OAR-2019-0055-1304-A1, p.5]

Organization: *Port of Seattle, Port of Tacoma, and Northwest Seaport Alliance (NWSA)*

Technical assistance to owners/operators on maintenance of their new trucks: Battery electric and hydrogen fuel cell technologies are complex compared to diesel engines. Drivers, fleet operators, and the truck maintenance and repair industry on which they depend should be provided with additional resources to maintain their engines when needed, to ensure proper emission controls and avoid tampering. Technical assistance should be offered in numerous languages to ensure communications are equitable across the fleet. [EPA-HQ-OAR-2019-0055-1312-A1, p.3]

Organization: *Repair Association/Repair.org*

Another important contribution to the future repair of emission control systems will be the education of service personnel and equipment owners about the proper software settings for the control system on any given machine. It is insufficient to have the proper functioning of emission control systems the sole control of the manufacturer or franchise dealerships. [EPA-HQ-OAR-2019-0055-1036-A1, p.6]

EPA Summary and Response

Summary:

Commenters provided perspectives on improved service information through education and voluntary incentives, including the use of educational programs and voluntary incentives to improve maintenance and real-world emissions benefits. Commenters supporting educational programs and voluntary incentives stated that manufacturers should be required to provide online or in-person training sessions to drivers and repair technicians to better understand the engine's emission control system, dashboard warnings, inducements, maintenance, etc. They commented that education programs will help minimize manufacturer warranty costs, unhappy operators, and avoid unplanned downtime, which would result in a more successful HDE program. One commenter stated that technical assistance should be offered in numerous languages to ensure communications are equitable across the fleet, while another encouraged EPA to consider strategies to ensure that communications reach service and maintenance facilities and technicians, as well as owners and operators. Another commenter emphasized the importance of education for service personnel and equipment owners about the proper software settings for the control system on any given machine. Finally, one commenter supported providing increased education and information about the benefits of using the appropriate high-performing lubricants and oils throughout their useful life.

Response:

EPA appreciates feedback from commenters on the potential benefits that education and voluntary incentives can provide to improve maintenance and achieve real-world emissions benefits. EPA is not taking any final action on this topic at this time, but intends to continue to look for future opportunities to improve serviceability of emission control systems.

5.5 Other comments on serviceability

Comments by Organizations

Organization: *Booth, Norman (OOIDA)*

"The biggest problem is when it goes out the replacement cost is unaffordable that what kills the small business." [EPA-HQ-OAR-2019-0055-1266-A2, p.3]

Organization: *Compass Coach Inc.*

The broken sensor I had last month placed my $550,000 vehicle out of service for 5 (FIVE) weeks while we waited for Cummins first to look at it (that took 9 days), then to order the part and waiting for that to arrive and then trying to figure out how we get our bus which is 300 miles away. [EPA-HQ-OAR-2019-0055-2120, pp.1-2]

Organization: *Faircloth, Josh (OOIDA)*

The emissions guides you have done on diesel engines on commercial trucks is a complete financial disaster! The expense on keeping the emissions system operating is way off the charts! This will be my 3rd truck with emissions and 3/4's of my maintenance expense had been directly related to the breakdown of your emissions guide line and not to mention the lost revenue I have .incurred while in the shop for 2 to 5 days at a time! I do not know where you get your ideas for these emissions systems but they are really flawed and way too expensive to maintain! This will most likely be my last truck I will ever buy and hope it will last me 2 1/2 to 3 years, this will be a stretch! In other words, your emissions guide and system "royally sucks"!! [EPA-HQ-OAR-2019-0055-1266-A2, p.3]

Organization: *Flueger, Art (OOIDA)*

Several years ago I leased 3 2015 Kenworth t660. Cummins ISX. Mileage 525,000 to 550,000. I kept them 21 weeks and turned them back. I had to buy a protote wrecker attachment so I could get them home. Fleet maintained and checked by Kenworth dealer. Driver turned 1 off. Went to eat. Came back truck wouldn't start. Turbo locked up so tight it wouldn't run period. Had to hire local wrecker to get it out from trailer so another truck could take load. I towed 1 home every week. Parts were very expensive, especially the VGT turbos. No thanks. [EPA-HQ-OAR-2019-0055-1266-A2, p.4]

Organization: *Kenny Sites*

I am opposed to more restrictive emission regulations for all truck engines and equipment. As a former mechanic and as CDL driver the emission regulations today are causing less milage (MPG) and efficiency of trucks and equipment. The engines have become less durable and reliable due to the emission requirements today and any truck shop you go to has 20 30 trucks sitting waiting on parts. This is causing delays and safety issues on the road for everyone in the hauling and construction industries.

The engines today consume more fuel to overcome the restriction created by the emission systems, and in return causes less usable life from the trucks and equipment. There is a fine line between fuel economy and clean emissions. The systems today produce very clean emissions and do need further regulation from government agencies that do not have a clue about the real issues of supply chain and construction issues. The reality is when a piece of equipment or truck engine shuts down to a glitch in the emissions system it has to fixed by someone with a computer to analyze the problem and involves shutting down the construction for that day or several days until another piece of equipment can be brought out or for trucks it may block the road until it can be towed to a shop and then the delivery of the merchandise may be delayed for days. [EPA-HQ-OAR-2019-0055-1495]

Organization: *Kloke, Stephen (OOIDA)*

Emissions have cost me my business. I could no longer afford to fix my 2013 Peterbilt with a Cummins diesel because it ate turbos and constantly was broke down because of the emissions system. It bankrupted me. [EPA-HQ-OAR-2019-0055-1266-A2, p.4]

Organization: *Kubiak, Gene (OOIDA)*

The emission technology is horrible as a one truck owner it cost me more to repair the down time is longer and we are being beat down with all these regulations that cost a good dollar. [EPA-HQ-OAR-2019-0055-1266-A2, p.5]

Organization*: Midwest Bus & Motorcoach Association*

Our members are concerned with the availability of parts and the ability to service a vehicle while on the road or even when at the home base facility. Due to faulty design flaws and less than acceptable parts, operators experience an overwhelming amount of engine codes resulting from emission standards. Many times, motorcoach operators find themselves scrambling to locate a service shop with the knowledge and technology to repair the issue. Most of the equipment companies run require OEM software to force the regeneration of a motorcoach, which not all shops have access to. To add to this problem, there is a small chance the service locations carry the specific part needed to service the motorcoach. Of note, if a motorcoach is coding for a DPF issue, it will most likely be able to operate normally and perform catalyst as intended. [EPA-HQ-OAR-2019-0055-1158-A1, p.4]

Further issues involve parts accessibility and reliability. It is becoming all too common for our companies to experience difficulties, if not impossibilities, to find replacement parts that will fix the DPF system in a timely manner. Recently, several operators were informed by OEM engine manufacturers that there is a three-month backorder on a common NOx sensor. Aside from parts availability, additional issues arise in respect to parts performance and reliability. In a recent industry survey, it was determined that 80% of DPF system-related issues directly resulted from a wide-range of faulty sensors in addition to the NOx sensors and would lead to a derate or inducement. Unlike other parts that show signs of wear over time, there is no plausible way to determine when a faulty sensor will occur. Our members have experienced failed sensors on a new motorcoach with less than 1,000 miles. Sometimes sensors are put in place to deter operators from using less than standard DEF products and to make sure the operators are not running low or empty on DEF. However, the cost of DEF is minimal, and companies are committed to ensuring the proper use. Unfortunately, the quality and reliability of sensors need be evaluated as a determining factor of derating a motorcoach. [EPA-HQ-OAR-2019-0055-1158-A1, p.4]

Recommendations:

1. Allow Non-OEM and generic scanners to clear SCR codes or Tamper Codes

2. Program ECM and software to perform secondary checks in the system to monitor SCR instead of relying on one sensor.

3. Require engine and part manufacturers to guarantee reliable parts. This can be achieved by mandating a warranty of 5 years or 500,000 miles instead of 50,000 miles. Until OEMs are motivated ore required to produce quality parts our industry will not see any improvements to the less than acceptable products they have been selling. Our members cannot be expected to efficiently and safely operate on low quality replacement parts. [EPA-HQ-OAR-2019-0055-1158-A1, p.4]

Organization: *Motorcoach Companies*

We are further concerned with the readily availability of parts and the ability to service a vehicle while over the road or sometime even in house. Due to faulty design flaws and subpar parts, we experience an overwhelming amount of engine codes resulting from emission standards. Many times, motorcoach operators find themselves scrambling to locate a service shop with the knowledge and technology to repair the issue. Most of the equipment our companies run require

OEM software to force regen a bus, which not all shops have access to. To add to this problem, there is a small chance these service locations even carry the specific part needed to service the bus to get back on the road. It is important to note, although the vehicle is coding for DPF issue, the vehicle will most likely be able to operate normally and still perform catalyst as intended. [EPA-HQ-OAR-2019-0055-1149-A1, p.4]

Further issues involve parts accessibility and reliability. It is becoming all too common that our industries companies are finding it difficult if not impossible to find replacement parts to fix the DPF system in a timely manner. Just recently, several operators were informed by OEM engine manufacturers that there is a 3 month back-order on a common NoX sensor. Aside from part availability, additional issues arise in respect to a parts performance and reliability. In a recent industry survey, it was determined that 80% of DPF system related issues directly resulted from faulty sensors. This includes a wide range of sensors, not just NoX sensors, so any sensor that would lead to derate or inducement. Unlike other parts that wear over time, there is no way to determine when a faulty sensor will occur. We have seen them happen on a new bus with less than 1,000 miles on the vehicle. Some of these sensors are simply put in place to deter operators from using subpar DEF products and to make sure the operators are not running low/empty on DEF. However, the cost of DEF is minimal, and companies are committed to ensuring the proper use. Unfortunately, the quality and reliability of these sensors has been subpar in themselves and must be relooked at as a determining factor to derate a vehicle. [EPA-HQ-OAR-2019-0055-1149-A1, p.4]

Recommendations:

1. Allow Non-OEM and generic scanners to clear SCR codes or Tamper Codes

2. Program ECM and software to perform secondary checks in the system to monitor SCR instead of relying on one sensor.

3. Require engine and part manufacturers to guarantee more reliable parts. This can be achieved by mandating they extend warranty to 5 years or 500,000 miles instead of 50,000 miles. Until OEMS have a motivation to produce quality parts we don’t see any improvements to the subpar products they have been selling to consumers. It seems as though OEMs feel these part sales are revenue generating and would rather keep them subpar to increase sales. We need better more durable/reliable products. [EPA-HQ-OAR-2019-0055-1149-A1, p.4]

Organization: *National Association of Small Trucking Companies (NASTC)*

The older vehicles will remain in operation longer than they would today. To be sure, the handful of very large motor carriers will purchase new vehicles. But with used-truck-buyer behavior being what we expect, based on NASTC’s experience, the turnover rate of older vehicles will be reduced, as discussed above, on account of this rule. [EPA-HQ-OAR-2019-0055-1130-A1, p. 6]

NASTC surveyed its members in 2020 (see attachment 1) about their experience with post-2010 vehicles, which are equipped with complex emissions systems under the present emissions standard. It is a cautionary tale. Our motor carriers identified which emission control system components fail most frequently. The components most often named as failing were sensors, DPF, and DEF doser, hoses, pumps, and filters. Respondents mentioned other failing components: EGR valves, coolers, actuators, SCR catalyst, DOC, turbo, wiring, decomp tube, cracked head, and PDF. Many respondents emphasized how expensive it is to repair these emission systems. [EPA-HQ-OAR-2019-0055-1130-A1, p. 6]

Respondents indicated that emissions system failures occur routinely. Some have problems with a single component monthly or twice a month; others said they have a problem with a component constantly. Others experience problems with multiple components, there seeming to be something faulty all the time. [EPA-HQ-OAR-2019-0055-1130-A1, p. 6]

We would expect similar system and component problems to crop up with new generation and novel systems. Also, the degree to which this emissions reduction proposal is perceived as part of a “Green New Deal”-type government push toward zero-emission vehicles and eradication of diesel and other fossil-fuel-burning vehicles is likely to spark resistance from the hundreds of thousands of small motor carriers for whom the predominant diesel trucks best suit their business models.4 [EPA-HQ-OAR-2019-0055-1130-A1, p. 6]

> 4. NASTC has no objection to consumer-driven, market-based additions of alternative-fuel vehicles entering the market that perhaps someday replace diesel vehicles, as decided by consumers. Ours is an “all of the above” perspective, where electric, natural gas, and other alternative fueled energies vie for market share. We do have a problem with government fiat and manipulation of markets to drive such major shifts.

Of course, slowed turnover of older commercial trucks being retired and newer models replacing them through the used-vehicle market, coupled with what we expect would be markedly higher used truck purchase prices, along with increased retention of used vehicles in service will translate into less reduction of NOx and GHG levels in the atmosphere. [EPA-HQ-OAR-2019-0055-1130-A1, p. 6]

Organization: *Owner-Operator Independent Drivers Association (OOIDA)*

Following the January 2020 Cleaner Trucks Initiative Advance Notice of Proposed Rulemaking (ANPRM), many truckers told EPA about problems they’ve experienced and how the agency could work to address them. OOIDA commends the agency for listening to those comments and including provisions in the proposal regarding serviceability, inducement, and self-diagnostic tools that will help drivers better assess their emissions equipment. [EPA-HQ-OAR-2019-0055-1266-A1, p.6]

Organization: *Small, George (OOIDA)*

I am a very small transportation company and it has been an expensive maintenance issue [EPA-HQ-OAR-2019-0055-1266-A2, p.3]

Organization: *Starnes, Elvin (OOIDA)*

"I own a 2014 Prostar and I have had numerous problems with the EGR coolers and DPF problems at a cost of $3,700 to as much of $9,500 at least once a year. The fuel economy is worse than my older truck that didn't have any emissions on it also I wish that I never got rid of the older truck." [EPA-HQ-OAR-2019-0055-1266-A2, p.1].

Organization: *Virginia Motorcoach Association*

Our members are concerned with the availability of parts and the ability to service a vehicle while on the road or even when at the home base facility. Due to faulty design flaws and less than acceptable parts, operators experience an overwhelming amount of engine codes resulting from emission standards. Many times, motorcoach operators find themselves scrambling to locate a service shop with the knowledge and technology to repair the issue. Most of the equipment that our member companies run requires OEM software to force the regeneration of a motorcoach, which not all shops have access to. To add to this problem, there is only a small chance that the service locations carry the specific part needed to service the motorcoach. Of note, if a motorcoach is coding for a DPF issue, it will most likely be able to operate normally and perform catalyst as intended. [EPA-HQ-OAR-2019-0055-2715-A1, p.3].

Further issues involve parts accessibility and reliability. It is becoming all too common for our member operator companies to experience difficulties, if not impossibilities, to find replacement parts that will fix the DPF system in a timely manner. Recently, several operators were informed by OEM engine manufacturers that there is a three-month backorder on a common NOx sensor. Aside from parts availability, additional issues arise in respect to parts performance and reliability. In a recent industry survey3, it was determined that 80% of DPF system-related issues were direct results of a wide- range of faulty sensors in addition to the NOx sensors and would lead to a derate or inducement. Unlike other parts that show signs of wear over time, there is no plausible way to determine when a faulty sensor will occur. Our members have experienced failed sensors on a new motorcoach with less than 1,000 miles. Sometimes sensors are put in place to deter operators from using less than standard DEF products and to make sure the operators are not running low or empty on DEF. However, the cost of DEF is minimal, and companies are committed to ensuring the proper use. Unfortunately, the quality and reliability of sensors need be evaluated as a determining factor of derating a motorcoach. [EPA-HQ-OAR-2019-0055-2715-A1, p.4].

3. ABA Industry Survey, "Engine Derate," June 2021

Recommendations:

1. Allow Non-OEM and generic scanners to clear SCR codes or Tamper Codes

2. Program ECM and software to perform secondary checks in the system to monitor SCR instead of relying on one sensor.

> 3. Require engine and part manufacturers to guarantee reliable parts. This can be achieved by mandating a warranty of 5 years or 500,000 miles instead of 50,000 miles. Until OEMs are motivated or required to produce quality parts our industry will not see any improvements to the less than acceptable products that have been provided. Our members cannot be expected to operate safely and efficiently using low quality replacement parts. [EPA-HQ-OAR-2019-0055-2715-A1, p.4].

EPA Summary and Response

Summary:

EPA received numerous comments on the cost and downtime associated with maintenance and repairs, and availability of emission-related components. Commenters noted spending thousands of dollars per year on maintenance and extensive time out of service due to these repairs, and some quoted 2-5 days in the shop at a time per repair. One commenter noted that problems with a sensor took a bus out of service for 5 weeks and stranded the vehicle 300 miles away from base. Others reported safety issues, delays, difficulty analyzing service-related problems, and numerous and repeat failures. Motorcoach companies noted that availability of parts and service is not guaranteed, they have difficulty finding replacement parts in a timely manner (including an example of a NOx sensor being on a 3-month backorder), and they are overwhelmed with engine codes. Motorcoach companies stated that it is difficult to find shops that can repair a bus due to specialized parts, tools, and software. Motorcoach companies stated these issues are made worse by repeated failures of many sensors (not just NOx sensors) which lead to derate or inducement, including on buses with less than 1,000 miles on them. They also commented that these concerns include sensors that evaluate whether a vehicle should be in inducement, and that such sensors are not dependable and should not be used to evaluate whether buses should be in inducement. Other commenters reiterated that maintenance expenses, towing expenses, and quick vehicle and engine shutdowns result in businesses like construction and hauling not able to complete tasks as contractually obligated. Some commenters included lists of components that they assert commonly break, including: sensors (DPF and DEF-related), DEF dosers, hoses, pumps, filters, EGR valves, coolers and actuators, SCR catalysts, DOC, turbos, wiring, decomposition tubes, cylinder heads and DPFs. Motorcoach Companies included specific recommendations to improve serviceability, including a requirement to allow a generic scantool to clear inducement codes, to program ECM and software to perform secondary checks in the system to monitor SCR instead of relying on one sensor, and to meet warranty requirements over a longer period. These concerns (frequent component failures, difficulty locating parts, difficult diagnoses, extensive downtime, and the need for improved serviceability) were echoed by other individual operators.[23]

Response:

EPA is aware of the need to improve serviceability of heavy-duty highway engines and is confident the improvements we are finalizing as a part of this rule will improve repair experiences for owners. As an initial matter and as discussed, in RIA Chapter 3, the technologies we expect to be used to meet the final standards build upon the technologies used in today's

[23] For example, see EPA-HQ-OAR-219-0055-2022 and EPA-HQ-OAR-219-0055-2483.

light- and heavy-duty engines, which we expect will help to address concerns related to serviceability of heavy-duty engines. In addition, we are finalizing serviceability provisions that we expect will help to address these concerns (see section IV.B.3. of the preamble for more discussion). Finally, see preamble Section III and section 3 of this document for further information and our responses to other comments related to the final standards, including technical feasibility of the final standards.

6 Maintenance

6.1 Minimum maintenance intervals

Comments by Organizations

Organization: *Cummins Inc. (Cummins)*

In §1036.125(a)(2), EPA proposes more stringent (longer) minimum scheduled maintenance intervals for adjustment/cleaning and replacement of various critical emission-related components. Changes are needed for certain components to reflect the possibility that manufacturers may need more frequent scheduled maintenance in the future due to more stringent emission standards and useful life and warranty requirements: [EPA-HQ-OAR-2019-0055-1325-A1, p. 15]

- In general, EPA's minimum intervals should be no longer than those finalized in CARB's recent HD Warranty and Omnibus rulemakings. EPA should revise any proposed intervals that are longer than CARB's intervals to match those in the CARB regulations. Improved alignment will allow manufacturers to better optimize their products and customers to experience more consistency in maintenance practices. [EPA-HQ-OAR-2019-0055-1325-A1, p. 15]
- NOx sensors are a specific example of misalignment between EPA and CARB maintenance intervals. EPA proposes to eliminate its existing sensor category and proposes that sensor maintenance should follow the requirements of an associated component, presumably a catalyst in the case of a NOx sensor. For catalyst systems (other than catalyst beds), EPA proposes a minimum replacement interval no shorter than today's UL, while CARB retains a separate sensor category with minimum replacement intervals less than today's UL. EPA should align the replacement intervals for sensors with CARB's: 100,000 mi / 3,000 hrs for SI HDE and Light HDE, and 150,000 mi / 4,500 hrs for Medium HDE and Heavy HDE. [EPA-HQ-OAR-2019-0055-1325-A1, p. 16]
- Another example is for Exhaust Gas Recirculation (EGR) system cleaning, where CARB retained previous minimum cleaning intervals of 100,000 mi / 3,000 hrs of use initially and 150,000 mi / 4,500 hr intervals thereafter for Medium HDE and Heavy HDE. EPA should retain the initial shorter period for Medium HDE and Heavy HDE before changing to the longer interval for subsequent maintenance events on adjustment and cleaning of any component with those intervals today. EPA indicates it does not intend to

change today's adjustment and cleaning intervals (87 FR 17523), but Table 2 of §1036.125 does not include the shorter initial maintenance intervals. [EPA-HQ-OAR-2019-0055-1325-A1, p. 16]

- DEF filter replacement may need to become more frequent due to flowing more DEF to meet future emission standards. Cummins recommends a minimum replacement interval of 100,000 mi / 3,000 hrs for DEF filters across Light, Medium, and Heavy HDE. [EPA-HQ-OAR-2019-0055-1325-A1, p. 16]
- For spark plugs, ignition wires, and coils, replacement intervals should remain at today's values due to the increased gap and amperage of the heavy-duty system needed for commercial applications. [EPA-HQ-OAR-2019-0055-1325-A1, p. 16]
- EPA's proposed standards are premised on the use of CDA and dual SCR systems for diesel engines. EPA should be flexible in approving minimum scheduled maintenance intervals for components associated with new technologies not yet in production for heavy-duty vehicles. Whether it is an "additional" component already included in Tables 1 and 2 of §1036.125(a)(2) but not employed today, such as a second DEF doser or added light-off catalyst, or fully "new" technology such as CDA, EPA should be open to shorter minimum intervals than shown in the tables. Cummins requests that EPA confirm it would not expect the same minimum intervals for new components as for components which manufacturers already have significant experience. [EPA-HQ-OAR-2019-0055-1325-A1, p. 16]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

In the Proposed Rule, EPA expresses its intent to 'continue to restrict replacement of catalyst beds and particulate filter elements, requiring that manufacturers pay for the repair […] if needed, within regulatory useful life.'125 EPA proposes to accomplish this through two specific new regulations in Sections1036.125(a)(2) and 1036.125(g). Proposed Section 1036.125(a)(2) would read as follows:

- (2) Minimum scheduled maintenance intervals. You may not schedule replacement of catalyst beds or particulate filters during an engine's useful life. […] [EPA-HQ-OAR-2019-0055-1168-A1, p.111]

As written, this provision suggests that no catalyst or DPF replacements could be scheduled during the engine's useful life. However, proposed Section 1036.125(g) appears to qualify the above statement in 1036.125(a)(2), stating that:

- *(g) Payment for scheduled maintenance*. Owners are responsible for properly maintaining their engines, which generally includes paying for scheduled maintenance. However, you may commit to paying for scheduled maintenance as described in paragraph (a)(1)(iv) of this section to demonstrate that the maintenance will occur. **<u>You may also schedule maintenance not otherwise allowed by paragraph (a)(2) of this section if you pay for it.</u>** You must pay for scheduled maintenance on any component during the useful life if it meets all the following conditions: […] (emphasis added).

Daimler Truck believes that these provisions, taken together, meet EPA's intent as expressed in the Proposed Rule preamble, but are needlessly complicated and could accidentally be misinterpreted in the future—specifically, by reading (a)(2) without realizing it is later modified in (g). [EPA-HQ-OAR-2019-0055-1168-A1, p.111]

We propose that EPA clarify its intent and prevent misinterpretation by changing 1036.125(a)(2) as follows:

(2) Minimum scheduled maintenance intervals. You may not schedule replacement of catalyst beds or particulate filters during an engine's useful life, unless you pay for that replacement during useful life, per 1036.125(g). […] [EPA-HQ-OAR-2019-0055-1168-A1, p.111]

With this change to 1036.125(a)(2), EPA would not need to adjust 1036.125(g), since it applies to more than just catalysts and particulate filters. [EPA-HQ-OAR-2019-0055-1168-A1, p.111]

125 Id. at 17,525.

Organization: *PACCAR, Inc (PACCAR)*

PACCAR recommends that EPA revise the proposed provisions governing 'minimum scheduled maintenance intervals' within 40 C.F.R. 1036.125. As proposed, 1036.125(a)(2) provides that '[y]ou may not schedule replacement of catalyst beds or particulate filters during an engine's useful life.' However, PACCAR respectfully submits that EPA should follow the California Air Resources Board's regulatory approach and allow OEMs to replace and/or repair catalyst beds and particulate filters during an engine's useful life. See California Exhaust Emission Standards and Test Procedures for 2004 and Subsequent Model Heavy-Duty Diesel Engines and Vehicles (as amended April 18, 2019)1 (incorporated by reference at 13 CCR 1956.8(d)) (incorporating 40 C.F.R. 86.004-25 with changes, including the addition of catalytic converter beds and particulate filters to the list of functions that manufacturers can replace during an engine's useful life) (stating in relevant part that 'manufacturers may schedule replacement or repair of particulate trap elements (or trap oxidizer elements), catalytic converter beds (including NOx adsorber, diesel oxidation catalyst, and selective catalyst reduction beds) . . . provided that the manufacturer demonstrates to the Executive Officer's satisfaction that the repair or replacement will be performed according to the schedule and the manufacturer pays for the repair or replacement.') [EPA-HQ-OAR-2019-0055-1346-A1, p.43]

1 Available at https://ww2.arb.ca.gov/sites/default/files/2020-06/hddtps_warranty_clean%20complete_10_19_accessible.pdf.

If EPA's final rule retains the general proposed catalyst beds or particulate filters prohibition – and even though PACCAR urges EPA to promulgate reasonable, technically-feasible emissions standards, useful life and warranty provisions that will not force the replacement of catalyst beds to remain compliant -- PACCAR respectfully requests that EPA provide an exception under which OEMs may repair or replace catalyst beds and particulate filters if the manufacturer demonstrates to EPA's satisfaction that the repair or replacement will be performed according to the manufacturer-proposed maintenance schedule and the manufacturer pays for the repair or replacement. [EPA-HQ-OAR-2019-0055-1346-A1, p.44]

Such an exception is particularly warranted in light of EPA's substantially extended useful life and warranty proposals beginning in MY 2027. Moreover, revising the prohibition on replacing or repairing catalyst beds or particulate filters would be consistent with EPA's preamble, which provides: 'Current 40 CFR 86.004 25(i) clarifies that these components could be replaced or repaired if manufacturers demonstrate the maintenance will occur and the manufacturer pays for it. We propose to continue to restrict replacement of catalyst beds and particulate filter elements, requiring that manufacturers pay for the repair or replacement of catalyst beds and particulate filter elements, if needed, within the regulatory useful life.' 87 Fed. Reg. at 17525. [EPA-HQ-OAR-2019-0055-1346-A1, p.44]

PACCAR therefore respectfully submits that EPA should modify proposed 1036.125(a)(2) as follows: 'You may not schedule replacement of catalyst beds or particulate filters during an engine's useful life., except as allowed in paragraph (g) [Payment for scheduled maintenance]. However, manufacturers may schedule replacement or repair of particulate trap elements (or trap oxidizer elements), catalytic converter beds (including NOx adsorber, diesel oxidation catalyst, and selective catalyst reduction beds), provided that the manufacturer demonstrates to EPA's satisfaction that the repair or replacement will be performed according to the schedule and the manufacturer pays for the repair or replacement.' [EPA-HQ-OAR-2019-0055-1346-A1, pp.44-45]

Organization: *Truck and Engine Manufacturers Association (EMA)*

EPA proposes to modify the emissions-related maintenance provisions, and to establish new requirements related to making information about service-related maintenance available to the vehicle owner. EPA has also updated the minimum maintenance intervals for various components. The proposed maintenance intervals are not aligned with the intervals CARB has finalized in its Omnibus low- NOx regulations. CARB conducted extensive analysis to understand current industry practices and capabilities, and established the intervals accordingly. EMA recommends that wherever EPA's requirements are more stringent (longer) than CARB's, that they be reduced to align with the CARB requirements. This will ensure that manufacturers have the greatest opportunity to optimize product configurations and maintenance practices based on the latest technical data. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 125 - 126]

Of particular concern is EPA's proposal to prohibit scheduled maintenance on all sensors at intervals less than today's UL (though the NPRM mentions only NOx sensors at 87 FR p. 17523). Most sensors, and especially NOx sensors and most likely NH_3 sensors (where there is little experience), do not have the kind of durability necessary to last throughout the current UL, let alone the new proposed extended UL of the engine. Table 1 of §1036.125 is unclear whether sensors are allowably replaced at current UL (for example, at 435,000 miles for HHDE), as there is no definition of "catalyst systems," and sensors are not always integrated into catalyst systems. Notwithstanding this point, the interval provided is too short for current sensor durability. Manufacturers may be changing their recommended maintenance practices with respect to sensors given the myriad changes in the proposed regulations, including significantly more stringent standards, and longer UL and warranty requirements. EMA recommends that the Agency specify that manufacturers may require scheduled replacement of sensors every 150,000 miles or 4,500 hours for HHDE and MHDE, and every 100,00 miles or 3,000 hours for LHDE and SI engines, just as permitted under the CARB Omnibus regulations. [EPA-HQ-OAR-2019-0055-1203-A1, p. 126]

Another example is for EGR system cleaning, where CARB retained previous minimum cleaning intervals of 100,000 mi/3,000 hours of use initially, and specified 150,000 mi/4,500 hour intervals thereafter (MHDE and HHDE.) EPA should retain the initial shorter period for MHDE and HHDE before changing to the longer interval for subsequent maintenance events. [EPA-HQ-OAR-2019-0055-1203-A1, p. 126]

Similarly, EMA recommends that §1036.125(a)(2) be modified to read, "You may not schedule replacement of catalyst beds or particulate filters during an engine's useful life, except as allowed in paragraph (g)." [EPA-HQ-OAR-2019-0055-1203-A1, p. 127]

Organization: *Volvo Group*

More frequent maintenance or replacement interval flexibility is requested due to the lack of data from applications that comply with the proposed lower emission standards. [EPA-HQ-OAR-2019-0055-1324-A1, p. 7]

EPA Summary and Response

The summary and response for this section includes a summary of the subtopics raised and the responses follow each summary.

EMA and Cummins suggested that some sensors should have their own minimum maintenance intervals; not be tied to a "system". Both organizations recommended EPA match the intervals from CARB's HD Omnibus regulation.

Response:

- We agree that there are sensors that are not integrated into components or systems and that those sensors should have a separate minimum interval. As noted in section IV.B.2 of the preamble, we are finalizing a separate set of minimum maintenance intervals for "sensors, actuators, and related control modules that are not integrated into other systems" that match the intervals specified in 40 CFR 86.004-25(b) and are consistent with commenters' requested minimum interval values.
- We are retaining in the final rule our proposed requirement that the minimum intervals specified for each component or system applies to any actuators, sensors, tubing, valves, and wiring that *are* integrated into that component or system.

Cummins and EMA commented that, while EPA stated it was not changing adjustment and cleaning intervals for EGR systems, the proposed intervals were set at 150,000 miles or 4,500 hours and did not include an initial interval of 100,000 miles or 3,000 hours as currently applies.

Response:

- As noted in preamble section IV.B.2, we are correcting in the final requirements the proposed intervals to include an initial minimum maintenance interval of 100,000 miles or 3,000 hours for adjusting and cleaning catalyst system components, EGR system components (other than filters or coolers), particulate filtration system components, and turbochargers, with intervals of 150,000 miles or 4,500 hours thereafter, consistent with existing 40 CFR 86.004-25(b). As we stated in the NPRM, we did not intend to change these intervals.

Cummins requested EPA allow a DEF filter replacement of 100,000 miles or 3,000 hours for all engine classes, since higher flow volumes to meet the new standards may require more frequent filter replacements.

Response:

- The proposed minimum interval for DEF filter replacement was based on the most frequent replacement interval manufacturers specified in their owner’s manual for recent model year engines to meet current standards. After considering comments, we are finalizing minimum interval of 100,000 miles or 3,000 hours for DEF filter replacement. We note that this final interval is less frequent than the minimum interval of 50,000 miles or 1,500 hours that currently applies for CI engines.

Cummins requested that spark plugs, ignition wires, and ignition coil replacement intervals stay at today’s interval values, suggesting these components may wear under the commercial applications of the heavy-duty engines.

Response:

- We proposed intervals of 100,000 miles or 3,000 hours for ignition wires based on maintenance intervals specified in owner’s manuals for recent model year engines. We are revising in the final rule the proposed intervals for ignition wires to match the current intervals in existing regulations, 50,000 miles or 1,500 hours. We are also including ignition coils, which were inadvertently omitted in the proposal, at the same intervals.

DTNA, PACCAR, and EMA noted that the proposal disallowed scheduled replacement of catalyst beds or particulate filters in 40 CFR 1036.125(a)(2) and suggested EPA add a clarifying reference to 40 CFR 1036.125(g) where we state that such replacement would be allowed if the manufacturer pays for it.

Response:

- We are revising in the final rule the proposed 40 CFR 1036.125(a)(2) by adding a reference to 1036.125(g), to clarify the proposed and finalized exception that applies to scheduled maintenance not otherwise allowed by paragraph (a)(2).
- We note that we are also revising 40 CFR 1036.125(a)(2) by replacing the statement that "You may not schedule replacement of catalyst beds or particulate filters during an engine's useful life" with a new line in Table 1 to Paragraph (a)(2) of § 1036.125 for catalyst substrates and particulate filter substrates. The minimum maintenance intervals for catalyst substrates and particulate filter substrates match the useful life miles and hours of 1036.104(e) for each engine class.

Volvo requested flexibility for more frequent maintenance intervals than EPA proposed. Cummins requested EPA be flexible in approving shorter intervals for new technologies (e.g., CDA) and requested that EPA confirm it would not expect the same minimum intervals for new components as for components which manufacturers already have significant experience

Response:

- We are finalizing maintenance intervals with some revisions from our proposed values as discussed in preamble section IV.B.2.
- We note that our final maintenance provisions include minimum intervals for certain components and manufactures may request approval for critical emission-related maintenance on other components at intervals that they specify (see 40 CFR 1036.125(a)(2)).
- In 40 CFR 1036.125(g), we are finalizing as proposed that manufacturers may schedule maintenance not otherwise allowed by paragraph 40 CFR 1036.125(a)(2) if they pay for it. Manufacturers choosing this option for a component may request approval of scheduled maintenance at a more frequent interval than those specified in paragraph (a)(2).
- As noted in section IV.B.2 of the preamble, we are finalizing as proposed 40 CFR 1036.125(a)(3), which is migrated from 40 CFR 86.094 25(b)(7)(ii) and (iii), specifically for new technology not identified in (a)(2). We cannot confirm and will not commit to accepting more frequent intervals for components on the categorical new technology basis commenters requested; instead, we intend to make such determinations through the process finalized as proposed in 40 CFR 1036.125(a)(3), which includes evaluating the specific facts in the manufacturer's request regarding the data to support the need for the maintenance at the recommended interval and a demonstration that the maintenance is likely to occur at the recommended interval using one of the conditions specified in 40 CFR 1036.125(a)(1).

6.2 Other kinds of scheduled maintenance

Comments by Organizations

Organization: *Cummins Inc. (Cummins)*

Cummins appreciates EPA's proposed addition of a new type of maintenance called "special maintenance" in §1036.125(c) to allow more frequent maintenance in case of special situations, such as atypical engine operation. Cummins requests EPA to provide more specific examples of situations or operation that could be considered special or atypical. [EPA-HQ-OAR-2019-0055-1325-A1, p. 16]

EPA Summary and Response

Summary:

Cummins supports EPA's proposed new special maintenance category in 1036.125(c) and requests specific examples of special maintenance.

Response:

We are updating 40 CFR 1036.125(c) to include an example of biodiesel use.

6.3 Source of parts and repairs

Comments by Organizations

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

EPA proposes a new paragraph 40 C.F.R. 1036.125(f) that would prohibit manufacturers from limiting the source of components or service required for engine maintenance and would clarify that manufacturers may not condition an emission warranty on a requirement that the engine be serviced by a franchised dealer or any other service establishment with which the manufacturer has a commercial relationship (unless the manufacturer provides the component or service without charge or unless it obtains a waiver from EPA).124 These provisions are intended to implement CAA Section 207(c)(3) and mirror the companion prohibitions in 40 C.F.R. 1037.125(f) for heavy duty vehicle manufacturers. [EPA-HQ-OAR-2019-0055-1168-A1, p.110]

124 See Proposed Rule, 87 Fed. Reg. at 17,525.

Daimler Truck has an established track record of honoring the valid emissions and other warranty claims of its customers, recognizing that reliable warranty coverage is an important part of the customer experience. The Company recognizes its obligations under CAA Section 207(c)(3) to not unreasonably condition its emission warranties on the use of brand-affiliated parts or services. Nonetheless, Daimler Truck notes that—even within the proposed 1036.125(f) and existing legal framework under CAA Section 207—manufacturers should not incur warranty liability for faulty or off-spec components from third party suppliers that contribute directly to an emission system failure. In other words, denial of an emission warranty claim would be appropriate where a manufacturer discovers that the emission system performance or durability issue in question was caused by a technical shortcoming in a non-OEM component or system. Similarly, any faulty or off-spec component determined to contribute directly to increased emissions should not create emissions compliance liability for the engine manufacturer during in-use emissions testing or otherwise. Daimler Truck believes that current law accommodates this interpretation but would appreciate clarification that EPA's proposed Section 1036.125(f) is not to the contrary. [EPA-HQ-OAR-2019-0055-1168-A1, pp.110-111]

Organization: *PACCAR, Inc (PACCAR)*

PACCAR agrees with, and incorporates by reference, the following EMA comments: While EPA may permit an engine manufacturer to void an in-use test (or reject a candidate vehicle) if an aftermarket DPF or other third-party components are used, there are no such guarantees available to manufacturers when utilizing some of the alternative compliance demonstration methods. For example, among the DF verification procedures a manufacturer may use is one which involves submitting NOx sensor-based emissions results from a high volume of vehicles (50% of the family volume) in operation. Similarly, the in-use testing provisions at 1036.405(g) permit manufacturers to use on-board NOx sensor data as a surrogate for PEMS-based testing as a means to satisfy an in-use test order (the volume requirements are not specified, but EPA may similarly require a high volume of vehicles to use this provision). In both of those cases, it is impossible for the manufacturer to inspect each vehicle to confirm that there are only manufacturer-approved components, or to review vehicle records to confirm that independent repair facilities have not (mis)performed maintenance or repairs. In fact, there is no obvious way for a manufacturer even to investigate those matters, as the affiliated dealers would not possess such records. In this regard, it is impossible for a manufacturer to adequately screen to exclude such vehicles from consideration. In the final rule, EPA should eliminate the requirement to make the independent repair and third-party component statement as proposed. [EPA-HQ-OAR-2019-0055-1346-A1, pp.31-32]

If EPA chooses not to delete the requirements of 1036.125(f), EPA has allowed the provision to be disregarded only under one of two conditions. The first condition is that the manufacturer commit in the purchase agreement to provide components or services free of charge. While it is not clear whether this is with respect only to any isolated, named components or services, or to all components or services, the requirement is nonetheless unreasonable. The second condition is to demonstrate to the Agency that the 'engine' will work properly with the 'identified' component or service. This would mean that the manufacturer would have to be aware of all possible sources for the service or components, and to have explicit knowledge about all the services or components and their potential impact to emissions, which is impossible, and therefore unworkable. See EMA Comments at 123-25. [EPA-HQ-OAR-2019-0055-1346-A1, p.32]

Proposed section 1036.125(f) also should be revised. The NPRM provides: 'Source of parts and repairs. State clearly on the first page of your written maintenance instructions that a repair shop or person of the owner's choosing may maintain, replace, or repair emission control devices and systems. Your instructions may not require components or service identified by brand, trade, or corporate name. Also, do not directly or indirectly condition your warranty on a requirement that the engine be…..' 87 Fed. Reg. at 17514. [EPA-HQ-OAR-2019-0055-1346-A1, p.53]

This aspect of EPA's Proposed Rule is inconsistent with the goals of EPA's UL to ensure long-term emissions compliance. Allowing stakeholders to use unvalidated, non-branded parts to repair emissions systems that are must meet new Low NOx extended durability and performance requirements does not make sense. First, the proposal does not expressly require that any stakeholder validate that the parts meet the durability and variance requirements needed to maintain the performance of the original equipment manufacturer's emissions system throughout full useful life. The OEM should not be legally responsible for these unbranded parts, let alone have to include the failure in the warranty failure analysis. [EPA-HQ-OAR-2019-0055-1346-A1, p.53]

Organization: *Truck and Engine Manufacturers Association (EMA)*

Other aspects of the Agency's proposed maintenance requirements are problematic as well. As an initial matter, it is unreasonable to require manufacturers to prominently "advertise" to vehicle-owners their right to have emissions-related repairs performed at non-affiliated independent repair facilities using third-party components of the owners choosing. Manufacturers have invested billions of dollars developing products that are compliant with the Agency's ever increasingly stringent emissions standards. Putting the entirety of that effort, at huge customer and societal expense, at risk by prominently highlighting this "right-to-repair" appears to be at odds with ensuring the feasibility and durability of the new low-NOx controls and systems that the Agency is seeking to mandate. On top of that, it is discouraging that EPA is willing to compel this type of advocacy for independent repair facilities, directly in competition with the companies who have made these significant investments, time and time again, in response to the Agency's latest emissions standards and diagnostic requirements. While the CAA does not permit manufacturers to require repairs at their own facilities as a condition to honor emissions warranties, it does not require manufacturers to actively encourage owners to seek repair elsewhere from independent repair facilities, or to use third-party components, putting emissions compliance at risk. [EPA-HQ-OAR-2019-0055-1203-A1, p. 126]

While EPA may permit an engine manufacturer to void an in-use test (or reject a candidate vehicle) if an aftermarket DPF or other third-party components are used, there are no such guarantees available to manufacturers when utilizing some of the alternative compliance demonstration methods. For example, among the DF verification procedures a manufacturer may use is one which involves submitting NOx sensor-based emissions results from a high volume of vehicles (50% of the family volume) in operation. Similarly, the in-use testing provisions at §1036.405(g) permit manufacturers to use on-board NOx sensor data as a surrogate for PEMS-based testing as a means to satisfy an in-use test order (the volume requirements are not specified, but EPA may similarly require a high volume of vehicles to use this provision). In both of those cases, it is impossible for the manufacturer to inspect each vehicle to confirm that there are only manufacturer-approved components, or to review vehicle records to confirm that independent repair facilities have not (mis)performed maintenance or repairs. In fact, there is no obvious way for a manufacturer even to investigate those matters, as the affiliated dealers would not possess such records. In this regard, it is impossible for a manufacturer to adequately screen to exclude such vehicles from consideration. In the final rule, EPA should eliminate the requirement to make the independent repair and third-party component statements as proposed. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 126 - 127]

If EPA chooses not to delete the requirements of §1036.125(f), EPA has allowed the provision to be disregarded only under one of two conditions. The first condition is that the manufacturer commits in the purchase agreement to provide components or services free of charge. While it is not clear whether this is with respect only to any isolated, named components or services, or to all components or services, the requirement is nonetheless unreasonable. The second condition is to demonstrate to the Agency that the "engine" will work properly with the "identified" component or service. This would mean that the manufacturer would have to be aware of all possible sources for the service or components, and to have explicit knowledge about all the services or components and their potential impact to emissions, which is impossible, and therefore unworkable. [EPA-HQ-OAR-2019-0055-1203-A1, p. 127]

EPA's proposal requires that engine manufacturers "state clearly on the first page of your maintenance instructions that a repair shop or person of the owner's choosing may maintain, replace, or repair emissions control devices and systems." (§1036.125(f)) Repairs performed by independent repair facilities that do not have proper training, and that are installing unapproved third-party components to correct issues caused by the use of biodiesel, can create serious problems. For example, an untrained service technician may install a lower efficiency fuel filter to overcome issues with filter clogging due to operation on biodiesel blends at low temperatures. While this action may appear to have resolved the issue, the impact to the high-pressure fuel system may be significant and catastrophic. [EPA-HQ-OAR-2019-0055-1203-A1], p. 142]

As discussed above, EPA's proposed requirement to allow service by independent repair facilities using third-party emissions control components further jeopardizes the integrity of the manufacturer's design of an integrated fuel, engine and aftertreatment management system critical to compliance with the applicable emissions standards throughout the useful life. In addition, the burden of proof for denying a customer claim for misfuelling, mal-maintenance or use of unapproved biodiesel falls upon the manufacturer at the time of repair. The OEM can accurately determine that damage has occurred, but not when, or under what circumstances (e.g., prolonged use of biodiesel) the damage occurred or how fuel deficiencies or deferred maintenance contributed to the failure. Absent the ability to reliably control or know the biodiesel blend level when refueling occurs, it is unrealistic to assume that customers or manufacturers will be able to adequately prescribe an appropriate maintenance schedule that prevents damage from biodiesel use. [EPA-HQ-OAR-2019-0055-1203-A1, p. 142]

EPA Summary and Response

Summary:

DTNA acknowledged the "legal framework under CAA Section 207" that is the basis of source of parts and repairs provision proposed in 40 C.F.R. 1036.125(f), but commented that manufacturers should not be liable for non-OEM components or systems, such as "faulty or off-spec components from third party suppliers" directly linked to an emission system failure. PACCAR commented that allowing owners to use "unvalidated, non-branded parts" would not ensure long-term emissions compliance. EMA commented that it was “unreasonable” for EPA to require manufacturers to state on their first page that owners could use non-affiliated facilities and third-party components for repairs, noting manufacturers’ investments in developing EPA compliant products. EMA commented (and PACCAR commented in agreement with EMA) with a wide range of concerns related to testing vehicles with third-party components. EMA (and PACCAR) also stated concerns with the two proposed options for a manufacturer to disregard the limitations of proposed 40 CFR 1036.125(f). EMA stated that it is unclear if the option to pay for components or services can apply to a specific component or service or if it must apply to all. EMA also stated that it is impossible for a manufacturer to be aware of all possible sources of parts or services, so it is “unworkable” for manufacturers to convince EPA that an engine will only work properly with an OEM part or service.

EMA commented with several maintenance concerns relating to the use of biodiesel fuel, including that it is challenging for manufacturers to specify a maintenance schedule to prevent damage from “unapproved biodiesel”.

Response:

As noted in section 4 of this document, we are revising 40 CFR 1036.120(c) to clarify that warranty covers components that are part of the certified configuration even if they are produced by a company other than the engine manufacturer.. We also note that we proposed no changes and are finalizing no changes to the existing 40 CFR 1068.115, which specifies when manufacturers may or may not deny warranty claims.

See preamble Section IV.B.2 for the final provisions related to proposed 40 CFR 1036.125(f) and supporting rationale, after consideration of comments.

We are updating 40 CFR 1036.125(h)(2) as described in section 6.5, which also includes moving and revising the proposed “source of parts and service” provision from 40 CFR 1036.125(f) to be part of paragraph (h)(2) in the final rule in order to emphasize the connection to proper maintenance.

We are not finalizing at this time the proposed 40 CFR 1036.125(f) requirement regarding specific statements on the first page of written maintenance instructions; after consideration of comments, we agree with commenters that the final regulatory text accomplishes the intent of our proposal without the additional proposed first sentence.

We are finalizing as proposed the two options manufacturers have to disregard the limitations on the source of parts and service. In response to EMA, we clarify in this document that the first option allows manufacturers to isolate the payment to a specific component or service. For example, if a manufacturer chooses to pay for only their DEF filters to be installed, we would not require manufacturers to pay for all emission-related components. For the second option, we agree with the commenter to the extent that they suggest that it is not easy to demonstrate that only a manufacturer’s components or services are appropriate for properly maintaining an engine, as this exception is intended to be narrow.

With respect to EMA's comment on biodiesel, in the section IV.B.2 of the preamble to this rule, we describe the types of maintenance, including special maintenance. Manufacturers can specify more frequent maintenance (e.g., replacing filters) for atypical engine operation, which could include biodiesel use. As noted in section 6.2 of this document, we are adding an example of biodiesel use to the description of special maintenance in 40 CFR 1036.125(c). For additional discussion relating to biodiesel considerations, see section IV.E of the preamble to this rule, chapter 1.3 of the final RIA, and section 11.5 of this document.

6.4 Payment for scheduled maintenance

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

U.S. EPA requested comment on including turbochargers as components that should have limited replacement irrespective of the four 40 CFR 1036.125(g) criteria. CARB staff have significant concerns regarding owner payment for scheduled maintenance of a turbocharger. The repair cost and the emission increase of turbocharger failure were of a similar magnitude as those of diesel oxidation catalysts, DPF, and SCR for which requiring replacement at owner's cost during UL is already prohibited. The proposed 40 CFR 1036.125(g) states that manufacturers would pay for scheduled maintenance, including parts and labor, only if all the following criteria are met:

1. Each affected component was not in general use on similar engines before 1980,
2. The primary function of each affected component is to reduce emissions,
3. The cost of the scheduled maintenance is more than 2 percent of the price of the engine, and
4. Failure to perform the maintenance would not significantly degrade the engine's performance. [EPA-HQ-OAR-2019-0055-1186-A2, pp.115-116]

According to these criteria, manufacturers would not be required to pay for scheduled maintenance of turbochargers because a turbocharger's primary function is not to reduce emissions and because a turbocharger's failure would degrade engine's performance (thereby failing to meet criteria #2 and #4). [EPA-HQ-OAR-2019-0055-1186-A2, p.116]

CARB staff believes the criteria are too restrictive. In California's Step 1 warranty rulemaking, CARB staff analyzed repair cost and emissions increase for HHDD components and showed that the repair cost of a turbocharger is $5,100, and the failure of turbochargers would result in 147 percent increase in NOx emissions.178 Therefore, CARB staff believes the fact that turbocharger repairs are costly and have significant impact on NOx emission is enough to require manufacturers to pay for scheduled maintenance of turbochargers. [EPA-HQ-OAR-2019-0055-1186-A2, p.116]

178 Staff Report: Initial Statement of Reasons for Proposed Rulemaking, 'Public Hearing to Consider Proposed Amendments to California Emission Control System Warranty Regulations and Maintenance Provisions for 2022 and Subsequent Model Year on-Road

Heavy-Duty Diesel Vehicles and Heavy-Duty Engines with Gross Vehicle Weight Ratings Greater Than 14,000 Pounds and Heavy-Duty Diesel Engines in Such Vehicles,' (Step 1 Warranty), May 8, 2018, page III-16, https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2018/hdwarranty18/isor.pdf?_ga=2.159591101.1089019171.1648488649-859068364.1628622434

Organization: *Truck and Engine Manufacturers Association (EMA)*

The provisions of §1036.125(g) allow manufacturers to pay for emissions-related maintenance under various circumstances. The sentence reads, "You must pay for scheduled maintenance on any component during the useful life if it meets…" That statement, as written, is overly broad. It should read, "You must pay for scheduled maintenance not otherwise allowed by this section on any component during the useful life if it meets…"

EPA Summary and Response

Summary:

CARB responded to EPA's request for comment on restricting the replacement of turbochargers irrespective of the four criteria in 40 CFR 1036.125(g). Instead of relying on the criteria to determine if scheduled maintenance of a turbocharger should be paid by the manufacturer, CARB would like turbocharger replacement to always be the manufacturer's responsibility, citing the cost of repair of the component. EMA stated that proposed 40 CFR 1036.125(g) was "overly broad" and suggested we add the phrase "not otherwise allowed by this section" to narrow the scope of the proposed requirement to pay for scheduled maintenance.

Response:

See section IV.B.2 of the preamble for our response to CARB's comment related to turbochargers and the final provisions. We disagree with EMA that paragraph (g) is overly broad. We believe that it identifies specific provisions that define requirements that are already largely covered by 40 CFR 1036(a)(1). The four qualifying criteria serve a narrow purpose of informing manufacturers under which conditions EPA will require manufacturer payment as the only acceptable demonstration that scheduled maintenance is reasonably likely to occur.

6.5 Emission-Related Components

Comments by Organizations

Organization: *Lubrizol Corporation (Lubrizol)*

1) EPA Should Include Lubricants and Engine Oils on the List of Critical Emissions- Related Components

Compared with prior generations of internal combustion engines (IC engines), today's IC engines operate with extremely high temperatures, high pressure, high shear, and other extremely sensitive operating environments. In order to operate efficiently, durably, and with low emissions, today's IC engines need to use the appropriate engine oil or lubricant at all times throughout its useful life. Using the wrong lubricant can impact the engine's performance and durability, as well as the performance and durability of emissions control systems. Numerous studies have been done in the past that highlighted the relationship between lubricant composition and emission system durability (see Appendix 2 for a summary of pertinent research). It can be expected that lubricant compatibility will become even more important when the next generation of emission control systems is deployed to meet the new standards. To help ensure that vehicle owners or operators use the appropriate engine oil or lubricant, we strongly urge EPA to include lubricants on the list of Critical Emission- Related Components.2 Doing so will enable EPA to require regular service intervals for oil changes, as well as require that engines are consistently using the appropriate higher-performing lubricant oil for each particular engine - at all times throughout its useful life. [EPA-HQ-OAR-2019-0055-1304-A1, p.2]

2 See Proposal, Tables IV-11 and IV-12 and related discussion.

By including lubricants on the list of Critical Emission-Related Components, EPA would be able to require that owners or operators use specified higher-performing lubricants, or oils, throughout an engine's useful life. Such specified lubricants would provide the engine with the appropriate level of performance, engine protection, and protection of emission control technology, according to objective characteristics as determined by the OEMs. These characteristics could be in the form of an OEM performance specification or an industry category defined by an entity like the American Petroleum Institute (API) or the European Automobile Manufacturers' Association (ACEA), along with a maximum viscosity level. (To be clear, Lubrizol does not suggest that EPA should specify particular lubricant brands or servicing locations as a warranty requirement.) [EPA-HQ-OAR-2019-0055-1304-A1, p.3]

OEMs already use these higher performing lubricants in the development and certification of their powertrain systems. They rely on them to demonstrate that their engines will meet EPA's requirements throughout the full useful life of their engines and emissions systems. [EPA-HQ-OAR-2019-0055-1304-A1, p.3]

By adding lubricants to the list of Critical Emission-Related Components, EPA would be taking an important step to ensure that the same category and maximum viscosity level that is used for certification and initial fill is used when the vehicle is serviced to maintain vehicle powertrains, engines, and emission control technologies throughout their useful life. Doing so will help ensure that engines maintain their emissions durability throughout their useful life, thereby helping to ensure that real world emissions remain at the levels EPA seeks to achieve in this Proposal. [EPA-HQ-OAR-2019-0055-1304-A1, p.3]

Lubrizol provides the following additional information to support our request that EPA adds lubricants to the list of Critical Emission-Related Components. [EPA-HQ-OAR-2019-0055-1304-A1, p.11]

There is a significant amount of research that explores the impact of engine lubricants or oils on catalysts and filters, in addition to the core emissions benefits from keeping the engine clean and free from wear over the course of each lubricant's service interval. [EPA-HQ-OAR-2019-0055-1304-A1, p.11]

Below, Lubrizol lists several of the most relevant papers, including some pertinent research conducted by Lubrizol. [EPA-HQ-OAR-2019-0055-1304-A1, p.11]

CATALYST POISONING:

Sulfur and phosphorus are both known to contaminate (or, as more commonly described, poison) catalysts. Sulfur poisoning may be reversible at high temperatures. Damage due to phosphorus poisoning is considered to be much more permanent. [EPA-HQ-OAR-2019-0055-1304-A1, p.11]

Numerous papers have investigated the extent of phosphorus-related catalyst poisoning, dating back to the 1980s. [EPA-HQ-OAR-2019-0055-1304-A1, p.11]

Brett, P. S., et al. 'An Investigation into Lubricant Related Poisoning of Automotive Three- Way Catalysts and Lambda Sensors.' SAE Transactions, vol. 98, 1989, pp. 269–80

- 55 engine tests on 24 oils of varying formulations
- 99% confidence of link between lubricant phosphorous level and catalyst performance.
- High phosphorus oils reduce oxygen sensor performance, especially at low temperatures [EPA-HQ-OAR-2019-0055-1304-A1, p.11]

Dieselnet.com contains additional information on deactivation of diesel catalysts

- See, e.g., https://dieselnet.com/tech/cat_d_deactiv.php
- Lube oil additives, including phosphorus (P), zinc (Zn), calcium (Ca), and sulfur (S) are recognized as poisons [EPA-HQ-OAR-2019-0055-1304-A1, p.11]

- Lubrizol field trial research
- 9 car / 3 oil field trial in Shanghai
- Significant difference in back pressure
- Effects on efficiency and power recorded [EPA-HQ-OAR-2019-0055-1304-A1, p.12]

Organization: *Truck and Engine Manufacturers Association (EMA)*

Finally, EPA should include definitions of "particulate filtration system," "particulate filter," "Catalyst system," and "catalyst bed" to clarify the distinctions being made in Table 1 of §1036.125. [EPA-HQ-OAR-2019-0055-1203-A1, p. 127]

EPA Summary and Response

Lubrizol requested that EPA add lubricants as a critical emission-related component, suggesting that doing so would "enable EPA to require regular service intervals for oil changes, as well as require that engines are consistently using the appropriate higher-performing lubricant oil." Lubrizol provided several summaries of research related to lubricants in support of their request.

EMA requested that EPA define the particulate filtration systems, particulate filter, catalyst systems, and catalyst beds.

Response:

We thank Lubrizol for sharing the resources related to lubricants. As noted in preamble section IV.B.2 of this rule, we are not including a specific list of critical emission-related components in 40 CFR 1036.125. Lubrizol's comment suggests that they would like to ensure more frequent oil changes, but EPA's minimum maintenance intervals do not serve that purpose. Rather, we are specifying *minimum* maintenance intervals to prevent the manufacturers from creating unrealistic expectations for maintenance from users beyond what is necessary for maintenance and at intervals that would be less likely to occur in-use. Furthermore, we also note that lubricants are a consumable product and are not considered components.

With respect to EMA's requests for definitions, we are finalizing a new paragraph (a)(4) to clarify which components are included in particulate filtration and catalyst systems. We note that particulate filter and catalyst bed are terms used in current 40 CFR part 86, subpart A. We have replaced those terms with "particulate filter substrate" and "catalyst substrate" in our migration to 40 CFR part 1036.

6.6 Maintenance Instructions

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

U.S. EPA allows manufacturers to deny warranty claims if vehicle owners do not have proper recordkeeping documenting that the engine and emissions control system are properly maintained. U.S. EPA is proposing that manufacturers be required to describe in the owner's manual the documentation they consider appropriate to demonstrate that the engine and emissions control system are properly maintained. CARB staff will continue to not allow manufacturers to deny warranty claims if vehicle owners do not have proper recordkeeping of maintenance records. [EPA-HQ-OAR-2019-0055-1186-A2, pp.116-117]

CARB staff recommends that U.S. EPA consider omitting regulatory language that allows manufacturers to deny warranty claims if vehicle owners do not have proper recordkeeping. Warranty claims should only be denied if it can be proven that improper maintenance was the direct cause for needing the repair or replacement of a part. [EPA-HQ-OAR-2019-0055-1186-A2, p.117]

CARB staff believes that U.S. EPA's warranty program will be improved if CARB's requirements are adopted because of the reasons summarized below:
U.S. EPA's warranty program allows manufacturers to deny warranty claims based on improper recordkeeping of maintenance. This can be problematic as manufacturers may deny warranty coverage even though all maintenance was performed on the vehicle but was improperly documented. Additionally, it may cause vehicle owners to delay repairing their vehicles in a timely manner due to the cost of performing a repair that should have been covered under warranty. This may cause vehicle owners to continue to operate their vehicle with a failed emission control component resulting in their vehicle producing excess emissions. CARB staff allows manufacturers to deny warranty claims if it can be proven that improper maintenance is

the direct cause of the need for a repair or replacement of a part. Manufacturers cannot deny warranty coverage based on a lack of proper recordkeeping of maintenance. [EPA-HQ-OAR-2019-0055-1186-A2, p.117]

CARB will continue to maintain its separate warranty program as it has done so in the past. The program has proven to be effective, and CARB staff is unaware of many instances where warranty has been denied due to improper recordkeeping of maintenance. Therefore, it is anticipated that adopting a warranty program similar to CARB's would not be overly burdensome to the manufacturers. [EPA-HQ-OAR-2019-0055-1186-A2, p.117]

Organization: *PACCAR, Inc (PACCAR)*

PACCAR agrees with, and incorporates by reference, the following EMA comments: EPA's maintenance-related requirements go on to require additional information to be included in the owner's manual. Under 1036.125(h)(2), manufacturers must 'identify steps owners must take to qualify their engines as properly maintained, consistent with the requirements of this section.' The owner's manual must also instruct owners as to what 'documentation you [the manufacturer] consider appropriate for making these demonstrations.' These requirements are not practical. First, there's an implication that owners are 'on notice' as to documentation responsibilities, and are somehow responsible to maintain emissions-related maintenance records. Second, it makes no sense for the manufacturer, speaking through the owner's manual, to advise what should be done to 'qualify' their engines as 'properly maintained.' Not only is it totally foreign to customers to 'qualify' their purchased products in any way, but there would be an underlying sentiment that overlooking other maintenance requirements might nonetheless still provide for a vehicle that is 'properly maintained.' The whole of 1036.125(h)(2) is inappropriate and unreasonable on its face, and should be removed from the final rule. [EPA-HQ-OAR-2019-0055-1346-A1, p.32]

Organization: *Truck and Engine Manufacturers Association (EMA)*

EPA's maintenance-related requirements go on to require additional information to be included in the owner's manual. Under §1036.125(h)(2), manufacturers must "identify steps owners must take to qualify their engines as properly maintained, consistent with the requirements of this section." The owner's manual must also instruct owners as to what "documentation you [the manufacturer] consider appropriate for making these demonstrations." These requirements are not practical. First, there's an implication that owners are "on notice" as to documentation responsibilities, and are somehow responsible to maintain emissions-related maintenance records. Second, it makes no sense for the manufacturer, speaking through the owner's manual, to advise what should be done to "qualify" their engines as "properly maintained." Not only is it totally foreign to customers to "qualify" their purchased products in any way, but there would be an underlying sentiment that overlooking other maintenance requirements might nonetheless still provide for a vehicle that is "properly maintained." The whole of §1036.125(h)(2) is inappropriate and unreasonable on its face, and should be removed from the final rule. [EPA-HQ-OAR-2019-0055-1203-A1, p. 127]

EPA Summary and Response

Summary:

CARB recommended that EPA omit regulatory language allowing manufacturers to deny warranty claims if owners do not keep records. Instead, CARB indicated that it is the manufacturer's responsibility to prove improper maintenance directly caused the need for a repair/replacement. CARB stated that they will maintain their separate warranty program and are "unaware of many instances" of warranty being denied do to improper maintenance records. EMA commented (with PACCAR commenting in agreement with EMA) that a requirement for owners to maintain records was "not practical", "inappropriate", and "unreasonable" and 40 CFR 1036.125(h)(2) should be removed.

Response:

In section IV.B.2 of the preamble to this rule, we clarify that the proposed 40 CFR 1036.125(h)(2) was not intended as a *requirement* for owners to keep maintenance records; instead, it was intended to require manufacturers to communicate what records they expect when owners file a warranty claim. While 40 CFR 1036.120(d) allows manufacturers to deny warranty claims for improper maintenance and use, owners have expressed concern that it is unclear what recordkeeping is needed to document proper maintenance and use, and both the proposed and final 40 CFR 1036.125(h)(2) are intended to ensure manufacturers are communicating their expectations to owners. For example, if there are any maintenance steps that the manufacturer intends to expect or intends to require certain documentation for filing a warranty claim, the owner will be well served to know that from the beginning.

In the final 40 CFR 1036.125(h)(2), to clarify the provision consistent with this intent, we removed the proposed sentences stating that manufacturers would identify steps to "qualify the engine as properly maintained" and identify types of "engine operation that would not qualify their engines as being properly used". The replacement text makes a clearer connection to warranty without the term "qualify": *Identify all maintenance you consider necessary for the engine to be considered properly maintained for purposes of making valid warranty claims.*

6.7 Prognostics as Scheduled Maintenance

Comments by Organizations

Organization: *Cummins Inc. (Cummins)*

Prognostics systems, which use proprietary data and algorithms to predict component failures on in-use engines before they happen and notify the owner of upcoming maintenance needed, are becoming more prevalent. They can be an important technology for eliminating unplanned downtime. Cummins requests EPA to include a provision for manufacturers to request approval of scheduled maintenance for a component that occurs at variable intervals, as determined by the prognostics algorithm. In lieu of the traditional fixed intervals, the interval would be dependent on duty cycle which could vary on an engine-by- engine basis. [EPA-HQ-OAR-2019-0055-1325-A1, pp. 16 - 17]

Organization: *PACCAR, Inc (PACCAR)*

Proposed section 1036.125(a) Critical emission-related maintenance, states: 'Critical emission-related maintenance includes any adjustment, cleaning, repair, or replacement of components listed in paragraph (a)(2) of this section. This may also include other maintenance that you determine is critical, including maintenance on other critical emission-related components as defined in 40 CFR part 1068, if we approve it in advance. You may perform scheduled critical emission-related maintenance during service accumulation on your emission-data engines at the intervals you specify.' PACCAR submits that, in the spirit of lengthening useful life to improve long-term performance durability, EPA should allow manufacturers to implement proactive, predictive maintenance strategies if they proactively monitor and identify potential maintenance issues. Under this type of maintenance regime, the manufacturer can become aware, but would not necessarily know in advance, that a particular component is in need of maintenance. This approach would incentivize preventative maintenance, and even goes further by promoting vehicle service before any malfunction occurs, which would lead to emission reductions. EPA should therefore support and encourage these initiatives, including by allowing targeted maintenance subject to EPA approval. Rather than penalizing maintenance initiatives as failures, EPA should encourage manufacturers to take the initiative to prevent malfunctions in the first place. The following proposed regulatory provision would accomplish this goal: 'Vehicle connectivity and advanced analytics (machine learning, cloud computing, etc.) enable pattern recognition and predictive analytics. The OEM shall be allowed to use advanced predictive measures to proactively remedy potential emissions related part failures, and these actions shall not be counted as a failure for the purpose of the emissions warranty. This strategy recognizes the breadth of customer use conditions and the potential uneven impact on long-term engine performance. The OEM may choose how and when to alert the driver when a proactive measure is required. The cost of these repairs would be covered by the OEMs. EPA must approve the OEM's proposed action before it is initiated.' [EPA-HQ-OAR-2019-0055-1346-A1, pp.33-34]

Examples of Predictive Preventive Maintenance include:

- Component is predicted to fail within a prescribed number of days
- OEM identifies next scheduled maintenance
- OEM includes the component repair with next scheduled maintenance
- Pro-actively repaired vehicles avoid unplanned downtime
- These actions must be excluded from filtered failures for reporting [EPA-HQ-OAR-2019-0055-1346-A1, p.34]

PACCAR encourages EPA to revise the Proposed Rule to allow for more preventative maintenance in the spirit of emissions reduction under the Clean Air Act. [EPA-HQ-OAR-2019-0055-1346-A1, p.35]

PACCAR summarizes below the major issues that EPA should take into account as it moves forward with this rulemaking: In the spirit of lengthening useful life to improve long-term performance durability, EPA should allow manufacturers to implement proactive, predictive maintenance strategies if they proactively monitor and identify potential maintenance issues. [EPA-HQ-OAR-2019-0055-1346-A1, p.60]

EPA Summary and Response

Summary:

Cummins and PACCAR commented to request that EPA consider “prognostic systems” and “proactive, predictive maintenance strategies”, respectively, as allowable maintenance. Cummins specifically requested that EPA allow the prognostic system to determine variable maintenance intervals based on the particular duty cycle of an engine. PACCAR indicated that predictive maintenance can notify a user that a vehicle may need service “before any malfunction occurs”. PACCAR provided examples of scenarios where predictive preventative maintenance may be used and suggested regulatory text revisions.

Response:

We recognize the value that engine prognostics can provide for ensuring emissions systems are functioning as designed and generally support the recommendations from Cummins and PACCAR. We agree there is an environmental benefit to providing a warning for owners to indicate that it is time to adjust, clean, or replace emission-related components as part of general maintenance, allowing them to delay replacement in lieu of requiring them to discard a functional component at a specific interval. We recognize there is also a benefit to notifying owners that an emission-related component is at risk of failing so they can replace the part before its emission control performance deteriorates. However, we are not finalizing provisions that would remove a manufacturer’s liability for warranty, defect reporting, or recall simply for including prognostic systems on their engines. It continues to be the manufacturer’s responsibility to design durable components, determine the components’ deterioration over the useful life, and schedule maintenance as appropriate and consistent with our regulations. For example, if a component fails before its scheduled maintenance interval or the component did not have a maintenance interval specified in the engine configuration’s application for certification, we would continue to treat that failed emission-related component as an emission-related defect subject to the reporting requirements of 40 CFR 1068, subpart F.

We proposed and are finalizing an update to 40 CFR 1065.410(c) to clarify that inspections performed during testing can include electronic monitoring of engine parameters, such as prognostic systems. The provisions of 40 CFR 1065.410 would apply for the service accumulation testing for certification.

We generally support and may further consider aspects of PACCAR’s comment to request allowances for predictive preventative maintenance, but we do not support extending such allowances to malfunctions and failures where a component is defective or otherwise not properly functioning as designed.

We did not propose and are not finalizing specific revisions to 40 CFR 1036.125 related to predictive maintenance or prognostics systems, but we recognize that manufacturers may wish to apply prognostics in their durability testing and demonstration that maintenance will occur in-use. We encourage those manufacturers to work with EPA if they wish to account for prognostics when they request approval of maintenance intervals.

6.8 Other Maintenance-Related Comments

Comments by Organizations

Organization: *American Trucking Associations (ATA)*

The current performance of NOx sensors continues to raise concerns with fleets trying to keep their equipment on the road. In addition, on-going chip shortages nationwide cannot keep pace with fleet repair needs. To help demonstrate this point, ATA conducted an independent survey of its members on costs and frequency involving NOx sensor failures. Fleets have indicated that sensors start going bad in as early as two years. Including parts and labor, replacing one sensor today generally ranges in price from $500 - $700. Tack on downtime and those overall cost estimates increase substantially – in one case up to $1,600 per sensor replacement. One large fleet reported that they typically experience two weeks of downtime per failure (including out-of- service time for the repair and return of the equipment). [EPA-HQ-OAR-2019-0055-1326-A1, p. 8]

Another large fleet broke down their current monthly NOx sensor repairs at $30,000/month in parts, $10,000/month in labor, and $45,000/month in downtime. Over a 12-month period, this fleet's costs average $1.14 million – no small amount for NOx sensors that have now been in use for over 10 years. Since these events do not normally align with routine fleet maintenance schedules, equipment is frequently required to be taken out-of-service to undertake diagnostics and repairs. Fleets with emission control systems under warranty do not typically experience costs for parts and labor – only downtime. However, fleets consistently report that downtime costs far exceed parts and labor costs. These costs are typically neglected when undertaking EPA cost calculations. Given the need for highly sensitive NOx sensors under either proposed Option, fleet maintenance shops have expressed that they are extremely concerned. Memories from the 2010 NOx emission implementation period left a permanent stain that remains to this date. [EPA-HQ-OAR-2019-0055-1326-A1, p. 8]

Organization: *Evergreen Action*

As stronger NOx regulations are promulgated it is critical that state and local air agencies have the capacity to thoroughly enforce compliance with emissions controls. This means ensuring that local authorities have the funding and appropriate staffing levels to provide routine inspections to minimize efforts to tamper with pollution control devices. Regular inspections are also needed to assure that necessary maintenance and repairs are done so that all heavy duty vehicles are in strict compliance with new standards. The millions of Americans living in counties with unsafe levels of air pollution rely on the EPA and local authorities to protect their health, which is why every effort must be made to adequately enforce MHDV standards. [EPA-HQ-OAR-2019-0055-1289-A1, p.2]

Organization: *Great Rivers Environmental Law Center and Dutchtown South Community Corporation (DSCC)*

The undersigned support inclusion of the following requirements in the Final Regulation:

- Mandatory additional maintenance requirements and onboard diagnostics to help combat mal-maintenance and tampering, and to ensure long-term emissions performance. [EPA-HQ-OAR-2019-0055-1323-A1, p.6]

Organization: *Manufacturers of Emission Controls Association (MECA)*

MECA supports the implementation of robust state-led diesel inspection and maintenance programs. [EPA-HQ-OAR-2019-0055-1320-A1, p.33]

To ensure truck engines and aftertreatment systems are properly maintained and operating over their full useful life especially after the warranty has expired will require periodic inspection. This is particularly true for large class 7 and 8 tractor trailer trucks that may be on their second or third owner. MECA supports EPA's activities that encourage states to develop enforceable I/M programs for all vehicles. [EPA-HQ-OAR-2019-0055-1320-A1, p.33]

MECA believes that sensors, already on vehicles, that are an essential part of the OBD system to monitor the NOx emissions from trucks over their operating lives can be used for the purpose of compliance monitoring in the future. MECA members provide their customers with the full spectrum of temperature, NOx, ammonia, PM and numerous other sensors and OBD control units to allow them to comply with CARB and EPA OBD requirements. Real Emissions Assessment Logging (REAL) requirements, which are now in force, require OEMs to store NOx and CO_2 emissions information on the vehicle and report to CARB periodically. MECA members offer telematics capability, that in the future, could be combined with robust sensor monitoring to provide real-time reporting. [EPA-HQ-OAR-2019-0055-1320-A1, p.33]

On-Board Monitoring (OBM) has been adopted by China beginning in 2023 and this will be combined with telematics to report emissions and OBD information in real time to the regulators. Beijing Environmental Protection Bureau has instituted a demonstration program on 50,000 trucks operating in the city to require OBM and telematics to report OBD information to the agency. All OBD functions are monitored in real time including NOx, DPF back-pressure, urea quality along with the normal engine operating parameters collected by the OBD system. A GPS installed on each truck monitors vehicle location and all data is stored for up to a year. Currently the system is being used only for monitoring and demonstration, however the agency will begin using it for enforcement before 2023 when it will be mandated nationally. If an emission or OBD problem is identified, the truck owner will be notified that they must fix the issue. [EPA-HQ-OAR-2019-0055-1320-A1, p.33]

Organization: *Motorcoach Companies*

In a recent industry survey, it was determined that 80% of DPF system related issues directly resulted from faulty sensors. This includes a wide range of sensors, not just NoX sensors, so any sensor that would lead to derate or inducement. Unlike other parts that wear over time, there is no way to determine when a faulty sensor will occur. We have seen them happen on a new bus with less than 1,000 miles on the vehicle. Some of these sensors are simply put in place to deter operators from using subpar DEF products and to make sure the operators are not running low/empty on DEF. However, the cost of DEF is minimal, and companies are committed to ensuring the proper use. Unfortunately, the quality and reliability of these sensors has been subpar in themselves and must be relooked at as a determining factor to derate a vehicle. [EPA-HQ-OAR-2019-0055-1149-A1, p.4]

Organization: *North Central Texas Council of Governments (NCTCOG)*

Also, efforts to identify HD trucks on roadways that are in need of repair and HD trucks that have been tampered with must continue to be supported through state Inspection and Maintenance programs and other initiatives, including roadside inspections. [EPA-HQ-OAR-2019-0055-1254-A2, p.4]

EPA Summary and Response

Summary:

ATA commented that its members have experienced performance issues with sensors and that recent chip shortages are making it challenging to fix the components. ATA described the costs for sensor replacements, including parts, labor, and downtime. ATA also noted its member fleets have shared that sensors “start going bad in as early as two years”. Commenters from Motorcoach Companies also stated that faulty sensors are a problem that can happen with less than 1000 miles on the vehicle.

Evergreen Action, MECA, and NCTCOG commented in support of national inspection and maintenance programs to ensure owners maintain, repair, and do not tamper with emission controls. MECA added that existing sensors and OBD systems can provide real-time reporting of compliance.

Great Rivers Environmental Law Center and DSCC supported additional maintenance requirements to ensure long-term emissions performance.

Response:

With respect to ATA’s comment, as noted in preamble IV.B.1, we are lengthening the warranty periods for heavy-duty engines, which will lengthen the period over which failed or defective emission-related components (which includes any sensors used by emission control systems) would be covered by the manufacturer under warranty.

Manufacturers may schedule maintenance, including replacement, for emission-related components as long as they can demonstrate the maintenance will occur in-use and the specified maintenance interval is not more frequent than the EPA-specified minimum intervals. Manufacturers must demonstrate that the maintenance is needed at their maintenance intervals, and we note that maintenance is most often scheduled in mileage intervals, which may translate to only a few years for some high-mileage vehicle applications. As noted in preamble section IV.B.2, we are generally lengthening minimum maintenance intervals for replacing certain emission-related components to reduce the frequency that manufacturers can specify replacement. If a manufacturer receives approval from EPA to schedule maintenance for sensors, the cost would likely be covered by the owner, unless the manufacturer opts to pay for it as a demonstration that the maintenance will occur in-use. The combination of lengthened warranty and lengthened minimum maintenance intervals in this rule should reduce the frequency of owners paying for components to be replaced.

We regret that sensor replacement has been delayed by the recent chip shortages and that the delay may have contributed to increased downtime. We recognize the importance of keeping heavy-duty engines on the road. We hope that the serviceability provisions we are finalizing in this rule (see section 5 of this document and section IV.B.3 of the preamble) will provide additional information for owners and technicians to efficiently diagnose and repair components to get the engines back on the road.

In terms of inspection and maintenance programs, EPA acknowledges the value that inspection and maintenance programs can play in ensuring the proper function of emission controls in use, but a national inspection and maintenance program is out of scope for this rulemaking. The Clean Air Act mandates that the states operate light-duty vehicle I/M programs in certain areas based on criteria such as air quality attainment status, population, and geographic location. The purpose of these I/M programs is to periodically (either annually or biennially) inspect light-duty vehicles to identify and repair high-emitting vehicles to improve air quality in these identified areas. The Clean Air Act does not require a national I/M program that addresses heavy-duty vehicles, but some states and areas have developed strategies to reduce emissions from heavy-duty vehicles.

We thank Great Rivers Environmental Law Center and DSCC for their support of maintenance requirements.

7 Onboard diagnostics (OBD)

7.1 Adopting CARB’s OBD requirements

Comments by Organizations

Organization: *Allison Transmission, Inc. (Allison)*

EPA has proposed to align federal on-board diagnostic ("OBD") requirements with existing CARB requirements, last updated in 2019.59 At the same time, EPA is proposing additional OBD elements that it believes will be beneficial to federal OBD requirements, even if such requirements are not currently part of the CARB program. As a general matter, Allison supports the harmonization of federal and CARB OBD programs. The benefits of such alignment are obvious: to the extent practicable, aligning federal market for heavy-duty vehicles. [EPA-HQ-OAR-2019-0055-1231-A1, pp.28-29]

59 87 Fed. Reg. at 17,425.

EPA has specifically requested comment how OBD may present a barrier to the adoption of heavy-duty hybrid systems, and any potential opportunities for EPA to address such barriers. As discussed in the preamble of the Phase 2 rule (at XIII.A.(1)) OBD requirements generally apply for hybrid powertrain and components only if the engine manufacturer includes the hybrid system features or parameters as part of the certified configuration for their engines. Allison agrees with this approach and would recommend that it is retained in the final rule. [EPA-HQ-OAR-2019-0055-1231-A1, p.29]

At the same time, Allison recognizes hybrid systems could become included in engine or powertrain certification in order to reach a more aggressive NOx stringency in the future. In that event and for purposes of this rule, Allison would urge EPA to consider that there are various companies involved in the production of hybrid vehicles and not all are similarly situated. Vertically-integrated hybrid manufacturers hold several advantages in terms of regulatory compliance, not only due to their larger size but also in terms of longer-term planning of future vehicle types. In contrast, non-vertically integrated hybrid powertrain suppliers may interact with several OEMs and provide systems for different vehicle types on an intermittent basis. If EPA adopts a more comprehensive approach to OBD requirements for hybrid vehicles, EPA should be aware of these commercial differences and consider provisions similar to those that have been utilized for smaller vehicle manufacturers to allow additional time and flexibility for compliance.[EPA-HQ-OAR-2019-0055-1231-A1, p.29]

Allison also supports EPA flexibilities which have traditionally been part of the OBD program. First, Allison supports retention of the existing deficiency policy in 40 C.F.R. 86.010-18n, as EPA has proposed.60 We believe a deficiency policy is extremely valuable to manufacturers bringing new technologies to market. Allison has utilized CARB's deficiency program for HD hybrid powertrains and has found that this program has allowed Allison to develop new products and higher capability in onboard diagnostics through interactions with regulators during the certification and deficiency resolution process. [EPA-HQ-OAR-2019-0055-1231-A1, p.29]

60 87 Fed. Reg. at 17,528.

Organization: *American Truck Dealers (ATD)*

As EPA knows, when emissions related sensors and on-board diagnostic systems fail to operate properly, false positive or negative readings may result, frustrating the purpose of those sensors and systems (i.e., the proper diagnosis of potential emission failures) and/or aggravating CMV operators and dealership service personnel alike. Therefore, EPA in conjunction with the HDE and CMV OEMs, should carefully revisit existing CMV HDE OBD requirements in the context of appropriately tighter NOx standards to ensure that they will perform properly in-use. ATD also concurs with the OBD and serviceability issues raised by EMA, including harmonization between EPA and CARB OBD mandates. [EPA-HQ-OAR-2019-0055-1321-A1, p. 7]

Organization: *California Air Resources Board (CARB)*

The NPRM requests comment on harmonizing U.S. EPA's HD OBD regulations with future amendments in CARB's HD OBD regulations, specifically CARB's most recent updates proposed in July 2021. CARB staff strongly recommends that U.S. EPA adopt the same amendments once they have been officially adopted. CARB staff believes these amendments are necessary to help ensure the integrity of the HD OBD systems. The NPRM also requests comment on whether and to what extent the U.S. EPA regulations should harmonize with CARB's next expected update to their OBD regulation or whether the proposed language in 1036.110(b) is sufficient to accommodate future divergence in both regulations. CARB staff strongly encourages harmonization of U.S. EPA OBD with CARB OBD requirements and will work toward that direction. [EPA-HQ-OAR-2019-0055-1186-A2, p.66]

The NPRM requests comment to the proposal to keep the numerical values of the NOx and PM OBD thresholds unchanged from the current numerical thresholds to harmonize with CARB's Omnibus rule. [EPA-HQ-OAR-2019-0055-1186-A2, p.67]

First, the threshold in 1036.110(b)(5)(iv) (i.e., 0.60 g/bhp-hr NOx threshold) is not needed, since there are no thresholds of 3.0 times the applicable NOx standard required in 13 CCR section 1971.1 for 2027 and subsequent model engines. [EPA-HQ-OAR-2019-0055-1186-A2, p.67]

Second, while CARB generally agrees that harmonization between the federal and California requirements is appropriate, in this case, CARB staff believes the OBD thresholds can be more stringent than the proposed federal OBD thresholds. While CARB staff did not have enough time to research and propose more stringent thresholds when developing the Omnibus OBD thresholds, staff has since determined that more stringent thresholds are possible for vehicles certified to lower emission standards. [EPA-HQ-OAR-2019-0055-1186-A2, p.67]

Specifically, CARB staff has certified OBD systems (Appendix I) with three or fewer deficiencies for diesel engines that were certified to a NOx FEL of 0.16 grams per brake horsepower-hour (g/bhp-hr), which shows that the engines were able to meet the currently required OBD thresholds (e.g., NOx threshold of 0.32 g/bhp-hr) for all but at most 2 of the emission threshold monitors. [EPA-HQ-OAR-2019-0055-1186-A2, p.67]

Additionally, CARB staff also has certified an OBD system136 without deficiencies for a gasoline engine certified to a NOx FEL of 0.12 g/bhp-hr that was certified to meet all the currently required OBD thresholds for all emission threshold monitors. As such, CARB staff believes that more stringent OBD thresholds than those being proposed by U.S. EPA are feasible, and recommends that U.S. EPA adopt more stringent OBD thresholds based on existing certifications.137 [EPA-HQ-OAR-2019-0055-1186-A2, p.67]

136 https://ww2.arb.ca.gov/sites/default/files/classic/msprog/nvepb/executive_orders/EO%20Files/MDE-HDE/2020/GM/gm_hdoe_a-006-2249-1__date--20200616__year--2020__mfrcarb--gm__ver--orig__uid--7-3860__itr--1__fam--lgmxe06.6001_6d6_0d12-0d01.pdf

137 For these certifications, the HD OBD thresholds can be summarized as follows:
For diesels: 2.0xNMHC FEL, 2.0xNOx FEL or NOx FEL+ 0.2 g/bhp-hr, PM at 0.03 g/bhp-hr or FEL+0.02 g/bhp-hr.
For gasoline: 1.75xNMHC FEL and NOx FEL for catalyst, and 1.5xFEL (NMHC, NOx, PM) for all other monitors

As noted in comment 7.b above, CARB staff recommends that U.S. EPA harmonize the federal HD OBD regulations with future amendments in CARB's HD OBD regulations. However, CARB staff has concerns regarding the exceptions to CARB's 2019 OBD regulations that U.S. EPA is proposing to adopt, specifically the 'testing and reporting requirements in 13 CCR 1971.1(i)(2.3) and (2.4).' First, there is confusion about U.S. EPA's description of this exception. Specifically, U.S. EPA indicated that they have issues with the 'manufacturer self-testing (MST)' requirements in 13 CCR 1971.1(i)(2.3) and (2.4). However, CARB's MST requirements are contained in 13 CCR 1971.1(l)(4) and 13 CCR 1971.5(c), not 1971.1(i)(2.3) and (2.4), which contain the aging requirements for durability demonstration engine (DDE) testing. Based on the description of the requirement at issue, CARB staff believes U.S. EPA is specifically referring to the DDE aging requirements, not the MST requirements. CARB staff recommends U.S. EPA make clear the specific OBD requirements they are addressing. [EPA-HQ-OAR-2019-0055-1186-A2, p.68]

Second, CARB staff is concerned about the language in 1036.11 (b)(6), which states 'the testing and reporting requirements in 13 CCR 1971.1(i)(2.3) and (2.4) do not apply.' Both sections 1971.1(i)(2.3) and (i)(2.4) require manufacturers to use aged engines when performing DDE testing. So, the regulation language U.S. EPA is proposing seems vague and may be interpreted as not requiring aged engines to be used for testing. Further, while section 1971.1(i)(2.3) requires specific data to be collected from high mileage in-use engines to validate the manufacturer's aging process for diesel engines, section 1971.1(i)(2.4) does not contain any specific data collection requirements for gasoline engines. So, CARB staff is confused about why 1971.1(i)(2.4) was included in the exceptions in U.S. EPA's OBD regulation. [EPA-HQ-OAR-2019-0055-1186-A2, p.68]

The NPRM requests comment on whether there are opportunities for further reducing OBD compliance and certification costs of the federal program through increasing the modeling or other calculation-based methods as part of the certification process, which could potentially replace certain testing requirements like those for meeting the test-out criteria or calculating adjustment factors. CARB staff has concerns about such approaches. These systems can be very complex, and the modelling and calculations can be manipulated to generate desired results that may not represent the true performance of the system. If U.S. EPA considers modeling/calculation approaches, CARB staff recommends U.S. EPA adopt regulation language indicating that the manufacturer is still liable for compliance and enforcement if U.S. EPA conducts tests and the test results show non-compliance with the OBD requirements. [EPA-HQ-OAR-2019-0055-1186-A2, p.68-69]

The NPRM requests comment on whether or not OBD may present a barrier to adopted of HD hybrid systems and any potential opportunities for U.S. EPA to address such barriers. From CARB staff's experience certifying HD hybrid OBD systems, CARB staff has been accommodating of the horizontally integrated business structure of the HD industry, and has independently approved the hybrid system OBD systems and engine OBD systems. This dual approval strategy has been working for CARB staff and HD manufacturers for years. Further, CARB staff's experience certifying HD hybrid OBD systems has reinforced the importance of an appropriate evaluation of the engine and hybrid systems together to ensure compliance with all the OBD requirements (e.g., standardization, monitoring frequency) when the engine and hybrid systems are integrated into a vehicle. Hybrid systems inherently change the duty cycles and operating conditions experienced by the engines. Evaluating the systems separately and independently will not necessarily expose the shortcomings that result when the systems are integrated, and the consequence can be poor OBD performance or noncompliance in the field. [EPA-HQ-OAR-2019-0055-1186-A2, p.70]

CARB staff supports the proposal to allow manufacturers to continue to use a CARB OBD approval letter to demonstrate compliance with federal OBD regulations for an equivalent engine family where manufacturers can demonstrate that CARB OBD program has met the intent of the U.S. EPA OBD program, and the process U.S. EPA intends to apply when CARB and U.S. EPA provisions are different (e.g., the additional parameters U.S. EPA is proposing that do not exist in the CARB regulations). However, in the discussion on page 17534, it mentions proposing to migrate the language from 86.010-18(a)(5) to 1036.110(a), but that language from 86.010-18(a)(5) does not appear in the proposed 1036.110(a). Further, while the discussion mentions 1036.110(c)(4), this section does not appear in the proposed language. [EPA-HQ-OAR-2019-0055-1186-A2, p.77]

The NPRM requests comment on U.S. EPA's proposal allowing manufacturers to count two equivalent engine families as one for the purposes of determining the number of engines that are subject to OBD demonstration testing provided the two families are identical in all aspects material to expected emission characteristics, including whether additional restrictions should be included. CARB staff believes it is worth counting both families when determining the number of OBD demonstration engines if the manufacturer has elected to certify separate families despite the equivalency between the families. [EPA-HQ-OAR-2019-0055-1186-A2, p.76]

The NPRM also requests comment on allowing a similar provision for cases where equivalent engine families differ only in terms of inducement strategies. Specifically, the NPRM requests comment on provisions to accommodate equivalent engine families that are identical except for the diagnostic system adjustments needed to meet the different inducement protocols. CARB staff needs to understand why two different engine families would be created by the manufacturer. CARB staff believes a more straightforward approach would be to modify the engine family rules to allow these two engines to be in the same engine family. [EPA-HQ-OAR-2019-0055-1186-A2, p.77]The NPRM requests comment on U.S. EPA retaining the existing deficiency requirements in its entirety. CARB staff has concerns with the U.S. EPA's deficiency provisions. The proposed language in 1036.110(d)(2) states that a deficiency will be approved 'if you show us that full compliance is infeasible or unreasonable considering any relevant factors, such as the technical feasibility of a given monitor, or the lead time and production cycles of vehicle designs and programmed computing upgrade.' CARB staff is unsure if this language allows for typical software bugs or robustness issues to be granted deficiencies. [EPA-HQ-OAR-2019-0055-1186-A2, p.69]

Further, CARB staff has concerns with U.S. EPA's requirement in 1036.110(d)(4) that will not approve deficiencies retroactively. CARB's HD OBD regulation allows manufacturers to certify OBD systems with 'deficiencies' in cases where the manufacturer does not meet a requirement but has demonstrated a good faith effort to fully comply. While manufacturers generally perform some validation work before the start of production to ensure the OBD system is working properly and meeting the requirements of the HD OBD regulation, it is not always possible to find all problems with the OBD systems during this time. Therefore, CARB's HD OBD regulation requires manufacturers to perform thorough validation testing of the OBD system on production engines and vehicles after the start of production (and after OBD system certification). As an incentive, a manufacturer could request that any problem discovered during this testing be evaluated as a deficiency and take effect retroactively to the start of production of the engine. If the other factors necessary to qualify for a deficiency are indeed satisfied, the Executive Officer would amend the certification to retroactively assign the deficiency to the start of production of the affected engines. In contrast, problems discovered later by CARB staff during in-use testing would become noncompliance issues and handled in accordance with OBD-specific enforcement regulations. Additionally, manufacturers have often found problems through means other than this production engine/vehicle evaluation testing that require them to apply running changes and/or field fixes to address the problems. Without the allowance for retroactive deficiencies, CARB staff would most likely have granted a deficiency for this issue on the affected engines in the next model year, which would mean that manufacturers would be given an 'extra' model year to fix the issue given the 2-3 year carryover allowance for deficiencies. Furthermore, if the manufacturer cannot get a retroactive deficiency, then the manufacturer would be subject to the OBD enforcement regulations when the running changes and field fixes are submitted, and CARB staff is notified of the issues. In other cases, if that specific model year was the last model year for the engine, no deficiency would have been applied at all to the engine. CARB staff believes that this would incentivize manufacturers to approach CARB staff later than they should to report problems in the field and applicable running changes/field fixes, which is not appropriate. Therefore, CARB staff recommends U.S. EPA modify the requirements to allow for retroactive deficiencies. [EPA-HQ-OAR-2019-0055-1186-A2, pp. 69-70]

Organization: *Cummins Inc. (Cummins)*

Durability Demonstration Testing (DDE)

For the new aging protocol DDE/demo requirement in the CARB 2019 OBD regs, In §1036.110(b)(2), EPA proposes not to lower NOx and PM thresholds proportionally with the new emissions standards, which Cummins supports. It is not clear whether engine dynamometer-certified engines in vehicles <14k lbs GVWR are subject to OBD requirements in §1036.110(b) or in §1036.110(a)(1), the latter of which references EPA OBD requirements in §86.1806. Since those engines will also be required to meet EPA's new NOx and PM emission standards, EPA should ensure the same OBD threshold relief is applied. If those engines are indeed subject to §1036.110(a)(1), EPA should adopt similar relief provisions which includes freezing the OBD threshold limits and updating all references to the emissions standards contained within §86.1806-05 and §86.1806-17 (13 CCR 1968.2- equivalent). Additionally, where EPA references section 13 CCR 1971.1, EPA should consider also referencing section 1968.2 as appropriate (e.g., see §1036.111(a)(1)). [EPA-HQ-OAR-2019-0055-1325-A1, p. 14]

Cummins proposes EPA to consider adding an option to utilize EPA-approved durability protocol (DF). [EPA-HQ-OAR-2019-0055-1325-A1, p. 27]

For the 3 test-out requirements (2 feedgas and NMHC Catalyst), propose to remove these requirements from CARB 2019 OBD regs entirely as they add no environmental benefit (the requirements add no new diagnostic monitors, just additional unnecessary internal testing done each year to document justification data that doesn't change). [EPA-HQ-OAR-2019-0055-1325-A1, p. 27]

For failed part IRAF, propose to EPA to improve upon existing CARB OBD 2019 language to include good engineering judgement (based on historical data) that could severely reduce the testing costs associated with these requirements. An Improvement here, would allow more carry-over results (for carry-over products), especially for negligible failed-part IRAF numbers/results, which would reduce testing burden. [EPA-HQ-OAR-2019-0055-1325-A1, p. 27]

Production Engine/Vehicle Evaluation Testing (PVE)

For sister families (combined CARB/EPA sister 50-state families), propose to include language that indicates that EPA accepts CARB PVE results for sister EPA engine families. [EPA-HQ-OAR-2019-0055-1325-A1, p. 28]

For PVE1 CARB OBD 2019 requirements, propose modifying the requirements to testing only 3 production vehicles. Experience by engine manufacturers has shown a significantly reduced number of production vehicles (much less than the current requirement of 10) is sufficient to catch any issues. [EPA-HQ-OAR-2019-0055-1325-A1, p. 28]

For PVE2 CARB OBD 2019 requirements, CARB made changes to increase the scope of PVE testing to include testing demo diagnostics for PVE. These new requirements are costly (mainly in relation to acquiring the specific leased HD vehicles), and only proving MIL lamp activation (which is already done during demo with same engine rating). Propose to eliminate these DDE demo PVE2 CARB OBD 2019 updates. [EPA-HQ-OAR-2019-0055-1325-A1, p. 28]

For PVE2 CARB OBD 2019 requirements, propose updating test picks to one PVE2 pick per year. The time it takes to procure vehicles (leasing/purchasing) is a lot more burdensome for engine manufacturers than it is for vehicle manufacturers - we may need to wait for vehicles to be built, or for a built truck to go to a body builder for additional customization work. These are all factors that can impact the timeline and cost associated with this task, despite the fact that diagnostics are usually tuned the same across platforms and persist across multiple model years. [EPA-HQ-OAR-2019-0055-1325-A1, p. 28]

For PVE2 CARB OBD 2019 requirements, propose to include new language that for the PVE2 pick, an allowance to use a different rating within the family if the OBD system is the same. Child ratings are very similar to parent ratings, and if the DDE pick's rating happens to be one of low-volume production, it is burdensome and costly to acquire. [EPA-HQ-OAR-2019-0055-1325-A1, p. 28]

For PVE3 CARB OBD 2019 requirements, Cummins proposes that EPA considers removing the specific new language introduced in Section l (3.2.2) - "The Executive Officer may determine that the manufacturer is required to submit data representative of a subgroup of the monitoring performance group. The Executive Officer shall make this determination based on information indicating that the subgroup of vehicles differs from other vehicles in the monitoring performance group and that a reasonable basis exists to believe that the differences may directly impact the data submitted. " Rationale here is that the manufacturer should be working more upfront with EPA on unique duty cycles, on a specific sub-group in order to define the plan prior to certification. This introduced language has provided a level of uncertainty with how and when CARB has applied compliance upon certain subgroups with manufacturers. [EPA-HQ-OAR-2019-0055-1325-A1, p. 28]

Hybrid OBD

Hybrid vehicle IUMPR increases from 0.1 to 0.3 in MY 24 per CCR 1971.1. We propose that EPA includes IUMPR relief for the hybrid applications and keep IUMPR at 0.1. The higher limit of 0.3 can be a more difficult requirement to meet for hybrid applications and has the potential to push manufacturers to need more investments in new technologies and complex software in order to meet this requirement. That in turn would delay the implementation of hybrid technology and the emissions reduction that would be achieved. [EPA-HQ-OAR-2019-0055-1325-A1, p. 30]

While not mentioned in CARB's 13 CCR 1971.1 and 1971.5 HD OBD regulations, for an engine manufacturer not vertically integrated with the hybrid drivetrain manufacturer, CARB in practice requires a dual Executive Order (EO) OBD certification process, where both the engine manufacturer and the hybrid drive manufacturer independently submit certification documents for OBD approval for a combined dual EO approval. This process proves to be a major hurdle for non-vertically integrated manufacturers from launching into new hybrid solutions. EPA should retain the current conventional engine OBD certification process for obtaining a Certificate of Conformity. [EPA-HQ-OAR-2019-0055-1325-A1, p. 14Deficiency Provision

Cummins is in agreement with EPA on most of their deficiency provision proposal (to retain existing EPA requirements) except with regards to CARB's concept of retroactive deficiency. Retroactive deficiencies are key for issues found during PVE testing. It provides a mechanism for manufacturers that find any issues/concerns during PVE Testing (an event that takes place post-certification) to report to EPA.[EPA-HQ-OAR-2019-0055-1325-A1, p. 29]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

In the Proposed Rule, EPA proposes to update its outdated OBD standards by incorporating by reference CARB's recently amended OBD requirements. EPA also proposes adding flexibility to allow continued technical commonality between engines that are certified to CARB's OBD standards and engines that are not. Daimler Truck supports these proposals. [EPA-HQ-OAR-2019-0055-1168-A1, p.73]

A consistent technical basis for diagnostics and repair across all domestic HDVs is important. Allowing for common approaches reduces development and vehicle costs while providing a consistent repair experience for OEM and third-party repair facilities alike. Daimler Truck supports EPA's proposal to adopt the versions of 13 CCR 1968.2, 1968.5, 1971.1 and 1971.5 that CARB adopted on October 3, 2019. Such an approach ensures that EPA's OBD regulations reflect the most important changes to state-of-the-art diagnostics since the federal regulations were last updated in 2009. [EPA-HQ-OAR-2019-0055-1168-A1, p.73]

Daimler Truck also supports EPA's proposed Section 1036.110(b), whereby the Agency may certify an 'OBD system meeting alternative specifications if you demonstrate that it meets the intent of this section.'99 Such an approach is critical to maintaining long-term technical compatibility between EPA- and CARB-certified OBD systems. Without the flexibility provided by these provisions, the EPA regulation could limit technical advances of diagnostics systems beyond that envisioned by the current regulatory language. EPA rightly identifies communications standards as an example where this has happened in the past; CARB regulations have evolved with technical advances in diagnostics and communications technology, whereas the EPA rules have stayed static. Without the flexibility to certify an OBD system that meets the intent of the regulations, such a divergence in standards could threaten the technical compatibility and consistent repair experience across EPA- and CARB-certified vehicles. [EPA-HQ-OAR-2019-0055-1168-A1, p.74]

99 Id. at 17,665

EPA also requests comments on whether the Agency should adopt anticipated updates to CARB OBD regulations that were proposed in July 2021.100 Daimler Truck does not believe that this is necessary. Rulemaking efforts for the CARB's OBD regulations are nearly continuous in nature. For example, the program was updated in the Omnibus rulemaking package in December 2021 and is currently being updated as part of the passenger car OBD biennial review. It is likely that the HD OBD biennial review process will start soon, and further modify the relevant CARB regulations. Selecting a 'most appropriate' version of the CARB program for EPA to adopt is not necessary, and the version adopted by CARB on October 3, 2019 is sufficient for these purposes. Further, EPA's proposal in Section 1036.110(b)—where the Agency may certify an 'OBD system meeting alternative specifications if you demonstrate that it meets the intent of this section'— obviates any need to expressly incorporate expected future amendments to the CARB program. If CARB adopts newer diagnostic regulations, EPA has the flexibility to certify systems compliant with those newer regulations, as necessary and appropriate. Such flexibility can be leveraged to enable J1979-2, for example. [EPA-HQ-OAR-2019-0055-1168-A1, p.74]

> 100 See id. at 17,526

EPA also proposes a new Section 1036.110(b)(5) to set specific OBD emissions thresholds for monitoring, which are equivalent to their current absolute values under the existing CARB regulations. Daimler Truck supports this approach but does not believe that tighter OBD monitoring thresholds are technically feasible, as there are no predicted improvements in sensor technology that would enable thresholds tighter than the current requirements. [EPA-HQ-OAR-2019-0055-1168-A1, p.74]

EPA appears to have made an error in the proposed new Section 1036.110(b)(6). [EPA-HQ-OAR-2019-0055-1168-A1, p.74]

In the Proposed Rule, EPA expresses an intent to exempt manufacturers from the expensive in-use OBD system testing requirements under CARB's Manufacturer Self-Testing program based upon the Agency's continued concern 'that the cost of this testing may be significant and is not warranted for the federal program.'101 Daimler Truck agrees with this assessment and supports the intended exemption. [EPA-HQ-OAR-2019-0055-1168-A1, p.74]

> 101 See id. at 17,527.

However, EPA appears to have made an error in codifying this exemption in Section 1036.110(b)(6). EPA's proposed regulatory language states that 'the testing and reporting requirements in 13 CCR 1971.1(i)(2.3) and (2.4) do not apply,' whereas we believe the intended references are to 13 CCR 1971.1<u>(l)(3) and (l)(4)</u>. [EPA-HQ-OAR-2019-0055-1168-A1, pp.74-75]

> 13 CCR 1971.1 subsection (i) contains CARB's regulations on certification demonstration, and subsections (i)(2.3) and (2.4) specifically describe the 'aging and data collection of diesel test engines' and 'aging of gasoline engines' for use during the initial certification testing. [EPA-HQ-OAR-2019-0055-1168-A1, p.75]
>
> 13 CCR 1971.1 subsections <u>(l)(3) and (l)(4)</u> describe the in-use data collection programs in the CARB regulation, which more closely aligns with the requirements outlined in the preamble section. [EPA-HQ-OAR-2019-0055-1168-A1, p.75] Daimler Truck believes EPA should exempt manufacturers from the testing 13 CCR 1971.1(l) (3) and (4)—and additionally evaluate whether the aging provisions of (i)(2.3) and (2.4) are necessary and add sufficient value to justify their expense. [EPA-HQ-OAR-2019-0055-1168-A1, p.75]

Daimler Truck supports EPA’s proposed new Section 1036.110(d) and believes it is appropriate for EPA to review and approve deficiencies separately from CARB. However, EPA adds additional stringencies that unnecessarily deviate from CARB’s rules and add significant challenges for manufacturers. [EPA-HQ-OAR-2019-0055-1168-A1, p.75]

Specifically, Section 1036.110(d)(3) is unnecessarily limited. EPA proposes only to approve deficiencies for a maximum of two years, unless a manufacturer demonstrates the need for additional lead time to make substantial changes to engine hardware.102 This stands in contrast to CARB’s rules, which recognize that complex OBD function definition, software and calibration development, validation, and release can take more than two years to implement. Specifically, 13 CCR 1971.1(k)(4) allows deficiencies to be carried over for a maximum of two years – for a total of three years including the initial year of the deficiency. Accordingly, Daimler Truck requests that EPA change Section 1036.110(d)(3) to read ‘We will approve a deficiency for more than three years only if you further demonstrate that you need the additional lead time to make substantial changes to engine hardware.’ Daimler Truck believes that EPA rightly recognizes that substantial changes to engine hardware could take more time to remediate, and otherwise supports the rest of this paragraph. [EPA-HQ-OAR-2019-0055-1168-A1, p.75]

102 See id. at 17,666.

EPA’s proposed new Section 1036.110(d)(4), which would prohibit retroactive approval of deficiencies, is also too restrictive.103 Due to the wide variety of applications and duty cycles in the heavy-duty sector, it is impossible for manufacturers to be certain that all diagnostics will work without fail in all vehicles. A manufacturer may not discover until wide production exposure that a monitor has issues with certain duty cycles, and does not work as expected. For example, it is common for manufacturers to detect issues with In-Use Monitoring Performance Ratio after production. These issues may arise due to unforeseen production variability, unique vehicle applications (over which the engine manufacturer may have little control), or from unique duty cycles. It is important for EPA to leave manufacturers with a path to correct these unforeseen issues, including in circumstances where a retroactive deficiency might be necessary. Otherwise, EPA could force a situation where operators are confronted by false indications of failure, leading to increased expenses in unneeded repairs, unnecessary downtime, and frustration. Similarly, such false failures could undermine operator’s faith in the diagnostic system, leading to actual failures going unrepaired. [EPA-HQ-OAR-2019-0055-1168-A1, pp.75-76]

103 See id.

Organization: *General Motors LLC (GM)*

EPA proposes to incorporate by reference regulations and test procedures in many cases that are unclear, duplicative, or are not yet final. [EPA-HQ-OAR-2019-0055-1246-A1, p.5]

In "§ 1036.110 Diagnostic controls", EPA proposes that an "Engine must comply with the 2019 heavy-duty OBD requirements adopted for California…", but CARB considered many OBD requirements in 2019 and did not finalize a proposal until 2021. EPA's proposed regulatory language is unclear. In this specific example, GM asks EPA to make clear what regulation the Agency incorporates by reference. [EPA-HQ-OAR-2019-0055-1246-A1, p.6]

Incorporating standards by reference that are not finalized, unclear, or duplicative adds uncertainty to what is expected in a finalized regulation, and often increases the burden to industry to comply with standards. GM encourages EPA to not incorporate by reference regulations and test procedures that are unclear, potentially duplicative, or not finalized. [EPA-HQ-OAR-2019-0055-1246-A1, p.6]

Organization: *International Council on Clean Transportation (ICCT)*

The ICCT fully understands the importance of OBD systems as one of the most cost-effective ways to maintain in-use emissions within certification and OBD threshold levels. Ensuring that HDV operators and regulators have access to harmonized data would reduce the cost of maintaining and ensuring low emission levels. [EPA-HQ-OAR-2019-0055-1211-A1, p. 24]

The ICCT supports EPA's decision to harmonize with CARB's OBD provisions for MY 2022 to 2024 and with the intention to expand those signals as listed in the NPRM (FR page 17532). [EPA-HQ-OAR-2019-0055-1211-A1, p. 24]

Organization: *National Association of Clean Air Agencies (NACAA)*

EPA's existing onboard diagnostics (OBD) requirements, adopted in 2009, allow manufacturers to demonstrate how the OBD system they designed to comply with California's OBD requirements also complies with the intent of EPA's OBD requirements. (EPA maintains separate OBD regulations but manufacturers currently seek approval from California for OBD systems in engine families applying for 50-state certification and then use that approval to demonstrate compliance with EPA's requirements.) In this rulemaking, EPA proposes to update its OBD regulations by incorporating by reference the California Air Resources Board's (CARB) 2019 OBD regulations "as the starting point for our updated OBD regulations" and then "exclude or revise certain CARB provisions that we believe are not appropriate for a federal program" and "include additional elements to improve the usefulness of OBD systems for users." [EPA-HQ-OAR-2019-0055-1232-A1, pp. 15 - 16]

EPA should update its OBD requirements but should incorporate by reference CARB's current program without omission so there is alignment between the federal and California programs. [EPA-HQ-OAR-2019-0055-1232-A1, p. 16]

Organization: *Northeast States for Coordinated Air Use Management (NESCAUM)*

Should EPA instead promulgate Option 1, we urge the Agency to make the following changes to the proposed standards: EPA's existing onboard diagnostics (OBD) requirements, adopted in 2009, allow manufacturers to demonstrate how the OBD system they designed to comply with California's OBD requirements also complies with the intent of EPA's OBD requirements. (EPA maintains separate OBD regulations but manufacturers currently seek approval from California for OBD systems in engine families applying for 50-state certification and then use that approval to demonstrate compliance with EPA's requirements.) In this rulemaking, EPA proposes to update its OBD regulations by incorporating by reference the California Air Resources Board's (CARB) 2019 OBD regulations "as the starting point for our updated OBD regulations" and then "exclude or revise certain CARB provisions that we believe are not appropriate for a federal program" and "include additional elements to improve the usefulness of OBD systems for users." NESCAUM urges EPA to update its OBD requirements and incorporate by reference CARB's current program without omission so there is alignment between the federal and California programs. [EPA-HQ-OAR-2019-0055-1249-A1, p. 15]

Organization: *Roush CleanTech (Roush)*

EPA mentioned manufacturers concerns relating to manufacturer self-testing in 13 CCR 1971.1(i)(2.3) and 1971.1(i)(2.4) (p. 381 and others), and these sections are listed as excluded in the proposed 1036.110(b)(6). We believe this is an error, as 1971.1(i)(2.3) and (2.4) do not relate to manufacturer self-testing; those sections refer to the requirements of demonstration engines which we don't believe EPA intended to exclude. We believe the intended exclusion is to exclude 13 CCR 1971.5(c). Roush fully supports exclusion of the MST requirements in 1971.5(c) due to the high costs and logistical difficulties, especially given that any EPA-only OBD families would likely be specialty or low-volume applications. [EPA-HQ-OAR-2019-0055-1276-A1, p.6]

OEMs (including Roush) often utilize CARB's deficiency policy to avoid the profound financial implication of disruptions to the vehicle production plan, and to implement new emissions control technologies which may require some regulatory flexibility. This has been vital in implementation of new technologies; Roush has specifically used deficiencies as part of the implementation of new monitoring requirements associated with LPG and CNG, and for heavy-duty gasoline ORVR system. As required by ARB, these issues were all fully reviewed and resolved in a timely fashion. [EPA-HQ-OAR-2019-0055-1276-A1, p.6]

- We would fully expect manufacturers to continue to require the flexibility of OBD deficiencies in order to implement the technologies proposed in this NPRM; eliminating or restricting this existing flexibility would almost certainly jeopardize the feasibility assessments included here.
- Roush believes that the current EPA regulations for pre-production deficiencies are sufficient to provide OEM flexibility as is consistent with 13 CCR 1971.1(k). However, Roush is concerned that without the provisions of a retroactive deficiency as declared in 40 CFR 86.010 18(n)(3), manufacturers could endure excessive costs relating to a mandatory recall, or significant technological investments to generate remedies outside of the normal product development cycle plan. Roush believes that the EPA could incorporate the CARB provision for retroactive deficiencies up to six months after entry to commerce and thereby provide much greater OEM flexibility with no concern that this would degrade the emissions benefit of the program (since retroactive deficiencies are fully incorporated in the ARB rule under which nearly all engines/vehicles will be certified). [EPA-HQ-OAR-2019-0055-1276-A1, p.6]

Organization: *Truck and Engine Manufacturers Association (EMA)*

EMA supports EPA's proposal to harmonize (as much as possible) to CARB's 2019 OBD regulations, and further supports the overall framework to modernize the OBD requirements in EPA's regulations. Harmonization is key to the success of OBD overall, as it provides the certainty and clarity that manufacturers need to develop and implement more robust vehicle OBD systems. [EPA-HQ-OAR-2019-0055-1203-A1, p. 95]

That said, EMA agrees that there are some CARB provisions that are not well-suited to a federal OBD program. Accordingly, we support EPA's proposals for MST testing and deficiencies, with some exceptions. More specifically, while we support the majority of EPA's proposed deficiency provisions, we believe that EPA should more closely align with CARB with respect to certain of those provisions. In that regard, EPA's deficiency timeline is shorter than that provided under the CARB regulations, and would not allow for retroactive deficiencies. Retroactive deficiencies are key for resolving issues found during Production Vehicle Evaluation (PVE) testing, which may not be immediately apparent. Deficiency fines under CARB's OBD program are sufficiently punitive to facilitate compliance, yet the allowance for retroactive deficiencies provides additional necessary flexibility. [EPA-HQ-OAR-2019-0055-1203-A1, p. 95]

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. §1036.110(d)(3) and (d)(4): EMA requests that EPA provide clarity on the allowance for deficiency carryover and retroactive deficiencies (namely for small errors, as manufacturers do utilize retroactive deficiencies routinely and frequently). As noted above, we strongly recommend that EPA harmonize these specific deficiency provisions with those of CARB. [EPA-HQ-OAR-2019-0055-1203-A1, p. 102]

Additionally, EMA has concerns with the proposed incorporation by reference provisions of 40 CFR 1036.810(d), as discussed further below. There are multiple versions of CARB's 2019 OBD regulations. Thus, we request that EPA provide additional clarity as to which specific version is being referenced. EMA also is concerned with the proposal that manufacturers provide additional information that is not required in the California 13 CCR 1971.1 regulations, as this will lead to a lack of both harmonization and standardization across the two regulatory regimes. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 95 - 96]

As noted above, EMA supports EPA's proposal to harmonize with CARB's determination not to lower the OBD NOx and PM threshold levels at this time. We agree that more time is needed, as CARB has noted, to fully evaluate the capability of HD OBD monitors to accommodate lower NOx and PM thresholds, and to ensure adequate time for the development and prove-out of robust systems for both EPA and CARB's OBD programs. [EPA-HQ-OAR-2019-0055-1203-A1, p. 96]

Consistent with CARB's regulatory updates to 13 CCR 1968.2 with respect to the Low- NOx Omnibus rulemaking regarding engines under 14,000 lbs., EMA recommends that EPA carry forward the standard-relief provisions (e.g., freezing the OBD threshold limits, updating all references to the emissions standard contained within 40 CFR 86.1806-05 and 86.1806-17 (13 CCR 1968.2-equivalent), etc.). [EPA-HQ-OAR-2019-0055-1203-A1, p. 96]

We support the proposal to allow manufacturers to continue to use a CARB OBD approval letter to demonstrate compliance with federal OBD regulations. [EPA-HQ-OAR-2019-0055-1203-A1, p. 97]

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. Additionally, we request that EPA expressly state which 13 CCR 1971.1 provisions are being referenced in EPA's regulatory provisions. As noted below, there are incorrect references to CARB provisions, which makes it difficult in some instances to review the proposed regulations, since it is unclear which CARB provisions are actually being referenced. That lack of clarity will pose challenges for regulated entities during any implementation of the proposed program. [EPA-HQ-OAR-2019-0055-1203-A1, p. 99]

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. §86.010–18(a): "(a)… Note that 40 CFR 1036.150(u) allows for an alternative communication protocol before model year 2027…" This paragraph appears to have an incorrect reference; in the proposed regulatory text, the OBD communication protocol-related interim provisions are specified in paragraph (v). [EPA-HQ-OAR-2019-0055-1203-A1, p. 99]

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. §1036.110(b)(6): "(6) The testing and reporting requirements in 13 CCR 1971.1(i)(2.3) and (2.4) do not apply." Subsections (i)(2.3) and (2.4) cover aging requirements for diesel and gasoline engines; we believe EPA intended this to be a reference to "the Production Engine/Vehicle Evaluation testing and reporting requirements of 13 CCR 1971.1(l)(2.3) and (2.4)…". [EPA-HQ-OAR-2019-0055-1203-A1, p. 99]

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. §1036.110(b)(9) and (b)(10): "(9) Design compression-ignition engines to make the following additional parameters available for reading with a generic scan tool, if so equipped:"; "(10) Design spark-ignition engines to make the following additional parameters available for reading with a generic scan tool, if applicable:" EMA presumes that "if so equipped" and "if applicable" in the aforementioned paragraphs do not compel manufacturers to add the components implied by the listed parameters as requirements. Not all of the terms listed in proposed paragraphs (b)(9) and (b)(10) can be precisely matched to existing content in SAE J1939DA. For example, the broad statement in paragraph (b)(9)(vi) "any additional parameters" cannot be assessed independently, and the proposed air/fuel enrichment parameters requested in paragraph (b)(10)(i) do not appear to be defined in SAE J1939DA. Further, some of the proposed provisions, such as the requirements of paragraph (b)(9)(i), may not reside in the OBD boundary for engine manufacturers. We request that EPA consult with the SAE Truck and Bus Control and Communication Network Committee and the Vehicle E/E System Diagnostic Standards Committee to ensure that each of the requested items listed in the proposed regulations has been defined. [EPA-HQ-OAR-2019-0055-1203-A1, p. 100]

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. §1036.110(b)(11)(i): EPA is proposing that manufacturers provide additional information that is not required in 13 CCR 1971.1, thus leading to a lack of harmonization and standardization. [EPA-HQ-OAR-2019-0055-1203-A1, p. 100]

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. §1036.110(b)(11)(ii): This paragraph lacks clarity and seems to contain incorrect references to the California regulations: 13 CCR 1971.1(i)(2.3) and (2.4): Manufacturers can send the information at the time of certification; however, it is unclear if EPA intended to reference the OBD Durability Demonstration Engine testing results. This is unclear because 13 CCR 1971.1(i)(2.3) and (2.4) cover vehicle selection, and specifically aging. We recommend that EPA consider instead referencing "the Monitoring System Demonstration Requirements for Certification provisions of 13 CCR 1971.1 (i)". [EPA-HQ-OAR-2019-0055-1203-A1, p. 100]

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. §1036.110(b)(11)(ii): This paragraph lacks clarity and seems to contain incorrect references to the California regulations: 13 CCR 1971.1(l): This provision covers post-production engine evaluation testing, which cannot be provided at the time of certification. Such information, however, can be provided per the deadlines set out in 13 CCR 1971.1. [EPA-HQ-OAR-2019-0055-1203-A1, p. 100]

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. §1036.110(b)(11)(ii): This paragraph lacks clarity and seems to contain incorrect references to the California regulations: 13 CCR 1971.5(b): This provision is specifically for "Testing Procedures for ARBConducted Testing" – did EPA intend to reference 13 CCR 1971.5(c)? If so, we recommend that EPA specifically state "the Manufacturer Self-Test provisions of 13 CCR 1971.5(c)" for clarity. [EPA-HQ-OAR-2019-0055-1203-A1, p. 100]

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. 1036.810(d)(1)-(2): As noted, the proposed provisions to incorporate CARB's "2019" regulations by reference are confusing, as they lack clarity of which specific version is being incorporated. We recommend that EPA instead specific the regulations by their specific date of finalization, to ensure that there is not confusion about which version of the regulations EPA is incorporating. [EPA-HQ-OAR-2019-0055-1203-A1, p. 104]

EMA recommends that EPA retain its current conventional engine OBD certification process for procuring Certificates of Conformity. While not specified in the 13 CCR 1971.1 regulation, for engine manufacturers that are not vertically integrated with the hybrid drivetrain, CARB allows for a dual Executive Order OBD certification process, where both the engine manufacturer and the hybrid drive manufacturer independently submit certification documents for OBD approval for a combined dual E.O. approval. However, this process can be a significant burden for non-vertically integrated manufacturers launching new hybrid solutions. We also recommend that EPA include in-use monitor performance ratio (IUMPR) relief for hybrid applications to keep the IUMPR at 0.1, instead of the higher 0.3 limit. [EPA-HQ-OAR-2019-0055-1203-A1, p. 98]

EPA Summary and Response

General Comments

EPA received comments from Allison, ATA, EMA, DTNA, ICCT, and CARB supportive of the proposal for EPA to harmonize with CARB's most recent OBD requirements. DTNA also supported EPA's proposal to adopt language similar to that currently in 40 CFR 86.018-10 into 40 CFR 1036.110 allowing manufacturers to demonstrate they meet the intent of our requirements by meeting what could be a slightly different set of requirements from CARB. NACAA commented that EPA should adopt CARB's requirements without omission to ensure complete harmonization. EMA and GM noted that EPA must be clear in how they incorporate by reference these CARB regulations in 1036.810(d), as there are multiple versions of CARB's 2019 regs. EMA commented that they are not supportive of proposed requirements to provide additional information that differs from CARB. CARB also commented that EPA should adopt the future update to their OBD requirements to ensure we include important changes. DTNA commented that including more recent CARB regulations than the 2019 regulations was not necessary because CARB's OBD program is updated continuously and the 2019 version combined with EPA's "intent" language is enough to accommodate future divergences.

- EPA agrees that updating our OBD requirements is important, see preamble Section IV for further details on the final provisions and the rationale to support those requirements. EPA does not agree with NACAA that all of CARB's requirements are appropriate for a Federal program, as further explained in preamble Section IV. We have made adjustments from proposal in our final regulations and worked with CARB to ensure we are incorporating the appropriate version of CARB's 2019 regulations in the final 40 CFR 1036.810(d). EPA agrees with DTNA that our OBD regulations are not updated as frequently as the CARB regulations and we believe that it is important to include the final regulatory language to allow manufacturers to be able to demonstrate compliance with the intent of our OBD requirements, even though they may be meeting different CARB requirements (e.g., that may be more stringent), to ensure we can accommodate such changes in CARB OBD requirements as appropriate without delay. CARB's pending OBD update was not finalized in time for us to harmonize with it in this rule. We intend to monitor their rulemaking and may consider if we should take further action to harmonize in a future rulemaking.

  EPA recognizes EMA's comments that our information requirements are different than CARB's in certain cases. It is important to note, however, that this is because EPA is allowing manufacturers flexibility to use good engineering judgement to show that they meet the intent of our requirements by meeting a potentially different set of requirements from CARB. It would not be appropriate for manufacturers to use this flexibility without describing how their OBD system is compliant with the intent of our requirements.

Deficiencies

EPA received comments from Allison, EMA, Cummins, DTNA, Roush, supportive of our retention of existing deficiency requirements, but not supportive of omitting an allowance for retroactive deficiencies. DTNA commented they need retroactive deficiencies due to the wide variety of engine applications and duty cycles in the heavy-duty industry that makes it impossible to be certain that all diagnostics will work without fail in all vehicles. EMA commented retroactive deficiencies are important for resolving issues that cannot be discovered until testing that can only occur after the start of production. CARB expressed concern with EPA's lack of a retroactive deficiency policy stating it provides time for manufacturers to continue validation work after start of production ("SOP"), allows CARB to amend the certification documents to assign a deficiency as if it occurred prior to SOP, and without retroactive deficiencies, CARB would most likely have to wait until the next model year to apply deficiency.

EMA and DTNA commented that EPA's deficiency timeline is shorter than CARB's where EPA proposed a deficiency for a maximum of 2 years unless a manufacturer demonstrates the need for additional lead time to make substantial changes to engine hardware. They noted this is not consistent with CARB's requirements in 1971.1(k)(4) which allows deficiencies to be carried over for a maximum of 2 years for a total of 3 years.

CARB expressed concerned that EPA's proposed language in 1036.110(d)(2) will not allow for typical software bugs or robustness issues that may be granted deficiencies.

CARB also commented that if EPA modifies test out requirements, that we should finalize language saying OEMs are still liable for compliance and enforcement if allowed.

- EPA agrees that the adoption of our existing deficiency program is important. See preamble Section IV.C.1.i for discussion on the final provisions we are finalizing for deficiencies and our response to many of these comments.

  As discussed in preamble Section IV, EPA reviewed our proposed language regarding the proposed deficiency timeframe and agrees that it is not consistent with CARB's and we have adjusted the language from proposal in final 40 CFR 1036.110(d)(3) to reflect the allowance of three years to make substantial engine hardware changes. Further, in response to CARB's concern with the language used to describe acceptable deficiencies, EPA reviewed, but did not make any adjustments to our proposed language in 40 CFR 1036.110(c)(2) which states "We will approve a deficiency only if you show us that full compliance is infeasible or unreasonable considering any relevant factors, such as the technical feasibility of a given monitor, or the lead time and production cycles of vehicle designs and programmed computing upgrades." We believe this language will accommodate minor issues like software problems that may be infeasible or unreasonable to address.

  See preamble Section IV regarding test-out requirements. Existing approaches to compliance and enforcement continue to apply for these provisions.

Thresholds

ATA expressed concerns about OBD and the final lower standards which could result in false readings and OBD faults if OBD thresholds are too quickly and aggressively changed. ATA noted this would frustrate operators and repair facilities. CARB commented that since they finalized their Omnibus rule they have seen manufacturers meet lower thresholds, two CI engines with deficiencies and one SI engine with no deficiencies. Therefore, CARB commented that this indicated the thresholds can be lowered. DTNA supports EPA's proposal to not change thresholds because they do not believe tighter OBD monitoring thresholds are technologically feasible as there is no predicted improvement in sensor technology that can enable lower thresholds. EMA supported EPA's threshold proposal and commented that sufficient time is needed for development and prove-out of robust systems. Cummins and EMA commented that engines certified on an engine dynamometer installed in vehicles less than 14,000 lbs GVWR will be required to meet new lower NOx and PM standards and need the same threshold relief, and that it is not clear if EPA's proposal applies also to these vehicles.

- EPA appreciates the different perspectives on potential threshold changes. See preamble Section IV.C.1.ii for further discussion on the threshold requirements EPA finalized and our response to these comments.

Hybrid OBD

Allison commented that current OBD requirements generally apply for hybrid powertrains and components only if the engine manufacturer includes the hybrid system features or parameters as part of certified configuration. Allison agrees with this approach and wants it retained. CARB commented that their path to certifying hybrid OBD systems is appropriate. Cummins commented that CARB's program is not appropriate for engine manufacturers that are not vertically integrated with a hybrid drivetrain manufacturer and can be a major hurdle for non-vertically integrated OEMs launching new hybrids. Cummins said that EPA should retain the current conventional engine OBD cert process for obtaining a certificate of conformity. Further, Cummins commented EPA should increase the in-use monitoring performance ratio for hybrids from 0.1 to 0.3 in MY2024 to avoid a delay in hybrid production.

- EPA appreciates the comments on changes we can consider to improve outcomes of OBD certification for hybrid vehicles. We requested comment on this topic but are not taking any final action at this time regarding OBD certification changes specific to hybrid vehicles. We may continue to evaluate whether to consider changes in a future rulemaking.

Manufacturer Self Test

EPA received a number of comments on the regulations we cited in our proposal to exclude manufacturer self test requirements from our OBD program. CARB, DTNA, Roush, and EMA all commented on the need for EPA to clarify the cite in the proposed regulatory text for the CARB requirements for manufacturer self test requirements, stating that the cite in the proposal was incorrect.

EMA commented on the need for greater clarification on several aspects of the proposed regulation, including defining requirements in 1036.110(b)(9) and (10) and ensuring that all requirements in those section reside in the OBD boundary, and clearly stating which version of CARBs 2019 OBD requirements we are IBRing. EMA also pointed out an incorrect cite for the interim OBD communication protocol.

CARB commented that EPA did not need to include the 0.60 g/bhp-hr threshold in 1036.110(b)(5)(iv) since there are no threshold requirements of 3.0 times the applicable NOx standard in 13 CCR 1971.1 for 2027 and subsequent model engines.

Cummins provided multiple proposals in their comments including adding an option to use EPA-approved durability protocol for deterioration factor testing, remove the 3 test-out requirements (2 feedgas one NMHC catalyst), and to include language to use good engineering judgement based on historical data to reduce test burden for failed IRAF parts. Cummins also proposed

changes for PVE testing including using CARB PVE results for sister EPA engine families, reduce testing for PVE1 to 3 production vehicles as data has shown that fewer than 10 vehicles is sufficient to catch any issues, reduce test picks for PVE2 tesing to one vehicle per year, to allow PVE2 testing on an engine with a different rating within the same engine family if the OBD system is the same, and to remove the language "The Executive Officer may determine that the manufacturer is required to submit data representative of a subgroup of the monitoring performance group. The Executive Officer shall make this determination based on information indicating that the subgroup of vehicles differs from other vehicles in the monitoring performance group and that a reasonable basis exists to believe that the differences may directly impact the data submitted" from the PVE3 requirements.
CARB commented that EPA should count two equivalent OBD families separately to determine the number of engines for demonstration testing.
CARB commented that EPA should modify their engine family rules so that two engine families that are identical in all respects except for OBD adjustments required to accommodate differing inducement strategies to be considered one engine family.
CARB commented that EPA did not include language from 40 CFR 86.010-18(a)(5) in 40 CFR 1036.110(a) as was proposed and that 40 CFR 1036.110(c)(4) did not appear in the proposed language.

- We appreciate the comments correcting our cite of CARB's manufacturer self-testing and have updated to the correct cite in the final rule, see Preamble IV.C.1 for additional details. We have updated the requirements for additional OBD parameters to be more specific and ensured that they are appropriate, as detailed in preamble Section IV.

  We have included additional details about the version of CARB's 2019 OBD requirements, see Preamble IV.C.1, to more clearly specify the version of 2019 CARB OBD requirements that we are incorporating by reference.
  See preamble Section IV for further details on the final thresholds and EPA's response to those comments.

  We did not propose and are not finalizing any of Cummins' proposals for DF tesing, the 3 test-out requirement, IRAF parts, or PVE testing. As explained in preamble Section IV, our final provisions aim to maintain as much commonality with CARBs regulations as is appropriate for the Federal program. We note that we believe that the majority of engines applying for EPA OBD certification will have already received a CARB certification and adopting Cummins' proposals would likely not significantly reduce testing burden.

  See preamble Section IV.C.1.v for details on the final provisions regarding counting engine families for OBD demonstration requirements and our response to those comments.

  As explained in preamble Section IV, we are finalizing the migration of language from 40 CFR 86.010-18(a)(5) to 40 CFR 1036.110(b), as we proposed for the final rule. We also removed the proposed reference to 40 CFR 1036.110(c)(4), as the regulations have been updated from those proposed for the final rule and this reference is no longer valid in the final provisions.

7.2 Health monitors

<u>Comments by Organizations</u>

Organization: *California Air Resources Board (CARB)*

The NPRM requests comment on U.S. EPA's proposed health monitors for the SCR, DPF, and EGR systems for CI engines, including the benefits of the specific methods being proposed to inform a vehicle operator of the general health of these systems. Further, the NPRM requests comments on the U.S. EPA's proposal for a broad requirement that leaves identification and implementation of the specific methods up to each manufacturer, the alternative approach which would require a specific method to be used by all manufacturers, and any other approach that may be more beneficial or less costly but still provide benefits to the owner and result in environmental benefits from better performing emission control systems. CARB staff generally supports U.S. EPA's concept for proposed health monitors. Concepts to provide system health information could be taken from existing diagnostics and test results and made into more general output for a larger audience. Further discussion with manufacturers is needed to decide on the best approach to support health results and whether the output should be standardized. [EPA-HQ-OAR-2019-0055-1186-A2, p.71]

CARB staff has concerns about how the health monitors may affect the warranty program. CARB staff understands the benefits of having such a requirement and CARB staff has met with one manufacturer to discuss a similar concept using on-board and off-board analytics with driver notification to trigger maintenance or repair. However, in the context of in-use compliance and warranty reporting, CARB staff is still unclear how the manufacturer would identify a systematic component defect that would need corrective action. Also, how would these replaced components be reported on defect or emission warranty information reporting (EWIR)? CARB staff recommends that all components replaced due to the health monitors be reported on defect and EWIR reports, and the manufacturer do the same root cause analysis on failed parts. This way, systemic defects will be promptly addressed through corrective action. [EPA-HQ-OAR-2019-0055-1186-A2, p.71]

Additionally, the NPRM requests comments on whether additional monitors could be developed using existing OBD requirements which can further help prevent downtime, such as additional upstream health indicators (e.g., preventing excessive internal oil leaks) to proactively prevent damage to expensive aftertreatment components. Manufacturers today use diagnostic and sensor input data for purposes of engine protection. These are designed largely at the discretion of the manufacturer and not a CARB requirement, though they are required to disclose such strategies and get them approved by CARB staff. If such strategies were to be made mandatory, CARB staff would need clear regulation citations to support such a proposed rule. [EPA-HQ-OAR-2019-0055-1186-A2, p.71]

CARB staff has concerns regarding the proposed language in 1036.110(c)(3)(v). The language states that the proposed data for the DPF and SCR health monitors are required to be provided 'based on a default method of updating or resetting collected data.' For example, the current data may include information from the Active 100-Hour Array or Stored 100-Hour Array. The system must allow the operator to perform a manual reset to start collecting new data on demand.' CARB staff believes the language 'based on a default method of updating or resetting collected data' is not clear enough about what qualifies as an acceptable default method. CARB staff recommends that the language be modified to clarify this or to provide examples of acceptable default methods of updating and resetting collected data (e.g., 'based on a default method of updating (e.g., automatically replacing an older set of data with a newer one every 100 engine hours) or resetting collected data (e.g., setting collected data values back to zero via a code clear command).'). [EPA-HQ-OAR-2019-0055-1186-A2, pp.71-72]

The NPRM requests comment on the use of CARB's lifetime counter of DPF regens to meet the DPF health monitor proposal. CARB staff believes the DPF PID data could be an indicator of DPF health. [EPA-HQ-OAR-2019-0055-1186-A2, p.72]

The NPRM also requests comment on if the proposed regen frequency indicator is important enough to require it to be communicated when the frequency of regens reaches a particular level that may indicate the need for inspection and possibly repair, what this level would be, and what such warning system should look like. Considering the cost of aftertreatment, CARB staff supports providing an indication of regeneration frequency that could be used alert operators of potential problems and initiate inspection, maintenance and repairs as needed. However, CARB staff does not support a second light and warning notification system at this time, since this would require OBD resource evaluation and program planning to make sure the proper team is in place to lead such work. [EPA-HQ-OAR-2019-0055-1186-A2, p.72]

Further, the NPRM requests comment on whether the DPF health monitor should provide information like passive regens that occur during certain vehicle operation (e.g., OBD REAL Bin 14) on demand and if it should notify users of potential concerns. It is assumed the passive regens would add to deterioration of the DPF, but CARB staff's understanding is that it is the active regens that are primarily responsible for DPF and aftertreatment aging. Therefore, CARB staff does not see a specific need to track passive regen activity. [EPA-HQ-OAR-2019-0055-1186-A2, p.72]

Lastly, CARB staff supports the point in the NPRM that 'providing operators with notification of when active regens have been disabled by the system (even temporarily) as well as the reason it was disabled would provide benefits to operators and repair technicians. Manufacturers generally implement severe derates when DPF system faults occur that prevent active regens from occurring. Providing owners with information on the cause of a DPF-related derate would reduce frustration and may reduce downtime by allowing repairs to be made more quickly, increasing in-use emission system performance. [EPA-HQ-OAR-2019-0055-1186-A2, pp.72-73]

The NPRM requests comment on if the SCR health monitor should provide information about the DEF dosing being disabled and the reason (if accompanied by a derate) on demand and if it should also notify users of potential concerns. While CARB staff expects the malfunction indicator light (MIL) to be illuminated and an OBD fault code stored in such cases, CARB staff supports providing information to the operator about the disablement and the reason. [EPA-HQ-OAR-2019-0055-1186-A2, p.73]

The NPRM also requests comment on alternative methods to develop a health monitor for the SCR system, such as one that would use DEF dosing trim values (i.e., DEF dosing rates at particular operating points like within NTE operating zones or REAL bins) and compare the dosing rate occurring in real-time to what the dosing rate was when the vehicle was new. If U.S. EPA is trying to get an overall indication of system health, CARB staff believes a more direct comparison would be to compare SCR conversion efficiency rather than DEF dosing rate. [EPA-HQ-OAR-2019-0055-1186-A2, p.73]

The NPRM requests comment on other strategies that can help inform operators of the functionality of the EGR system to help prevent breakdowns due to EGR system failures, including whether or how to monitor for EGR cooler leaks or plugging, such as through the use of pressure or temperature sensors, and whether today's engines are equipped with sensors in the EGR system that could be used for this purpose. Regarding the monitoring of EGR cooler leaks or plugging, EGR plugging is required to be monitored today under CARB's OBD regulations, while EGR cooler leaks are indirectly monitored through the EGR cooler efficiency diagnostic requirements in CARB's OBD regulations. For monitoring of major emission control components (e.g., fuel system, boost control system, EGR system), the CARB OBD requirements generally require malfunction detection when the component degradation or malfunction causes significant emission impacts and emission thresholds are exceeded. However, CARB staff understands that lesser degradation than the OBD threshold for an upstream component may cause degradation/irreversible damage to downstream components (e.g., an EGR cooler leak causing after treatment fouling; fuel system, EGR, or boost system issues causing high engine out PM and filter overloading) without causing significant immediate tailpipe impacts. CARB staff supports measures to identify, maintain and repair such upstream components before consequent damage occurs to downstream components. [EPA-HQ-OAR-2019-0055-1186-A2, pp.73-74]

The NPRM also requests comment on whether fault codes related to the incidents of engine derate due to EGR-related failures should be displayed in the cab as part of the health monitor, similar to what is being proposed for SCR and DPF-related derate issues. CARB staff believes this may be proposed as a larger, more general question regarding a requirement to make OBD and/or health-related information available on the instrument cluster or driver display. [EPA-HQ-OAR-2019-0055-1186-A2, p.74]

CARB staff has concerns about the regulation language in 1036.110 (c)(iii) and (iv). Specifically, these sections require manufacturers to provide 'an indication of EGR valve health, such as by comparing commanded and actual EGR position' and 'an indicator of EGR cooler performance, such as by displaying parameters described in 13 CCR 1971.1(e)(3.2.5).' CARB staff believes the language is vague and does not provide clear direction of what indicators/indication are acceptable. While U.S. EPA provides one example each of the type of indicator/indication that would meet the requirements, there is no direction about what other examples would be considered acceptable. CARB staff recommends that U.S. EPA provide more details about the criteria that must be met to meet these requirements. [EPA-HQ-OAR-2019-0055-1186-A2, p.74]

Organization: *Cummins Inc. (Cummins)*

System Health Monitors (While Cummins is not in support of the System Health Monitors proposal, if EPA does finalize those provisions, changes are suggested here.)

40 CFR 1036.110(c)(3)(i)(C)

Propose to replace the DPF proposal stated here - “The estimated mileage until the particulate filter needs cleaning to remove accumulated ash" language with CARB's DPF language instead - Lifetime counter of PM filter regeneration events (1971.1, Section 5.8.2). [EPA-HQ-OAR-2019-0055-1325-A1, p. 30]

40 CFR 1036.110(c)(3)(i, ii, iii, iv)

Where appropriate (for example, EGR commanded vs. actual parameters), propose for EPA to include the reaction time expectation of data provided on the dashboard (i.e., state whether they expect the instantaneous or filtered versions of these parameters) as different manufacturers may do things differently. [EPA-HQ-OAR-2019-0055-1325-A1, p. 30]

40 CFR 1036.110(c)(3)(i, ii)

Where appropriate, propose that EPA adds more details/clarity on defining the boundaries between current and historical data that is being asked for. [EPA-HQ-OAR-2019-0055-1325-A1, p. 30]

In response to request for comment on including an advance notice/warning to the operator in the event of a plugged DEF line or doser, as opposed to actual tampering, Cummins proposes that EPA consider not including this concept as it is challenging to effectively differentiate blocked DEF line/doser due to direct tampering vs. actual urea crystallization/line plugging. [EPA-HQ-OAR-2019-0055-1325-A1, p. 31]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

Another area of concern with of the proposed off-cycle test procedures is the mismatch between the applicable NOx emissions and the detection capabilities of state-of-the-art OBD systems. Current generation OBD systems are designed and calibrated to detect degradation of emission control systems before such degradation results in tailpipe NOx emission of 0.4 g/hp-hr as measured on the cold/hot FTP, and RMC cycles. This limit was intentionally set higher than the existing applicable emission standards to recognize the limits of detection capability. [EPA-HQ-OAR-2019-0055-1168-A1, p.47]

EPA does not propose any modification to the diagnostics emission limit, and in fact enshrines the current emissions thresholds in its new OBD proposal. EPA is tacitly acknowledging that current technology does not allow for the design of OBD systems with a higher detection sensitivity. [EPA-HQ-OAR-2019-0055-1168-A1, pp.47-48]

Today, manufacturers are protected from in-use liability for failed emissions control components by their OBD systems. With the current emissions thresholds and OBD emissions limits, it is ve1y likely that the OBD system will detect a failure before the system's emissions are significantly increased. These vehicles will be identified and repaired- and would not be tested for compliance while an emissions failure is present. [EPA-HQ-OAR-2019-0055-1168-A1, p.48]

This protection against possible high emitters due to malfunctioning emission control systems is lost with EPA's proposed standards. With the proposed extremely low in-use limits for NOx emissions, manufacturers will be liable for the in-use emissions of vehicles with failed emissions control systems which the EPA acknowledges cannot be detected by OBD systems. [EPA-HQ-OAR-2019-0055-1168-A1, p.48]

EPA's proposal for emissions system health monitoring is likely to cause increased uncertainty, unnecessary repairs, and further operator frustration, rather than resolving these concerns. The Agency appears to believe that its proposal will provide vehicle owners information on the overall health of important emissions systems at a given point in time. However, the information that EPA proposes to make available to operators is neither necessary nor sufficient to make service decisions appropriately, and is not an adequate indicator of the overall health of the system. [EPA-HQ-OAR-2019-0055-1168-A1, pp.76-77]

EPA states in the Proposed Rule that existing OBD monitors and data parameters could be used to communicate to an operator 'how close a system is to exceeding an OBD threshold,' and enable operators to perform predictive maintenance.104 This misunderstands how diagnostics function, and risks the costly replacement of components which have not, and may never, fail. [EPA-HQ-OAR-2019-0055-1168-A1, p.77]

104 Id. at 17,529.

It is important to understand that diagnostic monitors do not report failure degradation in a linear manner, and there is a significant amount of statistical uncertainty that the manufacturer must account for before identifying a part as failed. In Figure 31 below, Daimler Truck shows a typical distribution of test results for an OBD monitor for a 'good part' which is not at risk of failure, and a part which has already failed and should be replaced. Daimler Truck uses here as an example an industry accepted margin of four sigma from the mean result for a good part, and two sigma mean for the failed part, to the fault threshold. This is a standard and accepted practice for evaluating the relative quality of an OBD monitor, and the provided example shows a typical 'target' level of robustness. [EPA-HQ-OAR-2019-0055-1168-A1, p.77]

Under the Proposed Rule, the operator would be presented with a diagnostic result value. EPA expects that if operators saw a value close to exceeding the threshold, they may desire to perform predictive maintenance. However, EPA's proposal would not communicate to the operator what the appropriate threshold for replacement would be—and this example illustrates that functioning systems could report results that are 'close to exceeding the threshold.' Extrapolating, a 'partially degraded' system, which is not failed and not in need of replacement, would be even more likely to report a result 'close to exceeding the threshold.' [EPA-HQ-OAR-2019-0055-1168-A1, p.77]

Manufacturers typically employ a variety of statistical methods to better identify whether parts are failed or not, including debouncing a fault over time, averaging a number of test results, employing exponentially-weighted moving averages, and evaluating the system over multiple key cycles. Similarly, the appropriate threshold at which a part should be replaced might be different at different times, depending on operating and ambient conditions. Additionally, while some components fail in a linear fashion, the vast majority of failures are catastrophic and cannot be predicted by linear degradation of a test result. Operators do not, however, have access to any of that additional information or context. Any decision made to perform predictive maintenance risks replacing components which are not failed and do not need replacement, increasing costs and further undermining public confidence in the diagnostics system, which threatens to further encourage tampering. [EPA-HQ-OAR-2019-0055-1168-A1, p.78]

EPA gives the deviation of actual EGR position from commanded EGR position as an example of information that might be used to evaluate the health of system or to inform a decision to perform predictive maintenance. In modern engines, with smart actuators and digital position control feedback, it is expected that deviation between a desired and actual EGR position should be very near zero. Any deviation at all likely indicates a system that has already failed, and is at risk of significantly damaging the system. Accordingly, it is expected that manufacturers would have already chosen to illuminate the MIL. Our engines, for example, do not expect or tolerate any significant amount of EGR valve position deviation before illuminating the MIL. Additionally, many EGR system failures are not related to EGR valve position deviation but are caused by fouling of the EGR cooler transfer tubes, leaks in the system, or catastrophic failures of other components in the system, which cannot be measured and provided to the operator accordingly. In that matter, EPA's proposal provides no actionable information to the operator, and only serves to add confusion.[EPA-HQ-OAR-2019-0055-1168-A1, p.78]

EPA also proposes that the frequency of passive and active regeneration be provided to the operator, further expecting this could be used to determine system health. Regeneration frequency is heavily dependent on duty cycle and control mechanisms and is not an indication of health of the system or remaining life. During a recent investigation into aging phenomenon, Daimler Truck conducted a survey of more than two thousand heavy-duty engines' electronic data records. All engines were of the same vintage and regeneration control mechanism, and were similar displacements. Daimler Truck found that the average frequency of regeneration varied significantly—with a median frequency of 5,249 miles per regeneration, and a standard deviation of more than 3000 miles per regeneration. With such a wide spread of healthy-system regeneration frequencies, it would be impossible to determine a 'healthy' or 'unhealthy' regeneration frequency—and to do so would risk contributing even further uncertainty to fleet operations. Similarly, one engine manufacturer might choose to perform more-frequent, shorter-duration regenerations than another manufacturer, which would lead to higher 'regeneration frequency' as envisioned under this proposal. [EPA-HQ-OAR-2019-0055-1168-A1, p.78]

Similarly, EPA proposes that manufacturers report on the frequency of passive regeneration events. Passive regeneration is not a discrete event with a target duration or end conditions, and it would be impossible to determine the 'number' of passive regenerations. Passive regeneration is a phenomenon that can occur in some circumstances that the engine enters naturally. Manufacturers can track when the system is in these conditions, and accordingly delay the need for an 'active regeneration'—but these conditions do not require any interaction with system controls and do not contribute to system aging. It would be inappropriate to use the frequency of passive regeneration to make any determinations about the health of the system. [EPA-HQ-OAR-2019-0055-1168-A1, pp.78-79]

Each of EPA's proposed emission system health monitors present similar concerns. While Daimler Truck does not oppose providing the information necessary to diagnose and service our vehicles, EPA must recognize that a one-size-fits-all approach to that information is counterproductive and confusing. For some components, prognostics like the EPA envisions may be possible, but manufacturers must be able to define their own thresholds to indicate such service is appropriate. In many cases, like for many emissions system health monitors, a prognostic is not feasible, and a pass-fail diagnostic is the best available technology. [EPA-HQ-OAR-2019-0055-1168-A1, p.79]

If EPA mandates that this information is available to the operator, the Agency must also recognize in the regulation that parts replaced using this information must not be considered as failed for the purposes of the emissions control system warranty, or for potential defect reporting or, ultimately, recall. Such a cursory evaluation of the system is not appropriate to determine the presence of a warrantable or recallable failure, and EPA should acknowledge this in the final regulations. Manufacturers cannot be held responsible for misinterpretation of generic information that may not indicate a failure. [EPA-HQ-OAR-2019-0055-1168-A1, p.79]

EPA's OBD proposals related to service are unworkable, unnecessary, or incomplete. [EPA-HQ-OAR-2019-0055-1168-A1, p.76]

EPA proposes a variety of new requirements intended to increase the usability of the diagnostics system for the purposes of repair and maintenance of vehicle emissions control systems. Daimler Truck understands the diagnostics-related concerns faced by our customers and the various stakeholders. However, we believe that EPA's proposals are unlikely to streamline or simplify repairs and could lead to increased confusion, uncertainty, and unpredictability concerning repairs, as well as increase cost by driving unnecessary replacement of components that have not failed. [EPA-HQ-OAR-2019-0055-1168-A1, p.76]

The OBD system is intended to detect failures of emissions controls systems at a 'system' level, rather than diagnosing the root cause and/or pointing towards a specific service action. For example, manufacturers are required to diagnose, at a system level, that EGR flow rates do not meet the specified flow expected, or that SCR conversion efficiency has degraded and emissions are increased. These diagnostics do not necessarily identify the root cause of the failure, which could result from a variety of different failure modes. Manufacturer-published troubleshooting procedures are used to identify the specific component that needs repair. [EPA-HQ-OAR-2019-0055-1168-A1, p.76]

Daimler Truck is also concerned with the requirement to present emission system health monitor information in the cab to the operator. Such a proposal ties the certification of the OBD system, and by extension, the engine, to display functions and components (instrument clusters, screens, etc.), which are typically controlled by the vehicle manufacturer. While it is relatively simple to ensure that a vehicle manufacturer will appropriately illuminates a MIL, it is more difficult to ensure the correct transmission of a wide variety of messages. Similarly, this will add expense to traditionally price-sensitive vehicles, which will be required to add digital instrument clusters capable of displaying this information. [EPA-HQ-OAR-2019-0055-1168-A1, p.79]

Organization: *Ford Motor Company (Ford)*

We appreciate that this element of the proposed regulation is intended to provide information to customers about when critical emissions components are expected to fail and to provide forewarning of vehicle inducements. However, we believe that the health warnings as proposed are likely to cause significant confusion for customers and service providers. For example, a customer may incorrectly infer from a health warning that a vehicle component has failed. Such a scenario could result in unnecessary component replacements and elevated levels of warranty claims. [EPA-HQ-OAR-2019-0055-1300-A1, p. 5]

Ford recommends that EPA eliminate the requirement for health monitors on critical emission control systems. We also recommend that EPA shift their focus to existing emission-related service information regulatory requirements found in § 86.010-38(j) as well as the Heavy Duty OBD and Production Vehicle Evaluation testing requirements found in 13 CCR 1971 (l)(1) to ensure that truck operators and qualified technicians have access to comprehensive diagnostic and repair information and that required diagnostic data is properly communicated to generic scan tools. [EPA-HQ-OAR-2019-0055-1300-A1, p. 5]

In addition to ensuring compliance with existing emissions related service information requirements, we believe that truck owners and operators would also benefit from changes to existing EPA guidance on "derate" inducements for component malfunctions that disable EGR. Ford recommends that EPA issue formal guidance recommending that a "countdown" operator notification strategy be implemented for such faults providing operators sufficient time to safely seek proper service before experiencing compromised engine operation. [EPA-HQ-OAR-2019-0055-1300-A1, pp. 5-6]

Organization: *General Motors LLC (GM)*

On-board diagnostic (OBD) systems monitor the performance of an emissions system. If a malfunction is detected, a malfunction indicator light (MIL) or check engine light will illuminate on the dashboard. In some cases where a fault is detected, the operating authority of the powertrain may be restricted to protect system components and occupants, or to lower the likelihood of increased emissions until the vehicle is serviced and the fault is no longer detected. [EPA-HQ-OAR-2019-0055-1246-A1, p.5]

Vehicle operators, through the Owner-Operator Independent Drivers Association (OOIDA), have provided feedback to EPA that faults associated with emissions equipment can disrupt operations.9 [EPA-HQ-OAR-2019-0055-1246-A1, p.5]

> 9 Testimony of Lewie Pugh, Owner-Operator Independent Drivers Association, EPA Virtual Public Hearing (April 12, 2022), transcribed at EPA-HQ-2019-0055, p. 165-168. Available online at https://www.epa.gov/system/files/documents/2022-04/hd-2027-stds-public-hearing-transcript-2022-04-12-day1.pdf

EPA proposes to address this concern by requiring manufacturers to estimate when components will fail, based on OBD information, and to display that information to the operator. This proposed solution is not practicable. [EPA-HQ-OAR-2019-0055-1246-A1, p.5]

Detecting if a fault has occurred is a different task than projecting when a fault will or may occur. Such a requirement would have significant implications to on board communications protocols, data streams, and onboard processors. The volume and esoteric nature of information that would need to be displayed to a driver could be overwhelming, confusing, and distracting. Further complicating this matter, EPA has proposed changes in stringency and useful life over the course of the program, which could require algorithms to be significantly redesigned after just a few years to comply with steps in stringency in some proposals. [EPA-HQ-OAR-2019-0055-1246-A1, p.5]

GM suggests a multi-party workshop, including both EPA and the California Air Resources Board (CARB), on practical ideas to address operator concerns related to fault detection. Many cross-functional problems would need to be solved to successfully address the underlying operator concerns as EPA proposes, including human machine interaction, repair procedures and replacement part specifications, operator training, service training, updates to service and owner's manuals, and the feasibility of prognostics on systems subject to regulations, just to name a few. GM stands ready to work with regulators to address operator concerns related to the MIL, to protect air quality, and to create a great customer and operator experience with equipment in the field. Proposed requirements for prognostics are premature. Prognostics and state-of-health monitors of emissions systems should be a standalone rulemaking given the multitude of cross-functional issues. [EPA-HQ-OAR-2019-0055-1246-A1, p.5]

Organization: *International Council on Clean Transportation (ICCT)*

Having access to SCR, DPF and DEF operational parameters would facilitate preventive maintenance and reduce cost to operators to ensure real world emission reductions over the lifetime of the vehicle. For regulators, access to these parameters would ensure that the data captured during in-use HDV emission testing with Portable Emission Measurement Systems can be correlated with these parameters. This is critical to better understand the emissions profile of each engine family tested as well as to identify potential deviations that may indicate the use of defeat devices. [EPA-HQ-OAR-2019-0055-1211-A1, p. 24]

Organization: *PACCAR, Inc (PACCAR)*

PACCAR is committed to ensuring OBD systems ‘generally detect malfunctions in the emission control system, store trouble codes corresponding to detected malfunctions, and alert operators appropriately.’ 40 C.F.R. 1036.110 Diagnostic controls (proposed). However, PACCAR has identified two primary issues with the proposed system health monitoring provisions that EPA should amend. [EPA-HQ-OAR-2019-0055-1346-A1, p.41]

First, for particulate filter information, EPA proposed to require an ‘[i]ndicator of historical and current active and passive regeneration frequency’ as section 1036.110(c)(3)(B) of the regulations. 87 Fed. Reg. 17414, 17666 (March 28, 2022) (emphasis added). But it is technically infeasible to control or track passive regeneration frequency due to, among other things, temperature and oxygen exhaust concentration variability. This variability would inevitably lead to inaccurate monitoring because the indicator would not be able to record correctly each passive regeneration event. PACCAR therefore urges EPA to remove the proposed passive regeneration frequency indicator requirement. [EPA-HQ-OAR-2019-0055-1346-A1, p.41]

Second, for SCR-related information, EPA proposed to require '[i]nformation describing any detected flow obstruction in DEF lines or dosing valve in anticipation of triggering an inducement.' Id. These proposed requirements are also technologically infeasible and should be withdrawn. The plethora of variables, e.g., ambient temperature at which the DEF freezes, whether there are thawing heaters, etc., makes it impossible to design a function that would accurately assess obstruction information. [EPA-HQ-OAR-2019-0055-1346-A1, pp.41-42]

In addition, PACCAR notes that the cross-referenced CARB citation in proposed 1036.110(b)(6) needs to be corrected. The proposed provision purports to cite to 'testing and reporting requirements' but instead incorrectly cites to engine aging requirements. Id. at 17665 (incorrectly citing to 13 CCR 1971.1(i)(2.3-2.4). EPA should revise the final rule to include the proper citation. [EPA-HQ-OAR-2019-0055-1346-A1, p.42]

Organization: *Truck and Engine Manufacturers Association (EMA)*

EPA's proposal to include health system monitors raises significant concerns. OBD is a diagnostic, not prognostic, tool. Proposing to change the function of OBD without robust consideration and prove-out utilizing input from the entire affected stakeholder community, especially in the timeframe being considered, is not reasonable. Accordingly, we request that EPA defer the finalization of health system monitors, and instead implement a pilot program to provide time to fully evaluate the proposed provisions, including an evaluation of the perceived benefits, along with an assessment of the necessary standardization, demonstration, etc. That would be especially helpful since the proposed requirements could result in the potential for false prognostics being broadcast to operators, leading to more confusion for drivers and service technicians. [EPA-HQ-OAR-2019-0055-1203-A1, p. 96]

We also have concerns with the Agency's proposal to include such health monitors in the cab – presumably on the dashboard. Adding another display to the dash, again without adequate prove-out (or standardization), also could contribute to operator distraction and confusion. (See Exhibit "I") We recommend that EPA focus on existing emission-related service information regulatory requirements found in §86.010–38(j), as well as the Heavy Duty OBD and Production Vehicle Evaluation testing requirements found in 13 CCR 1971.1(l)(1), to ensure that truck operators and qualified technicians have access to comprehensive diagnostic and repair information, and that required diagnostic data is properly communicated to generic scan tools. [EPA-HQ-OAR-2019-0055-1203-A1, p. 96]

To date, OBD requirements have led industry to provide standardized OBD data, and key operator displays. The ISO 2575 F.01 symbol and fault code standards are now ubiquitous across products approved by the Agency and offered for sale to the public. In the NPRM, EPA proposes to require manufacturers to provide health monitors that have no standardization model in SAE

J1939 or J1979 et. al. to support their orderly development and deployment. The implementation timeframe defined in the proposed rule would require engine manufacturers to invent disparate, proprietary communication methods for instrument clusters and dash displays. In many HD vehicles, instrument clusters and dash displays are controlled by the vehicle manufacturers, who would be required to develop new instrument clusters and dash displays to present the new health monitors to vehicle operators. An implementation requirement without supporting communication standards as a guide will lead to multiple inconsistent efforts across the industry, and increased costs and burdens, all while providing little if any appreciable air quality benefit. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 96 - 97]

Accordingly, EMA does not support health monitors as a general matter. Moreover, we strongly disagree with the incorporation of such monitors in the absence of communication standards that would provide the methods that can be used by all manufacturers. Without uniform supporting communication standards, manufacturers would face unacceptable risks due to their differing interpretations and methods for implementing the proposed requirements. We recommend that EPA consult with industry, the SAE Truck and Bus Control and Communication Network Committee, and the Vehicle Electrical/Electronic (E/E) System Diagnostic Standards Committee, prior to finalizing new requirements that would require new communications from the engine to new instrument clusters and dash displays. [EPA-HQ-OAR-2019-0055-1203-A1, p. 97]

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. §1036.110(c)(3)(i) through (c)(3)(iii): Many of the terms used throughout these paragraphs do not appear in the current SAE J1939DA protocol. Again, it is requested that EPA consult with the SAE Truck and Bus Control and Communication Network Committee and the Vehicle E/E System Diagnostic Standards Committee to insure each of the items that EPA proposes to request are defined. Specifically: Health monitoring specific metrics are not currently defined in SAE J1939DA. Proposed paragraphs (c)(3)(i)(B) and (c)(3)(ii)(A) refer to "current and historical"; however, the commonly used terms in SAE J1939DA and J1979DA are "lifetime", "trip", and "operating cycle." Furter, the timeframe for the proposed term "current" is not clear for the data items cited (e.g., is a resettable "trip" context intended, or a "start-to-start" operating cycle context intended?). We recommend that any items that are not currently required in 13 CCR 1971.1(h)(4.2) should not be utilized in EPA's regulations. [EPA-HQ-OAR-2019-0055-1203-A1, p. 101]

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. §1036.110(c)(3)(i)(B): "(B) Indicator of historical and current active and passive regeneration frequency." Passive regeneration events are not known, and thus should not be required by the regulations. EMA recommends deletion of "and passive" from paragraph (B). [EPA-HQ-OAR-2019-0055-1203-A1, p. 101]

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. §1036.110(c)(3)(ii)(C): "(C) Information describing any detected flow obstruction in DEF lines or dosing valve in anticipation of triggering an inducement under §1036.111(b)(2)." This paragraph would require tracking of DEF blockages and actual valve output to determine degradation; however, the DEF hardware may not be able to provide such degradation information. EMA recommends deletion of paragraph (C). [EPA-HQ-OAR-2019-0055-1203-A1, p. 101]

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. §1036.110(c)(3)(v): "(v) Provide current data under paragraphs (c)(3)(i) and (ii) of this section based on a default method of updating or resetting collected data. For example, the current data may include information from the Active 100-Hour Array or Stored 100-Hour Array. The system must allow the operator to perform a manual reset to start collecting new data on demand." 100-hour active resets on operator demand are not recommended, as they imply increases in non-volatile memory demand for array resets that cannot be confidently estimated. Writes to non-volatile memory are limited by the technology employed, and multiple non-volatile memory locations are employed to prevent memory locations from overuse. Further, on-demand resets need not include any 100-hour stored values. 13 CCR 1971.1 (h)(5.3.5) and (h)(5.7.3-4) require 100-hour active arrays to reset with a code clear command, and prohibit resets for stored 100-hour and lifetime array values. Inclusion of an operator-initiated 'clear fault' command is also not recommended, as previously noted in these comments. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 101 - 102]

Organization: *Walmart*

We recommend OEMs include in onboard diagnostics and signals like a distance to empty (DTE) display for alternative energy powered vehicles that are commonly found in both ICE and passenger EVs today] [EPA-HQ-OAR-2019-0055-1191-A2, p. 4]

EPA Summary and Response

EPA received adverse comment from Cummins and DTNA on the concept of health monitors with DTNA citing an increase in uncertainty of the status of the emissions system as well as an increase in repairs due to the uncertainty.

CARB expressed general support on this concept, but CARB also stated the need to work with manufacturers on developing this concept further. CARB was concerned about the effects of repairs due to health monitor reporting on warranty claims and suggested that all repairs made from health monitor results should be reported on defect and EWIR reports. CARB also suggested that some of the current OBD monitors could be used as part of the health monitor concept for the DPF and EGR system. CARB supported indicating to the operator when DPF regen was disabled and the reason why as a benefit to operators and repair technicians. They also noted that severe derates generally accompany faults that prevent the DPF system from regenerating. CARB also noted that SCR dosing disabled is a MIL on condition and a fault code would be stored.

Several commenters provided perspectives on EPA's request for comments to improve serviceability of electric vehicles. Commenters were generally supportive of the concepts that EPA requested comment on; several commenters also suggested additional ideas to consider (e.g., new requirements for original equipment manufacturers (OEMs) to provide standard repair time (SRT)).

- See Section IV.C.1.iii of the preamble for the final provisions related to health monitors and our response to these comments.
-

  EPA appreciates the comments on serviceability of electric vehicles. EPA requested comment on this topic but is not finalizing at this time serviceability provisions specific to electric vehicles. We may consider this topic in a future rulemaking.

7.3 OBD communication protocol

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

The NPRM requests comment on whether U.S. EPA should finalize provisions to allow the SAE J1979-2 protocol if CARB staff does not finalize their update before U.S. EPA completes the final rule, and on potential challenges with this change. The NPRM also requests comment on the interim provision in 1036.150(v) that would allow the use of J1979-2 for model years before 2027 and the provision in 1036.110(b) that would allow J1979-2 for 2027 and subsequent model years, including whether any additional changes need to be made to the existing or proposed OBD requirements to accommodate the use of J1979-2. CARB staff is supportive of the U.S. EPA proposal to allow the SAE J1979-2 protocol if CARB staff does not finalize its update prior to the U.S. EPA rule. [EPA-HQ-OAR-2019-0055-1186-A2, p.77]

The NPRM requests comment on whether the use of J1979-2 could have negative impacts on the existing U.S. EPA OBD program, and on the potential impacts on the U.S. EPA service information requirements. CARB staff is supportive of the use of SAE J1979-2 and does not anticipate negative impacts on the existing U.S. EPA program, CARB OBD program, or U.S. EPA service information requirements. [EPA-HQ-OAR-2019-0055-1186-A2, pp.77-78]

The NPRM requests comment on how tool vendors would be affected by this J1979-2 proposal, whether they would be able to support the new services and data, and if there are any concerns tool manufacturers have regarding access to vehicle data at a fair and reasonable cost. CARB staff anticipates tool vendors will be able to fully support the SAE J1979-2 protocol at a fair and reasonable price for the vehicle repair industry and consumers. [EPA-HQ-OAR-2019-0055-1186-A2, p.78]

Organization: *Cummins Inc. (Cummins)*

Cummins supports EPA providing an allowance for the J1979-2 protocol but proposes to not include the corresponding 2022 Biennial CARB OBD rulemaking that mandates manufacturers using this protocol to provide support for new and additional requirements like Supplementary Monitor Activity Data (SMAD) requirements, new DataStream/freeze frame requirements, new readiness requirements, new trackers etc. [EPA-HQ-OAR-2019-0055-1325-A1, p.27]

Organization: *International Council on Clean Transportation (ICCT)*

We support efforts that would communicate in natural language and not computer codes the fault conditions that may trigger inducements. Lowering these communication barriers would reduce the impacts of trigger inducements on vehicle down-time. [EPA-HQ-OAR-2019-0055-1211-A1, p. 24]

Organization: *Truck and Engine Manufacturers Association (EMA)*

EMA supports the proposal at 40 CFR 1036.150(v) allowing the option to use J1979–2 for manufacturers seeking EPA OBD approval prior to MY 2027. We further support the interpretation that proposed §1036.110(b) would provide a path for the use of J1979–2 when the proposed program becomes effective. Additionally, EMA recommends that EPA also allow for the use of the SAE J1939 protocol beyond MY 2027. [EPA-HQ-OAR-2019-0055-1203-A1, p. 97]

<u>EPA Summary and Response</u>

EPA received comments from CARB, EMA, ICCT, and Cummins that all supported the provisions allowing the use of SAE J1979-2 communication protocol as early as MY 2022 and to allow the use of SAE J1979-2 after MY 2027. Cummins also commented that EPA should not adopt the 2022 Biennial CARB OBD which mandates new and additional requirements like Supplementary Monitor Activity Data, data stream and freeze frame parameters, readiness requirements, and new trackers.

CARB commented that they do not expect any negative impacts from allowing SAE J1979-2 protocol on tool vendors, and that the tool vendors will be able to accommodate SAE J1979-2 requirements at a fair and reasonable price.

- See our response to these comments and the final provisions in preamble Section IV.C.1.vi.

7.4 Other requirements

<u>Comments by Organizations</u>

Organization: *Allison Transmission, Inc. (Allison)*

EPA has also requested comment with respect to provisions designed to improve diagnosis and repair, specifically whether additional data parameters should be included in the freeze frame data to identify the source of the malfunction more effectively.61 Allison's preference is to ensure that a primary controller such as the engine control module (ECM) stores its own freeze frame and parameter data and other secondary controllers on the vehicle are not required to store data from the primary (i.e., ECM) controller. EPA has set precedent that transmission controllers are comprehensive component controllers that do not need to store other system data, and Allison recommends continuing this approach because it keeps OBD systems simpler and more streamlined. [EPA-HQ-OAR-2019-0055-1231-A1, p.29]

61 Id. at 17,529.

Organization: *American Bus Association (ABA) (1070 and 1308)*

In addition, one of the major issues that many of the motorcoach fleet operators face is the lack of available diagnostic equipment. For each of the engine manufacturers, different diagnostic licensed software is required, in addition to specialized training. Very few motorcoach fleet operators are going to have many of the computers equipped with the requisite software readily available, particularly with those software licenses retailing in excess of $20,000 each. With many motorcoach fleets averaging 5-7 operational units, only the largest operators or the manufacturers will even have equipment capable of diagnosing an emissions control system issue, much less potentially resolving one. As a result, many motorcoach operators have to send their vehicles to the motorcoach manufacturers or to the engine manufacturers. If the generic scan tool is going to be as scarcely available or as costly as the currently diagnostic software, those costs will need to be factored into this rulemaking as well as the cost of increased down time. And any cost savings anticipated by offering the generic scan tool option to delay the derate inducement should be reduced by a factor of the availability of that tool. [EPA-HQ-OAR-2019-0055-1308-A1,p.8]

iv. Self-Heal and Generic Scan Tools – ABA appreciates EPA's consideration but needs more time to review this proposal with motorcoach operators. On face value, the proposal appears meritorious, but it also raises a number of questions. Such as who is to provide the generic scan tools and at what cost? Who is expected to use the tools? Motorcoach drivers have an enormous responsibility in operating their vehicle safely and addressing passenger needs. They are not expected to be vehicle technicians. In addition to a driver shortage, as well as a lack of availability or access to the diagnostic software due to cost, there is also a severe technician shortage in the motorcoach industry. Again, this is a distinction of motorcoach operations versus property-carrying operations. [EPA-HQ-OAR-2019-0055-1308-A1, p.10]

Organization: *California Air Resources Board (CARB)*

CARB staff supports U.S. EPA's proposed additional parameters for CI engines. The NPRM requests comment on whether any additional signals should be included in this list and whether any other signals should be included such as any signals related to maintenance derates (outside of inducements). CARB staff believes it is worth considering expanding parameters where needed to support maintenance and repair of derates outside of inducements. CARB staff also notes that regulatory requirements for additional parameters require engagement with the SAE J1979 and J1939 committees. The regulation must allow sufficient time for the parameters to be developed and adopted into the standards before the requirement can take effect. [EPA-HQ-OAR-2019-0055-1186-A2, p.74]

CARB staff supports U.S. EPA's proposed additional parameters for SI engines. The NPRM requests comment on whether any additional signals should be included in this list and whether any other signals should be included such as any signals related to maintenance derates (outside of inducements). CARB staff believes it is worth evaluating expanding parameters where not currently required by the OBD regulations to support maintenance and repair of derates outside of inducements. CARB staff believes it is also worth evaluating adopting an OBD REAL requirement for NOx emissions based on on-board NOx sensors for spark ignited engines, including those derived from diesel engines. CARB staff also note that regulatory requirements for additional parameters require engagement with the SAE J1979 and J1939 committees. The regulation must allow sufficient time for the parameters to be developed and adopted into the standards before the requirement can take effect. [EPA-HQ-OAR-2019-0055-1186-A2, p.75]

CARB staff has concerns regarding U.S. EPA's statement about the difficulty of accessing many of the signals CARB requires to be made public with a generic scan tool. C ARB regulations require standardization tests (SAE J1699 and SAE J1939-84) on production vehicles to verify the OBD communications are working properly. So, any issues should be detected during these tests and reported to CARB as part of the reporting requirements. CARB staff would like to understand which signals are at issue and if issues were not properly identified through the OBD production vehicle testing and reporting requirements. [EPA-HQ-OAR-2019-0055-1186-A2, p.75]

The NPRM requests comment on U.S. EPA's proposal to require the parameters in CARB's regulation sections 13 CCR 1971.1(h)(4.2.1)(D), (h)(4.2.2)(H), (h)(4.2.3)(F), (h)(4.2.3)(G), and (h)(4.2.2)(I) to be included in freeze frame, and whether additional parameters should be included to more effectively identify the source of malfunction and increase the usefulness of freeze frame data, especially for conditions that result in inducement. CARB staff generally supports additional data where there is an identified benefit to owners, inspectors, or repair technicians. [EPA-HQ-OAR-2019-0055-1186-A2, pp.75-76]

U.S. EPA is proposing to require the DEF dosing test be made available for use with either a generic scan tool or an alternative method (e.g., an option commanded through a vehicle system menu). The NPRM requests comment on whether U.S. EPA should make SCR performance tests available via generic scan tool or other on-vehicle methods, and the need to make other self-tests accessible with generic scan tools to improve in-use emission systems maintenance and performance (e.g., being able to command the evaporative system on spark-ignited engines be sealed to allow for leak testing, ability to perform manual regens for DPF systems). Regarding the DEF dosing test, service shops already have DEF injector tests available using dealer tools or enhanced tools. While it can be difficult to standardize the test commands to support such testing in a generic scan tool, CARB staff supports the idea where standardized tests would be beneficial. Regarding the SCR performance test, however, the SCR system is designed to control emissions over a broad range of speeds, loads, temperatures and NOx concentrations. The shop service procedure for SCR performance may not be as useful as the REAL NOx tracking data primarily due to the limited conditions in the shop environment, since the high load, high speed, and high NOx operating points would not be experienced in the shop. An evaluation conducted under low load, low NOx, and low temperature conditions may lead to an erroneous health assessment or be of limited value. [EPA-HQ-OAR-2019-0055-1186-A2, p.76]

Organization: *Cummins Inc. (Cummins)*

Infrastructure/Scantool

Propose to remove the Over-the-Air (OTA) software reflash requirement from the CARB OBD 2019 requirements since EPA is not planning an updated EPA HD I/M program at the moment. Without an I/M program, the requirement introduces challenges like requiring an increase in ECM storage space as well potential burdensome administrative tasks during subsequent software changes. [EPA-HQ-OAR-2019-0055-1325-A1, p.27]

In Section H (4.2.3) (G) of the 2019 CARB 1971.1 regs, propose to remove specific new scantool reporting requirements (DataStream additions) w.r.t modelled/estimated NH3 storage level on SCR and target NH3 storage level on SCR. There is no benefit to service environment and not required to troubleshoot a vehicle. [EPA-HQ-OAR-2019-0055-1325-A1, p.27]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

To ease operator concerns, EPA includes a variety of new proposals, including emission system health monitors, increasing the number of publicly available data parameters, increasing the freeze frame data, and enabling certain self-testing capabilities for owners. [EPA-HQ-OAR-2019-0055-1168-A1, p.76]

Daimler Truck supports providing increased information in data stream and freeze frame, but only if such parameters are specified by the relevant SAE and ISO standards, and the requirement is updated to reference such standards specifically. This approach has been used for several decades to successfully implement data stream and freeze frame parameters, and EPA should continue to use this approach to specify any expansions in their expectations. Otherwise, EPA risks inconsistent implementation—both in terms of how the information is calculated, and how it is made available to a generic scan tool—which undermines EPA's stated goals for making this information available. [EPA-HQ-OAR-2019-0055-1168-A1, p.76]

Lastly, Daimler Truck is concerned about allowing generic control of service functions, such as the DEF dosing quantity check. Daimler Truck is concerned about allowing external, unverified control of any emissions control components, which might ultimately provide a path for malicious actors to tamper with emissions controls by allowing new paths to command software controls of emissions systems. Additionally, EPA's proposal prevents two-way verification of control—and many service routines have built-in safety and emissions checks before they can be executed. Forcing the system to respond to generic requests from unknown third party tools removes the ability of the manufacturer to verify proper system operation from 'both directions,' so to speak. EPA should also reconsider this aspect of its proposal in light of various functional safety standards, such as ISO 26262, and cybersecurity standards. EPA's proposals create a path of attack that could risk the safety and security of the systems. Manufacturers are already required to provide access to their service tools and directions at a reasonable cost; there is thus no reason to create an alternate diagnostic and control path. [EPA-HQ-OAR-2019-0055-1168-A1, p.79]

In summary, manufacturers are already providing state-of-the-art diagnostics systems, and EPA's proposal creates a secondary, less-effective, and more-problematic method of diagnosing failures that could ultimately lead to more expensive service, greater confusion and frustration, and increased interest in tampering. Manufacturers already have significant motivation to reduce downtime and improve the service experience as much as possible. EPA's proposals do not serve to improve that experience, and will have significant unintended consequences. Daimler Truck recommends that EPA adopt the CARB OBD regulations as proposed, without the added provisions for prognostics and service functions. [EPA-HQ-OAR-2019-0055-1168-A1, pp.79-80]

Organization: *Delaware Department of Natural Resources and Environmental Control (DNREC)*

EPA should not ease measures designed to prevent the avoidance of maintenance or repair costs. Delaware recommends that EPA maintain a robust onboard diagnostics (OBD) program that will ensure OBD continues to accurately detect system failures and vehicle problems can be promptly, proficiently and cost-effectively repaired. [EPA-HQ-OAR-2019-0055-1200-A1, p.3]

Organization: *Great Rivers Environmental Law Center and Dutchtown South Community Corporation (DSCC)*

The undersigned support inclusion of the following requirements in the Final Regulation:

- Mandatory additional maintenance requirements and onboard diagnostics to help combat mal-maintenance and tampering, and to ensure long-term emissions performance. [EPA-HQ-OAR-2019-0055-1323-A1, p.6]

Organization: *International Council on Clean Transportation (ICCT)*

The ICCT supports EPA's decision to harmonize with CARB's OBD provisions for MY 2022 to 2024 and with the intention to expand those signals as listed in the NPRM (FR page 17532). [EPA-HQ-OAR-2019-0055-1211-A1, p. 24]

Organization: *National Association of Small Trucking Companies (NASTC)*

Making it easier for truckers to make repairs themselves using generic scan tools while on the road and truckers or carriers to repair vehicles in-house. Having all inducement-related diagnostic data parameters accessible with generic scan tools, as well as scan tools being capable of removing an inducement condition after repair, would enable truckers to repair emissions systems themselves while on the road, respond to inducements more quickly, perform normal operation with less disruption, and reduce repair costs and wasted time. [EPA-HQ-OAR-2019-0055-1130-A1, p. 3]

Requiring that systems provide more, specific information, including diagnostic codes. Having cab displays that name the condition that triggered the pending or active derate and a countdown timer of the estimated time or distance before the next stage of derating (even if overridden) would give truckers more and better information about inducements as they happen, help them make informed decisions about trip management, repairs, etc., and make the inducement system more tolerable. Coupled with generic scan tools and new capabilities to diagnose and repair emission system problems, this empowers drivers with better information, better tools, and better options. Drivers are more likely to take action when enabled in the ways and by the means proposed. They would know not only the problem, but how to fix it, while better able to manage trip plans and commercial obligations. Moreover, NASTC supports the proposed additional information in owner's manuals, including how to use the OBD system to troubleshoot problems. [EPA-HQ-OAR-2019-0055-1130-A1, p. 3]

Organization: *Owner-Operator Independent Drivers Association (OOIDA)*

Many OOIDA members have the resources and means to maintain their trucks, and prefer doing this work themselves. According to the 2018 Land Line Reader Survey, 73% of owner-operators indicated that they complete minor repairs and maintenance to their truck, engine, and trailer themselves. Most owner-operators have their trucks on a regular maintenance schedule because they recognize the necessity of ensuring their truck is safe to operate on the roadways. The ability to diagnose and fix equipment problems without having to a visit a dealership saves small-business truckers both time and significant money. Unfortunately, many modern heavy-duty vehicles have taken self-maintenance options away from drivers. Newer trucks that incorporate more complex technology and components typically can only be serviced at dealerships, where charges can be hundreds of dollars per hour simply to inspect the engine or perform other routine work. [EPA-HQ-OAR-2019-0055-1266-A1, pp.6-7]

EPA must ensure that the provisions outlined in Section IV, B (Ensuring Long-Term In-Use Emissions Performance) and C (Onboard Diagnostics) are maintained. These provisions would assist drivers who perform their own maintenance and repairs. [EPA-HQ-OAR-2019-0055-1266-A1, p.7]

Following the January 2020 Cleaner Trucks Initiative Advance Notice of Proposed Rulemaking (ANPRM), many truckers told EPA about problems they've experienced and how the agency could work to address them. OOIDA commends the agency for listening to those comments and including provisions in the proposal regarding serviceability, inducement, and self-diagnostic tools that will help drivers better assess their emissions equipment. [EPA-HQ-OAR-2019-0055-1266-A1, p.6]

Further, on-board diagnostic tools and generic self-scan options will help drivers better analyze possible problems without having to make those costly visits to repair shops. [EPA-HQ-OAR-2019-0055-1266-A1, p.7]

Organization: *PACCAR, Inc (PACCAR)*

PACCAR supports having trained technicians perform DEF dosing diagnostic testing under proper conditions. But proposed section 1036.110(c)(2) would require that '[d]iagnostic testing to measure the effectiveness of DEF dosing . . . be made available for use with either a generic scan tool or an equivalent alternative method (such as an option commanded through a vehicle system menu). (emphasis added). This proposed provision is problematic for a number of reasons. [EPA-HQ-OAR-2019-0055-1346-A1, p.42]

Currently, trained technicians ensure proper conditions before conducting DEF dose diagnostic testing. Requiring generic scan tool or equivalent testing would lead to testing that is conducted under improper conditions, e.g., the catalyst must be at the appropriate temperature to ensure proper dosing, and misuse. Both scenarios likely will cause engine, catalyst or other systematic damage, which would have an adverse impact on emissions. PACCAR therefore submits that the risks associated with the DEF dosing diagnostic testing proposal significantly outweigh any purported benefits. EPA should revise its proposal to remove the DEF dosing diagnostic testing requirement and leave such testing to trained technicians. [EPA-HQ-OAR-2019-0055-1346-A1, p.42]

Organization: *Roush CleanTech (Roush)*

We believe that the added data stream items in 1036.110(b)(10) would more appropriately developed in conjunction with ARB and SAE for incorporation in 13 CCR 1971.1 and SAE J1979 and J1939, which would then be incorporated in EPA regulation by reference. We do not believe there is any benefit in including these requirements in this NPRM, or in EPA having unique federal-only data stream requirements. If EPA does wish to pursue unique federal-only data stream requirements, we would suggest at minimum adopting the framing language included in ARB 1971.1(h)(5), ensuring parameters are defined and implemented consistent with J1979 or J1939 standards, and including definition on when parameters should be tracked, when they may or should be reset, whether they should be paused during failure conditions, etc. [EPA-HQ-OAR-2019-0055-1276-A1, p.6]

Roush believes the discussion of making inducement-related information available to the vehicle operator for the purpose of potentially resolving inducements as they occur is valuable. We have no strong opinion on this issue as we are not principally involved in systems using inducements. However, we do have concerns relating the continuing language regarding potentially requiring other manufacturer-specific diagnostic functions to be available on generic scan tools or by on-vehicle request. We believe there is already a very robust industry dialog with EPA, ARB, and SAE, including both auto manufacturers as well as service tool providers, on defining requirements for generic scan tools. If EPA wishes to explore adding functions to GST, there is no need to burden the current proposed rule; simply raise the issue for discussion in the existing forums where practical implementation requirements and timeline could be developed. Regarding on-vehicle requests, we caution that typical off-board intrusive tests are designed under the assumption they are only performed by qualified personnel in controlled environments as part of a documented service procedure while physically connected to a service tool; making these tests available to untrained users outside of the service environment would likely require significant redesign to ensure they are performed safely, and do not potentially constitute adjustable parameters or defeat devices which would be in violation of other areas of the regulation. We would suggest limiting such requirements to those items which disable vehicle function and for which the operator has a reasonable ability to perform roadside repair without special tools or parts; otherwise it seems unclear what benefit is offered. [EPA-HQ-OAR-2019-0055-1276-A1, p.7]

Organization: *Truck and Engine Manufacturers Association (EMA)*

There is a similar concern regarding the diagnosis of multi-bed catalyst systems. SwRI has suggested that partial-volume OBD monitoring strategies might be deployed for configurations similar to the Stage 3 prototype system. However, OBD-certification staff have refused to approve partial monitoring strategies when proposed previously by some OEMs. EPA will need to clarify whether there has been a change of policy to account for the advent of systems such as those used on the Stage 3 engine. [EPA-HQ-OAR-2019-0055-1203-A1, p. 95]

EMA does not support the proposal to use a generic scan tool to measure the effectiveness of DEF dosing. Without either an established industry protocol (e.g., SAE), or a requirement that generic scan tools meet such a common protocol, this proposal sets the stage for varied testing among the various manufacturers, and potentially, safety concerns from using an unregulated generic scan tool with a system that is, necessarily, sealed. Further, regarding the request for comment on whether EPA should make SCR performance tests available via generic scan tools (or another on-vehicle method), EMA does not support this proposal. Making SCR performance tests available via either of those methods is not workable, as it would be extremely challenging for the Agency to develop a robust, standardized public SCR performance test that would fit multiple manufacturers' aftertreatment configurations. [EPA-HQ-OAR-2019-0055-1203-A1, p. 97]

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. §1036.110(c)(2): "(2) Diagnostic testing to measure the effectiveness of DEF dosing must be made available for use with either a generic scan tool or an equivalent alternative method (such as an option commanded through a vehicle system menu)." The proposed provision would require an on-demand test triggered by either a generic scan tool or a vehicle input to perform a DEF dosing test. We recommend deletion of this provision, as such a test could potentially damage the catalysts and may take an especially long time to run until the conditions necessary to actuate the DEF are correct. Further, making this control function available for anyone with a generic scan tool is not recommended due to safety concerns, negative impacts to air quality (e.g., NOx emissions, DEF spill, ammonia slip, etc.), and the potential for errors in conducting service procedures (and associated additional service actions and increases in repair costs). (See Exhibit "G.") [EPA-HQ-OAR-2019-0055-1203-A1, p. 101]

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. §1036.110(b)(8)(i): "(i) Data parameters specified in 13 CCR 1971.1(h)(4.2) and (4.3)." We note that 13 CCR 1971.1(h)(4.3) provides the complete description of freeze frame contents; the reference to subsection (h)(4.2) is not needed and should therefore be deleted. Moreover, expanding the freeze frame to include all of the data defined in (h)(4.2) will significantly increase the non-volatile ECU memory needed to store freeze frames. The SAE J1979-2 specification expands the required number of freeze frames from one to ten per ECU. For ECUs that are at or near their maximum capacity of non-volatile memory, this would drive new ECU hardware (a costly and long-lead time change.) We believe the parameters defined in (h)(4.3) are adequate and appropriate for servicing vehicles. If EPA believes additional parameters are required, those specific parameters should be identified in order to minimize the impact to limited non-volatile memory. We estimate an increase of around 500 bytes of data for this additional data, or a total of five kilobytes per ECU to account for the ‘ten freeze frames per ECU’ requirement for J1979-2. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 99 - 100]

EPA Summary and Response

Summary:

EPA received general support for requiring additional OBD data parameters from Great Rivers Environmental Law Center, DSCC, DNREC, OOIDA, and NASTC, stating the proposed requirements would reduce mal-maintenance, tampering, and ensure long-term emissions performance due to an increase in information available to repair technicians, vehicle operators, and fleets.

CARB also supported the proposed additional data parameters that aid diagnosing and repair of errors that cause derates but are not also inducements, where this information is useful for repair service. CARB suggested to adopt the OBD REAL requirements for NOx emissions based on on-board NOx sensors for SI engines.

Cummins proposed to remove the requirement in 2019 CARB 1971.1 of modeled and actual NH3 storage on the SCR, stating that there is no benefit in a service environment and this information is not required for troubleshooting vehicle problems. Cummins also proposed to remove Over-the-Air software reflash requirement from the 2019 OBD requirements stating that EPA is not planning an updated EPA HD I/M program and stating that this requirement introduces challenges such as an increase in ECM storage space and burdensome administrative tasks during subsequent software changes. CARB commented that requirements in the preamble of this rule that proposed spark ignition (SI) component temperatures that engage thermal protection modes are made available publicly, but this requirement was not reflected in the proposed regulations. CARB commented that they would like to work with the EPA to understand the problems found where publicly available data parameters were not available on a GST.

Roush, Allison, and DTNA all commented that additional data parameters are not required. Allison specifically requested that each control module store its own freeze frame and parameter data and there be no cross storage of system data. Roush and DTNA commented that if additional data parameters are adopted in the final rule, the framing language in 1971.1(h)(5) should be adopted and that the parameters should be defined and consistent with J1979 or J1939 definitions. DTNA further commented that repairs should be performed by professional technicians.

Cummins commented that SI requirements in 1036.111(b)(10)(i) need to be clearly defined, either more generically to allow other modes specified in this regulation to cover the requirement or more specifically in the context of the three modes (throttle, engine protection, or catalyst protection).

EPA received comment from ABA on the lack of availability of generic scan tools (GST) due to cost and lack of choice. They commented that the lack of availability of GSTs creates a dependence on the manufacturer developed diagnostic tools for which licensing can cost up to

$20,000 and this is cost prohibitive, especially for fleet operators that maintain vehicles from multiple manufacturers. ABA also commented that the cost of diagnostic tools and repair time should be included in the rule.

EPA received comment from EMA and CARB on additional parameters for freeze frame data. EMA commented that expanding freeze frame parameters in 1971(h)(4.3) to include 1971.1(h)(4.2) should be deleted since expanding the freeze frame parameter requirements to include all of 1971.1(h)(4.2) would increase nonvolatile ECU memory needed and that 1971.1(h)(4.3) is adequate for service requirements. CARB supported additional freeze frame parameters, but only where there is an identified benefit to owners, inspectors, or repair technicians.

EMA commented on the need for clarification on if a change in policy has been made to allow certification of OBD partial monitoring strategies for multi-bed catalyst systems as they have not been approved to date.

EPA received negative comments from DTNA, PACCAR, Roush, and EMA for the requirement of a DEF dosing and SCR test due to complexities in the manufacturing and operation of these systems. OOIDA and NASTC commented and both supported the requirements for a DEF dosing and SCR test, stating that it would aid operators and fleets in diagnosing errors in aftertreatment systems.

CARB commented that the DEF dosing and SCR tests are available with some manufacturer developed diagnostic tools and supported the requirement for these tests to be available on GSTs if these tests would be beneficial to operators and fleets.

CARB commented on an incorrect reference in the proposed 40 CFR 1036.110(c)(4) that should have referenced 40 CFR 1036.110(b)(10).

Response:

As explained in preamble Section IV, EPA is finalizing the additional parameters consistent with the existing CARB requirements for generic scan tools according to 13 CCR 1971.1(h)(4.2). The focus is on aftertreatment repair and derated engines; it is not clear what Allison's specific concern or request is.

EPA did not propose adopting OBD REAL requirements for NOx emissions based on on-board NOx sensors for SI engines and is not finalizing this requirement. We look forward to working with CARB, potentially in a future rulemaking, on this topic.

EPA appreciates the comments from DNREC, DSCC, ICCT, OOIDA and NASTC in support of adopting robust OBD requirements that help combat mal-maintenance to ensure long-term emissions performance. EPA is confident our requirements meet these goals.

EPA did not propose and is not finalizing changes to the Over-the-Air (OTA) software reflash requirement or other changes requested in Cummins' comment. EPA may consider changes to reduce OBD burdens as appropriate in a future rule.

EPA appreciates CARB's, Roush's, and DTNA's concerns that sufficient time is needed to adopt parameters through SAE and has finalized these requirements for MY 2027, as further explained in preamble Section IV. Many, if not all, of these parameters are from J1939 today. We appreciate CARB's support of additional data parameters and freeze frame data to improve serviceability experiences. We have finalized a reduced set of data parameter and freeze frame requirements from those proposed after further consideration, see section IV.C.1.iii of preamble for further discussion. Further, we appreciate Roush's concerns about adopting the framing language included in ARB 1971.1(h)(5), ensuring parameters are defined and implemented consistent with J1979 or J1939 standards. That was EPA's intent and we have clarified this in 40 CFR 1036.

EPA does not control GST availability or design. These requirements are designed to ensure that manufacturers make a sufficient number of critical emission parameters available for GST manufacturers to read and incorporate into their design if they choose to. Generic scantools for heavy-duty products are available today in a variety of combinations and with varying levels of capability. EPA has finalized these requirements to improve the availability of such data to GST manufacturers, which will likely provide operators with more information to help diagnose critical emission system failures, especially those resulting in derates. GSTs are not a substitute for OEM tools, rather, they are a lower cost alternative and will not have the full capability of OEM developed tools developed for specific applications. EPA has appropriately not included the cost of these tools in the cost analysis for the final program. These tool purchases are optional and assist an owner or operator to troubleshoot issues in the case an owner or operator chooses to investigate issues themselves.

EPA appreciates the comments from CARB, EMA, PACCAR, Roush, DTNA, OOIDA, and NASTC on DEF dosing and SCR tests. After consideration of comments and consideration of the complexity of robust implementation, we are not taking final action on these requirements at this time.

EPA appreciates EMA's comments on freeze frame data and we have revised our final requirements from those proposed to reflect a more limited set of parameters more in-line with our intent, see preamble Section IV.C.1.iii. for further information on these revisions.

Regarding EMA's comment on clarifying the policy of EPA on certifying partial OBD monitoring strategies for multi-bed catalyst systems, at this time EPA is not making any policy changes on certifying partial OBD monitoring strategies for multi-bed catalyst systems. However, we intend to continue assessing this issue as technology advances and these systems become more prevalent.

7.5 Other comments on OBD

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

The NPRM requests comment on whether to allow manufacturers to use onboard emission sensors to help reduce testing burden associated with OBD certification, specifically on ways to reduce test cell time associated with component threshold testing (e.g., ways to use NOx sensor data instead of test cycle NOx measurements). While CARB staff does not have a proposal, CARB staff is supportive of evaluating additional ways to use tailpipe emission sensors to reduce engineering and testing burden associated with OBD certification and other certification requirements while maintaining effective programs. [EPA-HQ-OAR-2019-0055-1186-A2, p.78]

Organization: *Cummins Inc. (Cummins)*

Durability Demonstration Testing (DDE)

Instead of the use of tailpipe emissions sensors to reduce cert burden, propose that EPA introduces flexible, less prescriptive testing methodologies in the current test cell environment and allow manufacturers to exercise engineering judgement during demo testing. This would include running a subset of demo diagnostics using representative hardware (less aged systems) meeting the intent of regulators, through unofficial/manufacturer-directed test procedures and simulation analysis where appropriate, to come up with the demo results for certification. [EPA-HQ-OAR-2019-0055-1325-A1, p. 29]

Organization: *Oshkosh Corporation*

EPA notes comments received on its Advanced Notice of Proposed Rulemaking (ANPRM) regarding opportunities to utilize on-board NOx sensors in lieu of pre-certification test data for OBD compliance in certain circumstances, and the Agency requests further comment on whether and how such sensors could be used to help reduce test burden associated with OBD certification. See Proposed Rule, 87 Fed. Reg. at 17,528, 17,535. As noted above, Oshkosh supports the use of on-board sensors for demonstrating OBD compliance. We welcome the opportunity to work further with EPA to evaluate appropriate reporting options for this scenario, including options to gather certain data from the trucks while in operation to provide assurance that monitors and emission control systems are adequate for the vehicle application.[EPA-HQ-OAR-2019-0055-1226-A1, p. 4]

Organization: *Roush CleanTech (Roush)*

Roush believes the use of tailpipe emissions sensors or other robust technologies in order to determine failure based on actual rather than inferred emissions could be promising, and could eventually lead to reduced costs (after the initial increase in costs associated with ensuring the change does not result in backsliding). However, we believe this is well outside the scope of what could realistically be implemented in the required timeframe of this proposed rule and believe EPA should not consider this change as part of this regulation. [EPA-HQ-OAR-2019-0055-1276-A1, p.7]Organization: Truck and Engine Manufacturers Association (EMA)

EPA requests comment on whether and how to allow manufacturers to use onboard emission sensors to reduce test burden associated with OBD certification, and specifically with regard to a reduction of the test cell time associated with component threshold testing. The Agency suggested use of NOx sensor data instead of test cycle NOx measurements. [EPA-HQ-OAR-2019-0055-1203-A1, p. 98]

Tailpipe NOx sensors are not a replacement for test cycle measurements. EMA would instead recommend that EPA provide flexible, less prescriptive testing methodologies in the current test cell environment, and allow manufacturers to exercise good engineering judgement during demonstration testing. [EPA-HQ-OAR-2019-0055-1203-A1, p. 98]

EPA has requested comment on opportunities to reduce the OBD compliance and certification costs of the federal program through the use of modeling or calculation-based methods to replace testing requirements. That request also references test-out provisions. However, it is unclear if EPA is seeking comment on potentially eliminating test-out provisions. More clarity is needed regarding this request, and regarding the potential provisions to reduce compliance and certification burdens. [EPA-HQ-OAR-2019-0055-1203-A1, p. 99]

Organization: *Volvo Group*

The Volvo Group appreciates the following EPA Onboard Diagnostic flexibility comments. "... whether and how to allow manufacturers to use onboard emission sensors to help reduce test burden associated with OBD certification" (87 FR at p. 17535) "…alternative methods to use onboard emission sensors that could be used to generate and provide real-world data that may enable improved diagnostics, assess the function of emissions critical components and assess the implementation of dynamic AECD inputs." (87 FR at p. 17535) [EPA-HQ-OAR-2019-0055-1324-A1, pp. 5 - 6]

Future optional concepts could simplify diagnostics, deterioration factor testing, and in-use testing based on future NOx and PM sensor performance and durability. [EPA-HQ-OAR-2019-0055-1324-A1, p. 6]

EPA Summary and Response

EPA received comments from CARB, Oshkosh, Volvo that gave general support to reducing test burden by utilizing onboard sensors and diagnostics to provide real-world emissions data of high enough quality to reduce the amount of prescriptive testing.

Roush commented that they support the idea of reducing test burden by utilizing on-board sensors and diagnostics, but they also proposed to not finalize these requirements as the implementation timeline is not feasible for this rulemaking.

EMA and Cummins both proposed an alternate method of reducing test burden without using on-board sensor or diagnostics. They proposed to use less prescriptive test methods, including the use of systems that are less aged but meet the intent of the regulations, and unofficial/manufacturer determined test procedures.

- While we requested comment on this topic, we are not finalizing the provisions to reduce test burden suggested in these comments at this time. EPA appreciates the comments on this section and looks forward to further discussions with stakeholders on such topics.

8.1 Concept of speed derates for named fault conditions

Comments by Organizations

Organization: *American Bus Association (ABA) (1070 and 1308)*

Further, ABA does not believe EPA properly accounted for the costs associated with its flawed inducement policy and design strategy, even with the Proposals provisions to address this issue which in many ways seem aspirational. [EPA-HQ-OAR-2019-0055-1308-A1, p.8]

Unfortunately, when ABA has raised these issues with EPA, the Agency has admitted it has not collected sufficient data on the issue of fleet related reliability issues or equipment availability. Still, EPA has proposed codifying several inducement provisions in the Proposal, in an effort to address concerns raised, while still intending to “appropriately motivate or restrict certain types of human behavior.” ABA believes, in general, several of EPA’s proposed principles make sense, IF they are actually put into practice and work and are not simply aspirational. For example, establishing a consistent inducement policy among all engine manufacturers, fundamentally makes sense. Below, ABA provides additional feedback on specific proposed principles/provisions:

Finally, in addition to feasibility and costs, a major concern of the motorcoach industry is engine reliability and EPA’s inducement policy. The ABA does not believe EPA sufficiently understands the scope of the problem or adequately addresses the issue in the Proposal, particularly when the proposed new standards and testing cycles have the potential to exacerbate the derate issue. [EPA-HQ-OAR-2019-0055-1308-A1, p.8]

First and foremost, EPA needs to clearly recognize that their SCR inducement policy is a problem, and not describe it as a “mix of incentives and behaviors.” (Notice, Section IV.D.) It is a serious and costly problem for the motorcoach industry. The EPA inducement policy creates undue safety risks for drivers, passengers and other roadway users. The comments referenced in the Notice repeatedly note that EPA’s inducement policy leads to vehicles, and thus people, stranded or parked along a roadway. This is particularly a hardship and safety hazard for the motorcoach industry. In addition to carrying the precious cargo of human lives, unlike the property carrying industry, the motorcoach industry does not have the same flexibility or accessibility to equipment to easily replace a stranded vehicle or find a service repair station. Further, the timeframes for reacting to and/or resolving a derate situation are unreasonable. Also, in terms of timing, as there is currently a driver shortage in the motorcoach industry, limits on the hours a driver is able to drive coupled with time to address a derate issue, further challenges motorcoach operations in the face of the inducement strategy. [EPA-HQ-OAR-2019-0055-1308-A1, p.9]

It is also not a problem solely related to the amount or quality of diesel engine fluid or DEF. Engine inducements or derates deriving from DEF-related triggers are problematic; however, as the comments highlight, DEF-related issues are not the only triggers for derates. Derates can occur from software glitches, loose wiring, faulty sensors, cold temperatures and so forth. Also, troubling, is the lack of consistency in inducement design among engine manufacturers. Regardless of whether it be a DEF-related inducement or other trigger outside of the operators' control, derates are a prevalent and costly occurrence in the motorcoach industry, that raises serious safety and economic concerns. EPA's inducement policy, ABA believes, again highlights EPA's lack of understanding of the motorcoach industry, a key stakeholder subject to its emissions control program. Inducements or derates lead to increased safety risks and often unnecessary operating costs, and loss of business credibility and good will. ABA and other motorcoach stakeholders provided survey results to the EPA, featuring the responses of a variety of fleet operators (Dated Oct. 15, 2021) to their experiences with SCR systems and derate conditions. A couple of highlights to note from that survey:

* 94.66% have had some kind of emissions-related repair issue.

* 92.2% have had an emissions-related issue occur mid-trip.

* 94% experienced a forced regeneration. Required with special software not available at most shops.

* 72.6% had to tow a bus to a facility as a result of an emissions-related breakdown.

* The cost of a tow and related repairs is estimated to average around $7500-8000 per instance.

* 75.8% said that their emissions related breakdown was a result of a faulty sensor. [EPA-HQ-OAR-2019-0055-1308-A1, p.9]

Overall, ABA would prefer to work with EPA further to ensure an adequate body of data is made available to inform development of proposals concerning derates, and believes the Proposal is too rushed. We do see potential value in terms of relief from derate burdens if they work as intended. Yet would like to work with EPA to explore additional relief options such as the voluntary application of auxiliary emission control device's (AECD) on previous model year engine's dating back to 2008 to help mitigate existing issues with faulty derate inducements. As to the specific questions EPA seeks comment on under the inducement strategy section, Section IV. D., ABA will consider providing additional input through supplemental comments. [EPA-HQ-OAR-2019-0055-1308-A1, pp.10-11]

Organization: *American Lung Association et al.*

Ensure pollution benefits are not reduced by credits or tampering. US EPA should work with California to develop a national approach to ensuring meaningful operator inducements to correct emission control failures in a timely manner and to protect against tampering with emission control systems. [EPA-HQ-OAR-2019-0055-1271-A1, p.3]

Organization: *American Trucking Association (ATA)*

While ATA cannot address every aspect of HD2027, we are supportive of the underlying environmental objectives and several of the elements being proposed. ATA's areas of support include: Modifications to the derate schedule are justified to improve access to repair facilities and avoid unsafe operating speeds. [EPA-HQ-OAR-2019-0055-1326-A1, p. 3]

The industry wholly understands EPA's rationale behind low-speed derates. To be perfectly clear, neither fleets nor drivers wish to experience derate episodes which have the potential to create both safety and delivery concerns. Yet, following more than a decade of experience, derates are still occurring at unexpected rates. In surveying fleets, the reasons behind derates do not involve inadequate DEF levels or quality, but rather include a variety of reasons such as:

• Sensor, parts, and wiring harness failures

• DEF quality, heaters, headers, dosers, coolers, and pump /level issues

• Bad pin connectors

• EGR coolers

• Aftertreatment Control Modules [EPA-HQ-OAR-2019-0055-1326-A1, pp. 17 - 18]

ATA supports EPA's efforts to modify the current derate schedule. ATA member companies, in response to the survey included as Appendix A, have indicated this modification should ensure adequate time for drivers to reach repair facilities while avoiding operating at unsafe speeds and/or the need to have the vehicle towed, which can add thousands of dollars to the cost of repair. Other considerations include providing adequate time for vehicles operating in remote areas to reach repair facilities as well as allowing drivers to finish their deliveries should the in-cab display appear during a shift. The proposed modification will also provide fleets with added time to access preferred repair facilities as opposed to the limited choices they may have under the existing 5-mph derate schedule. [EPA-HQ-OAR-2019-0055-1326-A1, p. 18]

Organization: *American Truck Dealers (ATD)*

ATD does not oppose the codification of existing guidance that SCR-equipped HDEs require power derating when SCR is not being properly used. Power derating has proven generally to be a reasonable and effective means to ensure that operators perform critical emissions related scheduled maintenance on the SCR system and that HDEs be operated using quality DEF.15 At the same time, ATD is concerned that improperly functioning SCR derate inducements can lead safety issues or to operator tampering. [EPA-HQ-OAR-2019-0055-1321-A1, p. 7]

15. Id at 17539.

EPA is proposing to require inducements to ensure that SCR systems are designed to be tamper-resistant, thereby reducing the likelihood that they will be circumvented. In addition, EPA is proposing to require monitoring of certain emissions-related components, and the triggering of an inducement if tampering is identified. NADA generally agrees with EPA that a standard list of tampering inducement triggers would aid owners, operators, and fleets in the repair of their vehicles by reducing the cost and time required to diagnose the reason for inducement. At the same time, ATD echoes the concern raised by EMA with respect to revisions to SCR inducement strategies and to allowed minimum maintenance intervals. [EPA-HQ-OAR-2019-0055-1321-A1, p. 7]

Organization: *California Air Resources Board (CARB)*

The NPRM requested comments on the proposed SCR derate schedule. CARB staff has serious concerns regarding the proposed inducement strategy for the SCR aftertreatment system and believes significant changes are needed to prevent unacceptable weakening of the SCR inducement requirements and the corresponding erosion of emissions benefits. The NPRM rightly states that 'operating an SCR-equipped engine without DEF would cause NOx emissions to increase to levels comparable to having no NOx controls at all.' A 2013 report by CARB staff showed vehicle NOx emissions increasing egregiously when DEF is depleted, contaminated, or tampered with, such that NOx emissions were six to ten times higher than baseline emissions.150 Thus, the proper function of the SCR aftertreatment system depends on an adequate supply of high-quality DEF and is critical to the control of NOx emissions from late model HD diesel trucks. [EPA-HQ-OAR-2019-0055-1186-A2, pp.88-89]

> 150 California Air Resources Board, Field Evaluation of Heavy-duty Diesel NOx Control Strategies, January 2013. https://ww2.arb.ca.gov/sites/default/files/2020-05/ADA__scr-field-eval_report-final.pdf

Over the last twelve years, the manufacturer’s guidance document, CISD-09-04R,151 and the joint U.S. EPA and CARB July 2010 workshop152 provided the structure and guidance for SCR inducement strategies to maintain an adequate supply of high-quality DEF to the SCR aftertreatment system and discourage tampering. As with the past joint effort on SCR inducement strategies, we request that U.S. EPA staff work together with CARB staff prior to the Final Rule to develop a unified national approach to inducements for indicated SCR system component malfunctions that would ensure that the SCR aftertreatment systems are functioning properly and are not tampered with, while also addressing truck fleets’ concerns regarding misdiagnosed malfunctions that lead to improper inducement. [EPA-HQ-OAR-2019-0055-1186-A2, p.89]

> 151 United States Environmental Protection Agency, Revised Guidance for Certification of Heavy-Duty Diesel Engines Using Selective Catalyst Reduction (SCR) Technologies, December 30, 2009. https://dis.epa.gov/otaqpub/display_file.jsp?docid=20532&flag=1
>
> 152 California Air Resources Board, Selective Catalytic Reduction Workshop, July 20, 2010. https://ww2.arb.ca.gov/sites/default/files/2020-05/ADA__workshop--2010-07-20--scr--presentation.pdf

The current strategies for SCR inducement are based on CISD-09-04R and a joint U.S. EPA and CARB July 2010 public workshop that explained the guidance with detailed examples of inducement strategies that could be used. Since the details of this joint July 2010 workshop are absent from the NPRM discussion, the following summarizes the examples given at the workshop to guide manufacturers in their design of current SCR inducement strategies. [EPA-HQ-OAR-2019-0055-1186-A2, p.89]

For DEF level problems, the workshop example given to manufacturers was to warn the operator (either via audible or visible indicators, or both) of low-DEF levels before inducement so the operator has time to refill the DEF tank prior to activating inducement. If the operator does not proceed to address the DEF fill level, the first step of the inducement is initiated. CISD-09-04R provides guidance for 'progressing to further degradation that could include operation of the engine being disabled or severely restricted, implemented in a manner designed to prevent operation without DEF'. When DEF is almost depleted, the operator is warned again before a final inducement of 5 miles per hour maximum vehicle speed or no power to the vehicle or idle only is initiated. This final inducement would only occur at a safe harbor condition so as not to cause any safety concerns.[24] [EPA-HQ-OAR-2019-0055-1186-A2, pp.89-90]

For DEF quality and tampering problems, the workshop provided guidance that manufacturers needed to detect the problem within one hour and to notify the operator immediately. If after four hours the issue is not resolved, the operator would be warned again before initiating final inducement down to 5 miles per hour maximum vehicle speed or no power to the vehicle or idle only, which would only occur under safe harbor condition. Again, at each step of the inducement, the driver should be warned both audibly and visibly of the consequence of not taking action to correct the problem. Once the problem is corrected, the workshop guidance allowed for exiting the triggered inducement (self-healing) so that the vehicle can return to normal function. [EPA-HQ-OAR-2019-0055-1186-A2, p.90]

To give the operator warning of the inducement, CISD-09-04R and the workshop provided guidance to the engine manufacturer to give multiple driver warnings, either via visible or audible indicators, or both, before the initial inducement step and at each step of inducement. [EPA-HQ-OAR-2019-0055-1186-A2, p.90]

Two reports prepared by CARB staff subsequent to the workshop, in 2011,153 and 2013,154 contain detailed descriptions of the actual driver warning protocol used by several engine manufacturers. These reports showed that the vehicle operators received various visible warnings through the electronic driver information display, flashing or illuminated dash lights, and/or check engine light. The electronic display provided details of each step of the inducement, including a countdown to the remaining miles for final inducement, and was often accompanied by single and periodic audible chimes. Based on the guidance and 2010 workshop and description of actual driver warning protocols used by manufacturers, it is clear that inducement due to SCR is not required to and should not happen suddenly and without warning. On the contrary, multiple visible and/or audible warnings were required and implemented to provide

[24] CARB refers to "safe harbor" as a condition a vehicle is in prior to an inducement being applied, such that the application of an inducement would not cause a safety concern. Examples include at the time of refueling, when a vehicle is parked or at idle, or prior to a vehicle being restarted.

adequate warning before inducement and hence to alleviate potential safety concerns for the operator. [EPA-HQ-OAR-2019-0055-1186-A2, p.90]

153 California Air Resources Board, Heavy-duty Vehicle Selective Catalytic Reduction Technology Field Evaluation, May 2011. https://ww2.arb.ca.gov/sites/default/files/2020-05/ADA__scr-field-eval_report.pdf

154 California Air Resources Board, Field Evaluation of Heavy-duty Diesel NOx Control Strategies, January 2013. https://ww2.arb.ca.gov/sites/default/files/2020-05/ADA__scr-field-eval_report-final.pdf

Over the last twelve years, as the inducement guidance has been implemented by engine manufacturers, U.S. EPA and CARB staff have monitored the impacts of these inducement strategies and gained experience with what worked and what did not work. We must remember the overall goals of SCR inducement strategies: i.e., to ensure compliance with NOx emission standards by inducing operators to use high-quality DEF and fix faulty DEF related components, and by discouraging any tampering of the system. In achieving these goals, consideration should be given to owners and operators, whose livelihoods depend on functional vehicles and to their desires to reduce false inducements, reduce costly repairs, and avoid inducements causing safety concerns. Nonetheless, we must ensure that any changes do not significantly reduce the effectiveness of today's inducement requirements. Any changes to today's inducement requirements must still require timely repair to SCR systems that are not functioning properly, and prevent excess NOx emissions. Thus, U.S. EPA and CARB staff should work together to make changes that would reduce inducement impacts on vehicle owners and drivers while still maintaining the effectiveness of inducement strategies to minimize air quality impacts. CARB staff believes U.S. EPA's NPRM proposal does not strike the correct balance between protecting air quality and being sensitive to the needs and desires of vehicle owners and operators. On the contrary, in an effort to respond to vehicle owner and operator concerns, U.S. EPA's NPRM proposal goes too far in impermissibly weakening and dismantling today's effective inducement requirements. [EPA-HQ-OAR-2019-0055-1186-A2, pp.90-91]

The NPRM notes that the majority of ANPRM comments expressed concern that in-use vehicles are experiencing inducements for reasons outside of the operator's control despite the use of high-quality DEF and in the absence of any tampering. The ANPRM comments stated that many inducements (not related to tampering) were occurring due to defective SCR system components. Such inducements, called false inducements, can be difficult to diagnose and require repeated visits to the repair shop. Part of the false inducement issue is related to the quality and durability of components used by engine manufacturers. [EPA-HQ-OAR-2019-0055-1186-A2, p.91]

Table 9-1 and Figure 9-1 below show the number of California heavy-duty diesel engine families that have emissions related component warranty claims greater than 4 percent or 50 claims in the last 5 years. Of the 308 engine families with 4 percent or 50 emissions related component warranty claims, 299 (or 97 percent) had components that were replaced under warranty that could result in SCR inducement. If these parts had been designed to work correctly through the engine useful life, the total potential inducement events could have been reduced significantly. [EPA-HQ-OAR-2019-0055-1186-A2, p.91]

Manufacturers need to ensure that they utilize components that are robustly designed and manufactured to minimize false inducement incidences. While CARB has required recalls for SCR inducements that did not work as approved, CARB has not initiated any recalls specifically to address false inducement. CARB's changes to the EWIR program as part of the Omnibus adoption should improve the effectiveness of identifying and repairing malfunctioning parts, and U.S. EPA should also consider adopting similar requirements in the CTP. EWIR changes include requiring corrective action once the warranty threshold is met. U.S. EPA's proposed NPRM changes to lengthen warranty will also help reduce false SCR inducements because manufacturers will be required to make repairs for much longer periods over the vehicles' useful life, driving manufacturers to reduce their cost liability and improve the design of components. [EPA-HQ-OAR-2019-0055-1186-A2, p.93]

Rather than simply proposing to significantly weaken inducement schedules to address false inducements, U.S. EPA should put in place more effective requirements to ensure manufacturers are addressing poor component quality and durability issues. In fact, CARB staff believes that U.S. EPA's proposed Option 1 changes to extend manufacturer warranty requirements will provide an effective incentive for manufacturers to make improvements to monitored SCR system components to reduce their future cost liability. [EPA-HQ-OAR-2019-0055-1186-A2, pp.93-94]

CARB staff has concerns with the proposed Selective Catalytic Reduction (SCR) anti-tamper inducement changes in 40 CFR 1036.111. CARB recommends that U.S. EPA direct staff to work with CARB to develop a nationally aligned SCR inducement requirement that both addresses fleet concerns and ensures SCR emission control systems are functional, effective and tamper resistant. [EPA-HQ-OAR-2019-0055-1186-A1, p.2]

CARB's Omnibus regulation that became effective in December 2021 requires more rigorous durability testing during the certification process and longer warranty and UL requirements for 2024 and subsequent model year engines. It is anticipated that these improvements will result in better quality and durability of emission control components. Additionally, the Omnibus regulations also improved California's EWIR program which requires manufacturers to conduct corrective actions such as providing extended warranties and/or recalling faulty components if component failure rates meet or exceed established thresholds levels. Lastly, the Omnibus regulations also established rigorous in-use compliance and recall provisions. The NPRM proposes many of these same Omnibus regulatory provisions, and CARB staff urges U.S. EPA to adopt provisions equivalent to those Omnibus provisions that will provide further assurance that SCR systems will become more durable and reliable. [EPA-HQ-OAR-2019-0055-1186-A2, p.94]

In response to the comments submitted during ANPRM, CARB staff initiated a limited survey of 33 randomly selected California fleets to better understand their experience with inducements (Appendix III) [Appendix III can be found at EPA-HQ-OAR-2019-0055-1186-A2, pp. 146-164]. Through our normal warranty and in-use testing processes, CARB staff had not been aware of the inducement-related concerns described in the ANPRM. The survey was conducted from October 2021 to February 2022, either in person or by phone. The survey requested information on fleet vehicle data, the frequency of derates, what problems caused the derate, safety concerns, and other issues. The fleet owner or operator was informed that derates may occur due to engine protection or due to SCR inducement as a result of system malfunctioning or tampering, and the survey requested their assessment of the knowledge of the two different types. Almost 80 percent of owners had good knowledge differentiating between derates for engine protection versus aftertreatment system performance. However, only 19 percent of the operators had a good knowledge to differentiate the 2 types of derates. Thus, it is highly possible that the vast majority of operators may not have adequate knowledge to take appropriate action on SCR derate conditions and to avoid entering into severe inducement, which makes the vehicle virtually inoperable. [EPA-HQ-OAR-2019-0055-1186-A2, p.94]

The survey information showed that on average, fleet owners and operators reported that 21 percent of the vehicles experienced engine protection or SCR related derates on an annual basis, with incidents of derates occurring more often with 2013 to 2018 MY vehicles that have more than 160,000 miles. Out of 33 fleets, 3 fleets reported no derates and gave the reason that they maintained their vehicles regularly, including sensor replacements, and/or had vehicles that were less than one year old. [EPA-HQ-OAR-2019-0055-1186-A2, p.94]

In the survey, fleets that experienced derates were asked for the cause, and 37 percent were for failed NOx or DEF quality sensors. This was by far the highest incident of experiencing a derate condition. The next highest was failure of the DEF doser at 17 percent of incidences, while low-DEF level was the cause of 9 percent of incidences. None of the fleets reported derates due to poor quality DEF, which would be the result of poor DEF quality sold in the marketplace or DEF fluid dilution that would be tampering. This is consistent with industry efforts to assure the high-quality DEF supply chain155 and CARB staff's earlier surveys of DEF availability and driver usage156. Other causes of derates were plugged DPF (8 percent), and other aftertreatment-related problems such as those resulting in poor NOx conversion, bad DEF pumps, DEF heater problems, wiring harness issues, and calibration problems (19 percent.) Other non-aftertreatment related problems, such as turbochargers, carbon buildup in the EGR system, and engine temperature problems, accounted for the remaining 9 percent. [EPA-HQ-OAR-2019-0055-1186-A2, p.95]

155 https://www.api.org/products-and-services/diesel-exhaust-fluid/

156 https://ww2.arb.ca.gov/sites/default/files/2020-05/ADA__scr-field-eval_report.pdf

To address the problem and override the derates, 84 percent of the fleet owners and operators responded that derates were able to be addressed without major disruption. However, often it took two or more visits to the repair facility to properly diagnose and address the problem. On average, 33 percent of the vehicles needed work done more than once in a year due to derates. Of the vehicles brought in more than once in a year due to derates, 29 percent were a result of a recuring problem that was not properly addressed in the first repair visit. Significantly, this multiple trip repair impacted almost 10 percent of the total number of vehicles experiencing derates covered by the survey. [EPA-HQ-OAR-2019-0055-1186-A2, p.95]

CARB staff's fleet survey also included fleets have safety related concerns regarding inducements. A large portion, 42 percent, of the owners and operators expressed that they would have safety concerns if they were to experience a derate. A significant minority of owners and operators, 18 percent, had actually experienced some safety concerns due to a derate, such as sudden power loss when operating at highway speeds, power loss coming down a step road grades or power loss during uphill grades and during heavy vehicle traffic conditions. The remaining 82 percent of owners and operators never encountered a dangerous situation with derates or had no comments on the safety concerns. [EPA-HQ-OAR-2019-0055-1186-A2, p.95]

In conclusion, CARB staff's fleet survey shows that current inducement requirements are effective in getting repairs done promptly, with 84 percent of the fleet owners' and operators' responses indicating that derates were easy to address. On average, about one-fifth of these fleet vehicles had experienced derates on an annual basis. Failed sensors, failed DEF doser, and low-DEF levels accounted for over 60 percent of the derate causes (37 percent, 17 percent, and 9 percent, respectively), and thus, the inducements were successful in correcting the problem. While a significant percentage of fleet owners and operators expressed some safety concerns concerning inducements, a much smaller percentage had actually experienced a derate condition that resulted in significant safety concerns. Within this group, it is uncertain whether the derate where the operator experienced significant safety concern was due to an engine protection derate, which may occur immediately to prevent damage to the engine, or whether it was an SCR inducement, which should have provided audible and visible warnings, per the current guidance, to the operator before a derate condition was implemented. Regardless, safety concerns are important to address, and improving and aligning these warnings protocols amongst all manufacturers through regulation may improve these safety concerns. NPRM's proposal to codify in-cab display requirements should provide adequate warning to the operator, as discussed later. [EPA-HQ-OAR-2019-0055-1186-A2, pp.95-96]

CARB staff also recommends removing the NOx sensor as a fault condition in the proposed 40 CFR 1036.111(b) since the NOx override factor, based on the NOx sensors, can be used to override the NOx sensor fault condition. [EPA-HQ-OAR-2019-0055-1186-A2, pp.103-104]

The NPRM requests comments on whether it was proper to use DEF fill level, quality, and tampering to determine fault conditions that may result in SCR inducement. The current inducement guidance defines these three parameters as critical to proper SCR function, and CARB staff continues to agree that these parameters must be monitored. [EPA-HQ-OAR-2019-0055-1186-A2, p.105]

In particular, the NPRM requests whether DEF quality continues to be an issue to monitor since operators have an established practice of using DEF and engines may now have built-in features to prevent diluting DEF or filling a DEF tank with water. Monitoring the use of high-quality DEF continues to be a critical parameter to achieve low NOx emissions from the SCR-equipped HD vehicles. Two HD vehicles tested by CARB staff in 2011/2012 showed that when the DEF was diluted with water, NOx emissions increased eight to ten times the baseline emissions where high-quality DEF was used.169 Without proper monitoring, DEF quality is too easily tampered with, which could lead to excessively high NOx emissions and multiple inducements. The current success and established practice of the use of high-quality DEF, along with engines that have built-in features to compensate for DEF quality, demonstrate the success of current guidance practices that are effective in assuring high quality DEF is used. Staff disagrees with the NPRM statement on page 17541 that 'the cost of DEF at the pump is not that different from the cost of distilled water.' As an example of recent DEF prices, the website price of DEF at Pilot and Flying J truck stops averages $3.89 per gallon across stations in the United States170 while the cost of distilled water is a mere $1.08 per gallon.171 Thus, since DEF costs more than three times the cost of distilled water, a substantial financial motivation still exists for operators to refill the DEF tank with fluids other than the manufacturer's recommended DEF or to tamper with DEF by diluting the tank with water. This will become even more important as the new more stringent CTP NOx standards will require an increased amount of DEF, increasing the desire to tamper with DEF quality to reduce cost. Any relaxation of current monitoring requirements may result in the increased use of poor DEF quality, causing significant increase in excess NOx emissions from tampered HD vehicles. [EPA-HQ-OAR-2019-0055-1186-A2, pp.105-106]

169California Air Resources Board, Field Evaluation of Heavy-duty Diesel NOx Control Strategies, January 2013. https://ww2.arb.ca.gov/sites/default/files/2020-05/ADA__scr-field-eval_report-final.pdf

171 https://www.walmart.com/ip/Great-Value-Distilled-Water-1-Gallon/10315382

The NPRM requests comment on the proposed circuit fault condition. CARB staff recommends that the word 'open' be eliminated from the 'open-circuit faults' in 40 CFR 1036.111(b)(4). This would allow a more general specification of circuit faults to include other types of faults that may occur with tampering such as short circuit faults and rationality faults, and thus provide a more comprehensive coverage of tampering and electrical functionality. Additionally, staff recommends adding a more general descriptor of DEF components at the end of the circuit fault list to include components other than those listed, such as 'and any other components that affect the performance of listed DEF components, as determined by the engine manufacturer.' [EPA-HQ-OAR-2019-0055-1186-A2, p.106]

CARB staff agrees that starting the fault condition of the low-DEF level at three hours is appropriate rather than when DEF is depleted. In fact, it is recommended that a dash warning of low-DEF level before three hours be given to the operator to provide additional opportunity to take action prior to inducement. CARB staff believes warning the operator before the point of DEF depletion is absolutely necessary from an emission abeyance perspective and to alert the operator prior to the initial torque and speed inducement. In CARB staff's fleet survey, nine percent of inducements were due to low-DEF levels, and thus notifying the operator of low DEF levels well ahead of inducement allows more opportunity for correcting this condition before inducement is initiated. This is one of the most easily correctable conditions, and advance notification to the operator to refill the DEF tank would reduce air quality impacts as well as help avoid vehicle downtime and costs due to severe inducement. [EPA-HQ-OAR-2019-0055-1186-A2, p.106]

CARB staff believes that current DEF freeze protection guidelines are important because DEF may freeze under certain circumstances and will not be available to flow to the SCR system, causing excess emissions. Thus, staff supports the current DEF freeze protection guidance and believes that it should be codified and described by the manufacturer to U.S. EPA through Auxiliary emission control device (AECD) disclosure requirements. Also, fault conditions due to tampering of freeze protection components should be included in 40 CFR 1036.111 (b). [EPA-HQ-OAR-2019-0055-1186-A2, p.106]

Organization: *Carreras Tours, LLC (2032)*

We had an experience where our bus got a check engine light going on interstate 5 in central California. We had students on board and the bus derate to 5 MPH. The good thing is that we happened to be less than a mile from an exit. We feared that a truck might rear end us and injure the passengers. It took several hours to get a rescue bus to pick up the group. All this could have been avoided if time for us to diagnose the problem in a shop, and in a safe place where the bus and the passengers were safe. If a sensor fails, the bus derate the bus immediately and gives us no chance to get to a safe place. In this instance, it was a $20 sensor that failed. [EPA-HQ-OAR-2019-0055-2032, p.1]

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

EPA should improve the stringency of its proposed modifications to its inducement program to better ensure that operators properly maintain emissions control equipment. As EPA notes, SCR systems depend upon ‘an adequate supply of diesel exhaust fluid (DEF).’ 87 Fed. Reg. 17,536–38. ‘Inducement’ systems—creating engine derates that reduce a vehicle’s maximum speed when the SCR lacks adequate DEF or the system has been tampered with—ensure that operators sustain that supply and properly maintain their aftertreatment systems. Id. at 17,537. In response to complaints that ‘vehicles are experiencing inducements for reasons outside of the operator’s control,’ which may be ‘difficult to diagnose,’ EPA has proposed ‘progressively increasing inducement derate schedules,’ which restrict the maximum speed of vehicles with tampered SCRs or which have failed to maintain adequate DEF supply. Id. at 17,538, 17,543. [EPA-HQ-OAR-2019-0055-1302-A1, p.62]

As EPA acknowledges, lack of adequate DEF can cause NO X emissions to increase to levels comparable to having no NOx controls at all.’ Id. at 17,536. That is likely to be especially harmful in urban areas where HDV operations are concentrated, and where vehicles are consistently operating at speeds well below EPA’s proposed derates. [EPA-HQ-OAR-2019-0055-1302-A1, p.63]

Organization: *Champion Auto Carriers*

Having been in the transportation industry for over 35 years I have witnessed what the DEF regulations has cost my business and drivers since 2012. Down time for DEF issues account for 90% of my overall downtime and driver expense. Maybe the EPA should be looking at better technology or systems to reduce NOx but allow for better performance and uptime. We can't afford any extra truck costs or maintenance costs and still deliver the goods and services trucking provides. [EPA-HQ-OAR-2019-0055-2733, p.1]

Organization: *Coach USA, Inc. (Coach USA)*

However, any derate program for buses is likely unable to ensure the level of safety needed to protect passengers. Coach USA thus supports the ABA proposal that motorcoaches be excluded from any derate requirements that would apply to most trucks and instead be allowed the flexibility of being treated the same as vehicles that respond to emergencies. This can be done by allowing engine manufacturers the flexibility to use approved Auxiliary Emission Control Devices with motorcoach engines. This would avoid the safety risks associated with applying a truck-centered derate system to passenger-carrying vehicles as well as the costs that our industry cannot tolerate. Coach USA thus encourages EPA to study such alternatives to the need for any derate inducement system for the motorcoach sector. [EPA-HQ-OAR-2019-0055-1307-A1, pp. 3-4]

With the above general caveats, if any Proposed Rule is adopted that would apply to motorcoaches, Coach USA believes that the proposed derate schedule would effectively lead bus owners/operators to address certain detected fault conditions within the duration of the schedule specified under the Proposed Rule. [EPA-HQ-OAR-2019-0055-1307-A1, p. 4]

Coach USA supports the latter proposal – that the engine be designed to warn an operator when the DEF supply is running low and the inducement start when the DEF supply is depleted. Coach USA closely monitors and maintains is buses, including ensuring adequate DEF supply at the start of each trip. Refilling of DEF supply, depending on bus routes, may occur within 3 hours of depletion. However, Coach USA believes that it, or its drivers, should not be penalized with the inducement starting at that time, before the DEF supply has been depleted. Coach USA also recommends that EPA require manufactures to provide more precise information to drivers to alert them about DEF levels and how long remaining DEF volumes will last; this will allow drivers to plan accordingly to address a fault condition, while taking into account route schedules and stops. [EPA-HQ-OAR-2019-0055-1307-A1, p. 5]

Coach USA believes that no less than 6 hours of non-idle operation is reasonable for the first stage of inducement to address low DEF, but is not a sufficient amount of time for more major fault conditions that may require repair. Interstate bus routes extend throughout the country, oftentimes far away from Coach USA facilities or other third-party bus repair facilities. Bus repair is also very specialized, with limited repair locations. It is also not a certainty that bus repair facilities will possess the required equipment/software to diagnose and repair a fault condition. Parts, as evidenced throughout the pandemic, may also not be readily available. [EPA-HQ-OAR-2019-0055-1307-A1, p. 5]

Accordingly, buses will not always have the ability to reach a bus repair facility within a 6-hour period when a fault condition prompts repair or replacement of components. Coach USA believes that a minimum 10-hour period for the first stage of inducement, and preferably longer, is appropriate for all default conditions due to other than low DEF levels. This longer period will ensure that passengers are kept safe and not potentially stranded along interstate bus routes. On this point, EPA should aware of the difficulty/inability of bus operators to locate alternative buses to pick-up passengers along interstate routes. Our industry is currently struggling with a serious shortage of drivers, which has reduced operational flexibility. The industry has also experienced a major reduction in the number of bus operators due to COVID, as noted above. Accordingly, Coach USA supports an approach that ensures the ability of its drivers to address a fault condition upon completion of a route. [EPA-HQ-OAR-2019-0055-1307-A1, p. 5]

The relatively short comment period allowed for the EPA's massive (475-page) and technically-complex proposed rules was grossly insufficient to allow Coach USA to adequately analyze all of the implications of the proposed rules on its business and its customers. [EPA-HQ-OAR-2019-0055-1307-A1, p. 2]

Organization: *Cummins Inc. (Cummins)*

EPA has appropriately defined key principles for updating SCR inducements to ensure that emission control function and emissions reductions occur in-use while reducing potential impacts to operators. Cummins is supportive of less severe SCR inducements such as those in EPA's proposed vehicle speed derate schedule in §1036.111(d). However, we recommend that EPA consult with NHTSA on the safety related aspects of the proposal before finalizing it. [EPA-HQ-OAR-2019-0055-1325-A1, p. 14]

In response to request for comment on including an advance notice/warning to the operator in the event of a plugged DEF line or doser, as opposed to actual tampering, Cummins proposes that EPA consider not including this concept as it is challenging to effectively differentiate blocked DEF line/doser due to direct tampering vs. actual urea crystallization/line plugging. [EPA-HQ-OAR-2019-0055-1325-A1, p. 31]

Organization: *District of Columbia Department of Energy and the Environment (DOEE)*

DOEE does not support EPA's proposed changes to the in-use strategies designed to ensure that operators maintain their NOx emission control equipment. [EPA-HQ-OAR-2019-0055-1299-A1, p. 5]

EPA proposes changes that would significantly weaken "inducements" for maintaining Selective Catalytic Reduction (SCR). Since SCR is the most effective means of reducing NOx emissions from diesel engines, when these devices are malfunctioning, NOx emissions soar. Such unacceptable NOx increases can occur from a combination of vehicle neglect, part failures, and malicious tampering with diesel exhaust fluid (DEF), hardware, and software. While the longer warranties proposed and discussed below should provide motivation to resolve design defects and inferior parts, the issues of neglect or tampering require an intentional and diligent approach in the inducement program to ensure adverse emission impacts are minimized. [EPA-HQ-OAR-2019-0055-1299-A1, p. 6]

EPA states in the NPRM that it has received many complaints about inducements, and specifically about the use of DEF, the majority of which express concerns "that despite the use of high-quality DEF and in the absence of tampering, in-use vehicles are experiencing inducements for reasons outside of the operator's control". It is unclear how many of the experiences leading to these complaints are specifically related derating due to SCR inducements verses general engine protection derating that operators can also experience. Among the cited reasons outside the operator's control are faulty sensors and software "glitches". Both would be warrantable issues that should receive increased manufacturer attention under the significantly longer warranty periods advocated here. Simply ignoring these design issues would be deeply problematic and fundamentally undermine the effectiveness of the NOx program. [EPA-HQ-OAR-2019-0055-1299-A1, p. 6]

Finally, rather than just relaxing inducements and potentially allowing a truck with improperly maintained SCR to continue operating with nominal constraint, EPA should put in place measures that will hold manufacturers accountable for addressing the durability and sensor issues about which the agency, dealerships, and manufacturers have received complaints. [EPA-HQ-OAR-2019-0055-1299-A1, pp. 6 - 7]

Organization: *FitzGerald Brothers Bus Co.*

Recently I had a group of 50 people in a bus at 2:00am 500 miles away and the bus decides to de-rate and then shut down because of some sensor is not reading emissions correctly. Lost $10k on that job, lost the customer, driver quit. Why- All due to a small little NOx sensor that needs to read emission input Vs. Output on the SCR. Could the software had allowed us another 8 hours, all this could have been avoided. Why such a quick setting for a shut down? [EPA-HQ-OAR-2019-0055-1149-A1, p.1]

Organization: *International Council on Clean Transportation (ICCT)*

ICCT agrees with EPA that an update of current inducement policies is appropriate. A decade of experience has confirmed inducements are successful in encouraging timely emission-related repairs. Based on operator comments, updates that reduce the downtime of trucks resulting from the inducements also need to be considered. We also agree it is time to replace nebulous guidance documents with clear regulatory requirements that govern certification approval of engine manufacturer inducement strategies and software. [EPA-HQ-OAR-2019-0055-1211-A1, p. 20]

EPA's proposal to modify SCR-related inducements includes several new approaches ICCT supports. These include derates based on speed, a separate derate schedule for trucks that operate mainly at lower speeds, and the use of NOx sensor data to provide an estimate of the importance of initiating inducements. However, ICCT believes the specific provisions of EPA's proposed changes will reduce the incentive for many truck operators to achieve emission-related repairs, and result in higher in-use emissions that are unnecessary. This contradicts EPA's stated belief that the proposed inducement modifications will provide a "net benefit…to the environment". [EPA-HQ-OAR-2019-0055-1211-A1, p. 20]

EPA proposes changes to SCR inducement provisions that we expect will increase real-world NOx emissions, undermining the important improvements the proposal makes in other areas to address this gap. [EPA-HQ-OAR-2019-0055-1211-A1, p. 3]

If the problems with false readings or failure of DEF quality sensors are addressed by engine producers developing and using more reliable sensors, it would reduce the adverse impact on operators. The much longer emission warranty proposed by EPA will increase the incentive for engine manufacturers to use more reliable sensors since they will have to cover the cost of repair for the majority of the truck's life. In addition, improved NOx sensors may also provide an alternative means of determining DEF quality without use of a physical quality sensor, as this approach was used by some OEMs when the inducement requirements were first imposed. [EPA-HQ-OAR-2019-0055-1211-A1, p. 23]

We recommend adoption of EPA's proposal to add additional monitoring of disconnection of devices. This will help prevent tampering. The EPA proposed extended warranty will provide an incentive to engine manufacturers to address operator claims of frequent defective electrical connections of SCR-related devices. [EPA-HQ-OAR-2019-0055-1211-A1, pp. 23 - 24]

We support efforts that would communicate in natural language and not computer codes the fault conditions that may trigger inducements. Lowering these communication barriers would reduce the impacts of trigger inducements on vehicle down-time. [EPA-HQ-OAR-2019-0055-1211-A1, p. 24]

Organization: *Maine Department of Environmental Protection (Department)*

Using the CARB Heavy-Duty Omnibus Regulation as a bellwether, the Department requests the following revisions to the federal proposal: [EPA-HQ-OAR-2019-0055-1288-A1, p.6]

- EPA should not ease measures designed to prevent the avoidance of maintenance or repair costs. Rather than relaxing inducements and potentially allowing a truck with improperly maintained SCR to continue operating with nominal constraints, manufacturers should be held accountable for addressing durability and sensor issues. [EPA-HQ-OAR-2019-0055-1288-A1,p.7]

Organization: *Midwest Bus & Motorcoach Association*

Our primary concern involves the proposed "derate" or "inducement" schedule, which will result in a vehicle experiencing a significant loss of power and torque. This change in power has placed an undue burden on operators since 2008, when it was first implemented. There are numerous repercussions directly related to derates. Motorcoaches often travel to remote areas across the country unlike local transit or school buses that commonly transport intrastate and are home daily. Motorcoaches will drive far distances all times of the day or night making the ability to service a vehicle in a timely manner very difficult. Motorcoaches could be thousands of miles from home or even from an equipped service facility that could assist with a breakdown. This challenge for companies is far greater than what may be realized. [EPA-HQ-OAR-2019-0055-1158-A1, p.1]

When the equipment experiences an inducement, there are fewer options than other types of vehicles fitted with SCR. Since most of the vehicles have manufacturer-specific components, drivers are at most times limited to finding the right parts to fix a vehicle that is over the road. Additional costs involved include towing, outside repair service, reimbursing customers for missed events, refunding customers for long delays, contracting with other companies to move the passengers, and damaging the overall reputation of the company. [EPA-HQ-OAR-2019-0055-1158-A1, p.2]

Aside from the large expenses motorcoach operators must absorb, a more important point is the safety risk a derate presents our passengers. It is our opinion that a regulation crippling or limiting the speed of any vehicle is unacceptable, dangerous, and jeopardizes lives. **This industry is very unique as it transports the most valuable cargo on the road, human lives.** A large number of operators provide a significant amount of travel for school groups and young athletes. Having a motorcoach filled with children is quite different than transporting a truckload of consumer goods or raw materials. There is no room for error when it comes to safety practices and maintaining a proper speed to avoid a fatal rear-end collision on a highway. It will only be a matter of time before a distracted driver drives into the rear of a derated or stranded motorcoach full of passengers. [Emphasis in original; EPA-HQ-OAR-2019-0055-1158-A1, p.2]

Organization: *Motorcoach Companies*

Our primary concern involves the proposed “derate” or “inducement” schedule, which will result in a vehicle experiencing a significant loss of power and torque. This has put an undue burden on operators since 2008 when this first was implemented. The challenges these companies face are far greater than what you may realize or be aware of. There are numerous repercussions directly related to derates. Often times we are traveling in remote areas across the country and areas. Unlike local transit or school buses that are often Intra-State and home the same day, our coaches travel far distances, and at all times of the day or night. Therefore our ability to service a vehicle in a timely manner is significantly different given that our equipment could be thousands of miles from home or even from a equipped service facility that can help with break downs. [EPA-HQ-OAR-2019-0055-1149-A1, p.2]

When our equipment experiences an inducement, we have fewer options than other types of vehicles fitted with SCR. Since most of our vehicles have manufacturer specific components, we are at most times limited at finding the right parts to fix a vehicle that is over the road. There are several other expenses involved as well; including: towing costs, outside repair service costs, reimbursing customers for missed events, refunding customers for long delays, contracting other companies to move the group of passengers, and damaging the overall reputation of the company. [EPA-HQ-OAR-2019-0055-1149-A1, p.2]

Aside from the large expenses motorcoach operators must absorb, a more important point is the safety risk a derate presents our passengers. It is our opinion that the EPA crippling or limiting the speed of any vehicle is unacceptable. This is a blatant overreach that is jeopardizing lives. As we stated earlier, our industry is very much unique in that we are transporting the most valuable cargo on the road, human lives. A large number of operators do a significant amount of business with school groups and young athletes. Having a bus load of children is quite a bit different than transporting freight such as toilet paper, sneakers, or other material goods. We have no room for error when it comes to safety practices, and maintaining proper speed is of utmost importance to avoid a fatal rear end collision on the interstate. It will only be a matter of time before this takes place due to a distracted driver running into the rear of a derated or stranded passenger vehicle. **We want this to be on record that we have made our concerns**

widely known and that when an accident does occur, the blame will be on the EPA for any lives lost or hurt. [Emphasis in original; EPA-HQ-OAR-2019-0055-1149-A1, pp.2-3]

[Additional comment by several companies that joined this mail campaign:] **With this fair warning EPA will be held fully liable and any lawsuits resulting from such accident will be brought against EPA."** [Emphasis in original; EPA-HQ-OAR-2019-0055-1241 and 1267]

Organization: *National Association of Chemical Distributors (NACD)*

In this proposed rule, the EPA makes several adjustments to selective catalytic reduction (SCR) requirements. SCR systems are induced if a truck meets one of the prescribed triggers related to the vehicle's emissions. In this proposed rulemaking, the EPA adds provisions that would reduce the number of false inducements and implements a much more workable derate schedule. While the current derate schedule forces trucks to slow to 5 miles per hour (mph) in just 4 hours, the new regulations in this proposed rule would instead be implemented over 60 hours and reach final inducement speeds of 50 or 35 mph, depending on the typical speed of the vehicle. [EPA-HQ-OAR-2019-0055-1279-A1, p. 5]

NACD supports these important changes to SCR regulations. The current derate system is extremely difficult for drivers to operate under and creates hazardous roadway conditions where heavy-duty vehicles are forced to go a speed significantly under the speed limit. Moreover, it is important for fleet owners to have the ability to get their heavy-duty trucks to a mechanic who knows their vehicles. These adjustments make the roadways safer and improve a fleet-owners ability to get their trucks fixed. [EPA-HQ-OAR-2019-0055-1279-A1, p. 5]

Organization: *National Association of Clean Air Agencies (NACAA)*

NACAA does not support EPA's proposed changes to the in-use strategies designed to ensure that operators maintain their NOx emission control equipment. [EPA-HQ-OAR-2019-0055-1232-A1, p. 11]

EPA proposes changes that would significantly weaken "inducements" for maintaining Selective Catalytic Reduction (SCR). Since SCR is the most effective means of reducing NOx emissions from diesel engines, when these devices are malfunctioning NOx emissions soar. Such unacceptable NOx increases can occur from a combination of vehicle neglect, part failures and malicious tampering with diesel exhaust fluid (DEF), hardware and software. While the longer warranties proposed and discussed below should provide motivation to resolve design defects and inferior parts, the issues of passive neglect or active tampering require an intentional and diligent approach in the inducement program to ensure adverse emissions impacts are minimized. [EPA-HQ-OAR-2019-0055-1232-A1, p. 12]

EPA states in the NPRM that it has received many complaints about inducements related to SCR and the use of DEF, the majority of which express concerns "that despite the use of high-quality DEF and in the absence of tampering, in-use vehicles are experiencing inducements for reasons outside of the operator's control." It is unclear how many of the experiences leading to these complaints are specifically related to SCR inducements verses general engine protection derating that operators can also experience. Among the cited reasons outside the operator's control are faulty sensors and software "glitches." Both of these would be warrantable issues that should receive increased manufacturer attention under the significantly longer warranty periods advocated here. Simply ignoring these design issues would be deeply problematic and fundamentally undermine the effectiveness of the NOx program. [EPA-HQ-OAR-2019-0055-1232-A1, p. 13]

Finally, rather than just relaxing inducements and potentially allowing a truck with improperly maintained SCR to continue operating with nominal constraint, EPA should put in place measures that will hold manufacturers accountable for addressing the durability and sensor issues about which the agency, dealerships and manufacturers have received complaints. [EPA-HQ-OAR-2019-0055-1232-A1, p. 12]

Organization: *National Association of Small Trucking Companies (NASTC)*

Nevertheless, NASTC first and foremost appreciates that, with this proposed rule, the agency has carefully considered our sector's input from the 2020 advanced notice of proposed rulemaking, as seen from this NPRM's modernization of inducement and serviceability provisions. These updates would help address major problems motor carriers and truckers suffer under the existing inducements regime. The proposals rightly reform current policies in light of 12 years' worth of real-world data and real-life circumstances that regularly bedevil truckers. These proposals would mitigate extremely costly, dangerous, counterproductive problems the current rules create. [EPA-HQ-OAR-2019-0055-1130-A1, pp. 1 - 2.]

The proposal makes derating far more reasonable and evidence-based, as well as gives professional drivers greater predictability and appropriate flexibility. A truck traveling at the new derate speeds would no longer pose a serious threat to the safety of other drivers and vehicles, commercial or personal, on high-speed roads. Enhanced by a uniform derate schedule and speeds across manufacturers, professional drivers would be able to deal with the situation in which inducement occurs in an appropriate, safe manner, while the driving public is protected from an inducement-caused road hazard. Also, circumstances that may spur road rage by passing drivers are avoided. [EPA-HQ-OAR-2019-0055-1130-A1, p. 3]

Further, older commercial equipment may pose safety and performance issues. For instance, a DEF sensor that suddenly derates a truck moving at highway speed to 5 miles per hour puts truckers and motorists at grave risk, whether the sensor reads an actual emissions issue or gives a false positive reading.5 [EPA-HQ-OAR-2019-0055-1130-A1, p. 6]

5. The DEF sensor shortage and forcible derating also cost shippers, consumers, and stores, the truckers who lose money with every mile they aren't driving, and the motor carriers that are forced to sideline power units of their fleets. Jobs hang in the balance at every level, threatening debilitating costs and losses.

Aside from DEF sensors requiring microchips amid a shortage, these sensors "derate" trucks, forcing them to slow to 5 mph. Whether derated by malfunction or actual noncompliant DEF levels, affected trucks cannot be used to haul freight. Also, as mentioned, the derating of an over-the-road commercial vehicle while under load creates an extremely unsafe situation for the driver, the driving public that shares the road with trucks, the shipper and/or receiver, and the Insurance provider responsible for the load. Without readily available parts, commercial motor carriers that fill a vital role in our economy face bankruptcy in short order. A derated power unit awaiting a new DEF sensor or other part has a tightening noose on a motor carrier's neck. A truck that can't move freight is a truck failing to generate income, which can put the entire motor carrier operation at risk of financial failure. [EPA-HQ-OAR-2019-0055-1130-A1, p. 7]

Organization: *NW Navigator*

Please exempt passenger carriers from any and all Inducements and Derate's of the vehicles from 2008 to current Why? [EPA-HQ-OAR-2019-0055-2789, p.1]

1) Causes large groups of people to be stranded often in remote areas and often without cellular service [EPA-HQ-OAR-2019-0055-2789, p.1]

2) The lives and safety of human beings, we transport People not toilet paper and paper towels and when were stranded we need water food and heat and Air conditioning we can't just jump in the next car that comes by to go find help!! [EPA-HQ-OAR-2019-0055-2789, p.1]

3) If you have a story about being down because of one of these issues please us it but don't put in too much detail [EPA-HQ-OAR-2019-0055-2789, p.1]

4) Our main passengers are the young and the elderly both are very susceptible to extremes so again it is unsafe to disable these vehicles [EPA-HQ-OAR-2019-0055-2789, p.1]

5) We are often first on scene for a disaster getting people out of the way of a hurricane or removing them when Flood waters hit or evacuating them out of a fires path and so on [EPA-HQ-OAR-2019-0055-2789, p.1]

6) We transport the military for maneuvers, deployment and anywhere there is trouble and they are need we move them there! [EPA-HQ-OAR-2019-0055-2789, p.1]

Organization: *NW Navigator Luxury Coaches*

At first everything was great but just over a year after purchasing a brand new $500,000 MCI motorcoach equipped with a DPF Filter things started to become unsafe. [EPA-HQ-OAR-2019-0055-1098-A1, p. 1]

That vehicle stranded a group of kids at a closed ski resort after everyone had left because it needed a regen after sitting and trying to heat the coach up for the passengers. [EPA-HQ-OAR-2019-0055-1098-A1, p. 1]

What if your kids were on board? How would you feel about them being stranded and unsafe and in the end finding out that it was a $38 sensor that failed, which told the vehicle to shut down-because it might let some exhaust into the air? Nothing was actually wrong the system was working perfectly other than that $38 sensor. [EPA-HQ-OAR-2019-0055-1098-A1, p. 1]

Not even 3 months later this same $500,000 vehicle stranded a group in high heat out in the Columbia River Gorge after first derating the speed and the driver was forced to get off the highway to find somewhere where he could travel at such low speeds and not be rear ended by some inattentive driver on the highway, leaving the group stranded just off the highway with no services or help in any direction for 50 miles or more and no cell service. We had over 50 passengers on board with an average age of 72. [EPA-HQ-OAR-2019-0055-1098-A1, p. 2]

What if your Mother or Father were on that motorcoach and suffered Heat Stroke again because a computer told it there was an issue? Again, in the end it was a failure of the system not a real issue but a failed sensor not the Motorcoach. [EPA-HQ-OAR-2019-0055-1098-A1, p. 2]

These systems were absolutely not ready to be forced on the transportation industry and the newer systems are still not ready but were forced out on us by someone putting an X on a calendar. [EPA-HQ-OAR-2019-0055-1098-A1, p. 2]

When systems fail at the enormously high rate we all are experiencing- and I know and have heard it from other operators in trucking and bussing that they are having the same issues, it is not fair or safe to shut down or even derate a vehicle especially with passengers on board when it is almost always due to the fact that these systems are defective and not ready for market due to a Policy that was pushed out too fast, untested and without regard to the consequences of passengers. [EPA-HQ-OAR-2019-0055-1098-A1, p. 2]

The motorcoach industry is and always has been a very Green mode of transportation and is currently the GREENEST mode on the planet, even cleaning the air in areas where pollution is a major issue, however, we cannot put children, adults, the elderly our Military and people we are evacuating during a disaster at risk for the ‘checking of some box’ in a policy that was rolled out inefficiently and hastily without proper testing. [EPA-HQ-OAR-2019-0055-1098-A1, p. 2]

Please consider and approve the request to separate out our industry into its own category and don’t derate us or shut us down on the side of the road possibly with your children or grandparents on board. [EPA-HQ-OAR-2019-0055-1098-A1, p. 2]

We also request this take effect immediately and cover all vehicles and coaches from 2008 to Current. [EPA-HQ-OAR-2019-0055-1098-A1, p. 2]

Below is what we are countering with and feel would be a more acceptable time frame:

Default maximum speed (mi/hr)	**Commercial Passenger Vehicles Counter**	**Commercial Passenger Vehicles Counter**
65	derate exempt	24 hours
60	derate exempt	48 hours
55	derate exempt	72 hours
40	derate exempt	96 hours

[EPA-HQ-OAR-2019-0055-1098-A1, p. 2]

Organization: *Owner-Operator Independent Drivers Association (OOIDA)*

OOIDA supports the proposed inducement schedules and various derate principles included in Section IV, D. These provisions focus on conditions that are within a driver's control, implement a multi-step derate schedule, and a backup check to override false inducements. [EPA-HQ-OAR-2019-0055-1266-A1, p.5]

OOIDA members have experienced emission technology failures that caused their engines to quickly derate, placing truckers and other motorists in unsafe situations. Clearly, the loss of power resulting from a technology failure is a serious safety concern that absolutely must be avoided in future regulations. OOIDA supports the proposed inducement schedules and various derate principles included in Section IV, D. These provisions focus on conditions that are within a driver's control, implement a multi-step derate schedule, and a backup check to override false inducements. [EPA-HQ-OAR-2019-0055-1266-A1, p.5]

Following the January 2020 Cleaner Trucks Initiative Advance Notice of Proposed Rulemaking (ANPRM), many truckers told EPA about problems they've experienced and how the agency could work to address them. OOIDA commends the agency for listening to those comments and including provisions in the proposal regarding serviceability, inducement, and self-diagnostic tools that will help drivers better assess their emissions equipment. [EPA-HQ-OAR-2019-0055-1266-A1, p.6]

Organization: *State Trucker Associations (1)*

We file these comments in support of the revised inducement provisions under EPA's proposed low-NOx rule. The trucking industry understands EPA's rationale behind low-speed de-rates after: (1) there are three hours of Diesel Emission Fluid (DEF) remaining in the tank; (2) DEF quality fails to meet manufacturers' concentration specifications; or (3) when certain SCR system tampering events have occurred. Current speed derating to five miles per hour within four hours of detecting certain NOx fault conditions pose on-going concerns over driver safety and presents potential hazards for all vehicles operating on roadways due to the stark speed differentials being created. [EPA-HQ-OAR-2019-0055-1075-A1, p.1][25]

---

[25] One commenter who joined this mail campaign added the following information: "A situation in which a truck was traveling on the highway at 5 miles per hour or less has been attributed to the cause of the death of a state trooper in Connecticut within the past few years. The trooper's vehicle rear-ended a slow moving tractor trailer truck, and the trooper passed away. The incident occurred on March 29, 2018 on Interstate 84 in Tolland, CT. A Hartford Courant article about the investigation published on March 6, 2019, stated this about the investigation into the incident: "The report said the truck in the right-hand lane of I-84 at a speed of less than 5 mph "created an emergency situation that had a high probability of causing a serious collision." https://www.courant.com/breaking-news/hc-br-trooper-kevin-miller-crash-report-20190306-jgkphof4f5h5vboa3f6zaccgju-story.html" [EPA-HQ-OAR-2019-0055-1088, p.1]

Fleets nor drivers wish to experience derate episodes which have the potential to create both safety and delivery concerns.[26] Yet, following more than a decade of experience, derates are still occurring at unexpected rates and do not involve inadequate DEF levels or quality, but rather a variety of other reasons particularly faulty sensors. [Additional comment by one of the 23 organizations that joined this mail campaign] One thing that is not in the rulemaking scenario is that any sensor that creates a de-rate situation should by law be produced domestically and be available in adequate quantities. Just last year one of our members had a truck de-rate in North Carolina. Peterbilt, Kenworth, Freightliner and Cummins all showed the part on national backorder. The carrier happened onto the part at NAPA via a search on the part number. When their driver arrived at NAPA he had less than 20 min left before the truck went into full derate. Trucking companies that cannot deliver goods in a timely manner lose hauling contracts and suffer financially – the last thing a fleet manager wants. This is why fleets routinely check DEF fluid levels and purchase DEF from reputable sources. [EPA-HQ-OAR-2019-0055-1075-A1, p.1; EPA-HQ-OAR-2019-0055-1095, p1.]

The overriding assumption should be that fleets routinely check all fluid levels and avoid derates at all costs. To do otherwise makes no business sense. [EPA-HQ-OAR-2019-0055-1075-A1, p.1]

Organization: *States of California, et al. (The States)*

In a similar way, EPA should ensure that its inducements provisions secure in practice the emission reductions projected under Option 1. If operators are not properly incentivized to maintain an adequate supply of high-quality diesel exhaust fluid (DEF) in their aftertreatment systems, the real-world operation of these vehicles will severely undermine the emission reductions secured "on paper" by Option 1. The inducements schedule—i.e., the progressive derating of engine performance when DEF supply becomes too low—thus remains an important component of effective NOx standards for heavy-duty vehicles. EPA is rightly attentive to the concerns raised by operators around inducements, especially the challenges of false inducements, and the States largely agree with the seven broad principles that EPA proposes for its inducements approach.80 However, the proposed derate schedules81 are too lenient to ensure that operators properly maintain their vehicles' aftertreatment systems for both low-speed and high-speed vehicles.82 [EPA-HQ-OAR-2019-0055-1255-A1, p. 19]

Organization: *Stephen Jackson"*

As a farmer and employee at a John Deere dealership, I have seen the increased complexity and cost associated with emissions components on equipment. If there are new changes made to

[26] Note: Several of the 23 letters represented do not include the phrase "which have the potential to create both safety and delivery concerns."

trucks and off-road equipment for emissions, please make sure the OEMs and repair facilities are up to the task to diagnose and repair these systems with a good supply of replacement parts. It is important to have a long-term warranty to keep these systems functioning correctly. It is important to have some sort of "limp home" mode to be able to move the vehicle some distance when there is a failure of the emissions system. We recently had to have our delivery semi towed when it experienced an emissions related failure on the road. This was complicated by the fact we were hauling over width machinery on the trailer which makes it difficult to find a tow company that can pull a disabled truck and trailer that is over width. Please be aware this will come with increased costs to whoever owns and operates the vehicles and this will get passed on to the end user as higher prices for consumer goods. I believe trucks and off-road equipment have really become much cleaner in recent years with tier 3 and tier 4 regulations. If new requirements push the cost of new equipment higher, I believe we will see a renewed effort by owner operators to continue keeping older "pre-emissions" equipment in service. I see this now with farm tractors, older pre-emission equipment sells for a premium price due to its simplicity and the huge gap in price between used and new equipment. [EPA-HQ-OAR-2019-0055-1481]

Organization: *Truck and Engine Manufacturers Association (EMA)*

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. §1036.111(b): We offer the following additional comments on the specific proposed provisions of this paragraph: (b)(4): “(4) Open circuit faults related to the following: DEF tank level sensor, DEF pump, DEF quality sensor, SCR wiring harness, NOx sensors, DEF dosing valve, DEF tank heater and aftertreatment control module.” NOx sensors should be removed from the proposed open circuit faults of paragraph (b)(4), as the NOx override factor is part of the derate engagement (specified at proposed paragraph (c)). [EPA-HQ-OAR-2019-0055-1203-A1, p. 102]

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. §1036.111(b): We offer the following additional comments on the specific proposed provisions of this paragraph: (b)(5): “(5) Monitor for a missing catalyst.” Regarding the proposed provision that monitoring for a missing catalyst be a trigger for inducement, EMA recommends that EPA consider adding specific language for dual-SCR technology (specifically, for a singular failure versus both failing). However, at the very least, we request clarity on how dual-SCR technologies would be treated. [EPA-HQ-OAR-2019-0055-1203-A1, p. 102]

EPA proposes to codify the SCR inducement strategies (proposed §1036.111) that heretofore have been covered by guidance documents since HDOH SCR technology was first introduced in 2010. EMA supports this proposal, including the proposed new speed-based derate schedule, but suggests EPA consult with NHTSA on the corollary safety aspects. [EPA-HQ-OAR-2019-0055-1203-A1, p. 124]

There needs to be better harmonization between EPA’s and CARB’s SCR inducement requirements for medium-duty and light-duty vehicles. If there is not better harmonization in inducement strategies, customers may be even more confused by inducement, since there could be a proliferation of differing strategies within a single manufacturer (e.g., Class 3 chassis-cert trucks vs. Class 4 dyno-cert trucks). Lack of harmonization also increases the burden on manufacturers, as they will have to integrate multiple inducement strategies when it is much more cost-effective to keep a common control strategy across products. [EPA-HQ-OAR-2019-0055-1203-A1, p. 99]

Organization: *United Motorcoach Association (UMA)*

Fortunately, EPA acknowledges these shortfalls and proposes corrective measures. UMA applauds the Agency for the time they have invested in understanding the scope of the problem. [EPA-HQ-OAR-2019-0055-1311-A1,p.3]

Some UMA Members have raised safety concerns regarding the prospects of a derating (5 mph) bus or motorcoach while in traffic. Similar concerns have been raised regarding disabled buses and motorcoaches roadside. [EPA-HQ-OAR-2019-0055-1311-A1, p.3]

Currently, buses and motorcoaches equipped with emissions reduction technology lacks the level of dependability consumers of bus and motorcoach services seek. The current inducement renders a bus or motorcoach basically inoperative after few hours. Imagine a college athletic team traveling overnight to a tournament and compelled to forfeit the came by not arriving. Imagine your first school field trip to Disney World thwarted by a motorcoach derated by an unknown code. Imagine missing a relative’s wedding or graduation due to an errant code on a scheduled service motorcoach. [EPA-HQ-OAR-2019-0055-1311-A1, p.2]

Bus and motorcoach companies seek to provide dependable economical passenger transportation to the consumer. Failure to do so will eventually lead to a cessation of business through a poor reputation and the related financial difficulties that follows. [EPA-HQ-OAR-2019-0055-1311-A1, p.2]

If individuals and groups cannot depend on modern, low-emissions, commercial buses for motorcoaches they will find alternative transportation less environmentally friendly, yet again defeating the goals EPA sought. [EPA-HQ-OAR-2019-0055-1311-A1, p.3]

The Agency outlines EPA’s goals regarding inducement as follows:

1. A description of how the emission control systems operate.
2. Diagrams of the engine and emission-related components and expected key operating parameters.
3. A description of how to use the OBD system to troubleshoot problems and access emission-related diagnostic information.
4. A wiring diagram to troubleshoot aftertreatment-related components.
5. Provide instructions on where to find emission recall and technical repair information that is available without charge.
6. QR code on engine label that links to engine information and owner’s manual.
7. QR code on engine label that links to engine information and owner’s manual with enlarged-view drawings with part numbers and basic assembly requirements
8. DPF-specific information:
a. Criteria for cleaning the DPF (e.g., pressures and filter weight).

b. Access to DPF inlet and outlet pressures with a generic scan tool
c. Access to DPF inlet and outlet pressures with a generic scan tool,
d. Instructions on how to remove DPF for cleaning.
9. Troubleshooting guide to address DEF dosing- and DPF regeneration-related warning signals
10. Codes associated with inducements and DPF engine derates would be displayed in the cab or with a generic scan tool. [EPA-HQ-OAR-2019-0055-1311-A1, pp.3-4]

EPA proposes SCR inducements would only be required based on detecting the following fault conditions:
1. Low-DEF fill level
2. Blocked DEF lines or dosing valves
3. Poor DEF quality
4. Open circuit faults as an indication of tampering (e.g., disconnection of DEF pump or quality sensor)
5. Missing catalyst [EPA-HQ-OAR-2019-0055-1311-A1, p.4]

EPA proposes additional SCR Inducement Proposed Provisions
1. A NOx Override to prevent false inducements.
2. A derate schedule in four stages implemented over 60 hours
3. Separate derate schedule for low-speed vehicles (defined as vehicles with 30 hours of non-idle engine operation at <20 mph)
4. Final inducement speeds of 50 mph, or 35 mph for low-speed vehicles
5. Any OBD signals involved in inducement-related conditions must be readable with generic scan tools. [EPA-HQ-OAR-2019-0055-1311-A1, p.4]

***Organization**: Virginia Motorcoach Association*

Our primary concern involves the proposed "derate" or "inducement" schedule, which will result in a vehicle experiencing a significant loss of power and torque. This change in power has placed an undue burden on operators since 2008, when it was first implemented. There are numerous repercussions directly related to derates. Motorcoaches often travel to remote areas across the country unlike local transit or school buses that commonly transport intrastate and are home daily. Motorcoaches will drive far distances all times of the day or night making the ability to service a vehicle in a timely manner very difficult. Motorcoaches could be thousands of miles from home or even from an equipped service facility that could assist with a breakdown. This challenge for companies is far greater than what may be realized. [EPA-HQ-OAR-2019-0055-2715-A1, p.2].

When the equipment experiences an inducement, there are fewer options than other types of vehicles fitted with SCR. Since most of the vehicles have manufacturer-specific components, drivers are at most times limited to finding the right parts to fix a vehicle that is over the road. Additional costs involved include towing, outside repair service, reimbursing customers for missed events, refunding customers for long delays, contracting with other companies to move the passengers, and damaging the overall reputation of the company. [EPA-HQ-OAR-2019-0055-2715-A1, p.3].

Aside from the large expenses motorcoach operators must absorb, an even more important point is the safety risk a derate presents our passengers. It is our opinion that a regulation which cripples or limits the speed of any vehicle is unacceptable, dangerous, and jeopardizes lives. **The motorcoach industry has the unique and considerable responsibility of safely transporting the most valuable type of cargo on the road – human lives.** Many operators provide a significant amount of travel for school groups and young athletes, a cargo which is substantially different and more vital than that of a truckload of consumer goods or raw materials. There is no room for error when it comes to safety practices and maintaining a proper speed to avoid a fatal rear-end collision on a highway. This condition increases the likelihood of the extreme danger of a distracted driver driving into the rear of a derated or stranded motorcoach full of passengers. [Emphasis in original; EPA-HQ-OAR-2019-0055-2715-A1, p.3].

Organization: *Volvo Group*

[Inducement] issues affect today the adoption of newer technology trucks in the marketplace. [EPA-HQ-OAR-2019-0055-1324-A1, p. 5]

Organization: *Wisconsin Department of Natural Resources (WDNR)*

EPA's heavy-duty NOx proposal includes multiple program elements, such as extended useful life and warranty periods, that are expected to reduce the incentive for operators to bypass, or delay maintenance on, emission control devices. However, it also proposes to significantly relax some current anti-tampering inducements in the hopes that making compliance easier will result in less tampering. [EPA-HQ-OAR-2019-0055-1162-A1, p. 3]

Instead of finalizing the relaxed inducement schedules as proposed, EPA should take steps to ensure the emission control systems required by this rule are resistant to operator tampering. [EPA-HQ-OAR-2019-0055-1162-A1, p. 3]

As this rule applies only to vehicles MY 2027 and beyond, EPA should continue to prioritize enforcement of vehicle tampering in the current heavy-duty fleet. While EPA has taken a number of steps in recent years to address vehicle tampering including issuing an enforcement alert to the regulated community and resolving multiple enforcement cases concerning aftermarket defeat devices, reports continue to indicate that the use of heavy-duty vehicle defeat devices may be widespread. Additionally, EPA should consider evaluating the impact of a national-level inspection and maintenance program for heavy-duty vehicles to identify tampered vehicles. [EPA-HQ-OAR-2019-0055-1162-A1, p. 3]

EPA Summary and Response

For the purpose of this section, each subtopic is summarized and responded to separately.

Inducements and Emission System Reliability

ABA, Northwest Navigator Coaches, OOIDA, and NASTC commented with concerns that 2010-era type of reliability problems will accompany new NOx standards which will once again exacerbate inducement problems in-use. Northwest commented that the systems already fail at too high of a rate and it is not fair to shut down an engine due to a defective system. UMA commented that operators continue to struggle with technology lacking the level of dependability that bus passengers and operators need. Coach USA commented that the bus industry is experiencing a shortage of drivers, noting the recent pandemic, and they support an approach to allow drivers to complete their route before addressing a fault condition. Volvo noted that inducement issues currently affect the adoption of newer technology trucks in the marketplace.

Response:

As described in preamble Section IV, this rule focuses on developing a comprehensive inducement scheme in regulation to replace the current inducement guidance developed over a decade ago.

The inducement requirements adopted in this final rule include several features that are intended to mitigate many of the issues operators identified as experiencing under the existing guidance.

First, EPA is adopting longer useful life requirements that should lead manufacturers to improve component durability. Second, new serviceability requirements are intended to give operators and independent mechanics better information to allow for timely diagnosis and repair. Third, initial derate speeds are set to allow an initial stage of continued operation at or near prevailing speeds. Fourth, separate derate schedules apply based on each vehicle's average operating speed, rather than applying a universally effective speed restriction to all vehicles. Fifth, the inducement applies gradually increasing restrictions over a schedule that is intended to accommodate drivers returning home or completing other essential activities before the restrictions take full effect.

We are not aware of any way for engine software to discern the difference between faults caused by operator activity (or inactivity) and faults caused by corrosion, component wear, or any kind of defect. The final derate schedules reflects consideration of the concern that operators may not be able to make simple adjustments to resolve issues caused by defective components.

With regard to Volvo's comment, as explained in preamble Section IV, EPA believes the regulations included in this final rule will address many of the inducement issues identified by commenters and thus will not discourage the adoption of new technology trucks.

EPA's Inducement Principles

ABA, CARB et al and OOIDA: Generally agree with seven principles EPA proposed.

Response:

EPA is encouraged that a broad group of stakeholders recognize the importance of balancing the needs and impacts of the many elements of the heavy-duty in-use fleet. EPA continues to want to encourage proper maintenance and functioning of emissions control equipment and discourage tampering. A minimally restrictive approach, which is not what EPA is finalizing, might result in increased emissions because of extended operation without maintenance and circumvention of the limit on the adjustable range (i.e., without use of sufficient high-quality DEF). In contrast, an overly restrictive approach might impose unnecessary costs and pose a threat to operators' businesses, as well as leading to potentially increased tampering with engines or reduced fleet turnover rates that would lead to increased emissions. Commenters have described similar concerns with the 5 MPH final inducement speed that exists in many manufacturers' current inducement designs under the existing guidance. EPA developed the inducement principles to balance these competing concerns.

Concerns with Cost of Inducements

ABA, Coach USA, FitzGerald Brothers Bus Co., NASTC, UMA: ABA, Coach USA, NASTC, OOIDA, 23 State Trucking Associations commented that inducements raise serious economic concerns, are too costly for operators, add unnecessary operating costs (e.g., bus operators must refund tickets for missed travel or events) and can result in loss of customers, business credibility, and reputation. FitzGerald Buses noted that they lost $10,000 on one job alone, and lost the customer, and their driver quit because at 2AM their bus experienced a problem with a NOx sensor 500 miles away from their destination. Coach USA highlighted that there are many unintended consequences of inducements occurring because their mode of transport takes them to remote areas, far distances, traveling day and night, finding parts and they have difficulty finding repair facilities that can work on buses when they are thousands of miles from home base. Coach USA added that in addition to towing costs and outside repair costs, they must reimburse customers for missed events, refund customers for long delays, and hire other companies to move stranded passengers. UMA noted that rendering buses inoperative after a few hours has created consequences like athletic teams having to forfeit games, school field trips being disrupted, and missed family events. UMA commented that failure to provide reliable, dependable, and economical transportation leads to eventual loss of business, poor reputation and financial difficulties. Further, UMA noted that one of the unintended consequence of inducements on the motorcoach industry is to discourage passengers from utilizing this type of travel, which can erode the environmental benefits if passengers instead choose a less efficient mode of transportation. NASTC commented that the costs of repairing away from home base due to the emergency created by the current inducement schedule escalate due to a lack of relationship between repair facility and owner, potential difficulty in getting parts, and the need for extended driver lodging during the duration of the delay – all while the truck is unable to earn money while stranded. NASTC added that contracts and customers are also at risk during these events which makes for a much costlier experience than the current inducement strategy considers. NASTC noted that these cost impacts can be debilitating and cause layoffs. CARB's survey noted it often took more than one visit to properly diagnose and make repairs related to inducements and that 33% of vehicles needed work done more than one time a year due to derates and 29% of those had to return to the shop to have the repair properly diagnosed and repaired. State trucking organizations pointed out that the overriding assumption should be that fleets always check all fluids and avoid derates at all costs, and that to do otherwise makes no business sense.

Response:

EPA received numerous comments on the cost of experiencing inducements as included in today's engine software. This includes, for example, the cost of towing and renting replacement trucks. EPA is aware that the inducement requirements in this final rule will substantially reduce costs borne by operators, but EPA has not attempted to estimate these reduced costs to the fleet. EPA notes that such costs are not costs of compliance for the manufacturer.

Several commenters described their difficult experiences with existing inducements. EPA continues to believe that designing SCR-equipped engines with power derating is an effective and reasonable measure to ensure that operators perform critical emission-related scheduled maintenance on the SCR system. Inducements also demonstrate that engine manufacturers can reasonably expect operators to regularly supply engines with quality DEF, consistent with requirements for adjustable parameters. We have taken stakeholder feedback and concerns into account and are finalizing inducement requirements whose objective is to ensure that emission controls function in-use while reducing potential adverse impacts to operators through consideration of seven key principles.

One of EPA's principles in developing the inducement is to ensure that scheduled maintenance has a reasonable likelihood of being performed and allow manufacturers to demonstrate that they meet adjustable parameter requirements at the time of certification, while addressing operator frustration with false inducements and severe inducement speed restrictions that may potentially lead to in-use tampering of the SCR system. We are concerned that engine designs under the existing SCR guidance may have resulted in high levels of false inducement and overly restrictive speed limitations. The resulting frustration may have increased in-use tampering. We have received several comments following the ANPR and NPRM that real-world inducements are not limited to taking effect in a manner that would "not create undue safety concerns," such as only after a key-off event or at idle. We are also aware that manufacturers do not take consistent approaches to implementing inducements. The final rule addresses both issues by requiring manufacturers to take a consistent approach to gradually reduce vehicle speeds. Further, existing inducements are based on a 'one size fits all' approach – whereas the final inducement requirements set a more appropriate inducement schedule that correlates with the extent of high-speed or low-speed driving for each vehicle. The final inducement program we are adopting allows for more time and higher speeds between inducement steps to allow operators to return home and to diagnose and repair systems. These changes will reduce the need for operators to choose between making repairs at the side of the road and towing vehicles to the nearest available repair facility. These changes will also increase the likelihood that operators will respond appropriately to the inducement to arrange for properly maintaining their engines.

Concerns with Safety and Inducements

ABA, ATA, NASTC, OOIDA, 23 State trucking Organizations, UMA, Stephen Jackson, Volvo, David Pedersen: Inducements raise serious safety concerns. Coach USA noted that for transporting people or school groups, maintaining proper speed is of the utmost importance to avoid fatal rear-end collisions. Many state trucking organizations noted that current inducements pose on-going concerns with driver safety and present potential hazards for all vehicles on roadways due to stark speed differentials. The Motor Transport Association of Connecticut highlighted this concern noting that a situation in which a truck was traveling on the highway at a derated speed of 5 miles per hour and caused of the death of a state trooper who had a high-speed rear-end collision with the truck. NW Navigator Coaches noted that too often inducements strand them in remote areas with no access to cell service, and when they are stranded passengers need access to food and water as well as environmental controls. NW Navigator also noted that their main types of passengers are elderly and the young – both of which are susceptible to environmental extremes (e.g., very cold or hot weather) and they have experienced being stranded in extreme heat with elderly passengers and no cell service or nearby help due to a failed NOx sensor.

CARB's survey showed that 42% of owners had safety concerns with inducements and 18% had experienced a safety concern due to a derate such as sudden power loss when operating at highway speeds, power loss when coming down a steep grade, power loss when attempting to travel uphill, or power loss during heavy traffic. CARB notes that based on existing guidance, SCR-related inducements should not happen suddenly and without warning. Carreras Tours, however, commented that while on Interstate 5 in California with a bus full of students, the bus derated immediately to 5mph after a check engine light came on raising safety concerns that they would be rear-ended. Carreras added that it took several hours to get a rescue bus to pick up the stranded group and noted their frustration that they are not provided adequate time to get to a safe place where the bus and passengers would be safe.

Motorcoach Companies stated that they have no room for error in their safety practices and that maintaining proper speed is of utmost importance to avoid a fatal rear-end collision on the interstate. NASTC commented that the proposed schedule provides a safer atmosphere for professional drivers to deal with the situation in which inducement occurs in an appropriate, safe manner, while the driving public is protected from an inducement-caused road hazard while also reducing incidents of road rage by passing drivers. David Pedersen described the proposed rule as a flawed approach because de-rating vehicle speed creates a hazard for the operator and others nearby. Stephen Jackson noted that inducements can create safety concerns especially in operations that carry unique loads, such as over-width loads that require special permits and generally must keep routes and schedules preapproved by state police.

EMA and Cummins recommended that EPA consult with NHTSA on aspects of the proposed rule related to safety.

<u>Response:</u>

EPA designed the proposed and final derate schedules with the clear expectation that derating at higher initial vehicle speeds would likely address many of the experiences that commenters have described with current vehicles. The initial derate speeds are intended to be slightly lower than the vehicles' typical peak speeds to prevent abrupt speed changes that could pose a traffic risk. As described in Section 8.3, we are revising the final rule from proposal to further protect against abrupt speed changes by specifying that engines need to gradually impose derates at a rate of 1 mph for every five minutes. In addition, the final rule allows manufacturers to design engines with a revised derate schedule that is intended to address the issues that apply uniquely to motorcoaches, as described in Section 8.3.

The process for preparing the proposed and final rule includes interagency review within the federal government. At the same time, we are not aware of any specific issues in the rulemaking that would relate to NHTSA's role for addressing safety for heavy-duty highway vehicles.

Concerns Proposal was Rushed

ABA, Coach USA: Commenters expressed a concern that the inducement proposal might not work as intended and existing problems won't be solved because the proposal was too rushed and they did not have significant time to respond.

<u>Response</u>:

EPA received extensive, detailed comments from these and other stakeholders to describe a full range of concerns, along with suggested alternative approaches. EPA considered these concerns and fully responded to them in the final rule, as detailed in this section of this document and preamble Section IV. See also our response in section 17 of this document regarding sufficiency of the comment period for the rule.

General Support or Opposition to the Proposal

ABA, ATA, Cummins, EMA, NACD, NASTC, OOIDA, State Trucking Organizations, and Volvo broadly support the proposal, though as noted below some of these commenters also suggested some modifications. NASTC commented that this more reasonable and evidence-based modernization of inducement provisions would mitigate extremely costly, dangerous, counterproductive problems the current rules create and provide more predictability for drivers. NASTC stated that the proposals rightly reform current policies in light of 12 years' worth of real-world data and real-life circumstances that regularly bedevil truckers.

CARB, CATF, NACAA: Does not support proposal, believes significant changes are needed to prevent erosion of emission benefits and provide proper incentive for operators to maintain DEF. ALA and CARB commented that EPA should work on a national approach to inducements. ICCT agrees that an update of the current inducement policies is appropriate. ICCT supports several aspects of the proposal including: more time to remedy an indicated fault than is allowed today, separate derate speeds for low-speed vehicles and a NOx override.

ICCT commented that they agree that EPA should replace nebulous guidance documents for inducement provisions with clear regulatory requirements and stated that current guidance successfully encourages timely emission-related repairs, but updated provisions should consider reducing downtime to address operator concerns. ICCT supports several new approaches for inducements in the proposed rule but believes the specific proposed changes will reduce the incentive for many truck operators to achieve emission-related repairs, and result in unnecessarily increased in-use emissions, rather than the net benefit that EPA claims. ICCT comments endorsed EPA's proposed provisions to identify disconnection of emission control devices as an inducement fault condition, which would help to prevent tampering.

Response

As further explained in preamble Section IV, after consideration of comments, the final inducement requirements include some modifications from the proposal. As further explained in preamble Section IV and in this section, the final provisions ensure that scheduled maintenance has a reasonable likelihood of being performed and allow manufacturers to demonstrate that they meet adjustable parameter requirements at the time of certification, while minimizing operator frustration with false inducements and severe inducement speed restrictions that may potentially lead to in-use tampering of the SCR system and likely resulting in fewer costs for operators from inducements. . The most common form of tampering is removal of the emission control systems (e.g., "delete kits") which dramatically increases the emissions from in-use vehicles. Tampering with even a small number of vehicles can substantially increase fleet-wide emissions. While exact tampering rates are not known, tampering does indeed impact emissions in real life. Operators tamper for reasons such as improving fuel economy, avoiding the cost to maintain emission control systems, or avoiding operating restrictions such as inducements. Tampering is not always easy to detect. In determining the final inducement provisions, EPA considered that if inducements are set too stringent (in terms of time, speed, and number of deterred fault conditions), the resulting derate conditions could lead to more tampering, such as to avoid the financial consequences of downtime.

The final rule additionally includes several provisions designed to make appropriate maintenance easier and potentially less costly, which is critical for maintenance to occur in-use long-term (see, e.g., 40 CFR 1036.125(h)). The final rule also includes provisions intended to further protect against tampering (see, e.g., Section XI of the preamble for more information on the final adjustable parameter requirements).

We appreciate ICCT's affirmation of the initiative to adopt updated inducement provisions in the regulation. We note that our concern with the current guidance is not that it is unclear; rather, as described in the preamble, applying the principles to achieve an effective program while also considering the potential impacts of an overly burdensome program leads us to a different set of conclusions. While the current guidance is intended to ensure that operators will never choose to run out of DEF and will make timely emission-related repairs, our assessment is that the 5 mph final derate included in most current inducement designs is much more severe than it needs to be to accomplish that purpose. Experience has also shown that defective components lead to many inducements. Thus, one of the unintended consequences of current derates is that they can increase the motivation for tampering as operators bear the burden of repeated component malfunctions leading to inducement. Based on our assessment of the various considerations at issue, we have determined that a 5 mph final derate is overly restrictive for an effective national inducement strategy and includes additional burden on operators and could potentially lead to increased tampering with engines or reduced fleet turnover rates, which may result in increased emissions.

We developed the proposed and final inducement provisions by asking an additional question—What is the least restrictive means that will still ensure that operators fill DEF tanks and make timely repairs? Consideration of several detailed comments have led us to make several adjustments to the proposed derate schedules, as further discussed in preamble Section IV.

Inducements and Warranty

CARB, DOEE, ICCT, Maine DEP, NACAA, Wisconsin DNR suggested EPA's lengthened warranty periods should incentivize manufacturers to improve their processes and reduce defective parts. CARB suggested the lengthened useful life periods would also incentivize manufacturers to improve the durability of their component designs. Further, CARB stated that EPA should adopt a program similar to CARB's EWIR program which could help identify false inducements that occur under warranty. DOEE and NACAA stated that EPA should put in place measures that "will hold manufacturers accountable for addressing the durability and sensor issues about which the agency, dealerships, and manufacturers have received complaints." The States of California et al. commented that although they understand the frustration with false inducements, these concerns should be solved by manufacturers and do not justify relaxing the inducement schedule.

Response:

EPA agrees that longer useful life and warranty provisions are expected to lead to improved durability and decreased repair costs of emission-related components. CARB's EWIR program may also have some benefits in improving component durability. EPA did not propose to adopt a program similar to EWIR and is not including such a program in the final rule. We note, however, that these provisions would not fully prevent components from failing in the field (e.g., warranty provisions do not address the period after the warranty period ends). As a result, both the improved durability provisions and the final inducement provisions are part of the solution to addressing the false inducements issues raised by commenters. See preamble Section IV for additional discussion of how the final rule includes derate schedules that are consistent with the principles expressed in the proposed rule and includes consideration of comments.

Inducement Triggers

ABA, ATA, Coach USA, NASTC, and OOIDA noted that inducements occur too frequently for reasons outside of the operator's control. ABA commented that existing inducement triggers are problematic and occur for many reasons unrelated to using high-quality DEF and tampering. Examples of such failures include: software glitches, loose wiring, faulty sensors, and cold temperatures. ATA commented that after nearly a decade of experience, derates are still occurring at unexpected rates for reasons unrelated to using high-quality DEF and tampering. Examples of such failures include: sensor, parts, and wiring harness failures, bad pin connectors or faulty modules. CARB commented that they did studies in 2011-2013 showing that inducement warnings were sufficient and that based on these reports and existing guidance it is clear that inducements should not happen suddenly and without warning; however, OOIDA noted that members have experienced emission technology failures that caused trucks to quickly derate, placing trucks and motorists in unsafe conditions.

ABA said there is a lack of consistency among manufacturer's inducement strategies. ATA said that they agree with EPA that a standard list of fault conditions to trigger a tampering inducement would aid owners, operators, and fleets in repairing vehicles by reducing the cost and time required for diagnosis. CARB commented that EPA should remove the word "open" before "open circuit" faults to apply inducements for tampering-related inducements and that EPA should expand the list of tampering triggers to any component that OEMs determine should be added. ICCT also recommended that EPA include additional monitoring for disconnected devices to prevent tampering. Finally, CARB added that freeze protection guidance should be codified and freeze protection components should be added to the list of tampering trigger components. ATD noted that improperly functioning inducements can lead to tampering. EMA commented that it is critically important that sufficient notification be allowed before applying an inducement.

CARB commented that DEF fill level, quality, and tampering must all continue to be monitored for potential inducement. CARB agreed with EPA's proposal that low-DEF level trigger should start 3 hours before DEF is depleted. Coach USA stated that inducements should not begin until DEF is depleted – that they monitor and maintain buses including topping off DEF prior to each trip and usable volume of the tank should not be subject to inducement. ABA believes bus operators would never risk running out of DEF. Champion Auto Carriers stated that DEF issues have resulted in significant truck downtime and extra expense for their business. CSM commented that trucks running on DEF are unreliable and costly. OOIDA commented that DEF issues are costly and cause significant downtime.

CARB commented specifically that EPA should not remove the DEF quality as a fault condition for inducements because of the financial motivation to dilute DEF with water or to refill the DEF tank with something other than DEF. CARB highlighted the financial motivation by pointing out that DEF costs more than three times as much as distilled water and the financial motivation for DEF substitution will increase with new standards that require greater quantities of DEF.

Some commenters noted that the lack of adequate DEF can cause NOx emissions to increase to levels comparable to having no NOx controls at all, which is likely to be especially harmful in urban areas where HDV operations are concentrated, and where vehicles are consistently operating at speeds well below EPA's proposed derates.

EMA recommended that EPA clarify how to treat the failure of an SCR catalyst in a dual-SCR configuration, ideally with specific language to describe how the regulation applies for one or two failing catalysts.

Response:

EPA received comments from many operators who reported experiencing false inducements from faulty hardware that were not a result of tampering. For example, one manufacturer noted that it is difficult to effectively differentiate a blocked DEF line or doser due to direct tampering from a maintenance issue. In considering the comments, EPA reviewed current engine designs regarding fault conditions triggering a tampering inducement. We are concerned that these existing designs may be applying inducements to circumstances outside the intended scope of inducements for SCR systems, and believe that it may be difficult for manufacturers to design inducement strategies to be able to distinguish between tampering and faulty hardware. EPA reviewed various manufacturer's inducement strategies in their certification documents and compared those to our existing guidance. Some manufacturers have certified engines with nearly 200 different fault conditions causing a derate condition, including nearly 50 fault conditions for an SCR-related inducement. Many of those fault conditions are for engine protection; we are not adopting any regulatory provisions that would affect how manufacturers include engine protection in their AECD designs. As detailed in preamble Section IV, we are adopting a specific list of SCR system fault conditions to trigger inducement for meeting critical emission-related maintenance and adjustable parameter requirements. These final provisions focus on specific emission control components and conditions that owners can control, such as disconnecting a DEF pump or other SCR-related emission control hardware. The finalized list includes the tamper-resistance inducement triggers included in CISD-09-04R as well as additional components. Regarding the example of blocked DEF lines, as further explained in preamble Section IV, after further consideration EPA has decided not to finalize this as one of the requirements required to trigger inducements.

EPA agrees with ATD that improperly functioning inducements can lead to tampering and believes that standardizing a regulatory list of tampering inducement triggers will aid owners, operators, and fleets in repairing vehicles by reducing the cost and time required for diagnosis. EPA does not agree with CARB that this tampering list should include other fault conditions. CARB’s reports from 2011-2013 were largely focused on use of DEF in the field, DEF availability, and the effectiveness of the inducement strategies used by manufacturers based on CARB and EPA guidance. For example, in one test program, CARB found that 50 mph with some torque derate was adequate to render a vehicle unacceptable for typical driving (see, e.g., 76 FR 32886, 32889-32890 June 7, 2011). The recent survey data CARB submitted with their comments did not include supporting information to justify treating the additional fault conditions as tampering, or to clarify how manufacturers could reasonably differentiate between tampering and manufacturing defects for these additional fault conditions. EPA has identified the critical components in the list that should be monitored for disconnection. Defining a list of required triggering fault conditions will support a standardized approach for manufacturers to provide servicing information to operators.

EPA agrees with CARB that tampering with freeze protection components should trigger a tampering inducement. EPA proposed to include the DEF tank heater on the list of tampering items in §1036.111; after additional consideration, the final rule includes an update to the proposed list to also include the DEF tank temperature sensor in the final list of elements to be monitored for tampering.

EPA agrees with CARB that the low-DEF level trigger should start 3 hours prior to the DEF tank being depleted. As reflected in the final inducement schedules, EPA believes it is important to start the inducement for low-DEF level at this point in order to provide operators with advance notice that the DEF tank is approaching empty with enough time for them to find a place to refill the tank. As explained further in preamble Section IV, the inducement program adopted in this final rule initiates the inducement with an initial vehicle speed derate that is meaningful—not high enough for the vehicle to continue being used for its commercial purpose, but high enough to not completely disable it such that it would require a tow. We are including DEF quality as a fault condition in the final rule.

With respect to commenters noting emission levels in urban areas where vehicle speeds are slower, as further explained in preamble Section IV, the final inducement provisions include some changes from those proposed regarding derate schedules and final derate speeds. We believe that the final provisions will address many of the concerns raised by commenters. To the extent that the comments presume vehicle operators will not perform maintenance to remedy a detected fault condition until vehicles reach the final derate speed, the commenter did not provide data to support this assertion and EPA disagrees that operators uniformly do not remedy fault conditions until the final derate speed is reached. The proposed rule describes principles and analysis of in-use operating characteristics to support our expectation that operators will typically respond to the proposed derate schedule by performing needed maintenance once they are able to return home, if not sooner. Commenters on the proposed rule representing operators consistently affirmed this expectation. The expectation for performing timely maintenance applies especially for maintenance as simple as adding DEF to an empty DEF tank.

Regarding the commenter stated that vehicles consistently operate well below EPA's proposed derated speeds, we note that while it may be true, EPA disagrees that the existence of some operation below a given speed is a proper measure to evaluate the effectiveness of inducements. For example, refuse haulers, street sweepers, and utility trucks might operate for extended periods at very low speeds, but they need to get to and from the areas of low-speed operation, often on roads where prevailing speeds are well above the derated speed. If those low-speed vehicles can't accomplish those high-speed trip segments, they will be substantially restricted by the speed derate. The commenters offered no information to suggest why operators would be so motivated to continue operating with a fault condition that they would prefer to continue operating at restricted speeds rather than performing needed maintenance. All the information available to us show that all low-speed, medium-speed, and high-speed vehicles would be substantially impaired by the final speed derates. All the information available to us shows that all low-speed, medium-speed, and high-speed vehicles would be substantially impaired by the final speed derates.

With respect to EMA's request for clarification, we have revised from proposal the final regulation to state that any failing catalyst would be a fault condition to trigger inducement. If a second catalyst fails, that would be a separate fault to process.

Parts Shortages

Coach USA commented that parts may not be readily available, as seen during the pandemic, which further supports allowing more time to address fault conditions. A commenter from the State Trucker Associations (1) recommended that EPA deal with the parts shortage by requiring that all inducement-related sensors be produced in the United States and be available in adequate quantities.

Response:

We expect that the final derate schedules should address Coach USA's concern while also ensuring use of high-quality DEF in SCR systems.

Mandating where inducement-related sensors need to be produced or in what quantities is not within the scope of this rulemaking.

Inspection and Maintenance

Wisconsin DNR suggested that EPA continue to prioritize enforcement of vehicle tampering in the current heavy-duty fleet since reports continue to indicate that the use of heavy-duty vehicle defeat devices may be widespread. Wisconsin DNR also suggested that EPA consider evaluating the impact of a national inspection and maintenance (I/M) program for heavy-duty vehicles to identify tampered vehicles.

Response:

EPA indeed intends to prioritize enforcement of vehicle tampering for heavy-duty vehicles. The Clean Air Act mandates that the states operate light-duty vehicle I/M programs in certain areas based on criteria such as air quality attainment status, population, and geographic location. The purpose of these I/M programs is to periodically (either annually or biennially) inspect light-duty vehicles to identify and repair high-emitting vehicles to improve air quality in these identified areas. The Clean Air Act does not require a national I/M program that addresses heavy-duty vehicles, but some states and areas have developed strategies to reduce emissions from heavy-duty vehicles. As explained further in preamble section IV, the inducement program finalized in this rulemaking is designed to immediately detect mal-maintained or tampered SCR systems on heavy-duty vehicles sold and operated nationally and should result in timely action that will better achieve expected emission reductions, and we anticipate that the final provisions should decrease incentives to tamper that may be present under existing inducement strategies.

Light-Duty Inducements

EMA advocated for better harmonization between EPA's and CARB's SCR inducement requirements for medium-duty and light-duty vehicles to avoid user confusion, especially for similar vehicles. EMA also stated that lack of harmonization increases the burden on manufacturers, as they will have to integrate multiple inducement strategies when it is much more cost-effective to keep a common control strategy across products.

Response:

EPA is adopting inducement requirements in this rule for engines certified under 40 CFR part 1036. We expect these new requirements will give us important insights and may be helpful in considering whether, when, and how to codify updated inducement requirements for light-duty and medium-duty vehicles certified under 40 CFR part 86, subpart S. Inducement provisions for those vehicles are outside the scope of this rule.

8.2 Onboard Diagnostics and Overriding Inducements based on measured NOx conversion

Comments by Organizations

Organization: *American Bus Association (ABA) (1070 and 1308)*

ii. Faulty Inducements – Similar to establishing consistent inducement policy among manufacturers, ABA believes stopping inducements from occurring when a fault code is flagged by the system, but the SCR system is still controlling NOx emissions, is a good idea. However, motorcoach operators often experience reliability issues with NOx sensors, which would diminish the value of this proposal. Also, if an engine manufacturer does not have control over third party suppliers for SCR components, such as NOx sensors, ABA questions if this issue can/will be addressed. As well, ABA needs additional time to review the NOx override feature with motorcoach industry members. [EPA-HQ-OAR-2019-0055-1308-A1, p.10]

Organization: *California Air Resources Board (CARB)*

The NPRM requests comment on whether improvements could be made to OBD to monitor inducement for false inducements conditions, and whether OBD systems should monitor the inducement process and detect system malfunctions prior to a failure (e.g., for deterioration of the diesel exhaust fluid (DEF) delivery system). CARB staff believes the OBD system requirements are not the place to address these issues to the extent they exist. Rather, instead of relying on the OBD system, manufacturers should be implementing robust inducement systems that avoid false inducements and provide adequate warning prior to final inducement. CARB staff believes that the longer warranty periods proposed by U.S. EPA will encourage manufacturers to develop more robust inducement systems. [EPA-HQ-OAR-2019-0055-1186-A2, p.70]

CARB staff is also concerned that the NPRM proposed inducement could be avoided completely by tampering with the NOx sensor signal. This single point of contact tampering could allow all the SCR system components to be removed, disabled, and ignored. Operators could avoid the need to refill the DEF tank and obtain a meaningful cost savings. U.S. EPA is certainly aware of the prevalence of tampering with motor vehicle emission control devices and the excess emissions associated with such tampering.163 [EPA-HQ-OAR-2019-0055-1186-A2, p.100]

CARB staff believes that the proposal would only increase the likelihood that tampering of SCR systems would increase with U.S. EPA proposal compared to under today's inducement requirements. Truck owners and operators would be tempted to tamper to avoid SCR repair costs and downtime, as well as to eliminate the cost of purchasing DEF when refueling the vehicle. Savings from avoided repairs, downtime and DEF could be substantial, and so the economics and the reduced complexity needed to tamper with the SCR inducement would drive more tampering. Under the current SCR inducement protocol, tampering would be more difficult because it would require a multifaceted approach and any one inducement condition that gets triggered would introduce severe inducement.

A trade press publication within the last year ran six articles advocating precisely this means of tampering with the SCR system sensor signals using widely available off the shelf components to defeat sensors including pictures, linking how-tos, and describing active strategies to defeat engine control unit detection of the signal tampering.164 The ease with which heavy duty pickup owners have obtained engine control software modifications and other electronic tampering devices as outlined in U.S. EPA’s own summary of enforcement actions illustrates just how little effort is required for a bad actor to perform such tampering on their vehicle.165 These types of tampering strategies are well known166 and commercialized with a market even described as 'flourishing'.167 In a report by the Danish government, the police inspected nine heavy duty vehicles in a pilot remote sensing program and found two HD vehicles that used tampering devices and three HD vehicles with malfunctioning SCR catalysts (e.g., lack of DEF or a defective sensor.)168 We urge U.S. EPA to carefully consider the programmatic and emissions control hazards from such widely available tampering means and intentionally construct inducement strategies that do not reward such illegal actions. [EPA-HQ-OAR-2019-0055-1186-A2, pp.100-101]

14 In light of this information, U.S. EPA’s failure to consider the aforementioned factors that will likely incentivize tampering of the SCR systems, including the likelihood that the proposal to implement a NOx sensor override may incentivize greater rates of tampering and consequently result in increased emissions, constitutes a failure to consider an important aspect of this rulemaking. State Farm, 463 U.S. at 43. See also Genuine Parts Co. v. EPA, 890 F.3d 304, 312 (D.C. Cir. 2018) (arbitrary and capricious for an agency to ignore evidence contradicting its

position). Indeed, the arbitrary and capricious nature of U.S. EPA's proposal is especially apparent given that the proposed NOx override provision would only increase the risk of tampering, the very harm U.S. EPA is seeking to address in the proposal, thereby failing to demonstrate a 'rational connection between the facts found and the choice made' State Farm, 463 U.S. at 42. [EPA-HQ-OAR-2019-0055-1186-A2, p.101]

The NPRM proposes to allow the NOx override described in 40 CFR 1036.111(c) to override fault conditions that would initiate SCR inducement, because the SCR system is still controlling NOx emissions and the override may be helpful to reduce false inducements. CARB staff agrees that allowing leniency for fault conditions where NOx emissions are controlled is appropriate and would address many of the ANPRM commenter concerns. However, CARB staff believes that the use of the NOx override should only be used in a limited circumstance to determine which of the 2 derate schedules should be used, as discussed in the previous section and shown in Tables 9-1 and 9-2. [EPA-HQ-OAR-2019-0055-1186-A2, p.104]

The NPRM states that ANPRM commentors 'reported that some of these cases were traceable to incidents where the system detected a problem that did not exist and did not create emission concerns, for example a vehicle with a full DEF tank experienced an inducement due to a faulty DEF level sensor which reported an empty tank.' In this example, while the fix of the faulty sensor under some circumstances may not need to occur immediately to maintain immediate emissions control, but as the DEF is used up in the tank the faulty sensor would not be able to inform the operator when the DEF tank is getting low or empty. While this type of fault does not impact emissions immediately, fixing the faulty sensor in a timely manner is important before it could impact emissions. The operator, in good faith, may continue filling the DEF tank despite the faulty sensor; however, a functional diagnostic system is critical to ensure that DEF is properly filled. The proposed NOx override would not result in operators fixing faulty components if SCR NOx conversion efficiency is within 10 percent of lifetime. [EPA-HQ-OAR-2019-0055-1186-A2, p.99]

Since the NOx override criterion plays an important role in determining derate schedules in CARB staff's proposal, the margin of error threshold to determine NOx efficiency is critical to ensure that NOx emissions are controlled and thus the vehicle not subject to a severe derate schedule. CARB staff agrees with the NPRM margin of error of 10 percent of NOx efficiency as a reasonable threshold to detect NOx emissions at the low NOx engine levels. Any margin of error greater than 10 percent is not acceptable for the allowance to use CARB staff's more lenient derate schedule. As NOx sensor technology improves, the margin of error threshold should be adjusted to a lower level in a future rulemaking. [EPA-HQ-OAR-2019-0055-1186-A2, p.104]

The NPRM requests comment on whether OBD Active 100 Hour Array and the specified OBD REAL Bins 13 and 14 are appropriate for determining the NOx override. CARB staff recommends that OBD Active 100 Hour Array not be reset at the detection of a fault condition, but rather a new temporary active array for Bins 13 and 14 be created and used for the remaining time until the Active 100 Hour Array is completed, stored in the Stored 100 Hour Array, and reset. Currently, OBD regulation restricts the Active 100 Hour Array from being reset until 100 hours of active data is completed and stored, and this Array is used to determine the functionality and performance of many other parameters besides SCR inducement. Such disruption of the Active 100 Hour Array is not necessary if a temporary array is established. [EPA-HQ-OAR-2019-0055-1186-A2, p.104]

In addition to the NOx override feature, CARB staff also recommends including OBD SCR conversion capability monitoring in 13 CCR section 1971.1 (e)(6)(D.2.1)(D)(i) to determine which derate schedule of CARB staff's proposal that the vehicle would be induced. This regulatory subsection specifies that OBD system will detect a catalyst malfunction when the catalyst conversion capability decreases to the point that would cause an engine's emissions to exceed the applicable NOx standard by more than 0.2 g/bhp-hr. If OBD detects this SCR catalyst malfunction, regardless of the value of NOx override the more severe derate schedule would be triggered. The inclusion of this OBD SCR criterion would provide additional protection that the SCR continues to effectively reduce NOx emissions, resolve any concerns about the appropriateness of using OBD REAL Bins 13 and 14, and prevent attempts to tamper with the NOx sensors to override inducements. [EPA-HQ-OAR-2019-0055-1186-A2, pp.104-105]

CARB staff also recommends removing the NOx sensor as a fault condition in the proposed 40 CFR 1036.111(b) since the NOx override factor, based on the NOx sensors, can be used to override the NOx sensor fault condition. Rather, staff suggests adding detected NOx sensor functional problems as a separate subsection, not subject to the NOx override condition, and requiring NOx sensor problem to be subjected to the derate schedule in Table 9-1, which is a less severe derate schedule, to induce its repair. If a fault condition is also detected with the failed NOx sensor, then a more severe derate schedule as shown in Table 9-2 would be necessary to induce an immediate repair of the fault conditions. [EPA-HQ-OAR-2019-0055-1186-A2, pp.103-104]

Organization: *Cummins Inc. (Cummins)*

While supportive of EPA's efforts to improve the accuracy of triggering SCR inducements and reduce instances of false inducements, Cummins has concerns with the use of OBD REAL for this purpose. OBD REAL was originally developed with a different purpose in mind than EPA's proposal to calculate NOx conversion efficiency for use in activating and deactivating inducement. Data collected and OBD REAL binned by WVU, as part of the collaborative work between EMA, EPA, and CARB investigating B-MAW techniques, concluded that the OBD REAL bins typically contain averages that have large Coefficients of Variance (COV). The large COV values indicate that within-bin OBD REAL data is uncorrelated with respect to NOx conversion efficiency, and that suggests that it would not be appropriate to apply NOx thresholds to OBD REAL binned data for any purpose. Without considerations for NOx sensor data collection (e.g., collecting data when SCR dosing is active, avoiding extreme ambient conditions or AECD events, raw vs. filtered data, etc.), the NOx override factor may lead to situations that drive false positive or false negative inducements. Cummins requests that EPA work with CARB, industry, and SAE to revise, harmonize and standardize OBD REAL with its use in EPA's proposed inducement re-design in mind. [EPA-HQ-OAR-2019-0055-1325-A1, pp. 14 - 15]

OBD REAL

In response to this request for comment (and the regulatory language not explicitly specifying the bins associated with low- or high-speed vehicle), Cummins proposes that EPA considers specifying a range of Bins for both low-speed and high-speed vehicles (for example, Bins 7, 8, 9, 11, 12, 13 could be used for low-speed vehicles, and Bins 10 and 14 for high-speed vehicles), in order to give both operating conditions a chance to properly fill the bins over 100 hrs. This proposal needs to also go along with a significant increase in the override factor threshold of 10% in order to prove more robust. [EPA-HQ-OAR-2019-0055-1325-A1, p. 31]

Organization: *International Council on Clean Transportation (ICCT)*

In an effort to mitigate the possibility of false failure indications, the EPA has overcorrected by allowing an inducement override if NOx sensor data indicate SCR efficiency is reduced by less than 10 percent. Not all vehicles with SCR efficiency degraded by less than 10 percent are false failures. Many may have faults that are causing excess emissions that would be corrected due to the proper inducement. Because the SCR efficiency required to meet the proposed NOx standards approaches 99 percent, an in-use truck with SCR efficiency degraded to 90 percent will emit NOx emissions in excess of the current 0.2 gram/hp-hr. standard, an order of magnitude emission increase. With EPA's proposal, many trucks with this high level of excess NOx emissions will have no inducement applied, and there will be no incentive for the operator to seek repair. [EPA-HQ-OAR-2019-0055-1211-A1, p. 21]

ICCT suggests the availability of NOx sensor emission data be used in a different way that provides more balance between achieving emission reductions while reducing inconvenience for operators once an inducement is initiated. Instead of using the NOx sensor-based SCR efficiency loss factor to override inducements, it could be used to determine which of two derate schedules should be required – a more gradual one where emission increases due to a fault are smaller, or a more aggressive one where emission increases are expected to be higher.

We recommend that the EPA proposal to completely override inducements be abandoned. Instead, an indication of SCR efficiency loss of 10 percent or less would be a prerequisite for the more gradual EPA proposed speed derate schedule, but with a lower speed fourth step. [EPA-HQ-OAR-2019-0055-1211-A1, p. 21]

• If indicated SCR efficiency loss is 10% or less, we recommend using the EPA proposed derate schedule with the fourth step speed derate lowered;

• If indicated SCR efficiency loss is more than 10%, we recommend using an accelerated derate schedule with the fourth step occurring at 12 hours, and addition of a final derate to 5 mph at the first stop or refueling after 16 hours of operation from fault detection. [EPA-HQ-OAR-2019-0055-1211-A1, p. 21]

EPA's concept of using the NOx sensors to distinguish between SCR-related failures that are causing very high emissions from those with less impact on emissions or false failures, has some merit. However, EPA's specific proposal to allow no inducements under certain conditions when SCR efficiency has dropped by 10 percent or less will result in many emission-related failures never repaired. [EPA-HQ-OAR-2019-0055-1211-A1, p. 21]

The implication of this inducement override is that an indicated loss of less than 10 percent SCR efficiency is not important enough to require repairs simply because it might be caused by a NOx sensor inaccuracy. This logic is faulty for two reasons. First, not every NOx sensor reads low. For those sensors that are not reading low due to inaccuracy, an indicated loss of SCR efficiency of less than 10 percent is likely a valid indication of excess NOx emissions that deserves attention. Second, a true 10 percent loss of SCR efficiency would result in NOx emissions higher than the current 0.20 gram NOx standard, completely negating the emission reduction benefit of any of the proposed new NOx standards for that truck. For these reasons, we recommend against implementing the use of NOx sensor readings to override all disincentives. [EPA-HQ-OAR-2019-0055-1211-A1, p. 21] We recommend EPA use the NOx sensor-based calculation of SCR efficiency loss to determine the appropriate derate schedule. [EPA-HQ-OAR-2019-0055-1211-A1, p. 21]

For these reasons, we are recommending EPA reconsider and modify its inducement strategy, as indicated below, to assure more vehicles with high emissions are incentivized to seek repair, while reducing unintended inconvenience to truck and bus operators. [EPA-HQ-OAR-2019-0055-1211-A1, p. 21]

Organization: *National Association of Small Trucking Companies (NASTC)*

A derate override feature, triggered when a faulty DEF sensor starts the inducement cycle while an emission level sensor shows the system continuing to reduce NOx emissions.

We endorse the proposed override feature that would operate when a faulty DEF sensor otherwise would prompt inducements, despite sufficient levels of and adequate quality DEF being present and the system continues to reduce emissions. [EPA-HQ-OAR-2019-0055-1130-A1, p. 3]

Organization: *Truck and Engine Manufacturers Association (EMA)*

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. §1036.111(c): EMA does not support the proposed "within 10 percent" NOx override factor of paragraph (c) and the use of only Bins 13 and 14 to calculate the override factor. EMA recommends that a better approach is for the NOx override factor to start from +/-15% which is the standard test-out requirement, and then include the accuracy of commercially available NOx sensors. Emissions lab data indicates that 15% is a reasonable value for normal testing variation. Considering commercially available NOx sensors accuracy is +/-10% to +/-15%, +/-25% is a reasonable value for the override factor; +/-15% accounts for normal testing variation, and +/-10% accounts for NOx sensor accuracy and impact to binned NOx values. [EPA-HQ-OAR-2019-0055-1203-A1, p. 102]

As an initial matter, the new SCR inducement proposal depends on data recorded using the REAL binning functions required by CARB's OBD regulations. (EPA has proposed to incorporate the obligation to track REAL NOx emissions in §1036.110.) There are several concerns with how the SCR inducement strategies are tied to the REAL data. First, the SCR inducement is only triggered if a fault is confirmed by the "NOx override" function described in

§1036.111(c). Under that provision, the inducement derate should be overridden if the NOx conversion efficiency in the 100-Hour Array is within 10% of the NOx conversion efficiency of the Lifetime Array for REAL Bins 13 and 14. Conversion efficiencies, both lifetime and 100 hour, are going to be calculated based on on-board NOx sensors. Those sensors, however, are known to have significant inaccuracy, as much as +/- 10 ppm according to manufacturers' specifications in the range of data expected to be recorded in Bins 13 and 14 (the highest engine power level bins). Aged sensors have been known to be significantly less accurate. It is imperative that EPA evaluate the sensitivity of these SCR inducement controls for this purpose. Operation on a very cold day may lead to incorrect inducement determinations based on the NOx override function. EPA should consider alternative confirmation methods, at least for some fault types, such as loss of DEF pressure at the DEF pump in the case of an empty-DEF tank fault. [EPA-HQ-OAR-2019-0055-1203-A1, p. 124]

EMA is willing to work with EPA to determine other similar opportunities. For most of the conditions being evaluated, such as empty DEF tank, blocked DEF lines, or missing catalyst, the NOx conversion efficiency should be 0%. A threshold much closer to this value should be applied when inducing for those reasons, in order to account for potential errors. [EPA-HQ-OAR-2019-0055-1203-A1, p. 124 - 125]

A second issue of concern is that for certain applications, there may actually be no data in Bins 13 and 14, making the assessment impossible. [EPA-HQ-OAR-2019-0055-1203-A1, p. 125]

EPA Summary and Response

Summary:

EPA received several comments supporting the concept of a NOx override. Other commenters supported the concept, but suggested improvements. ABA expressed concerns with NOx sensor reliability causing problems. CARB and ICCT suggested that speed derates similar to what EPA proposed should apply for cases where the engine detected a fault condition even though NOx measurements showed good emission reductions over the catalyst.

Some commenters agreed that the proposed threshold for the NOx override was appropriate, while other commenters suggested recognizing a lower level of NOx control as being sufficient for the NOx override. CARB and ICCT suggested tying the threshold for the NOx override to the OBD threshold related to catalyst conversion efficiency.

EMA, Cummins, and CARB suggested that the NOx override algorithm should not depend on the proposed approach of tracking operation in REAL bins. EMA also commented that some failure modes may call for alternative confirmation methods.

CARB expressed a concern that the proposed NOx override could introduce a risk of creating a single point of contact for tampering. CARB suggested addressing that concern by setting speed derates based on catalyst conversion separate from any NOx override. CARB also suggested that the NOx override should not apply if the engine detects NOx sensors as being faulty.

Response:

We continue to believe that the NOx override has the potential to provide important diagnostic information to allow manufacturers to avoid applying speed derates when the catalyst system is working properly to reduce NOx emissions. However, we recognize from the comments that we need to further develop the measurement techniques, calculation algorithms, and thresholds for designing an effective NOx override. Given the timing of this final rule, we are not taking final action at this time on the NOx override feature. We are adopting the final rule with inducements in 40 CFR 1036.111 without the NOx override feature. We intend to continue to consider these issues regarding NOx override and may propose revised inducement provisions to include a NOx override in a future rule.

There are at least two advantages of deferring action on the NOx override in this final rule. First, the NOx override substantially increases the complexity of the algorithms for applying speed derates. Increased complexity corresponds with an increased risk of computational errors that could create unintended outcomes. Additional time to explore alternative methodologies will help to ensure that the engine is able to provide a robust indication of catalyst activity for the full range of possible fault conditions. Second, as noted in Section 8.1, the final rule includes provisions to improve component durability. We may learn that manufacturers are able to comply with new inducement requirements in a way that greatly reduces the experience of engines going into inducement even though the catalyst is functioning normally. We may also learn that less severe initial derates in the final inducement provisions address issues with existing inducements raised by commenters such that the NOx override does not have the same value that it would for engines on the road today.

8.3 Derate schedule

Comments by Organizations

Organization: *American Bus Association (ABA) (1070 and 1308)*

In addition to the rushed nature and time constraints for this complex rulemaking, the ABA identified feasibility, cost and reliability concerns the motorcoach industry has with the Proposal. In the interest of facilitating EPA's rulemaking effort, ABA also offers a proposal to alleviate some of the cost and derate concerns identified, while accounting for the environmental benefits provided by the motorcoach industry and promoting motorcoach travel. Akin to emergency vehicles that rely on heavy-duty engines, manufacturers providing heavy-duty engines to the motorcoach industry should be afforded similar regulatory flexibility with regard to inducement strategy. In line with EPA's 2012 relief measures, EPA could expand the application of the AECD as part of the certification process for engines to be used in motorcoach vehicles. [EPA-HQ-OAR-2019-0055-1308-A1, p.11]

Providing engine manufacturers producing engines for use in motorcoach vehicles with the same flexibility afforded to engines used in emergency situations, would address a number of concerns. First, and foremost, EPA's inducement policy creates a serious risk to life within motorcoach operations. By eliminating the threat of reduced engine performance or derating, particularly for motorcoach drivers who are focused on driving safely and the comfort and care of their passengers, EPA address one of the motorcoach industry's greatest concerns not only with the Proposal but also current emission control requirements. This action would significantly reduce the risk of stranding vehicles and passengers on the road and the stranded vehicle becoming a roadside safety obstacle for other vehicles. Motorcoach operations are heavily dependent on passenger designed and driven schedules. Unlike property, transport of passengers requires providing certain necessities to meet human needs. Along with those motorcoach vehicles serving in an emergency response capacity who are performing work directly related to reducing risk to human life from natural disasters or other emergency situations, motorcoaches should not be subject to artificial inducements that prevent the vehicles from performing as necessary. [EPA-HQ-OAR-2019-0055-1308-A1, p.11]

Additionally, by providing engine manufacturers with flexibility to apply the approved AECD to motorcoach engines, it would eliminate a substantial amount of cost for motorcoach operators. Motorcoach operators would avoid repair costs associated with faulty triggers or components that result in unnecessary derates. Further, it could also reduce the costs under the Proposal associated with extending the useful life of the engine and warranty, and the durability requirements for components. Indirectly, such action would also eliminate the indirect costs outlined in the comments to the ANPRM, related to towing, reimbursements owed due to not meeting schedules, and cost to reputation. The flexibility would also reduce the number of dashboard distractions for drivers, allowing them to remain focused on safely driving the heavy-duty vehicle. By reducing costs and improving safety, by this proposed action, EPA would clearly make a statement on the importance of transport by motorcoach and recognize the benefits motorcoach travel brings by taking cars off the road. [EPA-HQ-OAR-2019-0055-1308-A1,pp.11-12]

The loss of a key transportation option for underserved and price-sensitive communities is also a key concern. The EPA devotes significant attention in the Notice to environmental justice concerns and the need to ensure all communities benefit from air quality improvements. However, the EPA makes no mention of the key role motorcoach services play in meeting the transportation needs of all communities, in particular economically disadvantaged and rural communities. As mentioned, for many of these constituencies, the motorcoach industry is the primary and sometimes the only mode of transportation available. Motorcoach services connect these communities to jobs, education, necessary medical services, and other intermodal transportation services across the country. In FY 2021, the Department of Defense made extensive use of the motorcoach industry, contracting for the motorcoach movements of nearly 28,000,000 military personnel through their military bus program (https://www.defensetravel.dod.mil/site/bus.cfm). According to key emergency transportation coordinator Transportation Management Services, they organized over 500 bus movements as part of emergency transportation and evacuation movements during the 2020 hurricane season getting thousands of people out of harm's way. [EPA-HQ-OAR-2019-0055-1308-A1, p.5]

Different Inducement Schedules and Speeds – ABA believes there is merit in this approach, but has questions as to determining the appropriate category and how it would work in application for motorcoach operations. For example, where would a motorcoach fall, in terms of high-speed and low-speed vehicles? If the vehicle profile changes or fluctuates, does the inducement schedule assessment change for the vehicle? ABA also believes adjusting the derate schedule into a 4-steps along with setting more appropriate maximum and final inducement speeds over the inducement interval has merit; however, ABA has not had sufficient time to review this proposal with motorcoach operators for specific feedback. ABA plans to hold further discussions with motorcoach operators on both the step interval approach and maximum speeds. [EPA-HQ-OAR-2019-0055-1308-A1, pp.9-10]

Conversely, the risk of motorcoach operators not maintaining necessary quantities or quality DEF in their tanks to ensure the RSC is properly working, is low. Motorcoach equipment is expensive to purchase and maintain; motorcoach operators do not want to risk damage to their engine or loss of warranty coverages by not properly maintaining their equipment. Because operators are solely dependent on the availability of their equipment to operate and generate revenue, there is little incentive for operators to circumvent the engine emissions control system. [EPA-HQ-OAR-2019-0055-1308-A1,p .12]

However, returning to the inducement schedule, there needs to sufficient time for the motorcoach to reach a safe location. It is not unusual for motorcoach routes to traverse remote stretches of the country. Also, there are not as many service locations available to a motorcoach, as opposed to a truck. [EPA-HQ-OAR-2019-0055-1308-A1, p.10]

Organization: *American Trucking Associations (ATA)*

EPA’s proposed high speed inducement speed settings will impact typically operations while avoiding operating vehicles at a speed that impedes the normal and reasonable movement of traffic. According to 2020 data collected by ATRI, among reported trucks with speed limiters, 76 percent of them had a speed setting between 65 to 68 mph.16 Thus, while the initial six hours of derate should have minimal operational impacts and allow time for the vehicle to access a repair facility, the second six hours and beyond, where speeds range from 60 to 50 mph, should present an adequate deterrent to prompt a repair response in the event the initial notification and speed restriction did not. [EPA-HQ-OAR-2019-0055-1326-A1, p. 18]

> 16. Williams, Nathan and Murray, Dan. An Analysis of the Operational Costs of Trucking: 2020 Update, American Transportation Research Institute (November 2020).

Organization: *California Air Resources Board (CARB)*

As discussed in the previous section, the NOx emission reductions associated with reduced emission standards will only be achieved with a properly functioning SCR aftertreatment system, by ensuring adequate dosing of high-quality DEF, by timely repair of faulty DEF related components, and by effective diagnosis of SCR system tampering. This becomes even more important as the proposed CTP NOx emission standard is reduced further by up to 90 percent. Every one of these elements for proper SCR function must be accounted for when establishing SCR inducement. The derate schedule proposed in the NPRM does not achieve this objective for the reasons presented below. [EPA-HQ-OAR-2019-0055-1186-A2, p.96]

Because SCR systems that are operated without DEF will not achieve any reductions of NOx,159 as discussed in Section IV.D of the NPRM, U.S. EPA has promulgated proposed policy guidance that is designed to ensure that vehicle owners supply sufficient quantities of high-quality DEF needed to ensure SCR equipped vehicles will in fact comply with applicable NOx emission standards as such vehicles are operated on highways. That guidance includes, in pertinent part, an 'inducement mechanism' that reduces an engine's output and consequently reduces the maximum speed of the vehicle to a degree that is unacceptable for typical driving.160 U.S. EPA is also aware that affected vehicle owners may attempt to override the adverse driving effects by tampering or disabling the inducement mechanism, and is therefore also proposing provisions intended to deter such tampering.161 However, the proposed provisions present legal and technical concerns. [EPA-HQ-OAR-2019-0055-1186-A2, pp.96-97]

159 NPRM at p. 17536.

160 NPRM at p. 17536.

161 NPRM at 17540-17544.

As explained below, U.S. EPA failed to consider important aspects of the inducement proposal that are directly relevant to the effectiveness of the proposed inducement speeds to compel corrective actions by vehicle owners, and the corresponding emissions impacts. The failure to consider those factors constitutes arbitrary and capricious agency action, and contravenes U.S. EPA's statutory duty to ensure heavy-duty engines and vehicles comply with applicable emissions standards over their useful lives. [EPA-HQ-OAR-2019-0055-1186-A2, p.97]

First, the proposed initial inducement speed of 65 mph for high-speed vehicles and 50 mph for low-speed vehicles is insufficiently stringent to compel a vehicle operator to seek timely repairs of SCR systems. The vehicle speed distribution from two real-world driving datasets consisting of 109 trucks with over 20,000 hours of driving shows that these proposed initial maximum speeds would have very limited, if any, impact to induce an operator to fix the inducible fault (see Appendix IV [Appendix IV can be found at EPA-HQ-OAR-2019-0055-1186-A2, pp.165-174] for further analysis of real world on-road heavy-duty activity data analyzed with respect to U.S. EPA's proposed SCR inducements). [EPA-HQ-OAR-2019-0055-1186-A2, p.97]

Furthermore, for high-speed vehicles, the maximum speed limit for line-haul trucks in many states is 65 mph; in fact in California, it is only 55 mph. Eleven other states have 55 mph speed limits for urban freeways.162 Setting the initial inducement at the maximum highway speed limit in many states (and in California and eleven other states, 10 miles above the maximum speed limit) would not compel the operator to make timely repair of SCR components when there is a significant NOx emission impact. While the NPRM noted that the U.S. EPA 'data show that combination long-haul vehicles spend nearly almost 40 percent of their driving time over 65 mph,' this high-speed operation is not evenly distributed nationally, particularly for states with a maximum speed limit of 65 mph or less where this initial inducement speed will not effectively induce the operator to act promptly. [EPA-HQ-OAR-2019-0055-1186-A2, pp.97-98]

162 https://www.iihs.org/topics/speed/speed-limit-laws

In addition, it does not make sense for California to set an initial inducement speed that is 10 mph higher than California's highway maximum speed limit for most trucks. Likewise for low-speed vehicles, whose average speed is at or below 20 mph, these regional or urban vehicles spend most of their time on city streets and are likely able to choose delivery routes that would not be restricted by a 50 mph inducement. Thus, the proposed initial inducement schedule for many trucks would allow long-term delays of needed repairs because of the limited disruption that could be easily dealt with by the operator. [EPA-HQ-OAR-2019-0055-1186-A2, p.98]

U.S. EPA's failure to consider the maximum speed limits in each of the states, the distribution of high speed operations of heavy-duty vehicles throughout the nation, and the possibility that regional or urban vehicles would likely travel on delivery routes not restricted by the proposed 50 mph initial inducement speed constitutes a failure to consider an important aspect of the problem, State Farm, 463 U.S. at 43, because those omissions affect U.S. EPA's analysis and conclusions regarding the effectiveness of the proposed inducements to trigger corrective action. U.S. EPA also failed to propose a 'rational connection between the facts found and the choice made,' State Farm, 463 U.S. at 43, because the proposed initial inducement speeds are unlikely to compel corrective vehicle owners to take corrective actions. [EPA-HQ-OAR-2019-0055-1186-A2, p.98]

Second, the final inducement step of 50 mph for high-speed vehicles and 35 mph for low-speed vehicles is still not severe enough to induce an operator to immediately make repairs (see Appendix IV) [Appendix IV can be found at EPA-HQ-OAR-2019-0055-1186-A2, pp.165-174], especially if this problem has been ignored for the first 60 hours of inducement using operator work-around strategies. This proposed final derate step would be significantly less effective to the operator than the current inducement guidance of driving vehicle speed down to 5 mph at safe harbor conditions. As shown in CARB staff's recent field survey, a severe final inducement is effective at getting timely repairs and minimizing air quality impacts. The NPRM's final inducement step does not cause 'degradation that includes operation of the engine being disabled or severely restricted' as noted in CISD-09-04R, and hence departs significantly from the current effective guidance. This major proposed relaxation of the current guidance would be ineffective to induce the operator to make expeditious repair of the SCR system because the proposed final inducement speeds would allow a vehicle to be driven for *unlimited miles at lower speeds without ever fixing the fault condition.* [EPA-HQ-OAR-2019-0055-1186-A2, p.98]

U.S. EPA's failure to consider the effectiveness of the proposed final inducement speeds to compel corrective actions, and the potential excess emissions resulting if final inducement speeds do not ultimately result in corrective repairs constitutes a failure to consider an important aspect of the problem, State Farm, 463 U.S. at 43, and a failure to propose a 'rational connection between the facts found and the choice made,' State Farm, 463 U.S. at 43, because the proposed final inducement speeds are unlikely to compel corrective vehicle owners to take corrective actions and will therefore increase the risk that defective and/or tampered SCR systems will result in excessive emissions. The extent of such excess emissions may be substantial, in light of the facts that heavy-duty vehicles with defective or tampered SCR systems exhibited NOx emissions that were 6 to 10 times higher than baseline NOx emissions levels, and given CARB staff's concern that the proposed final inducement speeds would allow heavy-duty vehicles with defective or tampered SCR system to operate indefinitely. [EPA-HQ-OAR-2019-0055-1186-A2, pp.98-99]

Moreover, U.S. EPA has not, and cannot demonstrate that the proposed inducement strategy 'is permissible under the statute, that there are good reasons for it, and that the agency believes it to be better...'FCC v. Fox Television Stations, Inc., 556 U.S. 502, 515 (2009). [EPA-HQ-OAR-2019-0055-1186-A2, p.99]

The emissions standards prescribed under the CAA section 202(a)(1) and 202(a)(3) apply to motor vehicles and motor vehicles throughout their useful lives, i.e., as such vehicles and engines are actually operated on highways, for prescribed periods of time. As discussed in Section 5, the overriding directive of the CAA section 202(a) is the protection of the public's health and welfare, and the nation's air quality. U.S. EPA's proposed inducement strategy, unlike the preexisting inducement strategy, is inconsistent with those statutory mandates because it would, as demonstrated by CARB staff's comments, allow vehicles to operate for potentially unlimited periods of time, even if those vehicles are emitting pollutants well in excess of applicable emissions standards, in direct conflict with those unambiguous statutory provisions. Chevron, 467 U.S. at 842-843. CARB staff's comments also make it clear that U.S. EPA has not established that the proposed inducement strategy is more effective than the preexisting inducement strategy in achieving its stated goal of ensuring the reduction of excess emissions from defective SCR systems and of deterring tampering of SCR systems to override inducement systems, and it is accordingly clear that the proposal is arbitrary and capricious. [EPA-HQ-OAR-2019-0055-1186-A2, p.99]

163 See footnotes 504 and 505, NPRM at p. 17512.

Table 1 of 40 CFR 1037.510 - Weighting Factors for Duty Cycles provides the weighing factors for three different emission test cycles (transient, 55 mph cruise, and 65 mph cruise) for tractors and for urban, multi-purpose, and regional vocational vehicles in determining GHG emission compliance. While the weighing factor for tractors is over two-thirds for the 65 mph cycle, the weighing factors for multi-purpose vehicles are only less than one-quarter for the 65 mph cycle and about one-quarter for the 55 mph cycle, with the remaining half for the lower-speed transient cycle. [EPA-HQ-OAR-2019-0055-1186-A2, p.107]

Furthermore, the vehicle speed distribution from two real-world driving datasets consisting of 109 trucks with over 20,000 hours of driving shows that the low 20 mph low-speed vehicle threshold would prevent many urban vehicles that rarely drive at highway speeds from being classified as low-speed vehicles. The 20 mph low-speed threshold would instead make these vehicles subject to the ineffective proposed initial and high inducement maximum speeds of 65 mph and 50 mph, respectively (see Appendix IV) [Appendix IV can be found at EPA-HQ-OAR-2019-0055-1186-A2, pp.165-174]

The NPRM requests comments on the definition of low-speed vehicles. The low-speed vehicle definition having an average speed of 20 mph or less over the preceding 30 hours of operation may only capture urban vehicles, and multi-purpose vehicles that have a mix of city and highway driving may be considered high-speed vehicles. Because NPRM's high-speed vehicle inducement schedule is based on line-haul vehicle operation, the derate speeds for high-speed vehicles would not be as meaningful to multi-purpose vehicles. As stated above, the initial NPRM inducement step is at 65 mph and last inducement step is at 50 mph. [EPA-HQ-OAR-2019-0055-1186-A2, p.107]

CARB staff recommends that NPRM's average speed threshold for low-speed vehicles be increased to 30 mph to capture vehicle operation for multi-purpose and urban vehicles so that these vehicles are subjected to the low-speed vehicle derate schedule. [EPA-HQ-OAR-2019-0055-1186-A2, p.107]

To address fleet owners' concerns about inducements while still adequately protecting air quality, CARB staff proposes two different derate schedules. The first would be a less severe derate schedule when a fault condition is detected, and the SCR NOx override factor as calculated in the proposed 40 CFR 1036.111(c) is at or less than 0.10. In this situation, NOx emissions would not yet be impacted despite the fault condition, and immediate action would not be necessary to avert excess NOx emissions. Thus, a less severe inducement schedule would be preferable, similar to what the NPRM proposes in 40 CFR 1036.111(d). This schedule would allow the operator to continue to drive the vehicle to complete its present task and return to home base or a repair shop to get repairs done that is less disruptive to fleets and operators. The inducement schedule would provide reduced engine performance that encourages the operator to make plans for repairs but still allow the operator to complete the task at hand when inducement is triggered. This change to allow the operator more time to get faulty SCR components repaired, along with new lengthened warranty requirements that will drive improved component designs by manufacturers, should almost completely eliminate unnecessary severe inducements that could affect operators and interrupt fleet operations. CARB staff proposes the following inducement schedule in Table 9-1 for this type of scenario, assuming that NOx sensors are working properly, there is no tampering of components, and it is expected that the SCR system is functioning properly:

- 0 non-idle hours of engine operation
    - Maximum torque derate/max. speed for high-speed vehicles
        - 25% max torque derate
    - Maximum torque derate/max. speed for low-speed vehicles
        - 25% max torque derate
- 24 non-idle hours of engine operation
    - Maximum torque derate/max. speed for high-speed vehicles
        - 25% and 55 mph (from governed top speed lower speed 1 mph every 5 min until 55 mph is achieved)
    - Maximum torque derate/max. speed for low-speed vehicles
        - 25% and 40 mph (from governed top speed lower speed 1 mph every 5 min until 40 mph is achieved)
- 48 non-idle hours of engine operation
    - Maximum torque derate/max. speed for high-speed vehicles
        - 25% and 45 mph (from 45 lower speed 1 mph every 5 min until 45 mph is achieved)
    - Maximum torque derate/max. speed for low-speed vehicles

        - 25% and 30 mph (from 30 lower speed 1 mph every 5 min until 30 mph is achieved)
- 72 non-idle hours of engine operation
    - Maximum torque derate/max. speed for high-speed vehicles
        - 40% and 35 mph (from 45 lower speed 1 mph every 5 min until 35 mph is achieved)
    - Maximum torque derate/max. speed for low-speed vehicles
        - 40% and 20 mph (from 20 and lowered speed 1 mph every 5 min until 20 mph is achieved) [EPA-HQ-OAR-2019-0055-1186-A2, pp.101-102]

As noted earlier, the NPRM's proposed initial inducement speed is higher than twelve (including California) states' maximum urban highway speed limits. Instead of NPRM's initial inducement of 65 mph, CARB staff recommends a derate of the maximum torque of 25 percent be applied for both high-speed and low-speed vehicles with no vehicle speed inducements. After 24 hours, if the operator does not repair the fault condition, a vehicle speed derate to 55 mph would occur in addition to the 25 percent maximum torque derate (or 40 mph for a low-speed vehicle). After another 24 hours, for a total of 48 hours after fault detection, the speed derate would decrease to 45 miles per hour (or 30 mph for low-speed vehicles.) Finally, if after a total of 72 hours the fault condition is still not fixed, then the final inducement step reduces the maximum torque by 40 percent and the maximum vehicle speed to 35 mph (or 20 mph for a low-speed vehicle). CARB staff is also proposing a more gradual speed inducement within each step of 1 mile per hour reduction for every 5 minutes until the step inducement speed is reached. This change would alleviate operator safety concerns during speed derates at highway speeds by inducing speed reductions of 1 mph at a time until the speed inducement is met. [EPA-HQ-OAR-2019-0055-1186-A2, pp.102-103]

For fault conditions when NOx emission control efficiency falls by more than 10 percent, a more severe inducement schedule is warranted and should be maintained, similar to what is currently required. In this situation, the SCR is not functioning at a sufficient NOx conversion efficiency, resulting in significant excess NOx emissions. Repair of the vehicle in a very short and timely manner is extremely important. Thus, CARB staff proposes the following derate schedule in Table 9-2 for this scenario.

- 0 non-idle hours of engine operation
    - Maximum torque derate/max. speed for high-speed vehicles
        - 30% max torque derate
    - Maximum torque derate/max. speed for low-speed vehicles
        - 30% max torque derate
- 3 non-idle hours of engine operation
    - Maximum torque derate/max. speed for high-speed vehicles
        - 30% and 55 mph (from governed top speed lower speed 1 mph every 5 min until 55 mph is achieved)
    - Maximum torque derate/max. speed for low-speed vehicles
        - 30% and 35 mph (from governed top speed lowered speed 1 mph every 5 min until 35 mph is achieved)
- 8 non-idle hours of engine operation

    - Maximum torque derate/max. speed for high-speed vehicles
        - 30% and 45 mph (from 55 lower speed 1 mph every 5 min until 45 mph is achieved)
    - Maximum torque derate/max. speed for low-speed vehicles
        - 30% and 25 mph (from 35 lowered speed 1 mph every 5 min until 25 mph is achieved)
- 10 non-idle hours of engine operation
    - Maximum torque derate/max. speed for high-speed vehicles
        - 40% and 35 mph (from 45 lower speed 1 mph every 5 min until 35 mph is achieved) and 5 mph at safe harbor
    - Maximum torque derate/max. speed for low-speed vehicles
        - 40% and 20 mph (from 20 and lowered speed 1 mph every 5 min until 20 mph is achieved) and 5 mph at safe harbor [EPA-HQ-OAR-2019-0055-1186-A2, p.103]

In this schedule, the time for each step of inducement is significantly shortened compared to the previous schedule in Table 9-1, with the final inducement occurring at 10 hours of non-idle operation. If the vehicle was operating at the top speed of each inducement step, this could still equate to hundreds of miles of vehicle operation before the final inducement takes effect, which still would allow vehicle operation at a maximum speed of 35 mph for high-speed vehicles and 20 mph for low-speed vehicles. Once the vehicle is at safe harbor, the final inducement would reduce the vehicle's maximum speed to 5 mph. This derate schedule still would provide opportunity for the operator to make needed repairs and reduce safety concerns and significantly reduce the frequency of towing vehicle to a repair shop when operators are proactively attempting to address the inducement. As mentioned above, this inducement schedule also incorporates gradual speed derates to significantly reduce safety concerns at highway speeds. [EPA-HQ-OAR-2019-0055-1186-A2, p.103]

Organization: *Carreras Tours, LLC (2032)*

I think this issue of having a bus derate when an issue arises with the engine needs to be extended to a longer period in order to be able fix the issue when the vehicle gets to a safe place. We had an experience where our bus got a check engine light going on interstate 5 in central California. We had students on board and the bus derate to 5 MPH. The good thing is that we happened to be less than a mile from an exit. We feared that a truck might rear end us and injure the passengers. It took several hours to get a rescue bus to pick up the group. All this could have been avoided if time for us to diagnose the problem in a shop, and in a safe place where the bus and the passengers were safe. If a sensor fails, the bus derate the bus immediately and gives us no chance to get to a safe place. In this instance, it was a $20 sensor that failed. We would like to request to have the time extended or miles extended before defraying the bus. Our goal is to keep all of our passengers safe. Please consider this request. [EPA-HQ-OAR-2019-0055-2032, p.1]

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

EPA's proposed inducement schedule offers insufficient incentives to ensure maintenance of SCRs. The Proposal indicates an initial derate that would allow most vehicles to continue to operate at up to 65 mph—close to the speed limit—decreasing after 60 hours of use to 50 mph. Vehicles with a recent history of low-speed operation—an average below 20 mph, for the previous 30 hours of engine operation—are initially restricted to 50 mph, decreasing to 35 mph after 60 hours of operation (the 'LSI' limit). Id. at 17,543–44. The former limits—to numbers at or near the speed limit—are unlikely to induce prompt corrective action.243 The LSI limit provides virtually no assurance of prompt corrective action. A vehicle that routinely operates at an average speed of 20 mph cannot be expected to respond to a derate that restricts its speed to 50 mph. In many cases (such as drayage and similar uses) such vehicles are unlikely to promptly respond even to the final derate, limiting speeds to 35 mph.244 [EPA-HQ-OAR-2019-0055-1302-A1, pp.62-63]

> 243 See FHWA, Freight Management and Operations, Freight Facts and Figures 2010 (2010), https://ops.fhwa.dot.gov/freight/freight_analysis/nat_freight_stats/docs/10factsfigures/table3_8.htm (reporting maximum interstate average speeds below 60 mph).
>
> 244 See Andrew Papson & Michael Ippoliti, Key Performance Parameters for Drayage Trucks Operating at the Ports of Los Angeles and Long Beach 6, CALSTART (Nov. 15, 2013), https://calstart.org/wp-content/uploads/2018/10/I-710-Project_Key-Performance-Parameters-for-Drayage-Trucks.pdf (noting maximum speeds for near-dock operations of only 40 mph, and average speeds under 7 mph).

And even for those vehicles whose owners might respond to the derates—which EPA suggests are limited to those that must travel substantial distances to reach a job site, 87 Fed. Reg. at 17,543—the Proposal's 60 hours of non-compliant use would still produce massive quantities of excess pollution. As EPA acknowledges, lack of adequate DEF can 'cause NOx emissions to increase to levels comparable to having no NOx controls at all.' Id. at 17,536. Commenters urge EPA to adopt a more stringent inducement regime than proposed, such as a dual schedule providing less severe derates when the detected fault is unlikely to lead to excess NOx emissions, but imposing more severe derates where NOx emissions are substantially affected so as to demand prompt repair. See Comments of CARB, to be filed in Docket EPA-HQ-OAR-2019-0055 on May 16, 2022. [EPA-HQ-OAR-2019-0055-1302-A1, p.63]

Organization: *Coach USA, Inc. (Coach USA)*

Coach USA is generally concerned that the selective catalytic reduction ("SCR") inducement proposal made applicable to motorcoaches does not adequately take the unique concerns of passenger transportation safety into account. Under no circumstances, can buses full of passengers be left stranded on the side of a roadway or a bus be unable to travel at a safe highway speed that does not present a potential obstacle to safety. Thus, any derate inducement schedule that might be applied to high speed motorcoach vehicles needs to be fashioned in coordination with highway safety foremost in mind. Unless and until that happens, motorcoaches should be excluded from any derate requirements under the EPA emissions rules. [EPA-HQ-OAR-2019-0055-1307-A1, p. 3]

Coach USA supports the proposed 65 MPH limitation at section 1036.111(d) for the initial speed restriction at least 10 hours after a fault condition is identified, although Coach USA would also support a longer inducement period. Coach USA believes that its drivers will be induced by the vehicle's emissions warning lights to take corrective action relative to the fault condition such that a lower speed restriction (such as 55 MPH) is not necessary. Nor would a lower speed restriction be as safe as a 65 mph limit given that the buses frequently operate on high speed highways where a restriction of less than 65 mph can present a safety problem where the bus would be unable to keep up with the flow of traffic. To the extent that substantial repairs are required to address a fault condition, the subsequent inducements – amounting to up to 60 hours – provide the minimum adequate time. Coach USA trains its drivers to pay close attention to fault condition alerts and requires them to take appropriate action at the next available opportunity, all the while taking into consideration passenger safety. In this regard, EPA should bear in mind the safety considerations that are unique to passenger transportation versus truck transportation, as well as the fact that passengers are often depending on bus transportation to meet connecting buses, flights, trains, job responsibilities and other schedule-dependent requirements. [EPA-HQ-OAR-2019-0055-1307-A1, p. 4]

Interstate bus operations conducted by Coach USA are designed to maintain reliable schedules for its passengers. A speed of 50 MPH, which is generally below interstate/highway speeds and potentially a safety risk, will prompt drivers to take action to address a fault condition, although even such a restriction is not generally going to be required given the sufficiency of the inducement created by the driver's attention to warning lights. Any lower restriction would compromise passenger and driver safety on congested roadways without better ensuring inducement. [EPA-HQ-OAR-2019-0055-1307-A1, pp. 4 - 5]

Accordingly, buses will not always have the ability to reach a bus repair facility within a 6-hour period when a fault condition prompts repair or replacement of components. Coach USA believes that a minimum 10-hour period for the first stage of inducement, and preferably longer, is appropriate for all default conditions due to other than low DEF levels. This longer period will ensure that passengers are kept safe and not potentially stranded along interstate bus routes. On this point, EPA should aware of the difficulty/inability of bus operators to locate alternative buses to pick-up passengers along interstate routes. Our industry is currently struggling with a serious shortage of drivers, which has reduced operational flexibility. The industry has also experienced a major reduction in the number of bus operators due to COVID, as noted above. Accordingly, Coach USA supports an approach that ensures the ability of its drivers to address a fault condition upon completion of a route. [EPA-HQ-OAR-2019-0055-1307-A1, p. 5]

In light of the comment above, Coach USA supports a longer schedule involving more time between stages. This will ensure the ability of drivers to reach repair facilities to address fault conditions, while also ensuring that passengers are safely transported to their destinations without interim stops or delays. Drivers are typically on a 10-hour route schedule. Fault conditions will be addressed, absent repair or part replacement issues, at the end of the period, preventing long-term operation of the bus with a fault condition. A shorter period is not necessary to address a fault condition and will not help to better ensure inducement on the part of the bus industry. [EPA-HQ-OAR-2019-0055-1307-A1, p. 6]

Should any derate inducement rules be adopted for motorcoahes, Coach USA supports the proposed 80 hours of operation. [EPA-HQ-OAR-2019-0055-1307-A1, p. 6]

Coach USA believes that the proposed schedule is both reasonable and effective to induce drivers to correct a fault condition if any rules are adopted. Shortening the proposed schedule would adversely affect interstate bus operations and also comprise passenger/driver safety. The 65 and 50 MPH inducement stages applicable to interstate buses will ensure that SCR systems will be maintained appropriately, although as noted Coach is concerned with any derate schedule applicable to motorcoaches and with a derate speed of less than 65 mph. [EPA-HQ-OAR-2019-0055-1307-A1, p. 6]

Coach USA does not believe that a high-speed vehicle should ever be treated like a low speed vehicle for purposes of inducement. While no inducement schedule should be applied to motorcoaches for the above reasons, a restriction of 50 MPH will induce interstate bus drivers to take corrective action to address a fault condition. An interstate bus cannot be maintained at a speed of less than 50 MPH while ensuring passenger safety and that schedules are maintained. [EPA-HQ-OAR-2019-0055-1307-A1, p. 7]

Organization: *Compass Coach Inc.*

I want to comment on EPA-HQ-OAR-2019-0055. As an owner of a PASSENGER carrier for the past 23 years I 100% believe these EPA regulations are hurting our industry and placing passengers at risk. The Government is so keen to passing rules and regulations that make travel safer. How can this be safe when we are given 4 hours or less once a Regen light comes on to find a safe place to park with our passengers. Attempt to get another vehicle to pickup our current passengers. It's not possible. [EPA-HQ-OAR-2019-0055-2120, p.1]

Don't even go down the road that says 4 hours is enough time to find a place to get it checked out. I literally just had a 2019 Temsa 45' coach sitting in a Cummins yard 300 miles away because we were waiting for a SENSOR. A SENSOR. The system are running fine. It's the sensors that normally go bad. [EPA-HQ-OAR-2019-0055-2120, p.1]

If the Government is dead set on getting more emmissions into these vehicles (which I am all for cleaning the air....100% support this idea), they need to separate passenger vehiles from OTR trucks. There needs to be more time to allow passenger vehicles to get back to their own shop to get looked at. Give us a 72 hour countdown. With 72 hours, any operator should be able to get another bus out to replace the broken one and also get our bus back to our garage so our local dealership can look at the unit. [EPA-HQ-OAR-2019-0055-2120, p.1]

Organization: *Cummins Inc. (Cummins)*

EPA should also allow for transitions between the vehicle speed levels rather than step changes. [EPA-HQ-OAR-2019-0055-1325-A1, p. 14]

EPA has appropriately defined key principles for updating SCR inducements to ensure that emission control function and emissions reductions occur in-use while reducing potential impacts to operators. Derate Schedule

In response to request for comment on dynamically switching the derate restriction of a high-speed vehicle during inducement to a low-speed vehicle derate restriction, Cummins proposes that EPA consider not to utilize this method. This is not only due to the software complexity for the manufacturer in handling such derate switching behaviors when applying the correct derate restrictions/schedule, but also due to the potential of further confusing the end-user during an active inducement. [EPA-HQ-OAR-2019-0055-1325-A1, p. 31]

Organization: David Pedersen

Regarding the proposed de-rating requirements, I believe that the Agency's approach is flawed. In-use de-rating poses a clear danger to the vehicle/machinery operator as well as others nearby, particularly for on-road vehicles, and should be abandoned. Instead, the Agency should require a "soft" mechanism similar to the one employed for light-duty vehicles, which is that the engine will refuse to start if compliance-imperiling faults are detected in any of the emissions controls and/or their components. This would also increase compliance as it would *require* operators to redress the faults prior to being able to operate the vehicle again. [EPA-HQ-OAR-2019-0055-1059]

Organization: *District of Columbia Department of Energy and the Environment (DOEE)*

EPA suggests that relaxing SCR inducements would more effectively result in truck operators properly maintaining SCR devices and proposes that for high-speed vehicles the initial inducement would be 65 miles per hour (mph) and the final inducement no lower than 50 mph (up from the current final inducement of 5 mph). For low-speed vehicles, the proposed initial inducement is 50 mph and the final inducement no lower than 35 mph. Such SCR inducements are too lax to encourage a truck operator to act in a timely fashion to fix a problem. Furthermore, the proposed derate schedules would allow up to 60 hours of operation before the final inducement takes effect. Because modern engines rely almost exclusively on SCR to control NOx, that would mean 60 hours of driving, without emission controls, possibly through vulnerable communities, past schools and recreational areas, and near homes and small-business and community hubs. EPA has proposed alternatives to the inducement schedules in the Notice which drop the initial inducements to the following:

- Low speed vehicles have an initial derated speed of 40 mph and a final derated speed of 25 mph;
- High speed vehicles have an initial derated speed of 55 mph and a final derated speed of 40 mph; and

• The time for all vehicles from when inducement begins to the final derated speed would drop to 40 hours. [EPA-HQ-OAR-2019-0055-1299-A1, p. 6]

DOEE is concerned that the proposed derating schedule does not do enough to sufficiently compel operators to properly maintain their equipment, and will cause excess pollution in areas that are already the most overburdened. [EPA-HQ-OAR-2019-0055-1299-A1, p. 6]

If EPA believes changes to the inducement strategies are technologically necessary, DOEE offers the following recommendations. First, EPA's proposed inducements, which would dramatically increase maximum speeds allowed under the derate schedules, should be revised considerably downward, at least to the alternative speeds that EPA has already proposed. Second, EPA should amend the definition of a low-speed vehicle from a 20-mph threshold to a 30-mph threshold so that these vehicles would be subject to a more appropriate low-speed vehicle derate schedules. Third, EPA should finalize derate schedules with less time between stages to reduce the total allowed hours of operation before the final inducement occurs.[EPA-HQ-OAR-2019-0055-1299-A1, pp. 6 - 7]

Organization: *International Council on Clean Transportation (ICCT)*

RECOMMENDATION: We recommend EPA strengthen proposed SCR inducement provisions to include a final speed derate inducement of 20 mph or less for low-speed trucks, 35 mph or less for other trucks with a possible exception for line-haul trucks, abandon proposed override disincentives, continue to monitor diesel exhaust fluid quality, and adopt the proposal to add additional monitoring of disconnection devices. [EPA-HQ-OAR-2019-0055-1211-A1, p. 3]

We recommend that EPA continue to require monitoring of DEF quality with more time allowed to remedy an indicated fault. If there is indication that the SCR is functioning with less than 10 percent loss of efficiency, a final derate would not occur for up to 60 hours, providing adequate time to obtain a repair. If SCR efficiency loss is greater than 10 percent, indicating very high NOx emissions, the operator would have a shorter period of time, up to 16 hours of operation to obtain repairs before a 5 mph derate is imposed. The extension of time to seek repair should help address operator concerns that the current 4-hour period before a 5 mph derate occurs is too short and can cause the vehicle to be stranded. [EPA-HQ-OAR-2019-0055-1211-A1, p. 23]

We recommend the EPA proposed speed derate schedules, with the fourth step derate speed lowered as discussed above, be followed only if the NOx sensors also indicate a SCR efficiency loss of 10 percent or less due to the indicated fault. This revised provision provides a more gradual set of speed derate over 60 hours (about 4 or more days) of operation, with no disabling 5 mph final derate, based on the probability that the NOx impact of the faulty component or failure to properly maintain the DEF system is relatively low. The greater time before the final speed derate occurs will give the operator more opportunity to resolve the indicated fault with less inconvenience. More vehicles with faults that increase emissions will be repaired. [EPA-HQ-OAR-2019-0055-1211-A1, p. 22]

For vehicles with indicated SCR efficiency loss of greater than 10 percent, we recommend adopting a new schedule of speed derates with a shorter period between steps. In addition, a fifth step would be added warning that after 4 more hours of operation speed will be limited to 5 mph after the next refueling or engine stop. [EPA-HQ-OAR-2019-0055-1211-A1, p. 23]

If the sensor indicates more than a 10 percent loss in SCR efficiency, the threat of extremely high emissions grows dramatically, with a hundred-fold increase in NOx possible in the event of a complete SCR failure. In this case, we recommend the vehicle be subject to a new, much quicker speed derate schedule so that repairs are made sooner. ICCT suggests the fourth step of speed derate occur within 12 hours of fault indication, rather than at 60 hours as EPA has proposed. In the event this final inducement does not cause the operator to seek repairs, we recommend the operator be warned that after another 4 hours of operation speed will be limited to 5 mph following the next refueling or engine shutdown. This extra step is needed to assure the highest emitting trucks do not continue to operate for long periods without repair. Note this final 5 mph speed derate is not new and has been part of the HD emission control program for a decade. Limiting the 5 mph derate to the highest emitting trucks with an indicated SCR efficiency decline of more than 10 percent as indicated by the NOx sensors will preserve important emission reductions. Providing a total of 16 hours from the initial fault notification before the 5 mph derate occurs will help address concerns of operators that the short period of time in the current guidance before the speed derate of 5 mph occurs (as little as 4 hours from fault indication) can create significant cost and inconvenience to operators and, in the case of non-transit buses, their passengers. [EPA-HQ-OAR-2019-0055-1211-A1, p. 23]

We recommend a final speed derate inducement of 20 mph or less for low-speed trucks. This will provide a meaningful incentive to seek repairs, thereby reducing excess emission operation. [EPA-HQ-OAR-2019-0055-1211-A1, p. 21]

EPA proposes a final derate speed of 35 mph for low-speed vehicles. These urban trucks could avoid repairs even with the final EPA proposed speed derate by operating only on local streets and arterials and avoiding urban freeways that require higher speed. This is possible for many small businesses such as lawn care and home repair that do not travel long distances between jobsites. The ability to continue operating without repair in urban areas could have a disproportionate impact on disadvantaged communities, an unacceptable outcome. [EPA-HQ-OAR-2019-0055-1211-A1, pp. 21 - 22]

We recommend a final speed derate inducement of 35 mph or less for trucks other than low-speed trucks, with the possible exception of line haul trucks. The unlikelihood of being able to operate on urban and regional highways at this maximum speed will provide a meaningful incentive to seek repair of indicated faults. [EPA-HQ-OAR-2019-0055-1211-A1, p. 22]

EPA’s proposed final speed inducement of 50 mph will be meaningless for many urban-based trucks capable of freeway speeds. The objective of speed derates is to keep trucks with failed components and high emissions from operating at highway speeds, thus providing an incentive for repair. While a 50 mph final speed derate may be a strong enough disincentive for line haul trucks, it will not provide a strong incentive to obtain repairs for many regional and urban-based trucks. [EPA-HQ-OAR-2019-0055-1211-A1, p. 22]

The truck speed limit in many urban areas is 55 mph, so a 50 mph derate limit will not prevent trucks from operating on the highways. For example, a 50 mile trip at 50 mph takes only 6 minutes longer than if the truck travelled at 55 mph, a relatively minor inconvenience compared to taking the truck out of service for repair. Many urban areas have considerable urban congestion during which speeds are less than the speed limit. The 50 mph final speed derate would have little or no impact on trucks during these frequent congested conditions. Another consideration is many regional and urban-based trucks regularly travel though or near residential neighborhoods surrounded by warehouses, ports and industrial sites, where air pollution is already higher than other urban areas. High truck emissions due to repair avoidance will disproportionately impact residents of these areas, who are often low-income persons of color, and who would benefit from more, rather than less protection from truck emissions. [EPA-HQ-OAR-2019-0055-1211-A1, p. 22]

If EPA believes a lesser speed derate is appropriate for line haul trucks, ICCT suggests allowing a higher final speed derate if the truck exceeds an average speed based on typical line haul operation. A 50 mph speed derate would provide an incentive for line haul trucks to seek repair since speed limits on interstate highways are often higher than 55 mph and it is common practice for trucks to operate at higher speeds. When these trucks age and become urban-based, such as moving shipping containers, their average speed may decline below the interstate speed average and the final 35 mph derate would be applied. [EPA-HQ-OAR-2019-0055-1211-A1, p. 22]

Organization: *Maine Department of Environmental Protection (Department)*

Using the CARB Heavy-Duty Omnibus Regulation as a bellwether, the Department requests the following revisions to the federal proposal: [EPA-HQ-OAR-2019-0055-1288-A1, p.6]

- EPA’s proposed speed derates (Table IV-13 of the NPRM) do not provide sufficient inducement for many low-speed vehicles to repair (or replace DEF) in a timely manner since locally operated vehicles could operate at the lowest speed of 35 miles per hour without a significant performance penalty in a congested traffic area.17 Even when engine derating is an incentive for operators to perform required maintenance, the new schedule allows for up to 60 hours of operation before the final inducement goes into effect. This could amount to 60 hours of driving on local streets, near schools, small businesses, and residences without emissions control. The Department strongly urges EPA to reconsider the low-speed vehicle inducement schedule and make the derated vehicle speeds significantly lower. [EPA-HQ-OAR-2019-0055-1288-A1, p.7]

17 Many roads in urban areas already have speed limits of 25 mph or lower

Using the CARB Heavy-Duty Omnibus Regulation as a bellwether, the Department requests the following revisions to the federal proposal: [EPA-HQ-OAR-2019-0055-1288-A1, p.6]

- SCR inducements. The limitations imposed on vehicle operation that occur when a vehicle runs out of diesel exhaust fluid (DEF), has poor quality DEF, or when tampering occurs to the SCR should be revised for low-speed vehicles. [EPA-HQ-OAR-2019-0055-1288-A1,p.7]

Organization: *Midwest Bus & Motorcoach Association*

Motorcoaches play an important role when a natural disaster occurs and people need to be evacuated. Each year this industry is asked to transport citizens out of an area that has experienced an environmental hazard such as a hurricane or wildfire. The industry is actively engaged in moving our nation's military in time-sensitive situations, such as national guard deployments. It is important to note that there is a current exemption of inducements applied to emergency vehicles. Because of safety concerns and risk to supporting human health, in 2012, EPA issued a DFR for all emergency vehicles such as ambulances and firetrucks, preventing them from losing speed or power. This ruling provided OEMs the ability to offer new engine software calibrations that eliminated the chance of inducements that would cause delays to life saving measures. With the multi-use purposes motorcoaches provide, including life saving measures, it would fall in line to include this industry in the derating exemption. [EPA-HQ-OAR-2019-0055-1158-A1, p.3]

This proposed rule change is not safe or sensible for our industry's vehicles. Rather than further restricting the industry and causing additional undue burdens, we need flexibility and reasonable timeframes that allow operators to transport their passengers back to the point of origin to receive proper maintenance. The motorcoach industry transports people and should be separated from the freight transporters. [EPA-HQ-OAR-2019-0055-1158-A1, p.3]

Organization: *Motorcoach Companies*

It is also important for us to mention the role we play in natural disaster and other evacuations. Every year our industry is called upon to offer relief when there are environmental hazards such as hurricane or wildfires to transport citizens out of harm's way. Our industry is also actively engaged in moving our nation's Military across country in time sensitive situations, such as the national guard being deployed. We would also like to point to the current exemption that emergency vehicles have for inducements. Because of safety concerns and risk to supporting human health, in 2012 the EPA issued a DFR for all emergency vehicles such as ambulances and firetrucks, preventing them from losing speed or power. This ruling then granted OEMs to offer new engine software calibrations that eliminated the chance of inducements causing delays to life saving measures. It makes perfect sense for the EPA to offer this flexibility and exemption to any vehicle that would be subject to derating in a life-saving situation. We feel that our industry should fall under this category of emergency vehicles. This alone should be reason enough to grant our industry an exemption as we are helping save lives in these emergency situations. [EPA-HQ-OAR-2019-0055-1149-A1, p.3]

What the EPA has proposed is not suitable for our industries vehicles. We are in need of increased flexibility and a more reasonable time frame to allow operators to transport their passengers back to the point of origin, allowing a vehicle to return to the operator's facility to receive proper maintenance. [EPA-HQ-OAR-2019-0055-1149-A1, p.3]

Given the nature of our business and the fact we are transporting large groups of people not freight, we feel our industry should be separated into its own category. If the EPA is not willing to grant us a derate exemption as they had all other emergency vehicles; we present the below counter option for your consideration and feel our counter offer would be a more acceptable time frame. [EPA-HQ-OAR-2019-0055-1149-A1, p.3]

Default maximum speed (mi/hr)	**Commercial Passenger Vehicles Counter 1**	**Commercial Passenger Vehicles Counter 2**
65	derate exempt	24 hours
60	derate exempt	48 hours
55	derate exempt	72 hours
40	derate exempt	96 hours

[Additional comment by several companies that joined this mail campaign:] *Four companies that joined this mail campaign recommend 50 mi/hr instead of 40 mi/hr; see* EPA-HQ-OAR-2019-0055-1198, 1199, 1241, 1267]

[Additional comment by several companies that joined this mail campaign:] There may be some opinions that this schedule offers too much flexibility and operators would be content to run at these speeds. We can assure you that would not be the case for our industry. With any speed limitations our ability to complete a trip without having a second relief driver would be much less likely. Our drivers have a 10-hour drive time for hours of service. Reducing them 5 mph over a course of 10 hours would take roughly 50 miles for each driver. This in turn would complicate our operations and prevent us from completing trips. With the national driver shortage, we are already having issues and stretch drivers to the maximum distance of 600 miles. In order to complete a 600-mile trip we would then need to add a second driver, decreasing the overall trips we could cover, ultimately reducing our full utilization and revenue. This alone would be reason enough for us to not be complacent and continue to operate a slowed vehicle. [EPA-HQ-OAR-2019-0055-1241 and 1267]

Aside from this point, is the customer dissatisfaction that would arise from a slower running vehicle. Most of our customers are on a strict time frame and plan far in advance of arrival times based on calculated ETA from mapping and routing software. If a group is traveling at a reduced speed there will be a lot of complaints and frustrated passengers contacting us. There could be missed flights, sporting events, shows, etc. .. all of these loses are a concern for operators because we pay for reimbursements and will lose a customer's trust. We cannot afford to keep a derated vehicle on the road and would do whatever is necessary to repair that vehicle so that it is capable of operating at posted speed. [EPA-HQ-OAR-2019-0055-1241 and 1267]

Again, there is the safety aspect of vehicles traveling at reduced speed and keeping up with other traffic. Anytime a vehicle is traveling at a slower speed than what is posted it is in a position of being rear-ended on the interstate from a distracted driver who had their vehicle set on cruise control, following the local speed laws. It is obvious that these factors were not considered and must be brought to attention. We will not be ok with running a vehicle at derated speeds and will fix any issue, in a reasonable time frame. Our problem is we currently do not have enough time to get that vehicle to our shop or other service facility, but what we have now is astonishing that it was ever even put in place. To cripple a vehicle is extremely foolish and needs to be corrected immediately. [EPA-HQ-OAR-2019-0055-1241 and 1267]

[Additional comment by one company that joined this mail campaign:] Differing from freight carriers, passenger carriers are many times much further away from homebase as well as much more limited access to repair facilities. Many times under current rules the vehicles end up parked for days or have to be towed to closer facilities just for a simple repair, that given a longer derate schedule or exemption would not happen. This problem is even more exacerbated when we have a group of passengers on board and now we have to find alternate transportation to get them to their destination. [EPA-HQ-OAR-2019-0055-1199]

Each motorcoach you see on the road takes roughly 50 vehicles off the road. There are currently 3500 Motorcoach companies in the United State comprised of roughly 36,000 passenger buses. If the goal of the EPA is to reduce overall emissions, they should be lifting our industry up and encouraging group travel as opposed to other modes of transportation. The bottom line is simple Motorcoaches reduce pollution [Emphasis in original. EPA-HQ-OAR-2019-0055-1199]

Organization: *National Association of Clean Air Agencies (NACAA)*

EPA reasons that relaxing inducements would more effectively result in truck operators properly maintaining SCR and proposes that for high-speed vehicles the initial inducement would be 65 miles per hour (mph) and the final inducement no lower than 50 mph (up from the current final inducement of 5 mph). For low-speed vehicles, the proposed initial inducement is 50 mph and the final inducement no lower than 35 mph. Such inducements are too lax to encourage a truck operator to act in a timely fashion to fix a problem and should not be finalized. [EPA-HQ-OAR-2019-0055-1232-A1, p. 12]

Further, the proposed derate schedules would allow up to 60 hours of operation before the final inducement takes effect. That would be 60 hours of driving, without emission controls, through vulnerable communities, past schools and recreational areas and near homes and small-business and community hubs. This should not be finalized either. [EPA-HQ-OAR-2019-0055-1232-A1, p. 12]

If EPA believes changes to the inducement strategies are technologically necessary, NACAA offers the following recommendations. First, EPA’s proposed inducements, which would dramatically increase maximum speeds allowed under the derate schedules, should be revised considerably downward. Second, EPA should amend the definition of a low-speed vehicle from a 20-mph threshold to a 30-mph threshold so that these vehicles would be subject to a more appropriate low-speed vehicle derate schedule. Third, EPA should finalize derate schedules with less time between stages to reduce the total allowed hours of operation before the final inducement occurs. Finally, rather than just relaxing inducements and potentially allowing a truck with improperly maintained SCR to continue operating with nominal constraint, EPA should put in place measures that will hold manufacturers accountable for addressing the durability and sensor issues about which the agency, dealerships and manufacturers have received complaints. [EPA-HQ-OAR-2019-0055-1232-A1, p. 12]

Organization: *National Association of Small Trucking Companies (NASTC)*

A derate schedule for high-speed trucking of four stages, each having varying lengths that should allow long-haulers to return to their home base or a trusted repair shop.

This proposed approach to inducement would allow many vehicle owners to more efficiently address conditions that trigger inducements and save on costs. For long-haul carriers, the 12 and 60 mile hours allotted for the latter derating stages are certainly an improvement. NASTC believes that having 20 and 120 hours, respectively, for the later stages would enable many more carriers to reach home, and we urge adopting the longer time allotments, at least for long-haul trucking. The ability to return to a motor carrier's garage or a known and trusted local repair facility to attend to emission system problems is very important and desirable. Safety and security issues are heightened when one must attend to repairs and parts replacements on sophisticated systems and attempts self-repair. There are also heightened risks when one entrusts repairs to an unknown shop—there are some unscrupulous actors who take advantage of stranded truckers. The costs of repairs away from home escalate, due to the potential for delayed acquisition of new parts and the need of extended lodging for the duration of the delay. Meanwhile, when a truck is not moving, it isn't earning money. Contracts and customers become at stake of finding another carrier, making a much costlier experience that the current inducement regime imposes. Therefore, having sufficient time to avoid such conditions and risks would be a tremendous improvement. [EPA-HQ-OAR-2019-0055-1130-A1, p. 2]

These changes are crucial. Long-haul truckers must minimize down-time. A truck that is stuck in the shop, poking along the interstate at 5 miles per hour, being towed, or repeatedly having the same emissions system problems costs truckers and motor carriers. And that costs all of us. That is because trucks haul more than 80 percent of America's freight. Trucks bring the goods that stock store shelves and online vendors' warehouses. Trucking is vital to our nation's and our personal well-being, health, quality of life, our communities' viability, and our prosperity. [EPA-HQ-OAR-2019-0055-1130-A1, p. 2.]

Derate speeds for high-speed vehicles from 65 mph to 50 mph in four stages, each derating in 5 mph increments.

Specifically, NASTC applauds separate inducement schedules for high- and low-speed vehicles — making it easier for truckers to make repairs while on the road, using generic scan tools, and providing more, specific information like diagnostic codes — and better warranty coverage of emission system and parts failures so as to keep trucks that remain in service performing emissions reduction while reducing truckers' costs of servicing the systems for the actual life of a vehicle. [EPA-HQ-OAR-2019-0055-1130-A1, p. 2.]

Separate inducement schedules for high- and low-speed commercial vehicles. Longer derate time periods and faster speeds for high-speed trucking, and shorter times and slower speeds for low-speed vehicles, are a much superior approach to inducements. The proposed schedules are much better suited to significantly different types of trucking. The requisite speed differentials for fast- and slow-moving vehicles experiencing inducement (legitimately or from false positives) take a common-sense approach of designing different schedules for vehicles engaged in very different operational models in very different settings. While we can only speak to the high-speed schedule particulars, we support this proposal. [EPA-HQ-OAR-2019-0055-1130-A1, p. 2]

Organization: *Northeast States for Coordinated Air Use Management (NESCAUM)*

Should EPA instead promulgate Option 1, we urge the Agency to make the following changes to the proposed standards: The maximum speeds for low-speed vehicles given in Proposed Inducement Schedules, Table IV-13 as 50, 45, 40, and 35 miles per hour (mph) should be revised. NESCAUM recommends that the maximum speeds given for all four proposed engine hours of operation for low-speed vehicles be reduced. Owners of low-speed vehicles, which are often locally driven delivery vehicles, will not be induced to repair their vehicles quickly with the proposed maximum speeds given in Table IV-13. A locally driven delivery vehicle could operate at the lowest speed of 35 mph without much of a performance penalty in a congested traffic area. Many roads in urban areas have speed limits of 25 mph or lower. In addition, many of the problems cited by commentators that arise when an engine is derated would not greatly affect low-speed, locally driven vehicles, such as large towing expenses and stranding vehicles and drivers far from home. Therefore, it is not appropriate or necessary to allow locally driven low-speed vehicles to drive as fast as allowed in the proposed Inducement Schedule. [EPA-HQ-OAR-2019-0055-1249-A1, pp. 13 - 14]

Even for vehicles where the engine derating is an incentive to perform required maintenance, the new schedule allows for up to 60 hours of operation before the final inducement goes into effect. This could amount to 60 hours of driving on local streets, near schools, small businesses, and residences, without emissions control. We strongly urge EPA to reconsider the low-speed vehicle inducement schedule and make the derated vehicle speeds significantly lower. [EPA-HQ-OAR-2019-0055-1249-A1, p. 14]

Organization: *Owner-Operator Independent Drivers Association (OOIDA)*

OOIDA supports the proposed inducement schedules and various derate principles included in Section IV, D. These provisions focus on conditions that are within a driver’s control, implement a multi-step derate schedule, and a backup check to override false inducements. [EPA-HQ-OAR-2019-0055-1266-A1, p.5]

Organization: *Ozone Transport Commission (OTC) and Mid-Atlantic/Northeast Visibility Union (MANE-VU)*

Even for those vehicles where the engine derating is an incentive to perform required maintenance, the new schedule allows for up to 60 hours of operation before the final inducement goes into effect. This could amount to 60 hours of driving on local streets, near schools, small businesses, and residences without emissions control. We strongly urge EPA to reconsider the low-speed vehicle inducement schedule and make the derated vehicle speeds significantly lower. [EPA-HQ-OAR-2019-0055-1250-A1, p.15]

The maximum speeds for low-speed vehicles given in Proposed Inducement Schedules, Table IV-13 as 50, 45, 40, and 35 miles per hour (mph) should be revised. OTC and MANE-VU recommend that the maximum speeds given for all four proposed engine hours of operation for low-speed vehicles should be reduced. Owners of low-speed vehicles, which are often locally driven delivery vehicles, will not be induced to repair their vehicles in a timely manner with the proposed maximum speeds given in Table IV-13. A locally driven delivery vehicle could operate at the lowest speed of 35 mph without much of a performance penalty in a congested traffic area. Many roads in urban areas have speed limits of 25 mph or lower. In addition, many of the problems cited by commentators that arise when an engine is derated, such as towing expense and time lost when drivers and their vehicles are stranded far from home, would not greatly affect low-speed, locally driven vehicles. Therefore, it is not appropriate or necessary to allow locally driven low-speed vehicles to drive as fast as allowed in the proposed Inducement Schedule. [EPA-HQ-OAR-2019-0055-1250-A1, p.15]

Organization: *Scruggs Company*

The Truck engines that out in the industry today have become cleaner from engineering a aftertreatment system. with that being said we ourselves have experienced several close calls on the roadway. letting these truck engine go further and of course derate the engines until they can get to a local shop without using towing companies or be put in an unsafe situation. [EPA-HQ-OAR-2019-0055-2800, p.1]

Organization: *Six Point Transport Incorporated*

65mph very good [EPA-HQ-OAR-2019-0055-2591, p.1]

Organization: *State Trucker Associations (1)*

The proposed changes for the freight sector reduce truck speeds in 5 mph increments beginning at 65 mph and ending at 50 mph at 60 hours of engine operation. Our member fleets have indicated this modification should ensure adequate time for drivers to reach repair facilities while avoiding operating at unsafe speeds or the need to have their vehicles towed which can cost thousands of dollars. Other considerations include providing adequate time for vehicles operating in remote areas to reach repair facilities as well as allowing drivers to finish their deliveries should the in-cab display appear during a shift. EPA's proposed modification will also allow fleets added time to access preferred repair facilities as opposed to the limited choices they may have under the existing derate schedules. [EPA-HQ-OAR-2019-0055-1075-A1, p.1]

[Additional comment by one of the 23 organizations that joined this mail campaign, EPA-HQ-OAR-2019-055-1185, P.2] Comments from Kennesaw Trans. people that deal with the Derate issues:

> "All for that here in the shop. We constantly have trucks going down on the NOx sensor codes. Luckily we keep them in stock, but out on the road that doesn't help. I cannot think of one instance where we had a truck have a fault code for a NOx sensor and it be anything more than the sensor malfunctioning. Right now with parts being hard to find, a

4 hour time frame before de-rate isn't sufficient time to have the repairs done on the road. This proposal would allow our trucks to seek repair facilities without long wait times or even make it back to our home terminal for repairs. This is all a win-win situation for us as it save us money on outside repairs, breakdowns, and deliveries wouldn't need to be repowered or rescheduled." Brandon Shuping - Shop Foreman

"I have always felt this was a huge safety concern that has been over looked for 10 years now. They did help somewhat recently with a countdown timer - allowing drivers to safety get to a dealership. If they propose changes as stated below, this would help tremendously. Not only safety of our drivers but everyone else out on the roads these days. –not to mention the savings to each commercial hauler in towing expense!" David H Rose Jr. - Maintenance Department

"I think this is a great idea. Cutting the speed to 5 mph is a big safety issue. This new plan will greatly increase the safety of our drivers and everyone else around them. Everyone seems to be a hurry these days. As for the money side, it will let us get our drivers and equipment to our preferred shops. Small local shops don't always have the programming or parts to repair our truck, which usually means towing to a dealership. It will save a lot of money on parts & towing." Evelyn Balsters – Former Driver

Organization: *States of California, et al. (The States)*

Notably, the proposed final derate speed restrictions—50 mph for high-speed vehicles and 35 mph for low-speed vehicles—equal or come just under the speed limits for roadways on which many of these vehicles will operate. For example, a heavy-duty tractor on certain urban interstates and major state highways in California, Connecticut, Delaware, Massachusetts, New Jersey, Oregon, and Rhode Island are subject to a 55 mph speed limit.83 EPA's statement that "final restricted speed of 50 mph prevents the vehicle from travel on most interstate highways with state laws regarding impeding traffic" is not true in most States, which, if they have minimum speeds at all, typically set those speeds at 40-45 mph.84 Low-speed vehicles such as a refuse hauler, street sweeper, or similar utility vehicle operating in residential neighborhoods and city streets will face typical speed limits of 25-35 mph.85 There is very limited incentive (or none at all) for these vehicles to replenish DEF levels even after 60 hours of inadequate maintenance under the proposed derate schedules. The States therefore disagree with EPA's statement that "the proposed derate schedules would be no less effective than the current approach,"86 and urge EPA to adopt a stricter schedule. Code 46.61.400(2)(a) (25 mph on city and town streets); Wis. Stat. § 346.57(4)(e)-(g) (25-35 mph speed limits in cities and outlying areas).

86. 87 Fed. Reg. at 17,543.

The States support efforts to prevent false inducements, which are understandably frustrating for operators and undermine public buy-in for emission controls.87 But the false inducement problem calls for a technological fix from manufacturers; it does not justify relaxing the derate schedule. The States likewise are sympathetic to the safety concerns around a final derate speed restriction of 5 mph in certain high-speed conditions.88 However, these concerns can be addressed with a derate schedule that is still far stricter than that proposed. For example, final derate speed restrictions of 35 mph for high-speed vehicles and 20 mph for low-speed vehicles, especially in combination with a gradual schedule of progressive derates, would still allow all vehicles to safely exit freeways, finish routes, and find repair facilities if needed, while providing sufficient incentive to proactively maintain aftertreatment systems. Organization: *Truck and Engine Manufacturers Association (EMA)*

EPA should also allow for transitions between the vehicle speed levels rather than step changes. [EPA-HQ-OAR-2019-0055-1203-A1, p. 124]

Organization: *United Motorcoach Association (UMA)*

UMA applauds these proposals; however, while the passenger carrier industry would prefer no inducements, similar to the emergency vehicle exemption, the schedule below reflects a widely supported schedule that helps meet the requirements of the consumer while working the inducement problem or making alternative arrangements.

Default maximum speed (MPH)	Commercial Passenger Vehicles
65	24 hours
60	48 hours
55	72 hours
50	96 hours

[EPA-HQ-OAR-2019-0055-1311-A1, p.4]

Organization: *Dennis Streif, Vandalia Bus Lines, Inc.*

I would hope that this regulation can be changed to allow more time (20 - 40 hours) for a vehicle to get to a safe operating spot and repair facility. This regulation is a burden and put operators and passengers in an unsafe predicament. We do want a clean air environment in this country and worldwide, however it would be a spirit of corporation for the EPA to provide some relief on the derate shut-down. Please give this another consideration [EPA-HQ-OAR-2019-0055-2811, p.1]

Organization*: Virginia Motorcoach Association*

It is important to note that there is a current exemption of inducements applied to emergency vehicles. Because of safety concerns and risk to supporting human health, in 2012, EPA issued a DFR for all emergency vehicles such as ambulances and firetrucks, preventing them from losing speed or power. This ruling provided OEMs the ability to offer new engine software calibrations that eliminated the chance of inducements that would cause delays to life saving measures. Motorcoaches also play an important role when a natural disaster occurs and people need to be evacuated. Each year this industry is asked to transport citizens out of an area that has experienced an environmental hazard such as a hurricane or wildfire. The industry is actively engaged in moving our nation’s military in time-sensitive situations, such as national guard deployments. With the multi-use purposes motorcoaches provide, including life saving measures, it would fall in line to include this industry in the derating exemption. [EPA-HQ-OAR-2019-0055-2715-A1, p.3].

This proposed rule change is not safe or sensible for our industry’s vehicles. Rather than further restricting the industry and causing additional undue burdens, we need flexibility and reasonable timeframes that allow operators to transport their passengers back to the point of origin to receive proper maintenance. The motorcoach industry transports people and should be separated from the freight transporters. [EPA-HQ-OAR-2019-0055-2715-A1, p.3].

Organization: *Volvo Group*

The Volvo Group supports the need to improve SCR (Selective Catalytic Reduction) inducements as noted by the following comment. In addition to replacing the 5mi/hr with a 50 or 35 mi/hr derate, we support introducing a bus exclusion to avoid potential safety issues. [EPA-HQ-OAR-2019-0055-1324-A1, p. 5]

Volvo Group recommends this change in inducement derate as well as an exclusion for buses to be implemented as soon as possible as these issues affect today the potential safety of buses. [EPA-HQ-OAR-2019-0055-1324-A1, p. 5]

Organization: *Wisconsin Department of Natural Resources (WDNR)*

EPA's proposed inducement schedules are not stringent enough to incentivize operators to address problems with malfunctioning SCRs in a reasonable timeframe. Robust engine emission standards lose significant effectiveness if control devices are bypassed in practice. [EPA-HQ-OAR-2019-0055-1162-A1, p. 3]

EPA Summary and Response

For the purpose of this section, each subtopic is summarized and responded to separately.

Comments on Exempting Motorcoaches

Motorcoach operators and trade groups commented that today's inducement approach has long created serious risk to life in their operations. Volvo commented that they supported exempting buses in this type of service as soon as possible because these issues affect potential safety of operations and uptake of advanced technology. ABA, Coach USA, Compass Coach Inc., and other motorcoach carriers requested that EPA allow motorcoaches to operate with the same exemption from inducements as emergency vehicles for one or more of the following reasons: (1) The transport of passengers requires different considerations that hauling conventional freight (e.g., need for food, water, and relief from climate extremes) and should not be stranded intentionally for hours while awaiting a rescue bus. (2) Motorcoach operators are already sufficiently compelled to perform proper maintenance and use DEF because they must reduce risk of breakdowns or damage to expensive engines – they depend on these engines for revenue. (3) Drivers are sufficiently motivated by warning lights to take action, and reducing the stress of a 5mph shutdown would allow them focus more on passenger safety. (4) Motorcoaches often serve in an emergency response capacity and should not be subject to artificial inducements that prevent performing this work. ABA noted that in FY2021, buses moved nearly 28,000,000 military personnel and in 2020 were critical to hurricane evacuation efforts. (5) Passenger motorcoach companies are driven to perform proper maintenance because operations are heavily dependent on passenger-driven schedules, any delay risks expensive reimbursements owed to passengers for missed events (e.g., airline tickets, theater tickets) and cost to reputation. For example, Motorcoach Companies. noted that even a 5mph speed decrease can cost an hour of time in a shift which can require a new driver be located for the bus (due to hours-of-service requirements that limit hours per day drivers can legally drive) and can disrupt schedules causing passengers to miss scheduled events. (6) Consistent with EPA's stated attention to environmental justice, an exemption would reduce risk of losing a key transportation option for underserved and price-sensitive communities which is sometimes the only mode of transportation available to connect to jobs, education, medical services, and other modes of transportation.
(7) There needs to sufficient time for the motorcoach to reach a safe location. It is not unusual for motorcoach routes to traverse remote stretches of the country. Also, there are not as many service locations available to a motorcoach, as opposed to those trucks.

Carerra Tours supports a schedule that enables them to safely deliver passengers and get to a safe place to repair a vehicle. Coach USA supports the proposed schedule but would support more time and is concerned the proposal doesn't take the unique concerns of motorcoach operations into account, noting that any speed below 65mph is unsafe on the highway. Compass Coach Inc. commented that they need time to find a safe place, get a vehicle looked at by a repair facility, acquire parts to fix a vehicle (noting most of the time it is a sensor failure that causes inducement) and that 72hours would be more appropriate.

Some motorcoach operators suggested an alternate derate schedule if the final rule did not include an outright exemption from inducements for motorcoaches. The alternate schedule started with derating to 65 mph, followed by further derates in 5 mph increments after every 24 hours of operation. The final derate condition would be 40 or 50 mph after 96 hours.

Response:

In a previous rule, EPA modified the definition of "Defeat device" at 40 CFR 86.004-2 to allow heavy-duty engine manufacturers to design their engines with auxiliary emission control devices to override SCR-related inducements for engines installed in ambulances or fire trucks (77 FR 34130, June 8, 2012). EPA adopted that rule to enable these dedicated emergency vehicles with diesel engines to perform mission-critical life- and property-saving work without risk of losing power, speed, or torque due to abnormal conditions of the emission control systems (79 FR 46356, August 8, 2014).

We recognize that motorcoach fleets operate with the grave responsibility of ensuring the safety of their passengers, and that they are also called into duty periodically for military support and various emergency response needs. All these functions depend on reliable engine performance to keep buses moving over long distances at typical highway speeds. This type of operation is not the same as that of the purpose-built function, mission, and typical operation of ambulances and fire trucks. Completely exempting motorcoaches from inducement provisions would leave many buses operating for most of their lifetimes lacking the assurances from inducements that maintenance of an adequate supply of DEF is reasonable likely to occur and that engine designs will deter SCR-related tampering.

In response to the suggested alternate derate schedule for motorcoaches, we have prioritized designing an inducement approach that allows for motorcoaches to have sufficient time and ability to reach a safe location, while maintaining inducement provisions to provide the assurance that SCR systems will continue to work properly. The inducements approach in this final rule involves modest speed derates to provide that assurance. We understand the comments explaining that motorcoach operators have various responsibilities to ensure that engines will serve reliably to complete their routes safely and on time. With this responsibility, it is clear that motorcoach operators will be highly motivated to perform any amount of maintenance that would be needed to avoid the risk of disrupting schedules or jeopardizing the well-being of their passengers. As a result, we believe an initial derate speed of 65 mph is appropriate because it should be effective in compelling motorcoach operators to address derates under normal circumstances. The final derate speed of 25 mph after 180 hours is intended to reflect the extreme emergency that would cause a motorcoach operator to continue operating without performing the maintenance necessary to resolve a fault condition causing the inducement.

We have provided a regulatory definition of motorcoach in 40 CFR 1036.810 to clarify that the alternate schedule applies for buses designed to travel long distances with row seating for at least 30 passengers. This is intended to include charter services available to the general public.

For the reasons described above, we do not expect that the inducement provisions adopted in this final rule will prevent motorcoaches from continuing to provide transportation for underserved and price-sensitive communities.

General Comments on EPA's Proposed Inducement Schedule

ABA commented that they believe adjusting the derate schedule with a more appropriate final inducement speed has merit but need additional time to review the merits with operators. ATA is supportive of the derate schedule and believes it is justified to improve access to repair facilities and avoid unsafe operating speeds. NASTC commented that the proposed schedule is an improvement over the existing schedule, but more time (120 hours) is needed to allow trucks to return to home base or a trusted repair shop which is extremely important. NASTC added that safety and security issues are heightened during breakdowns and add risk when one has to trust repairs to unknown facilities on an emergency basis where there can be unscrupulous actors who can take advantage of stranded truckers. The Scruggs Company commented that they have experienced several safety "close calls" on the roadway and trucks need more time and higher final inducement speeds to avoid an unnecessary tow or being put in an unsafe condition to get to a repair facility. Six Point Transport submitted comments in support of the proposal. Twenty-three individual State Trucking Associations submitted support for the proposal stating that the proposed schedule should allow drivers to reach preferred repair facilities while avoiding unsafe conditions and needless towing that can cost thousands of dollars.
CARB and ICCT proposed to apply speed derates to vehicles if the system detects a fault condition where the NOx override determines that the SCR catalyst is working properly. The recommended approach was to require a final derated speed of 35mph with a 40% torque derate for high-speed vehicles.

CARB suggested an alternative to EPA's proposed derate schedule that would result in a final speed of 5mph in 10 hours where the NOx override determines that the SCR catalyst is not working properly. CATF+ supported CARB's suggested derate schedule. CATF+ commented further that allowing 60 hours of operation before the final derate speeds would produce massive quantities of excess pollution; they also commented specifically that the proposed derate speeds are too high for low-speed vehicles. DOEE, NACAA, and the Wisconsin DNR stated they are concerned that the proposed schedule would not sufficiently compel operators to properly maintain vehicles. ICCT commented that similar to CARB's comments two schedules should be finalized, one that reduces speeds further after 60 hours if SCR efficiency loss is 10% or less, and 5mph after 12 hours (or 16 hours if safe harbor not implemented). The States of California et al. commented that although they are sympathetic to safety concerns with existing inducements, they have concerns that can be addressed with lower speeds than proposed.

Coach USA recommended increasing the time between the first and second stage of derated vehicle speeds, for faults other than low DEF, from six hours to at least 10 hours to allow for reaching a repair facility.

CARB, EMA, and Cummins suggested that we include a gradual transition to start each new derate speed to avoid abrupt changes in vehicle speeds while driving. CARB suggested that the derate should occur at a rate not to exceed 1 mph for every five minutes.
David Pedersen recommended an alternative approach, based on what applies for light-duty vehicles, of allowing vehicles to shut down, and then disallow engine starting if any component or system caused the engine to be noncompliant.

CARB commented that they do not support EPA's proposed derate schedule, that EPA has not and cannot demonstrate that the proposed schedule is permissible under the Clean Air Act ("CAA") because it could allow vehicles to operate for potentially unlimited periods of time even if those vehicles are emitting pollutants in excess of the standards, and that EPA has not established that the proposed schedule is more effective than the existing one to compel proper maintenance and deter tampering and is clearly arbitrary and capricious.

<u>Response</u>:

EPA has carefully reviewed all comments, and further reviewed and analyzed available data to finalize an adjusted schedule from that proposed that EPA expects will address many of the identified concerns (see Section IV of the preamble for further information on and the basis for the final schedule). The final speeds have been adjusted from the proposed rule in two ways. First, we have added a new category for medium-speed vehicles (see Section IV of the preamble for further discussion). Second, we have modified the low-speed category after consideration of concerns expressed in the comments (see our summary and responses in this section related to comments on low- and high-speed vehicle schedules). Further, EPA modified the time portion of the schedule for each of these speed categories, such that lower-speed vehicles have less time prior to final inducement due to different operating profiles and needs (see our summary and responses in this section related to comments on inducement schedule hours).

Inducements are a unique solution developed to ensure that SCR systems have adequate high-quality DEF and operators do not tamper with specific components that would render the SCR system inoperable. The revised schedule considers over a decade of experience with SCR systems and full market availability of DEF. The revised schedule also reduces the risk that owners will tamper due to an overly restrictive approach, for example, by allowing owners to spend money on repairs instead of unnecessary towing. It reduces that risk by creating more finely tuned derate schedules to prevent commercial operation of noncompliant vehicles, but without the additional burdens that may occur under a more restrictive approach.

Some commenters stated that the schedule was not sufficient for ensuring proper and timely maintenance. These commenters did not provide discussion or data of how EPA's balanced approach would result in more or less tampering and more or less compliance in the real-world. EPA recognizes that there is concern that trucks will operate for longer periods of time in need of repair, however commenters did not provide and we are not aware of data supporting that any potential emission increases from this would be more or less than the potential increase in emissions from tampering due to an overly restrictive inducement approach. Allowing trucks to return to their preferred repair shops can also result in more effective repairs, which can also serve to reduce emissions. Further, EPA has finalized a lower final speed after an additional period of time which will further encourage prompt and proper repairs, and should further decrease the already unlikely indefinite use of the vehicle without the operator addressing the cause of the inducement. Finally, as noted earlier in this response, EPA adjusted the schedules by developing a medium-speed category that results in a final inducement speed of 25mph faster than a high-speed vehicle and reduced the final inducement speed and schedule for low-speed vehicles as well. EPA's approach relies on the principle of selecting a derate schedule that accomplishes the intended effect using the least restrictive means. The proposed rule described how operators would be compelled to perform SCR-related maintenance with a derate schedule that avoided concerns raised by commenters about potential safety and cost problems associated with abruptly decreasing maximum vehicle speed to 5 mph. Commenters did not engage with the question of how a derate schedule could accomplish maintenance objectives using the least restrictive means. Rather, commenters focused simply on certainty of outcomes and potential consequences of any delay in performing maintenance. We note that even such an inducement approach provides no certainty in guaranteed emission reductions however, as it is possible for a fleet to substitute a derated vehicle (e.g., a school bus) with an older vehicle until the derated vehicle is repaired and returned to duty.

As further discussed in preamble Section IV, EPA has carefully analyzed NREL data to understand and categorize what effective final inducement speeds should be applied to a vehicle based on its recent vehicle operating profile. It would not be possible for vehicles operating primarily on the highway to continue to operate profitably if they can no longer operate on the highway. Commenters also provided no rationale to counter our assessment that a derate schedule allowing operators time to complete a job and return to a preferred repair facility without requiring a tow or rescue vehicle should reduce in-use real-world tampering rates. EPA believes the initial derate speeds we are adopting will be effective in leading operators to make timely repairs. Any increased emissions resulting from a delay in that maintenance would be dramatically offset by even a very small number of cases where operators installed SCR-delete kits to resolve their frustration with a more restrictive approach to inducements. NREL data show that even vehicles with lower average speeds will frequently travel at high speeds to accomplish their work. Removing the capability of achieving these high speeds will prevent operators from being able to complete necessary work and therefore provide proper incentives, while minimizing potential motivations for tampering that can result from over-restricted speeds and forcing the expense of repeated tows. See also our responses to similar comments related to operating hours in section.

EPA believes that the final derate schedule should allow operators to return to a preferred repair facility, which should help ensure that mechanics understand how to perform the necessary maintenance.

EPA agrees that inducements are an important part of the compliance program. EPA has considered that an overly restrictive inducement policy could increase operator frustration and lead to in-use tampering and that a lax inducement policy may not sufficiently compel owners and operators to maintain SCR systems with an adequate supply of high quality DEF. The inducement program in the final rule is expected to remove any reasonable possibility for operators to continue in commercial service without addressing detected fault conditions. The inducement program in the final rule recognizes the diversity of the fleet and appropriately applies speed reductions based on an individual vehicle's operating profile. Improved serviceability and more appropriate inducement schedules will reduce operator frustration that can create an incentive for tampering with emission control systems.

We agree that speed derates should include a gradual transition. We have modified the final rule to include CARB's suggested approach of specifying that derates occur at a rate of 1 mph for every five minutes. Manufacturers may apply this in steps or they may design the engine to apply derates as a continuous decrease in vehicle speed at the specified rate until the vehicle reaches the targeted speed.

Coach USA's comments on the time between first and second derate speeds are described in the context of motorcoach operations. See Section 8.3.1 for a discussion of this and other issues for motorcoaches. The response here addresses their concern as it applies for other types of vehicles. Years of in-use operating experiences has shown that many malfunctions present as a fault indicating low DEF level even though the DEF tank has good-quality DEF available. It would therefore be inappropriate to create a separate derate schedule for DEF fill level separate from other fault conditions. We selected six hours as the initial interval to allow for refilling DEF or taking other readily available actions to restore the engine to proper functioning. We also selected derate speeds in 5 mph increments to allow for continued operation while operators arrange for repair or take other actions to address the possible causes of the detected fault condition. This gradual escalation in the derate schedule is intended to achieve a balance between increasing the motivation to correct the fault condition with an understanding that operators may need more time to arrange for maintenance or repair that is best accomplished after returning to a home base.

CARB and ICCT proposed adopting a separate inducement schedule based on the NOx override determination that the SCR catalyst is working properly. The final rule does not include the requirement to include a NOx override as an input into inducement algorithms, so we are unable to consider whether to apply a separate derate schedule as CARB and ICCT suggested. Further, our proposal was based on the concept of applying inducements where fault conditions cause an increase in emissions. We proposed that the NOx override would only be used to prevent inducements from being applied when the SCR catalyst is working properly.

Other issues related to the number of operating hours specified in the derate schedule are addressed later in this section (see Section 8.3.6 of this document).

The comment from David Pedersen raises two separate issues. First is the recommendation to disallow engine starting in response to a detected fault condition instead of applying speed derates. Many operators of heavy-duty vehicles would keep their engines running indefinitely with a detected fault condition if that is what they need to do to continue operating. Letting engines run for long periods between trips would be an easy way to defeat the inducement; this would allow the combined adverse environmental of high emissions while operating and the additional impact of emissions during extended idle. Second is the recommendation to apply inducements for any malfunction leading the engine to exceed emission standards. Any inducements for components other than those SCR system components included in the proposal are outside the scope of this final rule; see preamble Section IV for our discussion on the final SCR system components covered by the final inducement provisions and the basis for those provisions.

For the reasons discussed directly below, EPA disagrees with CARB's comments that (1) we failed to consider important aspects of the inducement proposal intended to compel corrective actions by vehicle owners, and the corresponding emissions impacts, and (2) this failure constitutes arbitrary and capricious agency action, and contravenes U.S. EPA's statutory duty to ensure heavy-duty engines and vehicles comply with applicable emissions standards over their useful lives. Further, EPA disagrees with CARB's comments that EPA has not, and cannot, demonstrate that the proposed inducement strategy is permissible under the statute, that there are good reasons for it, and that the agency believes it to be better. EPA does not agree that the final inducement provisions violate the statute by allowing vehicles with emision system problems to continue operating. See preamble Section IV for a detailed discussion of the authority and basis for our final inducement provisions, which includes consideration of public comments on the proposed rulemaking and rationale for any changes from existing guidance in our final provisions. See also our response to inducement-related comments in section 8 of this document for further explanation, including why the final inducement schedules will not result in indefinite use of vehicles that are in inducement.

EPA has performed rigorous analysis, outreach, and request for comment in both the ANPR and NPRM, as well as fully considering the information provided in public comments, to develop this final rule. As discussed in those documents referenced above, EPA has carefully evaluated and finalized a final set of inducement requirements that EPA determined, through an assessment that balanced multiple considerations, will best ensure compliance without being so restrictive as to encourage tampering that may result in long-term noncompliance. While inducement strategies utilized over the past decade have relied on a final inducement speed set at 5mph, EPA believes, for the reasons explained in Section 8 of this document and Section IV of the preamble, that the different approach finalized in this rule will be as effective, if not more effective, in real-world compliance with emission standards and requirements overall and reduce tampering that can result in large emission increases long-term (including after vehicles have passed their regulatory useful life but remain in service). We believe a change in approach is also appropriate given that the prior guidance was developed (1) based on a different set of market conditions, such as the unknown availability of DEF, and (2) without giving as much weight as we now believe is appropriate, with the advantage of over a decade of experience to analyze, to the consideration of what is the least restrictive set of requirements necessary for manufacturers to be able to reasonably ensure use of adequate high quality DEF. Additionally, as we noted elsewhere in this section 8, in a 2010 evaluation of in-use vehicle inducement strategies performed by CARB, CARB concluded that "driving a truck with a 25 percent engine torque derate and a 55 mph speed limitation was neither acceptable nor tolerable, especially when trying to accelerate or driving up-hill, and would likely cause a driver to refill with DEF or correct the SCR problem as needed."[27]

Comments on the concept of a two speed (high- and low-) vehicle inducement proposal

ABA commented that there is merit to the proposed approach, but they were unsure how it would work in application for motorcoach operations and whether the inducement schedule would change if a vehicle's profile changed or fluctuated. Coach USA commented that they do not believe a high-speed vehicle should ever be treated like a low-speed vehicle for the purposes of inducement while ensuring passenger safety. Cummins supported the proposed development of a multi-speed inducement concept, but recommended EPA not finalize the dynamic switching from high- to low-speed vehicle inducement schedules because of software complexity and potential confusion for operators. EMA supported the concept of two different inducement schedules based on vehicle average speed. NASTC supported separate inducement schedules for high- and low-speed vehicles. NASTC added that longer derate time periods and faster speeds for high-speed trucking and shorter times and slower speeds for low-speed vehicles are a common-sense and superior approach to inducements and are better suited to significantly different types of trucking operations. OOIDA and Volvo supported the concept of two different final inducement speeds. ICCT suggested allowing a higher final speed derate if the truck exceeds an average speed based on typical line haul operation.

<u>Response</u>:

EPA has added a third category, medium-speed vehicles, to the final inducement schedules to provide a more appropriate way of considering the operation of the real-world diverse fleet; see Section IV of the preamble for more discussion on the final inducement schedules and why we think it is appropriate for the schedules to progress from higher speeds to lower speeds.

ICCT's suggested approach for a different derate schedule for line-haul trucks is a different way of describing why we are adopting a separate derate schedule for high-speed vehicles. Adding the medium-speed category allows for more carefully defining high-speed vehicles to include vehicles with substantial operation at highway speeds.

As proposed, the derate provisions in the final rule require that engines identify a vehicle's appropriate speed category based on average speed over the previous 30 hours of operation. As described in Section IV of the preamble, an individual vehicle is identified by speed category at the onset of an inducement. As suggested by commenters, the speed category for a given vehicles does not change after the system detects a fault condition. Instead, the derate schedule for each speed category accounts for the changing vehicle speeds as the vehicles progresses through the full derate schedule.

Comments on the Proposed High-Speed Vehicle Schedule

[27] See 76 FR 32889-32890 (June 7, 2011) for EPA's description of CARB's evaluation in a notice requesting comment on draft guidance for inducements.

ATA commented that the proposed high-speed schedule will impact operations and prompt a repair response prior to reaching the final inducement speed. CARB commented that EPA failed to propose an inducement schedule for high-speed vehicles that is unacceptable for typical driving, that the initial step of the high-speed inducement is insufficiently stringent based on CARB's vehicle speed data and would have a very limited impact on inducing operators to fix the problem. CARB commented that some states including CA have urban highway speeds of 55mph, and the final inducement speed for high-speed vehicles is not severe enough to induce the operator to make repairs and would not be as effective as the current 5mph guidance. CARB also objected to EPA's statement that minimum required highway speeds would prevent derated vehicles from operating on limited-access highways. DOEE commented that final derate speeds should be revised considerable downward. Coach USA commented that the proposed schedule is reasonable and effective to induce drivers to correct fault conditions and ensure proper maintenance but is concerned with any derate applied to motorcoaches with a speed of less than 65mph. ICCT recommend EPA adopt 35mph or less as a final inducement speed with a possible exception for line-haul trucks. NASTC commented that high-speed vehicles should have more time between stages of inducement and the first step should be 20 hours (not 12), and the final step should be at 120 hours, not 60 hours, to allow carriers sufficient time to reach home for long-haul trucking. States of California et al. commented that for high-speed vehicles the final inducement speed should be 35mph. UMA, Motorcoach Companies, and other motorcoach operators commented that while the motorcoach industry would prefer an emergency exemption, an alternative schedule that would help meet passenger requirements while operators work to resolve inducement-related problems or make alternative arrangements would have 24 hours between the four stages of the proposed high-speed inducement schedule resulting in a speed of 50mph after 96 hours. CARB, DOEE, NACAA, CATF+, and the States of California et al., commented that EPA should amend the definition of low- and high-speed vehicles by setting the average speed cutoff for low-speed vehicles at 30mph instead of the proposed 20mph, where high-speed vehicles would comprise the rest.

Response:

After consideration of comments and further assessment, EPA has determined that the proposed derate schedule for high-speed vehicles is appropriate for long-haul vehicles that are most often operating at highway speeds. At the same time, we recognize that defining high-speed vehicles to include all those with an average speed above 20 mph would include some vehicles that have a more even mix of highway and intra-city operation. Rather than changing the derate schedule for all high-speed vehicles, our additional analysis supports a conclusion that the best approach is to increase the average speed to qualify as a high-speed vehicle, and at the same time create a medium-speed vehicle category with derate speeds that fall between what we proposed for high-speed and low-speed vehicles. See preamble Section IV for further details.

CARB commented that speeds on urban highways are 55 mph for trucks, and EPA should take this into account. We recognize that it is common for highways near cities to have speed limits of 55 mph for trucks. We note, however, that high-speed vehicle operation will not be limited to urban areas. Rather, high-speed vehicle operation will include extensive driving between cities. All states except California, Washington, and Hawaii have rural speed limits on interstate highways that are at or above 65 mph.[28] For 47 states then, an initial derate speed of 65 mph will be meaningful and effective to prompt maintenance. Even though the initial derate speed in some of those cases matches the speed limit, it is clear that operators will be substantially motivated to avoid derates that prevent them from, for example, passing a truck that is operating slightly below the speed limit. Considering all these factors, we do not think that it would be appropriate in setting provisions at the national level to base the initial speed in the high-speed derate schedule on the speed limits that apply in only three states.

We understand that minimum specified highway speeds would sometimes not prevent vehicles from driving on limited-access highways or other specific roadways. Whether that would be limiting in certain cases or not, we believe the more important point is that the primary impact of any speed derates would simply be the practical effect on the driver's ability to maintain desired operating speeds.

CARB commented that speeds on urban highways are 55 mph for trucks, and EPA should take this into account. We recognize that it is common for highways near cities to have speed limits of 55 mph for trucks. We note, however, that high-speed vehicle operation will not be limited to urban areas. Rather, high-speed vehicle operation will include extensive driving between cities. All states except California, Washington, and Hawaii have rural speed limits on interstate highways that are at or above 65 mph.[29] For 47 states then, an initial derate speed of 65 mph will be meaningful and effective to prompt maintenance. Even though the initial derate speed in some of those cases matches the speed limit, it is clear that operators will be substantially motivated to avoid derates that prevent them from, for example, passing a truck that is operating slightly below the speed limit. Considering all these factors, we think it would not be appropriate here in setting provisions at the national level to base the initial speed in the high-speed derate schedule on the speed limits that apply in only three states.

Some commenters requested additional speed or time (up to 120 hours) for high-speed vehicles to return home. EPA developed the high-speed inducement schedule with the intent to provide operators of high-speed vehicles nearly three days to return home and bring the vehicle to a local repair facility. This would be tempered by allowable hours-of-service requirements that generally restrict driving to 10 hours per day. As explained elsewhere in this section 8 and preamble Section IV, EPA believes the initial stage of derate will be adequate to compel maintenance in almost all cases.

It would not be possible for vehicles operating primarily on the highway to continue to operate profitably if they can no longer operate on the highway. Commenters did not provide any data or rationale as to why removing the ability to travel on the highway would be ineffective as an inducement.

Comments on the Proposed Low-Speed Vehicle Inducement

[28] https://ww2.motorists.org/issues/speed-limits/state-chart/, accessed November 4, 2022.
[29] https://ww2.motorists.org/issues/speed-limits/state-chart/, accessed November 4, 2022.

CARB commented that the initial proposed inducement speed of 50mph for low-speed vehicles is insufficiently stringent to compel action and is concerned regional or urban vehicles may deviate routes to focus on traveling below the inducement speed limit. CARB also commented that the final inducement speed of 35mph is not severe enough and 5mph is more effective. CARB proposed a final speed of 20mph with a 40% torque derate for low-speed vehicles if the NOx override indicated that there was no emissions increase associated with the inducement-related fault. CARB also noted that they performed a survey which shows that severe derates are effective. Coach USA commented that for low-speed vehicles 50mp is below interstate/highway speeds and is potentially a safety risk. They added that the speed will prompt drivers to take action to address fault conditions, although this restriction is not necessary given driver's attention to warning lights, and any lower restriction would compromise safety without increasing compliance with inducements. Coach USA recommends an 80-hour window. ICCT recommends a final inducement speed of 20mph or less for low-speed vehicles and expressed concern that urban trucks may not be affected by the proposed low-speed inducement schedule. Maine DEP and NESCAUM commented that EPA's proposal does not provide sufficient inducement for low-speed vehicles, since locally operated vehicles could still potentially operate at 35mph in congested traffic to avoid remedying the problem. OTC commented that EPA should reconsider the low-speed inducement proposal and make speeds lower. DOEE commented that final derate speeds should be revised considerable downward, with the specific suggestion to set a final derate speed of 25mph for low-speed vehicles in 40 hours.

Response:

The proposal included a single low-speed derate schedule for all vehicles with average speeds below 20 mph. This would include a wide range of vehicles, including some mixed-use vehicles with some substantial operation at highway speeds and some vehicles that would rarely or never operate at highway speeds. Some vehicles with low average speeds might need to consistently operate at highway speeds, but others may operate at more consistent speeds in urban areas or in a confined space (such as a shuttle bus at an airport). As described above in the response to comment for high-speed vehicles, after further consideration, we determined that it was best to keep the low-speed vehicle category, but to add a medium-speed vehicle category with its own derate schedule for vehicles that have a mix of highway and urban driving. We agree that the proposed schedule of derating speed from 50 mph to 35 mph may not be as effective for ensuring an adequate supply of quality DEF for low-speed vehicles. We therefore determined instead that a better approach is to limit the low-speed vehicle category to vehicles with lower average speeds and set an appropriate final inducement speed lower than we proposed for this speed category. See Section IV of the preamble for more information on the final program.

There is no question that a derate speed of 5 mph will compel operators to perform necessary maintenance to keep SCR systems working properly; however, there are additional considerations that EPA believes are appropriate to balance in assessing true real-world compliance impacts, as discussed elsewhere in Section 8 of this document. As we described in the proposed rule, we developed the inducement provisions following several principles, which accounted for operator burden, cost, safety, the risk of frustration-induced tampering in addition to requiring that manufacturers design inducements to ensure an adequate supply of high-quality DEF is maintained in-use. CARB's comments on the proposed rule included a recommended alternative derate schedule that is similar to what engine manufacturers are doing today. As summarized and responded to earlier in this section 8, CARB's comments also included other, mostly conclusory statements claiming that EPA's proposed derate schedule would be insufficient to ensure maintenance of the SCR system. CARB's survey did not include a question on whether or not higher final inducement speeds would be equally effective for operators, and if so, what speeds should be considered. We have made several modifications to the proposed rule after consideration of comments, all in keeping with the principles described in the proposed rule which we maintain are the appropriate factors to balance. The resulting final rule represents our best effort to design an inducement program that ensures timely maintenance while taking into consideration real-world constraints associated with different types of commercial operation.

Comments on the Operating Hours Specified in the Derate Schedules

The sections above reference comments related to the timing aspect of the derate schedule—the number of hours the engine operates at each stage before the derate escalates to the next level. Commenters suggested that the derate schedule should allow more time, or less time before reaching greater levels of speed restrictions. These comments largely focused on outcomes, shifting the balance between minimizing adverse environmental outcomes and accommodating safety, technology, and business considerations. NESCAUM added a specific comment suggesting that the low-speed, locally driven vehicles are much less affected by problematic derates, which would support an accelerated derate schedule.

<u>Response</u>:

As described above, including a medium-speed vehicle category in addition to low-speed and high-speed vehicle categories in the final requirements resulted in a final time schedule for high-speed vehicles that is properly aligned with the human and logistical constraints associated with long-distance routes. We are finalizing as proposed the provision allowing high-speed vehicles to travel for up to 60 hours with derate speeds at or above 55 mph. This is enough to allow a truck driver to return home (and thus also allows operators to arrange for repairs after returning home). We continue to believe that this time schedule is necessary and appropriate for ensuring maintenance, but also accommodating the need for drivers of high-speed vehicles to be able to return home safely. Commenters did not provide specific rationale for why more time was needed. At the same time, we are aware that the long-distance driving considerations that led us to the proposed time schedule for all vehicles are very different for medium-speed and low-speed vehicles. Medium-speed and low-speed vehicles are much less likely to venture far from a home base. As a result, their derate time schedules should be shorter than the schedule for high-speed vehicles because there should be no need to account for several hours of driving to return home. We have compressed the final time schedule for medium-speed vehicles, and we further compressed the final time schedule for low-speed vehicles. See Preamble Section IV for additional information on the derate times and speeds for the final rule.

8.4 Logic for multiple faults, in-cab display, and deactivating derates and recurring faults

Comments by Organizations

Organization: *American Bus Association (ABA) (1070 and 1308)*

iii. Display Requirements – ABA is supportive of the proposed requirement that engine manufacturers display the triggering condition leading to an inducement and a countdown timer to estimate the time or distance till the next inducement stage. This information could be very useful to avoid the stranding of vehicles and passengers. The current display of numeric codes and not necessarily a dash icon light is extremely confusing and not easily discernable to many drivers. [EPA-HQ-OAR-2019-0055-1308-A1, p.10]

Organization: *California Air Resources Board (CARB)*

Adequate warning to the operator of impending inducement and at each step of the inducement is critical for providing adequate warning of the consequences of inaction to fix the fault before inducements occur. CARB staff supports the proposed in-cab display requirements and suggests the following additional specifications. In addition to indicating 'inducement pending,' the fault condition must be displayed such as 'low DEF' or 'poor DEF', so the operator is informed as to how to fix the problem. In addition, the inducement display at each step should identify at minimum what the derate in torque and/or maximum speed will be, so the driver is aware of the limitations of the vehicle. Finally, CARB staff recommends requiring progressively greater audible and visible warnings at each escalating inducement step to induce the operator to act more urgently to fix the fault. [EPA-HQ-OAR-2019-0055-1186-A2, pp.107-108]

The NPRM requests comments on the deactivating derate provisions. Once an inducement in activated, the means to deactivate the derate is important when the fault condition is fixed. Self-healing from an inducement is appropriate when the fault condition is fixed, and CARB staff concurs with the self-healing protocol of confirming the fault condition no longer exists and that the NOx efficiency override is within 10 percent of normal. However, staff has concerns with the use of a generic scan tool to clear codes and to deactivate derates. The generic scan tool was explicitly prohibited in the 2010 U.S. EPA and CARB July 2010 public workshop presentation. Abuse of using a generic scan tool to override the derate without fixing the fault condition is a high possibility because of the ease of obtaining generic scan tools. Using the generic scan tool over and over again to deactivate derates may become a strategy to tamper with the DEF system, resulting in excessive hours of vehicle operation where a fault condition has not been fixed and emissions are not compliant. It is reasonable, however, to allow the generic scan tool to be used to clear codes when repairs are done. CARB staff recommends a limit of up to two times to deactivate derates with a generic scan tool when reoccurring fault condition appears but only if the vehicle is not already at the final inducement step. For detecting a fault condition that may recur, CARB staff supports monitoring for 80 hours of engine operation for the same triggered condition, and if found, the vehicle would restart the derate at the same point that the system last deactivated the derate. [EPA-HQ-OAR-2019-0055-1186-A2, p.108]

Organization: *Coach USA, Inc. (Coach USA)*

EPA require manufactures to provide more precise information to drivers to alert them about DEF levels and how long remaining DEF volumes will last; this will allow drivers to plan accordingly to address a fault condition, while taking into account route schedules and stops. [EPA-HQ-OAR-2019-0055-1307-A1, p. 5]

Coach USA also recommends that EPA require manufactures to provide more precise information to drivers to alert them about DEF levels and how long remaining DEF volumes will last; this will allow drivers to plan accordingly to address a fault condition, while taking into account route schedules and stops. [EPA-HQ-OAR-2019-0055-1307-A1, p. 5]

Coach USA supports EPA obtaining information from engine manufacturers (mainly Cummins and Volvo for interstate buses) to understand options for easily notifying drivers of fault conditions. Coach USA supports a simple, informative alert for drivers to avoid inundating drivers with information that may compromise the driver's attention or passenger safety. While Coach USA opposes any inducement rule for the reasons noted above, it supports the proposed requirement at section 1036.111(f) that engine manufacturers display the triggering condition leading to an inducement and a countdown timer to estimate the time or distance until any next inducement stage is reached. Such a timer will promote safety to the extent it lowers the risk of a bus being stranded with passengers in a potentially dangerous highway setting. [EPA-HQ-OAR-2019-0055-1307-A1, p. 7]

Organization: *Truck and Engine Manufacturers Association (EMA)*

EMA offers the following comments on the specific OBD-related elements of the proposed regulatory text. §1036.111(b): With regard to the proposed fault conditions of paragraph (b), we note that it is critically important that sufficient notification be allowed before applying inducements. [EPA-HQ-OAR-2019-0055-1203-A1, p. 102]

- §1036.111(g)(1): "(1) Evaluate whether the detected fault condition continues to apply and reset the Active 100 Hour Array in the OBD system when the fault condition no longer exists. Deactivate derates if the engine confirms that the fault condition is resolved and the override factor for NOx conversion efficiency is at or below 0.10 for a full inducement drive schedule." EPA's proposed reset differs from CARB's requirement at 13 CCR 1971.1 (h)(5.3.6) to pause and resume data collection, while (for (h)(5.3.6)) employing the MIL-on bin (bin 17). We note that the proposal directly conflicts with the 13 CCR 1971.1 requirement that was incorporated by reference. Further, EMA recommends that EPA not make the proposed changes. However, in the future, if EPA wishes to make such changes: (i) it is imperative that the Agency coordinate with both CARB and the SAE standards committees to ensure standardization; and (ii) paragraph (g)(1) should be amended to state "Deactivate derates if the engine confirms that the fault condition is resolved and or the override factor for NOx conversion efficiency is at or below 0.10 for a full inducement drive schedule". [EPA-HQ-OAR-2019-0055-1203-A1, pp. 102 - 103]
- §1036.111(g)(2): "(2) Allow a generic scan tool to tentatively deactivate inducement related fault codes while the vehicle is not in motion. Reactivate the derate at the same point in the derate schedule if the engine detects the same fault condition during a full inducement drive schedule." EMA understands that this proposed capability may be implemented at the manufacturer's discretion. At issue is the fact that whether within the

four hours proposed in paragraph (g)(2), or the 80 hours proposed in paragraph (g)(3), there is no warning buffer if a similar fault code is detected within those warning periods, and the language indicates that you go back to wherever you were on the derate schedule (i.e., an operator believes that all is well, yet derate begins with little to no warning). This poses both a significant safety concern and contributes to customer dissatisfaction, as noted in previous comments cited throughout the preamble. EMA recommends that EPA consider a warning "buffer" or a specific hour requirement before activating derates. [EPA-HQ-OAR-2019-0055-1203-A1, p. 103]

- §1036.111(g)(3): "(3) Treat any fault condition that recurs within 80 hours of engine operation as the same triggering condition, which would restart the derate at the same point that the system last deactivated the derate." 80 hours represents up to 4,000 miles of travel; dual 125-gallon fuel tanks may be refilled up to four times in this same time period, and the accelerated derate may be faced by a different operator. This proposed provision would add additional complexity and would likely increase owner and operator dissatisfaction with the impact of the regulation on operations. [EPA-HQ-OAR-2019-0055-1203-A1, p. 103]

In addition, EPA proposes that the 100-Hour Array be reset upon confirming that corrective action has been taken (§1036.111(g)). Resetting the Active 100-Hour Array may be in conflict with CARB requirements. [EPA-HQ-OAR-2019-0055-1203-A1, p. 125]

There are additional concerns related to the proposed provisions for deactivating the inducement derates. Under §1036.111(g), the manufacturer must wait for the fault condition to no longer be detected, then reset the 100-Hour Array, and then wait for Bins 13 and 14 to populate with data to confirm NOx conversion efficiency is restored. That is a long chain of events for the system to be restored, especially for events that may not be related to failure to refill or tampering, such as blocked DEF lines. With respect to empty DEF tank inducements, EPA should allow for the derates to be deactivated as soon as the DEF level sensor indicates a level of refill. If the NOx override factor does not show adequate conversion (value greater than 10%), the derates could be quickly reactivated at the point where they were deactivated on suspicion of tampering. [EPA-HQ-OAR-2019-0055-1203-A1, p. 125]

In a related matter, EPA has proposed that engines must be compliant with any level of DEF concentration that does not trigger inducement (§1036.115(f)). That would not only mean that the DEF quality sensor ("DQS") must have a detection capability to support this outcome, linked to manufacturers' calibrations and compensation routines, but also that the NOx override function that CARB requires to confirm the "poor quality" DEF condition prior to triggering inducement must be supportive of the requirement. The role of the NOx override function is, of course, to confirm compromised emissions before triggering inducement. This means that §1036.115(f) and §1036.111(c) are in conflict with one another. As proposed, manufacturers would have to ensure compliance at the same level of emissions that they are confirming to be compromised emissions performance. That is obviously not workable. [EPA-HQ-OAR-2019-0055-1203-A1, p. 125]

Notwithstanding this clear conflict in the proposed requirements, manufacturers have too little experience with the complex future emissions control systems required to meet the proposed very stringent standards to know if compliance can be assured at the urea concentration limits detectable by DQS systems. EPA has made no such demonstration of that capability. The simple fact is that both the industry and EPA are uncertain whether the requirement can be met. EPA should regulate on the basis of data-based evidence, but no such evidence exists regarding this issue. EPA should not include §1036.115(f) in the final rule. [EPA-HQ-OAR-2019-0055-1203-A1, p. 125]

EPA Summary and Response

For the purpose of this section, each subtopic is summarized and responded to separately.

In-Cab display

ABA, CARB, and Coach USA expressed general support of EPA's proposal in §1036.111(f) to require an in-cab display showing the triggering condition that leads to an inducement and a countdown of time/distance until the next inducement stage. ABA commented that current notification systems are confusing to drivers. CARB notes that adequate warning of impending inducement is critical for operators to take appropriate action. CARB also included the following recommendations for an in-cab display: in addition to indicating "inducement pending" add the fault condition, inducement stage (i.e., include speed/time/torque limitations), and add "progressively greater audible and visible warnings" at each stage of derate to make the inducement more effective. Coach USA suggests a "simple, informative alert" (that avoids excessive information) will allow drivers to plan, avoid driver distraction, and lower the risk that a bus will be stranded. Coach USA also recommended EPA require manufacturers to provide more precise information to alert drivers to DEF levels and time remaining before DEF volumes fall to a level where inducement will occur. EMA commented that it is critical that sufficient driver notification be provided before inducements are applied.

Response:

EPA proposed in this rulemaking at §1036.111(f) that the in-cab display would include: the triggering condition (for active and pending inducements), the current stage of derating, and the time and distance until the next inducement stage. We are finalizing those provisions as proposed in the final §1036.110(c). For SCR-related inducements, we are requiring manufacturers identify the type of fault condition that is causing the inducement, specifically if it is related to DEF quantity, DEF quality, or tampering. These categories are enabled by our targeted list of triggers in 40 CFR 1036.111(b). We are also requiring manufacturers to display the fault code for the detected problem and a description of the fault code. This additional information will provide information to help the operator diagnose and correct the fault condition. The final rule also includes a requirement for manufacturers to provide troubleshooting information in the owners manual describing how to address potential inducement fault conditions (see final 40 CFR 1036.125). We are finalizing a similar set of requirements for other SCR- or DPF-related engine derates (see section IV.C. of the preamble for additional information). EPA is confident manufacturers will be able to make this information available in a way that it will not increase driver confusion while in operation.

The regulation at 40 CFR 1036.115(i) directs manufacturers to make DEF tanks big enough to correspond with typical refueling practices. This arrangement is intended to facilitate DEF refills in conjunction with refueling. If operators routinely refill DEF tanks when refueling the vehicle, there is no need for a separate DEF fill level indicator. At the same time, the regulation does not prevent manufacturers from providing this additional information in response to consumer demand. EMA's comment on the importance of notifying drivers in advance of applying inducements supports the expectation that manufacturers will include appropriate warning signals.

Deactivating derates and recurring faults

EMA recommends that EPA not adopt the provisions in proposed §1036.111(g)(1) that rely on the Active 100 Hour Array in OBD to deactivate a derate, citing a conflict with CARB's 13 CCR 1971.1 (h)(5.3.6). EMA suggests instead EPA state "Deactivate derates if the engine confirms that the fault condition is resolved and or the override factor for NOx conversion efficiency is at or below 0.10 for a full inducement drive schedule". In other words, EMA recommended deactivation if the engine confirms that the fault condition is resolved, independent of NOx emission rates; or if the engine detects successful NOx conversion even if the fault condition is not resolved. EMA notes that EPA's proposal to deactivate derates in §1036.111(g) involves a "long chain of events" that requires waiting for the fault condition to no longer be detected, and waiting for OBD REAL Bins to repopulate after being reset to confirm NOx conversion efficiency is restored. EMA states that this process may not be appropriate for all cases especially for issues that may not be related to tampering or lack of use of DEF (e.g., blocked DEF lines). EMA suggests that for DEF level faults derates should be deactivated as soon as the DEF level sensor indicates a level of refill; deactivation could resume if the system detects that NOx conversion efficiency is below 10% on suspicion of tampering.

CARB noted that allowing a generic scan tool to deactivate derates is currently prohibited; CARB is concerned that allowing the use of a generic scan tool to clear codes and to derate inducements could result in abuse. CARB is concerned use of a generic scan tool over and over again to deactivate inducements could become a strategy to tamper. However, CARB commented that it is, however, reasonable to allow a generic scan tool to be used when repairs are done and recommends limiting the use of the tool to deactivate derates to two times when a recurring fault condition appears but only if the vehicle is not in a final inducement step.

EMA commented that it is their understanding that the provisions of proposed 40 CFR §1036.111(g)(2) to allow inducements to be reset with a generic scan tool are at the manufacturer's discretion. EMA also warns that the four-hour period in the proposed §1036.111(g)(2) or the 80-hour period in §1036.111(g)(3) may restart inducements without warning. EMA suggests that EPA consider a warning "buffer" or a specific hour requirement before activating derates to avoid allowing a similar fault code triggered within the warning periods to avoid creating problems for safety or customer satisfaction.

EMA suggested that EPA's proposed 80-hour window to monitor for a fault condition would add complexity and likely increase operator dissatisfaction, noting that 80 hours could represent 4,000 miles of travel, several fuel tank refills, and potentially a switch to a new operator.

CARB supports monitoring for recurring fault conditions and restarting a derate at the same point that the derate was last deactivated if the same fault condition was triggered in the next 80 hours of engine operation.

EMA commented that they believe the proposed requirements in §§1036.111(c) and 1036.115(f) are in conflict. They state that EPA proposed that engines must be compliant with any DEF concentration that does not trigger an inducement, however they note that EPA also proposed to require that the NOx override must confirm "poor quality" DEF prior to triggering an inducement (via monitoring for higher emissions). EMA states this is a conflict because they would have to ensure compliance while simultaneously confirming emissions are compromised. EMA commented further that manufacturers do not have sufficient experience with the new technology that will be needed to meet existing guidance that states compliance can be assured at urea concentration limits detectable by DEF quality sensors. EMA commented that EPA has made no such demonstration of that capability, and given this uncertainty EPA should not include §1036.115(f) in the final rule.

Response:

As explained in preamble Section IV and section 8.2 of this document, EPA is not finalizing the proposed NOx override at this time.

EPA is finalizing, as proposed, the provision allowing operators to deactivate derates with a generic scan tool. We are not including any limitation on the number of resets. The fault conditions contemplated in the final 40 CFR 1036.111 are all detectable immediately. The final rule specifies, as proposed, that resets with a generic scan tool must occur while the vehicle is not in motion. The final rule also specifies that any fault condition that recurs during the 40 hours of operation following a reset or resolved fault condition would automatically resume engine derating at the same point. These provisions together make it completely impractical for an operator to operate for extended periods with an active fault condition by using a generic scan tool to repeatedly reset the system.

In particular, the operator would need to stop the vehicle, reset the system with the generic scan tool, and then resume driving. The system would detect within a very short time that fault condition was not resolved and resume derating. The operator could repeat that indefinitely but would likely not ever be able to exceed the currently applicable derate speed before the engine would reapply the derate and thus would achieve no net gain from such actions.
We note, consistent with the EMA comment, that provisions related to deactivating derates are much simpler without the proposed NOx override. Because the NOx override is not included in the final rule, there is no need to address the logic of allowing time for driving to determine whether the SCR system is controlling emissions appropriately.

EMA incorrectly read the proposed rule to allow them discretion on designing engines to reset fault conditions with a generic scan tool. EPA intended that the ability to reset inducements with a generic scan tool was a requirement for all vehicles. We are finalizing that requirement as proposed. EPA agrees with EMA that a warning buffer should be added prior to any inducement. The same requirement limiting each stage of derate to a maximum change of 1 mph over five minutes applies equally for recurring fault conditions.

EPA agrees with EMA's observation that 80 hours of operation, or about 4,000 miles, is too long for an operator to be subject to a new fault being treated as a recurring fault condition. EPA is therefore revising from proposal the final number of hours during which a recurring fault would occur, from 80 hours to 40 hours. This is also consistent with hours EPA has considered under existing guidance.

EMA's comments about a potential conflict between 1036.115(f) and 1036.115(c) are not at issue in the final rule because we are not adopting the NOx override provisions at this time. Fundamental to certification is the requirement for manufacturers to comply with emission standards throughout the practically adjustable range of adjustable parameters. We consider DEF quantity and DEF quality to be adjustable parameters based on the operators need to take steps to maintain an adequate supply and quality of DEF. This requirement has always applied under current regulations. The proposed rule in 40 CFR 1036.115 inadvertently required manufacturers to base the adjustable range for DEF quality on the range of values used to trigger inducements under proposed 40 CFR 1036.111. We are removing that proposed language from the final provision and will be instead continuing to rely on current guidance regarding physically adjustable range for DEF quality.

EPA is not finalizing the proposed provision that an inducement schedule is applied and tracked independently for each fault if multiple fault conditions are detected. Consistent with EMA's comments, at this time we have concerns about potential risks resulting from complexity in the software needed to apply and track multiple derate schedules and the final provision still ensures that the SCR system will receive an adequate supply of high quality DEF. Under the final provision, if a second fault condition starts while the engine already has an active inducement, the software would need to continue progressing through the derate schedule as specified. Once that fault condition is resolved, the engine would start at the beginning of the derate schedule for the new fault condition.

8.5 Retrofitting in-use engines and vehicles with software updates to incorporate new inducement regulation

<u>Comments by Organizations</u>

Organization: *California Air Resources Board (CARB)*

The NPRM requests comments on field fixes for in-use vehicles. As described in detail in a previous section, CARB staff does not support the SCR inducement strategy proposed by U.S. EPA and does not support allowing field fixes for in-use vehicles or to amend the certification application of current model year engines for the NPRM inducement strategy. The proposed inducement strategy is too weak compared to that recommended in the current inducement guidance to cause the operator to fix the fault condition and preserve low, controlled NOx emissions. However, CARB staff would support allowing field fixes for in-use vehicles or amending current certification applications only if an inducement strategy identical or similar to the one proposed by CARB staff is adopted in the Final Rule. [EPA-HQ-OAR-2019-0055-1186-A2, pp.108-109]

Organization: *Midwest Bus & Motorcoach Association*

We are requesting **all** current commercial passenger motor vehicles, 2008 and newer, that have an aftertreatment system, be recalibrated with an ECM update to eliminate any derate or inducement that would limit the power or speed of the motorcoach. This proposal must include all models 2008 and newer that would be subject to any condition leading to a derate. We cannot stress enough the importance of this stipulation in the proposed language so that it will require engine manufacturers to develop and implement a new adopted schedule for all currently operated vehicles to be eligible for the update. Without this adoption there will be no relief in the foreseeable future and the concerns we have addressed will be disregarded by the engine manufacturers. The current proposal indicates models 2027 and newer. We are requesting that wording be changed to 2008 and newer. [Emphasis in original; EPA-HQ-OAR-2019-0055-1158-A1, p.5]

Recommendation:

- Require OEM's to develop updated derate schedules for existing vehicles. Other aspects of the proposal do not apply such as retrofitting for secondary system checks. By changing the schedule in current equipment, it would provide the industry's needs. [EPA-HQ-OAR-2019-0055-1158-A1, p.5]

Organization: *Motorcoach Companies*

We are requesting that ALL current passenger transport CMVs (post 2008 and newer) that is fitted with an aftertreatment system be recalibrated with and ECM update to eliminate any sort of derate or inducement that would limit power or speed of a vehicle. This proposal must include ALL models 2008 and newer that would be subject any condition leading to a derate. We cannot stress enough the importance of this stipulation being directly spelled out in the proposal language, which will require engine manufacturers to develop and implement this new adopted schedule for all currently operated vehicles will be eligible for this update. Without this adoption we will not have any relief for the foreseeable future and the concerns we have addressed will be ignored by the engine manufacturers. This is a critical component to our comment and cannot be overlooked. As of now the proposal indicates models 2027 and newer, it must be reworded to include anything 2008 and up! [EPA-HQ-OAR-2019-0055-1149-A1, pp.4-5]

Recommendation:

1. EPA should direct or require OEM's to develop updated derate schedule for these existing vehicles only, all other aspect of proposal do not need to apply such as

retrofitting for secondary system checks. Simply changing the schedule in these vehicles would suffice for our needs. This would be relatively easy in recoding the software program to allow more time [EPA-HQ-OAR-2019-0055-1149-A1, p.5]

Organization: *United Motorcoach Association (UMA)*

Upon adoption of a final rule, UMA implores the EPA to require engine manufactures and/or original equipment manufacturers, at a minimum, to reprogram the existing fleet to the revised inducement standards. [EPA-HQ-OAR-2019-0055-1311-A1, p.5]

Reprogramming to the revised inducement standards will begin to restore the confidence in existing buses and motorcoaches, stimulate sales of new equipment, and reduce barriers to adopting new equipment that further reduces NOx emissions. [EPA-HQ-OAR-2019-0055-1311-A1, p.5]

The bus and motorcoach community takes considerable pride in their contribution to improving air quality by removing multiple cars from the road and adoption of market-ready equipment that further reduces emissions. [EPA-HQ-OAR-2019-0055-1311-A1, p.5]

We need dependable equipment. [EPA-HQ-OAR-2019-0055-1311-A1, p.5]

Organization*: Virginia Motorcoach Association*

We are requesting **all** current commercial passenger motor vehicles, 2008 and newer, that have an aftertreatment system, be recalibrated with an ECM update to eliminate any derate or inducement that would limit the power or speed of the motorcoach. This proposal must include all models 2008 and newer that would be subject to any condition leading to a derate. We cannot stress enough the importance of this stipulation in the proposed language so that it will require engine manufacturers to develop and implement a new adopted schedule for all currently operated vehicles to be eligible for the update. Without this adoption there will be no relief in the foreseeable future and the concerns we have addressed will be disregarded by the engine manufacturers. The current proposal indicates models 2027 and newer. We are requesting that wording be changed to 2008 and newer. [Emphasis in original; EPA-HQ-OAR-2019-0055-2715-A1, p.4].

Recommendation:

- Require OEMs to develop updated derate schedules for existing vehicles. Other aspects of the proposal, such as retrofitting for secondary system checks, do not apply. By changing the schedule in current equipment, it would provide the industry’s needs. [EPA-HQ-OAR-2019-0055-2715-A1, p.5].

Organization: *Volvo Group*

Consideration should be made to make these [inducement] changes an option retroactive to 2010 CMY vehicles. [EPA-HQ-OAR-2019-0055-1324-A1, p. 5]

EPA Summary and Response

Summary:

CARB would support allowing field fixes for in-use vehicles or amending certification applications for the current model year only if the modification involves an inducement strategy similar to the approach CARB recommends in comments on the proposed rule. CARB believes that any other approach would be too weak for preserving control of NOx emissions compared to what currently applies.

Motorcoach Companies want engine manufacturers to retrofit all model year 2008 and newer vehicles to eliminate any sort of derate or inducement that limits vehicle speed or power. Specifically, Motorcoach Companies recommend that EPA direct or require OEM's to develop updated derate schedule for model year 2008 and newer vehicles. They state that failing to address these retrofit needs would leave them without relief for the foreseeable future.

UMA implores EPA to require engine manufactures and/or vehicle manufacturers to reprogram the existing fleet to the revised inducement standards.

Volvo recommends that EPA consider making it an option to retrofit model year 2010 and newer engines to incorporate designs that conform to the newly adopted inducement specifications.

Response:

See Section IV.D.6 in the final rule preamble.

9 This section is Blank

10 Durability testing

10.1 Updating existing DF provisions for carry-across and engine dyno aging

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

- CARB recommends that U.S. EPA work with CARB staff to enhance the proposal in 40 CFR 1036.245 – Deterioration factors for exhaust emission standards. The current NPRM proposal does not consider the impacts of engine emission control component deterioration. CARB staff believes that a more comprehensive approach similar to what was adopted in the Omnibus regulation would enhance the durability demonstration process while establishing a level playing-field for all engine manufacturers. [EPA-HQ-OAR-2019-0055-1186-A1, pp.2-3]

CARB staff has significant concerns regarding the proposed methodology for demonstrating engine and aftertreatment system (EAS) durability and calculating the deterioration factors (DF) for HD diesel engines. [EPA-HQ-OAR-2019-0055-1186-A2, p.25]

On page 17548 of the NPRM, U.S. EPA requests comments regarding the proposed options for DF determination. [EPA-HQ-OAR-2019-0055-1186-A2, p.25]

CARB staff opposes the option to use fuel-based accelerated aging as proposed in 1036.245 (b)(1). Recently published documents54,55 clearly indicate that fuel-based accelerated aging procedures do not yield deteriorated emissions results that are representative of real-life, in-use HD diesel engine operations. [EPA-HQ-OAR-2019-0055-1186-A2, p.25]

> 54 EPA. ‘‘Guidance on Deterioration Factor Validation Methods for Heavy-Duty Diesel Highway Engines and Nonroad Diesel Engines equipped with SCR.’’ CD–2020–19 (HD Highway and Nonroad). November 17, 2020. https://dis.epa.gov/otaqpub/display_file.jsp?docid=51377&flag=1
>
> 55 PUBLIC WORKSHOP TO DISCUSS METHODS OF HEAVY-DUTY DIESEL AND OFF-ROAD DIESEL ENGINE DETERIORATION FACTOR VALIDATION. Mail-out #ECC-2020-03 [REVISED]. https://ww3.arb.ca.gov/msprog/mailouts/ecc202003/ecc202003_ada.pdf

Given the poor track record of fuel-based accelerated aging procedures, CARB staff opposes this option and recommends the elimination of this methodology. Instead, CARB staff recommends a comprehensive method that combines dynamometer aging (with no fuel-based acceleration factors) combined with aftertreatment bench aging. A complete description of this comprehensive durability demonstration process
56 is described in the Omnibus regulation diesel test procedures. [EPA-HQ-OAR-2019-0055-1186-A2, pp.25-26]

> 56 California Exhaust Emission Standards and Test Procedures for 2004 and Subsequent Model Heavy-Duty Diesel Engines and Vehicles. Pages 53-68. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2020/hdomnibuslownox/frob-1.pdf

Organization: *Truck and Engine Manufacturers Association (EMA)*

EPA is proposing new test procedures to determine deterioration factors (“DF”) for certification purposes. The most onerous of those new requirements is a manufacturer’s obligation to conduct DF testing for the Full Useful Life (“FUL”) of the engine’s primary intended service class, rather than using extrapolation as is permitted today. The limitations caused by FUL testing are significant, resulting in increased development costs, but more importantly such extended testing requirements present multiple challenges to OEMs' product development, verification and certification timelines. EPA's new requirements would be tempered somewhat by the flexibility manufacturers are given in defining aging cycles, and OEMs' option to bench-age aftertreatment systems, which would allow a much more favorable timeline for DF determination. Still, EMA recommends several improvements to these new provisions to make them workable. [EPA-HQ-OAR-2019-0055-1203-A1, p. 110]

The DF test is one of the many tests in a multi-year process to design, build and test for certification demonstrations. The prototype hardware and software included on the DF engine must be of sufficient design and manufacturing process maturity to establish that the test will "represent the deterioration expected from in-use engines over the useful life." (§1036.245) Once the test begins, the hardware and software revisions are frozen for the duration of the test, which has traditionally taken approximately 25-36 weeks for a typical MHDD or HHDD engine, when aged to 35% of FUL. [EPA-HQ-OAR-2019-0055-1203-A1, p. 110]

One undesirable outcome of FUL DF testing is that it requires that the DF test be started earlier on the project timeline, limiting the manufacturer's ability to iteratively introduce newer technologies that could provide additional GHG or emission benefits. EMA recommends that the Agency continue to allow manufacturers to run DF tests to 35 to 50% of FUL, and extrapolate results as is permitted today. Those extrapolated results could be used for certification purposes. A manufacturer could then be required to conduct DAAAC aging on the DF engine's aftertreatment system to FUL, submitting the subsequent FUL emissions data with the next model year's application, which would apply the new FUL DF results. [EPA-HQ-OAR-2019-0055-1203-A1, p. 110]

As mentioned, extending the DF testing requirement to 100% of FUL without extrapolation forces manufacturers to finalize hardware and software designs earlier in the development process. Currently, there is no regulatory flexibility to make hardware or software changes once the DF test is initiated. Because some of the components are necessarily fabricated from pre-production processes, they may, despite being representative of production intent, be prone to premature or even catastrophic failure. If severe, this can force manufacturers to restart the DF test, putting even more stress on an already challenging production launch schedule. EMA recommends that EPA provide greater flexibility to allow manufacturers to make hardware or software adjustments on the DF engine to facilitate timely test completion, while preserving the integrity of the test. This consideration should also extend to address replacement service parts, which may include sensors, catalysts or EGR components. [EPA-HQ-OAR-2019-0055-1203-A1, p. 110]

For example, downpipes and bellows can easily fatigue with extended dyno testing. Those components are not emissions-critical but cannot be replaced without EPA approval. NOx, PM and NH3 sensors currently are not robust enough to survive for 435,000 miles, let alone 800,000 miles. In the event of an engine failure that causes the aftertreatment system to be damaged, it would be desirable if the aftertreatment components could be rapidly aged to the last interim emissions measurement point. The bottom line is that EPA should offer more options and flexibilities to recover from those kinds of issues during the course of a DF test. [EPA-HQ-OAR-2019-0055-1203-A1, p. 110 - 111]

EPA has traditionally approved accelerated DF aging cycles based on fuel-burned or work completed equivalent metrics. When defining those aging cycles, manufacturers must balance the severity of the cycle against the design limitations of the individual components to replicate representative in-use wear without causing premature failure. EMA supports that EPA has proposed to allow the use of accelerated aging cycles to manage the total cost and duration of the DF test. EMA also supports that the Agency has not included requirements to stop and restart the engine at intervals during the service accumulation, as this has little or no bearing on the DF results. However, §1036.245(b)(1)(i) requires that the service accumulation "must also include light-load operation (or alternating light-load and high-load operation) representing in-use behavior that may contribute to aging of aftertreatment devices or systems." Light-load operation is not considered to be a contributor to engine component wear or aftertreatment degradation. We recommend that the Agency eliminate the obligation to include light-load operation. For example, the provision could be modified to state, "However, if you anticipate that including light-load operation may contribute to aging of aftertreatment devices or systems, you must also include light-load operation (or alternating light-load and high-load operation)." [EPA-HQ-OAR-2019-0055-1203-A1, p. 111]

An important issue that the Agency has failed to address in its proposal is how a manufacturer must conduct deterioration factor testing, either through dyno-aging or bench-aging processes, particularly in the case where the manufacturer will include major emissions-related maintenance actions to comply with the extremely stringent emissions standards and extended useful life requirements. For example, if a manufacturer recommends aftertreatment system replacement at 300,000 miles (before the 435,000 mile intermediate useful life interval for which results are required by the proposal), the manufacturer should be able to propose an alternative DF test plan, including a test at 300,000 miles, but eliminating the 435,000 mile test interval. Data-fitting processes also need to be reviewed. EMA is willing to work with the Agency to develop appropriate alternative procedures. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 111 - 112]

In sum, EMA supports the flexibility offered by the various options EPA proposes in the determination of deterioration factors and the DF verification procedures. [EPA-HQ-OAR-2019-0055-1203-A1, p. 115]

Perhaps even more concerning are the necessary data-generation projects that are completely unplanned at this time. More specifically, EPA intends to complete this rulemaking without having access to the following: Durability testing to determine whether cylinder deactivation (CDA) is a viable technology suitable for the rigorous demands of heavy-heavy-duty engines, or to determine whether it should be expected that NVH concerns can be managed over the broad and diverse range of products and applications unique to the commercial truck industry, or to assess if CDA is capable of lasting 800,000 miles without a major service intervention. CDA is a cornerstone technology for EPA's technical feasibility demonstration, critical to meeting the low-load NOx emission requirements that are a focus for this rulemaking. Yet no data regarding the feasibility of CDA in this context will be in the rulemaking record. [EPA-HQ-OAR-2019-0055-1203-A1, p. 172]

EPA Summary and Response

Summary:

The above comments address several aspects of the proposed revisions to the existing deterioration factor provisions, including for carry-across and engine dynamometer aging.

With regard to aging in general, CARB commented that they oppose using fuel-based accelerated aging as the emission results are not representative of real-life, in-use HD diesel engine operations. Instead, CARB recommend adopting the comprehensive methods set out in their Omnibus regulation that combines dynamometer aging (with no fuel-based acceleration factors with bench aging).

With regard to specific aspects of Full Useful Life (FUL) deterioration factor testing, EMA indicated their support for several aspects of the proposal such as the use of accelerated aging cycles to manage the total cost and duration of the DF test, and not including requirements to stop and restart the engine during service accumulation. However, EMA raised concerns about several other aspects and suggested certain revisions to the proposed program.

EMA noted that FUL DF testing would require testing to begin earlier and limit manufacturers to iteratively introduce technologies that may provide additional emission and GHG benefits. EMA noted that this concern could be addressed by allowing a manufacturer to run DF tests to 35-50% of FUL and extrapolate the results. EMA noted that the manufacturer could be required to conduct DAAAC aging on the DF engine's aftertreatment system to FUL and report that with the next model year's certification application, which would apply the new FUL DF results.

EMA also noted that FUL DF testing would require testing using hardware and software fabricated from pre-production processes, which may be prone to failure and could require restarting the DF testing. EMA noted that this concern could be addressed by allowing manufacturers to make hardware or software adjustment on the DF engine to facilitate timely completion while preserving the integrity of the test. EMA also suggested that consideration should also extend to address replacement service parts, which may include sensors, catalysts or EGR components.

EMA stated they do not support including light-load operation during service accumulation. EMA asserted that light-load operation does not contribute to engine component wear or aftertreatment degradation. However, EMA noted that light-load could be included if a manufacturer anticipates light-load operation may contribute to aging of aftertreatment devices or systems.

While EMA supports bench-aging of aftertreatment systems, they stated there is no need to define a minimum number of engine hours of dynamometer aging beyond what is needed to stabilize the engine and aftertreatment. EMA also said that EPA failed to define how a manufacturer is to conduct DF testing, either through dyno-aging or bench-aging, particularly in the case where the manufacturer will include major emissions-related maintenance actions to comply with the extremely stringent emissions standards and extended useful life requirements and that they are willing to work with the Agency to develop alternative procedures.

Finally, EMA noted their concern that EPA intends to finalize the rule without having access to certain important information on durability of CDA and NVH.

Response:

See preamble Section IV.F for our responses to many of these comments on the proposed options for determining the DF and our rationale for the final provisions for determining DF.

EPA thanks EMA for their support of the use of accelerated aging cycles to manage the total cost and duration of the DF test, and not including requirements to stop and restart the engine during service accumulation.

EPA agrees with EMA that FUL DF engine testing would require testing to begin earlier. This is why EPA proposed an option to use accelerated reactor bench aging of the emission control system, requiring as little as 400 hours of testing on an engine dynamometer. This option allows the DF determination to be completed within 90 days. EPA opposes EMA's request to allow an engine-based DF determination out to 35-50% of UL with extrapolation to UL, as this methodology has been shown historically to be inaccurate at determining deterioration.[30,31] See preamble Section IV.F for further discussion on this. EPA also disagrees with EMA's request to allow the manufacturer to determine DF using an engine-based test out to 35-50% of UL and following up that testing with DAAAC aging on the engine's aftertreatment system to UL with reporting of the DAAAC aging results with the next model year's certification application. Given our concerns with the accuracy of an engine-based tests out to 35-50% of UL, EPA thinks it is appropriate to require DF determination out to the service accumulation hours based on full useful life as determined in 40 CFR 1036.245(c) and that this be complete prior to application for certification for every model year; all final options to meet the DF determination requirements include that requirement.

EPA does not agree with EMA's suggestion that we should allow manufacturers to make hardware or software adjustment on the DF engine to facilitate timely completion, as this may affect the rate of deterioration compared to the initial configuration. EMA would also like this extended to service parts, which may include sensors, catalysts or EGR components. See section 6 of this document for the final maintenance provisions, including revisions to minimum maintenance intervals that generally match intervals manufacturers are specifying for components today. We expect manufacturers will continue to schedule replacement of components as needed to meet the DF testing requirements and to accurately represent the maintenance needs of engine in the field. Manufacturers can work with EPA if a component (pre-production or otherwise) unexpectedly fails during service accumulation. The final 40 CFR 1036.425(c) allows for critical emission-related scheduled maintenance, described in 40 CFR 1036.125(a), during service accumulation. As noted in Sections III and IV.A of the preamble to this final rule, we set final standards and useful life periods that will not require manufacturers to plan for scheduled replacement of catalysts. If manufacturers opt to replace their catalysts as part

[30] U.S. EPA. "Guidance on Deterioration Factor Validation Methods for Heavy-Duty Diesel Highway Engines and Nonroad Diesel Engines equipped with SCR." CD-2020-19 (HD Highway and Nonroad). November 17, 2020.
[31] Truck and Engine Manufacturers Association. "EMA DF Test Program." August 1, 2017.

of scheduled maintenance, at the expense of the manufacturer, manufacturers could request approval of an alternate DF test plan using existing provisions.

EPA disagrees with EMA regarding not including light-load operation during service accumulation for the reasons given in the discussion above and in preamble Section IV.F regarding required aging duty-cycles for determining deterioration.

EPA disagrees with EMA's comment that there is no need to define a minimum number of engine hours of dynamometer aging beyond what is needed to stabilize the engine and aftertreatment when the aftertreatment is bench aged. In this final rule, we are requiring a minimum number of testing hours on an engine dynamometer, with the allowance for the manufacturer to add additional hours of engine dynamometer-aging at their discretion. The minimum required hours, beyond what is needed to initially stabilize the engine and aftertreatment, are by primary intended service class and as follows: 300 hours for Spark-ignition HDE, 1,250 hours for Light HDE, and 1,500 hours for Medium HDE and Heavy HDE. EPA disagrees that we failed to define how a manufacturer is to conduct DF testing, either through dynamometer-aging or bench-aging, particularly in the case where the manufacturer will include major emissions-related maintenance actions to comply with the final rule emissions standards and final rule useful life requirements. We are finalizing critical emission-related scheduled maintenance as described in 40 CFR 1036.125(a)(2) and 1036.245(c) in this final rule. Under this final rule, manufacturers may make requests to EPA for approval for additional emission-related maintenance actions beyond what is listed in 40 CFR 1036.125(a)(2), as described in 40 CFR 1036.125(a)(1) and as allowed during deterioration testing under 40 CFR 1036.245(c).

10.2 DF procedures based on bench aging of aftertreatment devices

<u>Comments by Organizations</u>

Organization: *California Air Resources Board (CARB)*

On page 17548 of the NPRM, U.S. EPA requests comments regarding the proposed options for DF determination. [EPA-HQ-OAR-2019-0055-1186-A2, p.26]

The proposed aftertreatment bench aging procedures offer reduced durability testing time upfront with the requirement to prove compliance using in-field testing after certification. While this reduces the length of the product development cycle, any hardware or software component issues, especially on the engine, will be missed and require an overreliance on warranty or On-board Diagnostics (OBD) to detect those issues later. [EPA-HQ-OAR-2019-0055-1186-A2, p.26]

Common examples of durability issues that would not be demonstrated using 100 percent bench aged aftertreatment are fuel injector drift or premature failure of turbocharger components such as oil seals. Additionally, interactions between the engine (upstream) and the aftertreatment system (downstream) have been demonstrated to reduce the overall efficiency of the NOx aftertreatment system over time. In fact, such an interaction occurred during CARB's Stage 3 low NOx demonstration program57 where a faulty exhaust gas recirculation (EGR) valve caused damaged to the downstream zone-catalyzed soot filter. Although this failure could have been the result of component defect, it could have also been the result of poor engineering design that caused the component to fail prematurely. By limiting the durability demonstration program to focus strictly on aftertreatment bench aging, U.S. EPA's proposal would arbitrarily and capriciously fail to account for upstream/downstream interactions on the deterioration of aftertreatment systems, State Farm, 463 U.S. at 43, and would therefore not provide a reliable and accurate method of assessing durability of aftertreatment components and systems in real-life operating conditions. [EPA-HQ-OAR-2019-0055-1186-A2, p.26]

57 Low NOx Demonstration Program – Stage 3. Pg. 117. https://www.arb.ca.gov/lists/com-attach/79-hdomnibus2020-Uj4AaQB2Aj8FbAhw.pdf

CARB staff therefore opposes the allowance to demonstrate full UL durability that is dependent on only aftertreatment bench aging process as described in 1036.245 (b)(2). CARB staff recognizes the importance of allowing aftertreatment bench aging as part of the UL durability demonstration when the UL is significantly increased in 2027 and subsequent model years. California's Omnibus regulation allows for a combination of EAS engine dynamometer aging and further aftertreatment bench aging (comprehensive durability demonstration program) to demonstrate overall comprehensive EAS durability demonstration to full UL. This comprehensive methodology provides a level of assurance that all emission related components, including components that are not part of the aftertreatment system, demonstrate an acceptable level of durability. [EPA-HQ-OAR-2019-0055-1186-A2, pp.26-27]

If the durability of these components is not demonstrated at the time of certification, it is likely that some products with systemic design problems will be introduced into commerce, resulting in excess emissions and increasing fleet downtime to complete repairs. Under U.S. EPA's proposal, the lag time between the vehicles reaching the field and the verification of the deterioration of these products proposed in 1036.246 would be at a minimum 3 years. In that time, unchecked systemic failure of emission-related components could have significant impacts to air quality and public health. [EPA-HQ-OAR-2019-0055-1186-A2, p.27]

U.S. EPA's failure to analyze the scope and extent of the increased emissions resulting from this proposal, and their impacts on the public's health and welfare constitutes a failure to consider an important aspect of this proposal, State Farm, 463 U.S. at 43, and an impermissible abdication of U.S. EPA's duty under CAA section 202(a) to ensure affected HDEs and vehicles comply with applicable emissions standards throughout their useful lives. CAA sections 202(a)(1), 202(a)(3), Chevron, 467 U.S. at 842-843. (See CARB comments in section 5.a, infra). [EPA-HQ-OAR-2019-0055-1186-A2, p.27]

It should also be noted that currently light-duty diesel vehicles do not rely solely on aftertreatment bench aging to demonstrate durability. Instead, aging on a chassis dynamometer is used to verify component durability and establish the deterioration factors. [EPA-HQ-OAR-2019-0055-1186-A2, p.27]

On page 17548 of the NPRM, U.S. EPA requests comments regarding the proposed options for DF determination. [EPA-HQ-OAR-2019-0055-1186-A2, p.27]

CARB staff strongly recommends that U.S. EPA work with CARB staff and adopt a comprehensive durability demonstration program similar or identical to what is described in the Omnibus regulation. Such a comprehensive process should include a reasonable period of EAS aging on an engine dynamometer (without any fuel-based acceleration factors) to verify engine side emission-related component durability and to account for possible upstream/downstream interactions between the EAS as described earlier. A significant portion of the aging process could then utilize aftertreatment bench aging, provided that the accelerated aftertreatment aging method has been verified through correlation studies. [EPA-HQ-OAR-2019-0055-1186-A2, pp.27-28]

It should also be noted that the current version of the proposed CTP regulatory language does not provide a pathway for manufacturers to use a combination of EAS and accelerated aftertreatment aging, such as allowed in California's Omnibus. Thus, the only way for a manufacturer to meet the durability demonstration for both CARB and U.S. EPA would be to fully age the EAS on an engine dynamometer, which would be challenging for engines certified to future UL standards of up to 800,000 miles. [EPA-HQ-OAR-2019-0055-1186-A2, p.28]

CARB staff believes that the Omnibus comprehensive durability demonstration program is representative of in-use aging, cost-effective, and does not adversely impact the manufacturer's product development cycle. In terms of costs, the overall cost of the comprehensive durability demonstration program was estimated to make-up only 1.4 percent of the total cost of the Omnibus regulation.58 Therefore, additional durability demonstration costs are not going to have a major impact on the implementation of the proposed rule. The detailed methodology for calculating the incremental costs for the Omnibus durability program is provided in the Standardized Regulatory Impact Assessment document.59 [EPA-HQ-OAR-2019-0055-1186-A2, p.28]

58 Responses to DOF's comments on SRIA. Pg. 6. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2020/hdomnibuslownox/noticeattach.pdf

59 Omnibus - Standardized Regulatory Impact Assessment. Pg. 80-88. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2020/hdomnibuslownox/appc1.pdf

With regards to scheduling and product development, the required hours of aging for the Omnibus durability demonstration program ranges anywhere from 2,870 hours (LHDD) to 5,210 hours (HHDD) for 2031 and later MYs. CARB staff does not believe this would have an adverse impact on the product development plans. Although this could be a change for some certified on-road engines, many off-road compression-ignition (CI) engine manufacturers have used a 50 percent of UL (4,000 hour) durability demonstration program since the 2012 model year without reporting any product development issues. CARB staff estimates that running an additional 1,210 hours (5210-4000) would translate into an additional two months of aging. As such, there should not be any significant concerns regarding the length of the durability demonstration program. [EPA-HQ-OAR-2019-0055-1186-A2, p.28]

At a minimum, CARB staff strongly urges U.S. EPA to provide a pathway in the CTP regulations to allow CARB's comprehensive durability demonstration program as a substitute for satisfying U.S. EPA certification requirements. Without this, manufacturers may be required to expend substantial time and testing resources to comply with both California and Federal durability requirements. [EPA-HQ-OAR-2019-0055-1186-A2, p.28]

On page 17550 of the NPRM, U.S. EPA requests comments regarding the proposed Diesel Aftertreatment Rapid-Aging Protocol. [EPA-HQ-OAR-2019-0055-1186-A2, p.30]

CARB staff supports the codification of the protocols for rapid aging of the HD diesel aftertreatment system. By incorporating the methodology and procedures for aging the aftertreatment system, all manufactures would follow a well-defined and prescriptive process for rapid aftertreatment aging. A portion of the aging process in the Omnibus regulation relies on rapid aging of the aftertreatment, so codifying these procedures would be an important step in setting up a standardized process for all manufacturers. [EPA-HQ-OAR-2019-0055-1186-A2, p.30]

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

The Proposal's durability demonstration is substantially weaker than the Omnibus requirements, and it undermines the standards' effectiveness. 87 Fed. Reg. 17,547–48. In particular, EPA's demonstration allows for bench-aging of aftertreatment systems but does not require full testing of engines to ensure their emissions performance over their useful life. Given the centrality of engine design to emissions performance, that failure is likely to produce significant oversights in durability testing. Commenters ask EPA to adopt the comprehensive durability testing used in the Omnibus, combining dynamometer aging (with no fuel-based acceleration factors) with aftertreatment bench aging.242 [EPA-HQ-OAR-2019-0055-1302-A1, p.62]

> 242 See CARB, California Exhaust Emission Standards and Test Procedures for 2004 and Subsequent Model Heavy-Duty Diesel Engines and Vehicles (Aug. 27, 2020), https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2020/hdomnibuslownox/frob-1.pdf.

Organization: *Cummins Inc. (Cummins)*

Currently, determining emissions deterioration factors through testing requires long-hour engine dynamometer tests to age the entire engine + aftertreatment system. Even with accelerated test cycles and extrapolation to full useful life, engine dynamometer-based DF aging is time consuming, costly, and burdensome. A recent test program undertaken by engine manufacturers showed consistent engine out emissions over the full useful life, demonstrating little benefit to continuing long-hour aging of the base engine. EPA's proposed new provisions for determining DFs in §1036.245 include a new testing option using bench-aged aftertreatment, together with a stabilized emission-data engine. Manufacturers would be allowed to use an EPA-approved bench aging procedure to account for thermal and chemical degradation of aftertreatment or propose an equivalent bench aging procedure. Cummins supports inclusion of the aftertreatment bench aging option as a more efficient and accurate method for determining DFs for on-highway engines. Cummins also supports including the option in §1036.245(a) to request approval for DFs using engineering analysis from similar on-highway or nonroad engines. [EPA-HQ-OAR-2019-0055-1325-A1, p. 11]

Organization: *Ford Motor Company (Ford)*

We support the regulatory provisions that allow the use of bench aging-based emission deterioration factors for both spark- and compression-ignition engines. Allowing bench aging of aftertreatment systems will be critical to achieving development cycles which are executed with production-representative engine hardware and software. [EPA-HQ-OAR-2019-0055-1300-A1, p. 4]

Organization: *National Association of Clean Air Agencies (NACAA)*

NACAA does not support the proposed new option for durability demonstration. [EPA-HQ-OAR-2019-0055-1232-A1, p. 12]

EPA proposes a new option for determining a deterioration factor (DF) that would significantly weaken vehicle durability testing requirements. Under this new DF demonstration option, "to limit the burden of generating a DF over the proposed lengthened useful life periods," EPA would allow manufacturers to conduct dynamometer testing of an engine and aftertreatment system to a mileage less than regulatory useful life. Manufacturers would then bench age only the aftertreatment system to regulatory useful life, put it back on an engine representing the engine family, run the combined engine and bench-aged aftertreatment system for at least 100 hours and then collect emissions data to determine the DF. [EPA-HQ-OAR-2019-0055-1232-A1, p. 13]

EPA should discard this proposed option, which does not adequately simulate engine aging and, because the focus is on aftertreatment bench aging without consideration of engine-related component durability, could allow the certification of engines that do not meet the engine standards. EPA should continue to include both significant engine operation and accelerated aftertreatment aging in the DF determination, as is required by the Omnibus, and work with California to align the programs. [EPA-HQ-OAR-2019-0055-1232-A1, p. 13]

Organization: *Ozone Transport Commission (OTC) and Mid-Atlantic/Northeast Visibility Union (MANE-VU)*

Deterioration factor demonstration: EPA has proposed to establish a new deterioration factor determination option, where manufacturers would be able to perform dynamometer testing of an engine and aftertreatment system to a mileage that is less than regulatory useful life. Manufacturers would then bench age the aftertreatment system to regulatory useful life and combine the aftertreatment system with an engine that represents the engine family. Manufacturers would run the combined engine and bench-aged aftertreatment for at least 100 hours before collecting emission data for determination of the deterioration factor. OTC encourages EPA to continue to include the engine in the deterioration factor determination.

While it may be possible to move to the proposed new bench-aged aftertreatment option with more data, we do not believe there are sufficient data to ensure this method accurately evaluates the durability of the emission-related components in a certified configuration. We encourage EPA to align with CARB on the procedure for the deterioration factor determination. We believe both significant engine operation and accelerated aftertreatment are needed, and not accelerated aftertreatment aging alone. [EPA-HQ-OAR-2019-0055-1250-A1, pp.16-17]

Organization: *PACCAR, Inc (PACCAR)*

PACCAR supports that the Proposed Rule currently contemplates two ways in which OEMs may determine deterioration factors: either '[o]perate the emission-data engine in the certified configuration on an engine dynamometer to represent the useful life' or '[d]etermine deterioration factors based on bench-aged aftertreatment.' 1036.245(b)(1)-(2). PACCAR respectfully requests that EPA promulgate a third option that is essentially a combination of the two described above. [EPA-HQ-OAR-2019-0055-1346-A1, pp.46-47]

EPA appears to have contemplated including this third option – a combination of engine dynamometer aging and accelerated bench-aged aftertreatment aging. The preamble states: 'In addition, under our proposed new DF determination option, manufacturers would be able to perform dynamometer testing of an engine and aftertreatment system to a mileage that is less than regulatory useful life. Manufacturers would then bench age the aftertreatment system to regulatory useful life and combine the aftertreatment system with an engine that represents the engine family. Manufacturers would run the combined engine and bench-aged aftertreatment for at least 100 hours before collecting emission data for determination of the deterioration factor.' 87 Fed. Reg. at 17548. PACCAR therefore recommends that EPA promulgate this third option, which also would be consistent with CARB's regulatory approach. See FINAL California Exhaust Emission Standards and Test Procedures for 2004 and Subsequent Model Heavy-Duty Diesel Engines and Vehicles at B1.1.1.4. [EPA-HQ-OAR-2019-0055-1346-A1, p.47]

In addition, the proposed bench-aged aftertreatment option would require that the OEM '[c]reate a linear curve fit if testing includes intermediate points.' 40 C.F.R. 1036.245(2)(iv) (proposed). But EPA should amend this provision to allow for a nonlinear curve fit if there is sufficient supporting data. The common curve degrades quickly initially and then has a more gradual slope over the majority of the useful life. [EPA-HQ-OAR-2019-0055-1346-A1, p.47]

Organization: *Truck and Engine Manufacturers Association (EMA)*

EPA has proposed to allow bench-aging of aftertreatment systems as an alternative to traditional dyno-based aging processes. EMA fully supports this approach for HDOH engines. Expanding the utilization of bench-aging would significantly improve the product development cycle, reducing the costs and risks associated with traditional DF demonstrations (especially when extended FUL testing is required), while also improving the opportunity to deploy the latest technologies into the manufacturer's engine and aftertreatment designs. The SwRI-developed DAAAC protocol is an excellent example of a method that can be utilized to support bench-aging. EMA also supports EPA's proposal that alternatives to "EPA-approved" bench-aging procedures may also be approved. In that regard, EMA does not see the need for EPA to define a minimum number of engine hours of dynamometer aging beyond what is required to stabilize the engine and aftertreatment if a manufacturer were to utilize that bench-aging approach. Allowing for bench-aging of the aftertreatment system (after stabilization), without any prescribed minimums of dynamometer aging, would be the most time-efficient method of determining deterioration factors, and would be consistent with the findings of the “Industry DF” program. Such a provision would optimize the opportunities for engine manufacturers to include the latest technologies into their products, and would reduce testing costs and burdens. [EPA-HQ-OAR-2019-0055-1203-A1, p. 111]

EPA Summary and Response

Summary:

The state and environmental organizations (CARB, CATF, NACAA, and OTC) that commented on this aspect of the proposal did not support the proposed aftertreatment bench aging provision. While these commenters recognized certain benefits of the proposal, including reduced durability testing time upfront and improved product cycle timelines, they stated that the risks of hardware or software issues being missed means that this is not a reliable and accurate method of assessing durability of aftertreatment components. All of these commenters preferred the Omnibus approach. CARB recommended that EPA provide a way for manufacturers to use a combination of EAS and accelerated aftertreatment aging, and at minimum allow the Omnibus method as a substitute method. OTC also noted that there is not sufficient data to support using the bench-aged approach.

The engine manufacturers (Cummins, Ford, PACCAR, and EMA) that commented on this aspect of the proposal supported the proposed aftertreatment bench aging provision with some qualifications. Cummins noted that a recent engine manufacturer study shows there is little benefit to continuing long-hour aging of the base engine to determine deterioration. PACCAR recommended a 3rd option combining the two proposed options (dynamometer and bench-aged aftertreatment), and noted that EPA described consideration of this option in the proposed rule preamble, and that it is consistent with the Omnibus approach. PACCAR also recommended that EPA allow a nonlinear curve fit if testing includes intermediate points, if there is sufficient data to support that approach. EMA noted that the SwRI DAAAC protocol is a method that can be used to support bench-aging, and supported allowing alternatives to EPA-approved benching-aging procedures. EMA also noted that there is no need to define a minimum number of engine hours of dynamometer aging beyond what is needed to stabilize the engine and aftertreatment.

Response:

See preamble Section IV.F for our responses to many of these comments on the proposed options for determining the DF and our rationale for the final provisions for determining DF. While the purpose of EPA’s DF determination procedure is to determine emission performance degradation over the useful life of the engine, we acknowledge that there is value in performing some engine dynamometer aging. We are finalizing requiring a minimum number of testing hours on an engine dynamometer, with the allowance for the manufacturer to add additional hours of engine dynamometer-aging at their discretion. The minimum required hours, beyond what is needed to initially stabilize the engine and aftertreatment, are by primary intended service class and as follows: 300 hours for SI, 1,250 hours for Light HDE, and 1,500 hours for Medium HDE and Heavy HDE. These changes also allow manufacturers to include additional engine dynamometer testing above the minimum requirements, thus allowing the Omnibus method under the final requirements' options if manufacturers perform engine dynamometer testing to meet the Omnibus requirements and test over either of the Omnibus service accumulation cycles. Prior approval will not be needed for testing over the Omnibus cycles because the EPA required duty cycles include the engine shutdown and extended idle operation that the Omnibus cycles include. EPA disagrees with OTC that there is not sufficient data to support using the bench-aged approach. EPA has been evaluating accelerated aging methods under contract at SwRI and has provided data in the record for the final rule showing that the methods we have added to 40 CFR part 1036 will determine deterioration results that are comparable to those determined by testing out to useful life on an engine dynamometer and achieve a significant time and cost reduction for DF determination.

EMA noted that the SwRI DAAAC protocol is a method that can be used to support bench-aging and supported allowing alternatives to EPA-approved benching-aging procedures. EPA is finalizing as part of this rule in 40 CFR 1065.1131 through 40 CFR 1065.1145 a variation of the SwRI DAAAC accelerated aging protocol that was used in the accelerated aging test program that SwRI carried out for EPA under contract. The final requirements also include the option for manufacturers to use their own accelerated aging method with prior EPA approval.

10.3 Verifying deterioration factors

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

On page 17548 of the NPRM, U.S. EPA requests comments regarding the minimum number of hours required to stabilize the emissions from engines. [EPA-HQ-OAR-2019-0055-1186-A2, p.29]

CARB staff supports the provision to update the definition of 'low-hour' in 1036.801 to include 300 hours of operation for engines with NOx aftertreatment to be considered stabilized. This methodology harmonizes the emission stabilization requirements with the Omnibus regulation. [EPA-HQ-OAR-2019-0055-1186-A2, p.29]

On page 17548 of the NPRM, U.S. EPA requests comments regarding the proposed number of engines tested under the proposed DF verification procedures. [EPA-HQ-OAR-2019-0055-1186-A2, p.30]

CARB staff agrees that any DF created using a bench aged aftertreatment needs to be verified in-use. The Omnibus comprehensive durability demonstration program requires any engine family using a DF generated from a bench aged system to submit in-use emission data reports for more than 20 percent of the engines in the field for three consecutive years. The U.S. EPA proposal, based on the interim DF Validation program undertaken by U.S. EPA and CARB beginning in

2021, would test only a small sample (2 to 7) of in-field engines with up to 85 percent of UL miles. [EPA-HQ-OAR-2019-0055-1186-A2, p.30]

While the goal of these programs is the same, the requirements of the programs are not equivalent and could potentially require manufacturers to submit different data to each agency to satisfy the requirements. CARB staff believes the Omnibus approach is robust because the mandatory dynamometer aging requirements would address many durability concerns at the time of certification and would have a large dataset to identify unforeseen compliance issues in the field. The U.S. EPA approach would remain blind to durability concerns at time of certification with no dynamometer aging requirement and a relatively small sample size of test engines for DF validation that may not be statistically representative of the in-use population. [EPA-HQ-OAR-2019-0055-1186-A2, p.30]

Furthermore, U.S. EPA’s proposed DF validation program was never intended to become regulation; only to serve as an interim stop gap measure because of non-compliance issues revealed by the Truck and Engine Manufacturers Association durability study and because California was in the process of developing a comprehensive durability program as part of Omnibus beginning with 2024 MY engines. So even if such a DF verification approach were to be considered, further work needs to be performed to better assess the representativeness of the DF process to field engines prior to implementation. Again, CARB staff recommends that U.S. EPA evaluate the Omnibus durability program and work with CARB staff to address any concerns in the hope to establish a unified national durability demonstration program. [EPA-HQ-OAR-2019-0055-1186-A2, pp.30-31]

Organization: *Cummins Inc. (Cummins)*

In §1036.246, EPA is proposing to require one of three methods for verification of DF values by manufacturers using aftertreatment bench aging: engine dynamometer testing, PEMS testing, or onboard NOx sensor measurements, for several years each on successively higher mileage engines in production. The engine dynamometer testing verification option requires testing at least two engines annually, and the PEMS testing verification option requires testing at least five engines annually, for multiple years. However, the onboard NOx measurement verification option requires collecting 1 Hz data over a shift day of driving for at least 50% of engines produced annually for multiple years. Aside from the question of whether NOx sensors can even meet the verification, startup, and continuous operation requirements proposed by EPA in §1036.246(d)(3)(i), the 50% minimum is extremely high compared to the other verification options and to the existing EPA guidance CD-2020-19, upon which the proposed verification option is based. That guidance calls for testing a minimum of seven engines annually. Additionally, the telematics systems which EPA envisions manufacturers using do not collect 1 Hz data. EPA should work with manufacturers to determine a more reasonable, statistically valid requirement for DF verification using onboard NOx measurement for the final rule. Also, as it is unlikely that systems will exceed emissions standards early in their useful life, manufacturers should be permitted to propose alternate DF verification schedules for any of the three methods, such as testing smaller sample sizes prior to the 85% of useful life final verification point. [EPA-HQ-OAR-2019-0055-1325-A1, p. 11]

Organization: *Ford Motor Company (Ford)*

For spark-ignition engines which utilize the bench aging option, we recommend that the requirement to perform in-use verification testing of the emission Deterioration Factors be eliminated. Spark-ignition engine bench aging has followed a similar process to spark-ignition light-duty vehicle bench aging for many years and the deterioration levels of bench aging are well-aligned with aftertreatment deterioration observed from on-road vehicles. Further, eliminating in-use verification does not present risks of excess air pollution because vehicle on-board diagnostic systems will identify premature deterioration of the emissions control systems. [EPA-HQ-OAR-2019-0055-1300-A1, p. 4]

Organization: *Northeast States for Coordinated Air Use Management (NESCAUM)*

Should EPA instead promulgate Option 1, we urge the Agency to make the following changes to the proposed standards: EPA has proposed to establish a new deterioration factor determination option, where manufacturers would be able to perform dynamometer testing of an engine and aftertreatment system to a mileage that is less than regulatory useful life. Manufacturers would then bench age the aftertreatment system to regulatory useful life and combine the aftertreatment system with an engine that represents the engine family. Manufacturers would run the combined engine and bench-aged aftertreatment for at least 100 hours before collecting emission data for determination of the deterioration factor. NESCAUM encourages EPA to continue to include the engine in the deterioration factor determination. While it may be possible to move to the proposed new bench-aged aftertreatment option with more data, we do not believe there is sufficient data to ensure this method accurately evaluates the durability of the emission-related components in a certified configuration. We encourage EPA to align with CARB on the procedure for the deterioration factor determination. We believe both significant engine operation and accelerated aftertreatment are needed, and not accelerated aftertreatment aging alone. [EPA-HQ-OAR-2019-0055-1249-A1, p. 15]

Organization: *PACCAR, Inc (PACCAR)*

Corresponding changes would need to be made as well, including to the deterioration factor verification provisions. Specifically, 1036.246(c)(4) should be amended to allow using engines that undergo replacement or repair per the revised provisions above. [EPA-HQ-OAR-2019-0055-1346-A1, p. 45]

Certain aspects of the proposed deterioration factor verification provisions should be revised. First, PACCAR requests that EPA revise its proposal to make clear that DF verification testing is not required on model years that use carry-over DF data from previous model years. EPA should add clarifying regulatory language to proposed 1036.246, such as: ‘Carry-over of Deterioration Factors is allowed if there are no major hardware changes (e.g., a change in catalyst technology) that affect the deterioration of emissions; as such a single verification of deterioration factors on the first model year using the specific DFs should suffice to verify the validity of the DFs.’ [EPA-HQ-OAR-2019-0055-1346-A1, p.48]

In addition, PACCAR submits that proposed 40 C.F.R. 1036.246(d)(1)(i) requires clarification. Currently, the proposed section provides: 'Test at least two engines using the procedures specified in subpart F of this part and 40 CFR part 1065. Install the aftertreatment system from the selected in-use vehicle, including all associated wiring, sensors, and related hardware and software, on one of the following partially complete engines.' PACCAR respectfully requests that EPA clarify that this proposed provision would require testing two aftertreatment systems and that the testing can be done on a single engine. [EPA-HQ-OAR-2019-0055-1346-A1, p.48]

Proposed section 1036.246(d)(3) also needs to be revised. EPA proposes to require data from 50% of the engines produced for Option 3, as opposed to only 2 engines for Option 1, and 5 engines for Option 2. The option proposed by EPA requires 1Hz data, meaning that physical recorders must be installed in the vehicles to measure the required data. PACCAR proposes to reduce the demonstration requirements for Option 3 to five engines as in Option 2. [EPA-HQ-OAR-2019-0055-1346-A1, p.49]

PACCAR respectfully requests that EPA remove the proposed requirement that measured emission results must be adjusted for IRAF. See proposed 1036.246(d)(2)-(3) (requiring IRAF be added to the measured emission results). Although infrequent regeneration adjustment factors are determined during FTP, RMC and LLC test cycles, no IRAF values exist for in-use testing. In fact, the EPA proposed in-use test requirements in 1036.515 specifically exclude emissions during regeneration, i.e., no IRAF adjustment is required. [EPA-HQ-OAR-2019-0055-1346-A1, p.49]

Organization: *Truck and Engine Manufacturers Association (EMA)*

Regarding the DF verification procedures of proposed section §1036.246, EMA recommends a modification that will streamline those processes without impacting the integrity of the program. Regardless of the verification procedure selected, it is unlikely that systems will exceed emissions standards early in their useful life. EPA acknowledges this point by not requiring testing for the first two model years of production. EMA recommends extending this principle to the first years of validation testing by reducing sample size requirements in, for example, years 3 through 6. The number of tests required in years 7 and 8 could also be reduced if the results in years 3 through 6 demonstrate sufficiently compliant results. Indeed, it is unclear how relevant slightly elevated levels at early intervals might be. Accordingly, it may be reasonable to provide that a manufacturer has the option to perform these verifications only in the last stage of UL (the 85% of UL stage) if that manufacturer chooses to take the risk of failing results and potential recalls. EMA is willing to work with the Agency to establish appropriate streamlined parameters that will provide the Agency with the same level of assurance the DF verification process was intended to provide, but with reduced overall burdens for manufacturers. [EPA-HQ-OAR-2019-0055-1203-A1, p. 112]

It is noteworthy that the DF verification procedures were originally developed in guidance to confirm the validity of DF's developed through extrapolation of test results based on demonstrations conducted over less than FUL. The application of bench-aging would enable FUL DF determinations. As proposed, the extensive and burdensome DF verification testing requirements do not sunset. Manufacturers would be required to fulfill the DF verification requirements long after bench-aging has been confirmed as a reliable method of determining DFs. EMA recommends that the DF verification requirements sunset no later than 2035. [EPA-HQ-OAR-2019-0055-1203-A1, p. 112]

It is unclear why a manufacturer should be required to include non-emissions deteriorating components (wiring harnesses, DEF tanks and related sensors) when obtaining engine and/or aftertreatment systems for the engine dynamometer DF verification option. EMA recommends that the manufacturer be given more flexibility to propose a reduced list of necessary components. [EPA-HQ-OAR-2019-0055-1203-A1, p. 112]

There are additional DF verification provisions that require clarification. For example, the pass/fail criteria in section §1036.246(d) for all three verification options should clearly state that a manufacturer fails the verification test if "fewer than 70%" of the test samples pass. Additionally, sections §§1036.246(d)(1)(ii), (d)(2)(ii) and (d)(3) instruct the manufacturer to "apply infrequent regeneration adjustment factors as specified in §1036.522." EMA recommends clarifying this language to say "apply infrequent regeneration adjustment factors as included in your application for certification" to avoid any confusion that new adjustment factors should be generated or confirmed. EMA also recommends that EPA include flexibility allowing a manufacturer to propose alternative plans in the event that engines meeting the minimum mileage (or hours, for non-road or other applications for which hours are appropriate) requirements cannot be located or otherwise made available for testing. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 112 - 113]

The DF verification requirements from 40 CFR 1036.246 are triggered by the initial model year that relied on the DF determined per 40 CFR 1036.245. In the context of a new emissions rulemaking causing multiple engine families to start production in the same model year, the DF verification requirements would prove very burdensome for the manufacturer with no option to delay or stage each of the various stages of the DF verification program. We recommend adding a provision to limit the total number of DF verification test programs a manufacturer would be required to perform during a single year to no more than three (3). [EPA-HQ-OAR-2019-0055-1203-A1, p. 113]

Regarding the option to perform DF verification by utilizing on-board NOx sensors, EMA recommends some revisions for the final rule. The first item of concern is the requirement to include at least 50% of the manufacturer's production volume in this assessment. That could amount to a tremendous number of evaluations, all to be post-processed according to the complex 3B-MAW in-use test protocol. The reporting requirements of section §1036.246(f) include numerous details from each test, including VIN and serial numbers, and statements that "tested engines have been properly maintained and used and describe any noteworthy aspects of each vehicle's maintenance history," as well as explanations why data was "invalidated." Such detail cannot be automated for reporting processes. Providing 1Hz data on each test would require voluminous datafile submittals. All of these factors render the "50% of production volume" sample requirement completely unworkable. [EPA-HQ-OAR-2019-0055-1203-A1, p. 114]

EMA recommends that the number of engines to be included under the NOx sensor-based DF verification provisions be significantly reduced. Reducing the sample size to 20% or even 5% may still be unnecessarily onerous. EMA suggests that EPA use the same quantity of units as mentioned in the DF validation guidance (7 or more per year) if utilizing this DF verification option, or any number of sampling methods available to complete a statistically rigorous assessment in a less burdensome, more cost-effective way. EMA is willing to work with the Agency to propose a statistically sound basis for defining the number of engines to be included. If EPA finalizes the rule with a direct percentage, it should be a direct percentage of the parent engines produced. [EPA-HQ-OAR-2019-0055-1203-A1, p. 114]

With regard to §1036.520, which specifies the test procedures to submit NOx sensor-based data, including collection of 1Hz data and post-processing results according to the 3B-MAW protocol, EMA is again supportive of this forward-looking approach. There are, however, limitations as to the type of data that can be made available. For example, current telematic systems cannot transmit 1Hz data. CARB intends to modify REAL requirements in future OBD amendments, requiring that REAL include the capability to determine and store bin emissions according to the 3B-MAW requirements included in the Omnibus Regulations (and proposed in the NPRM). But that capability will not be in place until perhaps 2031. In the meantime, it could be possible for EPA to utilize the current REAL capabilities for the purpose of supporting DF verification requirements. Once 3B-MAW results are available, the process could incorporate those results for DF verification and in-use testing purposes. [EPA-HQ-OAR-2019-0055-1203-A1, p. 114]

There are other concerns with the proposed NOx sensor-based data acquisition requirements. For example, the requirement that on-board measurement capability must be verified as described in §1065.920(b) is unworkable. The replicates test option of §1065.920(b)(6)(ii) would not be available with the 6 to 9 hour road cycle, because that process does not include replicates in the same way that the current NTE-based requirements do when applied to §1065.920. The requirement that the NOx sensor be active within the first 100s of operation and remain active throughout the day is unworkable. Modern NOx sensors are not sufficiently robust to withstand all operating conditions, and must be turned off to avoid failure when dew point conditions are experienced in the exhaust stream. The ECU is switched off at key-off, so the NOx sensors are down under key-off conditions as well. Additionally, there is much to work out concerning CO2 emissions estimation from fuel delivery, calculation of CO2-specific results, and many other details. EMA stands ready to work with the agency to develop the appropriate processes to enable NOx sensor-based data acquisition capabilities. [EPA-HQ-OAR-2019-0055-1203-A1, p. 114]

EMA supports EPA’s proposal to allow a manufacturer to reverse a fail determination under the PEMS-based or NOx sensor-based verification procedures by applying the engine dynamometer-based procedures. This provision provides a reasonable method for addressing the potential shortcomings of the other methods. [EPA-HQ-OAR-2019-0055-1203-A1, p. 115]

EMA also requests that consideration be given to coordinating and streamlining manufacturer activities related to DF verification and the HDIUT program. The EPA/CARB in use test orders could be scheduled to coincide with DF verification obligations. EMA recommends that the Agency consider this opportunity to reduce manufacturer burdens. [EPA-HQ-OAR-2019-0055-

1203-A1, p. 115] However, for spark-ignition engines which utilize the bench-aging option, EMA recommends that the requirement to perform in-use verification testing of the emission Deterioration Factors be eliminated. Spark-ignition engine bench-aging has followed a similar process to spark-ignition light-duty vehicle bench-aging for many years, and the deterioration levels produce by bench-aging are well-aligned with aftertreatment deterioration observed from on-road vehicles. EMA stands ready to work with EPA to develop improvements to streamline those processes in the final rule. [EPA-HQ-OAR-2019-0055-1203-A1, p. 115]

EPA Summary and Response

Summary:

The above comments provide both general and specific comments on several aspects of the proposed procedures to verify deterioration factors.

NESCAUM stated they do not support the bench-aged aftertreatment option because of the lack of data to accurately evaluate the durability of emission-related components. NESCAUM stated that instead both significant engine operation and accelerated aftertreatment aging are necessary, and NESCAUM recommends EPA align with CARB on this.

EMA commented that the DF verification requirements should sunset no later than 2035, because bench-aging will be confirmed as a reliable method to determine deterioration factors before then.

With respect to bench-aged aftertreatment, CARB agreed that any deterioration factors created using this method must be verified in use, but stated that the number of engines tested in EPA's approach (would test only a small sample (2 to 7) of in-field engines with up to 85 percent of UL miles) is different from the Omnibus approach (data submitted from in-use engines for more than 20% of the engines in field for 3 consecutive years) and is less robust. CARB stated that, as a result, EPA's approach does not reflect durability concerns at the time of certification and may not be statistically representative of the in-use population, and it would also require manufacturers to develop two sets of data, one for CARB and one for Federal DF compliance. Finally, CARB commented that the EPA verification program that was originally in guidance and proposed in this this rulemaking was originally intended as an interim measure, and to date, enough data hasn't been collected to assess the representativeness of the DF verification process to field engines.

With regard to the requirements, there were many suggestions from multiple commenters to revise the proposal, including: limiting the number of DF verification tests per year to no more than three; reduced sample size requirements after the third year, and even in the 7th and 8th years if the results in earlier years are compliant, and allow an option to perform verification in only the 85% of useful life stage. To support these suggestions, these commenters stated that they were reasonable because systems are unlikely to fail early in useful life. Some commenters stated that manufacturers should also be allowed to propose alternate DF verification schedules for any of the three methods, such as testing smaller sample sized prior to the 85% useful life final verification point. One commenter suggested reducing the number of engines required to be tested in Option 3 to less than five, like Option 2. The commenter also suggested giving manufacturers more flexibility to propose a reduced list of necessary components, since some of those currently on the list are not emission-deteriorating (e.g., wiring harnesses, DEF tanks and related sensors), and suggested allowing manufacturers to propose alternative plans if engines meeting the minimum operation requirements (miles or hours) cannot be located or made available for testing. Finally, one commenter asked EPA to remove the requirement for measured emissions to be adjusted for IRAF, since no IRAF values exist for in-use testing. The comment also stated that the proposed in-use test requirements exclude regeneration emissions, so no IRAF adjustment is required. EMA recommended clarifying the IRAF language to say “apply infrequent regeneration adjustment factors as included in your application for certification” to avoid any confusion that new adjustment factors should be generated or confirmed for the verification.

There were several comments about the onboard NOx sensors approach for deterioration factor verification, and several manufacturers noted they are willing to continue to work with EPA to develop a reasonable, statistically reliable onboard NOx measurement method. With regard to the number of engines tested using this option, commenters said a requirement to test 50% of production volume is too high, compared to the other methods, and instead the number in EPA’s current DF validation guidance should be used (7 or more per year). Several commenters noted that current telematic systems cannot transmit 1 Hz data, and EPA should allow using REAL capabilities until 3B-MAQ results are available. Also, some commenters stated that there is more work needed to develop NOx sensor-based data acquisition capabilities. Some commenters stated that the requirements that on-board measurement capability must be verified and that the requirements that the NOx sensor be active within the first 100s of engine start up and remain active throughout the day are unworkable. Some commenters stated that they supported the EPA approach to allow manufacturers to reverse a fail determination under a PEMS-based or NOx sensor-based verification procedure by applying engine dynamometer-based procedures. Finally, there was a request to coordinate DF verification and the HDIUT program to reduce manufacturer burdens.

EMA commented that §1036.246(d) should clearly state that a manufacturer fails the verification test if “fewer than 70%” of the test samples pass, for all 3 verification options.

EMA commented that §§1036.246(d)(1)(ii), (d)(2)(ii) and (d)(3) should say “apply infrequent regeneration adjustment factors as included in your application for certification” to avoid any confusion that new adjustment factors should be generated or confirmed.

PACCAR commented that §1036.246(d)(1)(i) should be clarified that it would require testing two aftertreatment systems and that the testing can be done on a single engine.

PACCAR commented that §1036.246(c)(4) should be amended to allow using engines that undergo replacement or repair.

<u>Response</u>:

Regarding NESCAUM's statement that they do not support the bench-aged aftertreatment option because of the lack of data to accurately evaluate the durability of emission-related components, the accelerated bench aging method that we are finalizing has been shown to properly assess emission control system durability. See also preamble Section IV.F for our responses to comments on the proposed options for determining the DF and our rationale for the final provisions for determining DF.

As discussed further in the final rule preamble section IV.F.2, the final DF determination requirements do not include a requirement to verify the DF unless EPA specifically requests such verification, see final 40 CFR part 1036.246. EPA disagrees with EMA's request that the DF verification requirements sunset no later than 2035. EPA intends to request verification of DF if it suspects there is an issue with the DF generated by the manufacturer and thus does not think that a sunset date would be appropriate for the final DF verification requirement. EPA anticipates that a verification request may be appropriate due to consideration of, for example, data submitted to EPA from the manufacturer run in-use test program, or publications from test programs that indicate an engine family's deteriorated emissions are higher than the standard.

EPA disagrees with Ford's comment that in-use verification of DF is not needed due to the OBD system detecting premature deterioration. We are finalizing OBD thresholds that are many times higher than the final NO_x standards, so the emissions will have to deteriorate to emission levels many times the standard before the OBD system will detect it. We maintain that the option for EPA to require in-use verification of DF is appropriate.

In general, commentors provided many suggestions to revise the proposal regarding the specifics of a required verification program. See preamble Section IV.F.2 for what changes from proposal EPA is making in the final verification requirements, including our discussion of why we are not including the option for on board NO_x sensor-based verification at this time. Other than not including that option, for the reasons explained below and preamble Section IV.F.2, EPA is not finalizing any of the commenters' suggested changes. We are clarifying in the final provision that EPA will discuss with the manufacturer the number of verifications required in the event EPA requires verification, as described in section IV.F.2 of the preamble.

EPA disagrees with PACCAR who asked EPA to remove the requirement for measured emissions to be adjusted for IRAF. IRAF emissions are included in the DF determination, under the final requirement. EMA provided comments on 40 CFR 1036.246(d)(1)(ii), (d)(2)(ii) and (d)(3) (redesignated 40 CFR 1036.246(b)(1)(ii), (2)(ii), and (3)) and EPA agrees that those sections should say "apply infrequent regeneration adjustment factors as included in your application for certification" to avoid any confusion that new adjustment factors should be generated or confirmed. EPA is, however, retaining the option to request that manufacturers perform a new determination of IRAF emissions for engines tested using the engine dynamometer testing option in 40 CFR 1036.246(d)(1) (redesignated 40 CFR 1036.246(b)(1)), in the event that EPA has concerns regarding the effect of the higher-than-expected deterioration on IRAF emissions. Thus, where verification is requested by EPA, manufacturers must either 1) use the IRAF developed at the time of certification, or 2) develop new IRAFs during verification if EPA requests, to adjust the emission results during verification testing. EPA has updated this section for the final rule.

EPA also notes that the proposal included an option to reverse a fail determination under a PEMS-based or NOx sensor-based verification procedure by applying engine dynamometer-based procedures. As explained in preamble Section IV.F, we are finalizing this for PEMS-based testing where EPA requests DF verification.

EMA provided comments on proposed §1036.246(d) (redesignated 40 CFR 1036.246(b)) and EPA agrees that as proposed the requirement was not clear on whether the threshold was at or below 70% and it should clearly state, as originally intended, that a manufacturer fails the verification test "if fewer than 70% of the tested engines" pass, for both of the verification options. EPA has updated this section for the final rule.

EMA provided comments on §§1036.246(d)(1)(ii), (d)(2)(ii) and (d)(3) (redesignated 40 CFR 1036.246(b)(1)(ii), (2)(ii), and (3)) and EPA agrees that those sections should say "apply infrequent regeneration adjustment factors as included in your application for certification" to avoid any confusion that new adjustment factors should be generated or confirmed. EPA has updated this section for the final rule.

PACCAR provided comments on §1036.246(d)(1)(i) (redesignated 40 CFR 1036.246(b)(1)(i)) and EPA agrees that it should clearly state that it requires testing two aftertreatment systems and that the testing can be done on a single engine, as the engine is just being used as an emission source to test the aftertreatment performance against. EPA has updated this section for the final rule.

PACCAR stated that §1036.246(c)(4) (redesignated 40 CFR 1036.246(a)(4)) should be amended to allow using engines that undergo replacement or repair. 40 CFR 1036.246(c)(4) already allows the use of an engine that has undergone repair as long as it still has its original critical emission-related components. If the engine does not have its original emission critical components, this creates a disconnect between the age of the engine emission control components and the aftertreatment. EPA disagrees that we should allow testing of engines that have been replaced, because this will result in a mismatch of the age of any engine critical emission-related components and the aftertreatment system.

10.4 Certification decisions

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

On page 17548 of the NPRM, U.S. EPA requests comments regarding the use of standardized aging cycles. [EPA-HQ-OAR-2019-0055-1186-A2, p.29]

CARB staff strongly recommends the adoption of the standardized aging cycles based on certification test cycles, known as cycle-1 and cycle-2 as described in the Omnibus durability demonstration program. [EPA-HQ-OAR-2019-0055-1186-A2, p.29]

Historically, manufacturers have proposed and used customized duty cycles for aging the EAS. CARB staff believes that such an approach is problematic for two reasons:

- First, using customized aging cycles means that there is no level playing-field between different manufacturers when it comes to durability demonstration. It is not recommended to have different aging duty cycles for durability demonstration, as currently implemented.
- Second, certified HDEs are used in a wide variety of vehicle applications, so derivation of a customized cycle intended to represent the majority of vehicle operations is misleading. Typically, an engine family is certified to be used in both vocational and tractor applications with a wide range of power ratings. It is unclear how each manufacturer can design a single customized aging cycle which could represent such a large spectrum of vehicle applications. [EPA-HQ-OAR-2019-0055-1186-A2, p.29]

Omnibus cycle-1 and cycle-2 include the standard engine and chassis certification test cycles and have been derived by examining the operations of HD vehicles in a holistic fashion. They represent stop-and-go city operations, highway operations and also include large segments of idling, so CARB staff firmly believes that these cycles are appropriate for demonstrating durability and establish a level playing-field for manufacturers. [EPA-HQ-OAR-2019-0055-1186-A2, p.29]

Organization: *Eaton Vehicle Group (Eaton)*

Agency Request / Topic: In addition, we are interested in stakeholder input on our proposed approaches for the durability demonstration that manufacturers are required to include their application for certification (see Section IV.F for details). [EPA-HQ-OAR-2019-0055-1252-A1, p.9]

Eaton Comment Strategy / Materials: Same comments as above for the Eaton key components designed for the life of the truck. Our designs will be durability tested as part of our normal design practices and durability represents the value we bring to the system integrators. [EPA-HQ-OAR-2019-0055-1252-A1, p.9]

Organization: *Motor & Equipment Manufacturers Association (MEMA)*

EPA also requested stakeholder input on their proposed approaches for the durability demonstration that manufacturers are required to include in their application for certification. Highly Accelerated Life Testing (HALT) does not provide good data on the frequency of a failure's occurrence. Longer warranty terms may lead to higher costs and EPA data may significantly underestimate the cost impacts due to limited or extrapolated data. We do not have enough data to support this and even if a vehicle passed durability testing, certain in-use duty cycles may have additional failures. OEMs may have the required information, but typically not part and system suppliers. We are not the best group to comment on this, but we are concerned. [EPA-HQ-OAR-2019-0055-1322-A1, pp. 7 - 8]

Organization: *PACCAR, Inc (PACCAR)*

Finally, EPA should revise proposed 1036.246(h)(3). As proposed in the NPRM, this provisions essentially provides that a new deterioration factor must be established after one additional model year if verification testing indicates that the emissions do not meet legal requirements. However, OEMs must have sufficient time to perform a new DF procedure, and, for proposed MY 2027 regulations, this may take nine to twelve months. To illustrate this challenge, if an OEM were to determine in December 2028 that its MY 2027 DF verification test failed, it would likely take until early 2030 for the OEM to complete a new DF program, notwithstanding that the certification application for the MY 2030 program will need to be submitted by mid-2029. Because OEMs would reasonably need more than one model year to comply with the proposed requirements in (h)(3), PACCAR respectfully requests that EPA allow OEMs to carry-over the existing DF for two additional model years, rather than the proposed 'one additional model year.' [EPA-HQ-OAR-2019-0055-1346-A1, p.49]

EPA Summary and Response

Summary:

The above comments address different aspects of the certification-related provisions of the proposed durability testing requirements. With regard to the duty cycles themselves, CARB recommends EPA adopt Omnibus cycle-1 and cycle-2 aging cycles. CARB states that allowing customized duty cycles will not provide a level playing field between manufacturers. CARB also raises concerns about how customized aging cycles would be designed, since they state that it would be difficult to represent the range of vehicle applications in a single customized aging cycle. PACCAR recommends that a manufacturer be allowed to carry over the duty cycle for two years instead of just one year after a verification test shows emissions exceeds the standards. PACCAR stated that two-year carry-over is necessary because one year is not enough time to perform a new DF program. MEMA commented that it is concerned about the ability of Highly Accelerated Life Testing (HALT) to provide good data on failure frequency. MEMA stated that, when combined with longer warranty terms, the result may be higher cost impacts. Finally, Eaton commented that their designs will be durability tested.

Response:

See preamble Section IV.F for our responses to comments on the proposed options for determining the DF and our rationale for the final provisions for determining DF.
As EPA explained in section IV.F.2 of the preamble, the final DF requirements only require verification upon request from EPA. Regarding PACCAR's comment, see further discussion in Section IV.F.2 of the preamble regarding how EPA will address verification results where the DF is shown to be deficient. We note that we generally disagree that a manufacturer should be allowed to carry over the duty cycle for two years after a verification test shows emissions exceed the standards.

While Eaton's comment on durability testing indicated that their products will be durable, they did not comment specifically on the DF test procedure that engine manufacturers would use for certification. MEMA's comment suggested that Highly Accelerated Life Testing (HALT) does not represent in-use failure rates and costs of longer warranty periods. We clarify that we are finalizing an option for accelerated aging to assure manufacturers can certify their engines to our longer final *useful life* periods. Our DF test procedures are intended to demonstrate durability at time of certification, which manufacturers and suppliers would build into their products in their pre-certification development programs. We agree that the accelerated aging procedure does not represent the cost of longer warranty periods. We estimate the final warranty periods as impacting indirect costs for manufacturers and operating costs for owners. See section IV.B.1 of the preamble to this rule for more discussion of our final warranty periods and chapter 7 of the RIA for a discussion of the updated costs.

11 Off-cycle standards and Test Procedures

11.1 Windowing, Binning, and Test Procedures (Preamble III.C.2.i)

11.1.1 Three-bin MAW Structure (windowing and binning)

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

CARB staff agrees with U.S. EPA's characterization of the current not-to-exceed (NTE) method used in the HD in-use testing (HDIUT) program as deficient. CARB staff identified similar shortcomings of the current program in the staff report for the Low NOx Omnibus rulemaking.126 CARB staff analysis showed a significant percentage of tests without any valid NTE operation, and also indicated that valid events represent an extremely small fraction of total test time operation. A majority of engine operations and NOx emissions were also outside of the valid NTE region with the current method. In fact, even with a modified NTE analysis where data exclusion and limits were relaxed to include more valid operation, the method remained deficient. CARB staff agrees with the conclusion that European heavy duty-engine products performing better in-use than their U.S. counterparts is related to the moving average window method used in the Euro VI regulations. [EPA-HQ-OAR-2019-0055-1186-A2, p.57]

126 https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2020/hdomnibuslownox/isor.pdf

U.S. EPA requested comments to elements of the off-cycle standards and test procedures. CARB staff supports the replacement of the NTE procedures with off-cycle test procedures for 2027 and later model year engines. The off-cycle test procedures are mostly in alignment with the adopted 3B-MAW procedures in CARB's Omnibus program.127 CARB staff believes the proposed off-cycle test procedures would overcome the shortcomings of the current NTE method by providing more valid test data and by including low load operation. The CO2 binned approach would allow emission evaluation with similar certification cycle emission rates. [EPA-HQ-OAR-2019-0055-1186-A2, p.57]

127 https://ww2.arb.ca.gov/rulemaking/2020/hdomnibuslownox

CARB staff supports the windows size, binning structure based on the normalized average CO2 rate, 3 bins (idle, low load, and high/medium load), minimum window requirements of 2,400 for each bin, equation for emissions rate proposed in 40 CFR 1036.515, limited data exclusion criteria, and additional requirements for PEMS to limit environmental conditions influence on the accuracy and precision of PEMS. [This comment is also in 11.6.3] [EPA-HQ-OAR-2019-0055-1186-A2, p.57]

CARB staff has concerns with the language in 1036.420(c) stating: 'You may idle the engine anytime during the shift day to increase the number of windows in the idle bin. Increasing idle operation in the middle of a shift day would contradict trying to capture real world operation by the fleet operators. CARB staff suggests adding language adopted in the Omnibus regulation to allow for idle operation if necessary at the end of the shift day for a minimum of forty minutes and a maximum of 60 minutes if less than 2,400 windows are in the idle bin. [EPA-HQ-OAR-2019-0055-1186-A2, p.64]

U.S. EPA requested comment on elements of the proposed off-cycle testing section elements. CARB staff supports the changes to 1036.515 test procedures for off-cycle testing with a few concerns. The procedures for field testing provide important guidelines such as the emissions measurement procedures, engine start temperature requirements, test interval or window size, handling of key-off in the middle of testing, window creation procedures, excluded operation, valid operation, calculation of window emissions, binning of windows, calculating bin emission values needed for manufacturer-run in-use testing and administrator run in-use testing programs. [EPA-HQ-OAR-2019-0055-1186-A2, p.65]

CARB staff supports the inclusion of a cold start requirements, exclusion criteria, 300 second windowing definition, the creation of windows, valid operation, calculation of window emissions, binning of windows, and calculating bin emissions. [EPA-HQ-OAR-2019-0055-1186-A2, p.65]

135 Low NOx Demonstration Program – Stage 3. Pg. 131. https://www.arb.ca.gov/lists/com-attach/79-hdomnibus2020-Uj4AaQB2Aj8FbAhw.pdf

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

As part of Option 1, EPA proposes several changes to its laboratory-based duty cycle tests, in-use (sometimes called ‘off-cycle’) testing procedures, and verification testing. The current regulations must be revised to better regulate low load emissions and protect public health in communities overburdened by vehicle pollution. Commenters generally support making changes to close gaps in the current duty cycle and in-use testing procedures to reduce the amount of dangerous air pollution breathed by individuals living, working, and attending school in near-road communities. But Commenters oppose EPA’s proposed ‘flexibilities’ that would weaken verification testing. [Comment also included in Chapter 3.4] [EPA-HQ-OAR-2019-0055-1302-A1, p.54]

EPA also proposes changes to its in-use testing program to consider data across a wider range of operational conditions. Each 300-second moving average window of data would be sorted into one of three bins—idle, low load, and medium/high load, each of which would be subject to a different numerical emissions standard—based on the average power of the engine over that 300-second period, with measurement of the CO_2 emissions rate being used as a surrogate for engine power. 87 Fed. Reg. at 17,473. A complete in-use test would require at least 2,400 moving average windows per bin. 87 Fed. Reg. at 17,473. EPA still proposes to exclude certain data from consideration, specifically data that captures engine operation during times when: the engine is off, ambient temperatures are below a certain level, the engine is operating at more than 5,500 feet above sea level, an auxiliary emission control device is active, or periodic PEMS zero and span drift checks or calibrations are occurring. 87 Fed. Reg. at 17,474. [EPA-HQ-OAR-2019-0055-1302-A1, p.56]

Commenters support adopting in-use testing procedures that capture the higher emissions that occur when engines are at low load or idling so that the test captures the full range of real-world emissions. [EPA-HQ-OAR-2019-0055-1302-A1, p.56]

Organization: *Cummins Inc. (Cummins)*

EPA proposes to implement a new protocol, the Three-Bin Moving Average Window (3B-MAW) approach, for assessing in-use emissions against new off-cycle standards and to revise existing manufacturer-run in-use testing (IUT) provisions for MY 2027 and later CI engines. See §1036.104(a)(4), §1036 Subpart E, and §1036.515. 3B-MAW would replace the current Not-to-Exceed (NTE)-based approach for assessing emissions during in-use tests with Portable Emissions Measurement Systems (PEMS). [EPA-HQ-OAR-2019-0055-1325-A1, p. 12]

Cummins is supportive of efforts to improve real-world emissions and to expand coverage of in-use testing over a broader range of operation. However, many concerns and questions remain related to the accuracy and suitability of the 3B-MAW approach and associated in-use testing revisions. Cummins has been involved in an EMA study conducted by West Virginia University (WVU) to collect extensive in use NO_x data from 100 vehicles. WVU and EMA analyzed the collected data using numerous variations of 3B-MAW approaches. The comprehensive analyses highlight many concerns such as the need to balance collecting enough data vs. test time, issues caused by return-to-service events after idle or restarts unacceptably influencing Bin 3 emissions, and issues with use of the CO_2-normalized metric. [EPA-HQ-OAR-2019-0055-1325-A1, pp. 12 - 13]

EMA's comments and associated reports describe those issues and many others in detail, pointing to the need for continued work by both EPA and industry to evaluate improvements that should be implemented for the final rule, not just in the test and analysis protocols, but also with respect to compliance measures and stringency. As stated before, Option 1 is not feasible, including the proposed Option 1 off-cycle standards. For Option 2, a higher interim in-use conformity factor should be considered while manufacturers gain experience with new technologies and new 3B-MAW protocol. Also mentioned before, if EPA does finalize increases to today's useful life periods, it will need to account for additional uncertainty and variability in the deterioration of engines operated in the field by prescribing additional in-use margins to the off-cycle standards. [EPA-HQ-OAR-2019-0055-1325-A1, p. 13]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

Daimler Truck endorses EMA's comments detailing a number of over-arching concerns related to the proposed 3-B MAW protocol. These concerns are detailed in the '3-BAW and In use Testing' section of the EMA comments, the highlights of which are as follows:

- The proposed NOx-binning approach will result in individual seconds of data appearing multiple times in each of the 3 bins;
- The proposed methodology will result in a sorting, in effect a 'smearing,' of the same emission data points across all of the proposed bins;
- The 3-bin approach will disproportionally weight certain emission results over others (i.e., some data points will be included up to 300 times, while other points will not); [EPA-HQ-OAR-2019-0055-1168-A1, p.44]

Daimler Truck endorses EMA's comments detailing a number of over-arching concerns related to the proposed 3-B MAW protocol. These concerns are detailed in the '3-BAW and In use Testing' section of the EMA comments, the highlights of which are as follows:

- There is no discernible correlation among the data points that end up being binned together —the data variability and spread do not yield any consistent trends or significant differences among the 3 bins of data;
- The proposed binning method can result in randomly-binned data; [EPA-HQ-OAR-2019-0055-1168-A1, p.44]

Organization: *Manufacturers of Emission Controls Association (MECA)*

The proposed rule sunsets the NTE program and replaces it with a moving-average-windows (MAW) type of emissions analysis based on similar methodology to the in-service conformity (ISC) requirements used in Europe. ICCT has shown that in Europe, where a MAW analysis has been required during ISC testing since 2013, the same type of aftertreatment systems used on Euro VI compliant trucks achieve much lower emissions than U.S. 2010 technology trucks at the low speeds often experienced in the real world [23]. CARB's in-use testing has confirmed the limitations of the current compliance program based on the Not to Exceed (NTE) requirements for trucks that currently certify to the FTP standard of 0.2 g/bhp-hr. Over real duty-cycles and the many exclusions allowed by the NTE program the trucks must meet a 0.3 g/bhp-hr on the road. CARB has shown and the ICCT has confirmed (in the report above) that only about 5% of the tests meet the conditions of a valid NTE. [EPA-HQ-OAR-2019-0055-1320-A1, p.19]

> [23] F. Posada, H. Badshah and F. Rodriguez, 'In-use NOx emissions and compliance evaluation for modern heavy-duty vehicles in Europe and the United States,' 2020.

When the NTE was first adopted as part of the U.S. compliance program, there were no aftertreatment systems on trucks and the program was effective at ensuring that engine calibrations were not being modified at highway speeds. However, after 2010 when SCR systems were installed, CARB and EPA began to observe that because the SCR catalyst operates at reduced efficiency below exhaust temperatures of about 200â„ƒ, in-use trucks are emitting multiple times higher NOx emissions than the FTP certification limit, resulting in high NOx emissions in urban areas, communities and ports where truck speed is low. The proposed three bin approach with 30 second windows is a better methodology than a power-based window approach or CO2 equivalent based approach since it more evenly weights different engine operating modes, including extended idle and low power periods of operation. [EPA-HQ-OAR-2019-0055-1320-A1, pp.19-20]

Organization: *Moving Forward Network (MFN)*

EPA has appropriately proposed to revamp its in-use compliance program entirely. The "not-to-exceed" (NTE) test protocol have proven woefully inadequate for modern diesel engines—recent data shows that just 9.7 percent engine operation time is covered under the current NTE protocol.119 While the small number of NTE events averaged 0.18 g NOx/bhp-hr,120 total route emissions were more than double that, at 0.42 g/bhp-hr. Importantly, these ignored events are not random—low-speed operation is almost entirely excluded, even though it represents roughly half of the operational time for many vehicles, particularly in urban settings. Worse, it is exactly these low-speed operating conditions where modern diesel emissions controls are most likely to fail. [EPA-HQ-OAR-2019-0055-1277-A1, p. 28]

White paper from the International Council on Clean Transportation, November 26, 2019. Online at https://theicct.org/publication/current-state-of-nox-emissions-from-in-use-heavy-duty-diesel-vehicles-in-the-united-states/
>
> 120. Where possible, mg/bhp-hr are used, to directly compare with EPA's proposed standards. However, in research papers, such accuracy is not always reported. In response to EPA's request for comment on the use of SI standard units (87 FR 17472), we generally support the use of mg/bhp-hr and think it more accurately reflects the precision and accuracy of the standards and tools to enforce those standards.

We support EPA's proposal to move forward with the moving-average-window (MAW) approach, which will better capture all real-world behavior. [EPA-HQ-OAR-2019-0055-1277-A1, p. 29]

Organization: *Navistar, Inc. (Navistar)*

In particular, we support: A workable HDIUT protocol and standard that is robust and supports the lower NOx level [EPA-HQ-OAR-2019-0055-1318-A1, p. 3]

Often the entry and exit conditions dictate which bin an otherwise identical point may be in the represented bin. That is, the identical point can fall into either bin. This becomes more problematic due to the wide range of duty cycles represented in heavy-duty. We believe it would be more representative to combine bins 2 and 3 into a single bin to account for the variability seen in the heavy-duty context. In this, we further point EPA to the analysis in the EMA comments. [EPA-HQ-OAR-2019-0055-1318-A1, pp. 4 - 5]

Organization: *PACCAR, Inc (PACCAR)*

In particular, PACCAR agrees with the following aspects of EMA's comments: EPA has not sufficiently validated the new proposed in-use low-NOx standards and '3B-MAW' testing protocols, particularly those associated with 'Bin 3.' [EPA-HQ-OAR-2019-0055-1346-A1, p.2]

The proposed revisions to the HDIUT program include two major features that change the regulatory landscape. First, the Proposed Rule imposes a new Three Bin Moving Average Windowing ('3B-MAW') protocol that attempts to assign periods of engine operation to bins that represent three different ranges of load. Second, the Proposed Rule sets forth a new paradigm in which off-cycle standards are set at levels [EPA-HQ-OAR-2019-0055-1346-A1, pp.19-20]

PACCAR opposes the new 3B-MAW requirements because this protocol is ineffective. The 3B-MAW method seeks to distribute overlapping five minute periods of operation among three bins based on load. The idea is to classify similar operation together so that different standards can be applied to each bin to ensure the maximum appropriate level of control is applied to each type of operation. This protocol does not work well in practice due to varied operating conditions and lack of load correlation. PACCAR incorporates by reference the rationale set forth in EMA's comments, and submits the additional information below. See EMA Comments at 45. [EPA-HQ-OAR-2019-0055-1346-A1, p.20]

One practical issue with the 3B-MAW requirement is that MAW windows capture a variety of operating conditions that are not in character with the bin description to which they are assigned due to transient load changes that can occur within a window. Furthermore, emissions commonly do not correlate to load, especially for new technology engines that will employ better SCR heating strategies. These SCR heating strategies will result in operation at higher SCR temperatures, which in effect leads to very good emissions control at low loads. The test results from the SwRI demonstration engine confirm as much by demonstrating little NOx difference between bins. [EPA-HQ-OAR-2019-0055-1346-A1, p.20]

In the following example, a truck with a research engine is fitted with a PEMS and undergoes a cold start followed by operation on a test track in a linehaul driving mode. The entire cold start was captured in Bin 3, which elevated the Bin 3 BSNOx window result by 2.4 times after 2,400 windows relative to the rate observed under stabilized linehaul driving conditions observed between 6,000 and 12,000 seconds. Expanding the number of windows to 10,000 reduced the BSNOx in bin 3 but it was still 1.5 times the steady emissions rate. [EPA-HQ-OAR-2019-0055-1346-A1, pp.20-21]

In this example, 3B-MAW was not successful at characterizing the steady emission rate under linehaul conditions during a test designed to be exclusively linehaul driving. NOx breakthroughs can be more frequent under other driving conditions, as demonstrated in the following figure during the grocery delivery cycle. In this example, the Stage 3 engine was tested at SwRI and showed that it is even more unlikely that operating conditions imagined for Bin 3 can actually be captured in Bin 3 without also capturing data uncharacteristic of Bin 3. [EPA-HQ-OAR-2019-0055-1346-A1, pp.21-22]

Similar periods with transient emissions spikes are possible after engine braking, coasting, idling, and post regeneration which we can call return-to-service ('RTS') events. RTS events can be captured in any bin and have lasting impact on the final bin results. Even a hot start begins with a period where emissions controls need to stabilize and reestablish various models such as for ammonia storage. [EPA-HQ-OAR-2019-0055-1346-A1, p.22]

A successful in-use compliance strategy will need to target the lowest possible NOx emissions level at all times to pay for unavoidable NOx breakthroughs. Test results for Bin 2 and Bin 3 may be very similar in terms of level; however, because of the different standards, Bin 2 complies with excess margin, while Bin 3 fails to demonstrate compliance with adequate margin. [EPA-HQ-OAR-2019-0055-1346-A1, p.22]

Another 3B-MAW shortcoming is that bins can be left underpopulated when a drive cycle is either heavily loaded or lightly loaded causing the assignment of the vast majority of the windows to one bin or the other. Lightly populated bins do not have enough data to characterize the typical operation for the engine in that bin. The EMA comments discuss this topic in depth and support the conclusion that 10,000 windows is the minimum number needed to have an acceptable convergence level. EMA Comments at 77. The most effective way to collect 10,000 windows and still complete testing in one shift day is to combine Bins 2 and 3. [EPA-HQ-OAR-2019-0055-1346-A1, p.23]

Second, proposed 1036.420(c) contemplates 2,400 as the minimum number of windows in each bin. However, 2,400 windows is insufficient for a stabilized test result and is also too many windows to reliably finish a test in a shift day. Because there are no practical number of windows that could support the proposed binning scheme, Bins 2 and 3 should be combined into a single bin and EPA should establish 10,000 as the minimum number of windows. [EPA-HQ-OAR-2019-0055-1346-A1, p.56]

PACCAR further encourages the EPA adopt: The 3B-MAW in-use compliance protocol should be modified as follows:

- Bins 2 and 3 should be combined
- There should be a 10,000 window minimum in the combined bin [EPA-HQ-OAR-2019-0055-1346-A1, p.31]

The 3B-MAW in-use compliance protocol should be modified as follows:

- Bins 2 and 3 should be combined
- There should be a 10,000 window minimum in the combined bin[EPA-HQ-OAR-2019-0055-1346-A1, p.60]

Organization: *Truck and Engine Manufacturers Association (EMA)*

It is important to highlight from the outset that while there are various details of EPA's rulemaking proposal (particularly with respect to Option 1) that EMA and its members fundamentally disagree with, there are multiple major points of substantial agreement. In that regard, EMA agrees with EPA that:

> (ii) The current NTE-based in-use testing protocols to assess the in-use emissions performance from HDOH engines and vehicles should be revised to cover all in-use operations and should, at least in part, incorporate a moving average window ("MAW")-based "binning" scheme for assessing those in-use emissions; [EPA-HQ-OAR-2019-0055-1203-A1, p. 5]

In order to ensure the adoption of fully achievable and cost-effective HDOH low-NOx regulations, and notwithstanding our broader agreement, the Agency should revise the proposed standards in the following manner: The proposed 3B-MAW in-use compliance protocol should be revised to ensure that a sufficient quantity of data is acquired for a robust compliance assessment without the need for multiple test-days. Later in these comments, EMA proposes an alternative to achieve this goal, while also guarding against additional potential infeasibility issues, especially those associated with the proposed medium/high load "Bin-3" standards. [EPA-HQ-OAR-2019-0055-1203-A1, p. 7]

EMA has additional over-arching concerns related to the 3B-MAW protocol, including as follows: (i) the proposed NOx-binning approach will result in individual seconds of data appearing multiple times in each of the 3 bins; (ii) the proposed methodology will result in a sorting, in effect a "smearing," of the same emission data points across all of the proposed bins; (iii) the 3-bin approach will disproportionally weight certain emission results over others (i.e., some data points will be included up to 300 times, while other points will not); (iv) the proposal for "concatenating" data across key-off/key-on cycles will result in an unrepresentative binning of dissimilar data, which will yield wide spreads in the binned results; (v) there is no discernable correlation among the data points that end up being binned together – the data variability and spread do not yield any consistent trends or significant differences among the 3 bins of data; (vi) the proposed binning method can result in randomly-binned data; and (vii) despite EMA's best efforts to find a workable NOx-binning protocol, it is clear that using normalized CO2-rate parameters alone is not sufficient to yield a protocol for binning reasonably correlated in-use NOx data in three separate bins with three separate standards. [EPA-HQ-OAR-2019-0055-1203-A1, p. 49]

EMA was an initial proponent of moving to a new in-use-based emissions assessment paradigm, where each vehicle would become, in effect, its own mobile emissions lab. Such a new in-use paradigm, ultimately coupled with telematics, could allow for significant regulatory streamlining and greater assurance of real-world emissions control. EMA remains highly motivated to find a new in-use emissions-assessment protocol that can provide the framework for this new in-use regulatory paradigm. [EPA-HQ-OAR-2019-0055-1203-A1, p. 49]

In the interim, EMA and its members have devoted significant amounts of time and expense to exploring the strengths and weaknesses of MAW-based emissions binning tools and other potential in-use protocols. To that end, as noted above, EMA contracted with WVU to equip 100 HDOH vehicles with measurement technology capable of tracking emissions in real-world heavy-duty applications over extended periods. EMA has used that vast accumulation of fleet emissions data to evaluate numerous iterations of "binning" and other in-use emissions assessment approaches. Those iterations have included windowing techniques of various durations, exponentially-weighted moving windows, non-overlapping windows (or "tip-to-tail" windows), 1Hz-based approaches without windowed averages, and methods to better differentiate windowed emissions data on the basis of the engine's short-term operational history. EMA's research has included compliance evaluations not only on the basis of binning techniques, but also on the basis of the vehicle's shift-day "sum-over-sum" emissions. EMA's work also has included evaluation of adaptations to the Euro VI-based in-use testing protocol. Idle-bin boundaries based on vehicle and engine speed were studied, as were higher power level boundaries based on afterteatement thermal state to promote thermal management strategies, as well as brake-specific, CO2-specific, time-specific, and distance-specific metrics. [EPA-HQ-OAR-2019-0055-1203-A1, p. 49]

Unfortunately, notwithstanding EMA's and WVU's extensive efforts (which are detailed in WVU's Report, see Exhibit "A"), EMA has not been able to identify a suitably robust bin-based in-use emissions-data assessment protocol. While EMA is continuing its investigations, one thing has become abundantly clear: EPA's proposed 3B-MAW protocol – which the Agency has copied from CARB – is not a well-reasoned regulatory framework for assessing in-use emissions compliance. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 49 - 50]

Consistent with the spirit and purpose of those comments, EMA has specific recommendations for how to revise the B-MAW approach so that it can serve as the basis for a new more-comprehensive in-use testing program. EPA requested comments on whether the 3BMAW process should be modified, and more specifically whether combining bins might be a valid improvement over the protocol as proposed. As detailed later in these comments, EMA is recommending a modified two-bin approach. [EPA-HQ-OAR-2019-0055-1203-A1, p. 50]

The proposed 3B-MAW in-use testing method and standards do not sufficiently distinguish between modes of in-use engine operation, and so cannot adequately separate in-use emissions into separate bins of idle, low-load, and medium-to-high load operations. As demonstrated by the extensive analyses performed by WVU, the proposed 3B-MAW method can spread (or "smear") and comingle in-use emissions data across and among all of the three proposed bins. As WVU's work reveals, the binned data under the 3B-MAW method have no adequate correlation, trend lines, consistency, repeatability or reliability of results to support the establishment of separate regulatory standards for the three proposed bins. Moreover, EPA has not supported the proposed NOx-binning method with any actual in-use testing data derived from compliant test articles or a low-NOx HDOH prototype vehicle in-use. It is significant that the Agency originally committed to undertake real-world in-use testing of the proposed 3B-MAW protocol utilizing a Stage 3 prototype engine installed in a vehicle, but then reneged on that commitment, claiming that the Agency has run out of time. [EPA-HQ-OAR-2019-0055-1203-A1, p. 50 This comment is also in section 11.3.1]

WVU has prepared a comprehensive report of its findings and conclusions regarding the 3B-MAW in-use protocol. As noted, a copy of the WVU Report is appended hereto as Exhibit "A." The WVU report is based on emissions data acquired from WVU's testing of 100 vehicles of multiple vocations operating primarily in Southern California. The chart below shows the wide range of vehicle categories that WVU tested, and the number of tested vehicles in each category. [EPA-HQ-OAR-2019-0055-1203-A1, p. 50]

Each tested vehicle was equipped with NOx-measurement instrumentation for a period of approximately one month, accumulating 20 to 30 test-days per vehicle. The second-by-second emissions and supporting engine and vehicle data were recorded and stored, and subsequently post-processed by the WVU Center for Advanced Fuels, Engines and Emissions ("CAFEE"). Of particular relevance, WVU has post-processed the large in-use emission data set using the proposed 3B-MAW protocol, and several variations thereof. WVU's results highlight the multiple problems inherent with the proposed 3B-MAW in-use protocol. [EPA-HQ-OAR-2019-0055-1203-A1, p. 51]

As an initial matter, the three proposed MAW-based "bins" do not actually represent idle, low-load, and medium-to-high load operations. Instead, they amount to a varying amalgam of all three bins when the binning methodology is applied. Moreover, in the end, the 3B-MAW protocol, with three separate in-use standards for each "separate" bin, in effect amounts to three potentially random chances to fail the 3B-MAW-based program. [EPA-HQ-OAR-2019-0055-1203-A1, p. 51]

By moving the proposed 300-second windows forward on a second-by-second basis, each measured one-second data point is included in up to 300 windows. Those windows are then sorted into one of the three bins. That means that single one-second data points end up being sorted typically 300 times into some varying combination of the three bins. For example, when second-by-second emissions data were recorded on a vehicle tested over CARB's "Southern Route," 25% of the datapoints fell into two bins, and 7% fell into all three B-MAW bins, rendering the "data segregation" among the three bins a metaphorical mixed bag. Consequently, under the proposed approach, much of the in-use data ends up being sorted and, in effect, "smeared" across two or even all three of the proposed bins. One consequence of that smearing of results is that the binned data will have limited correlation to any emissions standard that might be applied to the "separate" bins, which undermines the rationale for applying separate regulatory standards to the "separately"-binned emissions data. [EPA-HQ-OAR-2019-0055-1203-A1, p. 51]

WVU's analysis demonstrates the degree to which the 3B-MAW approach can randomly assign data to the 3 "operational" bins. In the graph below from their report, WVU shows how often single data points fall into two or even three bins over the course of a test day, as assessed for the various vehicle categories included in WVU's 100-vehicle test program.11 The percentage ranges shown for datapoints in one or more "bins" for a given vehicle category represent the range of individual test-day outcomes for all vehicles in the category. The chart that accompanies WVU's graph shows that, in the aggregate, more than 26% of the measured datapoints end up in two bins at the end of the accumulated test-days. That level of cross-binning of data demonstrates that the 3B-MAW protocol does not effectively sort emissions data according to the targeted binned engine-operating normalized-power characteristics. [EPA-HQ-OAR-2019-0055-1203-A1, p. 51]

> 11 WVU's nomenclature often refers to the three bins this way: "Bin 1" is the idle bin, "Bin 2" is the low-load bin, and "Bin 3" is the medium/high-load bin.

Another very important consequence of the overlapping window approach is that while some measured datapoints will be included in the data set of a particular bin up to 300 times, other points will be included only once, and other data points anywhere in between. That has the effect of variably weighting individual datapoints in the dataset as a whole, and especially within a given bin. The fact that some datapoints can have up to 300 times greater influence on the averaged bin emissions – most acutely at the start of a vehicle's work day when the emissions system may not be fully warmed up – is not consistent with with a fair compliance assessment protocol. [EPA-HQ-OAR-2019-0055-1203-A1, p. 52]

WVU depicts this variable weighting phenomena in the figure below, which indicates the number of times individual data points are used in each of the 3 bins after a shift-day of line-haul vehicle operation. (To understand how to interpret the graph, consider Bin 2: approximately 40% of the datapoints are used 100 or fewer times, 85.4% are used less than 300 times, and 14.6% are used 300 times.) Again, this does not seem to be a fair way to weigh in-use emissions data. [EPA-HQ-OAR-2019-0055-1203-A1, p. 52]

EPA acknowledges the importance of variable datapoint weighting in the draft RIA. In section 2.2.3.2, EPA writes: In what we believe to be an improvement to a work-based window, we are proposing a moving average window (MAW) approach consisting of time-based windows. Instead of basing window size on an amount of work, the proposed MAW includes a window size of 300 seconds. The time-based windows are intended to equally weight each data point collected. [emphasis added] [EPA-HQ-OAR-2019-0055-1203-A1, p. 53]

Later in section 2.2.3.4 of the RIA, EPA considers data point weighting as justification for their proposal regarding concatenating data over excluded data segments. Here, EPA writes: Except for the data points as the beginning and end of the test and those around long data exclusions, this methodology equally weights emissions at each data point during the in-use testing. We believe this is appropriate, as the under-weighted data points consist of a small percentage of the HDIUT data, which contain a minimum of 10,800 1- Hz data points. [emphasis added] [EPA-HQ-OAR-2019-0055-1203-A1, p. 53]

EPA underscores the importance of equal data point weighting in both of those instances, but fails to consider arguments regarding unequal data point weighting in the instance where it matters most – in the accumulated 1Hz data within any bin where compliance judgments are made. [EPA-HQ-OAR-2019-0055-1203-A1, p. 53]

WVU has broken down the bin placement of data over an almost 4-hour segment of the CARB NTE Southern Route. The second graph in the figure below depicts the bin placement overlap (where bins overlap, and data is being distributed with unequal weighting in the bins), and the fourth graph tracks how many times individual data points are being used in each of the 3 bins.

With every transition from one bin to the next, there is a slow walk of uneven data point weighting. In this data segment of less than 4 hours, there are no less than 13 bin transitions, where a transition culminates into finally achieving equal datapoint weighting in a bin (300 times per data point). It is important to point out that these 13 transition observations are without regard to all of the "partial" transitions where the 300x equal data point weighting goal is not even reached before the transition reverses due to a change in engine load. These data clearly shows a major departure from the equal data point weighting objective. Thus, EPA's emphasis on the value of equal data point weighting falls apart under this analysis, revealing overlapping windows as one of the more serious flaws of the 3B-MAW protocol. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 53 - 54]

The additional graphs below from WVU's report represent approximately 6 hours of data from a line-haul truck (EMFAC category 1a). The upper graph depicts the number of times individual data points (any point along the X-axis) are placed into Bins 1, 2, and/or 3. Based on those data, WVU concludes that it is "obvious from [the figures] that transitioning between different bins results in un-equal weighting of an individual data point in a given bin," which could undermine the objective to regulate in-use emissions in a reasonable and representative manner. [EPA-HQ-OAR-2019-0055-1203-A1, p. 54]

The fundamental problem with this highly variable data point weighting system is that within a bin, when assessing emissions against a bin standard, some data segments (e.g, 20 seconds of data) will be given 10, 20, even 30 times more weighting in the compliance assessment for that bin than other 20 second stretches of data. While EMA has shared this concern with EPA multiple times, the Agency has not even tried to address the issue. [EPA-HQ-OAR-2019-0055-1203-A1, p. 55]

WVU also highlights (in the yellow shaded area in the figure above) a period of 55 to 60 mph sustained highway speed over a period of about 17 minutes. Illogically, the 3B-MAW protocol places the majority of this operation in the idle bin (demarked by the green line). As WVU states, "It is clearly evident from the vehicle speed trace that this type of operation is definitely not typical idle operation that should be compared to the idle emissions standard." [EPA-HQ-OAR-2019-0055-1203-A1, p. 55]

Another example of illogical data placement is presented in the data WVU has captured on a line haul vehicle below. Two segments of data are worthy of note in this test. The first is a 3.3 minute stretch of 55 to 60 mph crusing data, for which all datapoints are included in windows that are placed solely in Bin 1, the "idle" bin. Some 15 minutes later in the same test trace is a 2.3 minute data segment of curb idle operation, for which all data points are included in windows that are placed only into Bins 2 and 3, the "low power" and "medium/high power" bins. [EPA-HQ-OAR-2019-0055-1203-A1, p. 55]

In another assessment of whether the proposed 3B-MAW approach effectively segregates emissions data according to engine-operation characteristics, WVU analyzed the medium/high bin (Bin 3) windows from multiple days of testing of a single line-haul vehicle, and separated those data into three ranges of vehicle speed: urban (<31 mph), rural (>31 and ï,£ 46.6 mph), and highway (> 46.6 mph). WVU's graph below shows the variability in day-to-day emissions results from the three speed ranges within Bin 3, the supposed medium/high bin. Clearly the lower speed ranges of the urban cycle produce overall higher emissions results than the higher speed ranges, and show much greater variability from one day to the next. Thus, there are factors in play that have a more significant effect on the level and variability of in-use emissions than the normalized-power-based bin boundaries that EPA has borrowed from CARB. [EPA-HQ-OAR-2019-0055-1203-A1, p. 56]

Significantly, none of the WVU analyses concerning the problems with the proposed 3BMAW approach, with the exception of the vehicle speed breakdown in the medium/high load bin, has anything to do with specific tailpipe emissions levels or low-NOx technologies. Those results (and problems) would bear out, and the resultant concerns hold true, regardless of whether the analyses involved assessments using today's emisions control systems, enhanced emissions control technologies, or even EPA's Stage 3 RW prototype. Thus, the concerns with the 3B-MAW approach will be present no matter which low-NOx technologies are envisioned.12 [EPA-HQ-OAR-2019-0055-1203-A1, pp. 56 - 57]

12 WVU's Report, Exhibit "A" hereto, contains a more detailed explanation and demonstration of each of the multiple flaws inherent with CARB's unverified and untested 3B-MAW protocol.

Perhaps the most compelling analysis in the WVU Report is a series of figures showing the real-time percentage of operation at normalized CO2-rate data points compared to how the 3BMAW method distributes those same data into the three bins. The figures below break that information down for each of the vehicle-types that WVU tested. As depicted below, the 3B-MAW process distorts the vehicles' true operating characteristics, capturing and redistributing the data in a way that simply does not match the reality of the vehicles' actual operations on the road. The actual real-time second-by-second operation of a category 1b short-haul vehicle, for example, exhibits predominantly idle and very light load operation with a relatively flat distribution of data at low levels of frequency across the rest of the normalized CO2 rage. Compare that true 1Hz operation (in red), however, with the 300-second 3B-MAW windowing process distribution in blue, which shows the same vehicle as having a strong peak of operation at the boundary separating the low and medium/high load bins, an operating profile that clearly and markedly differs from reality. [EPA-HQ-OAR-2019-0055-1203-A1, p. 57]

Similarly, comparing real-time and 3B-MAW distributions of data for a more vocational vehicle application, such as a category 6b food/beverage delivery vehicle, results in a distortion of data that is even more apparent. [EPA-HQ-OAR-2019-0055-1203-A1, p. 57]

Another concerning aspect of the binning process that WVU has analyzed is presented in the following graphics. The basis for the analysis is represented in the two graphs below, which depict the bin placement of the first second of each valid 3B-MAW window when deployed over the FTP cycle. Each data point in the graph is the first data point of a 300 second 3B-MAW window. The horizontal dashed lines represent the bin boundaries (6% and 20%), and the y-axis position of each data point reports the average normalized CO2 level for the window that starts with that 1Hz data point. As shown, the first approximately 300 seconds of the FTP cycle is initiating windows that fall into Bin 2 (between 6 and 20% normalized CO2). Window placement then transitions into Bin 3 where the line turns blue (though the transition takes 5 minutes in total before all data points in those Bin 3 windows have normalized CO2 levels greater than 20%). The windows eventually fall back into Bin 2 over the last portion of the cycle.13 [EPA-HQ-OAR-2019-0055-1203-A1, p. 58]

> 13 The FTP cycle is 20 minutes, or 1200 seconds long. The graphic stops at 900 seconds, because it reports data on the basis of the first datapoint of each window. After 900 seconds, no new 300 second windows are completed (are valid). The last valid window is the one which has its first second of 1Hz data at 900 seconds.

The graph to the right is specific to data that falls into Bin 1 when the FTP cycle is processed through the 3B-MAW protocol. Recalling that any window can be comprised of individual data points with widely varying average normalized CO2 levels (or, practically speaking, average power levels), we can see in the graph at right, for Bin 1, the percentage of the 1Hz data points that were at <6% normalized CO2 (that is, were representative of what EPA calls Bin 1 operation). The percentage of data points in each window that were at Bin 2 and Bin 3 normalized CO2 level can be similarly reported. [EPA-HQ-OAR-2019-0055-1203-A1, p. 58]

With that explanation of the analysis technique, the next graphic indicates the compositional breakdown of three 3B-MAW windows recorded during the FTP cycle. [EPA-HQ-OAR-2019-0055-1203-A1, p. 59]

The first window selected for consideration (where the first 1Hz data point is circled in black in each of the graphs above), is a window that, by the 3B-MAW process, was placed into Bin 2 (as can be seen in the upper graph). That window is comprised of 300 data points, 80% of which are <6% normalized CO2 (and so representative of Bin 1 operation), 7% of which are between 6 and 20% normalized CO2 (representative of Bin 2 operation), and 13% of which are greater than 20% normalized CO2 (represntative of Bin 3 operation). Remarkably, this window, which was placed into Bin 2 (and judged against the Bin 2 standard), has a mere 7% of its 1 Hz data points coming from operation that EPA has determined to be “Bin 2” operation. The other two data points isolated for consideration (circled in blue and red in the graphic above) demonstrate similar gross imbalances in operational representation relative to bin placement when 3B-MAW is applied to the FTP cycle. A similar analysis of the LLC cycle evaluated by the 3B-MAW technique reveals similarly counter-intuitive outcomes (the window initiated at 3400 seconds falls into Bin 2, despite that fact that only 9% of the 1Hz data points are recorded at normalized CO2 levels within the 6% and 20% Bin 2 boundaries.) Clearly, this analysis shows that 3B-MAW is not a logical, reliable system for binning emissions, and, therefore, not a legitimate, representaitve system for setting and enforcing in-use standards. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 59 - 60]

When considering the results of the above analysis, it is important to point out that the FTP is not a “one-off” cycle rarely represented in real world operation. Indeed, the FTP has been the cornerstone of emissions demonstration cycles for more than four decades. Moreover, this imbalance in bin composition will play out in every real world duty cycle. It is also very telling that the FTP cycle, 41% of which, on a time bais, is comprised of idle operation, produces not a single idle bin window when evaluated using the 3B-MAW protocol. That simple fact alone raises serious concern about the validity of the protocol, which has not been validated by even a single minute of real-world chassis testing. [EPA-HQ-OAR-2019-0055-1203-A1, p. 60]

Based on the foregoing, WVU has concluded that the “proposed bin boundaries are misaligned with actual in-use vehicle operations.” EMA fully agrees with WVU’s assessment. Accordingly, significant revisions to EPA’s proposed 3B-MAW protocol are required. [EPA-HQ-OAR-2019-0055-1203-A1, p. 60]

If EPA maintains the 3B-MAW approach in the final rule, which EMA opposes, EMA recommends that the 20% normalized CO2 boundary between Bins 2 and 3 be increased to 25%. EMA bases this recommendation on the emissions characteristics of the 100-vehicle testing conducted by WVU in Southern California. Examining the sum-over-sum emissions characteristics of the fleet is informative. The graph below shows the average sum-over-sum emissions of the fleet as a function of the average normalized-CO2 level for each recorded shift day. The red line indicates the average NOx emissions of all vehicle test-days where the average normalized CO2 level was less than the x-axis value. The blue line indicates the average NOx emissions of all vehicle test-days where the average normalized CO2 level was more than the x axis value. An inflection point in the low average normalized CO2 level data (the red line) is clearly evident at 25% normalized CO2. Accordingly, EMA recommends that the 3B-MAW boundary between the low-power bin and the medium/high power bin be established at 25% normalized CO2 in lieu of the proposed 20% level. [EPA-HQ-OAR-2019-0055-1203-A1, p. 60]

All of the analyses above raise the fundamental question of why EPA is proposing to process data in overlapping windowed segments. Both EPA and CARB have argued that capturing data in windowed segments permits data to be evaluated, at least in part, on the basis of a segment of operating “history.” That argument appears to be reasonable, because the efficiency of the most effective NOx reduction tool, SCR, is dependent upon the catalyst temperature, and therefore the “recent history” of the exhaust temperature profile. The problem with that argument, however, is that the 3B-MAW protocol actually makes no distinction whatsoever regarding the characteristics of engine-operating history within any given window. A window’s bin placement, and therefore its linkage to any relevant in-use standard, is based solely on the average normalized CO2 level (effectively the average power) of that window, without any consideration of the “history” that purportedly compelled EPA to “window” emissions data in the first place. Two windows can end up having mirror-image time traces (engine speed, torque, etc.), one with rising SCR temperature, the other with falling SCR temperature, which can certainly yield very different emissions results. An example of this phenomenon, represented with actual data recorded by WVU, is captured here: [EPA-HQ-OAR-2019-0055-1203-A1, p. 61]

Notwithstanding the clearly different emission results, the 3B-MAW protocol would bin those two differing windows identically, and hold them to the same in-use emissions standards. Consequently, while EPA’s rationale is that engine operating history is important, the 3B-MAW protocol does nothing to account for the particular details of that operating history, and therefore completely undermines the “operating history” rationale for the Agency’s proposal. [EPA-HQ-OAR-2019-0055-1203-A1, p. 62]

The fact that windowing data serves no useful purpose could perhaps be tolerated if the new in-use protocol also did not raise the other concerns at issue, including imbalanced data point and data segment weighting, and illogical bin placement that is disconnected from any vehicle's actual duty-cycle. Yet despite EMA's repeated demonstrations of the need for revisions to the 3B-MAW protocol – again, a protocol that EPA simply copied from CARB – EPA has simply refused to engage on those important issues. In particular, EPA staff have rejected out-of-hand EMA's proposal to adopt a much more straightforward, more representative view of emissions impacts through a "sum-over-sum" approach to assessing a day's emissions performance. Therefore, later in these comments, EMA will make specific recommendations for revising and improving upon the proposed 3B-MAW protocols. [EPA-HQ-OAR-2019-0055-1203-A1, p. 62]

Other problems with the proposed binning proposal become evident when the new Low Load Cycle (LLC) certification test is processed according to the 3B-MAW in-use protocol. A significant number of windows, especially those including long periods of idle followed by a high load "return to service" period of operation, end-up in the medium/high-load bin. Consequently, the portions of the LLC most vulnerable to NOx "breakthroughs" would have to comply with the in-use standard linked to the more stringent FTP/RMC standards, not the higher LLC standard. More specifically, those LLC windows which would fall into the medium/high load bin would have to meet an Option 1 standard of 0.030 g/bhp-hr, established on the basis of the FTP/RMC standard multiplied by the conformity factor (1.5). If a vehicle is in a generally low-load application, a long idle period followed by a high-load return to power could be the only, or otherwise dominant, operating condition where data is placed into Bin 3, putting the in-use test at high risk for a non-compliance determination. The high (and potentially unfair) risk of noncompliance would stem from the fact that the limited amount of Bin 3 data would be the exact type of data that most likely would not meet the Bin 3 standard. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 62 - 63]

EPA envisions that the 3B-MAW protocol will assess emissions performance for all or almost all of a HD engine's operation over its entire shift-day. Indeed, that expectation is one of EPA's primary objectives in implementing a new in-use protocol, given the relatively limited coverage of in-use operations provided by the current NTE method. EMA agrees with that objective. The NTE protocol was often problematic for manufacturers as well, because if there were only a handful of NTE events recorded over a vehicle's in-use test day, just one NOx breakthrough event could mean failing to meet the minimum NTE-based "pass" ratio. Despite EPA's intent, however, a similar risk exists still with the 3B-MAW protocol. A day's testing may very well capture 99% of the vehicle's operating time, yet, depending on the duty cycle, any single "bin" still may have a minimal amount of in-use emissions data stored for assessment. Consequently, EMA supports including a minimum data requirement for each bin, expressed as a number of windows, or total operating time, or a similar metric. [EPA-HQ-OAR-2019-0055-1203-A1, p. 68]

EPA's proposal is to require a minimum of 2,400 windows in each of the 3 bins. When conducting an in-use test, if a day's testing does not accumulate at least 2,400 windows in each bin, the manufacturer must test for as many additional days as necessary to accumulate at least 2,400 windows in each bin. As stated above, EPA supports including a minimum window count requirement because it is important that the HDIUT requirements not create a situation where an engine's emissions compliance is judged on the basis of a small sample of data. However, EMA is concerned about the specific proposal for minimum window counts. [EPA-HQ-OAR-2019-0055-1203-A1, p. 68]

As an initial matter, we are concerned that 2,400 windows, as proposed, could be insufficient to make a robust determination of compliance. EMA understands that this figure, which could represent as little as 40 minutes of data (though in most cases it will include more "real-time" data) is based upon the duration of typical test cell certification cycles. However, test cell certification cycles are not a good reference for this purpose, because there is much more randomness to the duty cycles, ambient conditions, engine operating conditions and other factors that can influence emissions during an actual in-use test compared to the strictly controlled cycle and conditions of a certification test in an emissions laboratory. Data convergence to a reasonably representative level has to occur during the test-day. For this reason, we believe that much longer time periods (i.e., much longer than 40 minutes) are necessary for a fair and reasonable assessment in-use. EPA should demonstrate with representative data how many windows are sufficient to reasonably represent a vehicle's emissions performance in any bin during an in-use test. [EPA-HQ-OAR-2019-0055-1203-A1, p. 68]

To analyze the practical consequences of the proposed 2,400 window threshold, we can turn again to real-world data as recorded by WVU on the 100-vehicle fleet in Southern California. Presented in the table below are the percentage of test-days where <2,400 windows were recorded for the day. The table includes the view for the entire fleet, and for two of the worst-case categories for bin window-count. [EPA-HQ-OAR-2019-0055-1203-A1, p. 68]

It is clear from this data that manufacturers will very frequently encounter test-days that fail to accumulate the proposed requisite number of 2,400 windows in each bin. The data presented here from the 100 vehicle test fleet indicates a higher percentage of vehicles requiring more than one test day than the data EPA presents in Figure 2-24 of the RIA. That data is based on 168 shift days of testing, from which it is estimated that about 8% of test days would fail to meet the 2,400 window minimum in the Idle Bin, about 3% in the Low-load Bin, and less than 2% in the Medium/high load Bin. [EPA-HQ-OAR-2019-0055-1203-A1, p. 69]

WVU's analysis presented in the table above, however, is based on a much more robust and statistically significant 2077 days of testing, and therefore provides a more reliable projection of the probability of the need for additional test days. WVU's analysis also includes assessments of particular vehicle types. To the extent that EPA may select an engine family that is dedicated to light load applications, such as food and beverage or drayage, we can plainly see the very high probability of multiple test-day requirements. Based on more than 400 test-days' experience, drayage applications would require a second day of testing about 34% of the time. Food and beverage distribution would require a second day of testing roughly 70% of the time, based on more than 300 days' worth of testing. That in-use testing burden is not practical or sustainable. [EPA-HQ-OAR-2019-0055-1203-A1, p. 69]

Examination of the likelihood of the idle bin not accumulating 2,400 windows in a test day is especially concerning. EMA therefore supports EPA's proposal to permit the manufacturer to intercede "anytime during the shift day to increase the number of windows in the idle-bin." Due to the “hands-off” nature of the in-use test program, the only real option for manufacturers to make any kind of effort to idle the vehicle for the sake of accumulating windows is at the end of the shift day. EMA nonetheless considers this a reasonable approach and supports the manufacturers’ opportunity to fulfill idle bin requirements in that way. [EPA-HQ-OAR-2019-0055-1203-A1, p. 69]

Unfortunately, if a vehicle is equipped with an automated 5-minute shutdown timer, as required under various state and local regulations, it will not idle for the required time of the proposed amendment without shutting down. The same would be true if the fleet from which vehicle is being tested has programmed the vehicle for automated shutdown after a period of time. The Agency should allow the manufacturer to override the automated shutdown feature where possible, or to “blip” the throttle periodically as needed to reset the automated shutdown timer. [EPA-HQ-OAR-2019-0055-1203-A1, p. 69]

While the option to accumulate additional windows in the idle bin by idling the engine for a period of time is a workable solution to meet the idle bin minimum window count requirements for most vehicles, there are no convenient options to address the minimum window count requirements of Bins 2 and 3 – requirements that will, according to WVU’s analysis, all too frequently require additional test-days. EMA recognizes that there is a tension between having enough data to make a responsible judgment about bin compliance on a test article, while also needing to limit the data requirements to avoid an excessive number of test-days to fulfill the minimum data needs. In the next section, EMA will present additional WVU analyses that demonstrate the need for window count requirements much greater than 2,400 windows to ensure that an accurate and robust assessment is made based on data that has reasonably converged on the average emissions performance of the test article in each bin. The greatly increased number of additional test-days that would be required to accumulate that elevated minimum window count requirement will also be assessed. Additionally, EMA will propose a modification to the 3BMAW process that is responsive to EPA’s request for comments regarding the possibility of combining 3B-MAW bins, and that should largely overcome both the data convergence issue and the multiple test-days issue that undermine the feasibility of the current 3B-MAW proposal. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 69 - 70]

As discussed above, EPA has proposed a minimum window-count requirement for each bin to ensure that sufficient data has been acquired on a test vehicle to accurately judge its emissions control performance in-use. EMA recognizes the importance of that goal, as it is the only fair way to conduct an in-use compliance assessment. We have expressed concern earlier in these comments, however, that EPA’s proposal for establishing a minimum window count of 2,400 lacks a sufficient technical basis. While not discussed in the preamble or the RIA, it is understood from earlier discussions with EPA staff that 2,400 windows was selected as a minimum window count requirement for each bin because the equivalent duration of time represented by 2,400 windows, 40 minutes (actually 45 minutes considering the 5-minute window length), is the time required to complete the RMC steady-state emissions dyno test. [EPA-HQ-OAR-2019-0055-1203-A1, p. 70]

EMA requested that WVU conduct a deeper investigation of data convergence tendencies during in-use testing under 3B-MAW requirements using the 1Hz data recorded from the more than

2200 days of testing of the 100-vehicle Southern California fleet. The results of that analysis are presented in the graphics that follow (the complete summary analysis is included in Exhibit "H"). [EPA-HQ-OAR-2019-0055-1203-A1, p. 70]

By way of explanation, consider the graphs below, which report bin emissions results over one day of emissions testing of a line-haul vehicle. Each graph tracks the bin's sum-over-sum emissions results as they develop, window by window, from the very first window to the very last window acquired in the test day. For each bin, the red line is reporting individual window results as they come in (and is thereby highly variable). The blue line is reporting the bin's cumulative emissions results from all accumulated windows up to any window count point (on the horizontal axis). For example, the first window in Bin 1 had a NOx level of about 14 g/hr. At the time the 2000th window was captured, that 2000th window had a NOx level of approximately 2 g/hr, whereas the cumulative Bin 1 results by that time (representing essentially the average emissions from all 2000 windows per the 3B-MAW process) calculates to just over 14 g/hr. By the end of the test day, some 3,600 to 3,700 windows had accumulated in Bin 1, with the day's Bin 1 results at approximately 19 g/hr. It is interesting to observe how the more extreme instantaneous results "pull" the average up or down. The Bin 2 and Bin 3 results are presented in a similar manner, but using the appropriate metric of g/bhp-hr as required by the 3B-MAW process. By this analysis technique, one can see how individual window results vary widely depending on operating speeds and loads and other varying conditions throughout the day, but, with the accumulation of sufficient windows, the data "settles in" to the reported average day's emissions. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 70 - 71]

If we focus on the "blue line" cumulative bin results, and graph multiple days from a single test vehicle in the same plot (again, for each bin), we can see below how the data convergence trends develop with each test day. The horizontal dashed line represents the average NOx emissions from all of the test days combined. [EPA-HQ-OAR-2019-0055-1203-A1, p. 71]

To support the data-convergence assessment desired from this analysis, it is helpful to normalize individual-day data traces relative to the average emissions results from all test days. This allows us to see the convergence trends more clearly, reducing the effects that the day-to-day variation of bin emissions results can have on clouding the picture of when sufficient convergence is achieved. This is especially helpful when reporting the results from multiple test days with multiple vehicles, and so helps to avoid the disproportionate impacts from the unique emissions characteristics of individual trucks. The results from the normalized data highlight the convergence we are trying to identify, as depicted below: [EPA-HQ-OAR-2019-0055-1203-A1, p. 71]

Also shown in this set of graphs above are the 90th and 10th percentile results (the red lines) from the multiple vehicle, multiple test-day results for these line-haul vehicles. As should be expected, these 90th and 10th percentile levels are very high or very low (respectively) during the earliest portions of each test day, until the windows accumulate, and the data begins converging toward each vehicle's representative emissions. [EPA-HQ-OAR-2019-0055-1203-A1, p. 72]

The most important thing to observe in these graphs is that by the 2,400th accumulated window in each bin, the data (it is best to consider the 90th and 10th percentile trends) appears to have not yet adequately converged to a "settled" level of emissions. This is especially evident in Bin 3, where sufficient convergence does not occur until perhaps 15,000 windows. [EPA-HQ-OAR-2019-0055-1203-A1, p. 72]

These analyses point to the need for significantly more than 2,400 windows in a test day to accurately and fairly assess a vehicle's "nominal" emissions results in each of the proposed 3BMAW bins. The complication that finding presents, however, is a potential need for multiple test days to accumulate the requisite number of windows. For this reason, WVU pulled the test-days' correlation into this data convergence analysis. The process for estimating test-day requirements for various assumed window count requirements was again based on analysis of the 20 to 30 test days conducted on each of the 100 vehicles tested in Southern California. By capturing the number of windows accumulated in each bin from each test day, WVU strung together multiple combinations of test days to generate essentially random effects of combined test day window counts. The technique is explained here: [EPA-HQ-OAR-2019-0055-1203-A1, p. 72]

Probabilities to test multiple days were developed for each vehicle category (line-haul, short-haul, drayage, and so on). Some of the vehicle categories' results are presented in the following pages, along with tables that report the probability of having to test one, two, three or even more days depending upon various minimum window count assumptions. The tables also report the benefits of including the end-of-day idle option to accumulate windows in Bin 1 if necessary (the assumption is that Bin 1 will never compel a second test day on its own). To illustrate, by way of example, a line haul vehicle will have an 81.5% chance of requiring more than 1 day of testing if a minimum window count of 10,000 windows per bin were applied, a 36.3% chance of requiring more than 2 days of testing, and a 15.8% chance of requiring more than 3 test-days, even while utilizing the end-of-day idle test option. [EPA-HQ-OAR-2019-0055-1203-A1, p. 73]

For the Short-haul category: In this case, WVU is also showing the benefits of using vehicles in applications where the engine's activity included a minimum of 3 hours of non-idle operation. [EPA-HQ-OAR-2019-0055-1203-A1, p. 74]

For the entire fleet (all categories combined): In this case, only the 90th and 10th percentiles are plotted by category for clarity (see the table near the introduction of this section to understand the category references in the legend). [EPA-HQ-OAR-2019-0055-1203-A1, p. 76]

In each of the vehicle-category examples presented above, it is clear that the 2,400 minimum window count requirement that EPA has proposed is not adequate to ensure a fair and accurate assessment of a vehicles' emissions performance. It is also clear from the test-day requirement tables that increasing the minimum window-count requirements to more appropriate levels, perhaps 10,000 to 15,000 windows, to ensure a reasonable probability of data convergence, will very frequently lead to two, three, and occasionally even four days of testing as a matter of regular practice. Obviously, that is an untenable situation, as it will present undue burden for manufacturers, and undermine customers' willingness to support the HDIUT program. [EPA-HQ-OAR-2019-0055-1203-A1, p. 77]

There is a question regarding the relevance of the results and conclusions of the foregoing analysis because it is based on test results from engines compliant to US10 emissions standards, rather than engines designed and calibrated to the protocols and the range of emissions standards that EPA is proposing in this rulemaking. In response, EMA first points out that the analyses that relate number of required test-days to minimum window count provisions are completely independent of the emissions levels in question. The consequences are strictly related to operational activity, which is not expected to be altered by the proposed regulations. [EPA-HQ-OAR-2019-0055-1203-A1, p. 77]

Regarding the data convergence tendencies, it is correct that the data that served as the basis for these analyses were recorded on US10 vehicles. However, the relevant data variability will increase, not decrease, relative to the proposed low-NOx emissions standards. That additional variability can be attributed to several of the issues raised in these comments, including (1) the inability to control tailpipe emissions with greater precision than today, without any significant improvements in sensor accuracy or actuator precision, (2) the inaccuracies of PEMS equipment relative to the anticipated standards, (3) other sources of production variability expected to lead to similar absolute levels of tailpipe uncertainty, yet with lower absolute tailpipe emissions levels, and (4) the impacts of system degradation, including SCR efficiency loss, on a control system that depends even more heavily on high catalyst conversion efficiencies than today's US10 systems. Accordingly, it is unlikely that data convergence will occur over fewer windows with future technologies. [EPA-HQ-OAR-2019-0055-1203-A1, p. 77]

If EPA staff believes that this is an invalid assessment, they should produce the data necessary to demonstrate that 2,400 windows are adequate to make an accurate and fair assessment of any vehicle's emissions in any bin. Unfortunately, the Agency's testing of "future technology" is limited to test cell demonstrations, with at most 3 protype test articles, primarily run over dyno based certification cycles, with only a handful of road cycle simulations, also run on an engine dyno. Without creating the robust data to make a better case than EMA has made on these important issues, EPA should use the best available data. The best available data is the 100 vehicle SoCal study conducted by WVU, which is the basis for EMA's analysis. [EPA-HQ-OAR-2019-0055-1203-A1, p. 78]

In the preamble to the NPRM, EPA requests comments on ways to improve the 3B-MAW in-use protocol, including, specifically, combining certain of the bins. The bin combination that EPA discusses briefly in the NPRM is combining Bin 1 and Bin 2. EMA does not find that type of combination to be practical or justified. First, the emissions characteristics of Bins 1 and 2 are very different and less consistent, especially when compared to the greater similarities in the Bin 2 and Bin 3 results. More specifically, the SwRI 800,000-mile results show average brake-specific Bin 1 emissions as calculated by the 3B-MAW process (but in g/bhp-hr to enable comparison of results) across the five road cycles tested to be 0.081 g/bhp-hr, whereas the Bin 2 average is 0.042 g/bhp-hr, and the Bin 3 average is 0.030 g/bhp-hr. The spread in those results (delta from lowest to highest) is significantly more consistent between Bins 2 and 3 than Bins 1 and 2 (Bin 1 spread = 0.113 g/bhp-hr. Bin 2 = 0.015, Bin 3 = 0.024). Secondly, there is interest to have an independent evaluation of the idle condition that EPA proposes to control with the optional low-NOx idle standards. EMA supports that EPA is not proposing a stand-alone vehicle-level idle test such as that CARB proposed in its Omnibus regulations, and instead has proposed to assess idle or near-idle emissions within the 3B-MAW protocol. For these reasons, EMA does not recommend combining Bins 1 and 2. [EPA-HQ-OAR-2019-0055-1203-A1, p. 78]

Instead, EMA and WVU have considered a modification to the proposed 3B-MAW protocol that would overcome the identified data-convergence and multiple test-days issues. One promising modification in that regard is to combine the Low Power (Bin 2) and Medium/High Power (Bin 3) windows into a single bin. [EPA-HQ-OAR-2019-0055-1203-A1, p. 78]

As noted above, EMA finds that the end-of-test idle option is a reasonable approach to meeting the 2,400 minimum window-count requirement in Bin 1. No such convenient method exists, however, to ensure adequate window-count, and thereby adequate data convergence, in Bins 2 or 3 after a day of testing. To remedy that, EMA proposes to combine Bins 2 and 3 into a single bin when determining bin emissions levels. Adding the Bin 2 and Bin 3 windows will greatly improve the chances to avoid multiple test-days when window-count requirements are set to levels that reasonably assess – and converge around – a vehicle's nominal emissions characteristics. [EPA-HQ-OAR-2019-0055-1203-A1, p. 78]

The Bin 2 and Bin 3 definitions with respect to normalized CO2 cut-points can be maintained as a means to ensure that vehicle activity is reasonably distributed across the operating spectrums represented by those bins. By combining those two bins before calculating a combined Bin 2+3 emissions level, to be evaluated for compliance against an appropriate combined Bin 2+3 emissions standard, data convergence can be achieved without the onerous need for multiple test-days to achieve reasonable convergence in the combined Bins 2 and 3. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 78 - 79]

Combining Bins 2 and 3 not only resolves the data convergence and test-day requirements of 3B-MAW as proposed, it is also supported by the Stage 3 RW engine data as reported by SwRI. When this future technology configuration was tested over the five road cycles discussed earlier, the NOx emissions levels of Bins 2 and 3 were largely the same. The enhanced thermal management routines and LO-SCR improvements to control Bin 2 emissions result in Bin 2 NOx levels on par with those in Bin 3, as seen from the Stage 3 RW results (at 435,000 miles equivalent) below.16 [EPA-HQ-OAR-2019-0055-1203-A1, p. 79]

> 16 As mentioned earlier, these results do not consistently comply with the 2031 NOx standards EPA has proposed.

As mentioned, the Agency's proposed Bin 2 and Bin 3 definitions could still play an important role to ensure that manufacturers are demonstrating emissions compliance over a broad range of operational modes. For example, EPA could require that among the total windows accumulated in the combined Bin 2+3, at least some minimum percentage of those windows would need to be Bin 2 windows, and a similar minimum percentage would need to be Bin 3 windows. Such a fleet-level operational activity requirement in the in-use test program would ensure that manufacturers' compliance demonstrations include emissions generated from multiple types of operations consistent with EPA's 3B-MAW definitions. [EPA-HQ-OAR-2019-0055-1203-A1, p. 80]

Consistent with the foregoing discussion, EMA proposes the following adjustments to the 3B-MAW protocol as proposed: Minimum data requirements: Minimum 3 hours of non-idle operation; Minimum 3 hours of non-idle operation should also be an acceptable vehicle screening criteria.; Minimum engine coolant temperature of 20°C. Idle bin (Bin 1) minimum data requirement should be 2,400 windows as proposed: End of test-day idling option should be adopted. Bin 2 + Bin 3 minimum window count requirement: 10,000 windows. Test additional days if not met [EPA-HQ-OAR-2019-0055-1203-A1, p. 80]

Consistent with the foregoing discussion, EMA proposes the following adjustments to the 3B-MAW protocol as proposed: Emissions calculations: Bin 1: As proposed by EPA. Bin 2 + Bin 3: Calculate emissions from all combined Bin 2 and Bin 3 windows as if a single bin. [EPA-HQ-OAR-2019-0055-1203-A1, p. 80]

In the proposal outlined above, the 3 hour non-idle operation requirement is consistent with acquiring adequate data to make a fair and accurate assessment of a vehicle's compliance. With the recommended requirements on fleet-level minimum Bin 2 and Bin 3 activity, manufacturers can modify their vehicle recruitment path as they progress in the test program to meet these targets (with EPA approval as necessary). [EPA-HQ-OAR-2019-0055-1203-A1, p. 81]

Regarding the minimum Bin 2+3 window-count requirement for any test-day, EMA is proposing 10,000 windows. We believe this is the appropriate window-count requirement that balances data-convergence concerns and risks to test multiple days. There is considerable uncertainty with respect to the in-use emissions performance that should be anticipated from the types of emissions control packages that EPA has investigated as the basis for this rulemaking. Considering the infinite number of road cycles that will be encountered in-use, the barely evaluated impacts of NOx breakthroughs (especially those involving cold-start emissions, or resulting from return-to-service events that can be numerous under some untested duty cycles), the range of ambient conditions, the known SCR-degrading impacts of "any commercially available" fuels, the untested durability of cylinder deactivation technology, and all of the other factors that EMA has outlined regarding compliance margin requirements, the need to ensure robust data convergence in this matter is paramount. [EPA-HQ-OAR-2019-0055-1203-A1, p. 81]

In setting the standard for the combined Bin 2+3, EPA must take all of this uncertainty into account, as well as the simple fact that EPA has so far demonstrated that the Stage 3RW package is incapable of meeting the proposed standards, both dyno certificaton standards and in-use standards, despite its having been operated solely in the carefully-controlled laboratory setting. In that regard, EPA cannot simply establish emissions standards on the basis of "wishful thinking." Accordingly, EMA proposes that the Bin 2+3 emissions standard be set at the average of Option 2-like LLC and FTP/RMC standards, adjusted upward by the appropriate in-use conformity factor, which should be 2.0 for at least seven model years before dropping down to 1.5. [Also included in section 11.3.1 EPA-HQ-OAR-2019-0055-1203-A1, p. 81]

SwRI also highlighted what WVU's analyses have revealed: the MAW-based method does not yield any clear trends in emissions behavior, and can disproportionally weight brief spikes in

NOx emissions (i.e., NOx “breakthrough events”). SwRI’s specific observations on those issues is discussed below. [EPA-HQ-OAR-2019-0055-1203-A1, p. 83]

First, SwRI observed that the MAW-based approach “indicates no clear trend [in emissions] other than a high frequency of very low numbers, but the rest of the distribution is scattered somewhat randomly between 0.05 and 0.35 g/bhp-hr.” (SwRI Report, CARB ISOR Reference 191, p.77.) (Emphasis added.) SwRI also noted that the MAW-based approach “provides little information about where emissions are coming from in terms of engine operating modes.” (SwRI Report, CARB ISOR Reference 191, p. 79.) SwRI depicted that overall variability in the MAW-based emissions data as follows: [EPA-HQ-OAR-2019-0055-1203-A1, p. 83]

Second, SwRI, like WVU noted, that the MAW-based approach tends to overweight “return to service events after a long low-load period,” which “could result in an overemphasis of those relatively brief spikes in a Low NOx environment,” with “a large number of windows being driven by a small number of breakthroughs.” (SwRI Report, CARB ISOR Reference 191, pp. 66, 69 and 74.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 83]

EPA Summary and Response

Summary:

There is broad agreement among commenters that the previous in-use not-to-exceed (NTE) testing methodology was insufficient and improvements in the methodology are appropriate. CARB and MFN comment that the NTE method used in the HDIUT program is deficient. Likewise, Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club support HDUIT procedures that capture more of the full range of in-use emissions. Cummins supports a HDIUT testing that includes a broader range of operation, and Navistar supports a workable HDIUT protocol that supports a lower NO_x level. Additionally, EMA comments that the current NTE-based testing process should be revised to incorporate a moving average window (MAW)-based “binning” scheme.

CARB comments that they support a three-bin MAW structure with 300-second windows and 2400 minimum windows per bin. CARB also support the cold start requirements and exclusion criteria in the proposal. Likewise, MFN supports the adoption of the proposed MAW approach. MECA comments that the three-bin MAW approach is better than the current NTE method.

EMA and Daimler comment that the windowing approach proposed by EPA will result in individual seconds of data appearing in multiple bins, effectively “smearing” the data across bins and disproportionately weighting some data points within bins. EMA and Daimler also state that, within a bin, some individual 1 Hz data points are weighted disproportionately, and in particular that brief spikes in NO_x emissions (breakthrough events) can be disproportionately weighted. EMA and Daimler further comment that this process results in uncorrelated data being placed in the same bin. In support of their comment, EMA cites a WVU study that shows more than 26% of the measured datapoints end up in multiple bins. EMA additionally cites examples of data points being included in bins that do not appropriately reflect the 1 Hz operation.

PACCAR comments that they oppose the 3B-MAW requirements, stating that the process will assign a variety of operating conditions to a specific bin, some of which will be inappropriately assigned.

EMA comments that accumulating 2400 windows in each bin for a wide array of vehicle types may be difficult. EMA presents a study by WVU showing that in some application a second shift day would be required for many tests, and state that the additional test burden is not sustainable.

EMA further comments that accumulating 2400 windows in the idle bin in a shift day can also be difficult, and that they support allowing manufacturers to intercede "anytime during the shift day to increase the number of windows in the idle-bin." They also state that the only real option for adding windows is at the end of the shift day.

In addition, EMA states that some vehicles are equipped with an automated 5-minute shutdown timer, required under various state and local regulations, which will turn off the engine after five minutes of idle. They recommend that manufacturers be allowed to override the automated shutdown feature where possible, or to "blip" the throttle periodically as needed to reset the automated shutdown timer.

CARB comments that the provision in §1036.420(c) allowing additional idle to increase the number windows in the idle bin allows additional idle "anytime during the shift day." They state that allowing the additional idle in the middle of the shift day would contradict the real-world behavior of the vehicle, and that additional idle should be restricted to the end of the shift day, for times between 40 and 60 minutes.

Additionally, EMA and PACCAR comment that 2400 windows are inadequate to adequately characterize the operation in non-idle bins. EMA and PACCAR present data, stating that at least 10,000 windows are required for the data to converge and to adequately characterize the operation in non-idle bins. Furthermore, EMA presents data they state shows that, if 10,000 windows were required in both bin 2 and bin 3 in a single shift day, a high percentage of tests would require more than one shift day, leading to an unreasonable test burden. Thus, EMA and Navistar recommend combining bins 2 and 3 into a single bin, and requiring a minimum of 10,000 windows in the combined bin. EMA further states that, optionally, some minimum percentage of the windows in the combined bin could be required to be "bin 2" windows and "bin 3" windows, in order to demonstrate compliance over a range of activities.

EMA further comments that the combination of bins 2 and 3 is supported by the Stage 3 RW engine data as reported by SwRI, where the NOx emissions levels of Bins 2 and 3 were largely the same. EMA recommends that the standard for the combined bin be set at the average of Option 2-like LLC and FTP/RMC standards, adjusted upward by the appropriate in-use conformity factor.

EMA comments that if the current three-bin stricture is maintained, the dividing line between bins 2 and 3 should be moved from 20% normalized CO_2 to 25%.

<u>Response</u>:

EPA has considered comments on combining bins 2 and 3, and setting the minimum number of windows for a valid test. Discussion of these comments is contained in the preamble Section III.C.2.a. Additionally, EPA believes that there is no need to have minimum percentage of operation for bin 2 and bin 3 as the intent is that the engine operation should be representative of how that vehicle operates over the shift day.

EPA agrees with CARB that allowing additional idle in the middle of the shift day is contrary to the intent of real-world testing. EPA also notes that EMA states that the end of the shift day is the only realistic time to add idle windows. EPA's response to these comments and final regulations are described in preamble Section III.C.2.a. The final regulations specify that the ability to add idle time is restricted to the end of the shift day.

EPA's response to comments on individual seconds of data being "smeared" over multiple bins are addressed in preamble Section III.C.2.a. EPA further notes that alternative approaches suggested by commenters like using shorter windows, or even the instantaneous 1-Hz data, can result in segments of data within larger macro-operation being mis-categorized. For example, creep operation (categorized in bin 1) can result in frequent spikes that instantaneously increase CO_2 emissions above the bin 1-2 threshold. Alternatively, short decelerations during high-speed operation will have instantaneous CO_2 emissions under the bin 1-2 threshold, mis-categorizing this operation as idle. Thus, windows of any size would likely result in some data being placed in what might be considered inappropriate bins. The 300 second window length proposed provides an adequate averaging time to smooth any anomalous emission events. See Section III.C of the preamble for a description of the binning structure and how this structure addresses these comments.

EPA also acknowledges some commenters' concerns that individual 1-Hz data points can be weighted differently within the same bin. However, EPA notes that reducing the number of bins from three to two will ameliorate this concern to some extent. EPA further notes that all 1-Hz data points (save those at the beginning and end of the day, and around long exclusions) will be equally weighted across both bins.

11.1.2 Normalizing CO_2 emissions for power

<u>Comments by Organizations</u>

Organization: *California Air Resources Board (CARB)*

CARB staff supports the windows size, binning structure based on the normalized average CO2 rate, 3 bins (idle, low load, and high/medium load), minimum window requirements of 2,400 for each bin, equation for emissions rate proposed in 40 CFR 1036.515, limited data exclusion criteria, and additional requirements for PEMS to limit environmental conditions influence on the accuracy and precision of PEMS. [Also in 11.6.1] [EPA-HQ-OAR-2019-0055-1186-A2, p.57]

Organization: *Cummins Inc. (Cummins)*

The 3B-MAW approach uses the engine's FTP CO2 FCL in calculations to determine both placement of each window into one of the three bins and the brake specific emissions for a bin. However, using the FTP CO2 FCL is not always representative of engine thermal efficiency on other duty cycles such as those encountered during in-use testing. Additionally, CO2 does not always correlate well to power produced, such as when excess fuel is burned for thermal management. Using the FTP CO2 FCL will result in higher emissions calculated for more efficient duty cycles, which penalizes manufacturers with more efficient engines. Cummins shared data as CBI with EPA in May 2020 showing inaccuracies between CO2 and power. One approach to address this issue could be to reconsider the use of broadcast torque to determine work for bin placement and emissions calculations, instead of normalizing by CO2 and scaling by FCL. [EPA-HQ-OAR-2019-0055-1325-A1, p. 13]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

Daimler Truck endorses EMA's comments detailing a number of over-arching concerns related to the proposed 3-B MAW protocol. These concerns are detailed in the '3-BAW and In use Testing' section of the EMA comments, the highlights of which are as follows:

- Despite EMA's best efforts to find a workable NOx-binning protocol, it is clear that using normalized CO2-rate parameters alone is not sufficient to yield a protocol for binning reasonably correlated in-use NOx data. [EPA-HQ-OAR-2019-0055-1168-A1, p.44]

A g-NOx/g-CO2 thresholds approach could have the unforeseen effect of dis-incentivizing improvements in CO2 perfo1mance of an engine. For example, if a new technology is developed that would significantly improve fuel economy, and consequently CO2 emissions, that technology could not be implemented without similar improvements to NOx performance. A theoretical example at low load might be the following engines shown in Table 8, where Engine A and Engine B are two different engines, with similar NOx rates but Engine B has significantly improved CO2 em1ss10ns. [EPA-HQ-OAR-2019-0055-1168-A1, p.48]

Engine B in the example above objectively emits less NOx and less CO2, and is consequently better for the environment than Engine A on any metric. However, when evaluated on a g-NOx/g-CO2 threshold in-use emissions standard, as shown in the example, it would appear that Engine B ranked worse than Engine A. [EPA-HQ-OAR-2019-0055-1168-A1, p.48]

A g-NOx/g-CO2 in-use metric will have the effects of (1) penalizing the development of enhanced fuel economy, i.e. , CO2 measures that can be implemented in the future, and (2) incentivizing worse CO2 performance in certain operating conditions for better a NOx/ CO2 metric. In summary, an engine that is more fuel-efficient is penalized in terms of in-use NOx emissions thresholds compared to engines which are less fuel-efficient. EPA must consider the adverse impacts of such rules-lest they limit potential future CO2 improvements, or worse, cause manufacturers to backslide on CO2 emissions to meet their NOx obligations. [EPA-HQ-OAR-2019-0055-1168-A1, p.48]

Organization: *Truck and Engine Manufacturers Association (EMA)*

The CO2-specific metric that EPA proposes as the basis for assessing in-use emissions under the 3B-MAW protocol includes a factor in the bin emissions calculation that attempts to "correct" for engine efficiency variances. More specifically, the engine family's certified CO2 emissions performance over the FTP cycle is included in Equation 1036.515-5 (calculation of emissions for the low-load bin and medium/high-load bin) as shown below: [EPA-HQ-OAR-2019-0055-1203-A1, p .65]

Including the FTP CO2 correction factor (eCO2FTPFCL) is sensible on its face, because otherwise, reduced CO2 emissions (from a more efficient engine) accumulated in the denominator would increase measured emissions results for a given amount of criteria emissions accumulated in the bin. Multiplying that result by the certified CO2 emissions performance of that engine family would, in theory, inversely reduce the net emissions result, correcting for this issue. ("Efficient" engines having lower FTP CO2 levels generate reduced bin emissions, all other things being equal.) Unfortunately, the FTP CO2 emissions result is not necessarily an accurate assessment of the in use CO2 emissions from an engine. Indeed, it can be quite inaccurate for this purpose. [EPA-HQ-OAR-2019-0055-1203-A1, p. 65]

To demonstrate this point, we turn to additional WVU analysis of the 100 vehicle SoCal test fleet14. In the plot below, each data point represents a single vehicle's performance over approximately 20 to 30 days of testing. The graph compares actual in-use CO2 emissions (in g/bhphr, as would have been accumulated in Bin 2) to the certified FTP CO2 emissions used as the correction factor in Equation 1036.515-5. (The category breakdown is a reference to the various EMFAC categories under which each vehicle application falls). [EPA-HQ-OAR-2019-0055-1203-A1, p. 65]

> 14 WVU presentation, "eCO2 vs bsCO2 comparison for FTP/RMC-FCL;" April 21, 2022.

Examining the two circled vehicle data-points, we have an example where the Category 1a vehicle and the Category 1b vehicle have very similar certified eCO2FTPFCL levels (shown as "eCO2" on the y-axis), yet very different average in-use CO2 emissions over the 20 to 30 days each was tested (as plotted on the x-axis). So, while Equation 1036.515-5 uses the certified FTP CO2 value for each of those engines to "correct" for their inherent efficiency characteristics, the reality is that the more efficient Category 1a engine (the more environmentally favorable engine) would have to accumulate 28% less NOx in the bin (per unit work) to generate emissions results equivalent to those of the less efficient Category 1b engine. Said another way, the more efficient engine in the real-world example above would effectively be held to a 28% more stringent emissions standard. That would be true for all of the criteria emissions constituents. This is an inherently unfair consequence of the in-use emissions protocol that EPA proposes. The fact that the data plotted above was not tested with Stage 3 low-NOx technology or equivalent has absolutely no bearing on the unlevel and unfair outcome described here. One approach to address this issue could be to reconsider the use of broadcast torque to determine work for bin placement and emissions calculations, instead of normalizing by CO2 and scaling by FCL. [EPA-HQ-OAR-2019-0055-1203-A1, p. 66]

EPA Summary and Response

Summary:

CARB comments that they support the use of a binning structure based on the normalized average CO_2 rate.

EMA, Cummins, and Daimler comment that the FTP CO_2 FCL is not always representative of engine thermal efficiency, and using this value in calculations will result in penalizing more efficient engines that produce lower CO_2. In support, EMA presents data showing two different engines could have similar NO_x rates, but very different CO_2 emissions. EMA and Cummins state that one approach to address this issue would be using broadcast torque to determine work for bin placement and emissions calculations.

Response:

In response, EPA disagrees with commenters suggestion to use broadcast torque rather than normalized average CO_2 rate. The data provided by EMA appears not to account for cycle variations in the in-use data; i.e., a high or low percentage of idle from engines of the same efficiency also greatly affects the actual in-use brake-specific CO_2 mass rate. Further discussion on the use of a CO_2 specific metric is contained in Section III.C.2.i of the preamble. As detailed in Sections III.B and III.C of the preamble, we have demonstrated that the off-cycle standards can be met without increasing the CO_2 emissions from the engine over the duty cycles or the fuel mapping test procedures.

11.2 Test procedures (Preamble III.C.2.ii)

11.2.1 Exclusions and data concatenation

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

CARB staff supports the inclusion of a cold start requirements, exclusion criteria, 300 second windowing definition, the creation of windows, valid operation, calculation of window emissions, binning of windows, and calculating bin emissions. [EPA-HQ-OAR-2019-0055-1186-A2, p.65]

CARB staff has concerns with the handling of exclusion events lasting longer than 300 seconds in 1036.515(b)(3)(ii), where windows are cut off and restarted after the invalid period. Aftertreatment devices can maintain thermal management passively through the thermal inertia of the system. Temperatures can be maintained for 10 minutes (i.e., 600 seconds) after transitioning from a heated catalyst to a lower load or idle operation. Emissions control after going into idle operation for an extended period has been demonstrated on the Low Load cycle where similar operation is observed between 4,250 seconds and 5,000 seconds.135 CARB staff adopted 600 seconds as the cut off for restarting the window to account for this. CARB staff suggests inclusion of language similar to language in the Omnibus regulation that creates new windows after 600 seconds. [EPA-HQ-OAR-2019-0055-1186-A2, p.65]

135 Low NOx Demonstration Program – Stage 3. Pg. 131. https://www.arb.ca.gov/lists/com-attach/79-hdomnibus2020-Uj4AaQB2Aj8FbAhw.pdf

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

Daimler Truck endorses EMA's comments detailing a number of over-arching concerns related to the proposed 3-B MAW protocol. These concerns are detailed in the '3-BAW and In use Testing' section of the EMA comments, the highlights of which are as follows:

- The proposal for 'concatenating' data across key-off/key-on cycles will result in an unrepresentative binning of dissimilar data, which will yield wide spreads in the binned results; [EPA-HQ-OAR-2019-0055-1168-A1, p.44]

Organization: *Truck and Engine Manufacturers Association (EMA)*

The proposed provisions at 1036.515(b)(3) relate to managing window concatenation when invalid data segments are recorded. Those provisions specify that a window cannot close unless more than 300 continuous seconds of invalid data are encountered. Otherwise, the window must continue to accumulate data until 300 seconds of valid data are captured to close the window. [EPA-HQ-OAR-2019-0055-1203-A1, p. 66]

Careful management of the procedures regarding concatenation is very important, as an analysis of the WVU 100-vehicle Southern California fleet data shows. EMA supports EPA's decision to reduce the 600s continuous invalid data criteria that CARB finalized in their Omnibus regulation to 300s. When WVU examined the impact of this change on tests of EMFAC Category 6b vehicles (Heavy towing/moving),15 the improvement in maximum window length is significant, as seen here: [EPA-HQ-OAR-2019-0055-1203-A1, p. 67]

15 WVU analysis, "Summary Results – 3B-MAW – Window Size Analysis CARB vs EPA;" April 1, 2022.

It makes no sense to allow windows to be open for extended periods of time, as much as 1000s (16 minutes) or more, when any connection that may actually exist between operational characteristics and emissions rates (according to EPA's own arguments) is completely lost. The longest window duration WVU observed when using the 300s continuous invalid data criteria is 1976s (more than 30 minutes). That is far too long. EMA supports the adoption of the proposed 300s concatenation criterion, but recommends that EPA limit that maximum size of any window to 900s (three times the nominal window length). [EPA-HQ-OAR-2019-0055-1203-A1, p. 67]

EPA appropriately proposes to exclude data that includes regeneration events (§1036.515(c)(3)). EPA should also provide an exclusion for windows accumulated for a period of time after the regeneration event is complete, to allow emissions control to be restored in a way similar to that provided for in proposed §1065.680. The SAE J1939/J1979 standards may require updating to support this proposal. [EPA-HQ-OAR-2019-0055-1203-A1, p. 67]

EPA Summary and Response

Summary:
CARB comments that they support the exclusion criteria. However, CARB states that windows should be concatenated across exclusions up to 600 seconds in length, rather than 300 seconds. In support, CARB states that aftertreatment temperatures can be maintained for 600 seconds after transitioning from a heated catalyst to a lower load or idle operation.

EMA and Daimler comment that they support the 300 second continuous invalid data criterion but recommends that the maximum length of real time any window can be concatenated across be limited to 900 seconds. They state that, without this limitation, a WVU study showed some windows could be concatenated across over 30 minutes of real time, and that concatenating this wide band of data would result in grouping of dissimilar data.

Response:

EPA agrees with CARB that windows should be concatenated across exclusions up to 600 seconds in length, rather than 300 seconds. In the preamble of the proposal, we proposed concatenation across exclusions up to 600 seconds; however, the proposed regulation amendatory text inadvertently stated 300 seconds. Consistent with the intended proposed requirements, the final regulation text we are promulgating in this final action specifies that concatenation across exclusions is limited to 600 seconds or less.

EPA disagrees with EMA and Daimler that concatenating data across a wide span of real time is likely to combine dissimilar data into a single bin. We see no reason to limit the maximum real time length of any window to 900 seconds. The only scenarios that justify starting a new window is when an extended period with the engine off results in the engine cooling off. Repeated short exclusions are unlikely to cool off the engine and aftertreatment. For this reason, we do not see a reason why repeat exclusions events would make combining data into a single window invalid. EPA also disagrees that the limit on concatenating data should be 300 seconds as the engine and aftertreatment have not cooled off enough over 300 second to adversely affect emission performance. Therefore, we are finalizing 600 seconds as proposed. This is further supported by the fact that the soak period between the cold and hot test intervals of the FTP is 1200 seconds.

11.2.2 Ambient temperatures and temperature exclusions

Comments by Organizations

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

Apart from the concerns highlighted above and detailed in the EMA Proposed Rule Comments, we elaborate below on a number of major pitfalls of associated with the proposed 3B-MAW in use analysis protocol, namely issues related to: (1) in-use cold start; (2) the lack of in-use real-world test data; (3) interactions with OBD requirements; and (4) the fact that in-use g-NOx/g-CO2 metrics fail to adequately scale for emissions. [EPA-HQ-OAR-2019-0055-1168-A1, p.44]

EPA's Stage 3 technology demonstration fails to prove technological feasibility, as real world environmental boundaries are not reflected in the proposed in-use testing procedures. For cold conditions, EPA's technology demonstration work was done in the test cell for cold FTP. EPA did not perform vehicle testing in the technology demonstration and hence there has been no environmental testing beyond the test cell conditions. It is well-known that engine oil and coolant temperature limits at the start of the engine crank for a valid cold FTP are in the range of 20 to 30 degrees Celsius. The Stage 3 technology demonstrated by EPA at SWRI was never tested in conditions characterized by engine coolant/oil temperature outside of the range accepted for cold FTP testing, and no data is available for cold starts with coolant and oil temperature below 20 degrees Celsius. Some of these Stage 3 demonstrated technologies, such as cylinder deactivation and EGR cooler bypass, can be affected by engine oil and coolant temperature due to combustion instability, increased load due to increased oil viscosity and friction losses, and EGR condensation. [EPA-HQ-OAR-2019-0055-1168-A1, pp.44-45]

The proposed 3B-MAW in-use testing procedure as written in the Proposed Rule extends the engine cold start boundaries down to -7 degrees Celsius ambient temperature, which is the same boundary condition in the current in-use NTE test procedure, but the proposed 3B-MAW test procedure would remove any exclusion of data based on coolant/oil temperature. Moreover, it does not offer any weighting protocol for the data collected immediately after cold start. In a test cell, the cold FTP emission data contribution to the final composite FTP is 1/7, but there is no such reweighting of the cold emission data in the in-use test procedures. This creates a significant mismatch between what is demonstrated in a test cell on a cold FTP versus what it is feasible in more challenging real world environmental conditions. [EPA-HQ-OAR-2019-0055-1168-A1, p.45]

By way of illustration, imagine the engine block, pistons, crank shaft and all the engine hardware cold soaked at -7 degrees Celsius—and the engine is supplied with air and fuel at these same cold temperatures. These cold temperatures will necessarily affect combustion kinematics and limit the options that manufacturers can use to control their emissions. The longer ignition delays impact combustion stability and efficiency due the combustion reactions starting late in the combustion cycle, leading to HC and white smoke emissions. High EGR under these conditions further increases the ignition delay, further negatively impacting combustion. Additionally, the control setpoints and functions needed to perform effective thermal management may not always be feasible in real-world conditions during the cold start with coolant/oil temperatures below 20 degrees Celsius, down to -7 degrees Celsius. These effects combine to slow the rate at which the system can warm the aftertreatment, significantly increasing emissions in the period when the catalyst has not reached reaction temperatures. EPA is aware of these effects but has not evaluated the effectiveness of its system during even moderately cool conditions. In fact, EPA and SWRI have not tested the system outside of test cell conditions, with a minimum ambient temperature of 20 degrees Celsius. [EPA-HQ-OAR-2019-0055-1168-A1, p.45]

EPA cannot claim to have demonstrated feasibility of the proposed standards without evaluating the system in all conditions in which it will be evaluated for compliance, especially in cold ambient temperatures that directly affect the system's ability to comply. EPA must either evaluate its system performance in these conditions or concede that the proposed standards are not feasible and adjust their rulemaking accordingly. Daimler Truck provides several recommendations to remedy this issue in Section III.E of these comments (regarding in-use test procedures). [EPA-HQ-OAR-2019-0055-1168-A1, p.45]

One notable deficiency of the EPA technology demonstration program is the lack of in-use real-world data. EPA Stage 3 testing at SWRI has shown emission results of the UL NOx system on test cell cycles that could be defined as 'vehicle simulation cycles.' These vehicle simulation cycles were created using real-world data; however, playing a repeat of engine speed and torque in a test cell is not fully representative of the challenges of an in-use test, including ambient conditions, real world fuel, aftertreatment hysteresis effects, and more. [EPA-HQ-OAR-2019-0055-1168-A1, p.45]

First, these vehicle simulation cycles were run at standard test cell conditions. Combustion air temperature, coolant temperature and humidity were well-controlled, the engine was already warmed up, and no cold start data was included in the study. Moreover, no cold start representative of – 7 degrees Celsius ambient temperature was ever performed, thus leaving doubts about the feasibility of running engine modes characterized by high rates of EGR and cylinder deactivation in these conditions. [EPA-HQ-OAR-2019-0055-1168-A1, p.46]

EPA's Off-Cycle Testing requirements should exempt in-use emissions data at coolant and oil temperatures less than 20 degrees Celsius, and ensure that shift-days contain, at a maximum, the same fraction of cold start testing as a Cold/Hot FTP, to ensure comparability with On-Cycle testing. [EPA-HQ-OAR-2019-0055-1168-A1, p.64]

It should be expected that all temperature-dependent emission control systems have reduced effectiveness at lower temperatures. This is evident in the early start portions of the FTP, but is exacerbated in colder temperatures, as it takes the engine longer to warm up a cold aftertreatment. The issue is further complicated by the fact that many engine temperature management strategies, which are effective in the conditions demonstrated on the FTP, or on the relatively warm in-use simulations performed, are not useable at the cold ambient temperatures and cold engine coolant/oil temperatures that EPA proposes. Specifically, aggressive combustion functions such as multiple injections, aggressive EGR rates, reduced boost, and cylinder deactivation strategies may not be useable, or may have reduced effectiveness, in these conditions. [EPA-HQ-OAR-2019-0055-1168-A1, p.66]

EPA makes no effort to evaluate whether any proposed technology is capable of providing the required emissions reductions at ambient and engine temperatures below 20 degrees Celsius. Nonetheless, the proposed off-cycle requirements would hold engine manufacturers responsible for all emissions, including cold start emissions, in ambient conditions as low -7 degrees Celsius, with no allowance for cold coolant/oil temperatures. [EPA-HQ-OAR-2019-0055-1168-A1, p.66]

In the existing in-use test protocol, EPA currently excludes emissions from in-use testing below a moderate coolant temperature threshold (roughly 70 degrees Celsius), because the Agency rightly acknowledges some emissions control mechanisms are not effective or feasible with cold engine conditions. Daimler Truck recommends that EPA analyze the state of emissions technology and its applicability at cold coolant and oil temperatures, and how this technology might be evaluated in-use under the current proposal—such as cold start emissions control on days with ambient temperature at or below 0 degrees Celsius. Without this analysis, EPA cannot determine the extent of emissions reduction that are feasible in such conditions. [EPA-HQ-OAR-2019-0055-1168-A1, p.66]

In other words, the off-cycle emissions test (intended to validate that engines are providing the same emissions performance they were originally certified to) must not hold the engine to emission standards and testing regimes that EPA's emissions standards do not attempt to test (such as cold ambient conditions), and whose feasibility has not been demonstrated. [EPA-HQ-OAR-2019-0055-1168-A1, p.66]

Daimler Truck believes that such an analysis will show that EPA must create an exclusion for these very cold coolant/oil temperatures, below the conditions on the Cold FTP. To resolve this issue, **we recommend that EPA create targeted cold start exemptions in the area where it is expected emissions controls will not, and cannot, be fully effective.** [EPA-HQ-OAR-2019-0055-1168-A1, pp.66-67]

Specifically, EPA should exclude cold start data when the engine coolant and oil temperatures are lower than 20 degrees Celsius. Given the opportunity to warm up the engine, we expect that the same emissions controls demonstrated on the FTP could be leveraged to rapidly warm the system and reduce NOx emissions at the same level demonstrated on the FTP—even when ambient temperatures are as low as -7 degrees Celsius. [EPA-HQ-OAR-2019-0055-1168-A1, p.67]

The relative effect of such an exclusion on the overall representativeness of the off-cycle test would likely be negligible, as it would only ever come into effect on days when the engine was completely cooled down to ambient temperatures, and the ambient temperature was below 20 degrees Celsius. While these cold start conditions are expected to occur relatively frequently, their duration is expected to be very short—engines warm up quickly, and, as they do, coolant/oil temperatures would rapidly exceed this 20-degree threshold. Further, all engines are already required to have diagnostics to detect failures that prevent the engine from warming up to thermostat operating temperatures—much higher than the threshold proposed here. This would ensure that all vehicles warm up, or otherwise illuminate a malfunction indicator light (MIL) indicating their need for repair. [EPA-HQ-OAR-2019-0055-1168-A1, p.67]

In Figure 29 below, Daimler Truck provides an analysis of the EMA-WVU data referenced in Section III.B, which shows that, in this dataset, the proposed coolant/oil temperature exclusion would have no effect on most shift-days of operation. [EPA-HQ-OAR-2019-0055-1168-A1, p.67]

Even when the dataset is filtered for only shift-days when the exclusion becomes active, the vehicles warm up so quickly that less than 1% of the shift-day's data is excluded. [EPA-HQ-OAR-2019-0055-1168-A1, p.67]

While other datasets in colder ambient conditions may contain slightly more data in these conditions, Daimler Truck expects that they would number in the minutes per shift-day. [EPA-HQ-OAR-2019-0055-1168-A1, p.68]

EPA's off-cycle test procedure must provide for adequate weighting of cold engine operation, to ensure the proposed standards are achievable. [EPA-HQ-OAR-2019-0055-1168-A1, p.68]

EPA's proposed off-cycle test procedure would, for the first time, test significant cold operation. EPA already rightly recognizes, in the proposed FTP procedure, that cold engine operation must be weighted less heavily than equivalent hot operations. The Agency adjusts for this by weighting the emissions contribution from the Cold Start FTP at 1/7th, and the Hot Start FTP at 6/7th, of the total emissions evaluated in the FTP. Any engine would exceed EPA's proposed emissions standards if only its Cold FTP emissions results were compared to the standard, without being adequately weighted against hot operation. [EPA-HQ-OAR-2019-0055-1168-A1, p.68]

Since EPA's proposed test measures cold operation, and bases the proposed off-cycle emissions standards for each bin on the on-cycle emissions standards, it is critical that the applicable test procedures do not result in a higher fraction of cold operation than what is included in the underlying on-cycle tests. As explained above, the off-cycle emissions test must not hold the engine to stricter standards than the on-cycle emissions tests. Under EPA's proposal, it is possible that engine off-cycle emissions could be evaluated in conditions with significantly more cold operation than represented by the FTP. [EPA-HQ-OAR-2019-0055-1168-A1, p.68]

Daimler Truck recommends that EPA control for this by requiring a maximum amount of cold operation weighting during any evaluated shift day. We recommend that each bin in the off cycle test be evaluated for the percent of windows that resemble 'cold start' operation. If this value exceeds the percentage as measured on the FTP for the same engine, the results could be weighted to resemble the FTP. An example equation is provided below: Bin SOS NOx = [(1/Ccold) * (NOx/CO2)cold windows + (1- 1/Ccold) * (NOx/CO2)hot windows] x FTP FCL (Where Ccold represents the relative weighting of Cold operations on the FTP, as determined by a proxy such as coolant temperature or cumulative engine work.) [EPA-HQ-OAR-2019-0055-1168-A1, pp.68-69]

Organization: *Navistar, Inc. (Navistar)*

Navistar is also concerned that EPA has not adequately addressed the return-to-service events in 3B-MAW procedure. The nature of vocational pick-up and delivery, as well as other commercial truck operation, requires drivers to periodically stop and unload freight or conduct other work operations. The "dwell" period at each discrete stop may be minutes or hours in duration depending on the application. The 3B-MAW protocol should take each of these events into consideration and address them in a consistent manner. The primary concern is that aftertreatment temperature may drop to a level, which will not provide a high initial conversion efficiency when the truck returns to service. Consequently, any high load transient event would result in a momentary spike in emissions that may display the emissions control system has malfunctioned, when in fact the system is transitioning up to normal operating temperatures. We recommend that engine coolant temperatures below 70C immediately after a return-to-service event be excluded from binning. Only when coolant temperature exceeds 70C would data collection resume. We further recommend that the proposed -7C ambient test exclusion be increased to 20C to more accurately reflect real-world conditions that may contribute to ozone formation. [EPA-HQ-OAR-2019-0055-1318-A1, p. 5]

Organization: *PACCAR, Inc (PACCAR)*

Exclusions – EPA should consider a higher threshold for the proposed ambient temperature exclusion of -7 °C. For the current HDIUT program the NTE cold temperature operating exclusion is based on a formula that considers intake manifold temperature and pressure. For PACCAR trucks the exclusion becomes active at an ambient temperature between 5 and 20 °C depending on conditions. The new HDIUT program will drive considerable changes due to the -7 °C ambient temperature threshold and much lower standards. The amount of heat needed to maintain an effective SCR temperature increases exponentially as temperature decreases. This is due to exhaust temperature being proportional to intake temperature and secondly as ambient temperature decreases heat loss through the walls of the exhaust system increases. More heat is needed and less is available, so manufacturers would need to design and calibrate their heating strategies to deliver an exponentially increasing large amount of energy into the exhaust as temperature decreases to meet in-use NOx limits at very cold ambient temperatures. While technologies exist that can aid in raising exhaust temperature (i.e., CDA) those technologies will have already been leveraged so the vast majority of the marginal energy increase for exhaust heat will come from increased fuel consumption. Furthermore, the capacity to deliver the necessary energy to the exhaust at -7 °C could require hardware changes that drive significant costs. [EPA-HQ-OAR-2019-0055-1346-A1, p.30]

The commercial trucking industry in the United States annually consumes about 40 billion gallons of diesel fuel so even a 0.2% fuel consumption increase will add nearly one million tons of CO_2 to the atmosphere annually. Because roughly half of truck operation occurs in conditions that are too cool to form ground level ozone, there is a significant opportunity to mitigate climate change by considering the ambient temperature exclusion for in-use NOx emissions. [EPA-HQ-OAR-2019-0055-1346-A1, p.30]

A more targeted approach would be to keep the ambient temperature exclusion at -7 °C and add another exclusion that would be active only when catalytic aftertreatment temperatures are below 250 °C that extends to a higher ambient temperature. This which would be similar to the exclusion for catalytic aftertreatment temperatures as codified in 40 C.F.R. 86.1370(g), except this exclusion would only be allowed during cold ambient conditions. This could be thought of as a 'GHG exclusion for cold ambient,' and would ensure engines continue to meet standards under most operating conditions while not being compelled to deliver an extreme amount of energy to the exhaust when the CO_2/ozone cost benefit is disproportionately high. Emissions control systems would still be required to be functioning in the exclusion zone due to requirements for Auxiliary Emission Control Device (AECD's). The nuance is that the -7 °C ambient temperature exclusion as proposed in the NPRM drives up the design target for the maximum capacity of the heating strategy increasing cost, possibly excluding technical options, and causing more GHG emissions. PACCAR believes the proposed exclusion is narrow enough to have no meaningful impact on formation of ozone or secondary PM. [EPA-HQ-OAR-2019-0055-1346-A1, pp.30-31]

PACCAR further encourages the EPA adopt: Ambient temperature exclusion: Increase the threshold for the ambient temperature exclusion proposed at -7 °C to a higher value or add a new exclusion only active under both the following conditions: · Catalytic aftertreatment temperature below 250 °C · Ambient temperature below a more modest threshold than -7 °C. [EPA-HQ-OAR-2019-0055-1346-A1, p.31]

PACCAR respectfully submits that EPA should revised proposed 1036.515(b)(1). Specifically, EPA should increase the allowable maximum engine coolant temperature at start of testing to 40°C rather than 30°C. If EPA chooses not to exclude cold starts in this manner, and also chooses not to combine Bins 2 and 3, then all cold start activity should be excluded from Bin 3, and only the first cold start should be included to prevent cold-start operation from being improperly over weighted during the test (i.e., successive cold starts should be excluded as should engine operation with a coolant temperature below 20°C). Moreover, data should be excluded completely or excluded from Bin 3 for five minutes post regen due to ammonia storage depletion that is caused by the regen event. [EPA-HQ-OAR-2019-0055-1346-A1, pp.58-59]

Ambient temperature exclusion: Increase threshold for the ambient temperature exclusion proposed at -7 °C to a higher value. [EPA-HQ-OAR-2019-0055-1346-A1, p.60]

Organization: *Truck and Engine Manufacturers Association (EMA)*

The issue of return-to-service events unduly impacting Bin 3 NOx emissions is exacerbated by conditions where the return-to-service emissions are generated shortly after a cold start. On occasions where a vehicle is started for the first time in the day, or started after an extended key off condition on a cold day, and soon after enters into a high-load condition, those emissions could almost exclusively be placed into Bin 3. It would take a considerable amount of Bin 3 operation under fully warmed operating conditions to dilute the cold start emissions to a level compliant to the very stringent Bin 3 standard. There can be no guarantee, of course, that sufficient operating time will accumulate in Bin 3 to do so. To address this issue, EMA recommends that EPA include a process to avoid accumulating cold-start emissions in the very stringent Bin 3. Cold-start engine conditions are associated with low SCR core temperatures, which are more representative of EPA's goal to segregate Bin 2 low-load emissions. Cold-start emissions therefore should be held to the Bin 2 emissions standard. EMA recommends that all Bin 3 windows recorded when the coolant temperature is less than 70°C at any point in the window should be placed in Bin 2 instead of Bin 3. The coolant temperature threshold of 70°C is consistent with CARB's cold operation exclusion applicable to MY 2024 through 2026 engines, and is a reasonable threshold to apply in this case. [EPA-HQ-OAR-2019-0055-1203-A1, p. 63]

The cold-start emissions profile is one that requires serious consideration. If EPA were to adopt a modified version of 3B-MAW, for example, the proposal that EMA details in subsections h. and i., below, the Agency would need to consider alternative methods to accommodate the very high emissions that would result if the engine were heavily loaded shortly after restart. This is especially true for a vehicle that may be stopped for prolonged periods of at least 30 minutes, 2 to 3 times or more per day. If the aftertreatment cools to levels unsupportive of NOx conversion, the initial NOx emissions surge could be impossible to recover from over the course of the remainder of the day's operation. This problem becomes even worse under conditions approaching EPA's minus7oC proposed ambient temperature threshold. One approach to limiting the impact that cold start emissions can have on the NOx compliance assessment is to limit the effective "weighting" that cold-start emissions can have in any bin. That would involve mathematically ratioing-back the time-based or work-based content of the cold-start emissions in the bin to some maximum regulated level. That would permit capturing and using all the data, but without unduly jeopardizing the compliance assessment because the day's operation included multiple cold-starts, potentially even in cold ambient conditions. [EPA-HQ-OAR-2019-0055-1203-A1, p. 63]

In that regard, the total impact of cold-start emissions associated with EPA's Stage 3RW engine and aftertreatment have barely been evaluated during this rulemaking. The FTP compliance evaluation with the Stage 3 engine only included a cold-start from 20 to 25oC. (tellingly, that cycle generated a non-compliant result, measuring 0.022 g/bhp-hr, so it is clear that there is little room for compromised NOx control due to cold starts from even colder temperatures.) The few tested road-cycles included cold-start operation, but again, never at temperatures less than the engine dyno 20 to 25oC range. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 63 - 64]

This discussion of cold ambient operation brings us back to the fundamental question of the technical feasibility of the proposed standards. The NPRM has been drafted without any testing experience in cold ambient conditions. But, as mentioned, EPA is requiring compliance down to minus-7oC. The Stage 3 engine has demonstrated only marginal or even non-compliant results over the 3B-MAW test protocol under the favorable test cell conditions. There is absolutely no on-road experience with this technology package, leaving it without any evaluation in cold ambient conditions at minus-7oC. In addition, EPA has no plans to conduct any testing under those extreme ambient temperatures before the regulation is finalized. In the absence of any direct evidence of how EPA's stringent requirements will be impacted by cold ambient conditions, it is imperative that the Agency provide protections from non-compliance determinations under those types of conditions. Accordingly, EMA recommends that EPA include a coolant temperature exclusion threshold of 20oC. [EPA-HQ-OAR-2019-0055-1203-A1, p. 64]

Maintaining compliance to the very stringent NOx standards that EPA is proposing all the way down to minus-7°C (20°F) ambient temperatures would require aggressive thermal management strategies to maintain exhaust temperatures conducive to high SCR NOx-conversion efficiency. Aggressive thermal management strategies under those very cold conditions (minus- 7°C, or 20°F) will lead to high levels of CO2 emissions as the controls work to heat the SCR. Those high CO2-emitting strategies will be active under cold ambient conditions where ozone formation does not even occur. The Agency should seriously consider whether the minus-7°C compliance threshold is striking the right balance in the CO2/NOx tradeoff. EPA should consider increasing the ambient temperature exclusion to a level closer to where ozone formation might be expected. Such a revision in the final rule would avoid the need to deploy high GHG-emitting thermal management strategies during operations in cold ambient conditions when ozone formation does not occur. [EPA-HQ-OAR-2019-0055-1203-A1, p. 64]

Returning to engine cold-start conditions, EPA has proposed to invalidate a test is if the engine coolant temperature at the point of first engine start for the day is more than 30°C (86°F). Such a requirement is overly restrictive, especially given the ambient temperature conditions typical over much of the southern U.S. For example, consider the proposed requirement in the context of the typical in-use test scheduling process. Should a manufacturer cancel all in-use testing for the day because the engine's coolant temperature failed to drop below 30°C during the course of the evening? What judgment is the in-use test team supposed to use to feel confident enough to start the engine and not witness the flow of warmer water resting in the engine block immediately increase to temperatures >30°C as that water flows past the temperature sensor? [EPA-HQ-OAR-2019-0055-1203-A1, p. 64]

Any such outcome would render the scheduling, time, resources and inconvenience to the customer's operations for naught if the test were to be declared invalid as EPA proposes. The Agency should remove the maximum coolant temperature criteria at engine-start, or at least increase it to 40°C to reduce the chances of this kind of wasteful outcome. The additional 10°C lower threshold that EPA proposes adds very little to the representativeness of the test data in terms of assessing compliance to in-use standards. EMA is not recommending to eliminate any data in the day's testing by this recommendation. Indeed, we are only recommending a small adjustment to the parameter that would declare a test fully invalid. [EPA-HQ-OAR-2019-0055-1203-A1, p. 64]

EPA Summary and Response

Summary:

Daimler, Navistar, PACCAR, and EMA disagree with the proposed rule's exclusion of data when ambient temperatures are below -7°C from being subject to the off-cycle standards. Daimler and EMA state that an additional exemption should be incorporated, exempting in-use emissions data at coolant and oil temperatures below 20°C. In support of EMA's position, they state that the Stage 3 technology demonstrated by EPA was never tested below 20°C; they further state that some of the technology in the demonstration will be adversely affected by colder oil/coolant temperatures, making it infeasible to maintain low NO_x emissions.

Daimler further comments that the effect of an oil and coolant temperature exemption below 20°C would be negligible, as the time duration of the exclusion would be short. In support, Daimler cites a WVU analysis of an in-use data set, which they state shows that this exclusion would affect a minority of the shift days in the dataset, and for those where the exclusion would be active, less than 1% of the data are excluded. EMA further comments that aggressive thermal management strategies used at very cold temperatures where ozone formation does not occur would lead to high levels of CO_2, and thus the CO_2/NO_x tradeoff over the temperature range should be re-evaluated.

Navistar also states that the low temperature ambient threshold should be set to 20°C. Navistar further states that data with engine coolant temperature below 70°C be excluded. They state that after extended dwell periods in which engine coolant and aftertreatment temperatures drop, a return to service event may cause a momentary spike in emissions. PACCAR further states that the ambient temperature threshold should be raised, or as an alternative, a more targeted approach could be adopted, which would be to exclude operation with catalyst temperatures below 250°C.

Additionally, Daimler and EMA comment that cold engine operation should be weighted, such that each bin of the in-use test contains a percentage of windows that resemble "cold start" operation which is no higher than the percentage as measured on the FTP for the same engine. They state that cycles which place most cold start emissions in any one bin would unduly jeopardize the compliance assessment.

PACCAR and EMA comment that the allowable maximum engine coolant temperature at start of testing should be raised to 40°C rather than 30°C. EMA further states that the limitation is overly restrictive, given the typical in-use test scheduling process and ambient temperature conditions typical over much of the southern U.S., and that maintaining the 30°C threshold may lead to wasteful delays in testing.

PACCAR also comments that data should be excluded completely or excluded from Bin 3 for five minutes after regeneration due to ammonia storage depletion that is caused by the regen event.

PACCAR and EMA comment that, if Bins 2 and 3 are kept separate, then cold start data in Bin 3 should be treated separately, to prevent over-including these high emissions in the stringent Bin 3. PACCAR states that all cold start activity should be excluded from Bin 3, and EMA states that all Bin 3 windows recorded when the coolant temperature is less than 70°C at any point in the window should be placed in Bin 2 instead of Bin 3.

Response:

After further consideration, EPA agrees with the concerns of Daimler, Navistar, PACCAR, and EMA regarding exclusion of data when ambient temperatures are below -7 °C and that the temperature limit EPA proposed was too low. EPA has received and reviewed data from SwRI testing the Stage 3 system at low temperatures over the Southern NTE route and Low Load Cycles. EPA is increasing the ambient exclusion temperature and incorporating an adjustment to the numerical value of the standard for temperatures below 25 °C, as described and for the reasons explained in Section III.C.2.ii of the preamble.

EPA disagrees with Navistar's recommendation that operation with coolant temperatures below 70°C be excluded. EPA also disagrees with PACCAR's proposal that operation with catalyst temperatures below 250°C be excluded. In both cases, important initial cold start operation would be excluded from all tests, and a number of return to service events would also be excluded. These are important operational regimes, and the MAW protocol is intended to capture emissions over the entire operation of the vehicle. Moreover, these exclusions would create incentives for manufacturers to cool down the aftertreatment or oil temperatures in order to exclude return to service events, thus increasing total emissions during in-use operation.

Additionally, because the moving average window test procedure averages data collected over the shift day, the time where the coolant temperature is below 70 °C should only be a small percentage of the total time in the bin, which will only have a small impact on the binned emissions over the entire shift day.

EPA disagrees with Daimler's comment that operation with coolant and oil temperatures below 20°C should be excluded. As discussed in preamble Section III.C, the standards are feasible without excluding this operation. Regarding any increase in CO_2 emissions from controlling NO_x under this operation, we have determined that the overall potential impact on CO_2 is small since, as stated by Daimler, the time when coolant and oil temperature are below 20°C is a small percentage of the total time the engine is operated over the entire shift day.

EPA disagrees with Daimler and EMA's comments that bins should be re-weighted to ensure cold-start operation is not over-represented. The shift day and the minimum window count are sufficiently long that true cold start operation – i.e., that operation at the very beginning of the shift day – is a small portion of the total. Other operation during the day where the aftertreatment temperature decreases can be managed with appropriate aftertreatment technology.

In regard to comments on re-allocating windows between bins 2 and 3, EPA's final requirements include a two-bin structure as described in Section III.C of the preamble, which EPA expects should address commenter's concerns.

EPA has considered comments from PACCAR and EMA on the maximum allowable engine coolant temperature; see our discussion in preamble Section III.C.2.b.

11.2.3 Process for stop-start vehicles

Comments by Organizations

Organization: *Truck and Engine Manufacturers Association (EMA)*

There is also a special case to consider where a manufacturer utilizes stop-start technology to reduce criteria emissions and GHG emissions. Engine shutdown would likely occur almost immediately upon entering an idle condition. Depending on how the manufacturer has implemented the technology, there may be no opportunity to override the stop-start function. That feature, implemented for emissions reductions reasons, could make it impossible to accumulate idle bin windows in almost all vehicles where it is deployed, regardless of application. EMA therefore recommends that EPA establish a policy that stop-start engines will not be held accountable to Bin 1 standards. [EPA-HQ-OAR-2019-0055-1203-A1, p. 69]

EPA Summary and Response

Summary:

EMA also comments that manufacturers may utilize stop-start technology, in which case the engine shuts down rather than idle. EMA states that, furthermore, manufacturers may make this feature impossible to override, which would make it impossible to accumulate idle windows. EMA recommends that stop-start engines not be held accountable to bin 1 standards.

Response:

EPA agrees with EMA that some manufacturers may utilize automatic engine shutdown (AES) and stop-start technologies, and agrees that special provisions should be incorporated for these vehicles. However, EPA disagrees that those engines should be automatically exempt from Bin 1 (idle bin) standards, as Bin 1 incorporates operation where the engine would be expected to be on, even for vehicles utilizing AES and stop-start technologies. Rather, in the final rule, EPA has included requirements applicable when testing vehicles with AES and/or stop-start technology as described in Section III.C.2.ii of the preamble.

11.3 Off-cycle Standards and feasibility (Preamble III.C.2.iii and III.C.3)

11.3.1 Off-cycle criteria pollutant standards, conformity factor, and feasibility

Comments by Organizations

Organization: *Allison Transmission, Inc. (Allison)*

EPA has also proposed updates to off-cycle emission testing and off-cycle emission standards for compression-ignition engines that would apply during MYs 2027 – 2030 and MY 2031 and later.64 EPA has requested comment on the proposed standards, which are differentiated as between Option 1 and Option 2, including the level of the standards in and the specific operating range covered by each "bin" of EPA's proposed 3-bin approach (i.e., idle, low-load and medium-to high-load). EPA has additionally requested comment on whether off-cycle standards and in-use testing should also apply for SI engines.[EPA-HQ-OAR-2019-0055-1231-A1, pp.30-31]

64 87 Fed. Reg. at 17,423, proposed 40 C.F.R. §1036.104(a)(4).

Allison would first note that off-cycle expands the area under the torque curve window where NTE events could occur. Therefore, Allison agrees that revised off-cycle could measure emissions across a broader range of engine operating conditions and therefore capture additional areas of "real world" operation. This, in turn, would help ensure that the actual emission performance of vehicles in the field would be closer to EPA's promulgated emission standards. [EPA-HQ-OAR-2019-0055-1231-A1, p.31]

However, although Allison recognizes the benefits of this more comprehensive emissions measurement, we remain concerned about insufficient validation for vocational drive cycles in Southwest Research Institute's emissions system durability testing. Allison cautions EPA regarding setting aggressive stringencies for new test procedures such as Low Load Cycle and off-cycle, as seen within Option 1 or the Alternative. Instead, Allison would recommend EPA take an approach with sufficient compliance margin across these new test procedures to recognize the research and development challenges of validation across vocational drive cycles and mitigate associated risks to vocational customers regarding technology availability and productivity. [EPA-HQ-OAR-2019-0055-1231-A1, p.31]

Organization: *California Air Resources Board (CARB)*

For in-use testing, U.S. EPA is proposing Option 1 off-cycle standards125 which are 2 times the Option 1 certification standards for the first 4 years, beginning with the MY 2027, to address the initial uncertainty in how the emissions control technologies deteriorate beyond current UL on a variety of HD vehicle applications. [EPA-HQ-OAR-2019-0055-1186-A2, p.55]

125 NPRM, at page. 17474. TABLE III–17

EPA's rationale for proposing higher in-use standards for off-cycle standards fails to consider the fact that other aspects of its proposal, such as the elements that establish more rigorous durability demonstration requirements (Section IV.F), and that lengthen the emissions warranty periods (IV.B.1), will individually and collectively effectively help to reduce any perceived uncertainty regarding how emissions control technologies used in heavy HDEs deteriorate when used to power a variety of heavy-duty vehicle applications, and also overlooks the fact that data relevant to such deterioration will be available prior to 2033, because the California Omnibus regulation's primary NOx emission standards will apply to 2024 and subsequent model year engines and vehicles using almost identical in-use testing method. U.S. EPA's rationale for the flexibility provisions is accordingly inconsistent with the evidence before the agency, and does not articulate a rational connection between the facts and its proposal. State Farm, 463 U.S. at 43. [EPA-HQ-OAR-2019-0055-1186-A2, p.55]

U.S. EPA requested comments to elements of the off-cycle standards. CARB staff supports the general structure of the off-cycle standards. CARB staff prefers the Alternative proposal where the off-cycle standards are a multiplier of 1.5 times the certification standards since U.S. EPA is considering also including a 10 percent measurement accuracy margin. The proposed structure would provide assurance that in-use emissions more closely align with certification standards. CARB's Omnibus standard provides a 2.0 multiplier margin (conformity factor) to the emission standards used to determine bin emission compliance for 2027 through 2030 MY engines and a 1.5 conformity factor for 2031 and later MY engines. A table summarizing the off-cycle thresholds in the Omnibus, Option 1, Option 2 and the Alternative are provided in Table 6-1. [EPA-HQ-OAR-2019-0055-1186-A2, p.58]

Although the Omnibus structure is similar to Option 1 where the off-cycle standards are 2.0 times the engine cycle standards for 2027 to 2030 MY engines, Option 1 is less stringent than the Omnibus proposal and the Alternative when including a measurement accuracy margin. Option 2 has a much higher standard, resulting in much higher off-cycle standards that are amplified with the application of a measurement accuracy margin that is a multiple of the standard plus conformity factor imbedded within the proposed off-cycle standards. Also, CARB staff suggests defining the off-cycle standards for the idle bin, if the engine is certified to the idle standards. [EPA-HQ-OAR-2019-0055-1186-A2, p.59]

Additionally, CARB staff suggests adding and defining an 'off-cycle emissions threshold' that is the sum of the off-cycle standard and applicable margins as described in 1036.420, similar to the existing structure of the NTE threshold in 86.1912. The proposed off-cycle emissions standard does not clearly identify the maximum emissions limit of off-cycle testing because it does not include the proposed PEMS measurement allowance margin. For example, the Omnibus establishes an in-use threshold and describes the maximum allowable emissions limit that is based on the standard and a sizable margin (conformity factor). The conformity factor in the Omnibus is large enough to account for both in-use operation variability and the use of field PEMS measurements. [EPA-HQ-OAR-2019-0055-1186-A2, pp.59-60]

U.S. EPA requested feedback on the in-use testing proposal. CARB staff supports most of U.S. EPA’s proposed Option 1 changes to the in-use testing procedures and programs applicable to both the manufacturer and U.S. EPA administrator for 2027 and later model year compression ignition engines and makes recommendations to change some provisions. [EPA-HQ-OAR-2019-0055-1186-A2, p.63]

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

While Commenters prefer the more stringent numerical emissions standards of Option 1 to the unjustifiably lax standards of Option 2, we urge EPA to further strengthen the standards in certain key areas: (1) duty cycle and in-use (off-cycle) standards, (2) idle standards, and (3) the FEL cap. EPA should also reject its proposed two-step approach for Option 1, finalizing the more stringent standards in MY 2027 instead of delaying their application until MY 2031 [EPA-HQ-OAR-2019-0055-1302-A1, p.57]

Increased stringency is particularly warranted for the low-load and idle bins of the in-use standards and the LLC of the duty cycle standards. The Proposal notes that European vehicles with similar highway-speed NOx emissions as American trucks have lower low-load emissions. 87 Fed. Reg at 17,472. EPA is correct to interpret this information as suggesting ‘that manufacturers are responding to the European certification standards by designing their emission controls to perform well under low-load operations, as well as highway operations.’ Id. Manufacturers of American HDEs should likewise be able to design emissions controls that perform well both under highway and low-load conditions. A number of available technologies can increase exhaust temperature at low load and thereby increase the effectiveness of SCR-based emissions controls, including cylinder deactivation and other forms of variable valve actuation. And some engines are able to currently achieve EPA’s proposed 2031 standard with compliance margins of 50% for the low-load bin. See Comments of MFN, to be filed in Docket EPA-HQ-OAR-2019-0055 on May 16, 2022. CARB also notes that its testing data supports the feasibility of an LLC standard stricter than that included in Option 1 or the Omnibus. See Comments of CARB, to be filed in Docket EPA-HQ-OAR-2019-0055 on May 16, 2022. [EPA-HQ-OAR-2019-0055-1302-A1, p.58]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

EPA's low-NOx demonstration using the Stage 3 / RW system assumes that the conditions specified by SWRI for system performance and aging are representative of an upper limit of combined real world conditions including: o Measurement tolerances; o Production tolerances; o Catalyst aging; o Direct NOx impacts from biodiesel, as well as fuel-quality related additional catalyst degradation; and o Installation/temperature drop. [EPA-HQ-OAR-2019-0055-1168-A1, p.26]

Aftertreatment catalysts age through a variety of mechanisms, most simply binned as thermal or chemical aging. While the Diesel Aftertreatment Accelerated Aging Cycle (DAAAC) protocol developed by SWRI and applied to the EPA demonstration system makes great progress toward capturing aging impacts, the accelerated aging protocol applied in this study has not been validated by any field data with a similar system layout. A single, controlled test does not fully capture the range of variability that real world systems experience in 600-800k miles, including but not limited to: o Metal contamination due to field fuel quality; o Variation in catalyst performance due to changes in fuel properties; o Ingestion of dust or road salt through the intake air system; and o Intrusion of contaminants via the Diesel Exhaust Fluid (DEF) system due to poor quality DEF, inappropriate DEF storage or mishandling, or failure to properly replace DEF tank caps. [EPA-HQ-OAR-2019-0055-1168-A1, p.26]

The thermal and chemical aging protocol applied by SWRI does not account for the above sources of degradation and instead assumes: o Constant engine oil formulation over lifetime; o Expertly handled lab grade ULSD and DEF; and o Controlled lab environment. [EPA-HQ-OAR-2019-0055-1168-A1, p.26]

Figure 3 below shows one example of the difference in SCR performance in a controlled, OEM on-highway fleet test setting (purple) versus an uncontrolled customer system (gray). These two systems ran similar duty cycles with similar mileage accumulation (approximately 435k) and thermal aging characteristics. The OEM fleet system ran on a standard ASTMD975 B5 fuel, whereas the uncontrolled test system filled at fleet or retail stations en route. For both SCR formulations shown below, the 435k mile field return system performs similarly to or worse than the 650k mile fleet test vehicle. The delta shown below in NOx conversion efficiency observed between a controlled test and uncontrolled test is significantly more degradation than what is observed in the test cell simulated 800,000 miles aftertreatment during EPA Stage 3 and rework investigations. We expect similar deltas as shown in the Figure 3 below between a lab-aged environment and fleet-aged environment: [Comment also included in 11.5.4] [EPA-HQ-OAR-2019-0055-1168-A1, pp.26-27]

Apart from the concerns highlighted above and detailed in the EMA Proposed Rule Comments, we elaborate below on a number of major pitfalls of associated with the proposed 3B-MAW in use analysis protocol, namely issues related to: (1) in-use cold start; (2) the lack of in-use real-world test data; (3) interactions with OBD requirements; and (4) the fact that in-use g-NOx/g-CO_2 metrics fail to adequately scale for emissions. [EPA-HQ-OAR-2019-0055-1168-A1, p.44]

Secondly, running a replay of engine speed and torque at the test cell inevitably links the emission results to the unique specification of the vehicle that originally collected the data in the real world. The specific payload and road speed limit, transmission, rear axle ratio, and tire dimensions all play a role in terms of how the engine operates on a particular route. In some quite different applications (e.g., down speed fleet day cab versus construction vocational truck), the engine operating points may differ substantially, thus affecting exhaust flow rates, fuel consumption (directly linked to the CO2 denominator of the 3B MAW), and NOx emissions. Therefore, the EPA Stage 3 demonstration at SWRI cannot be considered a valid representation of in-use data (because the demonstration system was never successfully tested in a vehicle running in the real world). Furthermore, it also fails to consider the great deal of variability that is intrinsically associated with vehicle testing due to multiple vehicle configurations, varying environmental conditions, and background emissions. [EPA-HQ-OAR-2019-0055-1168-A1, p.46]

To illustrate these observations, Figure 15 shows data from a current Detroit Diesel heavy duty engine installed in a real vehicle. This data was processed and binned according to EPA's proposed 3B-MAW protocol. When tested on a dyno, these engines emit well below the FTP/RMCs 0.2 g/hp-hr NOx limit. However, when installed in a vehicle and measured according to the 3B-MAW protocol, measured emissions are not representative of test cell emissions, as shown in Figure 15 below. In contrast, Figure 16 shows a very narrow spread of distribution of 3B-MAW moving average windows on a Detroit Diesel GEN5 heavy duty engine when tested on an engine dynamometer. [EPA-HQ-OAR-2019-0055-1168-A1, p.46]

We believe this difference is due, in part, to variability induced by different routes, payload, ambient conditions, and other variability only ever encountered in the real world. EPA asserts that this mismatch between 3B-MAW performance and test cell performance of current engines is a function of the inadequacies of existing technologies, and that the technologies the Agency has demonstrated with SWRI will improve this correlation. However, EPA has never demonstrated this to be true. We believe that, while some improvements can be made at low loads and temperatures, this lack of correlation is a fundamental consequence of the 3B-MAW procedure, which EPA has not considered in its feasibility analysis. [EPA-HQ-OAR-2019-0055-1168-A1, p.46]

To summarize, EPA never tested the low-NOx technology demonstration in the vehicle, and EPA must perform such an analysis to determine whether the NOx emission standards it has proposed are feasible under real-world conditions. [EPA-HQ-OAR-2019-0055-1168-A1, p.46]

As described above in this section of Daimler Truck's comments, there are a number of reasons why the SWRI test data does not demonstrate the feasibility of EPA's proposed NOx standards. To summarize:

- The EPA demonstration system configuration for low-NOx feasibility at SWRI testing was performed on the shortest possible exhaust length and most favorable rating;
- Necessary design margins—due to field fuel quality and fuel impacts—were not considered in evaluating the feasibility of the proposed standards;
- The test cell demonstration SWRI system does not package on the vehicle;

- The EPA preliminary vehicle paper study itself shows significant compromises with reduced SCR volumes than was demonstrated in the test cell; and
- The technology demonstrated never met the Phase 2 MY 2027 GHG standards, even with the shortest exhaust length configuration. [EPA-HQ-OAR-2019-0055-1168-A1, p.49]

In addition to these issues detailed above, EPA also fails to acknowledge the increased N2O emissions (shown in Figure 17), and, most obviously, that the demonstration results for PM reflect an emission rate of 0.007 g/hp-hr during some tests (as shown in Figure 18), notwithstanding the SWRI statement that all numbers from the demonstration are ‘below the new 0.005 g/hp-hr standard even after 800k miles.’ Further, we note that PM IRAF’s were not developed for the demonstration program, thus this factor would need to be added on the top of the failed demonstration result. These results clearly show failing PM in-use test results after the DPF ash-cleaning procedure. In other words, the data shows that the engine fails to comply with EPA’s proposed PM standards and raises questions about N2O compliance feasibility. [EPA-HQ-OAR-2019-0055-1168-A1, p.49]

Additionally, even taking into account the best technology (which cannot be installed on a vehicle) and test cell conditions (which are significantly favorable when compared to the conditions of vehicle testing), EPA’s demonstration results for field replay cycles in the test cell reflect failed NOx results at 10% above the standard as shown in Figure 19. The data clearly shows that EPA’s engine cannot demonstrate compliance with their proposed in-use standards. [EPA-HQ-OAR-2019-0055-1168-A1, p.49]

The EPA Stage 3 / RW engine, as demonstrated in a test cell, has CO2 emissions that are 5.3% higher than the MY 2027 HHD tractor CO2 emission standard, and 2.3% higher than the MY 2027 vocational engine CO2 standard. The technology considered for vehicle demonstration (which is demonstrated to be infeasible due to CO2 impacts, as discussed above) also shows significantly higher CO2 impacts (i.e., a 7.2% exceedance of the MY 2027 CO2 standard for HHD tractors and an 8.2% exceedance of the MY 2027 CO2 standard for vocational engines). The final SWRI calibration in the EPA test cell demonstration of the EPA Stage 3 / RW system does not meet the MY 2021 GHG standards and has CO2 emissions slightly higher than even the baseline MY 2017 Cummins X15 production configuration (from which the EPA Stage 3 / RW system was developed). [EPA-HQ-OAR-2019-0055-1168-A1, p.49]

SWRI in fact notes (in Figure 20) that despite all of their efforts, significant challenges still remain for EPA’s demonstration system to demonstrate the feasibility of EPA’s proposed standards. However, EPA considers this data as sufficient demonstration of feasibility. EPA must consider all of these factors, rightly mentioned by SWRI here, and detailed in these comments and in the comments of the EMA, in their feasibility analysis.[EPA-HQ-OAR-2019-0055-1168-A1, p.49]

To summarize, Daimler Truck submits that EPA’s proposed standards would not be feasible—and that the Agency has failed to show otherwise—for the following key reasons:

- EPA tests the best possible configuration and rating, in a configuration that cannot be installed in a vehicle.

- EPA's demonstration program tested technology that will not be available for commercial vehicles in 2027.
- The Agency did not attempt to test its demonstration system in cold ambient conditions, or with biofuel, nor did it age the system in a manner representative of real world aging and exposure to poisoning.
- EPA did not attempt to test the system in real-world, in-use performance against their proposed in-use emissions standard.
- Even under these extremely favorable conditions in which EPA's system was demonstrated, the Agency did not demonstrate that compliance with the proposed suite of requirements is feasible: the system fails PM emissions tests, fails EPA's proposed 3B-MAW evaluations, fails existing GHG Phase 2 CO2 standards, and provides insufficient margin with regard to NOx emissions and N2O emissions. [EPA-HQ-OAR-2019-0055-1168-A1, p.52]

As noted in Section I.B of these comments, Congress in the CAA set clear limitations on EPA's ability to prescribe emission standards for new heavy duty vehicles and engines, not the least of which is the requirement that EPA's standards reflect the 'greatest degree of emission reduction achievable' through the application of technology that EPA determines will be available for the model year to which such standards apply, giving 'appropriate consideration to cost, energy, and safety factors associated with the application of such technology.'80 While EPA has some discretion to project what future advances in pollution control technology may occur to facilitate compliance with its standards, this discretion is not limitless. Indeed, courts have recognized that the Agency's technological projections are 'subject to the restraints of reasonableness' and do not 'open the door to 'crystal ball' inquiry.'81 [EPA-HQ-OAR-2019-0055-1168-A1, p.52]

80 42 U.S.C. 7521(a)(3)(A)(i).

81 See NRDC, 655 F.2d at 328 (citation omitted).

In light of the shortcomings noted above, the demonstration results that EPA relies upon in support of the Proposed Rule amount to a 'crystal ball' inquiry into whether the standards proposed would be feasible in an actual vehicle operating under real-world conditions. EPA has thus failed to give reasoned explanation for believing that its feasibility projections are reliable. EPA must re-visit and substantiate its finding with greater data, or propose a suite of requirements that have in fact been adequately demonstrated—or that are supported by reasoned explanation as to why the Agency expects them to be achievable 'in the time remaining' before they will be enforced.82 [EPA-HQ-OAR-2019-0055-1168-A1, p.52]

82 Id. at 333.

EPA has not shown feasibility of its proposed off-cycle testing standards and has set standards that are not achievable with the technology that will be available. Daimler Truck provides significant evidence of this feasibility concern in Section II.B.3 of these comments. Many of the same concerns detailed in Sections III.B and III.C of these comments regarding the infeasibility of EPA's proposed FTP and RMC emissions thresholds inform our analysis of the Agency's proposed thresholds for in-use testing, which are similarly infeasible. Specifically, Daimler

Truck has significant concern about emissions variability that EPA has not accounted for in its analysis. As with the cycle emissions standards, EMA has calculated that various sources of variability for the off-cycle standards—including long-term deterioration due to fuel poisoning, ash and soot accumulation, increased emission due to biofuel's immediate NOx increases, and more—mean that manufacturers must design for emissions margin of at least 0.036 g/hp-hr NOx.87 The result is that EPA's proposed off-cycle standards and testing do not merely validate that trucks maintain their dyno-demonstrated emissions performance, but in fact create a level of technology forcing emissions stringency that goes beyond the cycle emission standards and procedures in the proposal. [EPA-HQ-OAR-2019-0055-1168-A1, pp.64-65]

87 See EMA Proposed Rule Comments.

Most importantly, EPA has never tested its proposed candidate UL NOx system in a truck. Daimler Truck believes that the system cannot be packaged in a vehicle as is, and its vibration and drivability characteristics may be unacceptable to the end users as designed. Accordingly, EPA has not demonstrated feasibility when considering the broad range of applications, operating conditions, environmental conditions, and aging effects that real trucks experience in the field. Since the system has never been installed in a truck, it has never been tested against EPA's proposed off-cycle standards. [EPA-HQ-OAR-2019-0055-1168-A1, p.65]

EPA and SWRI have performed some evaluation of the EPA Stage 3/RW System in an attempt to demonstrate feasibility. However, their data ultimately shows that, even in the limited conditions the EPA and SWRI have tested, the system is not capable of meeting EPA's proposed emissions requirements. The most recent results from EPA's investigation are shown below: [EPA-HQ-OAR-2019-0055-1168-A1, p.65]

These results demonstrate that the system cannot meet EPA's proposed standards, even though they:

- Do not test at Full Useful Life (435,000 miles instead of 800,000 miles);
- Do not expose the system to real-world fuel poisoning effects, or to biodiesel;
- Do not account for the wider variety of customer applications and maintenance procedures
- Only test on a limited number of cycles; and
- Most importantly, do not test in cold conditions that challenge the emissions control of the system. [EPA-HQ-OAR-2019-0055-1168-A1, p.66]

As Daimler Truck explains in Section III.B of these comments, most emissions in any UL NOx system occur during the initial cold conditions, before the system has come up to operating temperature. Despite this fact, EPA makes no effort to demonstrate the emissions in conditions colder than the FTP, which starts at a temperature of 20 degrees Celsius. [EPA-HQ-OAR-2019-0055-1168-A1, p.66]

Organization: *Eaton Vehicle Group (Eaton)*

Agency Request / Topic: We are also requesting comment on several aspects of the proposed off-cycle standards for heavy-duty CI engines, including the levels of the standards in proposed Options 1 and 2 and the specific operating range covered by each bin, and whether off-cycle standards and in-use testing should also apply for SI engines [EPA-HQ-OAR-2019-0055-1252-A1, p.8]

Eaton Comment Strategy / Materials: Eaton supports off-cycle testing for both certification and in-use testing. Compared to European regulations, the off-cycle limits seem to be equivalent to conformity factors of 1.5 to 3. We would suggest a revision of that factor, given that option 1 emissions post IUL are already elevated to account for emissions controls degradation. [EPA-HQ-OAR-2019-0055-1252-A1, p.8]

Organization: *International Council on Clean Transportation (ICCT)*

The latest SwRI results from April 2022 demonstrated excellent and consistent performance with respect to the proposed off-cycle NOx standards. For bin 1, the idle bin, the Option 1 proposal is 10 gr/hr for MY2027-2030 and 7.5 g/hr after that. The SwRI off-cycle NOx results demonstrate compliance below the standards with a margin of 60%, even at 800k miles with an aged system. For bin 2, the low load operation bin, the results demonstrate a 70% compliance margin, even at 800k miles of aging. For bin 3, the middle to high load operating bin, the aged system performs well at 800k miles, achieving compliance margins between 25-50%. For bin 3 the results are better at 800k miles than at 435k miles. Thus, SwRI results indicate that even more stringent limits can be adopted for off-cycle NOx compliance, especially at idle and low load. [EPA-HQ-OAR-2019-0055-1211-A1, p. 10]

Organization: *Manufacturers of Emission Controls Association (MECA)*

MECA suggests that EPA consider tightening two categories of the Proposed Option 1 standards such that they are more stringent than those finalized in CARB's Omnibus. This recommendation is based on new, previously unavailable test results that have been released since the adoption of the Omnibus. Further testing on certification and real-world field cycles suggest that tighter standards are possible while retaining sufficient compliance margin that engine manufacturers need to account for manufacturing and field variability. We strongly encourage CARB to review this new test information and harmonize with EPA on more stringent standards. The two standards that can be tightened are the LLC standard and the idle standard. Similar to CARB's Omnibus, the idle standard should also be required for certification rather than an optional standard as currently proposed. There is significantly more data available from the SwRI demonstration program since CARB developed its Omnibus regulation. These data show that the LLC and idle standards finalized by CARB and proposed by EPA in Proposed Option 1 can be achieved with significant margin. The NOx level achieved over the LLC with systems fully aged to 800,000 equivalent miles is 0.037 g/bhp-hr, which includes the infrequent regeneration adjustment factor (IRAF) [6]. [EPA-HQ-OAR-2019-0055-1320-A1, p.5]

[6] EPA, 'Test Results from EPA Diesel Engine Demonstration,' 10 May 2022. [Online]. Available: https://www.regulations.gov/document/EPA-HQ-OAR-2019-0055-1082.

MECA recommends that EPA tighten the in-use compliance standards and moving average bin limits commensurate with a lower LLC certification standard. In the SwRI demonstration program, the 800,000 mile aged parts were also tested over several field duty cycles and results calculated with the new three bin moving average window (3B-MAW) in-use compliance methodology. The results for the low load bin (Bin 2) ranged from 0.033 to 0.048 g/bhp-hr, which provides 70% or more margin to the standard (0.15 g/bhp-hr). The results for the idle bin (Bin 1) ranged from 0.4 to 3.3 g/hr, which provides 60% or more margin to the optional standard (7.5 g/hr). Tightening the standards in line with test data and compliance margin would prevent emission backsliding over the life of the engine and ensure emissions are maintained as low as possible in underserved communities where low speed operation and idling operations are most likely to occur. [EPA-HQ-OAR-2019-0055-1320-A1, p.5]

MECA supports the proposed changes to in-use requirements that achieve low NOx emissions in the real world. However, it is feasible to tighten the in-use compliance limits for Bin 1 and Bin 2 operation. [EPA-HQ-OAR-2019-0055-1320-A1, p.19]

SwRI engineers have tested the Stage 3 aftertreatment system, that was engine-aged to an equivalent of 800,000 miles, on a dynamometer over a speed-load trace from several actual drive cycles. These driving cycles include the Southern NTE route, drayage cycle, grocery cycle and a European in-use compliance drive cycle. The Southern NTE has been used by CARB for Heavy-Duty In-Use Testing and lasts approximately three hours and includes several challenging profiles, such as coasting, motoring and high transient return to service that requires the aftertreatment to stay hot as it prepares for acceleration under load. The CDA system on the engine retained heat in the aftertreatment by shutting down valves and cylinders during these coasting events and prevented cold air from being pumped by the engine into the aftertreatment system, thus keeping the SCR hot for the next transient acceleration. Over these real-world cycles, the system achieved extremely low tailpipe NOx emission limits for each bin. The results for the mid-high load bin (Bin 3) ranged from 0.022 to 0.046 g/bhp-hr, which provides 25-50% margin to the proposed Bin 3 limit (0.06). The results for the low load bin (Bin 2) ranged from 0.033 to 0.048 g/bhp-hr, which provides 70% or more margin to the proposed Bin 2 limit (0.15 g/bhp-hr). The results for the idle bin (Bin 1) ranged from 0.4 to 3.3 g/hr, which provides 60% or more margin to the proposed Bin 1 limit (7.5 g/hr) [6]. These results confirm the tremendous efficacy of the Stage 3 system for reducing emissions across the range of real-world operating conditions, especially in areas where reductions are most needed such as in urban city centers. [EPA-HQ-OAR-2019-0055-1320-A1, p.20]

Organization: *Motor & Equipment Manufacturers Association (MEMA)*

Furthermore, EPA should consider increasing the compliance margins for in-use standards. [EPA-HQ-OAR-2019-0055-1322-A1, p. 4]

Furthermore, EPA should consider increasing the compliance margins for in-use standards to make up for the lack of real-world in-use data. [EPA-HQ-OAR-2019-0055-1322-A1, p. 5]

EPA is requesting comment on several aspects of the proposed off-cycle standards for heavy-duty CI engines, including the levels of the standards in proposed Options 1 and 2 and the specific operating range covered by each bin, and whether off-cycle standards and in-use testing should also apply for SI engines. MEMA supports new HD NOx emissions standards and additional test cycles that will drive additional NOx emissions reductions on the road and encourages best-in-class technologies. These standards should be performance-based and technology-neutral and the test-cycles should reflect real-world use of vehicles. Both the standards and test cycles should enable multiple technology paths to achieve compliance. In addition, similar standards are important between CI and SI to avoid the unintended consequences of truck buyers switching between CI and SI as a way to “game” the regulatory standards. [EPA-HQ-OAR-2019-0055-1322-A1, p. 6]

Organization: *Moving Forward Network (MFN)*

We support EPA’s proposal to move forward with the moving-average-window (MAW) approach, which will better capture all real-world behavior. However, the numerical values used in this program in 2027 are wholly inadequate, arbitrary, and undermine the efficacy of the proposed NOx program. EPA itself even notes that its own system performed well below the Option 1 standards,123 and we’ve included Tables 1 and 2 to reinforce this point. [EPA-HQ-OAR-2019-0055-1277-A1, p. 29]

122. Ibid.

123. “As can be seen see from the results in Table III-18, the EPA Stage 3 engine performed well below the proposed Options 1 and 2 NOx standards,” 87 FR 17475.

In examining Table 1, it’s important to recognize that there is an additional compliance margin for the proposed MAW approach related to assumed measurement accuracy—as proposed, this is “10 percent of the off-cycle standard for a given bin.”124 Under EPA’s own proposed protocol, its demonstration powertrain already complies with the 2031 off-cycle requirements, for all load bins, under all representative test cycles. In fact, there is a compliance margin of more than 80 percent for the idle bin at intermediate useful life, and about 50 percent for the low-load bin even under the most stressing test cycle, well beyond what is reasonable. Even under the Omnibus regulation’s intermediate useful life requirements, which are more stringent in 2027-2030 than Option 1, there is more than sufficient margin for compliance, owing to the conservative approach taken by CARB in proposing those standards nearly two years ago. [EPA-HQ-OAR-2019-0055-1277-A1, pp. 29 - 30]

124. 87 FR 17477.

Table 2 shows that these margins are even greater over the full useful life of the vehicle for the low-load and medium/high-load bins—at 800,000 miles, the low-load bin has a 70 percent compliance margin, and the medium/high-load bin a 30 percent compliance margin. Given that this is an absolute worst case scenario, with more efficient test cycles showing as much as 80- or even 90-percent margins, this suggests that EPA should be setting off-cycle compliance standards that are even more stringent than those in the Omnibus regulation. [EPA-HQ-OAR-2019-0055-1277-A1, p. 30]

Moreover, it is not just EPA's data which shows that there is overly sufficient margins of compliance— Achates Power's test data on its own heavy-duty engine further confirms that it is possible to achieve CARB's limits.125 [EPA-HQ-OAR-2019-0055-1277-A1, p. 30]

> 125. "These results suggest that OP Engine can achieve future 2027 regulations with sufficient margin to satisfy the 800k mile warranty requirement, based on a 50% discount on aftertreatment degradation factors determined for zero to 435k miles applied to 435k to 800k miles," Salvi et al. 2022.

EPA has appropriately identified three bins which are representative of current test procedures (idle test, LLC, and FTP); however, EPA should maintain no worse than a 1.5X assumption on real-world operation (compared to the standards) under the proposed bin structure. [This comment also in Chapter 3.4] [EPA-HQ-OAR-2019-0055-1277-A1, p. 30]

At worst, we urge EPA to pull forward its 2031 off-cycle numerical requirements to the 2027 model year, and EPA should consider further tightening the limits of its idle and low-load bins, in particular, based on its own data. Communities cannot afford four more years' worth of trucks that are allowed to pollute well beyond what is technically achievable. [This comment also in Chapter 3.4] [EPA-HQ-OAR-2019-0055-1277-A1, p. 30]

Organization: *Navistar, Inc. (Navistar)*

In particular, we support: Establishing "in-use" compliance-assurance protocols throughout the (emissions/full) useful life to control emissions over a broader range of real-world operating conditions, provided such protocols include adequate compliance margins; [EPA-HQ-OAR-2019-0055-1318-A1, p. 2]

Organization: *PACCAR, Inc (PACCAR)*

Statistical analysis applied to test results from a research engine has predicted a log normal distribution of in-use results depicted in the upper right corner of the figure. The CFT fleet distribution is expected to take on that shape after application of new technology that will pull the peak toward the left and, to a certain extent, move the whole distribution to the left. Some operation missed by inactive NOx sensors would increase frequency counts to right of the peak if the fleet were measured with PEMS. Much of the long tail of the distribution can be addressed through OBD. However, we can expect frequency counts to remain higher than desired to the right of the peak over a considerable range of emissions levels. This area is shown as the 'challenge area' in the figure and will involve a mix of solutions:

- **Durability Improvement –** There is no evidence to support the idea that manufacturers will be better able to improve the durability of emissions control systems more effectively when motivated by the HDIUT program than when motivated by the strong incentives of the existing OBD regulations. Efforts to improve are continuous, but the scale of future improvements should not be overestimated. Further, the durability of new systems has not been proven, for example for CDA hardware and close coupled Catalysts, so it will be difficult not to move backwards. PACCAR believes that the off-cycle standards proposed by EMA are attainable through more modest improvements in durability in line with what PACCAR's experience has shown to be realistic but with significant risk in the early years when new technologies are deployed.

- **New Technology** – Application of improved technology will move the entire distribution to the left, but with limits. For example the proposed off-cycle standards will require greatly reduced transient emissions breakthroughs that are still present in test data from the SwRI demonstration engine and will require technology beyond that which was considered for the cost basis of the NPRM to meet option 1 standards. A technical solution can be imagined for every situation but there is a limit to what is cost effective. Other sections of this document go into more detail about technological limitations.
- **OBD** – OBD can be an effective tool when applied to the far right of the distribution. Application of OBD too far to the left side, without other solutions, will result in too much MIL illumination due to false detection or the misclassification of normal deterioration as component failure. It should be left to manufacturers to set the appropriate emission thresholds for each fault where root causes of malfunctions can be effectively identified.
- **Conformity Factor (CF) –** The conformity factor accounts for the variation caused by the drive cycle and values of 2 moving to 1.5 are implied by the NPRM. This makes a major contribution to why the in use test results fall along a spectrum. The cycle dependence of ultralow NOx engines is still largely unknown and remains a risk area for manufacturers.
- **Variability Allowance (VA) –** There are many variables that can affect the performance of a Low NOx system in the real world such as Sulfur in fuel, metals in biodiesel, differences in oil consumption, a spectrum of customer applications that leads to variation in aging, and variation among sensors. Variation could become significantly magnified under ultra-low NOx standards because sources of variation that are small by today's standards might not scale down in a linear way when new technology is applied contributing to sources of variation that are more significant relative to the standards. [Comment also in chapter 11.4.1] [EPA-HQ-OAR-2019-0055-1346-A1, pp.27-29]

Organization: *Truck and Engine Manufacturers Association (EMA)*

Similarly, the Agency has not fully demonstrated the feasibility of the new proposed "in use" bin-based low-NOx testing and compliance protocols, particularly with respect to "Bin 31," and, as noted, has not conducted any actual in-use testing with any prototype vehicles equipped with Stage 3 technologies. In that regard, EPA also has not adequately addressed the in-vehicle packaging requirements of the assumed low-NOx technologies (e.g., cylinder deactivation and close-coupled multi-stream dual aftertreatment systems) in any prototype HDOH vehicle, nor has EPA assessed whether current engine control units (ECUs) and data-processing protocols can be upgraded and reconfigured to accommodate the very significant data-processing demands that are associated with EPA's "3B-MAW" proposal. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 8 - 9]

> 1. Throughout these comments, the idle bin, the low-load bin, and the medium/high-load bin are alternatively referred to as "Bin 1", Bin 2", and "Bin 3."

Another of EMA's core concerns relates to the Agency's proposed new "3B-MAW" protocols and standards for assessing in-use compliance. Those in-use standards and protocols have not been developed simply to assess compliance with the underlying certification standards. To the contrary, the proposed 3B-MAW standards are, in effect, more stringent than the base certification standards, and will necessitate, among other things, larger catalyst volumes. That amounts to a fundamental paradigm shift in the scope and purpose of in-use testing. Heretofore, it was understood and agreed that in-use testing was a tool for assessing compliance with the corresponding initial certification standards, and was not intended to increase the stringency of those standards, or to compel additional emission-control technologies or hardware. That no longer will be the case under the 3B-MAW proposal. The Agency concedes as much: The proposed Option 1 in-use standard for the medium/high load bin [Bin 3] would likely require manufacturers to increase the volume of the SCR catalyst. We [also] project that the proposed off-cycle standards could be met through additional efforts to calibrate the duty-cycle technologies to function properly over the broader range of in-use conditions. We also recognize that manufacturers could choose to include additional technology. (87 FR at p. 17475.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 10]

The paradigm shift at issue raises the stakes of the feasibility issues that the Agency has failed to adequately address. Those issues are especially pronounced with respect to the proposed Option 1 "Bin 3" standards. Indeed, out of the five in-use off-cycle drive cycles that SwRI ran using EPA's Stage 3 prototype, two of those cycles yielded results that either just met or failed to meet the Bin 3 standard, even after additional "re-calibration" efforts at SwRI. [EPA-HQ-OAR-2019-0055-1203-A1, p. 10]

The Option 1 3B-MAW standards also are unrealistic because those in-use standards are at levels that essentially are equivalent to the emissions-detection capabilities of the latest portable emissions-measurement systems ("PEMS"), and an order-of-magnitude below the malfunction detection capabilities of the latest on-board diagnostic ("OBD") sensors and systems. EPA's proposed low-NOx regulations will rely on PEMS-based assessments and OBD sensor-based requirements to assure in-use compliance. But those systems cannot do so in a sufficiently reliable and consistent manner at the Option 1 NOx levels at issue. [EPA-HQ-OAR-2019-0055-1203-A1, p. 11]

Even in an emissions laboratory, PEMS NOx-detection technologies (based on nondispersive ultraviolet ("NDUV") detection methods for NO and NO2) have measurement "drift" that can be roughly equivalent to 20% of the proposed Option 1 in-use "Bin 3" NOx standard of 0.03 g/bhp-hr, before taking any in-use operational and environmental factors into account. Those factors include imprecise exhaust and fuel-flow estimations, time-alignment issues, adverse ambient conditions and vibration, and PEMS-installation concerns. [EPA-HQ-OAR-2019-0055-1203-A1, p. 11]

In that regard, it should be noted (again) that the Stage 3 prototype has not demonstrated robust compliance with the Option 1 3B-MAW standards. To the contrary, out of the five in-use drive cycles that SwRI used to test Stage 3 prototypes on an engine dynamometer, the Stage 3 system failed or just met the requisite standards over two of those cycles. If production families were to pass only at a rate of 3 to 4 out of every 5 vehicles tested, the vast majority of families would be determined to be noncompliant to the in-use requirements, and thereby potentially liable for recall. Thus, the feasibility of the Option 1 3B-MAW standards, like the Option 1 certification standards, has not been and cannot be established. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 48 - 49]

The proposed 3B-MAW in-use testing method and standards do not sufficiently distinguish between modes of in-use engine operation, and so cannot adequately separate in-use emissions into separate bins of idle, low-load, and medium-to-high load operations. As demonstrated by the extensive analyses performed by WVU, the proposed 3B-MAW method can spread (or “smear”) and comingle in-use emissions data across and among all of the three proposed bins. As WVU’s work reveals, the binned data under the 3B-MAW method have no adequate correlation, trend lines, consistency, repeatability or reliability of results to support the establishment of separate regulatory standards for the three proposed bins. Moreover, EPA has not supported the proposed NOx-binning method with any actual in-use testing data derived from compliant test articles or a low-NOx HDOH prototype vehicle in-use. It is significant that the Agency originally committed to undertake real-world in-use testing of the proposed 3B-MAW protocol utilizing a Stage 3 prototype engine installed in a vehicle, but then reneged on that commitment, claiming that the Agency has run out of time. [EPA-HQ-OAR-2019-0055-1203-A1, p. 50 This comment is also in section 11.1.1]

In setting the standard for the combined Bin 2+3, EPA must take all of this uncertainty into account, as well as the simple fact that EPA has so far demonstrated that the Stage 3RW package is incapable of meeting the proposed standards, both dyno certificaton standards and in-use standards, despite its having been operated solely in the carefully-controlled laboratory setting. In that regard, EPA cannot simply establish emissions standards on the basis of “wishful thinking.” Accordingly, EMA proposes that the Bin 2+3 emissions standard be set at the average of Option 2-like LLC and FTP/RMC standards, adjusted upward by the appropriate in-use conformity factor, which should be 2.0 for at least seven model years before dropping down to 1.5. [Also included in section 11.1.1 EPA-HQ-OAR-2019-0055-1203-A1, p. 81]

EPA’s proposed implementation of the 3B-MAW approach also includes the establishment of an in-use multiplicative conformity factor of 1.5 that links each of the three bins to a unique test-cell standard. But EPA has not demonstrated that the uniform 1.5 conformity factor was reasonably derived from an analysis of the three separate bins of NOx data, or is based on any independent assessment of technical feasibility. Nor has EPA demonstrated whether an additive rather than a multiplicative approach would be more appropriate. In that regard, and as discussed further below, the in-use conformity factor also needs to be assessed against the limits of detection of the instruments that will be used to assess in-use compliance. EPA’s proposal of a 10% NOx accuracy margin is neither sufficient nor adequately data-driven. These factors are addressed in more detail in the technical feasibility section of these comments. [EPA-HQ-OAR-2019-0055-1203-A1, p. 67]

Such a massive regulatory undertaking, with cost implications many times over any prior rulemaking directed at the heavy-duty engine and vehicle industry, should be supported by extensive research and analysis to prove-out and justify the very considerable expenses and burdens that will fall upon manufacturers and the public. Unfortunately, that is not the case here. To the contrary, there are many underlying research activities that are still underway, some which likely will not be completed by the time the rule is finalized, let alone when it was proposed, and there are other major gaps in the overall research effort that will not be filled at all. [EPA-HQ-OAR-2019-0055-1203-A1, p. 171]

The feasibility demonstration of the Stage 3 technology package that EPA proposes as justification for the proposed standards was incomplete when EPA drafted the requirements included in the NPRM. The initial 800,000-mile test results became available well after EPA staff had drafted the NPRM. [EPA-HQ-OAR-2019-0055-1203-A1, p. 171]

Dissatisfied that the results from the Stage 3 aging tests show multiple instances of noncompliance to the proposed standards, EPA has initiated testing of an “improved” technology package simultaneous with the release of the NPRM, with the hope of improving long-term emissions stability and reducing the significant increases in N2O emissions measured on the first attempt (N2O, has a 100-year scale global warming potential of 265 to 298.) Testing and aging of this new “System A” prototype is expected to extend out through October 2022, after the time EPA will be obliged to finalize this rulemaking so it can move on to inter-agency review, all in accordance with the Agency’s self-imposed year-end deadline for a published final rule. [EPA-HQ-OAR-2019-0055-1203-A1, p. 171]

Industry-funded testing of the EPA Stage 3 prototype technology package to understand tailpipe NOx sensitivity to sensor variabilities and cold weather operation will not be conducted until May or June of this year. The analyses of those data will require additional time. Without those industry-funded test results, there will be no assessment of those critical variabilities, which represent only a subset of the factors that “stack-up” into the compliance margin that manufacturers will need, but that EPA has yet to account for in this rulemaking process. [EPA-HQ-OAR-2019-0055-1203-A1, p. 171]

All of the critical research outlined above was not available or not completed in time to support the pending NPRM. Indeed, the vital research at issue is still in process, with much of it expected to be delivered just as the proposed rule is expected to “go final” in the fall, all to meet EPA’s goal of having the new low-NOx standards take effect in 2027. Thus, there is considerable risk that these critical data will be unavailable when these largely infeasible standards are to be finalized. [EPA-HQ-OAR-2019-0055-1203-A1, p. 172.]

Perhaps even more concerning are the necessary data-generation projects that are completely unplanned at this time. More specifically, EPA intends to complete this rulemaking without having access to the following: In-vehicle in-use testing of the Stage 3 low-NOx technology system, to understand if emissions compliance is really achievable over the full range of real-world ambient conditions and operating cycles covered under the completely revamped 3B-MAW in-use test requirements, and to see if the new multi-component system can even fit into the broad array of impacted trucks, will not be done. The rulemaking record will have no data from any vehicle equipped with a Stage 3-type engine system. [EPA-HQ-OAR-2019-0055-1203-A1, p. 172]

EMA has funded additional testing of the Stage 3 RW engine over five "road cycles." Engine parameters were recorded during five actual on-road cycles, and then set up for engine dyno testing. Those results were processed according to the new proposed "3-Bin Moving Average Windows" ("3B-MAW') in-use testing and compliance protocol. While only scratching the surface of the myriad cycles HD trucks will encounter in the field, the Stage 3 RW system (and the CARB Stage 3 system) failed one of the five initial road cycles (the EU ISC cycle, as developed by WVU according to EU In-Service Conformity requirements), since it yielded a NOx result that exceeded the most stringent in-use "Bin 3" (medium/high power bin) limit of 0.030 g/bhp-hr by 10%. A second of the five road cycles was just at the Bin 3 limit, which SwRI improved later by preconditioning the aftertreatment system to ensure robust pre-test ammonia storage, a preconditioning process not permitted according to the applicable manufacturer in-use testing requirements. [EPA-HQ-OAR-2019-0055-1203-A1, p. 25]

Actual in-vehicle road-testing of a Stage 3 system obviously would be highly informative to the rulemaking process. Unfortunately, EPA (and CARB) conducted no such actual in-use testing of a vehicle equipped with the Stage 3 prototype engine, despite earlier commitments to do so. Rather, EPA's proposal of aggressive in-use standards utilizing a completely new 3B-MAW emissions measurement protocol is based solely on the partially failed emission results generated with one prototype engine operated on an engine dyno over just five simulated road cycles. [EPA-HQ-OAR-2019-0055-1203-A1, p. 25]

It also is important to consider that the Stage 3 technologies that serve as the basis for EPA's feasibility demonstration offer little or no improvement to NOx emissions levels when operating over periods of sustained engine load, the types of operation that should be included in the medium/high-load bin ("Bin 3") of the proposed 3B-MAW protocol. For example, in the case of a line-haul vehicle pulling a load at highway speeds, a condition where SCR temperatures with current technologies would be at levels optimal for NOx conversion, none of the proposed Stage 3 technologies (i.e., cylinder deactivation, EGR-cooler bypass, LO-SCR, heated dosing, zone-coated catalyzed soot filters, switchback mixing tubes) would have any impact on lowering tailpipe emissions levels, save perhaps for some marginal effect from increased SCR sizing. Yet EPA's Option 1 "Bin 3" proposal includes a 90%-lower steady-state NOx standard associated with that type of already-optimized operation under quasi-steady-state engine operation. That is inherently infeasible. [EPA-HQ-OAR-2019-0055-1203-A1, p. 25]

The limited emissions test results generated with the Stage 3 RW prototype aftertreatment system, as aged in the laboratory environment, do not represent reasonable worst-case emissions performance, nor do they represent reasonable worst-case aging effects that can be expected from field-returned engines. There are in-use operating conditions and events experienced in the field that are not even considered in EPA's discussions of "technical feasibility," but for which diesel engine manufacturers are held accountable in assessing their compliance with EPA's emissions related requirements. [EPA-HQ-OAR-2019-0055-1203-A1, p. 26]

EPA Summary and Response

Summary:

CARB supports the general structure of the off-cycle standards, and prefers the Alternative proposal where the off-cycle standards are a multiplier of 1.5 times the certification standards. CARB states that other aspects of the regulation, (such as longer warranty periods and more rigorous durability demonstration) and the availability of data related to California Omnibus regulation's primary NO_x emission standards will reduce uncertainty regarding deterioration of emissions control technologies. Additionally, CARB suggests defining an "off-cycle emissions threshold" that is the sum of the off-cycle standard and applicable margins.

Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club comment that they prefer Option 1 standards to Option 2 standards. Additionally, they recommend further strengthening the standards, specifically in the idle and low load bins (bin 1 and 2). They further state that available diesel technologies can reduce emissions in these bins to a greater extent than determined by EPA.

MECA comments that it is feasible to tighten the standards for the idle and low load bins (bin 1 and 2). In support, they cite test data from SwRI on the Stage 3 aftertreatment system, that was engine-aged to an equivalent of 800,000 miles. These results provide 60% or more margin in bin 1 and 70% or more margin in bin 2. MFN also comments that standards for the idle and low load bins should be tightened. In support MFN refers to Achates Power's test data, stating the data demonstrate that there are overly sufficient margins for compliance. MFN also states that EPA should, at a minimum, pull forward the 2031 off-cycle numerical requirements to the 2027 model year.

Navistar comments that they support in-use compliance testing with adequate compliance margins and support a robust standard with a lower NOx level. PACCAR comments that a conformity factor of 1.5. to 2 is applied to account for the variations due to drive cycle, and an additional "variability allowance" should be included to account for variations due to contaminants in the fuel, oil consumption, aging differences, and other factors.

Allison comments that the off-cycle standards seen in option 1 may be too stringent, because there has been insufficient validation of vocational drive cycles in Southwest Research Institute's emissions system durability testing.

Daimler comments that the EPA Stage 3 demonstration at SWRI cannot be considered a valid representation of in-use data, as it does not include the variability intrinsically associated with vehicle testing. In support, they present data from a current Detroit Diesel heavy duty engine tested on a dyno and installed in a real vehicle, demonstrating the differences in measured emissions. Furthermore, they state that the EPA demonstration system configuration included the shortest possible exhaust length which cannot be packaged in a vehicle, did not consider necessary design margins, showed significant compromises with reduced SCR volumes, did not meet Phase 2 MY 2027 GHG standards, included technology that will not be available for commercial vehicles in 2027, did not test at cold temperatures or with biofuels, and did not age the system in a representative manner. They also comment that that the engine fails to comply with EPA's proposed PM standards and raises questions about N2O compliance feasibility. Finally, they state that demonstration results for field replay cycles in the test cell reflect failed NOx results at 10% above the standard. Thus, Daimler states that EPA has failed to show feasibility of the proposed off-cycle testing standards.

Daimler and EMA further state that the sources of variability mean that manufacturers need to design for tighter emissions levels than are required for the dyno-demonstrated emissions performance, creating a level of stringency beyond the cycle emission standards. In support, Daimler presents data comparing SCR performance in a controlled setting versus an uncontrolled setting. They state that the uncontrolled system shows significantly more degredation, and they would expect similar differences between a lab-aged environment and fleet-aged environment.

EMA comments that critical data from the SWRI Stage 3 testing is not available to EPA or industry to understand tailpipe NOx sensitivity to sensor variabilities. Additionally, EMA states that in-vehicle testing of the Stage 3 low-NOx technology system has not been accomplished, and that EPA committed to undertake real-world in-use testing but reneged on that commitment. They also state that the Stage 3 prototype system failed or just met the requisite standards over two of five in-use cycles.

EMA states that the Bin 2 and 3 emission standards should be set at the average of Option 2-like LLC and FTP/RMC standards, adjusted upward by the appropriate in-use conformity factor, which should be 2.0 for at least seven model years before dropping down to 1.5.

MEMA and Eaton recommend increasing the compliance margins for in-use standards. EMA also comments that the uniform 1.5 conformity factor and the 10% NOx accuracy margin are not sufficient and have not been derived from the data.

MEMA also comments that CI and SI engines should have similar standards to prevent truck buyers switching between CI and SI as a way to "game" the regulatory standards.

<u>Response</u>:

See preamble Section III.C.2 for the final off-cycle standards and Section III.C.3 for our feasibility analysis for those off-cycle standards.

EPA disagrees with Daimler and EMA that the final in-use off-cycle standards would be, in effect, more stringent than the new certification standards. See section 11.5.1 of this document for more detail.

EPA agrees with CARB on the general structure of the off-cycle standards and that the off-cycle standard multiplier of 1.5 times the certification standards is appropriate for this rule's final standards based on EPA's assessment of feasibility for the off-cycle standards as explained in preamble Section III.C.3. EPA disagrees with CARB that other aspects of the regulation, (such as longer warranty periods and more rigorous durability demonstration) will reduce uncertainty regarding deterioration of emissions control technologies to the extent that would result in more stringent standards than we are finalizing. EPA is finalizing standards and an interim in-use compliance allowance that take into account uncertainty that wasn't included in our technology demonstration, see Section III.C of the preamble for additional details. The off-cycle standards and applicable margins are clearly defined in 40 CFR 1036.104 and 1036.420.

EPA disagrees with Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club that available diesel technologies can reduce emissions in these bins to a greater extent and should result in lower emission standards than determined by EPA. EPA is finalizing standards that take into consideration technologies that are capable of achieving low NO_X emissions, but also take into account degradation in performance from in-use operation over the engine's useful life. We also take into consideration other sources of variability like the duty-cycles, fuel quality, test procedure variability, performance of other engine ratings, production engine variability, DEF quality, and the effects of sulfur, soot, and ash on aftertreatment performance. See preamble Section III.C for more information on how we consider each of these elements in setting the off-cycle standards.

EPA disagrees with MECA and MFN that the standards should be tightened for the idle bin because the idle standard needs to be met over much broader ambient conditions than were tested at SwRI. We are setting the standards to account for the effect of these conditions on engine emission performance. In regard to bin 2, for the reasons further explained in preamble Section III.C.3, we are combining bins 2 and 3 into a single bin with a standard that accounts for the additional margin that was demonstrated at SwRI at the 800,000-mile equivalent. EPA is finalizing a one-step program starting in MY 2027, and setting standards for spark-ignition, light, medium and heavy HDEs at the lowest level achievable taking into account the technology available starting in MY 2027, and giving appropriate consideration to cost and other statutory factors. See preamble Section III for details on how each of the standards were set.

EPA considered comments from MEMA, Eaton, and EMA on compliance margin, and Navistar and PACCAR comments that a conformity factor of 1.5 to 2 is needed to account for in-use variations. While EPA disagrees that a conformity factor of 2 is needed for these final standards based on our feasibility analysis explained in preamble Section III.C.3, EPA has set standards that provide adequate compliance margins to account for drive cycle variations as well as variation due to contaminants in the fuel, oil consumption, aging differences, and other factors as described in Section III.C of the preamble.

With regard to MEMA's comment on the stringency of CI and SI standards, we have not set standards at a level to encourage or prevent a purchaser from buying an SI engine over a CI engine or vice versa, but have set appropriate standards as discussed in preamble Section III for both CI and SI engines in a manner generally consistent with a fuel neutral approach, with the exception of CO for Spark-ignition HDE over the new SET duty cycle. We expand on our rationale for this deviation from fuel neutrality in preamble Section III.D.1.

Regarding Allison's comment, we are not finalizing as proposed all of the proposed Option 1 off-cycle standards after further consideration of feasibility and the other statutory factors for some of those standards, however we believe that the stringency of the final bin 2 (which is now combined with bin 3) should be increased and we have incorporated increased stringency in the final bin 2. We disagree with Allison that vocational vehicle operation was not captured within the five cycles tested at SwRI. These duty cycles were developed with consideration of input from engine manufacturers and incorporated field data consisting of in-use operation from hundreds of vehicles.

We disagree with Daimler that the standards we are finalizing do not include the variability intrinsically associated with vehicle testing. See preamble Section III.C regarding how EPA has accounted for the effects of in-use operation, as well as emission control system packaging and size, that were not accounted for within the SwRI Stage 3 testing. We also note that EPA is providing a process using the recall requirements in 40 CFR 1068.505 for a manufacturer to receive EPA approval to exempt test results from in-use off-cycle standards testing from being considered for potential recall if an engine manufacturer can show that the vehicle was historically fueled with biodiesel blends whose B100 blendstock did not meet the ASTM D6751–20a limit for Na, K, Ca, and/or Mg metal (metals which are a byproduct of biodiesel production) or contaminated petroleum based fuels (i.e. if the manufacturer can show that the vehicle was misfueled), and the manufacturer can show that misfueling lead to degradation of the emission control system performance. See preamble Section III.C.4 for further details.

Regarding Daimler's comment on meeting the Phase 2 GHG standards, the NO_X standards are incremental to the GHG standards, and the technology required to achieve both standards simultaneously can be independently applied to the engine. The Stage 3 engine was a MY 2017 engine that did not include the technology needed to meet the Phase 2 MY 2027 GHG standards. The demonstrated NO_x emissions were achieved without increasing GHG emissions from the base engine, and thus would have no adverse effect on GHG reductions achieved through the introduction of additional technology. See also discussion in preamble Section III. EPA expects that the four-year lead time will provide sufficient time for all of the technologies to become commercially available.

EPA has taken into account cold temperature effects on emission performance when setting the standards, as explained further in section 11.2.2 of this document. As discussed in preamble Section III.C.4, EPA is modifying the proposed approach to in-use off-cycle standards testing and will allow manufacturers to continue to exempt engines from in-use off-cycle standards testing if the engine is being operated on biofuel that exceeds the manufacturers maximum allowable biodiesel percentage usable in their engines, as specified in the engine owner's manual, as described in 40 CFR 1036.415.

EPA aged the Stage 3 emission control system using an established bench aging test procedure that has been validated and incorporated into 40 CFR 1065.1130, see preamble Section IV.F. With regard to "the mismatch between 3B-MAW performance and test cell performance", EPA agrees that the emissions from the EPA Stage 3 engine on the duty cycles do not fully match the emissions performance in each of the off-cycle bins, but we disagree that this means that there is a fundamental issue with the off-cycle test procedure or that the off-cycle standards are not feasible. As discussed in Section III.C of the preamble we have demonstrated that the off-cycle standards are feasible, with margin to account for effects that were not directly captured with the EPA Stage 3 demonstration. Furthermore, we have set the numeric level of the off-cycle standards independent of the duty cycle standards and at the most stringent level for MY 2027 engines after giving appropriate considering to cost and other statutory factors. EPA disagrees that the Stage 3 engine fails to comply with EPA's proposed PM standards. As further discussed in preamble Section III. the higher PM emission data points in the demonstration data occurred immediately following DPF ash cleaning, and the PM level returned to a level well below the 5 mg/hp-hr standard shortly after return to service once a soot cake layer reestablished itself in the DPF. These very short-term elevations in PM that occur after required maintenance of the DPF should not be the basis for the stringency of the PM standard. It has been shown that soot buildup in the DPF improves filtration efficiency and as with ammonia storage on SCR catalysts, EPA allows for preconditioning prior to carrying out the manufacturer's test of record for certification. This preconditioning not only establishes baseline ammonia storage on the SCR catalyst but reestablishes the DPF soot cake layer that was removed during the initial forced DPF regeneration that occurs prior to the preconditioning sequence. After considering the comments and evaluating the data from the Stage 3 engine, EPA is finalizing the proposed PM standard of 5 mg/hp-hr for the FTP, SET, and LLC and 7.5 mg/hp-hr for the bin 2 off-cycle standard. See preamble Section III for details on EPA's feasibility analysis for these standards. EPA disagrees with Daimler's concern regarding N_2O compliance feasibility, as the N_2O emissions from the EPA and CARB Stage 3 engine were below the N_2O standard, even after the aftertreatment was aged to the equivalent of 800,000 miles, which is beyond the final useful life for Heavy HDEs.

EPA agrees that the EPA Stage 3 engine had higher emissions than the most stringent off-cycle standards proposed, but as discussed in preamble Section III.C the level of the final off-cycle standards corresponds to at least a 40 percent compliance margin for the EPA Stage 3 engine.

EPA disagrees with EMA that NO_x sensitivity to sensor variabilities was not taken into consideration when setting the standards. Testing of the Stage 3 system at SwRI used production NO_x sensors and any variability associated with the use of those sensors was part of the test results. EPA acknowledges that in-vehicle testing of the Stage 3 low-NO_X technology system has not been accomplished, however we note that EPA has accounted for the effects on emission performance that were not included in the Stage 3 testing, which includes packaging and ambient effects as described in Section III.C of the preamble.

EPA disagrees with EMA that the 1.5 conformity factor and the PEMS NO_x accuracy margin were not derived from data. The PEMS accuracy margin that we are finalizing in 40 CFR 1036.420 was derived from data generated at SwRI with three commercially available PEMS units measuring emissions from the Stage 3 engine at NO_X levels that meet the standards. EPA is setting off-cycle standards as described in Section III.C of the preamble based on data from the Stage 3 engine tested over five representative field cycles.

In response to EMA's comment, EPA agrees the standard for the combined bin 2 and 3 should be based on the LLC and FTP/RMC standards and should be adjusted upward by the appropriate in-use conformity factor, but disagrees that the appropriate conformity factor is 2 based on EPA's assessment of the feasibility of the off-cycle standards. Further discussion of the proportionality of the off-cycle standards to the LLC and FTP/RMC standards is contained in the preamble Section III.C.2.c.

11.3.2 Other comments on criteria pollutant off-cycle standards

Comments by Organizations

Organization: *Center for Climate and Energy Solutions (C2ES)*

On-road NOx emissions are often concentrated in these communities, as they are produced by trucks traveling on highways located within or near them, as well as trucks idling at ports, warehouses, and other freight applications in these communities. Current lab testing cycles of these NOx levels may underestimate the true amounts of NOx emissions produced due to insufficient testing under real world conditions or artificially short regulatory useful life figures. [EPA-HQ-OAR-2019-0055-1165-A1, p.4]

Organization: *Odyne Systems, LLC (Odyne)*

Odyne worked with the U.S. Department of Energy to study emissions produced during Power Take-Off (PTO) operation by medium and heavy-duty vehicles. According to a report published by the National Renewable Energy Laboratory, very high NOx can be produced when vehicles are in a PTO mode. [EPA-HQ-OAR-2019-0055-1264-A1, p.2]

The PTO is a device that attaches near the engine and provides an output for rotational power. A PTO may receive power from the engine through a transmission, from a gear attached to the rear of an engine, such as a rear engine power take off or REPTO, or from a crankshaft, such as a front engine power take off, or FEPTO. The PTO provides power output from the engine to operate hydraulic pumps, compressors, and other devices. Devices such as hydraulic pumps rotate and enable vehicle mounted equipment to move, examples include bucket trucks, digger derricks, cranes, refuse compactors, cable pullers, dump trucks, tank truck and other applications. [EPA-HQ-OAR-2019-0055-1264-A1, p.2]

There are over 100,000 PTOs installed yearly on new chassis, per data from the NTEA, https://www.ntea.com , most on medium and heavy-duty vehicles. [EPA-HQ-OAR-2019-0055-1264-A1, p.3]

The typical operation of the chassis engine to power truck-mounted equipment through the PTO results in higher fuel consumption than idle and high emissions (GHG and NOx). [EPA-HQ-OAR-2019-0055-1264-A1, p.3]

The attached document provides information about high NOx output during PTO operation: https://www.nrel.gov/docs/fy20osti/75782.pdf File 75782 (attached) – Power Take-off (PTO) section on pages 35- 59 [EPA-HQ-OAR-2019-0055-1264-A1, p.3]

A side by side test of electrified PTO vs. conventional 100% engine power PTO was conducted by NREL, please see the attached report 75782: ‘Investigation of Emissions Impacts from Hybrid Powertrains’ Produced under direction of California Air Resources Board (CARB) by the National Renewable Energy Laboratory (NREL) under Work for Others Agreement number FIA-15-1802 and Task No WWGR.1000. Contract No. DE-AC36-08GO28308 January 2020 [EPA-HQ-OAR-2019-0055-1264-A1, p.3]

A typical chassis engine-driven PTO runs for long durations with relatively low loads, with occasional higher bursts of power output, such as when a hydraulic pump or compressor produces flow to move equipment or perform work. As a result of low loads and intermittent higher loads, the chassis engine emission control system is ineffective in PTO mode, resulting in very high NOx output, over three times as high as idling emissions, see page 54 and 55 of the NREL report. [EPA-HQ-OAR-2019-0055-1264-A1, p.3]

Many trucks operate PTOs for extended periods, often for many hours a day, as the trucks perform work at jobsites or when the trucks require stationary power, resulting in very high NOx output. [EPA-HQ-OAR-2019-0055-1264-A1, p.3]

Per the NREL report: ‘For explanation, the highest NOx emitting drive cycle was for the HHDDT transient cycle. If this cycle were continuously operated, it would average 30.8 grams/hour of NOx emissions out of the tailpipe.’ The conventional PTO operation produce more than twice as much NOx per hour as the HHDDT transient cycle, and typically operates for many hours. As an example, utility trucks often spend 75% of operational time in PTO mode. [EPA-HQ-OAR-2019-0055-1264-A1, p.4]

While the ‘EPA is proposing the addition of a low-load test cycle and standard that would require CI engine manufacturers to demonstrate that the emission control system maintains functionality during low-load operation where the catalyst temperatures have historically been found to be below their operational temperature,’ the proposed cycle does not appear similar to the engine operation of PTOs, where overall average power output of the engine is extremely low, followed by sudden power requirements (often still low compared to the output of the engine) and then followed again by idling. [EPA-HQ-OAR-2019-0055-1264-A1, p.4]

Note torque requirements above 50% require significant power which generates heat and increases the effectiveness of emissions systems. A PTO may require a fraction of the maximum torque output of the engine and will likely be at a much lower average power level due to the intermittent power requirements for many types of vehicle mounted equipment. [EPA-HQ-OAR-2019-0055-1264-A1, p.5]

For reference the Low Load Cycle (LLC), showing high torque requirements often over 50% https://ww3.arb.ca.gov/msprog/hdlownox/files/workgroup_20190926/staff/03_llc.pdf [EPA-HQ-OAR-2019-0055-1264-A1, p.5]

NREL report Page 54: Conventional PTO operation using 100% power for PTO from engine ‘…NOx emissions are at the highest rate during PTO use. This is likely due the nature of the engine and exhaust operating conditions during PTO work. The engine spends a majority of the time at idle which results in low exhaust temperatures and low SCR NOx conversion efficiency, but then work is commanded at abrupt segments very transient in nature resulting in large engine out NOx spikes. These spikes cannot be mitigated by the aftertreatment system because of the low temperatures which then results in high NOx concentration values out of the vehicle tailpipe.’ [EPA-HQ-OAR-2019-0055-1264-A1, p.5]

EPA: We request comment on the proposed Options 1 and 2 off-cycle standards, as well as the overall structure of the off-cycle program. We also request comment on the need for fewer or more than 3 bins. [EPA-HQ-OAR-2019-0055-1264-A1, p.5]

Odyne recommends adding a test cycle bin to the off-cycle standards that represents the operation of the vehicle engine when a typical power take-off (PTO) is operated, specifically very low average load with occasional relatively high spikes of power output. The U.S. Department of Energy's National Renewable Energy Laboratory (NREL) has further information on the operation of PTOs and likely duty cycles. The test cycle should apply to all powertrains that have the capability of readily installing a PTO, including those with transmissions that have an internal PTO gear within the transmission that would interface to a PTO when the PTO is installed. The test cycle would not apply to vehicles with transmissions that do not have the capability to accept a PTO, such as transmissions that are typically used for box trucks. [EPA-HQ-OAR-2019-0055-1264-A1, pp.5-6]

Odyne recommends that vehicles with an ePTO system should be operated in conformance with the operator's manual during the testing of the off-cycle PTO bin, including charging the battery through the grid if it is recommended as the primary means of recharging the ePTO system battery. The ePTO should be operated with the same load and duty cycle that would be applied to the ICE if it were to operate the PTO with a representative load. If the ePTO battery discharges to the point that the system would turn on the engine during a normal day, then the emissions should be measured and applied to the result. [EPA-HQ-OAR-2019-0055-1264-A1, p.6]

EPA: 'We are also requesting comment on a possible broadening of our in-use compliance strategy to cover more engines and more operation.' [EPA-HQ-OAR-2019-0055-1264-A1, p.6]

Odyne recommends that manufacturers include at least one vehicle with a Power Take-Off (PTO) in the group of vehicles that are subject to in-use compliance, if that manufacturer sells vehicles with PTOs. The vehicles with PTOs should be operated in a manner that is typical for work vehicles, such as turning on the PTO when the vehicle is stationary and operating a device powered by the PTO, such as an aerial bucket or small crane mounted to a truck, for many hours for one day. The PEMs should be active during the PTO test and the test should verify that the onboard diagnostics system is fully active during PTO operation. [EPA-HQ-OAR-2019-0055-1264-A1, p.6]

Based upon Odyne's interpretation of current regulations, portions of the diagnostic system, sometimes referred to as HDOBD, can be suspended during PTO operations, and no specific testing is performed to ensure that any emissions standards are met during PTO operations. [EPA-HQ-OAR-2019-0055-1264-A1, p.6]

For reference, see Section 4.5.2 of the HD OBD regulation, section 1971.1 of title 13, California Code of Regulations, link https://www.law.cornell.edu/regulations/california/13-CCR-Sec-1971-1 Note, the EPA commented that they often reference CARB regulations, so the CARB regulation is shown: (4.5.2) Within 10 seconds of the start of a PTO (see section (c)) operation that disables a monitor required to meet the monitoring conditions in section (d)(3.2), the OBD system shall disable further incrementing of the corresponding numerator and denominator for each monitor that is disabled. When the PTO operation ends, incrementing of all corresponding numerators and denominators shall resume within 10 seconds. ’Power Take-Off (PTO) unit’ refers to an engine driven output provision for the purposes of powering auxiliary equipment (e.g., a dump-truck bed, aerial bucket, or tow-truck winch). [EPA-HQ-OAR-2019-0055-1264-A1, pp.6-7]

Also note that idle shut-down regulations are not in effect when a PTO is activated, even if the equipment is not operated after the PTO mode has been selected. Some fleets report instructing their workers to select the PTO mode rather than turn off the engine, even if the PTO is not needed to power hydraulic equipment, so that the engine can remain on to power low voltage loads, such as a 12V lights and flashers and provide air conditioning and heat when the vehicle is used as shelter for workers. [EPA-HQ-OAR-2019-0055-1264-A1, p.7]

While in-use testing might address some scenarios, it remains unclear to Odyne whether comprehensive in-use testing of trucks with PTOs would be mandated to detect high NOx and GHG emissions. [EPA-HQ-OAR-2019-0055-1264-A1, p.7]

Based upon data from NTEA, Odyne estimates that approximately 30%+ of medium and heavy-duty vehicles operate a PTO, indicating that the number of vehicles is large, and testing of this operational mode is necessary. [EPA-HQ-OAR-2019-0055-1264-A1, p.7]

Odyne recommends that trucks tested for in-use compliance with an ePTO be fully charged as documented in the system operator’s manual, and then the equipment on the truck operated with the ePTO for the normal duty cycle and duration that is typical of a full day use. Emissions should be measured during the process, so that if the battery discharges and the engine turns on, emissions can be measured. [EPA-HQ-OAR-2019-0055-1264-A1, p.7]

Odyne supports efforts by the EPA to control air pollution for heavy-duty engines and vehicles. [EPA-HQ-OAR-2019-0055-1264-A1, p.9]

The currently proposed updated regulations appear to provide a potential loophole for a significant portion of annual medium and heavy-duty trucks produced in the U.S., those that operate power take-offs (PTOs), estimated to be approximately 30% of total U.S. production by Odyne. [EPA-HQ-OAR-2019-0055-1264-A1, p.10]

Power take off operation typically places engines under a different load cycle than the proposed low load cycle. Due to very low loads followed by occasional higher loads, the average load on the engine is very low and the higher loads cause high NOx emissions. Per testing by the U.S. Department of Energy, NOx emissions in grams/hour during conventional PTO operation, in which the engine is on continuously to power truck mounted equipment, can be more than three time higher than idle and twice that of high NOx output during driving. [EPA-HQ-OAR-2019-0055-1264-A1, p.10]

Odyne recommends changes to proposed Options 1 and 2 off-cycle standards to incorporate tests that represent PTO operation for vehicles that are configured to accept a PTO, such as those with a PTO gear installed internal to the transmission that would interface with a PTO. [EPA-HQ-OAR-2019-0055-1264-A1, p.10]

Odyne also recommends broadening in-use compliance standards to require the testing of one or more vehicles with the PTO operational, if that manufacturer produces vehicles that have PTOs installed in the field. [EPA-HQ-OAR-2019-0055-1264-A1, p.10]

Odyne also encourages the EPA to confirm that emission system diagnostics are required to be completely functional during PTO operation. [EPA-HQ-OAR-2019-0055-1264-A1, p.10]

Organization: *Valeria Trujilo Aguilar*

Evaluate Performance of HDVs Accurately

According to Badshah et al.[13], a disproportionate amounts of NOx emissions from HDV are emitted during low-speed operations, a characteristic of urban driving. A study conducted by the International Council on Clean Transportation (ICCT) found that vehicles operating at a speed lower than 25 mph results in 5 times more emissions than certification limit allows[14]. Also, this study found that single line-haul trucks emit the NOx equivalent of 100 cars under urban driving conditions[15]. The ICCT study states that EPA certified trucks under 2010 HDV diesel standards are not in compliance emitting 5-7 times more NOx under actual urban driving conditions than laboratory findings suggest[16].

EPA Summary and Response

Summary:

C2ES and Valeria Trujilo Aguilar comments that current lab testing cycles may underestimate the true amounts of NO_x emissions produced in real world situations. Valeria Trujilo Aguilar also comments that low speed operation results in NO_x emissions 5-7 times higher than suggested by laboratory tests.

Odyne comments that PTOs are installed on over 100,000 vehicles yearly. They further comment that PTO operation leads to high NO_x output due to its duty cycle, which alternates idle operation with sudden high power transient operation. They recommend adding a bin to the off-cycle testing that represents PTO operation, and further recommend requiring manufacturers to include at least one vehicle equipped with a PTO (and exhibiting typical PTO operation) in their in-use testing.

Response:

EPA thanks C2ES, Valeria Trujilo Aguilar, and Odyene for their input and notes that the final laboratory duty cycles in conjunction with the new off cycles standards and moving average window test procedures will significantly reduce real world emissions, making up for the shortcomings of the current NTE standards and test procedures. EPA believes that the "idle" bin (bin 1) is defined in such a way that 300-second windows would capture PTO operation for inclusion in this bin.

11.4 HDUIT: Selecting engines and vehicles (Preamble III.C.5.ii)

11.4.1 Timing of the testing program

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

CARB staff has concerns with the changes in 1035.405(d) where testing must be completed within 18 months of the test plan approval. In this case, no firm timeline is provided because the time to produce a test plan is undefined. CARB staff suggests adding a timeline for test plan submission or using the previous language that states testing would need to be completed within 18 months after the administrator directed to test an engine family. [EPA-HQ-OAR-2019-0055-1186-A2, p.64]

Organization: *PACCAR, Inc (PACCAR)*

PACCAR respectfully requests that EPA amend certain aspects of the proposed manufacturer-run field-testing program. First, proposed section 1036.405(d) states: 'We will typically select engine families for testing and notify you in writing by June 30 of the applicable calendar year.' PACCAR submits that EPA should make its selection in January of the applicable calendar year, rather than June. EPA has proposed an additional step that requires OEMs prepare a test plan that EPA must approve. Because the 18-month 'clock' does not start running until the test plan is approved, the test period must begin earlier than June so OEMs have two summers and one winter (instead of two winters and only one summer) for testing. Winter testing is logistically difficult and has certain risks. For example, PACCAR uses a trailer, which weighs nearly 10,000 pounds and contains analyzers and other equipment worth up to $1 million, to support PEMS testing that is towed with a light-duty truck. Not only does conducting PEMS testing in the winter on icy roads create unnecessary risks, it also increases workplace safety risks that are inherent to working outside in icy conditions. EPA should therefore make its selection in *January* to accommodate additional summer testing. [EPA-HQ-OAR-2019-0055-1346-A1, pp.54-55]

In addition, proposed 1036.430(c) would require a number of testing and reporting notifications but the Agency has not specified the time in which such notifications must be submitted to the Designated Compliance Officer. PACCAR respectfully submits that 30 days would be a reasonable time frame in which to require OEMs to submit these notifications. In addition, EPA should remove proposed 1036.430(c), which would require notification if two out of five tests fail because OEMs can pass with an average of ten engines. [EPA-HQ-OAR-2019-0055-1346-A1, p.58]

Organization: *Truck and Engine Manufacturers Association (EMA)*

EMA supports that EPA is maintaining similar requirements regarding vehicle recruiting routines, test processes, and reporting requirements to those that are in place today. There are, however, a few important issues in the proposal that the Agency should address before finalizing the regulation. [EPA-HQ-OAR-2019-0055-1203-A1, p. 91]

Regarding test plans to be submitted to the Agency, it is unclear whether the manufacturer must wait for EPA to approve the test plan before proceeding with setting up and executing the first tests. If EPA would require that they approve the test plan before it gets underway, EPA should specify that they will provide approval of, or specify changes to, the manufacturer's test plan within 30 days of its submittal. It is also unclear how EPA plans to coordinate with CARB on test plan approval to be sure to meet the 30-day response time. [EPA-HQ-OAR-2019-0055-1203-A1, p. 91]

Also with respect to timing and scheduling, EMA recommends that EPA (and CARB) issue annual in-use test orders earlier in the year than is the current practice. With the proposed 18-month period within which a manufacturer must satisfy all the requirements of the test order (from the date of plan approval), there is a significant benefit to manufacturers' ability to complete these requirements if the test orders are issued early in the year. More specifically, a manufacturer has a better chance of completing the testing over a period that includes a single winter rather than two winters if the test orders are issued sooner. Winter tests include the complication and inconvenience of PEMS installation and support in undesirably cold weather conditions, which can also introduce complications for PEMS performance and function. Winter tests also run a higher risk of inclement weather disrupting travel logistics for the manufacturers' test technicians, as well as last-minute interruptions to vehicle scheduling and completion of the shift-day as planned. Those complications and potential planning disruptions could be avoided if EPA and CARB issued in-use test orders by February 1st each year. [EPA-HQ-OAR-2019-0055-1203-A1, p. 91]

Regarding the various notifications described in §1036.430(c), those also do not include clearly stated requirements as to reporting deadlines from the actual events described. EMA recommends that manufacturers be required to submit any of those notifications within 30 days of the triggering event. [EPA-HQ-OAR-2019-0055-1203-A1, p. 92]

EPA Summary and Response

Summary:

CARB comments that section 1035.405(d) states that testing must be completed within 18 months of the test plan approval, but gives no timeline for test plan submission, leading to an undefined timeline. They suggest either adding a timeline for test plan or altering the language to require test completion within 18 months of the administrator's direction to test an engine family.

Both EMA and PACCAR request that rather than selecting engine families for testing by June 30, EPA instead make a selection by January. They state that the earlier selection would reduce test burden by allowing manufacturers more opportunities for warm-weather testing rather than the logistically more difficult cold-weather testing.

EMA comments that it is unclear whether the manufacturer needs to obtain EPA approval of a test plan before beginning testing. They recommend EPA should specify they will respond within 30 days. EMA and PACCAR also recommend that manufacturers be required to submit any notifications described in §1036.430(c) within 30 days. PACCAR also recommends that EPA remove the requirement for notification if two out of five tests fail because OEMs can pass with an average of ten engines.

Response:

EPA agrees with the commentor that the timeline to submit the test plan to EPA is open ended. We note, however, that the vehicle recruitment process can be challenging for an engine manufacturer, and EPA is therefore affording additional time in the final regulation for manufacturers to put together their test plan prior to the 18-month period that constitutes the testing and reporting time.

EPA does not agree with the commentors' request to change the engine selection test month to January. While EPA considered the issue raised by commenters, EPA also considered that we need time within the calendar year to determine which vehicles to have the manufacturer test. EPA notes that in both cases the 18-month period would encompass both winter and summer months and would not necessarily lead to more cold weather testing.

After consideration of comments, EPA's final requirements do not include a deadline for EPA approval of the test plan and the manufacturer is free to start testing once the test plan has been submitted. Once the manufacturer submits it, EPA intends to let the manufacturer know in a timely manner if there are any concerns with the plan.

EPA agrees with the commentors that a 30-day deadline is appropriate for any notifications required from manufacturers described in §1036.430(c), and the final 40 CFR 1036.430(c) includes a requirement to submit any notifications with 30 days.

EPA disagrees with the commentor, and the final regulation includes the requirement to provide the Agency with notification if only 2 out of the first 5 engines tested pass the emission standards. Under this scenario, a notification is appropriate so that EPA is informed of the failures as this is indicative of a potential engine family noncompliance. This notification does not alter that the manufacturer still can test 5 additional engines, for a total of 10, to show the engine family is in compliance as described in 40 CFR 1036.425(c).

11.4.2 MIL light illumination threshold: identifying malfunctioning vehicles in test program

Comments by Organizations

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

Another area of concern with of the proposed off-cycle test procedures is the mismatch between the applicable NOx emissions and the detection capabilities of state-of-the-art OBD systems. Current generation OBD systems are designed and calibrated to detect degradation of emission control systems before such degradation results in tailpipe NOx emission of 0.4 g/hp-hr as measured on the cold/hot FTP, and RMC cycles. This limit was intentionally set higher than the existing applicable emission standards to recognize the limits of detection capability. [EPA-HQ-OAR-2019-0055-1168-A1, p.47]

EPA does not propose any modification to the diagnostics emission limit, and in fact enshrines the current emissions thresholds in its new OBD proposal. EPA is tacitly acknowledging that current technology does not allow for the design of OBD systems with a higher detection sensitivity. [EPA-HQ-OAR-2019-0055-1168-A1, pp.47-48]

Today, manufacturers are protected from in-use liability for failed emissions control components by their OBD systems. With the current emissions thresholds and OBD emissions limits, it is very likely that the OBD system will detect a failure before the system's emissions are significantly increased. These vehicles will be identified and repaired- and would not be tested for compliance while an emissions failure is present. [EPA-HQ-OAR-2019-0055-1168-A1, p.48]

This protection against possible high emitters due to malfunctioning emission control systems is lost with EPA's proposed standards. With the proposed extremely low in-use limits for NOx emissions, manufacturers will be liable for the in-use emissions of vehicles with failed emissions control systems which the EPA acknowledges cannot be detected by OBD systems. [EPA-HQ-OAR-2019-0055-1168-A1, p.48]

Organization: *PACCAR, Inc (PACCAR)*

OBD is critical for ensuring in-use compliance by alerting the vehicle owner when an emissions-related repair is needed. This leads to truck servicing, a warranty claim, additional OEM costs, and customer inconvenience. As a result, there is a strong incentive for manufacturers to design their emission-control systems to be durable and to manufacture accurate OBD systems that can distinguish when the Malfunction Indicator Lamp ('MIL') must be illuminated. [EPA-HQ-OAR-2019-0055-1346-A1, p.23]

The new Off-Cycle standards set forth in the Proposed Rule create a major shift in regulatory strategy, because the limits are set at a small fraction of the current On-board Diagnostic Emissions Limit (OBDEL), and are well below what is technologically achievable for increased diagnostic sensitivity for most, if not all, fault monitors. This creates a new regulatory landscape where the manufacturer is incentivized to reduce MIL-on thresholds below regulatory requirements to manage the population of non-compliant vehicles in the field. [EPA-HQ-OAR-2019-0055-1346-A1, p.23]

OBD is a tool to detect malfunctioning trucks and is not intended to be used to reduce the population of units within the expected distribution of wear and deterioration. There are many factors such a technological feasibility, failure rates, emissions impacts, etc. that manufacturer are in the best position assess to optimize the OBD systems to correctly distinguish malfunction from normal wear at levels below the current OBDEL, helping to ensure in-use compliance. [EPA-HQ-OAR-2019-0055-1346-A1, p.24]

The figure below provides a graphical demonstration of how this new regulatory landscape could look. The green line represents how a future technology engine could perform during off-cycle testing, which will include considerable variability caused by the drive cycle and environmental conditions, production variability, and variability in deterioration rates. [EPA-HQ-OAR-2019-0055-1346-A1, p.24]

This graph illustrates a considerable slope representing the probability of setting a MIL. Diagnostics thresholds are based on an FTP, which is a controlled test, while off-cycle operation is more random and produces a broader spectrum of results. Also, some diagnostics may differ from others due to safety factors, and certain diagnostics can be affected by deterioration. [EPA-HQ-OAR-2019-0055-1346-A1, p.25]

There are limits to what is feasible for OBD diagnostic thresholds. For example, catalyst efficiency monitoring is limited by NOx sensor accuracy and has limited ability to pinpoint the cause, which leads the service technician to grapple with a complex troubleshooting tree and costly trial-and-error service actions. If this monitor is used too aggressively, there will be too many false fails and too many units in the normal deterioration range showing up in service bays where no clear service action can be identified to clear the fault. There is no new technological breakthrough for OBD monitors that would be analogous to the technology used for the Stage 3 demonstration engine. The proposed off-cycle limits are too low for OBD to be an effective or appropriate tool to limit the range of emissions rates expected in-use. [EPA-HQ-OAR-2019-0055-1346-A1, pp.25-26]

Statistical analysis applied to test results from a research engine has predicted a log normal distribution of in-use results depicted in the upper right corner of the figure. The CFT fleet distribution is expected to take on that shape after application of new technology that will pull the peak toward the left and, to a certain extent, move the whole distribution to the left. Some operation missed by inactive NOx sensors would increase frequency counts to right of the peak if the fleet were measured with PEMS. Much of the long tail of the distribution can be addressed through OBD. However, we can expect frequency counts to remain higher than desired to the right of the peak over a considerable range of emissions levels. This area is shown as the ‘challenge area’ in the figure and will involve a mix of solutions:

- **Durability Improvement –** There is no evidence to support the idea that manufacturers will be better able to improve the durability of emissions control systems more effectively when motivated by the HDIUT program than when motivated by the strong incentives of the existing OBD regulations. Efforts to improve are continuous, but the scale of future improvements should not be overestimated. Further, the durability of new systems has not been proven, for example for CDA hardware and close coupled Catalysts, so it will be difficult not to move backwards. PACCAR believes that the off-cycle standards proposed by EMA are attainable through more modest improvements in durability in line with what PACCAR’s experience has shown to be realistic but with significant risk in the early years when new technologies are deployed.
- **New Technology –** Application of improved technology will move the entire distribution to the left, but with limits. For example the proposed off-cycle standards will require greatly reduced transient emissions breakthroughs that are still present in test data from the SwRI demonstration engine and will require technology beyond that which was considered for the cost basis of the NPRM to meet option 1 standards. A technical solution can be imagined for every situation but there is a limit to what is cost effective. Other sections of this document go into more detail about technological limitations.
- **OBD –** OBD can be an effective tool when applied to the far right of the distribution. Application of OBD too far to the left side, without other solutions, will result in too much MIL illumination due to false detection or the misclassification of normal deterioration as component failure. It should be left to manufacturers to set the appropriate emission thresholds for each fault where root causes of malfunctions can be effectively identified.
- **Conformity Factor (CF) –** The conformity factor accounts for the variation caused by the drive cycle and values of 2 moving to 1.5 are implied by the NPRM. This makes a major contribution to why the in use test results fall along a spectrum. The cycle dependence of ultralow NOx engines is still largely unknown and remains a risk area for manufacturers.

- **Variability Allowance (VA) –** There are many variables that can affect the performance of a Low NOx system in the real world such as Sulfur in fuel, metals in biodiesel, differences in oil consumption, a spectrum of customer applications that leads to variation in aging, and variation among sensors. Variation could become significantly magnified under ultra-low NOx standards because sources of variation that are small by today's standards might not scale down in a linear way when new technology is applied contributing to sources of variation that are more significant relative to the standards. [Comment also in chapter 11.6.4] [EPA-HQ-OAR-2019-0055-1346-A1, pp.27-29]

Off-cycle standards are set far below the level at which OBD systems are able to detect emission control system malfunctions, which will contribute to a wider spectrum of results. Therefore, PACCAR supports pass/fail metrics to accommodate more non-passing engines. [EPA-HQ-OAR-2019-0055-1346-A1, p.57]

Organization: *Truck and Engine Manufacturers Association (EMA)*

Similarly, today's OBD NOx-sensor-based capabilities are insufficiently precise to detect in-use NOx emission as EPA is proposing, or to assess in-use emissions compliance or potential emission-control malfunctions down at the proposed Option 1 levels. To the contrary, the current OBD NOx-malfunction threshold is no lower than 0.40 g/bhp-hr. Tellingly, EPA is proposing to retain, not lower, that OBD NOx malfunction threshold under the new low-NOx regulations, implicitly recognizing that OBD NOx sensors and related emission-detection systems are not accurate or robust enough to allow for the implementation of lower in-use OBD malfunction and enforcement thresholds. That is very significant because the higher OBD thresholds could allow emissions to far exceed the proposed in-use NOx standards before detecting a fault or illuminating a MIL, which could increase manufacturers' potential in-use compliance risks, while, at the same time, reducing the benefits of the proposed emission standards by allowing potentially malfunctioning engines to operate without an indication of the need for emissions-related repairs. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 11 - 12]

In effect, then, EPA is proposing to maintain the NOx-related OBD in-use compliance assessment and enforcement criteria at a level that is an order of magnitude above the proposed applicable "3B-MAW"-based in-use NOx emission standards. The net result is that EPA is proposing in-use low-NOx standards (based on the Option 1 requirements) that could be below the ranges at which PEMS and OBD systems are able to accurately and consistently detect, measure or assess compliance with the proposed in-use NOx standards. Similarly, EPA has not assessed whether ECUs have the data-processing capacity and capabilities to implement the proposed 3BMAW program. [EPA-HQ-OAR-2019-0055-1203-A1, p. 12]

Yet another factor that EPA should consider before obligating manufacturers to stricter engine family pass/fail criteria is that manufacturers would be at much greater risk to recruit vehicles for testing that have a component failure in progress to the point of exceeding the in-use standards, but not yet progressed enough to have exceeded the threshold required to illuminate the OBD MIL. This much greater risk of recruiting such a "pre-MIL" vehicle, as well as tripling the number of standards against which compliance must be demonstrated under a broader range of operating conditions, should be considered when establishing the pass/fail criteria. [EPA-HQ-OAR-2019-0055-1203-A1, p. 87]

Today, the OBD "MIL-ON" emissions threshold requirement of 0.40 g/bhp-hr is 33% above the in-use NOx NTE standard of 0.30 g/bhp-hr. Since emissions rates during an NTE window tend to be lower than during the FTP, the provision that permits a manufacturer to exclude a vehicle from testing if it has an active fault effectively avoids recruiting an engine with a fault-based emissions exceedance into the test plan. Under the proposed Option 1 2031 MY requirements, however, the OBD MIL-on threshold of 0.40 g/bhp-hr is more than 13 times the medium/high bin in-use emissions standard of 0.030 g/bhp-hr. [EPA-HQ-OAR-2019-0055-1203-A1, p. 87]

Under current regulations, EPA clearly intends the in-use test program to be an assessment of a manufacturer's product conformance to applicable in-use standards when evaluated on properly functioning, well-maintained vehicles. That intention is clear from the vehicle recruiting practices that EPA requires under the current regulatory provisions of §86.1908, where a manufacturer "must" select vehicle/engine systems that "have been properly maintained" and "have not been tampered with, rebuilt, or undergone major repair." Importantly, among the conditions a manufacturer must satisfy is that "the engines do not have an illuminated MIL or stored OBD trouble code…" From the foregoing, it is abundantly clear that EPA did not intend for the in-use testing program to include vehicles with engines or aftertreatment systems that are operating in a manner inconsistent with manufacturers' design intent due to, among other things, an emissions-related component fault. [EPA-HQ-OAR-2019-0055-1203-A1, p. 88]

There are other provisions within the HDOH emissions regulations that serve to ensure that manufacturers have designed adequately robust components and systems for emissions control purposes (see emissions related warranty provisions proposed at §1036.120 and emissions defect reporting requirements at §1068.501.) The in-use testing program is clearly intended to confirm that manufacturers have designed and calibrated their properly-functioning products for compliant emissions control, which is why EPA requires that manufacturers confirm that recruited vehicles are properly maintained, without active diagnostic codes, and so on. The proposed in-use low-NOx standards, however, would work in contravention of that fundamental premise of excluding vehicles experiencing emissions-related component issues, simply due to the fact that current OBD systems cannot detect faults until emission levels significantly exceed the proposed in-use low- NOx standards. [EPA-HQ-OAR-2019-0055-1203-A1, p. 88]

The graphics below illustrate the difference between today's situation and the significantly expanded region of risk manufacturers would face under the proposed amendments. The area in yellow depicts the range of emissions a vehicle may exhibit without a MIL-ON condition, but which could produce a failing result of the in-use test. [EPA-HQ-OAR-2019-0055-1203-A1, p. 88]

To further illustrate the undue risk a manufacturer would face, consider the hypothetical example represented graphically below. In this example, an in-use test order has compelled testing of five vehicles, the fourth of which is experiencing a fault condition that has resulted in a Bin 3 NOx exceedance of 0.130g/bhp-hr (a level undetectable by the OBD system). The failure resulted in a sixth vehicle test which, in this example, failed the 3B-MAW requirements due to a minor NOx failure in Bin 1 or Bin 2, or perhaps a minor exceedance of another constituent. The manufacturer would be compelled to test four more vehicles in this case, and average each bin's NOx emissions from all ten vehicles (see proposed §1036.245). The Bin 3 NOx results for the ten vehicles in the example are as represented in the chart below. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 88 - 89]

With the exception of a single vehicle exceeding the Bin 3 NOx limit due to a component issue, and a second vehicle having a potentially minor exceedance in another bin or of another constituent, the engine family in this example is exhibiting excellent emissions control. However, because the average Bin 3 emissions exceeds the 0.030g/bhp-hr NOx limit, solely due to the fault-driven exceedance measured on vehicle 4, the family would not meet the requirements of the proposed family pass/fail criteria of §1036.425. Today, an exceedance of a percentage-magnitude like that exhibited by vehicle 4 would have excluded the vehicle from the in-use emissions assessment consistent with EPA's specific intention. That will change dramatically. The bottom line is that the proposed provisions would subject manufacturers to an increased risk of family-level failure, yet, at the same time, EPA is proposing even stricter family pass/fail criteria. That is untenable. [EPA-HQ-OAR-2019-0055-1203-A1, p. 89]

While it is true that the PEMS measurement accuracy provisions would change the arithmetic in the example above, it would not change the basic concerns with the outcomes. Indeed, the current 0.45g/bhp-hr measurement allowance-adjusted NTE limit is above the 0.30g/bhp-hr NTE NOx standard, providing almost complete assurance of excluding vehicles with engines experiencing an emissions-related fault, just as EPA intended. In contrast, EPA's proposed PEMS NOx accuracy margin of 10% of the standard (§1036.420(a)(4)), a mere 0.003g/bhp-hr in the case of the Bin 3 standard, would imperceptibly influence the pass/fail outcomes in the example above. It is important to recognize that the measurement allowances are not directly integrated into the relevant in-use standards. They are instead a means to compensate for potential measurement error, avoiding the case where a manufacturer's compliant product is incorrectly determined to be non-compliant simply due to weaknesses in state-of-the-art in-use measurement systems. [EPA-HQ-OAR-2019-0055-1203-A1, p. 89]

There is, then, a very real probability that a vehicle with a faulty or somewhat deteriorated component, a vehicle which EPA found important to exclude from in-use testing when designing the current in-use test program, could be recruited so as to cause, almost on its own, a family failure determination. The only question is the magnitude of that probability. The harsh reality is we do not know, nor does the Agency know, how the introduction of a much more complex technology package, being assessed with a new and very different in-use protocol, at extremely stringent levels, will impact that probability. But what we do know is that it is unrealistic and unreasonable to tighten the family pass/fail criteria in light of this significantly elevated risk. [EPA-HQ-OAR-2019-0055-1203-A1, p. 90]

As noted above, the NOx emission-assessment capabilities of current OBD systems and sensors could frustrate the implementation of EPA's proposed in-use low-NOx standards. Simply stated, current OBD systems and sensors are not capable of detecting and flagging emission exceedances at the proposed low-NOx levels. [EPA-HQ-OAR-2019-0055-1203-A1, p. 93]

Additional OBD issues also arise under the proposed regulations. EPA has rightly acknowledged that the multiple HD OBD requirements amount to real constraints on lowering emission standards, and that revising the current HD OBD requirements and monitoring thresholds as they would scale-down to the proposed low-NOx standards (i.e., at 2.0 x 0.020 g/bhp-hr) would further hinder the implementation of the technologies and multiple aftertreatment components necessary to achieving the types of low-NOx targets that EPA seeks to mandate. To mitigate that effect, EPA is proposing to leave the OBD thresholds where they are. (See 87 FR at p. 17527.) [EPA-HQ-OAR-2019-0055-1203-A1, pp. 93 - 94]

However, it still is not clear at what level of emissions impact a component will need to be measured by OBD systems to determine whether or not it has a meaningful impact on emissions. While that criteria is currently not measured directly against the emissions standard (e.g., a % of the NOx standard) it is often used as an informal metric of emissions impacts from a component failure. With the new proposed Option 1 NOx standards set to 0.020g/bhp-hr, a component failure that could have been considered to have no significant impact on emissions might now be considered significant if it approaches the level of the NOx standard. That could cause the new regulations to have a significant impact on OBD development costs and feasibility, even though EPA intends to keep the HD OBD standards as they are. This is yet another factor that shows the impracticality and infeasibility of the Option 1 requirements. [EPA-HQ-OAR-2019-0055-1203-A1, p. 94]

Even with respect to Option 2, it is very important for EPA to consider fully all of the impacts that the Low-NOx regulations will have on the myriad HD OBD requirements, and all of the necessary OBD revisions that should be included in the relevant OBD regulations. That necessary consideration will help to promote the implementation of revised HD OBD regulations in the future that do not frustrate the implementation of the Low-NOx Regulations. [EPA-HQ-OAR-2019-0055-1203-A1, p. 94]

As noted, EPA has tried to account for the technical infeasibility of scaling-down the OBD thresholds in a similar manner to the proposed reduced emission standards by maintaining the OBD thresholds at their current levels — e.g. 2x the existing NOx standard, and an additive 0.020 g/bhp-hr to their existing PM standard, for final OBD thresholds of 0.40 g/bhp-hr for NOx; and 0.030 g/bhp-hr for PM. However, the current in-use emissions standards also are tied to the certification-cycle emissions standards — e.g. 1.5 x the FTP NOx-threshold is the current NTE/In- Use emissions testing threshold. Today, that approach for correlating test-cell standards to in-use testing standards leads to an in-use NTE standard of 0.30 g/bhp-hr NTE NOx, with a 0.15g/bhp-hr additive measurement allowance, for an aggregate in-use NOx limit of 0.45 g/bhp-hr. The corresponding result, with respect to today’s standards, is an effective OBD NOx threshold of 0.40 g/bhp-hr, at which failed components must be detected and diagnosed. That currently leaves a small gap (0.05 g/bhp-hr) between the two emission values, where a component is required to be diagnosed, before a vehicle equipped with such a component could fail the PEMS-assessed in-use NTE standards. [EPA-HQ-OAR-2019-0055-1203-A1, p. 94]

Under the proposed new low-NOx standards, however, the in-use NOx standard would be lowered substantially, to 1.5x an Option 1 standard of 0.020 g/bhp-hr, with a corresponding OBD NOx threshold (if not adjusted) of 0.040 to 0.100 g/bhp/hr. The in-use PM standards would be similarly reduced. EPA acknowledges that it is impossible to diagnose emission thresholds at those values, and therefore would not require it for OBD at this juncture, but nonetheless is leaving the issue open for a potential tightening of the OBD thresholds through a follow-on OBD rulemaking. It is unrealistic to expect that OBD systems, strategies and calibration schemes will advance to the extent that EPA's proposed low-NOx standards might necessitate. If a manufacturer cannot diagnose an emissions-control system at such a low NOx level, then guaranteeing emissions performance at such low levels is inherently infeasible. EPA must take this into account fully before finalizing any new in-use emission standards. In that regard, EPA also should respect its own longstanding position that manufacturers should not be required to implement technologies that they cannot diagnose. Option 1 is clearly untenable in this regard. The Option 2 standards will still need to be adjusted upward to account for these issues. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 94 - 95]

EPA Summary and Response

Summary:

Daimler, PACCAR, and EMA comment that increasing the stringency of in-use standards will create a gap between the detection capabilities of OBD systems have and the in-use testing thresholds. They state that this affects in-use testing because, with the current in-use testing thresholds, it is likely that the OBD system would identify systems with incipient failure so these systems can be screened out before being tested. With the new lower in-use testing thresholds, there could be vehicles with failed emissions systems where emissions exceed in-use testing standards, but do not trigger the OBD diagnostic threshold.

PACCAR further comments that it is infeasible to lower the OBD diagnostic thresholds to a range which would be effective in screening out these faulty systems. They also state that the discrepancy between in-use testing standards and the OBD diagnostic threshold indicates that pass/fail metrics should accommodate more non-passing engines.

Response:

EPA disagrees with commenters that off-cycle standards or in-use testing should be adjusted because of the gap between OBD sensing capabilities and the off-cycle standards. EPA would like to point out that the current NTE standards were put in place well before the existence of OBD requirements for HD highway engines. The capability of emissions control diagnostics (which the statute left to the Administration's discretion to promulgate regulations for HD) should not dictate the stringency of the emission standards set under 202(a)(3). It is up to the manufacturer to devise a way to ensure that the engine and aftertreatment are functioning properly when verifying in-use compliance with the off-cycle standards.

11.4.3 Language clarifications

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

CARB staff has concerns with the addition of 1036.405(a)(3) because the language seems to conflict or contradict with 1036.405(c). In subsection (a)(3), the language states engine families with production volumes less than 100 would not be selected for testing. In subsection (c), it states any engine family regardless of sales volume may be selected for testing. CARB staff believes the current language already helps manufacturers when they have difficulty obtaining test engines of small families. In the history of the HDIUT program, CARB and U.S. EPA have never selected an engine family with a production volume of 100 or less. Thus, CARB staff does not understand why U.S. EPA is proposing this change and recommends keeping the current production volume provisions. Also, it is important that U.S. EPA has the ability to conduct in-use testing of all engines, so the regulatory language should make that clear. [EPA-HQ-OAR-2019-0055-1186-A2, p.63]

CARB staff supports U.S. EPA's proposal to remove the sentence in 1036.405(b): We will consult with you in reaching a conclusion whether clear evidence of a nonconformity exists for any engine family. If U.S. EPA has clear evidence of nonconformity as described in this subsection, then there is no need to consult with the manufacturers in selecting the particular engine family for in-use testing. Consulting with the manufacturer on engine families with clear non-compliance is not necessary and only serves to delay timely corrective action. [EPA-HQ-OAR-2019-0055-1186-A2, p.63]

CARB staff has concerns with the consistency of the applicability of 40 CFR part 86, subpart T. In 1036.601(b)(4), subpart T will continue to apply for 2026 and later model year engines. However, in 1036.401, subpart T will continue to apply for year 2026 and earlier engines. CARB staff suggests having the two sections being consistent where the 40 CFR part 86, subpart T would apply to 2026 and previous model year engines, and the requirements in 1036.401 apply for 2027 and later model year engines. [EPA-HQ-OAR-2019-0055-1186-A2, p.65]

Organization: *Truck and Engine Manufacturers Association (EMA)*

EPA describes the proposed pass/fail criteria for an individual test article in §1036.420. The engine passes the requirements if the bin emissions result is equal to or less than the relevant bin standard for each constituent after accounting for the relevant measurement allowances. EMA recommends that EPA describe the sum of the in-use standards and their relevant measurement allowances as in-use "thresholds," to avoid confusion with the in-use standards. This would be consistent with the current practice related to NTE in-use standards and thresholds as described in §86.1912. The proposed §1036.420(c) refers to "windows" and "valid windows" interchangeably, without defining what characteristics provide for a valid window. Also §1036.420(d) provides that, "having no valid bins for a bin category over a shift-day does not disqualify an engine from pass-fail determinations under this paragraph (d)." It is unclear what EPA's intention is with provision. It is unclear what a "bin category" is, or what it means to "disqualify a vehicle from pass-fail determination under this paragraph (d)", where the cross-reference to paragraph (d) is unclear. EMA needs to have the opportunity to understand the intention behind this provision before we can comment further. [EPA-HQ-OAR-2019-0055-1203-A1, p. 93]

Overall, the various requirements that EPA has proposed regarding manufacturers' interaction with EPA in completing an in-use test order are reasonable and well stated. That said, the foregoing recommendations need to be implemented in the final rule. [EPA-HQ-OAR-2019-0055-1203-A1, p. 93]

EPA Summary and Response

Summary:

CARB has three separate comments:

1. They state that §1036.405(a)(3) seems to conflict with §1036.405(c), where one section states that engine families with production volumes less than 100 would not be selected for testing, and the other states any engine family regardless of sales volume may be selected for testing. CARB recommends keeping the current production volume provisions.
2. They support EPA's proposal to remove the sentence in §1036.405(b): 'We will consult with you in reaching a conclusion whether clear evidence of a nonconformity exists for any engine family.' CARB states that there is no need to consult with the manufacturers if evidence of non-conformity exists, and such consultation only serves to delay corrective action.
3. CARB notes that there appears to be an inconsistency between §1036.601(b)(4) and 1036.401, where the former states that part 86, subpart T will continue to apply for 2026 and later model year engines and the latter states that subpart T will continue to apply for year 2026 and earlier engines. CARB recommends that subpart T apply to 2026 and previous model year engines, and the requirements in §1036.401 apply for 2027 and later model year engines.

EMA has three comments:

1. To avoid confusion, they recommend the use of the term "threshold" rather than "standard" when referring to the sum of the in-use standards and their relevant measurement allowances.
2. They comment that the term "valid windows" is used without definition.
3. They comment that the statement in §1036.420(d) that, "having no valid bins for a bin category over a shift day does not disqualify an engine from pass-fail determinations under this paragraph (d)" is unclear, as "bin category" is undefined, and the reference to "paragraph (d)" is unclear.

Response:

EPA agrees with the commentor that proposed 40 CFR 1036.405(a)(3) appears to conflict with proposed 40 CFR 1036.405(c). EPA's intent in proposed 1036.405 was to exclude from selection engine families from a given model year if the manufacturer's total U.S.- directed production volume was less than 100 engines. We based the drafting of the proposed 40 CFR 1036.405 on 40 CFR 86.1905, which did not include the 100-engine production volume exemption. When we added the exemption into 40 CFR 1036.405(a)(3), we wrongly assumed that the engine family selection limit in 40 CFR 1036.405(c) would also cover the production volume limit in 40 CR 1036.405(a)(3). This was an oversight and to correct the mistake, we have modified the final 40 CFR 1036.405(c) from the proposed text to read as follows: "We may select any individual engine family for testing, regardless of its production volume **except as described in paragraph (a)(3) of this section**, as long as we do not select more than the number of engine families described in paragraph (a) of this section. We may select an engine family from model year 2027 or any later model year." We believe this exclusion is appropriate due to the additional burden associated with manufacturers trying to locate vehicles to test for engines with extremely low production volume.

EPA thanks the commentor for their comment regarding 40 CFR 1036.405(b).

EPA agrees that we should clarify in 40 CFR 1036.601(b)(4) how manufacturers transition to meeting the in-use testing requirements under 40 CFR 1036.401. EPA's intent in the proposed part 86 migration to part 1036 regarding part 86, subpart T, was that part 86, subpart T, would apply to model year 2026 and previous engines, unless a manufacturer chose to meet the exhaust emission standards under 40 CFR part 1036 before model year 2027. In addition, the intent was that part 86, subpart T, would no longer apply beginning with model year 2027 engines, unless a manufacturer chose to certify engines through model year 2029 to the part 86 criteria standards under the limited production allowance. We have modified the final 40 CFR 1036.601(b)(4) to make it clear that part 86, subpart T, applies for engines subject to criteria exhaust emission standards under 40 CFR part 86. The requirements in 40 CFR 1036.401 apply for all engines certified to meet the criteria exhaust emission standards under 40 CFR part 1036.

EPA disagrees with the commentors suggestion that "standard" should be replaced with "threshold" when talking about the in-use off-cycle standard plus any relative accuracy margin to account for in-use testing variability. The in-use off-cycle standard that must be met under the HDIUT program is the in-use off-cycle standard from 1036.104 plus the PEMS accuracy margin from 40 CFR 1036.420.

EPA agrees that there is arguably inconsistency in the proposed requirements' use of "valid" when it applies to windows as for all intents and purpose, all windows are "valid". Only data that is excluded from a window because it meets the exclusion criteria in 40 CFR 1036.530(c)(3) is really "invalid". Since part 1036 never talks about invalid windows, we will delete all occurrence of "valid windows" and replace with "windows".

The commentor requested clarification on the intent of proposed 40 CFR 1036.420(d). The intent of the last sentence was to state that a pass/fail is still determined for the engine, even if all of the bins are not valid because one or more of the bins does not contain enough windows. We note, however that 40 CFR 1036.420(d) requires you to test over additional shift days until the minimum number of windows is achieved for all bins. The last sentence in 40 CFR 1036.420(d) that the commentor requested clarification on serves no purpose because you will always test until you obtain the minimum number of windows for all bins. We have deleted the last sentence in 40 CFR 1036.420(d) (now 40 CFR 1036.420(e) with revisions from proposal to the section).

11.4.4 Other comments on selecting engines and vehicles.

<u>Comments by Organizations</u>

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

Daimler Truck Requests Clarification on the Proposed Changes to 40 C.F.R. 1036.235(a) Concerning Demonstration Engine Selection. [EPA-HQ-OAR-2019-0055-1168-A1, p.70]

EPA proposes to modify Section 1036.235(a) to merge the regulatory requirements for selecting test engines for criteria pollutant and GHG emission testing into one section. EPA's proposed modifications would require manufacturers to 'select and configure a single emission data engine from each engine family.'91 For criteria pollutant emission testing, Section 1036.235(a)(1) would require manufacturers to select the engine configuration most likely to exceed (or have emissions nearer to) an applicable emission standard for FEL identified in Section 1036.205(e)(1).92 For GHG emission testing, Section 1036.235(a)(1) would provide that the standards of Part 1036 apply with respect to emissions measured from 'this tested configuration.'93 Read together, these proposed changes to Section 1036.235(a) would require that manufacturers use a single engine—and specifically, the worst case engine for applicable criteria pollutant emission standards—for both criteria pollutant and GHG emission testing. [EPA-HQ-OAR-2019-0055-1168-A1, p.70]

91 Proposed Rule, 87 Fed. Reg. at 17,680 (proposed 40 C.F.R. 1036.235(a)).

92 Id. (proposed 40 C.F.R. 1036.235(a)(1)).

93 Id. (proposed 40 C.F.R. 1036.235(a)(2)).

Such a requirement would change how most manufacturers select demonstration engines, as we interpret current regulations to accommodate the use of engines with different ratings and configurations for testing under the criteria pollutant and GHG emission standards.94 Under the proposal, if the engine selected for criteria pollutant testing must also be used for GHG testing, manufacturers may end up having to test a significantly worse-performing engine for their CO_2 demonstrations, which would effectively increase CO_2 stringency. If, for example, the 'worst-case' engine for criteria pollutant emission testing is a manufacturer's lowest-horsepower engine, the manufacturer would be required to demonstrate that engine for GHG testing. If this engine has higher CO_2 emissions than an engine from the same family that would otherwise be selected for GHG demonstration under the current program (for example, as a function of reduced cycle work), the manufacturer would have to declare a higher FEL for the relevant engine family. We request clarification that this is not the intent of the proposed changes—or, if this is the intent, we request that EPA explain why it believes that this that these proposed changes are warranted and how they factored in to EPA's determination that the proposed new standards, as a whole, are achievable. Assuming that the change described above was not intentional, Daimler Truck submits that the proposed modifications to Section 1036.235(a) could be changed slightly, to read as follows:

(a) Select and configure a single emission-data engine from each engine family for both criteria pollutant emission testing and greenhouse gas emission testing, as described in this subsection.

(1) For criteria pollutant emission testing, select the engine configuration most likely to exceed (or have emissions nearer to) an applicable emission standard or FEL identified in 1036.205(l)(1). To the extent we allow it for establishing deterioration factors, select for testing those engine components or subsystems whose deterioration represents the deterioration of in-use engines.

(2) For greenhouse gas emission testing, select an engine configuration for demonstration. T~~t~~he standards of this part apply only with respect to emissions measured from ~~this~~ the testing~~ed~~ configuration that you select and other configurations identified in 1036.205(1)(2). Note that configurations identified in 1036.205(1)(2) are considered to be 'tested configurations' whether or not you test them for certification. However, you must apply the same (or equivalent) emission controls to all other engine configurations in the engine family. In other contexts, the tested configuration is sometimes referred to as the 'parent configuration', although the terms are not synonymous. This configuration may be, but is not required to be, the same configuration identified in 1036.235(a)(l). [EPA-HQ-OAR-2019-0055-1168-A1, pp.70-71]

> 94 As EPA explains in the Proposed Rule, '[i]n general,' the migration of criteria pollutant regulations for MY 2027 and later engines from their current location in Part 86 to Part 1036 'is not intended to change the compliance program previously specified in part 86, except as specifically proposed in this rulemaking.' Id. at 17,426

Organization: *PACCAR, Inc (PACCAR)*

Proposed section 1036.410(c) would require the manufacturer to notify EPA 'before disqualifying any vehicle.' PACCAR seeks clarification that this proposal is a reporting requirement, as opposed to a statement that the disqualification is contingent on EPA approval. [EPA-HQ-OAR-2019-0055-1346-A1, p.55]

Organization: *Truck and Engine Manufacturers Association (EMA)*

EMA recommends that EPA permit manufacturers to install an "activity monitor," a physical device, on a test-candidate vehicle, where the device is capable of collecting data that determines bin-counts in each bin for that vehicle, and any additional information that would be helpful to the vehicle-recruiting process. The device could be prohibited from collecting any emissions data. Such an activity-assessment tool will improve a manufacturer's chances of recruiting vehicles that will successfully meet the bin-count requirements without multiple days of testing. EMA is available to help develop the complete list of acceptable activity-based parameters. [EPA-HQ-OAR-2019-0055-1203-A1, p. 91]

In proposed §1036.415(b)(1), EPA maintains the options to deal with a vehicle that has an illuminated OBD MIL or stored trouble code. Those options are fully appropriate because, as stated in the previous section, EPA's intention with the manufacturer-run in-use test program is to assess emissions compliance on vehicles with "healthy" emissions control systems, operating according to manufacturers' design intent. However, EPA stipulates that, "You may disqualify the vehicle only if MIL illumination or trouble code storage exceeds 12 hours." There is no reasonable justification for this minimum 12-hour constraint to be a condition for excluding such a vehicle from testing. If the OBD system has identified a component or system issue for which the manufacturer is compelled (by EPA's OBD regulations) to illuminate the MIL, why is the duration of the MIL illumination, or the time since a trouble code was stored, a material issue at all? A fault is a fault, regardless of whether it was identified one hour ago or 12 days ago. The emissions control system should be deemed as being in a compromised condition, so it should be disqualified from testing. Accordingly, EPA should not include the sentence regarding the 12-hour minimum condition in the final regulation. [EPA-HQ-OAR-2019-0055-1203-A1, p. 92]

EMA also recommends that a manufacturer be permitted to test a vehicle for more than a single test-day, even if all the requirements for a valid test are fulfilled at the end of the first test-day. Vehicle emissions can vary from one day to the next, subject to influences of ambient conditions, traffic conditions and, most especially, vehicle operation. With this degree of variability, it is conceivable that, on a given (first) test-day, a vehicle could have operated at the high end of its variable emissions performance. Supplementing the data with additional test-days could provide a more comprehensive view, a more representative picture of the vehicle's overall on-road emissions performance. For this reason, EMA recommends that manufacturers be permitted to conduct additional testing if the manufacturer elects to do so. Today, there is a similar provision in §86.1910(h), where EPA permits that, "You have the option to test longer than the two shift-day period described in paragraph (g) of this section." In a similar spirit, EMA recommends that proposed §1036.415 be revised to include a provision that additional test-days will be permissible at the manufacturer's discretion, whether the vehicle has passed or failed the in-use requirement at the end of any test-day. All additional data accumulated would be combined with, rather than replacing, earlier test-days' data. [EPA-HQ-OAR-2019-0055-1203-A1, p. 92]

EPA Summary and Response

Summary:

Daimler requests clarification on the process of merging the regulatory requirements for selecting test engines for criteria pollutant and GHG emission testing. They state that the process described appears to require the same engine be tested for both the criteria pollutant and GHG emission standards, which would effectively increase CO_2 stringency compared to the current process.

PACCAR requests clarification on whether the requirement that the manufacturer notify EPA 'before disqualifying any vehicle' is a reporting requirement, as opposed to a statement that the disqualification is contingent on EPA approval.

In their comments, EMA provided three recommendations:

1. EMA recommends manufacturers be permitted to install an "activity monitor" on candidate HDUIT vehicles to determine bin counts, and thus improve the chances of recruiting vehicles that will successfully meet the bin-count requirements without multiple days of testing.

2. EMA recommends that manufacturers be permitted to test a vehicle for more than a single test-day, even if all the requirements for a valid test are fulfilled at the end of the first test-day, to provide a more comprehensive view of vehicle performance if the first shift day has emissions on the high end of the variability range.
3. EMA recommends removing the condition that vehicles with MIL illumination can be disqualified only if MIL illumination or trouble code storage exceeds 12 hours.

Response:

EPA acknowledges the request for clarification from Daimler regarding the apparent proposed requirement to select and configure a single emission data engine from each engine family for criteria and GHG emission testing. It was not EPA's intent to require the same emission data engine for both criteria and GHG testing. We have modified the final 40 CFR 1036.235 from proposal to make it clear that the manufacturer can use separate emission data engines for testing criteria and GHG emissions.

EPA acknowledges the requests for clarification from PACCAR regarding proposed 40 CFR 1036.410(c), specifically whether the requirement that the manufacturer notify EPA 'before disqualifying any vehicle' is a reporting requirement, as opposed to a statement that the disqualification is contingent on EPA approval. As proposed, the final 40 CFR 1036.410(c) requirement is a reporting requirement. If EPA has any concerns with the disqualification of the vehicle, we intend to follow-up with the manufacturer.

EPA disagrees with EMA's recommendation to allow the installation of an activity monitor. This would allow manufacturers to sort through the duration and relative position of each operational mode and identify vehicles with the highest probability of maintaining aftertreatment temperatures over the shift day. Furthermore, EPA also disagrees with EMA's recommendation that manufacturers be permitted to test a vehicle for more than a single test-day, even if all the requirements for a valid test are fulfilled at the end of the first test-day. Adopting this recommendation would likely dilute the stringency of the rule, as manufacturers would be most likely to extend testing on those vehicles which have failed the first day's testing.

EPA agrees with EMA's recommendation to remove the condition from 40 CFR 1036.415(b)(1) that vehicles require a MIL illumination or trouble code storage of longer than 12 hours. Manufacturers may disqualify a vehicle for a MIL illumination of any time frame.

11.5 HDIUT (Preamble III.C.5.ii)

11.5.1 Elimination of Phase 1 testing

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

U.S. EPA requested comments on elements of the Heavy Duty in-use testing program. CARB staff supports the proposed changes to the HDIUT program of removing the HDIUT Phase 2 testing requirements in 40 CFR 86.1915 and the biodiesel fuel blend provisions in 40 CFR 86.1908(a)(6). These elements were also removed for 2024 and newer model year engines in the Omnibus regulation.128 [also in 11.2.1] [EPA-HQ-OAR-2019-0055-1186-A2, p.60]

128 https://ww2.arb.ca.gov/rulemaking/2020/hdomnibuslownox

The removal of Phase 2 testing would decrease the time to initiate corrective action for discovered non-compliance under the proposed HDIUT Phase 1 testing. The emission averaging of Phase 1 test engine bin emissions provides manufacturers an additional safeguard that eliminates the need for performing Phase 2 testing for confirming engine family non-compliance. [EPA-HQ-OAR-2019-0055-1186-A2, p.60]

Organization: *Navistar, Inc. (Navistar)*

EPA did not thoroughly evaluate the feasibility of the proposed rule with respect to its proposal for a new method for "binning" and evaluating in-use NOx emissions. The method uses a second-by-second moving-average window approach, with 300-second windows for collecting in-use NOx emissions, and a so-called 3-bin approach for evaluating in-use emissions based on average normalized CO2 rates (the "3B-MAW" protocol). The 3 bins are Bin 1 (Idle), Bin 2 (Low Power), and Bin 3 (Medium/High Power). As explained in EMA's comments, currently, if a manufacturer "fails" what is referred to as the "Phase 1" in-use testing of up to ten vehicles, then "Phase 2" testing is triggered, which can lead to a number of follow-up measures, but which does not automatically lead to engine recalls. The existing in-use testing requirements would change dramatically under the proposed rule. Under EPA's 3B-MAW proposal, "Phase 2" testing would be eliminated, and compliance would be assessed on the basis of the in-use test results from up to ten engines, which would likely lead to recall orders. [EPA-HQ-OAR-2019-0055-1318-A1, p. 4]

As a result, EPA's new 3B-MAW in-use compliance protocols effectively become the new emissions standards. This approach is unworkable. It underscores the need for EPA to include adequate compliance margins in the applicable NOx certification standards. It also demonstrates the infeasibility of the 3B-MAW standards under an Option 1 scenario, in which the in-use standards are equivalent to the emissions-detection capabilities of portable emissions-measurement systems ("PEMS"), and an order-of-magnitude below the malfunction-detection capabilities of the latest on-board diagnostic ("OBD") sensors and systems. [EPA-HQ-OAR-2019-0055-1318-A1, p. 4]

Organization: *Truck and Engine Manufacturers Association (EMA)*

The ramifications of the infeasible elements of the proposed off-cycle standards are further heightened due to the fact that the Agency is proposing to convert the in-use testing program into a de facto strict liability protocol. Currently, if a manufacturer "fails" what is referred to as the "Phase 1" in-use testing of up to ten vehicles, then "Phase 2" testing is triggered, which can lead to a number of follow-up measures, but which does not automatically lead to engine recalls. That would change dramatically under the NPRM. More specifically, under the Agency's 3B-MAW proposal, "Phase 2" testing would be eliminated in its entirety, and compliance would be assessed solely on the basis of the in-use test results from up to ten engines. In other words, recall orders seemingly would follow automatically from what before would have been only the “Phase 1” testing. The Agency’s truncation and conversion of the in-use testing protocols into a strict liability program augments the risks and costs of implementing what already are infeasible Option 1 standards, and likewise substantially augments the need for the robust compliance margins referenced above. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 10 - 11]

The new in-use 3B-MAW protocol and its related standards are integral components of the efficacy of the proposed low-NOx regulations. Consequently, that in-use methodology needs to be thoroughly evaluated to demonstrate its suitability and feasibility as a robust and effective in-use emissions-performance metric. The need to ensure a fully feasible 3B-MAW in-use compliance program is compounded by EPA’s proposal to convert that program into one that leads, in effect, to strict liability and automatic recalls. Heretofore, there have been two phases of in-use testing. If an engine family does not meet the passing requirements of “Phase 1,” then, following discussions with the OEM, “Phase 2” testing of 10 additional vehicles could be required to assess potential problems with emission controls. Even after that Phase 2 testing, however, engine recalls would not be automatic. By contrast, under the pending 3B-MAW proposal, all Phase 2 testing would be eliminated, and the need for engine recalls would be premised on strict compliance (or not) with the Phase 1 “pass” metrics. [EPA-HQ-OAR-2019-0055-1203-A1, p. 48]

That is a fundamental change in the rigor and consequences of in-use testing. Those consequences are further compounded by the fact that the in-use program, as proposed, will not merely assess real-world compliance with the underlying certification standards. Rather, and as noted above, EPA’s new proposed in-use emission requirements would be, in effect, more stringent than the new certification standards, and would require additional aftertreatment hardware and additional engine development. (See 87 FR at p. 17475.) In sum, EPA is changing the paradigm of the HDIUT program, and is doing so in the context of Option 1 standards that are not achievable. The resultant recall risks and costs to OEMs will not allow for an implementable program if the Option 1 standards are finalized. [EPA-HQ-OAR-2019-0055-1203-A1, p. 48]

EPA has proposed other procedural changes to the HDIUT program that are just as significant and problematic as the proposed numerical in-use standards. Those procedural changes will need to be revised in order to allow for an implementable in-use testing program. [EPA-HQ-OAR-2019-0055-1203-A1, p. 85] As noted above, EPA is proposing to eliminate “Phase 2” in-use testing, and to convert the “Phase 1” testing into what amounts to a strict liability program. Given the multiple uncertainties associated with the new proposed in-use testing protocols, that is not reasonable. [EPA-HQ-OAR-2019-0055-1203-A1, p. 85]

Under the proposed re-write of the HDIUT program, “failures” of the current “Phase 1” HDIUT procedures (where 5 out of 5, 5 out of 6, or 8 out of 10 vehicles need to “pass” the in-use compliance metrics) would be sufficient on their own to support a finding of “non-comformity” or “noncompliance,” and thus, presumably, sufficient for EPA to compel an HDOH engine family recall. [EPA-HQ-OAR-2019-0055-1203-A1, p. 85]

EPA's proposed amendment of the HDIUT program would impose unreasonable risks of recall liability on manufacturers. The HDIUT program (codified at 40 CFR Part 86, Subpart T, §§86.1901-86.1935) is a program that resulted from a negotiated settlement of litigation that EMA filed in 2001 challenging EPA's authority to require that manufacturers test previously-sold nonnew vehicles no longer in the manufacturers' possession and control. (See 70 FR at 34597.) As a result of a duly approved settlement agreement between CARB, EPA, EMA and manufacturers (which settlement was subject to a thorough public notice and comment process), the parties developed and specified the terms of the HDIUT program. (Id., n.2.) [EPA-HQ-OAR-2019-0055-1203-A1, pp. 85 - 86]

As negotiated and agreed, the current NTE-based HDIUT program does not compel recall or other noncompliance liability solely on the basis of an engine family failing to meet the engine family "pass" critieria (where 5 out of 5, 5 out of 6, or 8 out of 10 in-use vehicles pass) as tested under "Phase 1" of the program. Instead, under the current negotiated regulations, EPA enters into further discussions with the manufacturers regarding the extent of any appropriate follow-up steps, which steps can include no further testing, additional targeted "Phase 2" testing, engineering studies, or, if deemed necessary, targeted remedial actions. The core concept is that any initial "failure" of Phase 1 testing is simply a trigger for further discussions and assessments, not a trigger for strict noncompliance liability. (See 70 FR at pp. 34595-96, 34598 and 34601.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 86]

In light of the foregoing, EPA's proposed establishment of a de facto strict-liability HDIUT program — with automatic recall liability for any "failed" Phase 1 testing — is contrary to the foundational agreements and terms that created the HDIUT program. EPA should not alter the current HDIUT testing and flexible enforcement scheme. [EPA-HQ-OAR-2019-0055-1203-A1, p. 86]

EPA Summary and Response

Summary:

CARB supports removing the HDIUT Phase 2 testing requirements, stating that the removal would decrease the time to initiate potential corrective action, and that the emission averaging contained in Phase 1 provides manufacturers an additional safeguard that eliminates the need for performing Phase 2 testing.

EMA commented that EPA's new proposed in-use emission requirements would be, in effect, more stringent than the new certification standards, and would require additional aftertreatment hardware and additional engine development.

EMA and Navistar comment that the elimination of Phase 2 testing would likely lead to more recalls. EMA further comments that the removal of Phase 2 testing will automatically trigger a recall in the case of a failure in Phase 1 testing, rather than triggering further discussions and assessments. EMA stated that recall orders seemingly would follow automatically from what before would have been only the "Phase 1" testing. EMA stated that the Agency's truncation and conversion of the in-use testing protocols into a strict liability program augments the risks and costs of implementing what already are infeasible Option 1 standards, and likewise substantially augments the need for the robust compliance margins referenced above. EMA and Navistar state that the risk of failure is further compounded by the in-use emission requirements, which are effectively more stringent than the certification standards, and would require additional aftertreatment hardware and additional engine development.

Response:

EPA agrees with CARB that the emission averaging provided for in the Phase 1 testing adequately safeguards manufacturers, and that reducing time to initiate a corrective action likely has positive environmental impacts. Moreover, the HDUIT process proposed would not lead to an "automatic recall," as stated by other commenters, but as in the current process, would instead trigger further discussions between the manufacturer and EPA on the subsequent steps, as described in Section III.C.5.ii of the preamble. EPA has no intention of altering the process after an engine family fails from that currently followed for the NTE-based HDIUT program. Under the binned MAW test procedure that EPA is finalizing in this action, an engine family failing to meet the engine family "pass" criteria outlined in 40 CFR 1036.425 does not trigger an "automatic recall." EPA intends to continue the current process where we enter into further discussion with the manufacturer regarding the extent of any appropriate follow-up steps. While this can include further testing, engineering studies, or, if deemed necessary, targeted remedial actions; it will not include another "Phase" of testing under the HDIUT program. Thus any "failure" under 40 CFR 1036.425 is a trigger for further discussions and assessments, not a trigger for strict noncompliance liability.

EPA disagrees with EMA that the final in-use off-cycle standards would be, in effect, more stringent than the new certification standards. We acknowledge that complying with off-cycle standards is more challenging than meeting duty-cycle standards as there is more operational coverage off-cycle. We have taken this into account when setting the stringency of the off-cycle standards, including the conformity factor that was applied to the duty-cycle standards to arrive at the off-cycle standards. We have also included a PEMS accuracy margin on top of the off-cycle standards to account for the variability of field testing. Off-cycle standard field testing includes low ambient temperature operation which will require low temperature calibration, but as described in preamble Section III.C the numeric level of the off-cycle NO_x standards increase at lower temperatures based on EPA's consideration of the higher emissions performance of the EPA Stage 3 engine under low ambient temperature. As further discussed in Section III of the preamble, we have included an interim in-use compliance allowance for Medium and Heavy HDEs to account for additional in-use uncertainties from these engines at the final useful life values. For further discussion of feasibility and the considerations EPA took into account in setting the standards, see preamble Section III.

11.5.2 Pass criteria for engine families

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

CARB staff has concerns with the engine family compliance determination based only on the case of average of the sum-over-sum emissions of the ten tests. There could be cases where three or more tests fail for the same pollutant and same bin. Consistent deficiency for the same pollutant and bin is indicative of a defective emission control component causing non-compliance. CARB staff suggests adding language similar to what was adopted in the Omnibus regulation. An engine family is deemed to be noncompliant if the Phase 1 sum-over-sum emissions of the same pollutant and same bin exceed the off-cycle standards for three or more tests.' [EPA-HQ-OAR-2019-0055-1186-A2, p.64]

Organization: *PACCAR, Inc (PACCAR)*

Pass/Fail Determination – Under the current HDIUT program, if the MIL lamp is not illuminated then a passing HDIUT test result is almost guaranteed because the OBD emissions limit is similar to the in-use emissions limit, which allows the bar to be set relatively high to pass a test program. Beginning in MY 2027, EPA is proposing the same pass/fail thresholds of 5 out of 5 tests, 5 out of 6, and new for MY 2027 the program can be passed with the average of 10 test (for all bins and for all pollutants). This approach is flawed because the off-cycle standard is set far below the capability of OBD systems and within the range of expected in-use variation. PACCAR believes that this should be recognized with Pass/Fail metrics that accommodate more non-passing engines. Metrics of 4 out of 5, 5 out of 7, or the average of 7 or more would be more appropriate. The manufacturer should be allowed to test more than 7, and after some number of engines it would be appropriate to begin a discussion with EPA about the reason for the extended testing. Otherwise, these HDIUT tests are generally quite disruptive to OEM customers' businesses. This disruption drives the need for earlier consideration of the average emissions results after testing 7 engines. Testing a greater number of engines the non-normal distribution should be considered. While we could have an outlier on the high side we can never have an outlier on the low side by any significant margin (since negative emissions are not possible). A single outlier on the right side of the spectrum could be difficult to overcome through averaging and drive the need to test more engines. [EPA-HQ-OAR-2019-0055-1346-A1, p.29]

The NPRM does not adequately describe the consequences of a non-passing outcome from initial testing. EPA should include a provision for a consultation with the EPA if the pass/fail metrics are not being met to reach a common understanding of the issue and to agree on further actions to investigate the root cause before determining that the engine family fails to meet in-use standards. If the engine family fails to meet in-use standards, there should be an interim provision allowing the manufacturer to cover the non-compliance with credits to allow time for manufacturers to gain experience with the statistical nature of the distribution of in-use emissions rates for new technologies and a new in-use protocol. There should also be certain permanent alternatives to recall for bringing an engine family into compliance. [EPA-HQ-OAR-2019-0055-1346-A1, pp.29-30]

PACCAR further encourages the EPA adopt: Pass ratio:

- 4 out of 5
- 5 out of 7
- Or average of 7 or more
- Need provision to allow consultation with EPA if Pass Ratio is not being met

- An interim provision that allows HDIUT non-compliance to be covered with NOx credits [EPA-HQ-OAR-2019-0055-1346-A1, p.31]

EPA's proposed engine family pass criteria framework should be amended and focus more on averaging. Specifically, the initial criterion should require that at least four of the five tested engines pass; if not, at least five of the seven tested engines should be required to pass. EPA should allow (i) OEMs to take the average in each bin for each pollutant, reducing from 10 to seven the number of engines used to determine the test result and (ii) if the average of seven is above the standard that the manufacturer may elect to test more engines as such a reduction in engine number would decrease burdens on the OEM. Off-cycle standards are set far below the level at which OBD systems are able to detect emission control system malfunctions, which will contribute to a wider spectrum of results. Therefore, PACCAR supports pass/fail metrics to accommodate more non-passing engines. [EPA-HQ-OAR-2019-0055-1346-A1, p.57]

Pass ratio:

- 4 out of 5
- 5 out of 7
- Or average of 7 or more
- Add provision to allow consultation with EPA if pass ratio is not being met
- Add an interim provision that allows HDIUT non-compliance to be covered with NOx credits [EPA-HQ-OAR-2019-0055-1346-A1, p.60]

Organization: *Truck and Engine Manufacturers Association (EMA)*

EPA proposes to establish two-stage NOx emissions standards for HHDE engines, where the second, higher standard is applicable to the later portion of useful life. These two-stage standards would apply to in-use emissions requirements as well. EPA's engine family pass/fail criteria under proposed §1036.425 involves, under certain conditions, averaging bin emissions from multiple vehicles. Those provisions, however, do not contemplate the possibility that some vehicles included in the test group may have mileages associated with the first-stage NOx standard, while others may have accrued mileages triggering the second-stage. As the two stages have distinct standards, it would not be appropriate to average their emissions as though they were compliant to a single unform standard. [EPA-HQ-OAR-2019-0055-1203-A1, p. 86]

EMA recommends that the provisions of §1036.425 be finalized to state that late-stage vehicles should have their emissions results reduced by multiplying them by the ratio of the first-stage standards to the second-stage standards before being averaged with the vehicles in the first-stage. This adjustment should be made after the applicable PEMS measurement accuracy allowance (proposed §1036.420) is added to the measured and calculated bin results. [EPA-HQ-OAR-2019-0055-1203-A1, p. 86]

EPA has proposed to modify the engine family pass/fail criteria that apply when a manufacturer has conducted an emissions compliance evaluation in response to an EPA in-use test order according to §1036.425. In addition to eliminating the option for "Phase 2" testing, EPA also is proposing to establish more strict requirements regarding the number of engines that must be demonstrated as meeting the emissions standards in order for the in-use test order to be satisfied. Because of the increased risk associated with the relationship between these new and more stringent in-use standards and current OBD detection capabilities, EMA recommends that the pass criteria be relaxed instead. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 86 - 87]

The family pass/fail criteria currently in place according to §86.1915 provide that a manufacturer should first test 5 vehicles equipped with engines from the engine family specified in the test order. If all 5 vehicles meet the minimum NTE pass-ratio, the manufacturer has satisfied the in-use test order, and may stop testing. If 1 or more of the 5 vehicles do not pass, however, a sixth vehicle must be tested. If after testing the sixth vehicle, 2 vehicles' results do not meet the minimum NTE pass-ratio, the manufacturer must test 4 more vehicles, for a total of 10 vehicles. If 8 out of the 10 vehicles have met the minimum pass-ratio, the test order has been satisfied, and the manufacturer may stop testing. If, however, at least 3 vehicles failed to meet the pass-ratio requirement, the manufacturer is obligated to enter into discussions with the agency concerning additional analysis, and potentially more testing. [EPA-HQ-OAR-2019-0055-1203-A1, p. 87]

To summarize the current family pass/fail criteria, a manufacturer can meet the requirements of the in-use test order if 5/5 ("5 out of 5"), 5/6, or 8/10 vehicles meet the NTE minimum pass-ratio. However, as noted, EPA's proposed amendments would impose stricter criteria for a determination that the test order has been satisfied. More specifically, while EPA has carried over the first two passing thresholds of 5/5 and 5/6, the passing threshold of 8/10 has been eliminated. EPA instead proposes that if a total of 10 vehicles are tested, the average emissions from all vehicles must be below the in-use standard for all bins and all constituents to meet the requirements of the in-use test order. EPA has thereby proposed to eliminate the condition that if 8/10 vehicles pass the in-use emissions requirements, the manufacturer's obligations under the test order have been satisfied, and no further testing required. [EPA-HQ-OAR-2019-0055-1203-A1, p. 87]

Importantly, these new, stricter pass/fail criteria are imposed simultaneously with the new 3B-MAW in-use emissions protocol and new very stringent standards. EMA believes that there are underlying conditions associated with the totality of the proposed amendments that make it unreasonable to impose stricter pass/fail conditions on the first phase of testing under an in-use test order. Those underlying provisions include the fact that, for each constituent, EPA has proposed 3 separate evaluations for compliance in the form of the 3 "bins" with distinct standards. [EPA-HQ-OAR-2019-0055-1203-A1, p. 87]

Considering the foregoing, EMA recommends that EPA relax, rather than tighten, the family pass/fail criteria under an in-use test order. Specifically, EMA proposes that EPA replace today's 5/5, 5/6 or 8/10 pass criteria with a passing condition at 4/5 or 5/7 vehicles. If more than 2 vehicles have failed the in-use test requirements after testing 7 vehicles, the manufacturer should be permitted test any number of additional vehicles, up to a total of 15 vehicles (including the original 7), until a passing condition is determined on the basis that the average result for each valid bin is at or below the standard (adjusted for PEMS accuracy) as described in §1036.420(d). At any point in the test program following the condition that more than 2 vehicles out of 7 have failed, the manufacturer should be permitted to initiate discussions with the Agency concerning options available to move forward with actions deemed appropriate by EPA. EMA recommends these “relaxed” family pass/fail criteria to address, at least in part, the increased risk and probability that a pre-MIL vehicle could be recruited into testing under an in-use test order. [EPA-HQ-OAR-2019-0055-1203-A1, p. 90]

EMA’s proposal is appropriate and fair considering all of the circumstances mentioned. If EPA were to simply retain the 5/5, 5/6 and 8/10 family pass/fail criteria in place with today’s in use test program, overly punitive outcomes would result. A second example makes this clear. Consider the hypothetical test order results below. After testing 10 vehicles, two vehicles (vehicles 4 and 9) have Bin 3 NOx exceedances of 0.040 and 0.050 g/bhp-hr, at least one of them due to a component failure not severe enough to be signaled by an OBD MIL, and a third vehicle has a mild exceedance in another bin or of another constituent. Even with an 8/10 pass threshold, this high-performing engine family would nonetheless fail the in-use test assessment. The Agency should seriously consider whether this level of in-use performance justifies the potential of an emissions-related recall, especially given the real possibility that the results will have been unknowingly influenced by a pre-MIL vehicle. [EPA-HQ-OAR-2019-0055-1203-A1, p. 90]

In light of the foregoing, EMA recommends that EPA implement the MY 2027 and later in-use program in a manner consistent with the current principles that restrict the in-use assessment to vehicles that are operating according to manufacturers’ design intent. The only way to protect against the increased risk manufacturers face given current OBD detection capabilities, a risk that puts the in-use testing program at odds with those long-standing principles, is to relax, rather than tighten, the engine family pass/fail criteria. EMA believes that our recommended pass/fail criteria would largely fulfill the preservation of those principles in a fair and reasonable manner. [EPA-HQ-OAR-2019-0055-1203-A1, p. 91]

EPA Summary and Response

Summary:

CARB comments that they have concerns with making an engine family compliance determination based only on the case of average of the sum-over-sum emissions of ten tests. Specifically, they comment that in some cases, multiple engines may fail the same pollutant in the same bin, indicating a defective emission control component. They recommend limiting the pass criteria so that an engine family is deemed to be noncompliant if the Phase 1 sum-over-sum emissions of the same pollutant and same bin exceed the off-cycle standards for three or more tests.

PACCAR and EMA comment that the discrepancy between the in-use standards and OBD diagnostic thresholds indicate that a more relaxed pass/fail criterion is warranted. They state that rather than pass/fail thresholds of 5 out of 5 tests, 5 out of 6, and the average of 10 tests, more appropriate thresholds would be 4 out of 5 tests, 5 out of 7 tests, or the average of 7 or more tests. For the last, EMA comments that, if the 5/7 threshold is failed, manufacturers should be able to test any number of vehicles up to 15 and average the result to demonstrate compliance.

Additionally, EMA comments that if late-stage vehicles with higher standards are included in testing, then the calculations for averaging emissions should be altered. Specifically, these vehicles should have their emissions results reduced by multiplying them by the ratio of the first-stage standards to the second-stage standards before being averaged with the vehicles in the first-stage.

Response:

EPA disagrees with commenters that more or less stringency in the proposed pass/fail criteria is warranted for the overall, long term HDIUT program's final pass/fail criteria. However, EPA believes that an interim approach with less stringent pass/fail criteria in the initial two years of the program is appropriate, as manufacturers transition to the final standards, test procedures, and requirements, while still providing overall compliance assurance during that transition. The final requirements for the HDIUT program's pass/fail criteria include a specified maximum number of test engines and, as proposed, the ability to average the results across the engines if the maximum number of engines are tested. For the MYs 2027 and MY 2028 interim provisions, the maximum number of test engines is 15. For MYs 2029 and later, we are finalizing as proposed that the maximum number of test engines is 10. For the overall long-term program in MYs 2029 and later, EPA believes this allows manufacturers sufficient opportunity to demonstrate effective aftertreatment systems without reducing the pass/fail thresholds for the five test engines and six test engines steps. EPA believes manufacturers should be able to demonstrate compliance with an average of 10 vehicles for MY 2029 and later, and only agrees the additional testing of five more vehicles is appropriate to allow for the first two years of the new standards when manufacturers are first transitioning into the final program. Regarding comments on changing the second step to five out of seven test engines passing, we believe that keeping the interim pass rate at 80 percent (eight out of ten test engines passing) between step one and two, versus going from 80 percent to 71 percent, is more appropriate, since with more tests there is more confidence that the tested engines represent the emissions performance of the whole family. See preamble section III for additional details regarding the first two steps of the final interim provisions and final overall provisions pass/fail criteria.

EPA also disagrees with CARB that failing three tests with the same pollutant in the same bin would indicate a failed result. If manufacturers are able to demonstrate compliance over the average of ten tests for the pollutant, the root cause is unlikely to be a defective emission control component.

Regarding EMA's comment about late-stage vehicles, the final emissions standards are a single step in MY 2027 and do not include an IUL standard, so this concern is not applicable to the final rule.

11.5.3 Onboard NO_x sensors

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

CARB staff supports opportunity for manufactures to meet in-use testing requirements through onboard NOx sensors data with approval of an alternative test plan with some concerns. Although CARB staff supports the requirements for NOx sensors to be on with 100 seconds of the engine starting and remaining functional the entire shift day, this could still miss the high emissions occurring during cold starts. Also, CARB staff has concerns with the accuracy, stability, and drift of current NOx sensors for determining in-use compliance. Specifications should be identified for the accuracy and stability of NOx sensors commiserate with the applicable standards. Additionally, there should be specifications for instrument drift of the NOx sensors. CARB staff suggests a minimum percentage of the vehicles reported emissions data and require any data collected by the manufacturer be submitted to U.S. EPA to avoid biased selection of data for submission. CARB staff supports a minimum of two test engines be tested with PEMS, as this would add data that includes cold start emissions and other criteria pollutant emissions. [EPA-HQ-OAR-2019-0055-1186-A2, pp. 63-64]

Organization: *Cummins Inc. (Cummins)*

EPA proposes in §1036.405(g) to allow manufacturers to request approval of an alternative test plan using onboard NOx sensors and telematics to collect emissions data from in-use engines instead of full reliance on PEMS data. It is uncertain how readily this option can be utilized given the stringent Part 1065 verification, startup, and continuous operation requirements for NOx sensors that are also proposed. However, Cummins is supportive of EPA contemplating such an approach. With improved sensor technology and more widespread use of telematics, the possibility exists for a future “new paradigm” of in-use compliance where data is gathered from a much broader population of in-use engines to provide a more complete picture of real-world emissions. Cummins intends to continue working with EPA and the rest of industry to explore such a concept. [EPA-HQ-OAR-2019-0055-1325-A1, p. 13]

Organization: *PACCAR, Inc (PACCAR)*

Second, proposed 1036.405(g) allows OEMs to use on-board NOx measurement system verification per 40 C.F.R. 1065.920(b) in lieu of PEMS testing. But it would be impossible for OEMs to comply with the requirements in 1065.920(b), including with respect to how long sensors would be required to function. Rather than codify this impossible-to-meet option, EPA should amend proposed 1036.405(g) and simply include the following language EPA has already proposed: ‘You must show us that the alternative program gives comparable assurance that your engines meet the NOx standards of this part.’ [EPA-HQ-OAR-2019-0055-1346-A1. p.55]

Organization: *Manufacturers of Emission Controls Association (MECA)*

In anticipation of tighter emission standards and longer durability requirements for heavy-duty trucks, manufacturers are improving the accuracy and durability of their sensors [55]. NOx sensors only operate above an exhaust temperature threshold to prevent water condensation and thermal shock of the ceramic element. This may make it difficult to measure NOx during low load and low speed operation. Manufacturers are developing more durable sensor designs and experimenting with sensor placement in the exhaust to minimize these limitations and extend the temperature range of their sensors and improve their durability. [EPA-HQ-OAR-2019-0055-1320-A1, pp.33-34]

[55] Y. Kawamoto, Y. Todo, H. Shimokawa, K. Aoki, M. Kawai and K. Ide, 'Development of High Accuracy NOx Sensor,' in SAE Technical Paper 2019-01-0749, 2019

MECA, CARB, EPA and EMA are participating in the Emission Measurement and Testing Committee (EMTC) sensor task force project at SwRI that is characterizing the sensor accuracy and capability to measure at ultra-low NOx levels that are 90% below current tailpipe concentrations. MECA is also a member of the On-Board Sensor Monitoring and Reporting Consortium (OSAR) along with EPA, CARB, SCAQMD, EMA and manufacturers. This program will evaluate emission monitoring, telematic reporting and sensor durability to assess their suitability for long-term compliance assurance. [EPA-HQ-OAR-2019-0055-1320-A1, p.34]

Organization: *Truck and Engine Manufacturers Association (EMA)*

Finally, EPA has introduced an option whereby manufacturers may use NOx sensor-based in-use test data instead of PEM-based emissions tests. EMA supports the interest to use on-board sensor technology in this manner. There are several issues that require consideration for this process to be workable, however, including how to account for NOx sensor accuracy, CO2 emissions estimation, the quantity of vehicles to be tested, the duration of the "test period" in question (the test-day equivalent), and others. EMA is nonetheless pleased with the opportunity to work with EPA between now and the final rule to develop workable solutions, if possible. [EPA-HQ-OAR-2019-0055-1203-A1, p. 93]

EPA Summary and Response

Summary:

All comments discussing EPA's proposal to allow the use of onboard NO_x sensors to supplement PEMS testing for in-use testing were generally supportive of the proposal with some qualifications.

CARB comments that they are concerned about the accuracy and drift of onboard NO_x sensors, and the potential to miss high emissions during a cold start. Therefore, CARB suggests EPA

1. identify appropriate specifications for onboard NO_x sensors,
2. require any data collected by the manufacturer be submitted to EPA to avoid biased results, and
3. require a minimum of two test engines be tested with PEMS to ensure some cold start data are collected.

Both PACCAR and Cummins comment that the stringency of the requirements for onboard NO_x sensor operation would be difficult or impossible to meet. Additionally, EMA comments that there are several issues to be solved to create a workable process. PACCAR further recommends that rather than codifying requirements for sensor operation, EPA simply state: 'You must show us that the alternative program gives comparable assurance that your engines meet the NO_x standards of this part.'

Response:

EPA currently agrees with commenters' concerns on the feasibility of this alternate in-use testing option and acknowledges that at this time there are no available technologies that will enable this type of testing. We provide more discussion on this topic in Section III.C.4.ii in the preamble.

11.5.4 Misfueling, particularly with biodiesel

Comments by Organizations

Organization: *American Petroleum Institute (API)*

API provided comments on the 21 January 2020 Advanced Notice of Proposed Rulemaking for this regulatory activity in response to concerns about the potential role of biodiesel in relation to metal and water contaminants in highway diesel fuel. We agree with the finding (stated by EPA in this proposal) that available fuel survey data indicate that biodiesel is compliant with the ASTM D6751-18 limits for Na, K, Ca, and Mg and that there is no 'widespread off specification biodiesel blend stock or biodiesel blends in the marketplace.'3 We also would like to draw EPA's attention to the following remarks:

EPA should consider the results of the SwRI study on the impacts of bioderived fuels on low NOx emission control technologies for heavy-duty engines before finalizing this rule. [EPA-HQ-OAR-2019-0055-1171-A1, p.1]

2 See https://www.regulations.gov/comment/EPA-HQ-OAR-2019-0055-0276

3 See text at 87 Federal Register 17563 (March 28, 2022) 'Biodiesel Fuel Quality'

The Coordinating Research Council (CRC) and the Truck and Engine Manufacturers Association (TEMA) are extending EPA's ongoing heavy-duty engine test program at Southwest Research Institute (SwRI) with additional research that complements the Agency's work in support of this regulatory effort. The CRC program (CRC project RW-120 'Impact of Bioderived Fuels on Low NOx Feasibility') is intended to provide insights on potential fuel-related impacts on heavy-duty engine and aftertreatment performance and durability. EPA's proposed emissions standards for model year 2027+ heavy-duty vehicles and engines are expected to increase the performance demands for aftertreatment systems. Consequently, it is imperative to understand the impact of alternative fuels on system performance as related to engine-out NOx and other criteria pollutant emissions. Fuels of interest in the CRC program include petroleum-derived ultra-low sulfur diesel (ULSD), biodiesel and renewable diesel blends with ULSD. The test fuel blends are B20 and B50 (20%v and 50%v biodiesel in ULSD), RD100 (100%v renewable diesel) and combination blends of RD/biodiesel/ULSD. Test engine operating conditions include low-load cycles and incorporate the aftertreatment system currently used in the EPA low NOx technology assessment at SwRI. Testing is scheduled to start in mid-June and a report on the study is expected by mid-August 2022. [EPA-HQ-OAR-2019-0055-1171-A1, pp.1-2]

As described in Section 3.1.4 of the Draft Regulatory Impact Analysis, EPA has concluded, based largely on the findings to date from the SwRI test program, that the technologies and strategies anticipated for meeting the proposed standards can be designed and implemented to achieve significant NOx reductions that are GHG-neutral.4 Given the potential significance of the CRC program in supplementing and expanding the EPA findings to include alternative fuels, we respectfully request that EPA consider its results before the rule is finalized. [EPA-HQ-OAR-2019-0055-1171-A1, p.2]

4 EPA, Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards Draft Regulatory Impact Analysis, March 2022

Organization: *California Air Resources Board (CARB)*

U.S. EPA requested comments on elements of the Heavy Duty in-use testing program. CARB staff supports the proposed changes to the HDIUT program of removing the HDIUT Phase 2 testing requirements in 40 CFR 86.1915 and the biodiesel fuel blend provisions in 40 CFR 86.1908(a)(6). These elements were also removed for 2024 and newer model year engines in the Omnibus regulation.128 [also in 11.5] [EPA-HQ-OAR-2019-0055-1186-A2, p.60]

128 https://ww2.arb.ca.gov/rulemaking/2020/hdomnibuslownox

With regards to the use of biodiesel, it has been and remains CARB staff's position that engine manufacturers are required to design their engines to operate on all commercially available fuels (including fuels containing biodiesel). For many years, most commercial diesel fuels sold at California service stations and at truck stops dispense diesel fuel containing up to 20 percent biodiesel. CARB certification staff has reviewed owner's manuals to confirm that manufacturers are not prohibiting diesel fuel that meets the definition of CARB's diesel fuel and is legal for sale. If any fuel limitation is found (such as 20 percent biodiesel), CARB staff would contact the manufacturer to better understand the need for any biodiesel restrictions below 20 percent and whether the durability demonstrated at the time of certification is representative and whether the manufacturer is required to rerun durability testing to confirm emission results with existing commercial fuels. [EPA-HQ-OAR-2019-0055-1186-A2, p.60]

CARB staff agrees with the proposal to not continue with the engine misfueled criteria outlined in 40 CFR 86.1908(a)(6). For 2024 and subsequent MY engines, the Omnibus regulations made the fueling requirement more explicit for in-use testing. CARB staff recommends harmonization with the Omnibus proposal timeline for this change with MY 2024. [EPA-HQ-OAR-2019-0055-1186-A2, p.60]

CARB staff supports the inclusion of all commercially available fuels, including fuels that contain biodiesel up to 20 percent, to be included in off-cycle testing. [EPA-HQ-OAR-2019-0055-1186-A2, p.64]

Organization: *Clean Fuels Alliance America (Clean Fuels)*

Clean Fuels has a long history of working with users, fleets, and the OEM community to conduct technically credible research that validates the performance and positive impacts of biodiesel when used in existing diesel engines. Part of that effort has been to conduct testing, evaluate fuel specifications, and implement changes needed to ensure the fuels we support not only work in existing engines but will also work in all future new diesel engines as diesel engine regulations and technology change. Our cooperative efforts continue with our OEM partners and the technical community to conduct the needed testing and research. As such, we would like to thank EPA for recognizing biodiesel quality and for proposing to allow vehicles to be tested for compliance with available biodiesel blends meeting ASTM D7467. This change validates not only the quality of these blends in the marketplace, but also the standards development process within ASTM, in which the global fuel community participates. [EPA-HQ-OAR-2019-0055-1248-A1, p.3]

Assessment of BQ-9000 Biodiesel Properties

As the National Biodiesel Board, now Clean Fuels Alliance America, provided in our comments on the 2020 ANPR, the most recent studies by the National Renewable Energy Laboratory (NREL) and the Association Quality Management Biodiesel (AGQM) show that metals contamination on average is well below the standards set both in the United States and in Europe.3 [EPA-HQ-OAR-2019-0055-1248-A1, p.2]

> 3 U.S. Environmental Protection Agency. ANPR Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine Standards, 85 Fed. Reg. 3,306 (January 21, 2020). available at https://www.federalregister.gov/d/2020-00542

Over the last five years, BQ-9000 accredited biodiesel producers have willingly submitted sample analysis results that have been compiled and statistically analyzed into annual quality reports. NREL has produced four reports on the Assessment of BQ-9000 Biodiesel Properties for 2017, 2018, 2019, and 2020.4 In each of these assessments of BQ-9000 biodiesel properties, NREL helped to collect and statistically analyze the data from U.S.- and Canada-based BQ-9000 member companies to determine the quality of their production lots versus the ASTM D6751 specification in calendar years 2017, 2018, 2019, and 2020. NREL surveyed current BQ-9000 members for their monthly data on 14 critical parameters (not limited to metals) and determined an average, minimum, and maximum monthly values for each parameter. The analysis shows U.S. and Canadian biodiesel almost always meets D6751 specification limits and the average sodium (Na) and potassium (K) was found to also meet the D6751 specification limits. [EPA-HQ-OAR-2019-0055-1248-A1, p.2]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

Figure 3 below shows one example of the difference in SCR performance in a controlled, OEM on-highway fleet test setting (purple) versus an uncontrolled customer system (gray). These two systems ran similar duty cycles with similar mileage accumulation (approximately 435k) and thermal aging characteristics. The OEM fleet system ran on a standard ASTMD975 B5 fuel, whereas the uncontrolled test system filled at fleet or retail stations en route. For both SCR formulations shown below, the 435k mile field return system performs similarly to or worse than the 650k mile fleet test vehicle. The delta shown below in NOx conversion efficiency observed between a controlled test and uncontrolled test is significantly more degradation than what is observed in the test cell simulated 800,000 miles aftertreatment during EPA Stage 3 and rework investigations. We expect similar deltas as shown in the Figure 3 below between a lab-aged environment and fleet-aged environment: [Comment also included in 11.3.1] [EPA-HQ-OAR-2019-0055-1168-A1, pp.26-27]

Vehicles in the field do not run on lab-grade ULSD and most owners/operators are not specialists in fuel handling and maintenance. A recent study by the Fuels Institute found that only 21.6% of sites surveyed in the U.S., including both retail and fleet locations, reported performing any type of routine bulk fuel tank maintenance. Nozzle samples at these locations found that 27.9% of samples contained detectable levels of potassium and 20.5% of samples contained detectable levels of sodium.65 While these levels are low and meet the applicable ASTM standards, accumulation over lifetime can amount to significant catalyst degradation. For example, with the average contamination values reported in the Fuels Institute survey, the cumulative poisoning level introduced to the aftertreatment during a 435k full useful life (FUL) is more than double the maximum concentrations specified for DEF (which has recognized impacts on SCR aging), as illustrated in Table 5 below: [EPA-HQ-OAR-2019-0055-1168-A1, p.27]

65 See Fuels Institute, 'Diesel Fuel Sampling Study: An Evaluation of Diesel Fuel Sold and Consumed in the U.S. Market' (Dec. 1, 2021), https://www.fuelsinstitute.org/Research/Reports/Diesel-Fuel-Sampling-Study (Fuels Institute Diesel Fuel Sampling Study).

Daimler Truck's fuel sampling data aligns with the Fuels Institute survey findings and has been shared with EPA previously. We have observed metallic contamination at concerning levels in a significant number of samples collected from fleets, regardless of biodiesel content as shown in Table 6. These contamination levels will likely degrade catalysts considerably faster than the lab-grade fuel used in the EPA demonstration: [EPA-HQ-OAR-2019-0055-1168-A1, p.28] Daimler Truck recently collected data on real-world catalyst poison deposition in the field to evaluate degradation due to chemical aging. Poison deposition from aftertreatment catalysts was analyzed for a variety of trucks at approximately 250,000 to 650,000 miles, sourced from a variety of applications and fleets. From this study, a real-world representative poisoning level was determined for a variety of contaminants on the first catalyst exposed to exhaust flow. These contaminants were then applied to a copper zeolite close-coupled SCR catalyst, similar to the catalyst used in the SWRI demonstration system, via wet impregnation to accelerate poisoning. fu this study, we concluded that the three most detrimental contaminants on the copper zeolite technology were sodium, phosphorous, and potassium. Table 7 below summarizes the shift of T90 temperatures (temperature at which 90% SCR conversion occurs) due to the application of individual poisons compared to a hydrothermally aged (HTA) reference. Note that all poisoned samples are also hydrothermally aged: [EPA-HQ-OAR-2019-0055-1168-A1, p.29]

EPA's low-NOx demonstration utilized the DAAAC protocol, which accelerates oil borne poisoning (P, Ca, Mg, Zn) and sulfur. Based on these findings, we do not believe the applied DAAAC protocol fully represents a real-world use case, where sodium and potassium levels (from diesel fuel and other sources) are also of significant impo1tance for a copper close-coupled SCR. The CCSCR performance used in the EPA investigation to demonstrate low-NOx feasibility has only accounted for a portion of the degradation expected in real-world operation. EPA has asserted that aging and poisoning can be corrected by increasing the size of the catalyst; however, adding more catalyst volume does not necessarily offset the shift in light-off after chemical poisoning. Increasing catalyst volume also increases thermal inertia, which is counter to the fast SCR light-off required for low cold strut emissions. EPA also does not consider the packaging, cost, backpressure, and fuel economy impacts of simply adding additional catalyst. Daimler Truck does not see this as a workable solution to fuel poisoning. [EPA-HQ-OAR-2019-0055-1168-A1, p.29]

EPA did not adequately consider the effects of the alkali metals (Na and K) on SCR catalysts in the accelerated aging protocol applied at SWRI. Daimler Truck's data on field fuel quality and catalysts sampled from the field indicates catalyst poisoning levels in excess of what has been applied in the EPA demonstration. Additionally, Daimler Truck has observed significant variability in chemical contamination in the field and believes that the EPA demonstration is a best-case scenario, and is not proof of durability or feasibility for a product in the field. [EPA-HQ-OAR-2019-0055-1168-A1, pp.29-30]

In addition to long term aging impacts, tank-to-tank changes in fuel properties can also significantly impact engine-out emissions and catalyst performance. The chemical structure of fatty acid methyl ester (FAME) biodiesel causes an increase in engine-out NOx as compared to conventional diesel, regardless of engine make. This is demonstrated in the CARB Biodiesel Characterization and NOx Mitigation Study, where engine-out NOx increases were observed for both a 2006 Cummins ISM and 2007 MBE 4000 engine.66 At a B20 blend level, NOx increases of up to 6.6% were measured on the FTP cycle, an increase of up to 6.9% over 50 mph cruise cycle as shown in Figure 4.67 [EPA-HQ-OAR-2019-0055-1168-A1, p.30]

66 See CARB, Biodiesel Characterization and NOx Mitigation Study, available at https://www.arb.ca.gov/fuels/diesel/altdiesel/20111013_carb final biodiesel report.pdf.

67 Id.

More recent data (Figure 5) shows that this effect persists, even with more modern emissions control technologies. For example, CARB’s Low Emissions Diesel (LED) study shows that biodiesel blends above B20, even when blended with ULSD or Renewable diesel biofuel, produce significantly more engine-out NOx.69 [EPA-HQ-OAR-2019-0055-1168-A1, pp. 30-31]

> 69 See Durbin, et al., Low Emission Diesel Study: Biodiesel and Renewable Diesel Emissions in Legacy and New Technology Diesel Engines (Nov. 2021) at Table ES-2, available at https://ww2.arb.ca.gov/sites/default/files/2021-12/Low Emission Diesel Study Final Report 12-29-21.pdf ('CARB LED Study').

Internal Daimler Truck test results on more recent engine technologies align with the results of the CARB LED study, noting a direct engine-out NOx increase up to 7%, while showing no engine-out CO2 reduction on the composite FTP cycle with the use of B20. Daimler Truck expects that this impact will be significantly more important with the proposed ultra low-NOx (UL NOx) systems, which are much more sensitive to increased engine-out NOx and require much higher levels of NOx conversion efficiency across the aftertreatment. [EPA-HQ-OAR-2019-0055-1168-A1, p.31]

The data used at SWRI to support the CARB Omnibus regulation does not account for the adverse effects of biodiesel, either from the immediate emissions increases as demonstrated by this study, or from the long-term aging effects of biodiesel which are understood by the industry. These increases in emissions and associated harm to the environment are in the range of what Daimler Truck would expect from biodiesel blends and are in opposition to both industry and EPA goals. [EPA-HQ-OAR-2019-0055-1168-A1, p.31]

Additionally, when considering proposed blends of renewable diesel, biodiesel, and traditional ULSD, EPA should consider the chemistry and physics that govern blending outcomes. Renewable diesel fuels mix well with traditional ULSD, because they consist of the same hydrocarbon chain. These fuels, both individually and blended shed water and impurities well. By contrast, biodiesel and renewable diesel do not mix well. The culprit is the glycerin in biodiesel which is miscible with water, and therefore the blended fuel carries not only water but also impurities. This leads to fuel filter plugging, accelerated aging of after-treatment systems and ultimately increases emissions released into the environment. On a chemical level, to reduce these effects, any biodiesel fuel blendstock (B100) specification needs to include biodiesel distillation. Otherwise, blends of biodiesel and renewable diesel could carry the same impurities, and cause the same long term degradation to emissions control systems, as biodiesel alone. [EPA-HQ-OAR-2019-0055-1168-A1, pp.31-32]

We believe that the CARB LED Study and test cycles used are sufficiently representative and confirm the directional correctness of industry-known immediate impacts of biodiesel. No current technology exists that can mitigate the short- or long-term effects of emissions degradation from biodiesel, and the results in the CARB study confirm Daimler Truck's experience in this regard. [EPA-HQ-OAR-2019-0055-1168-A1, p.32]

EPA should further research negative emission impacts of biodiesel fuels, including both short-term effects and long-term degradation of emission control equipment, and use this information to inform the feasibility of new emission standards and whether these fuels should be approved or promoted. [EPA-HQ-OAR-2019-0055-1168-A1, p.32]

There is an ongoing CRC/EMA study that involves evaluating a range of market-available fuels on the SWRI demonstration system for both short term impacts and long term aging impacts. We expect the short term study to highlight critical fuel properties and their associated impacts on system performance. We encourage EPA to consider additional margin based on any findings of this study and/or pursue changes to fuel standards to minimize variation in the marketplace. Calibration efforts alone on the part of the manufacturer are not sufficient to ensure compliance with the stringent standards that EPA proposes under Option 1 or Option 2, and work best when critical fuel properties are known, which is not the case in real-world operation. Daimler Truck is aware of biodiesel detection algorithms (having introduced a method to detect B100, experimentally, in European applications), but we do not believe such algorithms meet the need that EPA's standards create—nor that they are feasible in combination with NAFTA onboard diagnostics (OBD) requirements. To date, no manufacturer has demonstrated the ability to accurately detect and correct for biodiesel content at the granularity required for UL NOx adjustments. No fuel quality or biodiesel content sensors are currently offered in the marketplace that are production-feasible. [EPA-HQ-OAR-2019-0055-1168-A1, p. 32]

We appreciate EPA considering a process for a manufacturer to reject heavy-duty in-use testing (HDIUT) results, given the catalyst poisoning concerns raised in the Proposed Rule and noted elsewhere within these comments. However, the method on which EPA requests comment in the Proposed Rule preamble is not reasonable or recommended.89 It is not feasible for the OEM to show a history of biodiesel where B100 does not meet the applicable ASTM standard, as fuel quality and recordkeeping by fleets and retail stations are not the responsibilities of the OEM. This method could be supported if a vehicle or HDIUT fleet were selected at start of mileage accumulation and a cooperative fuel sampling program put in place over lifetime. Setting up such program with a large pool of vehicles available for the Agency to select from would provide significant benefits for the Agency, manufacturers, and customers, in that it would provide fair, transparent, and auditable system for true FUL emissions performance evaluation. [EPA-HQ-OAR-2019-0055-1168-A1, p.69]

89 See Proposed Rule, 87 Fed. Reg. at 17,563 (requesting comment on a process for receiving EPA approval to exempt test results from in-use testing compliance (and test results being considered for potential recall) if an engine manufacturer can show that the vehicle was historically fueled with biodiesel blends whose B100 blend stock did not meet the ASTM D6751–20a limit for Na, K, Ca, and/or Mg metal).

Daimler Truck proposes that a manufacturer determine the level of poisoning on the aftertreatment's catalysts against a defined normal value for that product. This method would require the manufacturer invest in significant R&D work and sample a quantity of field aged catalyst systems to determine a normal range given typical exposure to approved fuels. Systems with abnormal results that significantly impact performance could be removed from the HDIUT analysis, and another system selected. This method would allow the manufacturer to fairly screen for abnormal chemical contamination without the burden of proof of the source, which is outside of the manufacturer's control. Normal chemical contamination via fuel borne metals, intrusion via the DEF system, and other potential sources is still significantly challenging for the proposed NOx stringency for FUL, and may result in costly catalyst replacement. EPA and ASTM must engage on reducing the sources of chemical contamination to enable significant NOx reductions. [EPA-HQ-OAR-2019-0055-1168-A1, p.69]

Under current regulation, manufacturers are allowed to specify maintenance procedures that are critical to the operation of their engines throughout their useful life. This has historically included specifying the required or recommended fuel types necessary to ensure that systems perform adequately and are not inappropriately degraded. Manufacturers are rightly allowed to later remove engines from in-use testing evaluations if the vehicles have not been maintained as directed, or if they have been fueled in a manner inconsistent with the instructions in their manuals. Similarly, manufacturers may limit their warranty liability and deny warranty claims when mis-fueling can be identified as the cause of an emissions control failure. [EPA-HQ-OAR-2019-0055-1168-A1, p.87]

EPA proposes to remove these manufacturer protections, which would expose manufacturers to liability regarding both in-use emissions performance and warranty. The Agency proposes to do so at the same time that it refuses to address the demonstrated fuel quality concerns in the field. The nation's collective fuel quality concern threatens the longevity of emissions control components and directly contributes to increased emissions, through immediate increases in NOx and through degradation of catalysts via metals contamination. Yet EPA simultaneously proposes to limit manufacturers' ability to control exposure to poor-quality fuel *and* to implement standards that are so stringent that manufactures must remove all potential sources of emissions variability and system degradation. [EPA-HQ-OAR-2019-0055-1168-A1, p.87]

EPA must mandate improvements to nationwide diesel and biodiesel fuel quality—or risk significant emissions impacts, or worse, the creation of an unfeasible emission standard with uncertainties that manufacturers cannot tolerate, leading to unavailability of product, and an eventual unwinding of EPA's proposed standards. [EPA-HQ-OAR-2019-0055-1168-A1, p.87]

Daimler Truck continues to engage in and support fuel quality improvement efforts in a variety of forums. We support ASTM in the ongoing proposed revisions to ASTM D7467 (B6- B20), which include moving metals values from the non-mandatory appendix to the mandatory table. The Company also supports the revision of the test method to lower the limit of detection and the lowering of metal content allowed in ASTM D6751 (B100 blendstock) to a 4ppm maximum limit. However, we do not believe these changes alone will serve the needs of modern UL NOx engines, as is evident by formations of groups like Top Tier, where manufacturers are working outside of ASTM to improve fuel quality at the pump. We believe it is necessary and appropriate for EPA to set finished fuel quality standards, measured at the pump, to enable their proposed emissions programs. [EPA-HQ-OAR-2019-0055-1168-A1, p.87]

In Section II.B.3 of these comments, Daimler Truck provides significant evidence that contaminants found in fuels contribute to catalyst degradation. We provide detailed information on this effect, and we present evidence of the metal contamination present in fuels in Section II.B.3, which addresses EPA's demonstration of feasibility. To summarize, chemical degradation from contaminants present in field fuel account for significant degradation beyond the 'best case fuel' degradation experienced in laboratory settings, which directly leads to increased NOx emissions as catalyst NOx conversion efficiency is reduced. This is illustrated in Figure 32 below: [EPA-HQ-OAR-2019-0055-1168-A1, p.88]

Degradation of ATS conversion efficiency, even by 1%, cannot be tolerated with EPA's proposed stringent standards. Fuel standards must be improved to prevent such degradation. [EPA-HQ-OAR-2019-0055-1168-A1, p.88]

Catalyst degradation via fluid impurities is widely acknowledged in this industry for other fluids outside of fuels. For example, ISO 22241-1 for DEF states 'The quality of the urea solution used for that technology needs to be specified to ensure reliable and stable operation of the SCR converter system.'111 As such, the contaminant limits for DEF are outlined in Figure 33 below: [EPA-HQ-OAR-2019-0055-1168-A1, p.88]

111 See ISO 22241-1:2019, 'Diesel engines — NOx reduction agent AUS 32 — Part 1: Quality requirements' (2019), https://www.iso.org/standard/66408 html.

These <0.5 mg/kg limits on DEF combined with the relatively low usage of DEF compared to fuel, result in lower overall contribution of contaminants from the diesel exhaust fluid. For example, a line haul vehicle with a 6 mpg fuel economy, and 3% DEF:Fuel ratio could consume up to 9.7 grams of sodium from DEF, and 21 grams of sodium from fuel based on the average value reported in the DFQC study. The <100 ppb contribution referenced by EPA in the NPRM results in significantly more contamination via fuel than DEF. Table 11 below outlines the maximum contribution from DEF compared to the average values reported in the DFQC survey, as well as the 100 ppb result referenced by EPA in the Proposed Rule: [EPA-HQ-OAR-2019-0055-1168-A1, p.89]

As fuel is consumed in much larger quantities than DEF, DTNA believes that the metallic contamination limits in finished fuel should be at least as stringent as DEF (0.5 mg/kg) or lowered to a level to result in similar levels of contamination, which requires a limit of approx. 40-50 ppb maximum. [EPA-HQ-OAR-2019-0055-1168-A1, p.90]

The chemical structure of fatty acid methyl ester (FAME) biodiesel causes an increase in engine-out NOx compared to conventional diesel, regardless of engine make, as demonstrated in the CARB Biodiesel Characterization and NOx Mitigation Study, where engine-out NOx increases were observed for both a 2006 Cummins ISM and 2007 MBE 4000 engine.114 At a B20 blend level, NOx increases of up to 6.6% were measured on the FTP cycle.115 [EPA-HQ-OAR-2019-0055-1168-A1, p.90]

114 See CARB, Biodiesel Characterization and NOx Mitigation Study, available at https://www.arb.ca.gov/fuels/diesel/altdiesel/20111013_carb final biodiesel report.pdf.

115 See id.

More recent data shows that this effect persists, even with more modern emissions control technologies. For example, the CARB LED Study shows that biodiesel blends above B20, even when blended with ULSD or Renewable diesel biofuel, produce significantly more engine-out NOx:117 [EPA-HQ-OAR-2019-0055-1168-A1, p.91]

117 See Durbin, et al., Low Emission Diesel Study: Biodiesel and Renewable Diesel Emissions in Legacy an New Technology Diesel Engines (Nov. 2021) at Table ES-2, available at https://ww2.arb.ca.gov/sites/default/files/2021-12/Low Emission Diesel Study Final Report 12-29-21.pdf.

Internal Daimler Truck test results on more recent engine technologies align with the results of the CARB LED Study noting a direct engine-out NOx increase up to 7%, while showing no engine-out CO2 reduction on the composite FTP cycle with the use of B20. Daimler Truck expects that this impact will be significantly more important with the proposed UL NOx systems, which are much more sensitive to increased engine-out NOx, and require much higher levels of NOx conversion efficiency. [EPA-HQ-OAR-2019-0055-1168-A1, p.92]

Low oxidation stability is a prominent issue among ULSD and biodiesel fuels, and it directly affects operability and durability of emission control components including fuel injectors. Internal Daimler Truck studies show that fuel containing 5% biodiesel aged to 6 hours of stability caused injectors to seize after 13 test cycles while ULSD aged to 6 hours of stability allowed injectors to complete 30 cycles. Additionally, water and acid content in fuel directly contribute to corrosion in the fuel system, leading to higher repair costs and replacement of emissions-critical components. EPA must address these concerns to ensure it has accurately assessed whether costs for the advanced emissions controls proposed are reasonably—especially at the extended useful life and warranty periods that the Agency proposes. [EPA-HQ-OAR-2019-0055-1168-A1, p.92]

Daimler Truck has presented significant evidence in these comments to show fuel quality is an important limiting factor for emissions performance and durability of emissions relevant components. To enable EPA's proposed new standards, ASTM and EPA must set fuel standards that meet the needs of modern engines. We recommend that EPA take steps to improve fuel standards and enforcement, similar to lowering sulfur content in ULSD to enable compatibility with EGR and aftertreatment. [EPA-HQ-OAR-2019-0055-1168-A1, p.92]

Specifically, we recommend a maximum biodiesel content of 20% nationwide. As evidenced by the CARB LED Study of higher biodiesel blends, the emissions impacts of biodiesel increase significantly as blend percentage increases. [EPA-HQ-OAR-2019-0055-1168-A1, p.92]

Additionally, Daimler Truck recommends the following fuel standards (enforceable at the pump) based on industry experience, experimental data, and supplier input: [EPA-HQ-OAR-2019-0055-1168-A1, p.92]

In addition to these finished fuel specifications, we recommend improvements to the B 100 blendstock specification, to help enable higher quality finished fuels with biodiesel content. The following Bl00 specifications and recommendations refer strictly to Bl00 as a blendstock (used for blending up to a maximum of B20) and not as a finished product. [EPA-HQ-OAR-2019-0055-1168-A1, p.93]

Daimler Truck recognizes and supports the use of renewable diesel (R l00) as a greener alternative to ULSD. This fuel has been validated and released in our current production engines, and in testing has shown superior stability and reductions in engine out emissions compared to biodiesel and ULSD. Our evaluation has shown that renewable diesel offers a 9% reduction in engine-out NOx on the composite FTP and 6% reduction in engine-out CO2 compared to B20, without sacrificing engine operability. Mandating renewable diesel penetration offers significant real world lifecycle CO2 improvement in addition to per vehicle CO2, NOx, and PM reduction. These improvements can be realized easily and inexpensively and provide dramatic emissions improvements to the commercial sector immediately—improvements that may be realized for trucks that have already been built, not just new, expensive UL NOx vehicles that will not be available in the marketplace for several years. [EPA-HQ-OAR-2019-0055-1168-A1, pp.93-94]

Additionally, Daimler Truck recognizes that biodiesel may have a lower carbon intensity score than ULSD and renewable diesel as well as the time value of carbon, but that the issues with the fuel discussed in these comments make it incompatible with UL NOx engines in high concentrations. We urge EPA to consider a uniform, nationwide biodiesel blending proposal (e.g. B5 standard for all diesel fuel sold). This allows for lifecycle GHG reductions to be realized while minimizing the negative effects of biodiesel on per vehicle GHG emissions and engine operability and durability. With lower maximum blend rates and wider distribution, the NOx increase is mitigated while wider lifecycle GHG reductions can be achieved, suppressing the negative environmental impacts over the course of a vehicle lifecycle. [EPA-HQ-OAR-2019-0055-1168-A1, p.94]

Organization: *Manufacturers of Emission Controls Association (MECA)*

Some metals found in engine oils can also result in deterioration in catalyst performance. Lube oil phosphorus is a non-selective poison that effectively masks surface active catalyst sites, independent of the type of catalyst formulation. Generally, phosphorus deposits heavily at the front end of the catalyst brick, and typically resides mostly on the surface of the washcoat. There is some concern that phosphorus could react with other poisons and a catalyst washcoat to form phosphates that persist on the washcoat surface and mask the catalyst sites [29]. More research is needed here to determine the durability requirements to meet future full useful life provisions; however, the results of the lube oil poisoning as accelerated in the SwRI program show good durability of the close-coupled SCR, which receives the bulk of the lube oil metal poisons. Possible future mitigation actions that catalyst suppliers can deploy include increasing catalyst volume and/or inclusion of poison-resistant catalyst designs. [EPA-HQ-OAR-2019-0055-1320-A1, p.24]

> [29] B. Bunting, K. More, S. Lewis and T. Toops, ‘Exhaust Phosphorus Chemistry and Catalyst Poisoning,’ in 2004 Department of Energy Diesel Engine Emissions Reduction Conference, 2004.

Other metals that are found in some fuels and oils, such as biodiesel, include calcium, sodium, potassium and magnesium. Calcium deposits uniformly across the catalyst and can physically block active sites. Elevated levels of sodium and potassium could displace the active metals and reduce the NOx conversion and N2 selectivity. At this time, MECA is not aware of any data that shows that magnesium has a negative effect on catalyst performance. Recent research has shown how biodiesel metal contaminants can affect emission control systems [30, 31]. Extensive testing of light-duty and heavy-duty aftertreatment systems exposed to biodiesel exhaust at the 10-ppm metal impurity specification for biodiesel has been published by NREL with funding from the National Biodiesel Board (NBB) and support from MECA. A medium-duty pick-up truck aftertreatment system equipped with a front-SCR was aged out to 150,000 accelerated miles on fuel doped with metals to the current maximum specification and met the FTP emission limit for that vehicle [32]. Similarly, in a later study, a heavy-duty 2010 style aftertreatment system architecture was aged in an accelerated fashion to represent 435,000 equivalent miles of thermal aging using a similar doped biodiesel fuel and met the FTP emission limit after aging [31]. [EPA-HQ-OAR-2019-0055-1320-A1, pp.24-25]

The metal content of B100 from field samples analyzed by researchers at NREL [33] [34] [35] have shown metal content far below the current specification for the vast majority of samples collected, and the impurity level has been coming down over the sample years in 2013 and 2019. MECA supports more stringent limits of fuel additives that contain metals including evaluating their potential impact on aftertreatment components. We have been working with NBB, OEMs and biodiesel producers to generate the necessary data that supports tighter ASTM specifications for metal impurities in biodiesel at or near the detection level of analytical techniques as a way to provide confidence to engine manufacturers that biodiesel fuels can be as clean as possible. Current fuel quality in the market: CARB staff reported sulfur and metals levels in today's fuel supply for diesel engines without any applied corrections for volumes represented or market share of producers [36]. To better understand sulfur content and variability in the California fuel supply for diesel engines, CARB-collected over 400 fuel samples from California producers, importers and distribution terminals during 2017 to 2019 calendar years. These samples included diesel and some biodiesel and renewable diesel blends with maximum sulfur content observed of 13 ppm and an average sulfur content 4 ppm with a standard deviation of 3 ppm. These sulfur levels in current ULSD are adequate for engine and aftertreatment systems to meet the Proposed Option 1 standards. [EPA-HQ-OAR-2019-0055-1320-A1, p.25]

[36] CARB, 'Regulations.gov,' 25 February 2020. [Online]. Available: https://www.regulations.gov/document?D=EPA-HQ-OAR-2019-0055-0471.

CARB staff also collected and analyzed over 400 diesel and biodiesel blend samples collected at retail fuel pumps throughout California in 2019 [36]. The findings concluded that phosphorus and metal contents of biodiesel were significantly lower than current ASTM limits, which supports minimal impact of biodiesel metals and phosphorus on the full useful life durability of diesel exhaust aftertreatment systems. CARB staff also analyzed 27 B100 samples that EPA collected from biodiesel production facilities nationally and did not identify metals contamination. These results are consistent with trends seen in national biodiesel fuel surveys conducted by NREL and referenced above. [EPA-HQ-OAR-2019-0055-1320-A1, p.25]

Organization: *Navistar, Inc. (Navistar)*

The recently published CARB Low Emissions Diesel ("LED") study1 demonstrates that fuel quality has a significant impact on emissions. Poor fuel quality, especially driven by the biodiesel production and distribution process is more prevalent in the U.S. as compared to Canada, European Union, and Japan. The current ASTM D975 and D7467 are inadequate when compared to EU and other worldwide standards. These inadequacies have led to increased downtime, and a risk of elevated and irreversible in-use emissions. Common fuel contamination from magnesium, zinc, calcium, potassium, sodium can irreversibly poison aftertreatment systems. Low oxidation stability can lead to significant increases in acid formation in the oil, which can cause corrosion and accelerated wear in bearing and sealing surfaces. Navistar recommends the adoption and enforcement of both Top Tier and EU biodiesel standards in lieu of the ASTM D975, D7467 and D6751 standards. [EPA-HQ-OAR-2019-0055-1318-A1, p. 6]

Organization: *Neste US, Inc*

Renewable fuels can be used by older engines equipped to run on fossil diesel, and can therefore be used to cut emissions immediately. Neste has worked with leading original equipment manufacturers (OEMs) to test renewable diesel in diesel engines. As a result, many OEMs, including Cummins, Volvo Trucks, Caterpillar, and Detroit Diesel endorse renewable diesel for use in their equipment. Last year, Neste's advanced biofuels helped our customers prevent 10.9 million tons of CO2 equivalent from entering the atmosphere. We want to get that number up to 20 million tons by 2030. [EPA-HQ-OAR-2019-0055-1225-A1, p.1]

Renewable diesel produced via hydrotreating removes metals, and other contaminants

The proposed rule mentioned biodiesel fuel quality and related compliance issues, expressing EPA's concerns that trace metals in biodiesel may adversely affect engines and emission control systems.6 However, the Agency ignores that renewable diesel produced via hydrotreating removes molecules of sulfur, nitrogen, oxygen and heavy metals such as P, Ca, and Mg from the same feedstocks to produce high quality diesel fuel for modern exhaust aftertreatment systems. Elimination of these contaminants means that renewable diesel has improved properties and removes significantly fewer contaminants on combustion, and that the product can be further treated catalytically without poisoning the catalysts used.7 Neste would also like to emphasize significant differences between biodiesel and renewable diesel, for EPA's consideration should the agency decide to address its concern about metals in biodiesel in a more formal way in the future. [EPA-HQ-OAR-2019-0055-1225-A1, p.4]

In addition to renewable diesel lowering GHG emissions by up to 75% over the fuel's lifecycle when compared with fossil diesel, our fuel also provides, depending on the age and make of the engine, a cost-effective solution for reducing transport-related local emissions and improving local air quality in cities, on average:

- 33% lower levels of fine particulates (and a smaller number of particulates in general)
- 30% less hydrocarbons (HC)
- 24% lower carbon monoxide (CO) emissions and reduced levels of polyaromatic hydrocarbons (PAH)
- 9% less nitrogen oxides (NOx) [EPA-HQ-OAR-2019-0055-1225-A1, pp.4-5]

Organization: *Renewable Energy Group*

[*From Hearing Testimony, April 13, 2022, Martin Haverly, Renewable Energy Group*] I'm the senior manager of research and development and innovation with Renewable Energy Group. As you've already heard from my colleague earlier, Renewable Energy Group is an industry leader delivering high-quality low-carbon biodiesel and renewable diesel fuel to markets in the U.S. and abroad. I would like to reiterate our support for the EPA and its finding that the pool of biodiesel available to vehicle and equipment operators across the country is of very high quality while biodiesel blends above 5 percent, or B5, are not expected to impede the performance of next-generation after treatment, devices developed to meet this proposed new tailpipe standard. According to findings, including the proposed rulemaking, EPA reports that the presence of metals and other quality metrics has greatly improved. These findings are derived from a robust fuel sampling survey conducted by the agency, the California Air Resources Board, and the National Renewable Energy Laboratory. The vast majority of fuel samples show the presence of impurities far below specified and allowable levels. We support EPA in its proposal to require engine manufacturers to provide detailed evidence to document claims of off-spec biodiesel when seeking an exemption of test results as part of an end-use compliance. Decades ago, REG developed processes to produce and deliver to the marketplace the highest quality biodiesel. As the industry leader, we are encouraged to know that our competitors have also stepped up to develop and deliver high-quality low-carbon bio-based diesel fuel including biodiesel, and that plays a disproportionate role in reducing transportation sources of greenhouse gas emissions. Evidence in this proposed rule demonstrates that access to high-quality biodiesel is prevalent and that higher blends of biodiesel are not expected to impede the performance of after treatment devices. Through the renewable fuel standard, the EPA has proposed growth in bio-based diesel volumes in 2022 and we believe that even more fuel may be delivered to the market this year and beyond. Blends of 20 percent biodiesel, or B20, should be the norm and we encourage engine manufacturers to work alongside fuel producers like Renewable Energy Group to support blends above B20. The diesel commercial trucks of the future can deliver cleaner air through the next-generation after treatment devices while delivering even greater climate benefits when operating using higher blends of low-carbon bio-based diesel fuels. Thank you very much for this opportunity to present our views and suggestions at this public hearing. As already noted, Renewable Energy Group will also be submitting written comments and we look forward to supporting the EPA as you continue your important mission to fight global warming and increase investment in renewable fuels while improving air quality and reducing emissions. [EPA-HQ-OAR-2019-0055-2867]

Organization: *State Soybean Associations*

In its Proposed Rule, EPA raises concerns about trace metals in biodiesel and their potential to adversely affect emissions control systems and engines. Its stated concern is that metals, such as sodium, potassium, calcium, and magnesium can enter the production of biodiesel and impact the diesel particulate filters or selective catalytic reduction catalyst. EPA has insufficient scientific data to back up this conclusion, however. EPA should not let this kind of unsubstantiated concern limit the use of biodiesel, given its proven utility in significantly reducing GHG emissions. [EPA-HQ-OAR-2019-0055-2035-A1, p.3]

Organization: *Truck and Engine Manufacturers Association (EMA)*

EPA’s proposed procedures for in-use testing require that MY 2027 and later products comply with all in-use standards when operating on “any commercially available biodiesel fuel blend that meets the specifications for ASTM D975 or ASTM D7467.” (See §1036.415(c)(1).) There is a significant body of evidence accumulated over the last decade29 showing that fuel quality has a significant impact on emissions. Poor fuel quality, especially driven by the biodiesel chemistry, production processes, and distribution impacts, is prevalent in the U.S. compared to the rest of the leading markets (USMCA, EU, Japan). This is driven to a large extent by inadequate fuel quality standards as published by ASTM compared to other world-wide standards. Those inadequate standards and associated lack of regulatory oversight have led to vehicle downtime, and risks of elevated in-use emissions. Those risks will be even greater for engines and vehicles compliant with the proposed low-NOx emissions standards, where a single tank of poor-quality biodiesel fuel can permanently compromise the emission reduction efficacy of the entire aftertreatment system. The effect of this is shown in the CARB LED study. [EPA-HQ-OAR-2019-0055-1203-A1, p. 137]

29. CARB Low Emission Diesel Study (LED): Low Emission Diesel (LED) Study: Biodiesel and Renewable Diesel Emissions in Legacy and New Technology Diesel Engines - Final Report (ca.gov)

Furthermore, the recently published Fuels Institute's Diesel Fuel Quality Council's (DFQC) field fuel quality study30 revealed that over 50% of nozzle samples contained metals such as magnesium, calcium, and zinc, which are all elements poisonous to the aftertreatment system. While those metals values were within the ASTM standard, several manufacturers expressed concern that even at low levels, those metals could be impactful to aftertreatment deterioration at higher mileages. Those results, combined with the fact that 32% of the samples failed to meet the 20-hour oxidation stability threshold, raise serious concerns about the potential impacts of fuel quality going forward as new low-NOx requirements take effect. Finally, it is known that regular preventative tank maintenance can aid in minimizing unfavorable fuel properties such as high oxidation stability and high metal contamination. The DFQC field fuel quality study reported that less than 22% of tank sites reported performing routine tank maintenance. [EPA-HQ-OAR-2019-0055-1203-A1, p. 138]

30. Fuel Institute Diesel Fuel Sampling Study: An Evaluation of Diesel Fuel Sold and Consumed in the U.S. Market | Fuels Institute

Biodiesel also can degrade some gaskets and seals with prolonged exposure, particularly those made from natural or nitrile rubber. The lack of oxidation stability of biodiesel can put materials at risk of swelling, leaking, and/or failure. Fuel lines containing elements such as brass, bronze, copper, lead, tin, and zinc, may accelerate the oxidation process of biodiesel, thereby creating fuel insoluble compounds or gels and salts. [EPA-HQ-OAR-2019-0055-1203-A1, p. 138]

As acknowledged by EPA in the Draft RIA, metallic contamination in the aftertreatment due to fuel-borne contaminants has been shown in a variety of studies to degrade emissions control catalysts. "Brookshear et al. 2012 studied the impact of Na on heavy-duty diesel engine aftertreatment devices. In this accelerated aging study, they doped a B20 fuel to 5,000 ppm each of Na and S and aged to an equivalent 435,000 miles. They found impacts on SCR function if the SCR was positioned before the DPF." Due to the cold-start stringency proposed, leading concepts for system layouts, including EPA's Low-NOx Stage 3 demonstration system at SWRI, rely heavily on an SCR placed before the DPF. EPA further acknowledges these concerns, as follows: “Williams et al. 2013 studied the effect of Na, K and Ca on a 2011 LD 6.7L diesel engine aftertreatment. They doped their B20 fuel to 14 times the pseudo 1 ppm Na and Ca limit of a B20 fuel and accelerated aged the emission control systems out to 150,000 miles. The authors aged sets of production exhaust systems that included a DOC, SCR catalyst, and DPF. Four separate exhaust systems were aged, each with a different fuel: ULSD containing no measurable metals, B20 containing sodium, B20 containing potassium, and B20 containing calcium. Analysis of the aged catalysts included Federal Test Procedure emissions testing with the systems installed on a Ford F250 pickup, bench flow reactor testing of catalyst cores, and electron probe microanalysis (EPMA). The thermo-mechanical properties of the aged DPFs were also measured. [EPA-HQ-OAR-2019-0055-1203-A1, p. 138]

EPA further acknowledges these concerns, as follows: EPMA imaging of aged catalyst parts found that both the Na and K penetrated into the washcoat of the DOC and SCR catalysts, while Ca remained on the surface of the washcoat. Bench flow reactor experiments were used to measure the standard NOx conversion, NH3 storage, and NH3 oxidation for each of the aged SCR catalysts. Flow reactor results showed that the first inch of the SCR catalysts exposed to Na and K had reduced NOx conversion through a range of temperatures (Figure 1-8 and Figure 1-9) and also had reduced NH3 storage capacity. The SCR catalyst exposed to Ca had similar NOx conversion and NH3 storage performance compared to the catalyst aged with ULSD.” [EPA-HQ-OAR-2019-0055-1203-A1, pp. 138 - 139]

EPA has also referenced “A level of 1 mg/kg (1 part per million) of trace metal in the fuel result in an estimated accumulation of about 22 g of trace metal in diesel particulate filters per 100,000 miles (assuming a fuel economy of 15 mpg and 100% trapping efficiency).” Even at that low concentration, this equates to an additional 132 grams of DPF ash in a 600,000 mile full useful life. The additional ash accumulation caused by low levels of metals in the fuel will require more frequent DPF ash maintenance. [EPA-HQ-OAR-2019-0055-1203-A1, p. 139]

EPA suggests manufacturers can overcome this challenge by simply increasing the size of their emissions control catalysts, but fails to recognize that while a 5% conversion loss due to metallic contamination may have been acceptable with a 0.2 g/hp-hr standard, it is not acceptable with a 0.02 g/hp-hr standard, or even a 0.05 g/hp-hr standard. Increasing catalyst size also increases the thermal inertia of the system, which is counterproductive to the rapid catalyst light-off required by these regulations. Finally, increasing catalyst size adds additional cost to the product and requires additional installation space in the vehicle, potentially driving additional complexity around aftertreatment variants in vehicle applications. [EPA-HQ-OAR-2019-0055-1203-A1, p. 139]

In addition, metals are technically unregulated in ASTM D975 and ASTM D7467, which does not clearly translate to a design criteria. Since EPA’s data shows metallic contamination is low, EMA recommends EPA work with ASTM to adopt lower limits, in the range of 1ppm, for all metals, and particularly phosphorous, sodium and potassium, in all finished fuel blends. With regard to ASTM D6751, EMA strongly recommends a reduction to the phosphorous limit from 10ppm to something in the range of 1ppm. Individually, these contaminants at concentrations >1ppm can have irreversible impacts on aftertreatment elements. [EPA-HQ-OAR-2019-0055-1203-A1, p. 139]

Engine manufacturers develop products to meet a range of emissions, safety and performance requirements driven by customer demand and regulatory requirements. Manufacturers believe that the availability of biodiesel fuels presents a significant risk to compliance with emissions standards and to customers' satisfaction. Fleets expect a minimum level of performance and durability from the engine products they purchase, with total operating costs equal to or better than the products currently in the fleet. Significant changes to the engine and aftertreatment system, coupled with increased useful life requirements, make it particularly important to minimize the variables that can impact emissions compliance and customer downtime. Requiring that manufacturers allow operation (and testing) on any commercially available biodiesel blends up to B20 is not supportive of those important goals. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 139 - 140]

The expanded use of biodiesel poses a significant risk to the performance of low-NOx engine and aftertreatment technologies. While many manufacturers currently approve the use of up to B20, the impact of those fuels in widespread use is still unknown given the currently limited use of biodiesel nationwide. Customers are often unaware of the blend level of the fuel being dispensed when refueling. Despite the limited deployment of biodiesel and low-carbon alternative fuels, OEMs have seen increased incidences of wear and downtime associated with these fuels. Several manufacturers recommend reduced oil change intervals by up to 30% when using B20 or higher blends. In sum, the Agency should not eliminate the current provision allowing manufacturers to restrict operation and testing with B20. [EPA-HQ-OAR-2019-0055-1203-A1, p. 140]

ASTM specs for biodiesel stability are the lowest in the world. This causes oxidation byproducts and raises TAN in the fuel, which either form fuel system deposits, or cause corrosion within the fuel system. This makes the fuel unsuitable for use in any application where the equipment may sit for as little as a week. [EPA-HQ-OAR-2019-0055-1203-A1, p. 140]

The following are real-world examples of problems experienced by customers operating on fuels not meeting specification. These examples illustrate just how sensitive engines and aftertreatment systems are to these contaminants, justifying the need for tighter, well-enforced controls: Injector Deposits caused by carboxylate salts from water contamination: Customer complaint with nearly 100% failure rate at two facilities. Both locations had heavy amounts of water, sediment, and significant microbial growth in tank bottoms. One location had >10,000 ppm sodium content (limit <5 ppm). Fungible supply in biodiesel creates acid in the water layer. The presence of sodium and acid combined creates a reaction. [EPA-HQ-OAR-2019-0055-1203-A1, p. 140]

The following are real-world examples of problems experienced by customers operating on fuels not meeting specification. These examples illustrate just how sensitive engines and aftertreatment systems are to these contaminants, justifying the need for tighter, well-enforced controls: Injector Deposits caused by carboxylate salts from fungible supply: 3 different customers were having consistent injector failures where all customers were LTL operators and were located in the same area. Two customers fueled at different retail locations, while one customer had its own bulk tank. However, the fuel distributor for all 3 locations was the same fuel terminal. Analysis was nearly identical between all 3 customers – spectrums indicated that the deposit was most likely a carboxylate soap. [EPA-HQ-OAR-2019-0055-1203-A1, p. 140]

The following are real-world examples of problems experienced by customers operating on fuels not meeting specification. These examples illustrate just how sensitive engines and aftertreatment systems are to these contaminants, justifying the need for tighter, well-enforced controls: Plugged filters: All customer vehicles activated a “fuel filter plugged” diagnostic within 1 week. Fuel samples ranged from 16-22% biodiesel and all fuel samples failed ASTM D7467 (B6 to B20) standards with an oxidation stability in the range of 3-5 hours. TAN/TBN loss ranged from 0.16 to 0.25 mg KOH/g, all within D7467 limits, but extremely high compared to most fuel samples. All fuel filters showed media collapse and media discoloration once removed. Black gum was extracted from the fuel filter and was analyzed and determined to be consistent with byproducts from biodiesel oxidation. [EPA-HQ-OAR-2019-0055-1203-A1, p. 141]

It is clear from the foregoing that acids in the presence of metal can lead to deposits. Fuel system corrosion causes injector and pump failures from water and fuels with high TAN. Although increased acidity provides increased lubricity, the increase in TAN can lead to deposit formation on fuel injection system hardware. [EPA-HQ-OAR-2019-0055-1203-A1, p. 141]

Prior to implementing compliance requirements on any commercially available B20, manufactures would need to develop sensors that can detect the oxygen concentration or other markers that define the biodiesel fraction in conventional diesel. This will need to be correlated to service frequency requirements to prevent component failures due to loss of oil oxidation and loss of TBN. Given the new emphasis on variable oil life attributed to biodiesel content, manufacturers would also need to update their diagnostic, adaptive calibration and maintenance prognostics to account for variable biodiesel blends and the associated impact to tailpipe emissions. Finally, OEMs would need time to work with lube oil manufacturers and ASTM standards committees to develop oil formulations that are resistant to oxidation and degradation over time. [EPA-HQ-OAR-2019-0055-1203-A1, p .141]

In addition to the durability concerns discussed above, fuel characteristics have the potential to alter engine out-emissions, as has been reported in CARB’s Biodiesel Characterization and NOx Mitigation Study. Table 1 from that study (reproduced below) illustrates the significantly increased NOx emissions levels observed when compared to a reference B0 diesel fuel. [EPA-HQ-OAR-2019-0055-1203-A1, p. 141]

The foregoing data further confirm that the requirement to allow the use of any commercially available biodiesel blends will pose serious risks to manufacturers’ ability to comply with in-use emissions standards. EMA supports that EPA has proposed to permit manufacturers to use results from fuel sample testing to void in-use test results after-the-fact (see §1036.415(c)(5)), but it is very uncertain whether manufacturers will able to identify improper fuel usage records or otherwise determine the cause of a failed in-use compliance test that might be attributable to previous operation on poor-quality fuels. In the event of a test failure, manufacturers would be compelled to differentiate normal system wear, contamination, or deactivation from that attributed to the use of biodiesel and/or inadequate maintenance procedures appropriate to account for the use of biodiesel. The ability to identify the source of damage resulting from the use of biodiesel may be difficult or inconclusive in many cases. The serious and costly consequences for recall due to compromised in-use compliance could result in manufacturers being compelled to reduce maintenance intervals to mitigate the risk of damage from biodiesel fuels, even to the point of requiring aftertreatment replacement within the useful life period, significantly increasing the cost of vehicles compliant with the new standards. [EPA-HQ-OAR-2019-0055-1203-A1, p. 142]

It is important to reiterate that EPA indicated in the RIA that the impacts of biodiesel would not significantly increase emissions and could be addressed by increasing the catalyst size. However, that data is based on engines compliant to a 0.20 g/bhp-hr NOx standard rather than the proposed Option 1 or 2 standard, where a "small" increase of just 0.002 g/bhp-hr could render a product non-compliant. That risk is exacerbated by a 800,000 mile useful life requirement. [EPA-HQ-OAR-2019-0055-1203-A1, p. 142]

The Coordinating Research Council (not EPA) is evaluating the influence that diesel fuel variables, as wells as varieties of renewable diesel and biodiesel fuels, have on tailpipe NOx emissions from the Stage 3 low-NOx technology EPA is relying on in this rulemaking. That testing is scheduled to be completed in May or June, with follow-on data analysis thereafter. Additional testing to understand long-term effects of operation on biofuels has yet to be planned, but should be very informative to the setting of standards as well, given EPA's new requirements for compliance using "any commercially available" biodiesel fuel meeting the current inadequate ASTM specifications. EPA has formulated its proposal without any of those fuels-impacts data. [EPA-HQ-OAR-2019-0055-1203-A1, p. 172]

All of the critical research outlined above was not available or not completed in time to support the pending NPRM. Indeed, the vital research at issue is still in process, with much of it expected to be delivered just as the proposed rule is expected to "go final" in the fall, all to meet EPA's goal of having the new low-NOx standards take effect in 2027. Thus, there is considerable risk that these critical data will be unavailable when these largely infeasible standards are to be finalized. [EPA-HQ-OAR-2019-0055-1203-A1, p. 172.]

Accordingly, EMA recommends expanding the fuel requirements beyond the current ASTM standards to include the more stringent European biodiesel standards and the Top Tier requirements. This would apply to both feedstocks (B100) as well as finish stock. It is widely understood that after metals contamination, poor fuel oxidation stability is a key factor contributing to much of the biodiesel-based engine damage and the cascading downstream collateral damage impacts to aftertreatment. [EPA-HQ-OAR-2019-0055-1203-A1, p. 143]

Additionally, EMA recommends that the applicable regulations explicitly provide for a maximum biodiesel content of 20% nationwide. The emissions impacts from biodiesel increase significantly as blend percentages increases. [EPA-HQ-OAR-2019-0055-1203-A1, p. 143]

Finally, EMA recommends that EPA support updating ASTM D975 and D7467 to reduce the allowable concentrations of Calcium, Magnesium. Sodium, Potassium and Phosphorous. EMA stands ready to work with EPA and other stakeholders to determine appropriate limits for those properties, reducing them to levels in the range of 1ppm. These new fuel standards should be developed based on industry experience, experimental data, and supplier input, and should be enforceable at the pump. [EPA-HQ-OAR-2019-0055-1203-A1, p. 143]

In addition to these finished fuel specifications, EMA recommends improvements to the B100 feedstock specification as well, to help enable higher quality finished fuels with biodiesel content. The following B100 specifications and recommendations refer strictly to B100 as a blendstock and not as a finished product. [EPA-HQ-OAR-2019-0055-1203-A1, p. 143]

To summarize, EMA opposes the requirement that manufacturers must comply on any commercially available biofuel meeting current ASTM D975 or ASTM D7467 standards. Manufacturers should be permitted to continue to specify the maximum allowable biodiesel blend levels for their products, and vehicles operating on, or having operated on, fuels inconsistent with the manufacturers’ recommendations, should not be required to comply with the final standards. In addition, EPA should take action to assist in the development and enforcement of the improved biofuel specifications listed above before holding manufacturers liable for compliance when operating on such fuels. Only after improved fuel quality standards are developed, implemented, and enforced at the pump can the industry embrace the widespread deployment of alternative fuels, and promote their usage, so as to realize the rapid and significant reductions in GHG emissions they might offer. [EPA-HQ-OAR-2019-0055-1203-A1, p. 143]

Organization: *Valero Energy Corporation*

In the preamble to the NPRM and the Regulatory Impact Analysis, EPA raised concerns about the potential for trace metals (especially sodium, potassium, calcium and magnesium) in biodiesel to adversely affect the performance of engines and emission control systems, suggesting that trace metals can accumulate in and impact the effectiveness of diesel particulate filters or poison selective catalytic reduction (SCR) catalyst. The potential routes for metals introduction into the fuel mentioned by EPA include: presence of metals in vegetable oil seeds used to produce the biodiesel feedstock; introduction of metals from catalysts or filtration media; and introduction of metals from hard wash water. EPA believes it is possible for ASTM D6751 and ASTM D975-compliant biodiesels to have trace metals present at levels that could impact emission control systems, and EPA indicates that ASTM is evaluating a possible revision to the measurement method in D6751 to a method with a lower detection limit. [EPA-HQ-OAR-2019-0055-1328-A2, p.8]

Although we have no basis to agree or disagree with EPA's concern regarding biodiesel, Valero is confident that metals are not an issue with renewable diesel. Any metals introduced via vegetable oil or animal fat feedstocks are removed as part of the unique processing involved in making renewable diesel. We recognize that EPA does not propose any regulations to address this issue. If EPA were to consider addressing the issue, however, we urge EPA to recognize that renewable diesel is processed in a different manner than biodiesel and should be distinguished accordingly. [EPA-HQ-OAR-2019-0055-1328-A2, p.8]

Organization: *Volvo Group*

The Volvo Group appreciates the following EPA Biodiesel Quality comments. "…metals (e.g., Na, K, Ca, Mg) can enter the biodiesel production stream and can adversely affect emission control system performance if not sufficiently removed during the production." (87 FR at p. 17563.) [EPA-HQ-OAR-2019-0055-1324-A1, p. 6]

While off-specification blends may not be widespread, continued focus on specifications that protect emission reduction performance and component durability is needed. In support of this objective, the Volvo Group promotes endorsement of the following ASTM B100 specifications contaminant limits: Na+K+Ca+Mg 4 ppm, P 1 ppm. [EPA-HQ-OAR-2019-0055-1324-A1, p. 6]

EPA Summary and Response

Summary:

Regarding the use of biodiesel and the effect of contaminants from biodiesel, EMA, Daimler, and Navistar state that current ASTM standards for biodiesel are inadequate compared to other worldwide standards, and the use of even a small amount of poor-quality biodiesel could damage the aftertreatment system. These commenters further state that increasing the size of the aftertreatment system to compensate for use of biodiesel would be counterproductive, and introduce packaging, cost, and fuel economy concerns. Therefore, they recommend that the Agency should not eliminate the current provision allowing manufacturers to restrict operation and testing with B20. Daimler further recommends that EPA consider a uniform, nationwide biodiesel blending proposal (for example, B5 standard for all diesel fuel sold).

Daimler states that they have observed concerning levels of metallic contamination in fuel samples collected from fleets. EMA states that a field fuel quality study revealed that over 50% of nozzle samples contained metals such as magnesium, calcium, and zinc. Additionally, EMA cites several instances of real-world problems experienced by customers operating on biodiesel fuels not meeting specification.

EMA, Daimler, and Navistar recommend EPA mandate more stringent standards on biodiesel fuel, such as improving the current ASTM specifications to lower metal content, and/or adopting of both Top Tier and EU biodiesel standards in lieu of the ASTM D975, D7467 and D6751 standards. Volvo also recommends more stringent limitations on contaminants. Further, EMA and Daimler recommend setting a maximum biodiesel percentage of 20% nationwide. EMA and Daimler state that the impact on emissions increases significantly as biodiesel percentages are increased beyond 20%.

Furthermore, EMA and Daimler support EPA's proposal to permit manufacturers to use results from fuel sample testing to void in-use test results after-the-fact. However, EMA and Daimler comment that identifying a test failure due to the use of biodiesel would be difficult or inconclusive, as fuel quality and recordkeeping by fleets and retail stations are not the responsibility of the OEM. Daimler further recommends that a more supportable program would be where if a vehicle or HDIUT fleet were selected at start of mileage accumulation and a cooperative fuel sampling program put in place over the vehicle's lifetime.

EMA comments that they oppose the requirement that manufacturers must comply on any commercially available biofuel meeting current ASTM D975 or ASTM D7467 standards. They recommend that manufacturers should be permitted to specify the maximum allowable biodiesel percentage usable in their engines, and further state that manufacturers should not be required to comply using engines which have not been fueled to the stated specification.

However, CARB comments in support of the inclusion of all commercially available fuels, including fuels that contain biodiesel up to 20 percent, in off-cycle testing. The Renewable Energy Group comments that blends including 20 percent biodiesel should be the norm. API also agrees with EPA that there is no widespread off specification biodiesel blend stock or biodiesel blends in the marketplace. Clean Fuels comments that the most recent studies have shown that metals contamination in biodiesel is, on average, well below the standards set both in the United States and in Europe. MECA comments that results of a survey by researchers at NREL of biodiesel has shown metal content far below the current specification for the vast majority of samples collected. Both MECA and the Renewable Energy Group state that CARB also collected diesel and biodiesel samples, finding that phosphorus and metal contents of biodiesel were significantly lower than current ASTM limits. Additionally, the State Soybean Associations comments that there is insufficient evidence to conclude that metals can enter the production stream of biodiesel.

API also recommends that EPA consider the results of the SwRI study on the effect of biofuels on low NO_x emission control technologies before finalizing this rule.

MECA comments that sulfur is found in diesel fuels, and testing has shown some loss of aftertreatment performance due to the presence of sulfur from 435,000 miles to 800,000 miles. MECA also comments that metals found in lube oil can also cause deterioration in catalyst performance.

Multiple organizations, including Daimler, Neste, and Valero, support the use of renewable diesel. Valero comments that they are certain metal contamination is not an issue with renewable diesel.

Response:

In regard to water and acid content of the fuel; we do not have evidence that this is a widespread issue. In addition, engines are already equipped with fuel-water separators that mitigate the effects of water and inorganic acid by removing them prior to the fuel entering the fuel injection system. Based on this, we believe that we have adequately assessed the costs of this rule; our cost analysis is detailed in the preamble and RIA for the final rule.

The rest of EPA’s response to these comments is detailed in preamble Section III.C.4.ii.

11.5.5 PM emissions measurement

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

U.S. EPA requested comment on the need to measure PM emissions during in-use testing. CARB staff opposes eliminating PM emissions measurement during heavy duty in-use testing. PM emission measurement is critical to determine if an engine is emissions compliant and even more so now that the PM emission standard is lowered to 0.005 g/bhp-hr to ensure current wall flow DPF technology will be used. Unfortunately, CARB staff has discovered that manufacturers have been inappropriately screening their HDIUT vehicles. This includes but is not limited to rejecting engines based on visual inspections that identify excess PM on the exhaust tailpipe and replacing DPFs prior to in-use testing. These inappropriate screening practices were discussed by CARB staff at industry workshops. Since it is unclear how the historical engines in the HDIUT program were screened for PM testing, we believe it is necessary to continue PM testing. CARB staff strongly opposes the NPRM proposal to consider opacity testing for determining PM compliance. CARB staff believes that while opacity testing may well provide an indication of a failed DPF, it cannot, define PM emission compliance, especially with the proposed lower PM standard. Hence, CARB staff would not accept an opacity test method for determining compliance in lieu of current 1065 PM test requirements. [EPA-HQ-OAR-2019-0055-1186-A2, p.61]

Organization: *PACCAR, Inc (PACCAR)*

Proposed 1036.415(g) provides that '[y]ou may ask us to waive testing relative to one or more emission standards if you can show that field testing for such emissions is not necessary.' EPA must provide OEMs additional flexibilities. [EPA-HQ-OAR-2019-0055-1346-A1, p.55]

As a general matter, the proposed HDIUT testing needs to be streamlined to make the individual tests less burdensome because overall testing is expected to increase due to (i) more cases where 7 to 10 engines will need to be tested and (ii) possible separate engine families for California. PEMS testing requires skilled engineers and technicians who are willing and able to carry out challenging, physical work while traveling in harsh environments and expending long hours often during the night. These individuals are always very difficult – and currently nearly impossible – to find. [EPA-HQ-OAR-2019-0055-1346-A1, pp.55-56]

HDIUT testing also significantly disrupts OEM customers rendering recruiting participants extremely challenging. To sustain a base of customers that are willing to participate, and to make the proposed program potentially feasible, OEMs would need to drastically reduce installation time, vehicle space, and electrical power. On this issue, PACCAR incorporates EMA's Comments on this subject. See EMA Comments at 41. [EPA-HQ-OAR-2019-0055-1346-A1, p.56]

Organization: *Truck and Engine Manufacturers Association (EMA)*

In the Preamble to the NPRM, EPA requests comment on whether in-use testing for PM is still necessary. It is not, and should be eliminated. In fact, since the beginning of 2015 – more than seven years ago – EMA has been requesting that the Agency eliminate in-use testing for PM. EPA staff agreed with EMA on this matter in mid-2020, but have not taken the necessary steps to revise the relevant regulations. Now is the time to do that. [EPA-HQ-OAR-2019-0055-1203-A1, p. 44]

The background for this issue is important. The heavy-duty in-use testing (HDIUT) program, including for PM, resulted from the 2003 settlement of extensive NTE-related litigation (asserting that there were no sufficient test procedures for the then-new NTE standards). As part of that settlement, the parties (EMA, EPA, and CARB) negotiated a comprehensive outline of the NPRM for the HDIUT program, which included the following express provisions: The goal of this [HDIUT] program is to generate data on in-use emissions of heavy-duty on-highway diesel engines that can be used by EPA, CARB, and diesel engine manufacturers to ensure that emission standards are met throughout the useful life of 2007 and later model year heavy-duty on-highway diesel engines under conditions normally experienced in-use. The program is intended to monitor for NTE compliance and to help ensure overall compliance with emission standards. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 44 - 45]

The background for this issue is important. The heavy-duty in-use testing (HDIUT) program, including for PM, resulted from the 2003 settlement of extensive NTE-related litigation (asserting that there were no sufficient test procedures for the then-new NTE standards). As part of that settlement, the parties (EMA, EPA, and CARB) negotiated a comprehensive outline of the NPRM for the HDIUT program, which included the following express provisions: In-use NTE emissions testing will include total hydrocarbons (THC), carbon monoxide (CO), oxides of nitrogen (NOx), particulate matter (PM), and carbon dioxide (CO2) (and also O2)….Recognizing that experience may show that the effectiveness, durability and overall performance of new engine technologies and aftertreatment systems may demonstrate that in-use testing for certain pollutants may not be necessary, EPA/CARB will consider requests from the engine manufacturers to discontinue reporting and/or measurement of one or all engines based on test experience. [EPA-HQ-OAR-2019-0055-1203-A1, p. 45]

The follow-on final HDIUT rule was fully consistent with the parties' negotiated outline, and stated in relevant part as follows: All manufacturers will be regularly providing EPA with a significant quantity of data generated from engines used in regular service, which EPA will evaluate to ensure the engines comply with specified emissions requirements. The rule is a result of an agreement between EPA and the Engine Manufacturers Association. (70 FR at 34594.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 45]

The follow-on final HDIUT rule was fully consistent with the parties' negotiated outline, and stated in relevant part as follows: [HDIUT] is specifically intended to monitor compliance with the NTE exhaust emission standards and to help ensure that heavy-duty diesel engines will comply with all applicable emission standards (including those based on the FTP) throughout their useful lives. (70 FR at 34595.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 45]

The follow-on final HDIUT rule was fully consistent with the parties' negotiated outline, and stated in relevant part as follows: Recognizing that experience may show that the effectiveness, durability and overall performance of new engine technologies and exhaust aftertreatment systems may demonstrate that in-use testing for certain pollutants is unnecessary, we will consider requests from the engine manufacturers to discontinue reporting and/or measurement of one or more pollutants from some or all engines based on future test experience. (70 FR at 34610.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 45]

Test experience, which EMA catalogued and shared with the Agency starting in 2015, has conclusively demonstrated that the measurement and reporting of in-use PM emissions is both unnecessary and costly. Thus, EPA should honor its commitment to eliminate HDIUT for PM. More specifically, since 2006, the relevant test results from the HDIUT program have demonstrated that there have been no “failures” for PM emissions. While one failure was initially reported, that vehicle was subsequently found to have a cracked DPF due to misfuelling. Indeed, EPA has acknowledged that there have been no in-use testing failures for PM under the HDIUT program. At the same time, in-use testing for PM is expensive, and requires a separate PEMS, elaborate installation configurations and vehicle mountings, significant additional vehicle recruiting and set-up time, and significant additional de-installation and post-processing time. [EPA-HQ-OAR-2019-0055-1203-A1, p. 46]

The proposed reduction of the certification standard for PM (from 0.010 g/bhp-hr to 0.005 g/bhp-hr) does not alter the justifications for eliminating PM from the manufacturer-run HDIUT program. As EPA concedes, that reduced standard will not drive any new DPF technologies; it is simply intended to prevent hypothetical “backsliding.” Accordingly, no new risks of noncompliance are at issue. Moreover, eliminating manufacturers’ in-use testing for PM will also eliminate the Agency’s legitimate concerns of whether PM PEMS are up to the challenge of assessing in-use PM levels below 6 or 7 mg/bhp-hr. (See NPRM, 87 FR at 17468.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 46]

There is an additional technical reason supporting the elimination of in-use testing for PM. In-use PM compliance is already monitored by on-board PM sensors. The failure mode for a DPF is cracking, which is easily detected by a PM sensor. Thus, if the goal of the HDIUT program for PM is to monitor DPF performance in-use, that is already robustly built-in with today’s engines. Consequently, and as EPA staff has previously agreed, it is time to eliminate HDIUT testing for PM. There is no reasonable basis to do otherwise at this point. [EPA-HQ-OAR-2019-0055-1203-A1, p. 46]

It also is time to eliminate in-use testing for NMHC. The reasons for this are many and well-documented. First, there is a growing need to streamline HDIUT testing because the test burdens (the number of engine families and potentially the number of tests per family) continue to grow. Second, the HDIUT program is very disruptive to an OEM’s customers, which makes it extremely difficult to recruit willing fleet-owner participants A smaller footprint in terms of installation time, vehicle space, and electrical power is required to streamline HDIUT testing to maintain a sustainable base of willing customers needed to support this program. [EPA-HQ-OAR-2019-0055-1203-A1, p. 46]

This is not a trivial concern. Installation of PEMS often involves the removal of certain items that can include passenger seats, windowpanes, storage boxes, bedding and personal belongings, and other accessories and equipment belonging to the customer or driver. There is always risk of damage to a customer vehicle, and customers are often surprised by the intrusive nature of a PEMS installation and left questioning what they agreed to. When a PEMS test needs to be repeated, the altered configuration of the vehicle sometimes limits flexibility in terms of the next assigned task for the customer vehicle. It is not unusual for a customer to need to alter their activities and/or driver schedules to accommodate an OEM's need for extended in-use testing. The ancillary in-use testing of NMHC and PM adds significant risks that additional days of testing will be necessary due to an issue with an analyzer. In sum, in-use testing needs to be less invasive to be sustainable. [EPA-HQ-OAR-2019-0055-1203-A1, p. 46]

Third, a streamlined PEMS (i.e., gas PEMS, without FID or PM PEMS) is much lighter and has a much lower power requirement, such that it is feasible to power it with Li-ion batteries or 12 volt power from the chassis electrical system, or both, potentially eliminating the need for a gasoline-powered generator and its associated hazards, space requirements, and possible delays during inspection at a truck scale, which can adversely affect customers' operation. A streamlined PEMS's would reduce staffing pressure for executing PEMS tests, could be installed in a reasonable amount of time with minimal disruption to the customer vehicle, and would eliminate the risks of voiding a test or rescheduling a test trip due to a PM or FID analyzer issue. [EPA-HQ-OAR-2019-0055-1203-A1, p. 47]

Other more technical issues also warrant the elimination of in-use NMHC testing going forward: Diesel engines are inherently low emitters of NMHC, and there have been few, if any, failures of in-use tests for NMHC emissions since the inception of the HDIUT program. [EPA-HQ-OAR-2019-0055-1203-A1, p. 47]

Other more technical issues also warrant the elimination of in-use NMHC testing going forward: Hazards and associated HazMat handling protocols for the use of FID fuel (DOT special permit and HazMat shipper certification) is an unnecessary risk. Customers often express concern over the FID fuel, and recognize that it adds risk for major disruptions during an inspection at a weigh station. NMHC testing puts OEMs in the position of directly asking a customer to assume that risk. [EPA-HQ-OAR-2019-0055-1203-A1, p. 47]

Other more technical issues also warrant the elimination of in-use NMHC testing going forward: The supply of FID fuel is expensive and unreliable due to the continuing Helium shortage. [EPA-HQ-OAR-2019-0055-1203-A1, p. 47]

Other more technical issues also warrant the elimination of in-use NMHC testing going forward: The 181°C heated line and FID temperatures that are necessary to avoid HC hang-up to keep HC's in gaseous form drive high demand for power that is limited in a PEMS application. Long heated lines are often necessary due to constraints on the location of the PEMS, which draw even more power due to their length. [EPA-HQ-OAR-2019-0055-1203-A1, p. 47]

Other more technical issues also warrant the elimination of in-use NMHC testing going forward: OEM's are already incentivized to reduce NMHC to manage risks of thermal runaway of an aftertreatment system contaminated with HC. [EPA-HQ-OAR-2019-0055-1203-A1, p. 47]

Other more technical issues also warrant the elimination of in-use NMHC testing going forward: Actions necessary to control engine-out PM also reduce HC emissions (i.e., high injection pressure, droplet size, and distribution). Low engine-out PM is desired to minimize EGR cooler fouling and to reduce regen frequency to improve IRAF and fuel economy driving a co-benefit of HC reduction. [EPA-HQ-OAR-2019-0055-1203-A1, p. 47]

Other more technical issues also warrant the elimination of in-use NMHC testing going forward: The base architecture of diesel aftertreatment systems includes an NMHC-reducing DOC necessary to support combustion of the injected HC that, in turn, is needed to support DPF regen cycles. [EPA-HQ-OAR-2019-0055-1203-A1, p. 47]

Other more technical issues also warrant the elimination of in-use NMHC testing going forward: The base architecture of diesel aftertreatment systems includes an AMOX catalyst necessary to control ammonia slip, which can also reduce NMHC. [EPA-HQ-OAR-2019-0055-1203-A1, p. 47]

Other more technical issues also warrant the elimination of in-use NMHC testing going forward: NMHCs from diesel engines are composed of heavy long-chain HCs lacking the volatility needed to contribute to ozone formation.[EPA-HQ-OAR-2019-0055-1203-A1, p. 47]

Other more technical issues also warrant the elimination of in-use NMHC testing going forward: HC standards are to be lowered under the NPRM, but that is driven by goals for SI engines (EPA stated goal is to maintain the same numerical standard for CI and SI). There is no intent to force any new technology to control HCs from CI engines, and CI engine currently easily comply with the NMHC standard. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 47-48]

In sum, there is no need for further incentives to control NMHC emissions; there is no undeployed control technologies for NMHC; and no environmental need that justifies the continued burdensome measurement of NMHC with PEMS in the HDIUT program. Accordingly, just as for PM, EPA should eliminate the need to conduct in-use testing for NMHC. [EPA-HQ-OAR-2019-0055-1203-A1, p. 48]

EPA Summary and Response

Summary:

CARB opposes eliminating PM emissions measurement during heavy duty in-use testing. They comment that manufacturers have been inappropriately screening their HDIUT vehicles by rejecting engines based on visual inspections that identify excess PM on the exhaust tailpipe and replacing DPFs prior to in-use testing, and thus it is not clear in what way engines were historically screened for PM testing. CARB also opposes using opacity testing for determining PM compliance.

EMA comments that testing for PM emissions is unnecessary and costly. EMA states that since 2006, there have been no test failures for PM emissions, and that the reduction of the certification standard for PM will not introduce further risks of noncompliance. Additionally, they state that the failure mode for a DPF is cracking, which is easily caught by onboard PM sensors.

EMA also comments that testing for NMHC should be eliminated. They state that streamlining the PEMS unit would reduce cost and test burden and reduce the intrusion on the vehicle owner's time and space from installing the PEMS unit. They further comment that there have been few, if any, failures of in-use tests for NMHC emissions since the inception of the HDIUT program, and that there is no environmental need that justifies the continued burdensome measurement of NMHC with PEMS in the HDIUT program. PACCAR states that HDUIT testing needs to be less burdensome, and explicitly agrees with EMA's comments on streamlining testing.

Response:

EPA does not agree with the comment by CARB that removing the requirement for in-use off-cycle PM standards testing will lead manufacturers to stop using wall flow DPF technology to meet the PM standards. Wall flow DPF technology will still be needed to meet the standards at the time of certification, especially given the PM standard of 5 mg/hp-hr promulgated in this action. EPA also does not share CARB staff's concern that manufacturers have been inappropriately screening their HDIUT vehicles for PM related concerns. If a DPF is properly maintained there will be no visible soot on the tailpipe. If soot is found on the tailpipe, that is indicative of a DPF failure, typically due to cracking of the substrate that allows PM to slip between the catalyst channel walls. Measurement of PM from a failed trap due to cracking is not representative of the level at which a properly maintained and functioning system emits PM.

EPA has considered comments on elimination of requirements to measure PM and NMHC emissions; a discussion is included in preamble Section III.C.4.b.

11.5.6 Notification and data reporting

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

CARB staff supports the new requirement in 1036.430(c)(1) where notification is required after the testing of an engine is completed. This would aid in real time assessment of the test plan and provide updates sooner than the previous quarterly reporting requirements. [EPA-HQ-OAR-2019-0055-1186-A2, p.64]

Organization: *PACCAR, Inc (PACCAR)*

PACCAR respectfully request that EPA revise certain aspects of its proposed reporting requirements provisions. Proposed 1036.430(a)(3)(ix) would only authorize gaps in the 1 Hz test data file over the shift-day during analyzer zero and span verifications. This overlooks the fact that data gaps will exist when the engine is off. Any data transmitted by the engine ECU will stop when the key is off because a shut-off ECU is unable to send data. Therefore, EPA should add a 'key off' condition to the list in the Agency's proposed provision. [EPA-HQ-OAR-2019-0055-1346-A1, p.57]

EPA should also clarify the effect, if any, of potential data gaps. PACCAR respectfully submits that data gaps should not necessarily void a test, especially because occasionally an analyzer or measuring instrument will encounter a temporary issue. Proscribing any data gaps is unrealistic and overly burdensome – as long as the minimum window count is met, the test should be valid notwithstanding potential data gaps. EPA should revise its proposal accordingly. [EPA-HQ-OAR-2019-0055-1346-A1, pp.57-58]

PACCAR is also concerned with proposed 1036.430(a)(3)(ix)(O), which currently provides: 'Any parameter sensed or controlled to modulate the emission control system or fuel-injection timing.' As drafted, this provision is too broad and vague to provide regulatory certainty and enable compliance. EPA should therefore remove it. [EPA-HQ-OAR-2019-0055-1346-A1, p.58]

Organization: *Truck and Engine Manufacturers Association (EMA)*

In the reporting requirements of §1036.430(a)(3)(ix), EPA proposes to require that "gaps in the 1 Hz data file over the shift-day are only allowed during analyzer zero and span verifications." That is an impractical and unworkable requirement. First, the vehicle's CAN communications are interrupted whenever there is a key-off event. The PEMS may continue to record, but much of the required data provided by vehicle systems is not available during these engine-off events. Second, because PEMS are imperfect devices, it is currently difficult to complete a day of testing without at least one incident of data interruption. In some cases, toward the end of a test day, the FID may exhaust its fuel supply, terminating measurement capability. The provision as drafted is outside the test technician's control and should be eliminated in the final rule. [EPA-HQ-OAR-2019-0055-1203-A1, p. 92]

Another item of concern relates to EPA's proposed §1036.430(a)(3)(ix)(O), where it would be required, for each vehicle tested, that manufacturers provide 1 Hz data for "any parameter sensed or controlled to modulate the emissions control system or fuel injection timing." That requirement simply cannot be fulfilled. There are hundreds if not thousands of calculations performed in the ECU that contribute in some way to engine and aftertreatment control that would be subject to this requirement. SAE standards J1939 and J1979 would require updating to include this multitude of parameters, which, in reality would be an impossible task given that each manufacturer has its own set of control algorithms. The requirement is unworkable, and should be eliminated in the final rule. [EPA-HQ-OAR-2019-0055-1203-A1, p. 93]

EPA Summary and Response

Summary:

CARB supports the provision in §1036.430(c)(1) requiring notification after the testing of an engine is completed.

EMA and PACCAR comment that only allowing gaps in the 1 Hz data file over the shift day during analyzer zero and span verifications is unworkable. EMA and PACCAR state that data interruptions can occur during a key-off event, and PEMS units can also experience data interruptions; stating that both of these occurrences are unavoidable. EMA and PACCAR further state that the requirement that manufacturers provide 1 Hz data for "any parameter sensed or controlled to modulate the emissions control system or fuel injection timing" is also unworkable, as there are hundreds if not thousands of calculations performed which affect the emissions control system.

Response:

EPA agrees with EMA and PACCAR that gaps in the collection of emissions data in the 1 Hz data files when the engine is keyed off are unavoidable and is adding this as an allowed exclusion in the final 40 CFR 1036.430(a)(3)(ix). In response to this concern EPA is finalizing a new 40 CFR 1036.430(a)(4)(vi) that was not in the proposal, that covers summary information that must be included with the data submission and states "Describe the number and length of any data gaps in the 1 Hz data file, the reason for the gap(s), and the parameters affected." Requiring a summary report of these exclusions will limit the number of allowable exclusions and protect against manufacturers not including data that is unfavorable in the test and representing them as data gaps. In the windowing process, these gaps must be treated as exclusions and concatenated across as described in 40 CFR 1036.530.

Additionally, EPA agrees that the recording of ECU calculated parameters is unworkable and this was not the intention of what we proposed. The final requirement to provide 1 Hz data in 40 CFR 1036.430(a)(3)(ix)(O) applies only to parameters sensed or controlled and available on the Controller Area Network (CAN), and not parameters internal to the ECU. This requirement is no different than the current requirement for HDIUT NTE testing in 40 CFR part 86.1920(b)(4)(xii)(O). CAN signals that indicate changes to fuel injection timing or operational parameters of the emission control system are important to understand the operation of the engine in concurrence with what is being emitted from the engine.

11.6 PEMS and measurement accuracy margin (Preamble III.C.5.iii)

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

U.S. EPA requested comment on PEMS measurement uncertainty. CARB staff has significant concerns with U.S. EPA adding a PEMS accuracy margin for NOx in addition a certification standard multiplier for establishing the off-cycle standards. CARB staff views the use of both a multiplier and a separate PEMS accuracy margin to be redundant and unnecessary; having both a multiplier and accuracy margin would unnecessarily raise the off-cycle emissions threshold and allow excess emissions. The effects of applying multiple in-use margin is clearly listed in Table 6-1 above. Furthermore, U.S. EPA's impermissibly failed to consider the extent to its proposal will likely result in in-use emissions exceeding the off-cycle standards. State Farm, 463 U.S. at 43. [EPA-HQ-OAR-2019-0055-1186-A2, p.61]

CARB staff agrees with the JRC study estimated the uncertainty of PEMS measurements to be 10 percent. The PEMS accuracy evaluation conducted by JRC recommends the multiplier between the standard and the in-use threshold for the In-Service Conformity testing be reduced to the PEMS uncertainty (i.e., using a conformity factor of 1.10 multiplier to set the off-cycle standard). The U.S. EPA proposed off-cycle emission thresholds would be between 10 to 120 percent greater than the Omnibus thresholds. CARB staff believes the conformity factor in the 3B-MAW in the HD Low NOx rulemaking 129 and the multipliers in the off-cycle emission standards are already inclusive of the PEMS accuracy margin for NOx. The recommendations in the JRC report130 are to reduce their conformity factor to the estimated error rather than having an additive PEMS margin as proposed by U.S. EPA. CARB staff suggests not to have an additional PEMS accuracy margin of 10 percent of the off-cycle emissions standard to be applied when evaluating bin emissions. CARB staff also suggests that U.S. EPA review the latest PEMS measurement results from the Achates engine.131,132,133 [EPA-HQ-OAR-2019-0055-1186-A2, pp.61-62]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

Daimler Truck supports an adequate Portable Emissions Measurement System (PEMS) measurement error allowance. [EPA-HQ-OAR-2019-0055-1168-A1, p.69]

Finally, Daimler Truck supports EPA’s proposal to include a margin for PEMS measurement error. While EPA references some initial studies on PEMS uncertainty on EPA’s candidate system, the Agency has not performed a broad study across a wide variety of test cycles and ambient conditions. It is well known that PEMS variability is heavily dependent on ambient conditions. We believe that EPA must perform a joint study with industry to determine an appropriate margin to apply. Manufacturers must have certainty that their systems will pass based on the merits of their actual emissions performance, and not be held liable for inaccurate measurements performed in the field. Moreover, we point the EPA to EMA’s extensive comments on this topic.90 We believe industry must participate in the testing to determine an adequate allowance. [EPA-HQ-OAR-2019-0055-1168-A1, p.69-70]

90 See EMA Proposed Rule Comments.

Organization: *General Motors LLC (GM)*

Real world emissions testing plays an important role in confirming that emissions systems are performing as designed in the field. Portable Emissions Measurement Systems (PEMS) are laboratory devices that may be temporarily installed on a vehicle to estimate emissions produced during real-world driving. The measurement capability of these systems to estimate emissions is less precise, accurate, and repeatable than dedicated lab facilities. Similarly, the test procedures, and binning of emissions results based on a wide range of conditions,8 produce significant variance in the estimate of emissions relative to proposed standards. EPA is considering standards, as measured in the laboratory, that reduce emissions rates to a small fraction of the current standard. As a result, the noise typically associated with data collected from PEMS is amplified relative to the size of the standard. EPA should carefully consider the precision, accuracy, and repeatability of measurements in PEMS devices when finalizing conformity factors. Low conformity factors in combination with standards with very small emissions increase the likelihood of misdiagnosing emissions performance when measured with PEMS. [EPA-HQ-OAR-2019-0055-1246-A1, p.4]

8 Idle, start-stop, highway driving, laden highway driving, etc.

GM recommends that, if PEMS must be used to verify compliance with very stringent criteria emissions standards, a larger conformity factor be specified to properly account for the capability of the PEMS device to accurately estimate emissions. [EPA-HQ-OAR-2019-0055-1246-A1, p.4]

Organization: *PACCAR, Inc (PACCAR)*

Proposed 1036.420 is flawed because a ten percent margin is much too small. In any event, PACCAR expects SwRI's ongoing work will support a much different PEMS accuracy margin and encourages EPA to use those findings to establish the margin. [EPA-HQ-OAR-2019-0055-1346-A1, p.56]

Organization: *Truck and Engine Manufacturers Association (EMA)*

In order to ensure the adoption of fully achievable and cost-effective HDOH low-NOx regulations, and notwithstanding our broader agreement, the Agency should revise the proposed standards in the following manner: The proposed in-use standards should be adjusted to account for the measurement variability and capabilities of portable emission measurement systems ("PEMS"), and to reflect the fact that the current OBD thresholds will not be able to screen-out potentially malfunctioning vehicles, as is done under the current in-use testing program. While EMA agrees with the Agency that the in-use standards should be reduced, the safeguards to ensure proper vehicle screening and to guard against "false" or otherwise unwarranted failures need to be retained. [EPA-HQ-OAR-2019-0055-1203-A1, p. 7]

EPA is proposing to address this issue by providing for a 10% measurement allowance (accuracy margin) based on an earlier European study that did not evaluate PEMS in the context of testing ultra-low-NOx engines in-use. (87 FR at p. 17477.) Nevertheless, on the basis of that one earlier study, EPA is proposing to reduce the current in-use accuracy allowance margin for NOx from

150 mg/bhp-hr to what amounts to 3 mg/bhp-hr with respect to the “Bin 3” standard – a 98% reduction. That is an unreasonable reduction. The accuracy of PEMS at low-NOx levels certainly has improved, but not by 98%. EPA should wait for the results from the pending PEMS Measurement Allowance Study at SwRI before proposing, in effect, to eliminate the in-use accuracy margin for NOx. [EPA-HQ-OAR-2019-0055-1203-A1, p. 11]

An additional component of SwRI’s work has included a technical assessment of the type of MAW-based approach on which EPA intends to build its 3B-MAW in-use compliance program. SwRI’s research and findings indicate that the necessary sensors and electronically-broadcast engine parameters may not be accurate or robust enough to implement EPA’s 3B-MAW-based approach as envisioned. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 81 - 82]

Specifically, SwRI has examined whether state-of-the-art NOx sensors are sufficiently accurate at low-NOx levels to support the proposed in-use regulations. As depicted in Figures 72 and 73 below from the SwRI Report, SwRI found that “substantial errors can be seen on the order of 10% to 20%, which errors grow larger at low overall NOx mass levels,” and that “NOx sensor data at present are not yet at the same level of accuracy as some of the other EMC broadcast measurements, such as exhaust flow.” (SwRI Report, ISOR Reference 191, p. 63.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 82]

In summing up its conclusions regarding CARB’s (and now, EPA’s) MAW-based approach, SwRI highlighted the facts that NOx sensors will “require considerable improvement in application and accuracy to support in-use compliance measurements at Low NOx levels,” and that “further investigation of the [in-use] metrics is needed, as well as to set a proper compliance threshold for whichever new metric is chosen.” (SwRI Report, ISOR Reference 191, p.88.) Accordingly, SwRI ended its report with the following recommendation: “More analysis needs to be performed before setting a final in-use measurement protocol, and the appropriate compliance thresholds [plural] for that protocol.” (SwRI Report, ISOR Reference 191, p. 89.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 83]

Following on that recommendation, and with funding from EMA and other stakeholders, SwRI has conducted additional research on the capabilities of current NOx-sensors to assess emissions at the ultra-low NOx values at issue. The results of that follow-on research are significant. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 83 - 84]

Perhaps just as significant as the concerns related to the 3B-MAW protocol, which concerns support the adoption of EMA’s alternative combined-bin approach, there are a number of concerns regarding whether the portable emissions measurement systems (PEMS) that will be used to implement and enforce the proposed in-use testing program are capable of measuring and “binning” NOx emissions at the near-zero levels that the low-NOx regulations would require. [EPA-HQ-OAR-2019-0055-1203-A1, p. 84]

Current PEMS may not be capable of measuring and sorting NOx emissions at levels below the Option 1 Bin 3 NOx standard of 0.030 g/bhp-hr level. To the contrary, the regulatory-capable NOx-detection and measurement range of current PEMS is at a level that can be equivalent to a significant percentage of the in-use NOx limits that EMA’s regulations envision, and that is before any in-use operational and environmental conditions and impacts are taken into account. [EPA-HQ-OAR-2019-0055-1203-A1, p. 84]

All stakeholders have recognized the critical importance of evaluating and quantifying the incremental low-NOx accuracy and variability of current PEMS. Accordingly, multiple stakeholders, including EPA, are collaborating on a PEMS Measurement Allowance (PEMS-MA) Evaluation Project at SwRI. Work under that program is still on-going, and an additional follow on PEMS-MA in-use validation program will be initiated soon. EPA will need to account for those measurement allowance results before finalizing this rule. [EPA-HQ-OAR-2019-0055-1203-A1, p. 84]

The need for a sufficient PEMS-related measurement allowance is well-established. The current PEMS measurement-accuracy adjustment factor was determined in 2008 through an extensive series of tightly controlled laboratory and in-vehicle tests designed specifically for the assessment of PEMS measurement accuracy and variability. EPA was an active participant in the development of that testing program, which was performed at SwRI.17 [EPA-HQ-OAR-2019-0055-1203-A1, p. 84]

> 17 See "Determination of PEMS Measurement Allowances for Gaseous Emissions Regulated Under the Heavy-Duty Engine In-Use Testing Program." SAE Paper, 2009-01-0938/0939/0940, SAE International Journal of Fuels and Lubricants (2009); EPA Report No. EPA 420-R-08-005 (Feb. 2008); EPA, Direct Final Rule, "In-Use Testing for Heavy-Duty Diesel Engines and Vehicles; Emission Measurement Accuracy Margins for Portable Emission Measurement Systems," (73 FR 13441-52, March 13, 2008).

To put this issue into perspective, today's NTE-based in-use NOx standard of 0.30 g/bhphr (0.45 when the authorized NOx measurement allowance of 0.15 g/bhp-hr is added on) involves measuring NOx concentrations on the order of 45 ppm. In comparison, the proposed medium/high load 3B-MAW "Bin 3" in-use Option 1 NOx standard of 0.030 g/bhp-hr would require measuring NOx concentrations of approximately 4 to 5 ppm, or closer to 3 ppm since manufacturers would need to design for some minimum level of compliance margin. Those single-digit ppm levels are not far removed from the "drift" of PEMS NOx measurements over an 8-hour period, before factoring in any of the actual in-use sources of PEMS' measurement inaccuracy and variability, such as signal noise, span errors, time-alignment, fuel and exhaust-flow estimates, interference from other emissions species in the exhaust stream, and varying environmental and ambient conditions. To be able to tolerate unavoidable NOx breakthroughs in the medium/high bin, the overall window result would basically have to be zero. Thus, 2 or 3 ppm of PEMS measurement error, on its own, could lead to a non-compliant in-use NOx result. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 84-85]

Significantly, the measurement "drift" that is permitted under the relevant federal and CARB specifications for emissions-measurement equipment (see 40 CFR 1065.550) would equate to a 0.0008 g/bhp-hr drift limit at the low NOx levels that EPA is targeting, a drift limit that would be difficult even for laboratory grade instruments to meet, let alone PEMS. [EPA-HQ-OAR-2019-0055-1203-A1, p. 85]

Given the foregoing, it is vitally important for EPA to fully account for the results of SwRI's current PEMS-assessment program before finalizing the in-use compliance elements of EPA's low-NOx regulations. EPA's proposal to provide for a 10% accuracy margin (see NPRM, p. 219) is simply not adequate nor sufficiently data-based. It would amount to a 0.003 g/bhp-hr NOx margin for Bin 3, as compared against the current NOx accuracy margin of 0.15 g/bhp-hr. EPA has not and cannot demonstrate that such a 98% reduction in the in-use accuracy margin for NOx is appropriate. [EPA-HQ-OAR-2019-0055-1203-A1, p. 85]

Such a massive regulatory undertaking, with cost implications many times over any prior rulemaking directed at the heavy-duty engine and vehicle industry, should be supported by extensive research and analysis to prove-out and justify the very considerable expenses and burdens that will fall upon manufacturers and the public. Unfortunately, that is not the case here. To the contrary, there are many underlying research activities that are still underway, some which likely will not be completed by the time the rule is finalized, let alone when it was proposed, and there are other major gaps in the overall research effort that will not be filled at all. [EPA-HQ-OAR-2019-0055-1203-A1, p. 171.]

The PEMS measurement variability study, involving extensive testing, modeling, analysis, and verification, is incomplete. SwRI anticipates completing that work, which also will be supported through on-road validation testing by UC Riverside (CE-CERT), by the end of August 2022, likely just weeks before EPA will be obliged to finalize this rulemaking according to the Agency's internal self-imposed schedule. [EPA-HQ-OAR-2019-0055-1203-A1, p. 171]

All of the critical research outlined above was not available or not completed in time to support the pending NPRM. Indeed, the vital research at issue is still in process, with much of it expected to be delivered just as the proposed rule is expected to "go final" in the fall, all to meet EPA's goal of having the new low-NOx standards take effect in 2027. Thus, there is considerable risk that these critical data will be unavailable when these largely infeasible standards are to be finalized. [EPA-HQ-OAR-2019-0055-1203-A1, p. 172.]

EPA Summary and Response

Summary:

CARB comments that they believe adding a PEMS accuracy margin within off-cycle standards is unnecessary, as the conformity factor used is already inclusive of the PEMS accuracy margin for NOx. In support, they cite a JRC study which recommends a conformity factor equal to the PEMS uncertainty, without an additional PEMS margin. Furthermore, CARB comments that EPA impermissibly failed to consider the extent to which its proposal will likely result in in-use emissions exceeding the off-cycle standards.

In contrast, Daimler, GM, and PACCAR all state that a PEMS accuracy margin is necessary, and that a 10% margin is too small. EMA agrees in their comments, and furthermore states that the testing cited by the EPA in establishing this margin was based on a study that did not evaluate PEMS in the context of testing ultra-low-NOx engines in-use. In support, EMA refers to a SWRI study finding that NOx sensors have substantial errors on the order of 10% to 20%. Both EMA and PACCAR encourage EPA to account for results in the on-going PEMS-assessment program by SWRI before finalizing the PEMS accuracy margin value. Daimler recommends that EPA perform a joint study with industry to determine an appropriate margin to apply across a wide variety of test cycles and ambient conditions.

Response:

EPA disagrees with CARB that a PEMS accuracy margin is unnecessary. The conformity factor and PEMS margin, although both raise the numeric value of the in-use standard, are applied for different reasons and ultimately arrive at the same stringency whether the accuracy margin is part of or separate from the off-cycle standards. The final conformity factor was set at a level that was feasible based on the emission performance of the Stage 3 engine. The PEMS accuracy margin was set to capture the incremental measurement uncertainty of PEMS relative to the laboratory. EPA acknowledges the cited JRC study, but believes that having a conformity factor independent of the PEMS margin is necessary to separate the measurement variability from the standard, especially in situations where the in-use engine is removed from the vehicle and tested on an engine dynamometer. In such situations, the accuracy margin would not be applied to the off-cycle standard because the engine is being testing in the laboratory.

The PEMS accuracy margin work at SWRI on the Stage 3 engine included testing the engine over five field cycles with three different commercially available PEMS. EPA's conclusion after assessing the results from this study, as described in Section III.C of the preamble, was that 0.4 g/hr (which is 4 percent of the Bin 1 standard), is more appropriate for Bin 1 and 5 mg/hp-hr (which is 8.6 percent of the Bin 2 standard), is more appropriate for Bin 2. Thus, the proposed 10 percent uncertainty margin is reduced in the final provision.

12 Emission credits and averaging, banking, and trading (ABT)

12.1 General ABT provisions for NOx emission standards

Comments by Organizations

Organization: *Alliance for Vehicle Efficiency (AVE)*

AVE recommends EPA conduct compliance modeling based on different credit and flexibility scenarios and avoid backsliding. [EPA-HQ-OAR-2019-0055-1280-A1, p. 6]

Before adopting new flexibilities and credits, AVE recommends EPA provide modeling scenarios that outline possible compliance strategies manufacturers might deploy to meet future standards. The modeling would allow suppliers to better estimate the need for various advanced technologies to meet the future standards and to plan accordingly. [EPA-HQ-OAR-2019-0055-1280-A1, p. 6]

Organization: *American Automotive Policy Council (AAPC)*

The EPA HD Engine notice of proposed rulemaking includes provisions for using credits to meet fleet requirements. Averaging Banking and Trading (ABT) credits are an important flexibility for manufacturers to meet stringent emissions standards. [EPA-HQ-OAR-2019-0055-1293-A1, p. 1]

Flexibilities to earn credits and to move credits between years and product applications are helpful for manufacturers. Quick changes to production and product plans often result in stranded capital and disruptions to the supply chain and manufacturing workforce. Depending on the product lineup and lifecycle position of their product portfolio, a manufacturer may not have the ability to respond to large changes in stringency immediately, with limited lead time. Alternatively, a manufacturer may be able to transition quickly in one part of its business, but not immediately in another. Manufacturers are more likely to be able to respond to stringent regulations with adjustments to their portfolios over time, and an ABT program with sufficient flexibilities can help manufacturers smoothly transition to stringent regulations. EPA should consider adding flexibilities to trade credits between certification classes, such as light-heavy and medium-heavy, for criteria emissions and GHG. [Also in Section 28. EPA-HQ-OAR-2019-0055-1293-A1, p. 1]

A reasonably constructed ABT program can help industry achieve air quality targets cost effectively, without undermining the air quality regulatory objective. Such a program can acknowledge that a ton of emissions is a ton of emissions, regardless of source, while still reducing the overall emissions to levels required to meet regulatory objectives. Similarly, a program with sufficient flexibilities to trade credits between certification classes reduces the likelihood that a manufacturer would need to develop two engines to address the different regulations for different regulatory classes, when one engine could meet customer requirements and deliver overall emissions reductions in line with program regulatory objectives and emissions reduction targets. [EPA-HQ-OAR-2019-0055-1293-A1, p. 2]

President Biden’s Executive Order on Strengthening American Leadership in Clean Cars and Trucks encourages the EPA administrator to consider the role zero-emission heavy-duty vehicles might have in reducing emissions from certain market segments,1 and an ABT program is a practical structure in a regulatory program aligned with this Presidential order. The ability to carry credits between years is a helpful flexibility for manufacturers, especially given the proposed rapid ramp in stringency. [EPA-HQ-OAR-2019-0055-1293-A1, p. 2]

1. Sec. 3. (b) https://www.whitehouse.gov/briefing-room/presidential-actions/2021/08/05/executive-order-on-strengthening-american-leadership-in-clean-cars-and-trucks/

EPA has proposed reductions in NOx and PM FTP emissions for gasoline spark-ignited emissions to the same level as diesel engines. In addition to the California Low NOx Regulation, the EPA also is proposing to reduce hydrocarbon (HC) emissions by 57-71% and Carbon Monoxide (CO) emissions by 58% versus the current standards. The proposed HC and CO emission standards are challenging and technology-forcing for spark-ignition engines, particularly when coupled with the new requirement to certify to a Supplemental Emissions Test

(SET) standard. Given the stringency of the new standards and test procedures, we believe that an averaging, banking, and trading (ABT) requirement should also apply for HC and CO emissions. Having an HC and CO ABT program will allow additional compliance flexibility as manufacturer engineer new solutions for these stringent standards. [This comment can also be found in section 3.2 of this comment summary.] [EPA-HQ-OAR-2019-0055-1293-A1, p. 3]

EPA should consider averaging, banking, and trading for other regulated criteria emissions, including HC, PM, CO, and N2O. Zero emissions vehicles should be allowed to participate in these programs as well, given their potential to reduce real world emissions. [EPA-HQ-OAR-2019-0055-1293-A1, p. 3]

Organization: *California Air Resources Board (CARB)*

On page 17550 of the NPRM, U.S. EPA asks for comments regarding the proposed revisions to the ABT program. [EPA-HQ-OAR-2019-0055-1186-A2, p.10]

CARB staff supports the elimination of the hydrocarbon (HC) and particulate matter (PM) pollutants from the ABT program. As indicated in the NPRM, modern day HD diesel and Otto-cycle engines can easily meet the emissions standards for HC and PM. Therefore, an ABT program for the HD sector is no longer needed and should be eliminated. [EPA-HQ-OAR-2019-0055-1186-A2, p.10]

On page 17550 of the NPRM, U.S. EPA asks for comments regarding the proposed revisions to the ABT program. [EPA-HQ-OAR-2019-0055-1186-A2, p.13]

CARB staff supports the proposal to discontinue the use of old credits that were generated almost a decade ago. It is obvious that these older credits generated before 2010 were not needed to transition to the 2010 standards. Allowing the use of these very old credits now and in the future would only unnecessarily delay emission reductions and prevent the timely transitioning to the new standards. [EPA-HQ-OAR-2019-0055-1186-A2, p.13]

The ABT program was developed to assist manufacturers in their product planning schedule to ease the transition to new stringent standards. As mentioned, these credits were generated with engine and aftertreatment system (EAS) technologies that do not meet the 2027 MY requirements. As such these older credits should not be available for use starting with the 2027 MY. [EPA-HQ-OAR-2019-0055-1186-A2, p.13]

Manufacturers seeking additional flexibility for meeting U.S. EPA’s 2027 MY standards should begin certifying to lower FEL now. In fact, because of California’s more stringent 2024 MY standards, manufacturers will generate new credits to help them meet U.S. EPA’s 2027 MY CTP standards. [EPA-HQ-OAR-2019-0055-1186-A2, p.13]

Organization: *CALSTART*

Double-counting should also not be allowed for combustion engines required under states’ adoption of the Heavy-Duty Omnibus. [EPA-HQ-OAR-2019-0055-1313-A1, p.5]

Organization: *Cummins Inc. (Cummins)*

An Averaging, Banking, and Trading (ABT) program that includes an appropriate balance of flexibilities and constraints, coupled with an appropriate engine FEL cap, are important and necessary elements for a successful EPA heavy-duty engine NOx emissions regulatory program. ABT encourages earlier implementation of new technologies, allows manufacturers flexibility in planning their investments and managing product costs, and can provide some amount of relief when a manufacturer encounters technical or lead-time constraints. Those attributes of ABT all help manufacturers deliver reliable and affordable products that meet the diverse range of heavy-duty applications and customer needs. Therefore, Cummins generally supports EPA's proposed ABT program because it provides additional environmental benefits, while providing some of the flexibility manufacturers need to address customer needs. However, because of the wide range of emerging zero and near-zero NOx emissions technologies, and the uncertainty of the rates at which those technologies will be adopted by the U.S. heavy-duty market, Cummins recommends that EPA finalizes a few ABT-related constraints to prevent unintended consequences that otherwise could be caused by the ABT program itself. [EPA-HQ-OAR-2019-0055-1325-A1, pp. 8 - 9]

A relatively unconstrained ABT program could lead to competitive disruptions between manufacturers, based on the mix of technologies different manufacturers are able to sell into various market subsegments. Specifically, if zero NOx emissions technologies sold in one market subsegment are used to bank significant NOx credits, those could be used to offer higher-emitting, lower-technology, lower cost engines in a different market subsegment, where another manufacturer is only able to offer lower emitting, higher-technology, higher-cost engines. That would disrupt the current competitively level playing field in that subsegment, and it would discourage the investment of manufacturers developing and customers purchasing lower-emitting engines. To prevent such a scenario, EPA should maintain its current NOx ABT averaging set constraints, which are based on the engine family primary intended service classes prescribed in Part 1036, namely: Spark-Ignition HDE and Light, Medium, and Heavy HDE CI engines. Additionally, EPA should maintain its constraints prohibiting the exchange of NOx credits between light-duty and heavy-duty classes and between chassis-dynamometer certified vehicles and engine-dynamometer certified engines. [EPA-HQ-OAR-2019-0055-1325-A1, p. 9]

To include powertrains that are neither SI nor CI internal combustion engine-based, EPA should prescribe how to align its vehicle-level primary intended service classes from EPA's Heavy-duty GHG Phase 2 regulations in Part 1037 with the appropriate engine-based NOx averaging set. [EPA-HQ-OAR-2019-0055-1325-A1, p. 9]

Furthermore, Cummins does not support EPA justifying the feasibility of a HC standard based on the projected availability of HC emissions credits. That approach to standard-setting could lead to competitive disruptions between manufacturers, based on the mix of technologies different manufacturers are able to sell into various market subsegments. [EPA-HQ-OAR-2019-0055-1325-A1, p. 6]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

Daimler Truck supports EPA's proposal to maintain a NOx credit ABT program, giving manufacturers latitude to manage their development schedules and investments. The ABT program helps manufacturers address compliance risks and maintain a complete portfolio while transitioning to UL NOx products and, ultimately, to ZEVs. It also allows for the balancing of business needs while simultaneously providing real NOx emission reduction benefits. [EPA-HQ-OAR-2019-0055-1168-A1, p.80]

The NOx ABT program should, however, optimally incentivize ZEV development and increased penetration. It should also recognize manufacturers' current investments in improved emissions performance and seek to allow manufacturers to spread their investments across a number of years. EPA's proposal lacks sufficient flexibility to be effective in attaining these important objectives. [EPA-HQ-OAR-2019-0055-1168-A1, p.80]

EPA proposes to make manufacturers' existing NOx credits valueless for the purpose of offsetting emissions from new engines in MY 2027 and later. This retroactive invalidation of earned credits is in bad faith: manufacturers have made improvements today to improve emissions, and accordingly, have certified their engines to lower-NOx FELs, yet the EPA proposes to strip away these credits. Engines certified to lower FELs today are providing real world NOx benefits and should be recognized accordingly. [EPA-HQ-OAR-2019-0055-1168-A1, p.85]

Daimler Truck understands EPA's concerns that these current engines are not certified to all of the test conditions of the proposed program. However, that does not change the fact that these engines are generating improved emissions today—improvements that manufacturers made, in part, because of the opportunity to generate credit. EPA also asserts, as basis for its proposal, that the Agency did not require NOx credits to demonstrate feasibility of the standards in the Proposed Rule. Daimler Truck has provided evidence that EPA has not demonstrated feasibility at all (see Section II.B.3 of these comments), and therefore credits will be necessary for manufacturers to meet the proposed standards. [EPA-HQ-OAR-2019-0055-1168-A1, p.85-86]

EPA's proposal to change the rules of the credit program this significantly threatens to discourage manufacturers from proactively improving emissions performance (and accepting additional in-use risk), since EPA may later decide to devalue those very improvements. EPA states in the proposal that it wishes to 'provide flexibility for manufacturers to spread out their investment and prioritize technology adoption in the applications that make the most sense for their businesses during the transition to meeting new standards.'108 Utilizing existing credits to accomplish this would improve manufacturer flexibility and is supported by real world emissions improvements. [EPA-HQ-OAR-2019-0055-1168-A1, p.86]

108 Id.

Daimler Truck recognizes that the EPA wishes to prevent decades-old credit windfalls from undercutting the effectiveness of the proposed program. Nevertheless, manufacturers are making improvements today that are rightly generating NOx credits and should be recognized accordingly. We recommend that EPA allow credits generated after the release of the Cleaner Trucks Initiative Advanced Notice of Proposed Rulemaking109 to be used in MY 2027+, as this is the benchmark date when manufacturers became aware of potential future increases in NOx stringency and the possibility of using NOx credits to manage the transition. [EPA-HQ-OAR-2019-0055-1168-A1, p.86]

109 EPA, Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine Standards; Advanced notice of proposed rulemaking, 85 Fed. Reg. at 3306 (Jan. 21, 2020).

Organization: *Ford Motor Company (Ford)*

The proposed HC and CO emission standards are challenging and technology-forcing for spark-ignition engines, particularly when coupled with the requirement to certify to a Supplemental Emissions Test (SET) standard. Given the stringency of the new standards and test procedures, we believe that an averaging, banking, and trading (ABT) requirement should apply for HC and CO emissions. Having an HC and CO ABT program will allow additional compliance flexibility as manufacturer engineer new solutions for these stringent standards. [EPA-HQ-OAR-2019-0055-1300-A1, pp. 3 - 4]

Organization: *General Motors LLC (GM)*

The ability to use ABT is an important tool for manufacturers, especially as the potential stringency ramps up in future model years. This allows OEMs to manage compliance over a longer time horizon, and across fuel types and averaging sets, in conjunction with the turnover of its portfolio and aligned with the preferences of its customers. [EPA-HQ-OAR-2019-0055-1246-A1, p.4]

Proposed restrictions to averaging, banking, and trading credits decrease a manufacturer's ability to respond to these stepped changes. [EPA-HQ-OAR-2019-0055-1246-A1, p.4]

Organization: *Maine Department of Environmental Protection (Department)*

Using the CARB Heavy-Duty Omnibus Regulation as a bellwether, the Department requests the following revisions to the federal proposal: [EPA-HQ-OAR-2019-0055-1288-A1, p.6]

- Averaging, banking, and trading. The Department fully supports EPA’s proposal to not allow averaging, banking, and trading for PM or hydrocarbons for model year 2027 and later engines. [EPA-HQ-OAR-2019-0055-1288-A1, p.7]
- Eliminating averaging, banking, and trading would maximize nationwide NOx reductions. If EPA retains these provisions, it should consider establishing a 0.05 grams NOx cap in 2027 that is consistent with that in the CARB Heavy-Duty Omnibus regulation in lieu of EPA’s proposed family emission limits (FEL) of 0.15 grams NOx in 2027 and 0.05 grams NOx in 2031. Manufacturers have already conducted engine development work to prepare for and comply with California 2024-2026 standards and if the CARB FEL caps are implemented federally, all states can benefit from this research

and development. [EPA-HQ-OAR-2019-0055-1288-A1,p.8] [Also appears in Section 13.2 of this document]

Organization: *Moving Forward Network (MFN)*

The total impact of the above crediting provisions is quite large, yet EPA has not completed any analysis of the environmental and/or public health impacts of these provisions. EPA has not required the necessary mechanisms to track the crediting provisions or guidance to prioritize environmental justice communities for the deployment of ZEV. If the agency had done a complete analysis, it would see clearly the deleterious effect such actions have on the efficacy of the program. [EPA-HQ-OAR-2019-0055-1277-A1, p. 49]

Below, we detail the harms posed by the agency's proposed flexibilities. In short, the proposed flexibilities are weak enough to virtually turn the 2027-2030 phase of the Option 1 standard from a 0.035 g NOx/bhp-hr standard, on paper, into a 0.05 g NOx/bhp-hr standard, in practice. These flexibilities under status quo deployment eliminates 12 percent of the benefits of the first step of the proposed Option 1—some of the more likely scenarios of electric vehicle adoption and/or the likely possibility that additional states adopt the Omnibus standards would only further erode the benefits of EPA's proposed program as a result of these unnecessary flexibilities. [EPA-HQ-OAR-2019-0055-1277-A1, p. 49]

In order to estimate the impacts of the program, we have primarily relied upon three key sources of data: 2022 heavy-duty engine certification data;182 engine production and installation data for 2019,183 the last year for which data is available which predates the temporary supply chain issues which have occurred as a result of the pandemic; and new vehicle registration data for 2019-2021,184 sorted by vehicle class, fuel, and state. [EPA-HQ-OAR-2019-0055-1277-A1, p. 50]

183. https://wardsintelligence.informa.com/WI964489/North-America-Factory-Sales-December-2019

184. Atlas EV Hub, Medium- and Heavy-duty Vehicle Registrations Dashboard, which collects data from IHS Markit: https://www.atlasevhub.com/materials/medium-and-heavy-duty-vehicle-electrification/

While engine configurations are available in numerous horsepower configurations, they are generally certified under a single FEL, so we have reduced the number of engines to 34, covering the different fuels and engine classes the engine might be deployed.185 While the Wards data identifies engine manufacturers for a given gross-vehicle-weight rating (GVWR) class, it does not identify which of the engines manufactured by a given supplier is deployed to those vehicles, except in the case of Class 8 sales, where the data distinguishes between engines greater than or less than 10 liters in volume. Therefore, to assign these engines we have used our best technical judgment in assigning engines, including distinguishing between classes within a given engine class (e.g., LHDD encompasses both Class 4 and Class 5 vehicles) as well as additional data on engine configurations from manufacturers (for example, the engine manufacturers themselves or specific applications such as transit or school buses, where only a subset of engines might be deployed), or data from the Phase 1 greenhouse gas program.186 [EPA-HQ-OAR-2019-0055-1277-A1, p. 50]

185. For example, while Cummins' L9 engine is available in at least 9 different configurations, our analysis reduces this to 4 separate assigned engines, first to distinguish between L9 diesel and L9N compressed natural gas fuels, and then assigning each of those to both medium- and heavy-heavy-duty diesel engine classes (MHDD and HHDD, respectively).

186. https://www.epa.gov/compliance-and-fuel-economy-data/epa-heavy-duty-vehicle-and-engine-greenhouse-gas-emissions

Our analysis identifies three main buckets of credits: 1) engines certified below today's standards which will qualify for the transitional credit program; 2) engines certified to the Omnibus standards, which will qualify either for the transitional credit program or will, on average, achieve a standard below the federal requirements; and 3) zero-emission vehicles, which earn credits under the proposed provision for plug-in and fuel-cell electric vehicles. [EPA-HQ-OAR-2019-0055-1277-A1, p. 53]

While current certification procedures are not identical to the certification procedures required to qualify for the transitional credit program, as noted in Section IV.D.3 there is sufficient compliance margin such that these engines will almost certainly qualify for the program, and these credits are of such a large magnitude that it is obviously within the polluting industry's interest to take advantage of such a generous crediting program. Moreover, this is a conservative estimate of the likely availability of credits because this assumes no improved performance in the next two years of engines. Finally, for simplicity engines which would likely qualify for EPA's early credit program (and thus be able to use a credit multiplier) have been lumped into the transitional credit program only, and there has been no attempt to quantify the credits earned by those engines beginning in 2027, an additional conservative estimate. [EPA-HQ-OAR-2019-0055-1277-A1, p. 53]

For the Omnibus credits, it was assumed that all six states which have currently adopted ACT will move forward to adopt the Omnibus. To-date, three ACT states have done so (California, Oregon, and Massachusetts), representing 60 percent of the current ACT sales volume. Washington and New Jersey both have ongoing regulatory procedures to align with the Omnibus, and it is likely that New York, which just completed its ACT process less than six months ago, could follow.190 [EPA-HQ-OAR-2019-0055-1277-A1, p. 53]

> 190. Washington: https://ecology.wa.gov/Regulations-Permits/Laws-rules-rulemaking/Rulemaking/WAC173-423-400Jan18. New Jersey: https://www.nj.gov/dep/njpact/materials.html#NJPACT-co2trucks20200910-am. New York: https://www.dec.ny.gov/docs/air_pdf/adopted218.pdf.

Additionally, numerous other states could join the Omnibus program. Colorado is currently considering the program as part of its 2022 Clean Truck Strategy.191 Connecticut, which is not included in either ACT or Omnibus states, just passed a bill permitting the Commissioner of Energy and Environmental Protection to "implement the medium and heavy-duty motor vehicle standards of the state of California," which includes both ACT and Omnibus, signaling even more vehicles required to meet such standards.192 Moreover, there are numerous other advocacy efforts moving forward at the state level to adopt these stronger standards and additional complementary policies to cut freight pollution in light of federal inaction and the severity of the problem facing communities today. [EPA-HQ-OAR-2019-0055-1277-A1, p. 53]

> 191. https://freight.colorado.gov/sites/freight/files/documents/CleanTruckStrategy.pdf, p. 4, calls for "new trucks sold in the state to produce 90% less NOx emissions than current standards starting in 2027."
>
> 192. https://legiscan.com/CT/text/SB00004/id/2579528/Connecticut-2022-SB00004-Chaptered.pdf.

The determination of electric vehicle sales was described above. Because the proposal does not permit heavy-duty Otto-cycle (HDO) engines to receive credits, it was assumed consistent with the proposal that these credits would be allocated to the respective diesel engine class based on the GVWR of the according vehicle. Sales of HDO engines are dominated by Class 4-5 vehicles, so the majority of such generated credits (about 60 percent) applied toward LHDD engines. [EPA-HQ-OAR-2019-0055-1277-A1, p. 53]

To convert NOx certification levels into awarded credits, we've utilized the same procedure adopted by EPA in its MOVES modeling—for diesel engines, the work assumed over the FTP cycle is based on a linear function of the horsepower of the engine, where we've used the certified horsepower corresponding to the FEL; for gasoline engines, we've used a fixed value based on limited data.193 This is then combined with an assumed mileage factor for the FTP cycle (6.3 miles for gasoline vehicles, 6.5 miles for diesel) to yield an engines conformance factor. For reference, the average conformance factors for engine classes are: HDO, 3.07; LHDD, 3.50; MHDD, 3.90; and HHDD, 4.88. Because credits are not allowed to be traded between engine classes, however, there is little impact on any of the results stemming from the use of such estimates. [EPA-HQ-OAR-2019-0055-1277-A1, p. 54]

193. https://www.epa.gov/sites/default/files/2017-08/documents/03-heavy-duty-start-emission-rates-2017-06-07.pdf, slides 9 and 10.

The magnitude of these credit programs is quite large (Figure 10). This is, however, not surprising—the transition credit program awards credit compared to a 0.2 g/bhp-hr standard. HHDD engines see a large number of early credits related to the deployment of high-volume products like Detroit Diesel's latest DD13, which is certified to a 0.16 g/bhp-hr standard, as well as a small volume of CNG engines. HDO engines see a significant share of early credits due to the large volume of propane engines as well as the large share of gasoline engines certified below the 0.2 g/bhp-hr NOx standard. Very few LHDD and MHDD products are currently certified below today's standards so are not projected to earn a significant share of transitional credits; however, as indicated by Figure 2, there is plenty of room at the margins for that to change. [EPA-HQ-OAR-2019-0055-1277-A1, p. 54]

Under our analysis. over 325,000 metric tons of lifetime NOx emissions are credited through 2030, and nearly 450,000 metric tons through 2035. The majority of these credits stem from vehicles sold under state regulations that are stronger than the current federal program, representing a windfall credit for manufacturers that erodes the benefits of the proposed federal program. [EPA-HQ-OAR-2019-0055-1277-A1, pp. 54 - 55]

The majority of credits earned under our projections is granted for engines sold under the Omnibus standards, which are already required to achieve standards below the federal requirements in 2024 and beyond. For all but HHDD engines, these standards continue to be stronger than Option 1 in the 2027-2030 timeframe, yielding additional credits. [EPA-HQ-OAR-2019-0055-1277-A1, p. 55]

Owing to the nature of the banking and trading program, these credits have a significant impact on the emissions from the remaining vehicles in the fleet, especially in the early years of the program. Manufacturers have a range of ways in which they could utilize these credits, so it is impossible to capture every nuance in possible outcomes. Below, we consider two different ways to utilize those credits, as well as different limitations EPA could impose on the credit generation programs. [EPA-HQ-OAR-2019-0055-1277-A1, p. 55]

It should again be emphasized that we do not support the use of these credit programs, generally, as they undermine the real-world emissions reductions desperately needed in communities impacted by the freight sector. The analysis below is meant to be illustrative for EPA, emphasizing the need to consider the impacts of their proposed flexibilities in both their analysis of the feasibility of the standard and the degree to which they are upholding their legal requirements under the Clean Air Act. [EPA-HQ-OAR-2019-0055-1277-A1, p. 55]

The first way in which manufacturers could choose to deploy the credits earned under EPA's flexibilities would be to maximize the number of vehicles sold at the worst polluting level allowed under EPA's program. Such a deployment strategy is indicated in the panes of Figure 11 on the left side of the figure. Here it is assumed that manufacturers would sell as many engines with an FELFTP = 150 mg NOx/bhp-hr as possible in the 2027-2030 timeframe, and as many engines with an FELFTP = 50 mg NOx/bhp-hr in 2031 and beyond. [EPA-HQ-OAR-2019-0055-1277-A1, p. 55]

An alternative strategy would be to maximize the bare minimum improvements needed over the largest share of the fleet. As noted elsewhere in this document, the 50 mg NOx/bhp-hr FTP standard can be achieved with minimal changes in configuration and technology.194 Therefore, rather than target credit usage at a narrow selection of engines, a manufacturer may choose instead to minimize the improvements broadly over the entire volume of engines. This is represented by the panes of Figure 11 on the right. This FEL also represents the FEL for the Omnibus standards, and the required average FEL for Option 2. [EPA-HQ-OAR-2019-0055-1277-A1, pp. 55 - 56]

194. See https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2020/hdomnibuslownox/appi.pdf pp. 18-21 for an analysis of the small changes needed based on data from Southwest Research Institute.

EPA's proposed credit program has the potential to substantially erode the benefits of stronger NOx tailpipe standards, delaying the deployment of cleaner trucks. As proposed, EPA's proposal would mean that 27 percent of all engines sold in 2027-2029 would be no better than today's engines under Option 1. Under Option 2, this number would be 32 percent, with at least 10 percent of engines never being required to improve compared to today's engines. While excluding vehicles sold in states adopting California's truck standards or excluding the proposed transitional credit program can help reduce the impacts of these credit provisions, only excluding them entirely can forestall their adverse impacts on the efficacy of the federal NOx program, and EPA must carefully consider these impacts under its requirements under the Clean Air Act before finalization. [EPA-HQ-OAR-2019-0055-1277-A1, pp. 56 - 57]

The graphs in Figure 11 show the marketshare of a given FEL as a share of engines in a given engine class. The top-most figure represents the proposed Option 1 program. As indicated by the left-hand graph, we see that in the 2027-2029 period, nearly one-quarter of MHDD and HHDD engines, more than one-third of HDO engines, and nearly half of all LHDD engines could be deployed with an FELFTP = 150 mg NOx/bhphr. EPA considers this FEL level "consistent with the average NOx emission levels achieved by recently certified CI engines," so this would mean that 27 percent of all engines sold in 2027-2029 would be no better than today's engines. [EPA-HQ-OAR-2019-0055-1277-A1, p. 57]

In the right-hand graph, credits for LHDD engines are sufficient as to require no improvement in those engines, thanks to the overwhelming share of zero-emission credits earned and the disproportionately small share of certified LHDD engines. However, three-quarters of all engines sold in the first step of Option 1 could be certified at the average level required under the weakest standard considered by EPA (Option 2). In fact, more than 15 percent of the fleet would never be required to improve beyond an FELFTP = 50 mg NOx/bhp-hr, even under the more stringent second step beginning in 2031. [EPA-HQ-OAR-2019-0055-1277-A1, p. 57]

The bottom-most figure shows how the weakest standard considered by EPA would further be weakened by the adoption of this credit program. Nearly a third of engines sold in 2027-2029 would be allowed not to improve from today's certification levels, and more than 10 percent of all engines sold would never be required to improve beyond those levels. [EPA-HQ-OAR-2019-0055-1277-A1, p. 57]

In total, at least 12 percent of the lifetime benefits of the first step of Option 1 (2027-2030) are expected to be given away under the credit provisions proposed. For the weaker Option 2 over this same timeframe, this increases to 17 percent of a program that is, as proposed, substantially less effective. [EPA-HQ-OAR-2019-0055-1277-A1, p. 57]

Given the harm caused by the proposed credit program, the best option for EPA is to simply eliminate all bonus crediting provisions—given the extensive lead-time and technical feasibility to reduce emissions from the freight sector, manufacturers do not need help transitioning to the levels of standards required by Option 1 or even the Omnibus. The so-called flexibilities provided are clearly detrimental to EPA's obligation to protect public health and welfare from pollution, the response most consistent with the agency's legal obligations under the Clean Air Act is to simply eliminate these provisions. [EPA-HQ-OAR-2019-0055-1277-A1, p. 57]

However, should EPA not take the more protective step of eliminating the proposed crediting provisions, there are measures that can be taken to improve the proposed credit program. [EPA-HQ-OAR-2019-0055-1277-A1, p. 57]

One clear issue is the windfall that results from the result of state regulatory programs that are more protective than the federal program. Elsewhere, we have noted that EPA should be factoring in the impacts that these state actions will have on the industry in assessing the feasibility of the program. However, if the agency does not adjust its stringency in response to these regulations, it must isolate the impact of those regulations. To do this, it can do as it has previously done in heavy-duty engine regulations and exclude engines certified to stronger state standards.195 The results of this are shown in the third graph of Figure 11. The result of this is to substantially reduce the impacts of the crediting program by excluding zero-emission vehicles driven by state adoption of the ACT, but it also excludes the impact of credits earned in 2027-2030 from engine classes other than HHDD resulting from Option 1 being weaker than the Omnibus rule. On net, this cuts the number of available credits by more than 50 percent. [EPA-HQ-OAR-2019-0055-1277-A1, pp. 57 - 58]

195. "It is worth clarifying that this phase-in excludes California complete heavy-duty vehicles, which are already required to be certified to the California emission standards. It also excludes vehicles sold in any state that has adopted California emission standards for complete heavy-duty vehicles. It would be inappropriate to allow manufacturers to ''double-count'' the vehicles by allowing them to count those vehicles both as part of their compliance with this phase-in and for compliance with California requirements. We would handle heavy-duty engines similarly if California were to adopt different emission standards than those being established by this rule." (66 FR 5043)

One additional obvious issue is the delay that the transitional credit program specifically causes. As noted above, three-quarters of engines sold under the first step of Option 1 could be certified to an FELFTP = 50 mg NOx/bhp-hr, the dirtiest engine allowed under the Omnibus and a level required, on average, beginning in 2024, a full seven years before the second step in the Option 1 program. This level of delay allowed under EPA's proposal flies in the face of what is needed in areas around the country to meet federal air quality standards, which is immediate action to reduce emissions from the freight sector.196 To reduce the amount of delayed action allowed under EPA's proposal, the agency should eliminate the transitional credit program. Eliminating the transitional credit program would cut credits available in the first step of the Option 1 program by nearly 80 percent. By reducing the credits available in this critical, initial part of the proposed regulation, EPA would increase the likelihood that manufacturers deploy the much needed cleaner trucks more quickly. However, in the long run, eliminating the transitional credit program alone would not mitigate the harm caused by the agency's credit program, which would permit at least 15 percent of heavyduty vehicles sold under the second phase of the proposed

Option 1 program to be certified to the dirtiest allowed FEL. [EPA-HQ-OAR-2019-0055-1277-A1, p. 58]

196. "[California's South Coast Air] Basin will be unable to achieve the ozone standards by the attainment dates of 2024 and 2032 without the additional emissions reductions from a revision of the existing on-road heavy-duty engine exhaust emission standards for NOx. A nationwide standard is also critical in assisting other states to achieve the more stringent 2015 NAAQS." Letter to EPA Administrator Gina McCarthy from The South Coast Air Quality Management District, et al., June 3, 2016. https://www.epa.gov/sites/default/files/2016-09/documents/petition_to_epa_ultra_low_nox_hd_trucks_and_engines.pdf. "The Ozone Transport Commission concluded in its 2020 Annual Report that, to address the persistent air quality issues in the tri-state area [of Connecticut, New Jersey, and New York], reducing NOx from heavy-duty diesel vehicles is of 'utmost importance.'" Letter to National Climate Advisor Gina McCarthy and EPA Administrator Michael Regan from the Attorneys General of Connecticut, New Jersey, and New York, November 23, 2021. https://portal.ct.gov/-/media/AG/Press_Releases/2021/NY-CT-NJ-Letter-REHeavy- Duty-Truck-NOx-Emission-Standards_112321.pdf.

In addition to the above changes to the program, we refer EPA to our comments on the zero-emission vehicle crediting program specifically (Section II.B). [EPA-HQ-OAR-2019-0055-1277-A1, p. 58]

Organization: *National Association of Clean Air Agencies (NACAA)*

NACAA does not support the inclusion of a NOx emission credit or Averaging, Banking and Trading (ABT) scheme. [EPA-HQ-OAR-2019-0055-1232-A1, p. 15]

EPA acknowledges in the NPRM that its proposed NOx standards are feasible without the use of credits. Even so, the agency proposes a NOx credit-generation scheme and ABT that would allow manufacturers to use credits generated from producing engines with emission levels below the standards to produce engines with emission levels above the standards. With areas all across the country seeking every possible ounce of NOx reduction in order to protect the health of those who live and work in their jurisdictions, including those in overburdened communities where neighborhood truck traffic is disproportionately high, the concept of turning additional NOx emission reductions beyond those required by the new standards into currency to be used to negate those reductions seems senseless. [EPA-HQ-OAR-2019-0055-1232-A1, p. 15]

This approach would also open the possibility of the federal program issuing to manufacturers large NOx credits against the current 200-mg/hp-hr federal standard for engines sold in Omnibus jurisdictions at the 50-mg standard. This would allow manufacturers to continue making dirtier engines at the expense of the emission reductions intended to occur from the states' Omnibus programs and would effectively float the standard higher, increasing emissions across engines in all states. [EPA-HQ-OAR-2019-0055-1232-A1, p. 15]

Although NACAA supports efforts to encourage and expand the deployment of ZEVs, we do not support efforts that come at the expense of NOx reductions in the rule. EPA should not include in the final rule provisions for generating NOx credits or an ABT program that will, in any way, deplete or negate important NOx emission reductions achieved through implementation of new emission standards, especially when the standards are feasible without the use of credits. [EPA-HQ-OAR-2019-0055-1232-A1, p. 15]

EPA should, however, finalize its proposal to end the ABT program for PM and hydrocarbons for MYs 2027 and later engines. [EPA-HQ-OAR-2019-0055-1232-A1, p. 15]

Organization: *Navistar, Inc. (Navistar)*

Navistar also wants to be very clear on another point. Some commenters on the proposed rule to date have asserted that diesel engine manufacturers may actually raise NOx emissions levels as a result of the AB&T credit structures in the proposed rule. The concern seems to be that the NOx credits from ZEVs will be sufficient to allow engine manufacturers to raise NOx emission levels even from their current levels. To be very clear: Navistar will not raise its NOx emission levels. The AB&T program will be used solely to balance the transition to the lower emission standards across engine families and model years and help keep costs in line. Navistar is in favor of a rule structure that makes it clear that backsliding on NOx emissions levels is prohibited. [EPA-HQ-OAR-2019-0055-1318-A1, p. 2]

In particular, we support: Providing a stable structure for NOx emissions credit generation and use to allow continued investments in clean diesel engines and development of ZEVs; [EPA-HQ-OAR-2019-0055-1318-A1, p. 3]

Organization: *Northeast States for Coordinated Air Use Management (NESCAUM)*

Should EPA instead promulgate Option 1, we urge the Agency to make the following changes to the proposed standards: We support EPA's proposal to not allow Averaging, Banking, and Trading (ABT) for PM or hydrocarbons for model year 2027 and later engines. EPA proposes to continue to allow ABT of NOx credits generated against applicable heavy-duty diesel engine NOx standards. As part of this proposal, manufacturers could certify battery electric and fuel cell vehicles to generate NOx emissions credits. NESCAUM does not support the inclusion of a NOx emission credit or ABT scheme. [EPA-HQ-OAR-2019-0055-1249-A1, p. 14]

EPA acknowledges in the NPRM that its proposed NOx standards are feasible without the use of credits.44 Even so, the agency proposes a NOx credit-generation scheme and ABT that would allow manufacturers to use credits generated from engines with emission levels below the standards to produce engines with emission levels above the standards.

Given the urgent need to reduce NOx emissions in the Northeast, we are opposed to heavy-duty engine NOx ABT. [EPA-HQ-OAR-2019-0055-1249-A1, p. 15]

Organization: *Oshkosh Corporation*

EPA requests comments on multiple aspects of the Proposed Rule related to the emission credit ABT programs for heavy duty trucks. Oshkosh generally supports the ABT provisions and views them as this as an important tool for incentivizing the introduction of EV and other advanced technologies. In past rulemakings, EPA has significantly limited the ability of manufacturers to carry over legacy credits for vocational trucks certified under the Phase 2 GHG custom chassis provisions. As a result, in the move from Phase 1 to Phase 2 GHG programs, Oshkosh's CO2 credit bank was effectively eliminated, thus constraining the Company's ability to use earned emission credits. The current rulemaking presents an opportunity to obtain a different result. To this end, Oshkosh is pleased to provide these comments regarding EPA's ABT proposals: [EPA-HQ-OAR-2019-0055-1226-A1, p. 5]

To provide further incentives for EV development, Oshkosh also requests that EPA ensure harmonization of NOx and CO2 credit programs for heavy-duty vehicles. In general, we request that EPA modify existing credit ABT programs to (1) allow credit transport across all heavy-duty engine/vehicle families; (2) allow a credit life of 10 years for credits generated by EV, FCEV and hybrid technologies; and (3) guard existing credit banks to enable carry over of legacy credits to future programs. [EPA-HQ-OAR-2019-0055-1226-A1, p. 6]

Organization: *Ozone Transport Commission (OTC) and Mid-Atlantic/Northeast Visibility Union (MANE-VU)*

Averaging Banking and Trading: The OTC supports EPA's proposal to not allow Averaging, Banking, and Trading (ABT) for PM or hydrocarbons for model year 2027 and later engines. However, EPA proposes to continue to allow ABT of NOx credits generated against applicable heavy-duty diesel engine NOx standards. As part of this proposal, manufacturers could certify battery electric and fuel cell vehicles to generate NOx emissions credits. The OTC does not support the inclusion of a NOx emission credit or ABT scheme. [EPA-HQ-OAR-2019-0055-1250-A1, p.16]

EPA acknowledges in the NPRM that its proposed NOx standards are feasible without the use of credits.40 Even so, the agency proposes a NOx credit-generation scheme and ABT that would allow manufacturers to use credits generated from engines with emission levels below the standards to produce engines with emission levels above the standards. [EPA-HQ-OAR-2019-0055-1250-A1, p.16]

40 87 Fed. Reg. 17414 (March 28, 2022), at 17550.

Further, with a NOx ABT program, higher NOx emitting engines could be driven in Overburdened Communities in the OTR, potentially exacerbating the adverse health effects from gasoline and diesel vehicle emissions. Given these concerns and the urgent need to reduce NOx emissions in the OTR, we are opposed to heavy-duty engine NOx ABT. [EPA-HQ-OAR-2019-0055-1250-A1, p.16]

Organization: *PACCAR, Inc (PACCAR)*

PACCAR agrees with the following EMA comments: However, because of the uncertainty associated with market adoption of zero and near-zero NOx emissions technologies, EMA recommends that EPA modify the proposal to include certain constraints to prevent unintended consequences from the ABT program. For example, a relatively unconstrained ABT program could lead to competitive imbalances among manufacturers, especially where product mix differences exist. More specifically, if zero-NOx emissions technologies sold in one market subsegment are used to bank significant NOx credits, those could 132 be used to offer higher-emitting, lower cost engines in a different market subsegment, competing against another manufacturer without credits and that, as a result, is only able to offer lower emitting, higher-cost engines. That would disrupt the current competitively level playing field in that subsegment of the market, and could discourage the purchase of lower-emitting engines. To prevent such an unintended outcome, EPA should maintain its current NOx ABT averaging set categories based on primary intended service classes (i.e., HDE SI, LHDE CI, MHD CI, and HHD CI). To include zero-emissions powertrains (that are neither spark-ignited nor compression-ignited internal combustion engine-based) in the ABT program, EPA should prescribe how to align its vehicle-level primary intended service classes from EPA's Heavy-Duty GHG Phase 2 regulations in 40 CFR Part 1037 with the appropriate engine-based NOx averaging set. [EPA-HQ-OAR-2019-0055-1346-A1, pp.35-36]

PACCAR generally supports EPA's proposed Subpart H Averaging, Banking, and Trading amendments, including those addressing NOx Family Emission Limit (FEL) credits and credit generation for Zero Emission Vehicles. However, EPA should amend 1036.745, which currently only addresses 'end-of-year CO2 credit deficits' to address NOx credit deficits as well. Although OEMs are increasingly adopting ZEV technology and business strategies, there continues to be significant uncertainty about the extent to which consumers will embrace and purchase ZEVs in substantial quantities, and whether there will be adequate nationwide charging infrastructure in place in the near future to accommodate ZEV fleets. See e.g., McKinsey & Company, Building the Electric-Vehicle Charging Infrastructure America Needs, (April 18, 2022) (estimating that the United States would need almost 20 times more EV chargers than it has now to achieve federal ZEV sale targets).2 For OEMs, the uncertainty surrounding ZEV purchases means uncertainty about credit generation, and the final end-of-year MY accounting does not take place until September 30 of the calendar year following the MY, which makes resolving NOx credit deficits within one MY following the deficit extremely difficult. In light of this uncertainty, OEMs need to have the same flexibility for NOx credit deficits that exists for CO2 credit deficits. This includes allowing OEMs to remedy NOx credit deficits 'with surplus credits within three model years.' 40 C.F.R. 1036.745(e). [EPA-HQ-OAR-2019-0055-1346-A1, pp.51-52]

Organization: *States of California, et al. (The States)*

In the Proposed Rule, EPA rightly recognizes the imperative to "ensure that NOx emission credits . . . do not compromise the environmental benefits expected from the proposal."89 The averaging, banking, and trading program (ABT) has an important but limited role in supporting the heavy-duty sector's transition to stricter standards, reducing compliance costs for manufacturers and operators, and incentivizing early adoption of advanced technologies. The States strongly support EPA's proposed measures to tailor the ABT program to this role, including (1) limiting credit life to at most five years, (2) replacing existing credit balances with transitional credits, and (3) lowering family emission limit (FEL) caps to below the 2007 heavy-duty standards.90 The States also generally support EPA's proposed early adoption incentives and the proposal to generate NOx credits from heavy-duty hybrid, battery, and fuel-cell electric vehicles (HD ZEVs).91 However, EPA should carefully calibrate ZEV-generated credits to ensure their environmental benefits are not offset by higher-emitting conventional engines. [EPA-HQ-OAR-2019-0055-1255-A1, pp. 20 - 21]

89. 87 Fed. Reg. at 17,555.

90. Id. at 17,552-54.

91. Id. at 17,554-62.

Organization: *Truck and Engine Manufacturers Association (EMA)*

A successful heavy-duty engine emissions regulation necessarily includes an Averaging, Banking and Trading ("ABT") program with the appropriate balance of flexibilities and constraints, coupled with an appropriate engine Family Emission Limit ("FEL") cap. Such an ABT program provides manufacturers with the needed flexibility to plan investments and manage product costs while also providing opportunities to overcome technical or lead-time challenges. Those attributes of ABT all help manufacturers deliver reliable and affordable products that meet the diverse range of heavy-duty applications and customer needs. [EPA-HQ-OAR-2019-0055-1203-A1, p. 134]

For these reasons, EMA generally supports EPA's proposed ABT program, which provides environmental benefits and the flexibility manufacturers require to address customer needs. However, because of the uncertainty associated with market adoption of zero and near-zero NOx emissions technologies, EMA recommends that EPA modify the proposal to include certain constraints to prevent unintended consequences from the ABT program. For example, a relatively unconstrained ABT program could lead to competitive imbalances among manufacturers, especially where product mix differences exist. More specifically, if zero-NOx emissions technologies sold in one market subsegment are used to bank significant NOx credits, those could be used to offer higher-emitting, lower-cost engines in a different market subsegment, competing against another manufacturer without credits and that, as a result, is only able to offer lower emitting, higher-cost engines. That would disrupt the current competitively level playing field in that subsegment of the market, and could discourage the purchase of lower-emitting engines. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 134 - 135]

To prevent such an unintended outcome, EPA should maintain its current NOx ABT averaging set categories based on primary intended service classes (i.e., HDE SI, LHDE CI, MHD CI, and HHD CI). To include zero-emissions powertrains (that are neither spark-ignited nor compression-ignited internal combustion engine-based) in the ABT program, EPA should prescribe how to align its vehicle-level primary intended service classes from EPA's Heavy-Duty GHG Phase 2 regulations in 40 CFR Part 1037 with the appropriate engine-based NOx averaging set. [EPA-HQ-OAR-2019-0055-1203-A1, p. 135]

Organization: *Tesla, Inc. (Tesla)*

First, Tesla supports and agrees with EPA reasoning that existing banked credits should be eliminated and not used to meet the proposed MY 2027 standards.135 [EPA-HQ-OAR-2019-0055-1219-A1, pp.15-16]

135 87 Fed. Reg. at 17533.

The unlimited lifetime of existing credits would allow the existing credit bank to erode to effectiveness of the standard and extension is unjustified given use of these credits would reward outdated technology in perpetuity. [EPA-HQ-OAR-2019-0055-1219-A1, pp.15-16]

EPA Summary and Response

Many of the summaries of comments on the proposed ABT program in the proposed rule, and EPA's responses to those comments, are included in Preamble Section IV.G. Immediately below, we briefly summarize and respond to additional comments on the proposed ABT program.

Summary of comments supporting and opposing the proposed general ABT provisions:

One commenter (MFN) stated that EPA has not conducted analyses on the environmental and/or public health impacts of the proposed credit flexibilities. The commenter conducted analysis suggesting that, under proposed Option 1, program benefits in 2027-2030 would be 12 percent lower than expected due to the proposed credit flexibilities; in the same timeframe, benefits from proposed Option 2 would be 17 percent lower. In the commenter's analysis the reductions in program benefits would come from credits generated by: 1) engines certified below today's standards which quality for the transitional credit program, 2) engines certified to the Omnibus standards which will qualify for the transitional program or on average achieve a standard below federal requirements, and 3) ZEVs. In the first category (transitional credit program) the commenter recognized that there would be different certification requirements for engines to qualify for the program, but states that they expect almost all engines to qualify for the program due to manufacturers having sufficient compliance margin. The commenter's analysis suggests that credits generated through 2030, as well as through 2045 are largely through engines sold to meet more stringent standards in state regulations. Three commenters stated that EPA should exclude engines certified to stronger state standards from generating federal credits, and that doing so would reduce the available credits by 50 percent. One commenter also urged EPA to eliminate the transitional credit program; their analysis suggested that doing so would decrease the credits available in 2027-2030 by 80 percent. Finally, one commenter stated that EPA should require mechanisms to track crediting provisions or issue guidance to prioritize ZEV deployment in environmental justice communities.

In addition to commenting on whether EPA should finalize a NO_X ABT program, commenters also provided input on several more specific topics, such as a flexibility for Credit NO_X Deficits. A commenter urged EPA to allow manufacturers to carry a deficit of NO_X emissions credits for three model years, which is currently allowed for CO_2 emissions credits. The commenter stated this flexibility is necessary because of uncertainty in ZEV adoption rates and, in turn, the volume of ZEV credits manufacturers would have in a given model year.

Finally, a commenter stated EPA should model the possible compliance strategies that manufacturers could take to meet future standards in order to provide suppliers with information for their product planning. Another commenter also stated that EPA should prescribe how to align its vehicle-level primary intended service classes from EPA's Heavy-duty GHG Phase 2 regulations in Part 1037 with the appropriate engine-based NO_X averaging set for powertrains that do not include an internal combustion engine.

<u>Response to comments supporting and opposing the proposed general ABT provisions</u>:

See preamble Section IV.G for EPA responses to several of the comment themes summarized above; additional responses on more specific aspects of comments are included immediately below in Section 12.1 of this document.

EPA appreciates the suggestion for guidance on prioritizing environmental justice communities for ZEV deployment; we may continue to evaluate and consider the suggestion in the future. Additional discussion on ZEVs, including our decision not to finalize an allowance for manufacturers to generate NO_X emissions credits from ZEVs in the final rule, is available in Section 12.6 of this document. Similarly, we appreciate the suggestion to develop a publicly available tracking system for emissions credits; we intend to consider this suggestion separate from this rulemaking. (See also Section 30 of this document and preamble Section XI for additional discussion on EPA's determinations that certain information is emission data or otherwise not entitled to confidential treatment.)

We did not propose or take comment on allowing manufacturers to carry a credit deficit for NO_X emissions credits, and we are not taking final action to allow such in this rule. Further, as just noted and discussed in Section 12.6 of this document and Section IV.G of the preamble, we are not including in the final action the proposal to allow manufacturers to generate NO_X emissions credits from ZEVs; thus, manufacturers' uncertainty in the volume of ZEV credits in a given model year, which the commenter pointed to as the main reason for needing the additional flexibility, is not applicable to the final NO_X ABT program. Similarly, since we are not including in the final action the proposal to allow manufacturers to generate NO_X emissions credits from ZEVs, we have not included a description on how to align vehicle-level primary intended service classes from EPA's Heavy-duty GHG Phase 2 regulations in Part 1037 with the appropriate engine-based NO_X averaging set for powertrains that do not include an internal combustion engine.

12.1.1 Additional comments on general ABT provisions

<u>**Comments by Organizations**</u>

Organization: *Allison Transmission, Inc. (Allison)*

- An alternative approach that EPA should consider is the extent to which state programs and other efforts, including new federal funding,2 could result in the retirement of pre-2010 vehicles and equipment. Programs that provide incentives to replace older equipment have been highly effective, as validated by EPA's own analysis3 and could be further integrated into EPA's analysis of resulting costs and benefits of its proposed program and alternatives. [EPA-HQ-OAR-2019-0055-1231-A1, p.5]

2 See Pub. L. 117-58, Sec. 71101, containing $5 billion in appropriated funds for "clean school buses.".

3 See, e.g., DERA Fourth Report to Congress, EPA Office of Transportation and Air Quality, July 2019

Organization: *Environmental Defense Fund (EDF)*

Finally, we encourage EPA to consider creation of a voluntary alternative compliance pathway that recognizes the significant investments manufacturers are making in ZEV technologies and affords a pathway to achieve even greater levels of emission reductions and ZEV deployment than would otherwise be incorporated in the standards. Such a pathway could pull forward reductions prior to 2027, given that many manufacturers are introducing ZEV technologies now and also planning for compliance with more protective NOx Omnibus requirements in 2024. It could also allow manufacturers to opt in to protective reductions post 2030, thereby providing manufacturers with added certainty as EPA is developing its Phase 3 program and also building strong momentum toward ensuring 100 percent of all new vehicles sold by 2035 are zero-emitting. Such a voluntary pathway could also be expressly multipollutant in nature, which, as we discuss above can help to accelerate ZEV deployment without sacrificing NOx or GHG emissions reductions from ICE vehicles. [EPA-HQ-OAR-2019-0055-1265-A1, p.26]

A voluntary pathway could also provide EPA an opportunity to create needed incentives for manufacturers of electric drivetrains, which will not be subject to compliance certification obligations under the proposed adjustment to the Phase 2 GHG vehicle standards. Indeed, EPA has adopted programs in past medium- and heavy-duty rules that have included similar mechanisms.114 [EPA-HQ-OAR-2019-0055-1265-A1, pp.26-27]

114 See, e.g., Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards and Highway Diesel Fuel Sulfur Control Requirements, 66 Fed. Reg. 5002 (January, 18, 2001). See, e.g., Control of Air Pollution From New Motor Vehicles: Tier 2 Motor Vehicle Emissions Standards and Gasoline Sulfur Control Requirements, 65 Fed. Reg. 6698 (February 10, 2000).

Critically, however, such a voluntary program must achieve emissions benefits greater than would be achieved assuming manufacturer participation in the mandatory program. [EPA-HQ-OAR-2019-0055-1265-A1, p.27]

Organization: *Ford Motor Company (Ford)*

The Greenhouse Gas regulations do not currently allow trading of engine-based CO2 credits between averaging sets (e.g., between Light Heavy-Duty and Medium Heavy-Duty Diesel engines). This restriction is unnecessary and can drive costly investments for manufacturers who would otherwise be looking to invest in the advanced technology powertrains of the future (electric, fuel cell, etc.). A manufacturer with a single engine (which could be used to meet both the newly proposed NOx standards as well as the more stringent proposed GEM-based vehicle CO2 standards) could be forced to develop or purchase separate light-heavy-duty and medium-heavy-duty diesel engines simply to meet the "normalized to work" engine CO2 standards of both segments. This would not yield any additional GHG or NOx emission benefits. Ford recommends that EPA remove the restriction on trading of engine-based GHG credits between service classes or, at a minimum, allow trading in cases where engines and emission systems are substantially the same (e.g., displacement, combustion system design, emissions controls including aftertreatment chemistry and loading, etc.). This change would have no negative impact on fleet NOx or CO2 emissions and would enable manufacturers to more efficiently invest in the powertrains of the future. [EPA-HQ-OAR-2019-0055-1300-A1, p. 5]

Organization: *Lion Electric Co. USA Inc. (Lion)*

Lion strongly believes that incentive programs should benefit communities historically exposed to higher levels of air pollution. Lion suggests the EPA prioritize disproportionately impacted communities and disadvantaged business enterprises. These applicants often have fewer resources to supply a cash match and require extra support to start their fleet electrification process. Prioritizing these applicants will ensure a diverse range of applicants and geographic distribution of ZEVs. [EPA-HQ-OAR-2019-0055-1151-A2, p. 2]

Organization: *Natural Gas Vehicles for America (NGVAmerica)*

All clean options must be advanced to make a collective difference beginning today. We can't afford to pick the wrong solution or leave out available solutions. It is imperative that regulatory incentives not be used as a weapon to ensure market dominance for any one technology or company. It is abundantly clear that regulatory incentives influence today's market decisions. Our industry would not be where it is without the Renewable Fuel Standard and the low-carbon fuel standards adopted by several states. These programs have proven extremely valuable in encouraging the development, production, and use of a wide range of low-carbon fuels. It is also clear that regulatory incentives for electric vehicles have been disproportionately favorable to that technology (e.g., ignoring upstream emissions, providing sales multipliers, allowing credit trading from low-mileage vehicles to high-mileage vehicles, providing credits for fueling station capacity - not actual fuel use or emission reductions). [EPA-HQ-OAR-2019-0055-1330-A1, p.11]

Organization: *PACCAR, Inc (PACCAR)*

EMA Comments at 131-32. EPA should propose an initiative to encourage turning over outdated fleets. EPA should incentivize removing these high emission vehicles in an effort to accelerate the environmentally-beneficial newer Low NOx technologies. An analysis of vehicle registration data was conducted to explore the makeup of heavy-duty Class 8 vehicle on the road today. In this analysis, registration data updated in the first quarter of 2022 was evaluated to determine the number of trucks, by vehicle Model Year (engine Model Year is Vehicle MY-1) on the road today Vehicle registration data analysis shows that 41% of today's Class 8 vehicles on the road are pre-2010 MY vehicles. EPA should therefore revise proposed section 1036.705 (NOx credit generating and calculating emissions credit) to accelerate retiring these pre- 2010 vehicles. [EPA-HQ-OAR-2019-0055-1346-A1, p.36]

EPA should allow vehicle manufacturers to offer incentives to pre-MY 2010 vehicle owners in the form of vouchers that can be applied to the purchase of a new technology vehicle. In exchange for retiring a pre-MY 2010 vehicle, EPA should allow the manufacturer to bank NOx credits in the new federal NOx bank. [EPA-HQ-OAR-2019-0055-1346-A1, p.37]

An exploration of the NOx generation, using the NOx credit equation provided by EPA is used to illustrate the significance of this proposal. The NOx emission credit equation proposed by EPA is: [EPA-HQ-OAR-2019-0055-1346-A1, p.37]

This equation was used to explore the Mega gram of NOx emission (or displaced emission) from Zero Emission Vehicles and Current and Future CI diesel engines for a Class 8 HHDE. The lifetime emission was calculated by setting 'FEL' to zero. The lifetime NOx emission (for a CI diesel) or credit (for a ZEV) for an EPA MY2010-2026 powertrain is about 0.4 mega-grams. For the MY2027 and later vehicle certifying to a 0.05 NOx standard the lifetime emission of NOx is about 0.1 mega-grams of NOx. [EPA-HQ-OAR-2019-0055-1346-A1, p.37]

The analysis then explored the emission of NOx from a pre-2010 vehicles over approximately one year (assumed to be about 40,000 miles for illustration). The emissions from a Class 8 MYs 1996-2003 and a MYs 2003-2009 diesel engine over one year of operation was estimated to be 0.66 and 0.41 mega-grams of NOx, respectively. This example illustrates that these vehicles are emitting about four times the predicted lifetime emission of a proposed MY 2027 and later Low NOx diesel engine, every year. [EPA-HQ-OAR-2019-0055-1346-A1, p.38]

Therefore EPA should allow vehicle manufacturers to provide incentives to their customers to trade in their older vehicles for a new technology vehicle, and then OEMs should be allowed to bank NOx credits equivalent to one year of NOx emission from the older technology vehicle. OEMs would 'retire' the traded-in vehicle, meaning its engine would be seized or otherwise made permanently inoperable. This 'Credits for Clunkers' scenario would benefit both the Agency and manufacturers: EPA can realize accelerated real-world emission reductions and manufactures can use the displaced real-world NOx to ease the transition into the new Low NOx technology. Also, by taking only one year of credit, the benefit realized by the agency will be much greater than the credit given. Additionally, the new Low NOx technology trucks will also provide emissions control under low load operation, where the older technology vehicles are not as well controlled and produce much higher NOx emissions. [EPA-HQ-OAR-2019-0055-1346-A1, pp.38-39]

PACCAR summarizes below the major issues that EPA should take into account as it moves forward with this rulemaking: EPA should also allow vehicle manufacturers to provide incentives to their customers to trade in their older vehicles for new technology vehicles, after which manufacturers should be allowed to bank NOx credits proportional to one year of service for eliminating the trade-in vehicle from the population. [EPA-HQ-OAR-2019-0055-1346-A1, p.60]

EPA Summary and Response

Summary:

Several commenters provided additional perspectives on incentivizing additional emissions reductions, either through the proposed criteria pollutant ABT program, or alternative approaches through one or more specific technologies. One commenter (EDF) suggested a voluntary alternative compliance pathway to pull forward reductions prior to 2027. The commenter noted that many manufacturers are introducing ZEV technologies now and also planning for compliance with more protective NOx Omnibus requirements in 2024, but the commenter did not provide specific information on how the voluntary, alternative compliance pathway would work.

Two other commenters (Allison, PACCAR) suggested that EPA consider voluntary federal or state programs to encourage fleet turnover. One of these commenters (Allison) suggested that EPA could further integrate such programs into our cost and benefit analyses of the rule. The other commenter (PACCAR) provided an analysis of vehicle registration data that shows that 41% of today's Class 8 vehicles on the road are pre-2010 MY vehicles. The commenter stated that EPA should therefore revise proposed section 1036.705 (NOx credit generating and calculating emissions credit) to accelerate retiring these pre- 2010 vehicles, and the commenter provided a potential approach for allowing vehicle manufacturers to provide incentives to their customers to trade in their older vehicles for a new technology vehicle, which would in turn allow OEMs to bank NOx credits equivalent to one year of NOx emission from the older technology vehicle. Another commenter (Lion) stated generally that EPA should prioritize disproportionately impacted communities and disadvantaged business enterprises for incentive programs.

Another commenter (Ford) urged EPA to allow manufacturers to trade engine-based CO_2 credits between averaging sets, or at a minimum, allow trading in cases where engines and emission systems are substantially the same (e.g., displacement, combustion system design, emissions controls including aftertreatment chemistry and loading, etc.). The commenter claimed this change would have no negative impact on fleet NOx or CO_2 emissions and would enable manufacturers to more efficiently invest in the powertrains of the future.

Finally, one commenter (NGVAmerica) expressed concern that regulatory incentives for electric vehicles have been disproportionately favorable to that technology.

Response:

Related to the voluntary, alternative compliance pathway one commenter (EDF) presented, we agree with the importance of incentivizing manufacturers to pull forward emissions reducing technologies prior to MY 2027. As discussed in Section 12.4 of this document and Section IV.G of the preamble, we are finalizing a transitional credit program that we modified from the proposal after consideration of comments we received. We believe the Transitional Credit program we are finalizing will better incentivize manufacturers to participate in the transitional credit program, and therefore better achieve emissions reductions prior to MY 2027. While we believe the transitional credit program we are finalizing partially addresses the commenter's concern about pulling forward emissions reductions, we recognize that it is likely not the voluntary pathway for incentivizing electric drivetrains that the commenter suggests. We note that we are finalizing language that clarifies how heavy-duty ZEVs certify to criteria pollutants in 40 CFR 1037 (see Section 12.6 of this document and preamble Section III for details). We also note we are not finalizing the proposed allowance for manufacturers to generate NO_X emissions credits from ZEVs, as discussed in Section 12.6 of this document and preamble Section IV.G; our decision is based in part on ensuring that the final ABT program maintains the emissions reductions expected from the final standards, which is consistent with the commenter's stated interest in not sacrificing NO_X or GHG emissions from ICEs.

We also agree with the importance of encouraging fleet turnover, particularly for vehicles with engines that are compliant with pre-2010 emissions standards. In particular, we agree that state and other federal programs can result in the retirement of pre-2010 vehicles, and that some of these programs have been highly effective, and that some of these programs can be particularly impactful for disproportionally impacted communities.[32] Further, since we did not propose or ask for comment on incentive programs to allow vehicle manufacturers to generate NO_X emissions credits based on providing incentives to their customers to trade in their older vehicles for a new technology vehicle, we are not including such a program in the final rule.

Similarly, we did not propose or request comment on allowing heavy-duty vehicle manufacturers to trade engine-based CO_2 credits between averaging sets; this comment was outside the scope of the rule and we are not including such an approach in this final rule.

Finally, as just mentioned and discussed in Section 12.6 of this document and preamble Section IV.G, we are not finalizing the proposed allowance for manufacturers to generate NO_X emissions credits from zero-emissions vehicles; our rationale for that decision is detailed in preamble Section IV.G, but we anticipate the decision addresses the commenter's concern about this rule containing regulatory incentives favoring electric vehicle technologies. Further, as discussed in Section 3 of this document and preamble Section III, we are finalizing performance-based standards that do not specify a particular technology path for manufacturers to comply with the standards.

12.2 FEL Caps

[32] For example, the Bipartisan Infrastructure Law allows EPA to prioritize certain applicants in the Clean School Bus (CSB) Program, including school districts listed in the Small Area Income and Poverty Estimates (SAIPE) School district Estimates for 2020 as having 20% or more students living in poverty (EPA "2022 Clean School Bus Rebates – Prioritized School Districts" May 2022; available at https://www.epa.gov/system/files/documents/2022-05/2022-csb-rebates-prioritized-school-districts-2022-05.pdf, last accessed on August 29, 2022).

Comments by Organizations

Organization: *Alliance for Vehicle Efficiency (AVE)*

AVE supports additional modifications to Option 1 to provide the best opportunity for driving more rapid adoption of advanced engine and emission control technologies. These additional modifications include:

- Tightening the family emission limit (FEL) to 0.05 g/bhp-hr, down from the current proposal of 0.15 g/bhp-hr. [EPA-HQ-OAR-2019-0055-1280-A1, p. 3]

Organization: *California Air Resources Board (CARB)*

On page 17552 of the NPRM, U.S. EPA asks for comments regarding the proposed family emission limit (FEL) caps. [EPA-HQ-OAR-2019-0055-1186-A2, p.11]

CARB staff strongly encourages U.S. EPA to adopt an FEL cap lower than the 150 milligram per brake-horsepower hour (mg/bhp-hr) nitrogen oxides (NOx) FEL cap included in both Options 1 and 2. As described further below, an FEL cap of 150 mg/bhp-hr would allow engines only slightly cleaner than those being certified today (FEL of 160 mg/bhp-hr) to be produced until 2030. It should be noted that the current Omnibus regulation NOx FEL caps are specified as:

- 2024-2026 model years (MY): 100 mg/bhp-hr for all service classes
- 2027 and subsequent MYs: 50 mg/bhp-hr (light heavy-duty diesel (LHDD), medium heavy-duty diesel (MHDD)), 65 mg/bhp-hr (2027-2030 MY heavy heavy-duty diesel (HHDD)) and 70 mg/bhp-hr (2031 and subsequent MY HHDD) [EPA-HQ-OAR-2019-0055-1186-A2, p.11]

California's adopted HD Low NOx regulation (or Omnibus regulation) establishes a 50 mg/bhp-hr NOx emission standard in 2024 MY. Under U.S. EPA's proposed rule, manufacturers would have a four-year lead time to redesign their products to meet the future standards. It is not clear why a 150 mg/bhp-hr NOx FEL cap would be needed for 2027 through 2030 MY engines because manufacturers will be producing engines meeting California's 50 mg/bhp-hr up to three MYs ahead of CTP implementation. Such a high FEL cap would only lead to continued production of relatively high emitting legacy HD diesel engines using today's emission control technologies. For example, Detroit Diesel Corporation (DDC) has certified two HD diesel-fueled engine families (Appendix I) [Appendix I can be found at EPA-HQ-OAR-2019-0055-1186-A2, p.136-142] with California for the 2022 MY at an FEL of 160 mg/bhp-hr, just slightly above the FEL cap U.S. EPA is proposing for five years from now and that, under U.S. EPA's proposal, would continue until the 2030 MY. It is CARB staff's understanding that there are no major emission control technology changes associated with this new family emission limit. [EPA-HQ-OAR-2019-0055-1186-A2, p.11]

On page 17555 of the proposed rule, U.S. EPA asserts that 'specifically, our proposed NOx FEL caps would ensure significant emission reductions from all HD highway engines compared to today's products'. CARB staff agrees with the concept that the purpose of an FEL cap is to prevent the use of old, legacy technologies. However, setting a 150 mg/bhp-hr NOx FEL cap would not achieve that purpose. U.S. EPA has impermissibly ignored the aforementioned considerations and evidence, which undermine its rationale for this proposal, Genuine Parts Co. v. Env't Prot. Agency, 890 F.3d 304, 312 (D.C. Cir. 2018), failed to consider an important aspect of the proposal, namely, the extent to which the proposed FEL caps may adversely affect the projected emissions benefits of the Option 1 and Option 2 standards. Motor Vehicle Mfrs. Ass'n v. State Farm Mut. Auto. Ins. Co., (hereinafter State Farm), 463 U.S. 29, 43, (1983), and has not set forth a rational connection between the facts and its proposal. State Farm, 463 U.S. at 43. [EPA-HQ-OAR-2019-0055-1186-A2, pp.11-12]

As discussed further in section 3.a, CARB staff has serious concerns that CTP's proposed HD electric vehicle NOx credits with no sunset date and federal NOx credits generated by manufacturers complying with Omnibus standards will provide manufacturers with substantial amounts of credits. Thus, these credits would allow manufacturers to continue producing legacy engines with high NOx FEL caps nationally, causing serious erosion of the environmental benefits generated by the proposed rule. CARB staff strongly recommends that U.S. EPA adopt the same FEL caps outlined in the Omnibus regulation. [EPA-HQ-OAR-2019-0055-1186-A2, p.12]

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

And third, EPA's proposed FEL caps are unreasonably high. See Section D.2.c, infra. That failure exacerbates the effect of the Proposal's credit mechanism, and results in unacceptable emissions and health impacts. [EPA-HQ-OAR-2019-0055-1302-A1, p.53]

Option 1's proposed FEL cap for NOx is far too lenient because it fails to require the greatest degree of emissions reduction achievable by technologies that will be available by MY 2027. See 42 U.S.C. 7521(a)(3)(A)(i). Flouting Congress's direction to set technology-forcing standards, EPA instead proposes FEL caps that are based on the 'average NOx emission levels achieved by recently certified CI engines.' 87 Fed. Reg. at 17,522. But 'recently certified' engines were designed to comply with standards promulgated more than twenty years ago, and do not utilize the improved pollution-control technologies that will be available in MY 2027. See id. at 17,419 (noting emergence of new technologies). EPA's proposed FEL cap of 150 mg/hp-hr for MY 2027 is twice as high as the Omnibus's FEL cap of 100 mg/hp-hr for MY 2024–2026, and three times higher than the Omnibus's general NOx emission standard of 50 mg/hp-hr (which will take effect in MY 2024).240 87 Fed. Reg. at 17,552; Comments of CARB, to be filed in Docket EPA-HQ-OAR-2019-0055 on May 16, 2022. Given that manufacturers will already be required to implement technologies to achieve a 50 mg/hp-hr standard and a 100 mg/hp-hr FEL cap in several markets three years before EPA's rule takes effect, the proposed 150 mg/hp-hr cap lacks any technical justification. Commenters also support and incorporate by reference comments by MFN and CARB demonstrating the technological feasibility of (and the health and equity rationales for) a lower FEL cap. See Comments of (1) MFN and (2) CARB, to be filed in Docket EPA-HQ-OAR-2019-0055 on May 16, 2022. Establishing a lower FEL cap is technologically achievable and would better conform with the Clean Air Act's core pollution-minimizing mandate. [EPA-HQ-OAR-2019-0055-1302-A1, pp.58-59]

240 The Omnibus's FEL caps decrease to 50–70 mg/hp-hr in later model years, depending on service class. See Comments of CARB, to be filed in Docket EPA-HQ-OAR-2019-0055 on May 16, 2022.

Organization: *Colorado Energy Office, et al.*

We support NESCAUM's recommendations to limit flexibilities that could significantly reduce the emissions benefits of Option 1. For example, we recommend establishing stronger family emission limit (FEL) caps that are consistent with the FEL caps in the Low NOx Omnibus rule to avoid potential erosion of the effectiveness of the rule from the use of ZEV credits. [EPA-HQ-OAR-2019-0055-1297-A1, p.2]

Organization: *Cummins Inc. (Cummins)*

To further prevent unintended consequences, EPA should constrain the NOx FTP/SET FEL cap for MY 2027 and later to be no higher than 100 mg/hp-hr for all service classes. Depending on other details in the final rule, setting the FEL cap at some value between 50-100 mg/hp-hr may be more appropriate. Setting that lower FEL cap also will help to prevent the competitive problems described above. [EPA-HQ-OAR-2019-0055-1325-A1, p. 9]

Organization: *Maine Department of Environmental Protection (Department)*

Using the CARB Heavy-Duty Omnibus Regulation as a bellwether, the Department requests the following revisions to the federal proposal: [EPA-HQ-OAR-2019-0055-1288-A1, p.6]

- Eliminating averaging, banking, and trading would maximize nationwide NOx reductions. If EPA retains these provisions, it should consider establishing a 0.05 grams NOx cap in 2027 that is consistent with that in the CARB Heavy-Duty Omnibus regulation in lieu of EPA's proposed family emission limits (FEL) of 0.15 grams NOx in 2027 and 0.05 grams NOx in 2031. Manufacturers have already conducted engine development work to prepare for and comply with California 2024-2026 standards and if the CARB FEL caps are implemented federally, all states can benefit from this research and development. [EPA-HQ-OAR-2019-0055-1288-A1,p.8]

Organization: *Motor & Equipment Manufacturers Association (MEMA)*

MEMA recommends that each HD manufacturer's fleet have a not to exceed limit (NTE limit) on individual vehicles by class to avoid very high emissions vehicles being permissible as part of the overall fleet. [EPA-HQ-OAR-2019-0055-1322-A1, p. 5]

Organization: Moving Forward Network (MFN)

To safeguard against potential underestimates of ZE truck sales under this approach, EPA must also significantly and progressively lower the FEL cap to ensure combustion engine families continue to utilize state-of-the-art technologies. [EPA-HQ-OAR-2019-0055-1277-A1, p. 20]

EPA's standards are defined as an average compliance value. This means that to the degree trucks are able to perform better than the average standard, a manufacturer can earn credits. These credits can then be used to offset vehicles that emit more of the harmful emissions than required by the average level of compliance. The only limit as to how dirty an individual truck can be is provided by the family emissions limit (FEL) cap. [EPA-HQ-OAR-2019-0055-1277-A1, p. 30]

For Option 1, EPA has proposed setting the FEL cap at 150 mg/bhp-hr NOx in 2027, a level "which is consistent with the average NOx emission levels achieved by recently certified CI engines."126 This means that at least through 2030, trucks can be certified to a level consistent with compliance with a standard promulgated three decades earlier. [EPA-HQ-OAR-2019-0055-1277-A1, p. 30]

126. 87 FR 17552.

Setting the FEL cap at a level consistent with today's technology falls well short of EPA's mandate under the Clean Air Act to set "standards which reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply."127 [EPA-HQ-OAR-2019-0055-1277-A1, p. 31]

127 42 U.S.C. § 7521(a)(3)(A).

SwRI's Stage 1 testing program showed that updates to engine calibration alone were able to reduce the tailpipe emissions of a modern diesel engine by 36 percent, to 0.09 g/bhp-hr.128 Simply by adding a heated catalyst, the system was able to reduce tailpipe NOx emissions below 0.05 g/bhp-hr, the Omnibus standard for 2024. These are minor changes to engine configurations, which is, in part, why they were used in the justification for the Omnibus standards in this timeframe.129 [EPA-HQ-OAR-2019-0055-1277-A1, p. 31]

The Omnibus standard will be enforced in a number of states by 2027, representing at least 9 percent of the total market, and likely more (see Section IV.D.5.c for further discussion). For three years, that standard will have been mandating an average requirement of 50 mg/bhp-hr, and in 2027 a maximum standard of 50 mg/bhp-hr. With such a substantial share of the market already required to achieve this standard or less, and a number of technological paths for manufacturers to achieve this standard, it is hard to argue on a technical basis that this should not be, at absolute worst, the upper level of emissions for all kinds of trucks. [EPA-HQ-OAR-2019-0055-1277-A1, p. 31]

EPA offers an historical precedent of setting the FEL at the previous standard level.130 However, this is not true for the rules currently on the books—the current HD diesel FEL cap is 0.5 g/bhp-hr NOx (2010+), whereas the previous average standard (2004-2006) was 2 g/bhp-hr.131 In citing the reason for not leaving the FEL at 2 g/bhp-hr and instead moving to the current 0.5 g/bhp-hr cap, EPA explicitly notes the 90 percent difference between the 0.2 and 2 g/bhp-hr NOx standards.132 [EPA-HQ-OAR-2019-0055-1277-A1, p. 31]

130. 87 FR 17552

131. The standard was either a combined 2.5 g/bhp-hr cap for NMHC+NOx, with a 0.5 limit on just NMHC, or a 2.4 g/bhp-hr cap on NMHC+NOx.

132 66 FR 5111

The situation the industry faces today is vastly different than in 2001. Whereas previously the new rules were predicated on unknown technologies, here there is much more certainty as to the capability of diesel powertrains to meet the requirements, with established technologies like variable-valve actuation, 48V hybridization, and evolutionary improvements in emissions controls. One similarity, however, is the tremendous disparity between the new average requirements and the old regulations. Here again EPA is expected to reduce emissions by 90 percent on the FTP cycle, and, as such, it is more important to worry about the disparity between different new trucks on the road and the capability of manufacturers to meet more stringent standards in the allocated timeframe. [EPA-HQ-OAR-2019-0055-1277-A1, p. 31]

It is clear based on available technology and the latest evidence that manufacturers are more than capable of meeting much stronger standards than have been on the books since 2010 (see Section III.B). This is precisely what the Omnibus program was meant to address, beginning 3 years prior to EPA's proposed rule. It is therefore appropriate that EPA align its FELs with the Omnibus program. These limits yield identical percentage improvements from the FELs and average standards from 2010 to 2027. [EPA-HQ-OAR-2019-0055-1277-A1, p. 31]

In 2027, EPA's FELs for LHDD and MHDD engines should be set no higher than 50 mg/bhp-hr, representing a 30 mg/bhp-hr shortfall from our recommended average standard, and a 90 percent reduction from the current FEL, consistent with the 90 percent reduction in the average standard. For HHDD engines, the gap should be identical (30 mg/bhp-hr), but the longer useful lifetime requires an additional margin, putting this limit at no more than 65 mg/bhp-hr. Should EPA set an intermediate lifetime limit on HHDD engines, its limits would be identical to the LHDD and MHDD engine requirements. [EPA-HQ-OAR-2019-0055-1277-A1, p. 32]

For 2031, the FELs appear to be aligned with the Omnibus rule. However, EPA should consider whether it is appropriate to allow in perpetuity a difference of 150 percent of FTP-cycle NOx emissions. Given the concerns about equity, and where the dirtiest trucks on the road inevitably end up (Section III.B.6.c), EPA should continue to tighten the FEL over time. [EPA-HQ-OAR-2019-0055-1277-A1, p. 32]

With respect to the 30 mg/bhp-hr value, it is important to note that it is not that 30 mg/bhp-hr is an appropriate gap, but that 50 mg/bhp-hr is a technically justified maximum, which so happens to have a difference of 30 mg/bhp-hr. The FEL is the level achieved by the worst-performing trucks. As technology continues to be improved and is broadly used across the entire fleet, the FEL should be reduced to reflect the fact that those worst vehicles can perform better than previously allowed, regardless of the value set by the average emissions standards. [EPA-HQ-OAR-2019-0055-1277-A1, p. 32]

Implicit in the existence of the FEL is EPA's belief that some trucks should be allowed to emit more pollution than others. However, 100 percent of today's heavy-duty diesel engines are certified to the required average standard (0.2 g/bhp-hr) or better. This indicates that there is no difference in technical capability across truck applications to meet today's standards. Therefore, FELs above the average technical capabilities of diesel engines should be considered a temporary, transitional option available only in the initial years of the standard, if at all. Given its mandate under the Clean Air Act and the wealth of evidence on the technological capability of diesel control technologies, not to mention the growing number of applications for zero-emissions vehicles, EPA should consider whether it is appropriate at all in the long run to maintain FELs that do not reflect the maximum technical capability to reduce emissions. [EPA-HQ-OAR-2019-0055-1277-A1, p. 32]

As noted above, the FEL cap (and by extension the averaging program) allows some trucks to pollute more than others. Unfortunately, those more polluting trucks are frequently in operation or operating conditions where they are likely to do the most damage–in communities already overburdened by pollution. For example, port drayage operations involve high volume freight flows, and freight operators use older trucks to limit the marginal costs, even in regions with targeted environmental policies meant to limit the use of older trucks.133 [EPA-HQ-OAR-2019-0055-1277-A1, p. 32]

> 133. See https://digitalcommons.law.ggu.edu/cgi/viewcontent.cgi?article=1150&context=gguelj and the references contained therein.

A recent study of real-world emissions control operations showed that under urban operating conditions, including goods movement and delivery with extended low-load conditions, diesel vehicles with modern emissions controls performed just 33 percent better on average than those without an SCR system,134 despite a required reduction of more than 90 percent on the federal test cycles. Other studies have shown similar conditions—while line-haul tractors may spend a significant share of time at highway speeds, the vocational operations most common in urban centers spend a lot more time at conditions where modern diesel controls are functioning suboptimally.135 [EPA-HQ-OAR-2019-0055-1277-A1, pp. 32 - 33]

"Real-world exhaust temperature profiles of on-road heavy-duty diesel vehicles equipped with selective catalytic reduction," Science of the Total Environment 634 (1 Sept 2018), 909-921. DOI: 10.1016/j.scitotenv.2018.03.362. https://doi.org/10.1016/j.scitotenv.2018.03.362.

EPA acknowledges this issue in its establishment of the low-load cycle (87 FR 17463). However, the flaws in the FELs on the FTP cycle are even further exacerbated on the LLC, which has even greater margins for compliance, virtually eliminating any possible potential gains this cycle could have for the worst performing vehicles: while the FELFTP is defined as 150 mg/bhp-hr for 2027-2030 diesel engines under Option 1, FELLLC is 150 / 35 × 90 = 385 mg/bhp-hr (87 FR 17551), a value that is worse than some 2017- 2019 diesel engines achieve today (87 FR 17470, Table III-12).136 [EPA-HQ-OAR-2019-0055-1277-A1, p. 33]

136. 150 mg/bhp-hr is the FEL_FTP limit; 35 mg/bhp-hr is the required standard on the FTP cycle; and 90 mg/bhp-hr is the required standard on the LLC cycle.

By setting its FEL as high as it has, EPA is proposing to allow in perpetuity vehicles that its own data show far exceed the levels of pollution allowed by current test procedures, in precisely the communities that are already overburdened by freight pollution. This is yet another example of how even EPA's most stringent proposed standard would prolong systemic environmental inequities in freight pollution and fall short of the Act's requirements. [EPA-HQ-OAR-2019-0055-1277-A1, p. 33]

Organization: *National Association of Clean Air Agencies (NACAA)*

EPA also seeks comment on a proposed Family Emission Limit (FEL) cap of 150 mg/hp-hr in 2027, which the agency says is consistent with the average NOx emission levels achieved by recently certified diesel engines. An FEL cap being achieved today is far too high for implementation more than four years from now and, at 150 mg, is inconsistent with the 50-mg/hp-hr standards applicable to engines that will be in production in 2026 to comply with the Omnibus. [EPA-HQ-OAR-2019-0055-1232-A1, p. 15]

Organization: *Northeast States for Coordinated Air Use Management (NESCAUM)*

We are especially concerned that EPA's proposed family emission limit (FEL) cap of 0.15 grams of NOx between 2027 and 2030 could cause significant erosion of the stringency of the heavy-duty engine NOx standards. [EPA-HQ-OAR-2019-0055-1249-A1, pp. 14 - 15]

Organization: *Ozone Transport Commission (OTC) and Mid-Atlantic/Northeast Visibility Union (MANE-VU)*

We are especially concerned that EPA's proposed family emission limit (FEL) cap of 0.15 grams of NOx between 2027 and 2030 could cause significant erosion of the stringency of the heavy-duty engine NOx standards. [EPA-HQ-OAR-2019-0055-1250-A1, p.16]

Organization: *PACCAR, Inc (PACCAR)*

To further prevent unintended consequences, EPA should reduce the FTP/RMC NOx FEL cap to be no higher than 0.100 g/bhp-hr for all service classes. Setting that lower FEL cap also will help to mitigate the competitive problems described above. [EPA-HQ-OAR-2019-0055-1346-A1, pp.35-36]

Organization: *States of California, et al. (The States)*

The States strongly support EPA's proposed measures to tailor the ABT program to this role, including (1) limiting credit life to at most five years, (2) replacing existing credit balances with transitional credits, and (3) lowering family emission limit (FEL) caps to below the 2007 heavy-duty standards.90 [EPA-HQ-OAR-2019-0055-1255-A1, pp. 20 - 21]

90. Id. at 17,552-54.

Organization: *Truck and Engine Manufacturers Association (EMA)*

To further prevent unintended consequences, EPA should reduce the FTP/RMC NOx FEL cap to be no higher than 0.100 g/bhp-hr for all service classes. Setting that lower FEL cap also will help to mitigate the competitive problems described above. [EPA-HQ-OAR-2019-0055-1203-A1, p. 135]

EPA Summary and Response

Many of the summaries of comments on the proposed FEL cap in the proposed rule, and EPA's responses to those comments, are included in Preamble Section IV.G. Immediately below, we briefly summarize and respond to additional comments on the proposed FEL cap.

Summary of comments on the FEL cap:

One commenter suggested that each manufacturer's fleet have a not to exceed limit (NTE limit) on individual vehicles by class to avoid very high emissions vehicles being permissible as part of the overall fleet.

One commenter stated that EPA should lower the FEL over time to reflect expected improvements in the maximum technical capability to reduce emissions. The commenter stated that the FEL cap allows some trucks to pollute more than others, and that more polluting trucks frequently operate in communities already overburdened by pollution (e.g., port drayage operations often use older trucks even in regions with polices meant to limit the use of older trucks). The commenter further stated that lowering the FEL over time would address concerns about equity given where the dirtiest trucks often end up, which is commonly in port drayage or urban operating conditions. The commenter provided data showing that trucks with modern emissions controls operating in urban driving conditions, including extended low-loads, performed only 33 percent better than trucks without an SCR system. They argued that the FEL for LLC is worse than some 2017-2019 diesel engines can achieve today and that finalizing the FEL caps as proposed would prolong systemic environmental inequities in freight pollution, and fall short of the Act's requirements.

Response to comments on the FEL cap:

EPA agrees with commenters that lower FEL caps than proposed are appropriate for the final rule. We believe the lower FEL caps in the final rule will ensure that the vast majority of engines make meaningful improvements from today's emissions levels, while also allowing manufacturers flexibility in their product plans.[33,34] We expect that this approach in the final rule will address the concern raised by one commenter regarding avoiding very high emissions vehicles as part of a manufacturer's overall fleet. Details on the FEL caps in the final rule, including EPA's analysis and rationale, are available in preamble Section IV.G.4.

As described in preamble Section IV.G.4, after further consideration, including consideration of comments, the FEL caps in the final rule will lower over time (i.e., progressively lowering the FEL cap to the level of the standards, as one commenter suggests). However, as proposed, we are not choosing to include an expiration date for the final ABT program. As discussed in Section IV.G.1, EPA continues to believe that an ABT program is an important flexibility for manufacturers to spread out their investment and prioritize technology adoption in the applications that make the most sense for their businesses during the transition to meeting new standards. In later years of the program when no changes in emission standards are involved, banking can provide manufacturers additional flexibility, provide assurance against any unforeseen emissions-related problems that may arise, and in general provide a means to encourage the development and introduction of new engine technology (see 55 FR 30585, July 26, 1990, for additional discussion on potential benefits of an ABT program). We note that the final FEL caps, particularly the FEL cap applicable to later years of the program, will require manufacturers to make meaningful improvements from the emissions control technologies used to meet the currently existing standards. Further, we note that credits banked prior to MY 2027 will expire as early as by MY 2030 and no later than by MY 2035 (depending on the extent to which engines used to generate credits meet the MY 2027 and later requirements, as explained in preamble Section IV.G.7); it is possible that at least some of the credits generated will not be used, particularly as the heavy-duty fleet continues to transition to ZEVs. Finally, as discussed in preamble Section IV.G, EPA is not finalizing the proposed allowance for manufacturers to generate NO_X emissions credits from ZEVs, and thus the growing number of ZEVs that the commenter points to is not a factor to consider in progressively lowering the FEL cap.

One commenter also stated that the FEL cap allows some trucks to pollute more than others and that more polluting trucks frequently operate in communities already overburdened by pollution (e.g., port drayage operations often use older trucks even in regions with policies meant to limit the use of older trucks). We acknowledge that an ABT program does inherently allow some engines to produce higher levels of emissions than other engines; however, the FEL cap constrains the extent to which engines can emit above the level of the standard and can be set to ensure that all engines improve. After further consideration, including consideration of comments from this commenter and others, we are finalizing lower FEL caps than proposed to

[33] As discussed in Section IV.G.9, we are finalizing an allowance for manufacturers to continue to produce a small number (5 percent of production volume) of engines that meet the current standards for a few model years (i.e., through MY 2029); thus, the vast majority, but not all new engines will need to include updated emissions control technologies compared to those used to meet today's standards until MY 2030 when all engines will need updated emissions control technologies to comply with the final standards. See Section IV.G.9 for details on our approach and rationale for including this allowance in the final rule. Except for this interim allowance, the FEL caps in the final rule are the maximum level to which manufacturers may certify an engine family while using NO_X emissions credits. In setting the FEL caps and requirements for this interim allowance, we considered concerns raised by commenters regarding the potential for high emissions from individual engines.

[34] We note that, as specified in 40 CFR 1036.101, each engine must meet the final standards unless participating in the voluntary ABT program. Under the current and final NO_X emissions standards, manufacturers must either certify that each of their engine families meets the numeric standards, or use NO_X emissions credits generated by engines certified to a numeric level below the standards

ensure that all engines improve at least 68% from today's standards in the early years of the program, and at least 75% in the later years of the program, compared to the 25% improvement that would have been required with the proposed FEL cap. The commenter argues that higher-emitting trucks are more likely to operate in communities that are already overburdened with pollution, such as port drayage operations; however, we have no data to suggest that engines certified to the FEL caps in the final rule would be more likely than other trucks to operate in these communities. While we agree that older trucks are more likely to operate in port drayage and other communities with environmental justice concerns, we do not have evidence that new trucks with an engine certified to 65 or 50 mg/hp-hr would be more likely than trucks with engines certified at 35 mg/hp-hr to operate in certain areas or operations. Further, by allowing manufacturers to participate in the NO_X ABT program in the final rule we are providing a flexibility for manufacturers to spread out their investments; as some commenters have noted, flexible program may help with fleet turnover as the new emission standards take effect (see Section 25 of this document for more discussion on fleet turnover). Fleet turnover would help replace older trucks, which emit at much higher levels than the FEL cap in the final rule, with newer trucks in port drayage and other communities impacted by freight operations. Finally, inherent in the ABT program is the requirement for manufacturers producing engines above the emissions standard to produce engines below the standard, or purchase credits from another manufacturer who has produced lower emitting engines. As a simplified example, the result is that any engine certified to a 50 mg/hp-hr FEL would need to be balanced by an engine certified to a 20 mg/hp-hr FEL. As the commenter points out, local or regional policies that limit the use of older, higher-emitting trucks could help to ensure that the lowest-emitting engines operate in communities overburdened by pollution. We also note that recent Federal funding may also help to encourage turnover of older, higher-emitting trucks.[35]

Finally, one commenter stated that the proposed FEL cap for the LLC is a value worse than what some 2017-2019 diesel engines can achieve today. After further consideration, including consideration of comments from this commenter and others, we are finalizing a lower LLC standard than proposed. As described in preamble Section III, the final LLC standard is based on the most recent EPA engine demonstration data, which includes emissions control technologies that are not widely used in current diesel engines (see Section 3 of this document and preamble Section III for additional details on the final LLC standard). As discussed in Section IV.G.2, manufacturers will base their final FEL_{FTP} for credit generation on their engine family's emission performance on the most challenging cycle. Thus, if a CI engine manufacturer demonstrates NO_X emissions on the FTP that is 25 percent lower than the standard but can only achieve 10 percent lower NO_X emissions for the low load cycle, the declared FEL_{FTP} would be based on that 10 percent improvement to ensure the proportional FEL_{LLC} would be met. We expect that the combination of the lower LLC standard and the lower FEL cap in the final rule address the concern the commenter raised about the FEL cap for the LLC.

12.3 Credit Life

[35] For example, see Sections 13403 (Qualified Clean Vehicles), 13404 (Alternative Fuel Refueling Property Credit), 60101 (Clean Heavy-Duty Vehicles), 60102 (Grants to Reduce Air Pollution at Ports), and 70002 (United States Postal Service Clean Fleets) of H. R. 5376,

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

On page 17553 of the NPRM, U.S. EPA asks for comments regarding the proposed five-year credit life. [EPA-HQ-OAR-2019-0055-1186-A2, p.12]

CARB staff supported the five-year greenhouse gas (GHG) emission credit life specified in 1036.740 (d) in the U.S. EPA Phase 1 GHG standards and aligned with them. CARB staff supports changes to also limit criteria emission credit life to five years. An unlimited credit life beyond five years would only serve to allow manufacturers to produce higher polluting engines when emission standards become more stringent many years from now, such as in the 2030 MY under the CTP proposal. For example, during development of the Omnibus regulation, CARB staff analyzed existing federal NOx credit banks and the credit accumulation practices of HD engine manufacturers for the 2007-2021 model year period and observed that several manufacturers had accumulated enough credits during the 2007-2009 MY period to be able to certify new 2024-2026 MY engine families at the proposed Omnibus regulation FEL caps. If CARB staff had not sunset the allowed use of these credits, it would have delayed needed emission reductions of the program. [EPA-HQ-OAR-2019-0055-1186-A2, p.12]

If manufacturers desire to have additional flexibility for meeting 2030 MY requirements, they would have the opportunity to certify lower FEL engine families up to five years prior to help transition to those standards. [EPA-HQ-OAR-2019-0055-1186-A2, p.12]

On page 17552 of the proposed rule, U.S. EPA asserts that the same credit life provisions for Carbon dioxide (CO2) emissions should also be applicable to NOx emissions. CARB staff strongly agrees with this assessment, which is in alignment with California's Omnibus regulation. [EPA-HQ-OAR-2019-0055-1186-A2, p.12]

"As specified in the proposed 40 CFR 1036.740(d), NOx emission credits generated for use in MY 2027 and later could be used for five model years after the year in which they are generated. … We request comment on our proposed five-year credit life." (87 FR 17552-3) [EPA-HQ-OAR-2019-0055-1277-A1, p. 49]

Organization: *Cummins Inc. (Cummins)*

With those averaging set and FEL cap constraints to protect against unintended consequences, Cummins supports unlimited NOx credit life, or at least credit life in-line with useful life, in lieu of EPA's proposed 5-year credit life. [EPA-HQ-OAR-2019-0055-1325-A1, p. 9]

Organization: *Moving Forward Network (MFN)*

"As specified in the proposed 40 CFR 1036.740(d), NOx emission credits generated for use in MY 2027 and later could be used for five model years after the year in which they are generated. … We request comment on our proposed five-year credit life." (87 FR 17552-3) [EPA-HQ-OAR-2019-0055-1277-A1, p. 49]

Three years, not five, is a reasonable timeframe to average out year-to-year variability and should therefore be an appropriate credit lifetime. EPA's three-year stability requirement under the Clean Air Act § 202(a)(3)(C) represents an industry standard pace of improvement to which manufacturers already adhere and plan against. Prior to EPA's elimination of credit lifetime, NOx and particulate emission credits had a three-year expiration (40 CFR § 86.091-14(f)(1) [2004]180). [EPA-HQ-OAR-2019-0055-1277-A1, p. 49]

180. This section of the CFR has since been amended, but an archival reference is available here: https://www.govinfo.gov/content/pkg/CFR-2004-title40-vol17/pdf/CFR-2004-title40-vol17-sec86-091-15.pdf.

Acknowledging the harm that the current indefinite credit system would cause were it allowed to persist, EPA has not justified its choice of five years, and a three-year lifetime is both more protective under the Clean Air Act and has previously been used by the agency. In fact, prior to its most recent elimination of a credit lifetime, EPA had proposed reintroducing the three-year lifetime after a temporary transition period but finalized an infinite credit lifetime based on a rationale it now rejects181— a return to the previous three-year lifetime for credits is thus the natural outcome of such action. [EPA-HQ-OAR-2019-0055-1277-A1, p. 49]

181. E.g., compare EPA-420-R-97-102, pp. 19-22 ("EPA believes that a limit on credit life would in this case to some degree stifle the development and introduction of new technology.") and 87 FR 17552-3 ("Manufacturers could continue to generate credits by adopting increasingly advanced technologies. … We believe a five-year credit life adequately covers a transition period for that option, while continuing to encourage technology development in later years.").

To appropriately limit the environmental harm caused by credit usage, EPA should reinstate the three-year (not five-) credit lifetime, if it is to have a banking and trading program at all. [EPA-HQ-OAR-2019-0055-1277-A1, p. 49]

Organization: *PACCAR, Inc (PACCAR)*

With those averaging set and FEL cap provisions in place to protect against unintended consequences, EMA recommends that EPA allow unlimited NOx credit life, in lieu of the Agency's proposed 5-year credit life. [EPA-HQ-OAR-2019-0055-1346-A1, pp.35-36]

Organization: *States of California, et al. (The States)*

The States strongly support EPA's proposed measures to tailor the ABT program to this role, including (1) limiting credit life to at most five years, (2) replacing existing credit balances with transitional credits, and (3) lowering family emission limit (FEL) caps to below the 2007 heavy-duty standards.90 [EPA-HQ-OAR-2019-0055-1255-A1, pp. 20 - 21]

90. Id. at 17,552-54.

Organization: *Truck and Engine Manufacturers Association (EMA)*

With those averaging set and FEL cap provisions in place to protect against unintended consequences, EMA recommends that EPA allow unlimited NOx credit life, in lieu of the Agency's proposed 5-year credit life. [EPA-HQ-OAR-2019-0055-1203-A1, p. 135]

EPA Summary and Response

A high-level summary of comments along with EPA responses to comments on credit life are available in preamble Section IV.G.

12.4 Transitional NOx credits

Comments by Organizations

Organization: *Alliance for Vehicle Efficiency (AVE)*

As of December 2020, approximately 50% of all commercial diesel trucks in operation, nationwide, were purchased after MY 2010 or later, while 50% of the heavy-duty trucks now on the roads continue to operate without the benefit of NOx and PM emissions control technologies. New heavy-duty trucks will be operational for decades. Incentives for compliant trucks, not just ZEVs, purchased prior to the MY 2027 will bring tremendous health benefits to at-risk communities and the nation. [EPA-HQ-OAR-2019-0055-1280-A1, p. 7]

Organization: *California Air Resources Board (CARB)*

On pages 17553-17554 of the NPRM, U.S. EPA asks for comments regarding the proposed transitional credits before 2027 model year. [EPA-HQ-OAR-2019-0055-1186-A2, p.13]

CARB staff recommends that the transitional credits for 2024 through 2026 MYs be subject to the following conditions:

• First, the five-year credit life should apply to these credits because these credits should be used to help manufacturers transition to the CTP 2027 MY standards that function within the proposed implementation schedule.

• Second, the 2024-2026 MY engines should be certified so that they are subject to all 2027 and subsequent model year requirements. This includes the low-load cycle, off-cycle standards, etc. Basically, there needs to be consistency between the way these credits are generated and the way they are used. [EPA-HQ-OAR-2019-0055-1186-A2, p.13]

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

EPA has proposed allowing various types of NOx credits to be used within its ABT program, with a credit lifespan of five years. 87 Fed. Reg. at 17,552–53. Under that proposal, 'transitional' credits, early adoption incentive credits, and BEV and FCEV credits could be generated as early as MY 2024. 87 Fed. Reg. at 17,552–57. EPA's Proposal does not adequately assess the impact of those pre-MY 2027 credit mechanisms on its emissions standards— especially given the gap between the EPA and Omnibus standards from MY 2024–26, and the extraordinarily large number of credits that could result from that gap. If EPA uses a single national credit bank, that credit surplus would threaten to drastically and unlawfully erode the emissions reductions achieved by the standards. See 42 U.S.C. 7521(a)(3)(A)(i). That potential erosion should be a central factor in EPA's decision whether to allow transitional credits, and (if it does allow them) how to limit those credits' use; EPA is consequently required to thoroughly address it before including transitional credits in its final rule. See Michigan v. EPA, 576 U.S. 743, 750 (2015) (to be lawful, agency decisions must rest on a consideration of all relevant factors). [EPA-HQ-OAR-2019-0055-1302-A1, p.61]

EPA's existing NOx standards that apply to MY 2024 through MY 2026 are much higher than the Omnibus standard—.2 g/hp-hr, rather than .05 g/hp-hr. Engines certified to the Omnibus standard in that time will, consequently, generate a very large quantity of credits against the federal standard (approximating .15 g/hp-hr per engine sold per year). California and other states adopting the Omnibus have a substantial market share; the credits generated prior to MY 2027 are therefore likely to be significant. Depending on the FEL cap incorporated into the final rule, whether the final rule allows BEVs and FCEVs to generate NOx credits, and manufacturers' decisions, the transitional credits generated between MY 2024–2026 could allow a large fraction of HHDEs to emit at the FEL cap even in MY 2030 and beyond. See Comments of MFN, to be filed in Docket EPA-HQ-OAR-2019-0055 on May 16, 2022. [EPA-HQ-OAR-2019-0055-1302-A1, pp.61-62]

That threat requires EPA to carefully assess the impact of the surplus credits generated by the gap between the pre-2027 EPA and Omnibus standards. Michigan, 576 U.S. at 750. And it further demands some adjustment to the Proposal's NOx crediting structure. EPA should adjust its standards to account for the effect of its transitional crediting program on manufacturers' actual compliance responsibility. In the alternative, EPA should eliminate or amend the transitional crediting mechanism (e.g., by establishing a separate credit bank for states adopting the Omnibus, and/or shortening the credit life of NOx credits to no more than three years) so as to ensure the 'greatest degree of emission reduction achievable' in the relevant model years. 42 U.S.C. 7521(a)(3)(A)(i). [EPA-HQ-OAR-2019-0055-1302-A1, p.62]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

EPA states that the intent of the credit program is, in part, 'to provide flexibility for manufacturers to spread out their investment and prioritize technology adoption in the applications that make the most sense for their businesses during the transition to meeting new standards.'107 Daimler Truck agrees with this approach and supports a credit program. New generation engines will require very significant investment across a variety of platforms. Manufacturers must be allowed to spread that cost over several years, determining which applications to prioritize. It is not possible for manufacturers to develop and release new engines across the entire breadth of their portfolios all at once. Manufacturers are limited on an annual basis in terms of investment dollars, but also in terms of resources—there are only so many engineers, test facilities, dynos, etc. available. [EPA-HQ-OAR-2019-0055-1168-A1, p.83]

107 Id. at 17,550.

To generate credits that could be applied in MY 2027 and later, manufacturers would have to certify to all of the test conditions of the proposed program starting in MY 2024. Given the infeasibility of manufacturers satisfying the proposed standards with one year's lead time, it will be virtually impossible to generate the proposed 'transitional' credits. In many cases, DF testing for MY 2024 engines has already started. It is not possible for manufacturers to adjust their engine development plans to meet new additional low load cycle and off-cycle test standards by MY 2024. As proposed, manufacturers would likely only be able to meet these new standards if by chance the engines they have already designed for MY 2024 happen to meet EPA's newly-proposed low load cycle and off-cycle standards. [EPA-HQ-OAR-2019-0055-1168-A1, p.86]

Compliance flexibilities such as credit ABT programs are arguably part of the whole package of program elements that constitute the emission 'standard' that EPA is proposing. In setting a new HD emission standard, the CAA requires EPA to provide at least four years lead time.110 For manufacturers that must rely on credits to meet the very stringent NOx standards that EPA is proposing for certain engine families, the ABT portion of the compliance program is a de facto standard that would have to be met in a period much shorter than the four years' lead time required under the Act. EPA's transitional credit proposal thus runs contrary to the spirit—and potentially the letter—of the CAA, which rightly recognizes that manufacturers require lead time to develop and validate new engine technologies. [EPA-HQ-OAR-2019-0055-1168-A1, p.86]

110 See 42 U.S.C. 7521(a)(3)(C).

More importantly, EPA's proposal serves to disincentivize the real world NOx improvements that could be (and are being) made for MY 2024+, unless manufacturers can design and validate their engines to meet the requirements of these newly proposed rules—which, as noted above, is virtually impossible in the time frame allowed. Under these circumstances, manufacturers have no regulatory incentive to make improvements that would otherwise go forward under their engine development programs. In other words, EPA's proposal would remove incentives for real world emissions improvements that could be made immediately—and thereby, if finalized, EPA's rule would actively discourage those improvements. [EPA-HQ-OAR-2019-0055-1168-A1, p.87]

Organization: *Moving Forward Network (MFN)*

There is no need to incentivize manufacturers to adopt the proposed test procedures earlier than required in MY 2027 because they are already required to adopt essentially identical test procedures beginning in 2024 under the Omnibus program. Moreover, any such transitional program will lead to a windfall of credits for manufacturers meeting the required state Omnibus standards, which are 75 percent lower in the 2024-2026 timeframe than the federal program. These credits will then be used to delay emissions reductions nationwide. [EPA-HQ-OAR-2019-0055-1277-A1, p. 46]

Model heavy-duty engines are all certified at or below the 0.2 g NOx/bhp-hr average FTP/SET requirements (blue bubbles). The sales-weighted average compliance margin for these engines is over 50 percent, with many achieving FTP test values far below the standard (green bubbles). The size of the bubble corresponds to sales volume estimates. Importantly, a high-volume product from a major manufacturer was just certified to a 0.16 FELFTP, which only bolsters concerns about windfall credits for today's engines delaying future progress. [EPA-HQ-OAR-2019-0055-1277-A1, p. 47]

In addition to the windfall credits from vehicles sold in states where the Omnibus standards are in place, manufacturers will likely be able to certify 2024-2026 engines to the new test procedures with little effort, and doing so will result in a substantial amount of credits owing to the current, weak average NOx standards. Every engine today is certified at or below the average required standard, with an average sales-weighted compliance margin of just over 50 percent between the FELFTP and the value from the certification test (Figure 8).179 This large compliance margin likely covers any difference owing to the new test procedures—the scalar provided for the 2027 FELLLC/FELFTP is 90/35 = 2.6, and the best-performing engines from 2017-2019 already achieved a scalar of 3.5, just a 25 percent difference, and well below the level of wiggle room provided by the current compliance margin. [EPA-HQ-OAR-2019-0055-1277-A1, p. 47]

We support EPA's proposal to exclude the current credit balances (87 FR 17553); however, the transitional credit program raises all the same concerns, and all the same risks. With only marginal improvements in performance owing to the new test procedures, it is far more critical that EPA push manufacturers to adopt new technology rather than meet new tests, and the best way to do this is to limit any flexibilities for manufacturers. The transitional credit program undermines efforts to reduce emissions in 2027 and beyond by rewarding the status quo. It should therefore be eliminated from the proposal in the final rule. [EPA-HQ-OAR-2019-0055-1277-A1, pp. 47 - 48]

While we oppose these credits, if EPA moves forward with this program, it must ensure that any credits are predicated on meeting all of the changes in program design changes adopted by EPA beginning in 2027 to improve the robustness of any test-cycle reductions in the real world. Critical to these changes is the elimination of the NTE program and the adoption of the moving-average-window approach to ensure that these newer trucks are seeing required reductions in real-world emissions on the road and the adoption of the low-load cycle, which better reflects the need to capture operations where today's vehicles fail miserably. If EPA moves forward with the credits they must ensure that reductions in medium- and heavyduty vehicle emissions occur within environmental justice communities by requiring the ZEVs are deployed in environmental justice communities. EPA must require that these vehicles are part of a publicly available tracking system to ensure adherence to the Rule. [EPA-HQ-OAR-2019-0055-1277-A1, p. 48]

We are absolutely opposed to credits for any engines that do not adhere to updated testing and compliance procedures that are at least as effective as those already met by the state Omnibus. [EPA-HQ-OAR-2019-0055-1277-A1, p. 48]

There should be absolutely no credits awarded for legacy engines nor legacy technologies. The difference is these engines cannot simply be captured in a conforming factor—it goes directly to the operation of the engine itself and the corresponding emissions controls. The current test procedures have not led to the reductions promised—there is absolutely no reason not to require that all certified engines moving forward are required to be certified under the updated procedure, directly assessing their emissions under the new protocol, without any conditional fudge factor that could be manipulated or gamed and would lead to a continuation of the inadequate compliance procedures to-date. [EPA-HQ-OAR-2019-0055-1277-A1, p. 48]

As is noted below, the impact that the credit program could have on future emissions requirements is substantial. This is particularly true in the years prior to 2027, when the difference between what is feasible and what is required is (at an absolute level) the greatest. While we oppose the generation of any credits in this time period, worse still is the possibility that any such credits could linger as late as 2031. If granting any such credits, EPA should propose a limit of no more than three years, as discussed below. [EPA-HQ-OAR-2019-0055-1277-A1, p. 48]

Organization: *Roush CleanTech (Roush)*

Roush supports the proposed use of transitional NOx emissions credits for 2024-26MY, and believes the proposed calculation method for credits and SET FEL's is reasonable. We cannot assess whether Roush will participate in this optional program or not, as we have not yet evaluated the impact on the SET requirements on our product design and customer acceptance, but we would expect to complete that analysis once the proposed rule is finalized. [EPA-HQ-OAR-2019-0055-1276-A1, p.2]

EPA Summary and Response

Many of the summaries of comments on transitional credits in the proposed rule, and EPA's responses to those comments, are included in Preamble Section IV.G.7. Immediately below, we briefly summarize and respond to additional comments on the proposed transitional credit program.

As part of their comments on the transitional credit program in the proposed rule, one commenter stated that EPA should require ZEV deployment in EJ communities and require the vehicles to be part of a publicly available tracking system. See Section 12.1 of this document for our response to the comment regarding ZEV deployment in EJ communities and a publicly available database for tracking emissions credits.

A commenter also stated that they oppose any allowance to use credits through MY 2031 if those credits are generated prior to MY 2027. Another commenter stated that the same five year credit life should apply to transitional credits as in the proposed ABT program. We have carefully considered appropriate credit life for the four transitional credit pathways and for the reasons we explained for each pathway in preamble Section IV.G.7, we have allowed the use of certain transitional credits through MY 2032 under two transitional credit pathways and through MY 2034 for one transitional credit pathway.

12.5 Early adoption incentives

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

On page 17555 of the NPRM, U.S. EPA asks for comments regarding the proposed early adoption incentives program. [EPA-HQ-OAR-2019-0055-1186-A2, p.14]

CARB staff recommends that the introduction of the early adoption incentives which would incentivize compliance with all future model year requirements be subject to the following conditions. CARB staff believes that most of the engines participating in this program would be designed to comply with California's Omnibus requirements. As such, CARB staff recommends that the term StdFTP in equation IV-2 (page 17555 of the NPRM) be redefined as the applicable current MY standard as specified in the Omnibus regulation. Doing so would match the amount of credits generated with what is calculated in the Omnibus regulation and avoids the generation of excess credits under the federal program. [EPA-HQ-OAR-2019-0055-1186-A2, p.14]

Excess credits could potentially be used to certify higher polluting engines in future model years, thereby eroding the environmental benefits of the CTP proposal. [EPA-HQ-OAR-2019-0055-1186-A2, p.14]

Organization: *Clean Energy (CE)*

We support the proposed structure of the early adoption credit multiplier which not only incentivizes early compliance for diesel engines but will also encourage the wider deployment of near-zero trucks. As proposed, zero-emission vehicles (ZEV) should remain ineligible for the early compliance credit multiplier since they already benefit significantly from state mandates and incentives as well as a plethora of federal incentives. Furthermore, incentives need to be focused on improving the emissions from internal combustion engines. ZEV incentives would be a distraction from the purpose of the rule and send a mixed message to engine manufactures. [EPA-HQ-OAR-2019-0055-1350-A1, p.4]

Organization: *Manufacturers of Emission Controls Association (MECA)*

MECA believes that incentivizing early introduction of technologies is an effective way of driving development of the cleanest technology ahead of regulations to deliver early emission reductions. We believe that staff's proposed use of NOx credit multipliers as phased-in by earliest year of introduction is appropriate and rewards manufacturers that have invested in the cleanest technology first with greater credits. Natural gas engines that are already emitting at the lowest 2027 limits will be able to generate these early compliance credits as investments are made to introduce diesel trucks that emit at these ultra-low NOx levels. [EPA-HQ-OAR-2019-0055-1320-A1, p.28]

Organization: *Moving Forward Network (MFN)*

EPA's generous early action credits must be removed as they unnecessarily dilute the emission standard while incentivizing a harmful, dead-end technology: natural gas vehicles. A strong fleet averaging system inherently incentivizes early action since earlier reductions can ease manufacturer compliance and provide flexibility, rendering early action credits redundant. Further, since natural gas vehicles, under the current inadequate testing and certification regimes, are falsely labeled as “low NOx” vehicles, early action credits functions as a carve out for these vehicles. [EPA-HQ-OAR-2019-0055-1277-A1, p. 44]

Organization: *Natural Gas Vehicles for America (NGVAmerica)*

NGVAmerica and its members submit the following recommendations for policies and programs that the EPA and other federal agencies can advance to encourage the use of cleaner trucks.

1. Support the early adopter NOx credits proposed by EPA to be included as part of the averaging, banking and trading program including the proposed sales multipliers for natural gas engines and vehicles and other technologies that certify to more demanding NOx levels ahead of schedule; [EPA-HQ-OAR-2019-0055-1330-A1, p.12]

Organization: *Southern Environmental Law Center (SELC)*

EPA’s proposed early incentive credit multipliers, however, should be scaled back or eliminated. [EPA-HQ-OAR-2019-0055-1247-A1, p.7]

Organization: *Tesla, Inc. (Tesla)*

Tesla supports early action crediting as it will hasten manufacturers’ pace of clean vehicle deployment. Early action NOx credits generated by BEVs will create an additional incentive for manufacturers to pull forward deployment of heavy-duty BEVs and accelerate the pace of fleet turnover to zero NOx vehicles.134 [EPA-HQ-OAR-2019-0055-1219-A1, p.15]

134 87 Fed. Reg. at 17556, fn. 681-2 (noting past Tesla comments).

While BEVs should play a central role in NOx compliance and credit markets, the various credit multipliers in the proposed crediting systems are unequitable toward electrification and will dampen actual near-term delivery of BEVs. Accordingly, the multipliers provided in the credit trading provisions should be eliminated. [EPA-HQ-OAR-2019-0055-1219-A1, p.15]

Second, regardless of technology eligibility, any multiplier for early adoption incentives should be eliminated.136 As proposed, the early adoption multipliers will provide the perverse incentive of a credit bonus encouraging new use of pollution emitting technologies.137 The multiplier will incentivize manufacturers to speed up deployment of improved but legacy, polluting technologies that will continue to load NOx emissions for years to come. Further, the multiplier will also create more credit accumulation and value for manufacturers that bring about a lesser emission reduction technology than BEVs. The early adoption multiplier should be eliminated. Tesla also agrees with the agency that providing credit multipliers can unnecessarily dampen actual deployment of the best emission control technologies and lead to a loss of emission reductions.138 This is true regardless of the technology to which a multiplier may be attached and is not applicable just to BEVs. [EPA-HQ-OAR-2019-0055-1219-A1, p.16]

136 87 Fed. Reg. at 17557.

137 87 Fed. Reg. at 17555.

138 87 Fed. Reg. at 17426.

For example, as proposed in MY 2024 thru and 2026 hybrid powertrains would generate two times as many credits as a BEV if deployed over the same period. Under this approach, the proposed regulation is asserting that hybrid powertrains are more valuable, in terms of NOx mitigation, than BEVs. Given BEV technology is available and provides greater emission reductions than other technologies, it simply does not make sense to favor hybrid technologies in the NOx rule over zero emission solutions. It is also consistent with the notion of technological neutrality. Accordingly, Tesla recommends eliminating the provisions in the regulation that provide credit multipliers for hybrid powertrains. [EPA-HQ-OAR-2019-0055-1219-A1, p.16]

As a general matter of policy development, in setting an emissions performance standard, such as the NOx rule, the regulation should be agnostic with respect to what technology is used to meet, and ideally outperform, the standard. Excluding or limiting ZEVs in the proposed regulation's crediting provisions would promote one set of solutions to reduce NOx, consisting of efficiency measures and post combustion emission controls, over better solutions, like BEVs that represent a more effective means of addressing the problem. [EPA-HQ-OAR-2019-0055-1219-A1, p.16]

Organization: *U.S. Chamber of Commerce*

EPA has often used various program elements to incentive early emissions reductions due to their ability to drive more estimated health benefits. Much as early investments help drive more retirement savings down the road, achieving earlier emissions reductions allows the time value of those health benefits to accrue over a longer period of time, thus providing more cumulative benefits. EPA has applied various incentives through its averaging, banking, and trading programs under both its mobile source and stationary source regulations. Early reduction credits, emissions reduction multipliers, and other incentives help businesses to take steps to reduce their emissions earlier. EPA does this recognizing that the benefits of earlier reductions, even if the standards are less stringent, will often outweigh potentially larger benefits achieved at a later date. [EPA-HQ-OAR-2019-0055-1245-A1, pp. 8 - 9]

Organization: *Western States Air Resources Council (WESTAR)*

Though, we caution EPA that the proposed early adoption credit program could undermine some of the benefits of the rule depending on the final design. If credits under the program can be generated from zero emission vehicles (ZEVs) that were already planned for production, those credits could allow more polluting conventional diesels to be manufactured. It is important that any credit system be crafted so that it does not incentivize the continued production of dirtier diesels when the technology exists to make them cleaner. Any benefits from this proposed rule to visibility in mandatory Class I federal areas will likely occur during the third and fourth regional haze planning periods, 2028- 2038 and 2038-2048, respectively. It is important to WESTAR that EPA be an active partner in making reasonable progress towards improving visibility in Class I areas. The final rule should reflect the choices and alternatives within the proposal that are technologically available to reduce the most emissions in the shortest period of time. [EPA-HQ-OAR-2019-0055-1230-A1, p.4]

EPA Summary and Response

See preamble Section IV.G for EPA's summary and response to comments on the proposed Early Adoption Incentives program.

12.6 NOx emission credits from electric vehicles

12.6.1 Proposal to Allow Electric Vehicles to Generate NOx Emission Credits

Comments by Organizations

Organization: *Advanced Engine Systems Institute (AESI)*

It is critical that zero emission trucks be excluded from generating NOx credits because they diminish the genuine NOx control reductions from internal combustion engines. [EPA-HQ-OAR-2019-0055-1281-A1, p. 2]

Organization: *Alliance for Vehicle Efficiency (AVE)*

AVE opposes the use of credits for battery electric vehicles (BEVs) or fuel cell electric vehicles (FCEVs) for low-NOx compliance. [EPA-HQ-OAR-2019-0055-1280-A1, p. 6]

As proposed, the credits being offered to manufacturers for BEVs, and FCEVs will undermine the goals of EPA's proposal to reduce NOx and other pollutants from heavy-duty engines. [EPA-HQ-OAR-2019-0055-1280-A1, p. 6]

Cost-effective technologies exist that will ensure enormous emission reductions from heavy-duty engines. To achieve the goal of improving engine emissions, compliance credits should be generated for compliance with a standard, not a technology. As proposed, manufacturers can over deploy BEVs or FCEVs at volumes higher than predicted, and easily backslide on engine improvements or emission control technology changes on ICE vehicles. For this reason, AVE recommends that EPA tighten the family emission limit (FEL) to 0.05 g/bhp-hr, down from the current proposal of 0.15 g/bhp-hr. Without a lower FEL cap, the opportunity for significant NOx reduction from new ICE trucks will be lost and the higher NOx levels will negatively impact at-risk communities for decades. [EPA-HQ-OAR-2019-0055-1280-A1, p. 6]

AVE also supports a sunset date of MY 2030 for all Heavy-Duty-ZEV NOx credits and adopt other protections such as tightening the family emission limit (FEL) to 0.05 g/bhp-hr, down from the current proposal of 0.15 g/bhp-hr. [EPA-HQ-OAR-2019-0055-1280-A1, p. 6]

Organization: *Allison Transmission, Inc. (Allison)*

In this regard, EPA's proposal to allow for generation of NOx credits by ZEVs, BEVs should not be finalized.68 While Allison generally favors incentives for development of new technologies, allowing vehicles with zero tailpipe emissions (albeit not zero CO2 emissions overall depending on the fueling source) does not provide an incentive for new technologies to reduce NOx in as much as it provides an additional incentive for the production of ZEVs. Thus, the credit is misaligned with the environmental gains it is seeking to address and unduly favors one technological approach over another. [EPA-HQ-OAR-2019-0055-1231-A1, pp.32-33]

68 86 Fed. Reg. at 17,557.

Organization: *American Automotive Policy Council (AAPC)*

It is appropriate for zero emissions vehicles to average into a fleet average on NOx standards, given the proposed step change in criteria emissions stringency. Zero emissions trucks are recognized as an important technology to meet air quality goals.2 President Biden encouraged the EPA Administrator to consider zero emissions vehicles when formulating emissions standards for 2027 and beyond. Accelerating the adoption and use of zero emissions technologies is widely accepted as a pathway for reducing GHG emissions by 50-52% from 2005 levels by 2030, which President Biden also ordered.3 Excluding zero emissions vehicles from an ABT program ignores real world NOx emissions reductions and subsequent air quality benefits that the use of these products can deliver. As a result, through unreasonable warranty and useful life requirements, there is a missed opportunity to incentivize and accelerate the adoption of zero emissions technologies. [EPA-HQ-OAR-2019-0055-1293-A1, p. 2]

2 "This requirement to shift to zero-emission trucks, along with the ongoing shift to electric cars, will help California meet its climate goals and federal air quality standards…" https://ww2.arb.ca.gov/news/california-takes-bold-step-reduce-truck-pollution

3 https://www.whitehouse.gov/briefing-room/statements-releases/2021/04/22/fact-sheet-president-biden-sets-2030-greenhouse-gas-pollution-reduction-target-aimed-at-creating-good-paying-union-jobs-and-securing-u-s-leadership-on-clean-energy-technologies/

Some stakeholders have expressed concern that allowing zero emissions vehicles to generate ABT credits for criteria emissions would allow "backsliding", or higher criteria emissions on next generation internal combustion engines, and that backsliding may threaten the ability of the program to achieve air quality policy objectives. These concerns are unfounded. The EPA proposal includes a maximum threshold for NOx emissions for any engine, via the NOx Family Emission Limit (FEL). The EPA proposed FELs that are 25% or more below the current manufacturer average standard, which is enough to prevent backsliding. The proposed fleet standards for 2027MY+ are a fraction of the FELs, meaning that only a very small portion of a manufacturer's portfolio (including credit generating vehicles) could certify near the FEL value and still meet the overall fleet stringency. Maximum threshold caps, in combination with overall stringency requirements, are an effective policy mechanism to address concerns of backsliding and to still include zero emissions vehicles in an ABT program. [EPA-HQ-OAR-2019-0055-1293-A1, pp. 2 - 3]

Organization: *BorgWarner*

BorgWarner urges against the use of NOx credits for EV or fuel cell vehicles, as doing so could unintentionally dilute NOx-reducing technology in HD trucks. These credits could disincentivize manufacturers from investing in and developing the next generation of cleaner ICE trucks. A manufacturer could overachieve on the production of EV trucks and backslide on NOx-reducing technologies for ICE trucks. [EPA-HQ-OAR-2019-0055-1234-A1, p. 3]

We recommend EPA consider adopting a sunset date of 2030 MY for all HD-ZEV NOx credits and adopt other protections such as lower family emission limit (FEL) caps. Sunsetting these credits will help ensure manufacturers will adopt cost-effective and feasible technologies to reduce NOx emissions from combustion engines. [EPA-HQ-OAR-2019-0055-1234-A1, p. 4]

Organization: *California Air Resources Board (CARB)*

- CARB has concerns that the proposed NOx credit generation mechanism for battery electric vehicles and fuel-cell vehicles described in 40 CFR 1036.741 and 1037.616 would seriously erode the environmental benefits of the proposed rule. In developing these provisions, U.S. EPA staff has assumed an unrealistically small penetration of heavy-duty zero-emission technologies (1.5 percent heavy-duty zero-emission trucks in 2027 model year). CARB staff believes that U.S. EPA should incorporate a sunset date of 2026 model year for generation of these credits similar to the proposal in CARB's Omnibus regulation. [EPA-HQ-OAR-2019-0055-1186-A1, p.3]

On page 17558 of the NPRM, U.S. EPA asks for comments regarding the proposed NOx credit generation program for battery electric vehicles (BEV) and fuel-cell electric vehicles (FCEV). [EPA-HQ-OAR-2019-0055-1186-A2, p.14]

While CARB staff believes in incentivizing the early development and production of HD fuel-cell and battery electric vehicles, we oppose the proposed crediting mechanism without a sunset date for the program. CARB staff strongly recommends U.S. EPA include a sunset date of the 2026 MY for generation of NOx emission credits from electric vehicles. [EPA-HQ-OAR-2019-0055-1186-A2, p.14]

As stated in page 17556 of the proposed rule: 'Forecasting models and studies generally agree that Hybrid electric vehicle, BEV, and FCEV production volumes will grow, yet the predicted rate of growth ranges widely across various forecasts and partly depend[s] on the specific market segments and time periods being evaluated, study methodologies, as well as underlying assumptions'. For analysis, U.S. EPA used a 1.5 percent projected penetration rate for BEVs in 2027 model year (page 17458 of the proposed rule). CARB staff believes this projected penetration rate is an underestimate for the following reasons:

- There are more than 140 models1 of zero-emissions medium- and HD trucks and buses commercially available today with additional models expected to enter production this year. [EPA-HQ-OAR-2019-0055-1186-A2, p.15]

1 HVIP eligible vehicles. https://californiahvip.org/vehiclecatalog/

- The Advanced Clean Trucks (ACT) regulation2 will help place nearly 300,000 zero-emission vehicles (ZEV) on California roads by 2035. In addition, the ACT regulation has been adopted by five other states (Washington, Massachusetts, Oregon, New Jersey, New York). [EPA-HQ-OAR-2019-0055-1186-A2, p.15]

2 ACT regulation. https://ww2.arb.ca.gov/our-work/programs/advanced-clean-trucks

- Multi-state action on heavy duty zero-emission policy and supporting activity is widespread. Seventeen states with the District of Columbia and supported by northerly neighbor Quebec are working under a memorandum of understanding3 (MOU) that commits to developing4 the multi-state action plan, currently in draft review,5 to identify barriers and propose solutions to support widespread electrification of medium and HD vehicles. [EPA-HQ-OAR-2019-0055-1186-A2, p.15]

- Ford, GM, and Rivian have new zero-emission pickup models that are commercially available for order. All three combined have already received over 300,000 orders on their respective pickup truck. This demonstrated demand is further underscored by a recent survey showing that 43 percent of current pickup owners expect to buy a ZEV pickup in the next decade.32 Although these pick-ups are class 3 vehicles, they are similar to Class 4 light HD vehicles and these powertrains will quickly transition to heavier class vocational vehicles. Ford has seen over 10,000 orders on their E-Transit vehicle as of January this year.33 Ford is also planning to nearly double production capacity for the second time of the all-electric F-150 Lightning pickup to 150,000 vehicles per year.34 GM has started deliveries of their BrightDrop vans35 and states 25,000 already on order.36 The United States Postal Service (USPS) has just placed an order for 10,019 BEVs Next Generation Delivery Vehicles37 and USPS Inspector General points out that 99 percent of the postal delivery routes are electrifiable today.38 [EPA-HQ-OAR-2019-0055-1186-A2, pp.17-18]

38 https://www.uspsoig.gov/sites/default/files/document-library-files/2022/RISC-WP-22-003.pdf

The aforementioned factors comprise an important aspect of the proposed crediting provision, because they are centrally relevant to the accuracy of U.S. EPA's assumption regarding projected numbers of HD ZEVs, and the likelihood that the projected NOx reductions from the CTP rule will be eroded because of ZEV NOx credits generation. U.S. EPA must therefore account for such factors in evaluating the impacts of NOx credits generated from electric vehicles. State Farm, 463 U.S. at 43. [EPA-HQ-OAR-2019-0055-1186-A2 p.18]

U.S. EPA should not permit NOx credit generation from electric vehicles to continue indefinitely. Such an allowance would allow these NOx credits to be used to certify higher polluting engines in future years, thereby eroding the overall environmental benefits of the CTP proposal. In order to assess the impacts of NOx credits from electric vehicles, CARB staff working on the Omnibus regulation performed an inventory analysis39 which showed significant losses of benefits from ZEV NOx credits if there is no sunset date for these credits. A summary of the results from that analysis is shown in Figure 3-1. As shown, having no sunset date would have reduced the overall benefits of the Omnibus regulation by 11 percent in 2050. [EPA-HQ-OAR-2019-0055-1186-A2 p.18]

39 Final Statement of Reasons for Rulemaking. Pages 196-203. https://ww2.arb.ca.gov/sites/default/files/barcu/board/rulemaking/hdomnibuslownox/fsor.pdf

CARB staff recommends that U.S. EPA perform a similar analysis using a penetration rate from one or more knowledgeable, independent sources40 for HD electric vehicles to quantify the potential losses of benefits in tons per year on nationwide basis. [EPA-HQ-OAR-2019-0055-1186-A2, p.19]

CARB staff asked International Council on Clean Transportation (ICCT) staff to perform a national emissions inventory analysis of CTP's Option 1 proposal based on a projected penetration rate of HD ZEVs, similar to that is estimated by ACT Research.40 As shown in Fig.

3-2, ICCT's analysis projects that about 14 percent of the projected benefits of U.S. EPA's Option 1 proposal would be lost due to manufacturers using HD ZEV NOx credits to certify engines to higher FELs. [EPA-HQ-OAR-2019-0055-1186-A2, p.19]

40 ACT: Third of Class 4-8 Vehicles to be Battery-Electric in 10 Years. https://www.truckinginfo.com/10144947/act-third-of-class-4-8-vehicles-to-be-battery-electric-in-10-years

Given the uncertainty in predicting the nationwide electric vehicle penetration rates and the strong possibility that HD ZEVs will soon make up a significant portion of new HD sales, CARB staff strongly recommends that U.S. EPA sunset the generation mechanism for the electric vehicle NOx credits in 2026 MY. This would almost fully align the opportunity manufacturers would have to generate ZEV NOx credits under Omnibus and CTP. To further align, U.S. EPA could allow ZEV NOx credits to begin with 2022 MY vehicles. This would further incentivize earlier uptake of these vehicles on a national level and would also align with the Biden administration goals of quickly transitioning to zero-emission technologies. [EPA-HQ-OAR-2019-0055-1186-A2, p.20]

CARB staff believes that the implementation of California's ACT, other states adopting ACT, and the fact that ZEVs are expected to become more cost effective than operating conventional combustion vehicles in the 2027 MY timeframe means that NOx credit incentives would lose their effectiveness and would only serve to delay needed NOx emission reductions from combustion vehicles. For some categories, ZEVs are already cheaper to operate today41 and this cost advantage is rapidly broadening to at least 42 percent of truck sales in 2030 according to a National Renewable Energy Laboratory (NREL) cost analysis42 while Lawrence Berkeley National Laboratory projects that even regional and long-haul ZEV trucks will be 50 percent cheaper to operate than diesel in 2030.43 [EPA-HQ-OAR-2019-0055-1186-A2, pp.20-21]

41 'ELECTRIC TRUCKS HAVE ARRIVED: The Use Case for Vans & Step Vans' https://www.nacfe.org/wp-content/uploads/edd-free-downloads-cache/Vans-and-Step-Vans-Report-Executive-Summary-FINAL.pdf

43 'Why Regional and Long-Haul Trucks are Primed for Electrification Now' https://eta-publications.lbl.gov/publications/why-regional-and-long-haul-trucks-are

In conclusion, U.S. EPA should re-analyze its estimates of the ZEVs market, craft the credit portions to deliver intended emissions benefits in a way that would be resilient to ZEV success, and include a sunset date of the 2026 MY for NOx emission credits from electric vehicles. If U.S. EPA adopts a sunset date that is later than the 2026 MY, then U.S. EPA needs to include provisions to limit ZEV NOx credits between 2026 and the adopted sunset date. A HD ZEV NOx credit backstop needs to be created to avoid the unanticipated consequence of HD ZEV credits undermining expected NOx reductions from HD combustion engines by allowing such engines to be certified to U.S. EPA's proposed high NOx FEL caps. CARB staff expects that this unintended detrimental impact will grow with time with the increase in sales of HD ZEVs, which will prevent progress reducing HDE emissions and have an especially detrimental impact on our most vulnerable communities. [EPA-HQ-OAR-2019-0055-1186-A2, p.21]

Organization: *CALSTART*

We also support a policy that gives vehicle manufacturers flexibility in meeting NOx emission targets through accelerated deployments of battery and fuel cell technologies. Crediting could be used to accelerate the deployment of zero-emission trucks before new NOx standards take effect in model year 2027. Credits could have higher value for earlier production, starting in model year 2024 for example, and phase down annually in advance of compliance dates, e.g., model years 2027 and 2031. [EPA-HQ-OAR-2019-0055-1313-A1, p.5]

EPA's credits for zero-emission trucks, however, should drive emission reductions and not erode intended reductions. Sales of zero-emission vehicles required under state policies, i.e., states' adoption of ACT, should not be credited and double-counted under the final rule. Double-counting should also not be allowed for combustion engines required under states' adoption of the Heavy-Duty Omnibus. The lifetimes of credits should be capped to ensure credits do not delay adoption of innovative combustion engine technology. Without the flexibility afforded by deployments of zero-emission vehicles, the policy should be backstopped with a 0.02 g NOx/bhp-hr standard for all engines no later than 2031. Engines allowed through zero-emission vehicle credits should emit no more than 0.05 g NOx/bhp-hr. [EPA-HQ-OAR-2019-0055-1313-A1, p.5]

To prevent the weakening of existing GHG standards and proposed NOx standards, the final rule should account for the number of zero-emission vehicles expected to be deployed from state policies and not allow double-counting of these vehicles. Credits for zero-emission vehicles in the Clean Trucks Plan should be awarded for deployments beyond those required from other polices, namely states' adoption of the ACT and Advanced Clean Fleets (ACF) standards. [EPA-HQ-OAR-2019-0055-1313-A1, p.11]

Credits for zero-emission trucks should not erode net criteria or GHG emission reductions from combustion engines and vehicles. [EPA-HQ-OAR-2019-0055-1313-A1, p.26]

Organization: *Clean Air Board of Central Pennsylvania*

We also ask that EPA eliminate Zero Emission Vehicle (ZEV) crediting towards NOx engine standard compliance. The ZEV crediting program should not be an offset mechanism that results in the production of higher emitting diesel engines. [EPA-HQ-OAR-2019-0055-1305-A1, p.1]

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

EPA must also modify its crediting proposals to ensure that 'transitional' credits and credits for battery electric vehicles (BEVs) and fuel cell electric vehicles (FCEVs) do not undermine the effectiveness of its criteria pollutant program. [EPA-HQ-OAR-2019-0055-1302-A1, p.8]

In a departure from its previous regulations, EPA has proposed to permit manufacturers to generate NOx emissions credits, from MY 2024 onwards, for BEVs and FCEVs. 87 Fed. Reg. at 17,556–57. Absent changes to the Proposal, those credits will substantially undermine the effectiveness of EPA's NOx standard. Commenters urge EPA to include BEV and FCEV technologies in its analysis of the appropriate NOx standard. See Section IV.B, supra. In the alternative, EPA should eliminate the provisions allowing BEVs and FCEVs to generate NOx credits, or at a minimum sunset the generation of those credits in MY 2026. [EPA-HQ-OAR-2019-0055-1302-A1, p.52]

EPA's proposed NOx emissions credits are intended to provide an incentive for adoption of zero-emission technologies and an 'opportunity for manufacturers to develop and refine transferable technologies to BECs and FCEVs (e.g., batteries, electric motors).' 87 Fed. Reg. at 17,556–57. EPA's Proposal would provide a one-for-one credit—that is, it does not include multipliers—because these technologies are relatively 'mature,' and in reliance on analyses indicating that 'BEV technologies will reach parity in the total cost of ownership with CI or SI engine technologies in most market segments by 2025 or earlier.' Id. at 17,561–62. Although the Proposal would allow manufacturers to generate credits from BEVs and FCEVs, EPA's underlying emissions standards do not consider '[hybrid electric vehicles (HEV)], BEV, or FCEV technologies,' based on EPA's conclusion that such technologies can achieve only limited penetration within the relevant model years. Id. at 17,458 (also requesting comment on whether EPA should instead include such technologies in its feasibility analyses for its NOx standards based on 'information showing higher BEV/FCEV market penetration in the MY 2027 or later timeframe'). [EPA-HQ-OAR-2019-0055-1302-A1, p.52]

As currently structured, the credit proposal would permit unnecessary and unlawful pollution. As EPA recognizes, NO X emissions credits create 'the potential for a greater portion of CI engines to emit up to the level of the FEL cap.' Id. at 17,560–61. Three elements of the Proposal sharply increase the likelihood and magnitude of those increased emissions. First, EPA has (as set forth in Section III, above) markedly underestimated HD ZEV market penetration in the relevant model years, even in a baseline scenario. See also 87 Fed. Reg. at 17,561–62 (recognizing that BEV technologies may reach cost parity in most market segments by 2025 or earlier). A more realistic estimate of baseline market penetration undermines EPA's rationale for providing NOx credits; there is no need to provide regulatory incentives for vehicles that will be built and sold based on their cost-competitiveness, to meet existing regulatory requirements, or to satisfy corporate or fleet commitments. And such an estimate suggests that the credits will erode the standards' effectiveness far more than the Proposal acknowledges, permitting a substantial number of vehicles to pollute at the FEL cap with concomitant adverse effects for surrounding communities.232 The result is a standard that, taken as a whole, fails to achieve the statute's requirement of the greatest achievable emissions reductions. 42 U.S.C. 7521(a)(3)(A)(i). [EPA-HQ-OAR-2019-0055-1302-A1, p.52]

232 See CARB, Final Statement of Reasons for Rulemaking Including Summary of Comments and Agency Responses 196–203 (Aug. 27, 2020), https://ww2.arb.ca.gov/sites/default/files/barcu/board/rulemaking/hdomnibuslownox/fsor.pdf (assessing impacts of credits on emissions reductions).

In the alternative, we ask EPA to eliminate the provisions of its rule allowing BEVs and FCEVs to generate NOx credits, see Section IV.E, infra (suggesting elimination of transitional credits), or at a minimum to 'sunset' the generation of BEV and FCEV NOx credits no later than MY 2026. EPA recognizes in its Proposal that once 'BEVs and FCEVs [have transitioned] into mainstream technologies in the heavy-duty market,' it would be appropriate to 'sunset, i.e., end, the generation and use of NOx emissions credits for BEVs and FCEVs.' 87 Fed. Reg. at 17,561. A more accurate projection of BEV and FCEV emergence indicates that the transition is occurring at a pace that warrants excluding those vehicles from the NOx credit program. See Section III, supra. If EPA does permit BEVs and FCEVs to generate NOx credits, the Agency should at least end the generation of credits well before MY 2027. Given the likelihood that BEVs and/or FCEVs will be cost-competitive in most applications by 2027, allowing credits beyond that point would needlessly dilute EPA's emissions standards. And if EPA retains non-ZEV transitional credits in its final rule, manufacturers will—even without BEV and FCEV credits—amass ample credits to retain any necessary flexibility in compliance with the standards. [EPA-HQ-OAR-2019-0055-1302-A1, p.53]

See Section IV.E, infra (describing glut of credits that will result from gap between federal and Omnibus standards during MY 2024–26). Commenters also agree that EPA should not adopt any emission credit multipliers, 87 Fed. Reg at 17,562 (requesting comments on whether emission credit multipliers should be included in the final rule). If EPA does permit the generation of NOx credits from BEVs and FCEVs, Commenters support EPA's proposed useful-life and warranty certification requirements for the generation of NOx credits from those vehicles, 87 Fed. Reg. at 17,553. We would also urge EPA to shorten the lifespan of any NOx credits generated by BEVs and FCEVs for the reasons explained in Section IV.E (discussing the effects of credit oversupply). [EPA-HQ-OAR-2019-0055-1302-A1, p.54]

Finally, EPA should in any event—but especially if it includes provisions for BEV and FCEV credits—make its FEL caps more stringent. See Section IV.D.2.c, infra. The inclusion of credits, as EPA acknowledges, increases the risk that a greater number of HDVs will pollute up to the level of the FEL cap. See also 87 Fed. Reg. at 17,552 ('The zero-tailpipe emissions performances of BEVs and FCEVs inherently provides the opportunity for manufacturers to generate more credits from these vehicles relative to conventional engines that produce between zero and the level [of] the standard.'). Ensuring that the FEL cap is appropriately stringent is, consequently, an especially critical component of any standard that includes credits. [EPA-HQ-OAR-2019-0055-1302-A1, p.54]

Organization: *Clean Energy Ventures et al.*

In the current Proposal, EPA is providing incentives that reward BEVs and FCEVs that are not available to other technologies or strategies that can achieve the same – or even greater – NOx or GHG emissions benefits when upstream and other indirect emissions are considered. Such an approach is likely to send market signals that will stifle innovation by companies that are developing non-BEV and non-FCEV decarbonization technologies, as well as reduce opportunities to increase the use of low-carbon, renewable, American-produced biofuels as part of the Clean Truck Plan's decarbonization strategy. [EPA-HQ-OAR-2019-0055-2339-A2, p.2]

Organization: *Coalition for Clean Air*

In addition, we are concerned that the Zero Emission Vehicle credits as proposed could inhibit reductions of diesel emissions. ZEVs should not be allowed to generate NOx credits, because those credits will be used to allow higher NOx emissions. [EPA-HQ-OAR-2019-0055-1139-A1, p.2]

Organization: *Consumer Reports (CR)*

In the rule, EPA is proposing to continue to use averaging, banking, and trading (ABT) of credits generated against heavy-duty engine criteria pollutant standards; provide incentives for early adoption of technologies to meet the standards; and allow manufacturers to generate NOx emission credits for hybrid electric (HEV), battery-electric (BEV), and fuel-cell-electric (FCEV) vehicles.52 While credits can be useful to encourage early adoption of technology, and to encourage adoption of low- or zero-emission technologies, they can also serve to disincentivize further improvements to internal combustion engine technology by allowing manufacturers to average out high-emitting internal-combustion engines (ICE) with ZEV and other credits.53 CR supports EPA's proposal to generate credits for early adoption of technologies prior to MY 2027. However, NOx credits from HEV, BEVs and FCEVs will ultimately limit the effectiveness of the proposed rule by generating too many credits. Manufacturers will be able to sell non-compliant polluting vehicles for many years and would lack incentive to adopt improved ICE technology. To prevent this outcome, EPA should not offer ZEV credits after 2027. Instead, EPA should set stringent standards that would drive adoption of the EPA HDV rule. However, if EPA ultimately decides to finalize the rule allowing ZEVs to generate NOx credits, EPA should not include any multipliers and should limit the use of NOx credits by sunsetting their use after five years or less, by limiting credit life to five years, and by lowering the family emission limit (FEL) cap. [EPA-HQ-OAR-2019-0055-1285-A1, pp.8-9]

52 87 F.R. 17426.

53 Sara Kelly and Ben Sharpe, Impacts of crediting zero-emission vehicles in the upcoming federal regulation for criteria pollutants from heavy-duty engines and vehicles, International Counsel on Clean Transportation, International Counsel on Clean Transportation, (January 2022). Organization: *Daimler Truck North America LLC (DTNA)*

EPA should allow ZEVs to generate NOx credits, in recognition of their significant emission reduction benefits and the need to help manufacturers manage their investments. [EPA-HQ-OAR-2019-0055-1168-A1, p.80]

131 We request that EPA keep in mind its statutory directive to ensure that criteria pollutant emission standards for heavy-duty vehicles reflect the 'greatest degree of emission reduction achievable' through the application of technology that EPA determines will be available for the model year to which such standards apply, giving

'appropriate consideration to cost, energy, and safety factors associated with the application of such technology.' 42 U.S.C. §7521(a)(3)(A)(i). Compliance flexibilities such as the NOx credit program are essential to the achievability of the very stringent NOx standards that EPA has proposed, thus the considerations in CAA Section 202(a)(3)(A)(i) are relevant to appropriateness of the requirements that EPA has proposed for credit-generating ZEVs. [EPA-HQ-OAR-2019-0055-1168-A1, pp.117-118]

Organization: *Eaton Vehicle Group (Eaton)*

However, NOx emissions are in fact local in nature in terms of harmful effects and they are also a powertrain attribute, not a vehicle attribute. The entire NOx rule (both the existing 2020 regulations and the proposed in the NPRM) treat NOx as an engine attribute and regulate engine performance. Thus, it does not make sense to average an engine performance attribute (NOx tested on FTP, LLC etc.) with a vehicle attribute (zero emissions in the absence of an engine). NOx emissions averaging with such high variance could have negative and unpredictable effects:

1. It can artificially maintain high NOx emissions in industrial areas such as around ports, distribution centers and freight corridors, which raises environmental justice concerns.
2. It can move the NOx emissions from the communities with high electrical vehicle penetration to those that live around fossil fuel or natural gas energy plants, where real NOx emissions will be emitted.
3. It makes it difficult for planners to achieve ozone attainment as the actual NOx emissions in any particular area does not match the commercial vehicle activity in that area. Thus, our recommendation is to not average engine NOx emissions with zero-emissions vehicles. [EPA-HQ-OAR-2019-0055-1252-A1, p.7]

Agency Request / Topic: We are also interested in stakeholder input on our proposed requirements for manufacturers choosing to generate NOx emission credits from BEVs or FCEVs, as well as whether EPA should consider for this final rule, or other future rules, restrictions for NOx emission credits in the longer term (e.g., beyond MY 2031) (See Section IV.I for details). [EPA-HQ-OAR-2019-0055-1252-A1, p.9]

Eaton Comment Strategy / Materials: Due to the local effects of NOx emissions, we believe NOx standards should be achieved on 100% of diesel-powered vehicles to ensure clean air around highways, urban centers, underserved communities regardless of fleet-level BEV/FCEV sales. This ensures environmental justice and allows planners to put in place effective ozone attainment strategies. As explained, BEV in fact move NOx emissions to the power plant; thus averaging can in fact increase NOx emissions in other regions. [EPA-HQ-OAR-2019-0055-1252-A1, p.9]

Organization: *Environmental Defense Fund (EDF)*

As we discuss above, EPA should adopt multipollutant standards that consider the availability of ZEVs in establishing both NOx and greenhouse gas standards. EPA's proposal, however, does not consider ZEV technologies in setting NOx standards but does provide NOx credits for ZEVs in demonstrating compliance. In particular, NOx credits earned in MYs 2024-2026 can be carried over to MY 2027 and beyond if the credit earning vehicles meet the 'other' requirements (useful life, warranty, low load NOx standard, etc.), which would begin in MY 2027. As a result of this approach, instead of delivering additional air pollution benefits, ZEVs will instead significantly dilute the efficacy of the standard and allow for higher-polluting diesel vehicles to be sold. [EPA-HQ-OAR-2019-0055-1265-A1, p.22]

EDF analyzed the impacts of these crediting provisions, including the number of MY 2027 and later heavy-duty vehicles that could be certified to the maximum family emission level (FEL) under EPA's proposal, as well as the total tons of additional NOx emissions allowed by the BEV averaging. (See Attachment H for the full analysis). [EPA-HQ-OAR-2019-0055-1265-A1, p.23]

Our analysis used ERM BEV sales Scenario 2b (reflecting existing and reasonably foreseeable ACT adoption) to project baseline nationwide BEV sales likely to generate NOx credits. To calculate NOx credits earned by these BEVs, we used EPA's NOx credit calculation from the proposal, assuming a NOx standard of 200 mg/bhp-hr in MY 2024-2026 and EPA's Option 1 NOx standards of 35 mg/bhp-hr for MY 2027-2030 and 20 mg/bhp-hr for MYs 2031 and beyond. Applying the equation for NOx credits to the BEV sales, we estimated that the cumulative NOx credits earned by all BEVs through 2035 are 190,000 megagrams (metric tons). [EPA-HQ-OAR-2019-0055-1265-A1, p.23]

In order to put these levels of NOx credits in perspective, we calculated the number of vehicles that can be certified to the FEL cap and the increase in NOx emissions. We assumed manufacturers would use the credits to allow some of their heavy-duty vehicles to avoid as much of the increased stringency of the MY 2027 and MY 2031 NOx standards as possible. We assumed that manufacturers would utilize their credits within the same vehicle type and regulatory class in which they were earned to avoid proposed limitations on the transfer of credits between classes. We also assumed credits earned in MYs 2024-2026 would be banked for use in MYs 2027-2030. [EPA-HQ-OAR-2019-0055-1265-A1, p.23]

We calculated the number of vehicles that could be certified to the FEL cap of 115 mg/bhp-hr NOx and the percentage of national sales of vehicles in each category. By 2030, nearly 90 percent of school buses, 80 percent of transit buses, 35 percent of single unit trucks and a quarter of all tractors could be certified to a level of 115 mg/bhp-hr instead of meeting the proposed NOx standard of 35 mg/bhp-hr. And by 2035, nearly half of all school buses, 45 percent of Class 4-8 single unit trucks and a quarter of all tractors would still be emitting NOx at 115 mg/bhp-hr – nearly six times higher than the emissions standard of 20 mg/bhp-hr for 2031 and beyond. [EPA-HQ-OAR-2019-0055-1265-A1, p.23]

The ability to certify vehicles at the FEL cap instead of the 35 or 20 mg/bhp-hr level increases onroad NOx emissions until all of these vehicles are retired. We estimate the impact of certifying to the FEL caps using lifetime NOx emissions from EPA's MOVES3. The increase in lifetime NOx emissions from FEL cap certified engines (in metric tons) would be 174,000-213,000 metric tons through 2035. This increase is over 33 percent of the 559,000 ton reduction in NOx emissions that EPA projects for the Option 1 standards in 2045. Appendix G describes the results of this analysis and the methodology we used to conduct it in more detail. [EPA-HQ-OAR-2019-0055-1265-A1, p.23]

As these results demonstrate, EPA's proposal to allow ZEVs to generate NOx credits is damaging and would substantially erode the NOx benefits of the proposal. Accordingly, if EPA continues to establish NOx standards in a manner that does not consider ZEV technologies, EDF urges EPA to sunset the BEV and FCEV credits that are proposed at 87 Fed. Reg. 17561. However, if EPA retains these credits in any form, it is critically important that the agency not adopt any credit multipliers and that EPA substantially strengthen the FEL cap to help ensure remaining diesel vehicles are not able to certify to higher emission levels based on the availability of ZEV credits. [EPA-HQ-OAR-2019-0055-1265-A1, p.23]

Accordingly, if EPA continues to establish NOx standards in a manner that does not consider ZEV technologies, EDF urges EPA to sunset the BEV and FCEV credits that are proposed at 87 Fed. Reg. 17561. [EPA-HQ-OAR-2019-0055-1265-A1, p.23]

Organization: *Environmental Protection Network (EPN)*

Allowing EVs to generate NOx credits used by manufacturers of internal combustion (IC) engines is a major change in the HD program. The NOx standard currently applies to the manufacturers of IC engines that are used in HD vehicles. Unlike the program for light-duty vehicles, EVs in the HD sector are not included in the demonstration a manufacturer makes to show compliance with the NOx standard for IC engines. Manufacturers upgrade and improve their IC engines and use the resulting reduction in NOx emissions to demonstrate compliance with the HD engine standards. [EPA-HQ-OAR-2019-0055-1233-A1, p. 1]

EVs clearly reduce emissions of NOx, along with other pollutants such as particulate matter (PM) and GHGs. A critical reason to promote the transition to EVs is their tremendous potential to reduce harmful emissions from HD vehicles. The importance of promoting EVs as a critical multi-pollutant control strategy does not mean EVs should be used in a way that undercuts emission control from IC-powered vehicles. [EPA-HQ-OAR-2019-0055-1233-A1, p. 2]

Unfortunately, EPA's proposed allowance for EV NOx credits does just that. EPN believes it is highly likely that most, if not all, of the EVs used to generate NOx credits would be produced with or without the proposed NOx credits. The NOx credits would not appear to incentivize any real increase in production of EVs, given the current market transition already underway. Since the NOx reductions from these EVs would occur without the allowance for credits, allowing the credits produces no greater NOx reductions than would otherwise occur. However, allowing the credits will lead to greater NOx emissions from IC engines, especially diesel engines, than would occur without the credits. This means EPA's proposed Zero-Emission Vehicle (ZEV) NOx credits could cause a substantial increase in NOx emissions from IC engines compared to what could and should occur with no offsetting reductions. It runs counter to the core goal of achieving major reductions in NOx emissions, and EPA fails to justify the need to allow this increase in emissions. EPN opposes the proposed allowance for NOx credits from EVs. [EPA-HQ-OAR-2019-0055-1233-A1, p. 2]

If EPA decides to adopt some form of NOx credits for EVs, EPN recommends that EPA severely limit their allowance. For example, no credits should be allowed for MYs prior to MY 2027, the first year that more stringent NOx standards would apply. The amount of such early credits could be very large, based on the difference between zero emissions and the current NOx standard, which is approximately 10 times higher than the proposed standards. Allowing EVs to generate very large numbers of credits against the current standard would be a windfall that could seriously undercut the future, more stringent NOx standards. EPN recommends that at most, EPA allow any credits generated prior to MY 2027 to be based on the difference between zero and the level of the NOx standards that would apply in MYs 2027 and later. EPN also suggests that EPA not allow EVs to both show compliance with the revised GHG standards and generate NOx credits. A manufacturer should use EVs to either generate NOx credits or use the EV in its compliance demonstration for the revised GHG standards, but not both. This would mean the volume of EVs generating NOx credits are above and beyond those produced to meet the GHG standards. This would at least move in the direction of reducing the risk that NOx credits are from EVs that would have been produced in any case. [EPA-HQ-OAR-2019-0055-1233-A1, p. 2]

EPN is not suggesting these options because we believe they are a reasonable or appropriate approach, but only as options to reduce the adverse emissions impact if EPA decides to allow NOx credits for EVs. EPN believes that EPA would have to clearly and robustly justify the technological or other need to provide manufacturers with this relaxation in the stringency of the NOx standard. EPN feels that EPA should not lightly decide to allow NOx credits for EVs given the transition already occurring without the credits and the great need for NOx reductions. It would take a clear and strong case to justify any allowance for NOx credits for EVs, and EPA’s proposal fails to provide one. [EPA-HQ-OAR-2019-0055-1233-A1, p. 2]

Organization: *Ford Motor Company (Ford)*

We support the regulatory provisions to generate NOx credits from ZEVs. However, given the uncertainty in the heavy-duty commercial truck segment about the durability of ZEV high-voltage batteries and fuel cells, we recommend that partial NOx credits be available for ZEVs with a declared full useful life below the designated full-useful life of the particular engine service class. This regulatory flexibility is appropriate in light of the emissions reductions achieved and will be vital to ensuring broader deployment of heavy-duty ZEVs. [EPA-HQ-OAR-2019-0055-1300-A1, p. 4]

Organization: *General Motors LLC (GM)*

Battery electric vehicles (BEVs) and fuel cell vehicles (FCVs) will help GM achieve zero emissions. Including ZEVs in an averaging, banking, and trading program appropriately recognizes the role of zero emissions technologies in reducing real world emissions. [EPA-HQ-OAR-2019-0055-1246-A1, p.6]

Organization: *International Council on Clean Transportation (ICCT)*

EPA proposes to allow manufacturers to generate credits towards compliance with NOx engine standards through the sale of zero-emission powertrains. Our view is that allowing ZEVs to count toward the NOx standards will not increase ZEV adoption and will only reduce the NOx emission benefits of the rule for diesel engines. We view these credits as creating an inappropriate trade-off between public health and climate change. We also see a risk that these higher-emitting internal combustion engines could be concentrated in and around disadvantaged communities, undermining the administration's goal of addressing racial inequities. [EPA-HQ-OAR-2019-0055-1211-A1, p. 3]

RECOMMENDATION: We recommend EPA eliminate ZEV crediting towards compliance with NOx engine standards in 2027 and eliminate early generation credits. [EPA-HQ-OAR-2019-0055-1211-A1, p. 3]

ZEV crediting as currently proposed under EPA Option 1 will permit manufacturers to produce higher polluting diesel engines in return for greater ZEV sales. The implicit trade-off between climate and health implied in this regulatory design goes against international best practices for motor vehicle regulation first defined by the ICCT in 2001.21 We think such an incentive structure actually undermines progress towards NOx control, particularly during the proposed interim period between MY2027-2030. We explain below the basis for our recommendation to remove these credits. [EPA-HQ-OAR-2019-0055-1211-A1, p. 18]

> 21. The Energy Foundation (2001). Bellagio memorandum on motor vehicle policy: Principles for vehicles and fuels in response to global environmental and health imperatives. Bellagio, Italy, 19-21 June

The reason for our concern is the following: ZEV crediting has the potential to turn the NOx FEL cap, the maximum allowable emissions level to which a family of engines can be certified, into the de facto standard for diesel engines. Table 5 shows the percentage of diesel engines in the U.S. that could be certified at the FEL cap using only ZEV credits under EPA Option 1 for different ZEV uptake scenarios. Under likely state actions on ZEV deployment (MOU), 8% of diesel HDVs could be certified at the FEL cap using ZEV credits in 2031, and this share could increase to 11% by 2035 without further ZEV policies. Assuming accelerated ZEV uptake, the need to phase out ZEV crediting toward the NOx standards would be much greater: allowing ZEV crediting after 2031 could result in 76% (Alternative 1) to 85% (Alternative 3) of diesel HDVs being certified at the FEL cap in 2035 using ZEV credits alone. [EPA-HQ-OAR-2019-0055-1211-A1, p. 18]

Table 6 gives average zero-mile emission rates (ZMERs) under various scenarios. (See Attachment 1 - Appendix A for a description of scenarios.) ZEV crediting under EPA Option 1 could lead to ICE emission rates up to 4 times as high as no crediting in MY 2027-2030 and up to 2.25 times as high in 2031. Under scenarios of rapid ZEV uptake (Alt 1-3), ZEV crediting after 2031 could allow new diesel engines sold after 2031 to emit more than those sold prior to 2031, despite the tightening of certification limits. Strengthening EPA's Option 1 to match state HDV Omnibus requirements starting in 2027 would ensure that diesel engines entering the fleet emit 89% less NOx than those certified to current EPA 2010 standards. [EPA-HQ-OAR-2019-0055-1211-A1, p. 19]

We recommend EPA remove ZEV crediting towards compliance with NOx engine standards in MY2027. If EPA does not adopt this recommendation, we recommend EPA reduce the FEL cap for MY2027–2030 from 150 mg/bbhp-hr to 65 mg/bhp-hr, which would lead to a maximum average zero-mile emission rate of 23 in model years 2027-2030. [EPA-HQ-OAR-2019-0055-1211-A1, pp. 19 - 20]

Figure 8 illustrates the benefits of increased ZEV deployment on total NOx emissions from model year 2027- 2030 vehicles. Because of ZEV crediting, higher levels of ZEV deployment in these early years leads to fewer emissions benefits across the heavy-duty sector. Removing ZEV crediting from the proposal reverses this trend, ensuring that higher ZEV deployment leads to more benefits. [EPA-HQ-OAR-2019-0055-1211-A1, p. 20]

Organization: *Lion Electric Co. USA Inc. (Lion)*

To encourage OEMs to meet these standards, we strongly support providing opportunities for manufacturers to generate NOx emission credits, along with the use of credit multipliers, at least in the first few years of the proposed changes. This is an excellent way to encourage more OEMs to manufacture ZEVs, bringing the electric vehicle market closer to cost parity with ICE vehicles and accelerate long-term ZEV adoption. Lion believes that these credit allowances will boost ZEV production and adoption, and can always be revisited in future rulemaking once the market has advanced. [EPA-HQ-OAR-2019-0055-1151-A2, p. 2]

Organization: *Maine Department of Environmental Protection (Department)*

Using the CARB Heavy-Duty Omnibus Regulation as a bellwether, the Department requests the following revisions to the federal proposal: [EPA-HQ-OAR-2019-0055-1288-A1, p.6]

- Unfortunately, EPA is proposing to continue to allow averaging banking and trading of NOx credits generated against applicable heavy-duty diesel engine NOx standards. As part of this proposal, manufacturers could certify battery electric and fuel cell vehicles to generate NOx emissions credits and offset higher NOx emission rates, which could unintentionally erode the stringency of the heavy-duty NOx standards if heavy-duty ZEV sales exceed those assumed in the NPRM.18 [EPA-HQ-OAR-2019-0055-1288-A1, pp.7-8]

18 The EPA used data from 2016 (and earlier) in its heavy-duty ZEV forecasts, which significantly underestimate the market penetration of ZEV technology. Significant technical and policy developments have occurred since those studies were published, including reductions in battery cell and pack costs, improvements in range, and reductions in battery weight. In addition, the policy landscape has changed with the finalization of the CARB Advanced Clean Trucks (ACT) and Advanced Clean Fleets regulations and the adoption of ACT in five Clean Air Act Section 177 states.

Organization: *Manufacturers of Emission Controls Association (MECA)*

MECA is concerned with the credit mechanisms proposed for zero-emission trucks for both NOx and GHGs. First, we recommend a reduction in the FEL cap down to 0.05 g/bhp-hr at 435,000 miles that scales with FUL, which harmonizes with CARB’s Omnibus. A higher FEL cap, such as the proposed 0.15 g/bhp-hr, would result in a loss in NOx emissions benefits that could disproportionately impact disadvantaged communities. Second, we support the exclusion of ZEVs from earning NOx credits. CARB originally proposed to allow ZEVs to earn NOx credits until MY 2030. However, after analyzing the impacts and considering the high anticipated uptake of electric vehicles over the next decade, CARB revised its proposal and will end ZEV NOx credits in MY 2026. MECA calculated that CARB's original proposal would lead to 12,000 higher emitting diesel trucks with service lifetimes of 10-15 years that could be sold in California alone, generating an additional 523 tons of NOx over their useful lives. [EPA-HQ-OAR-2019-0055-1320-A1, p.28]

We believe that the NOx inventory impact from direct NOx credit averaging and banking is a conservative estimate because ZEV NOx credits fail to take into account the upstream NOx emissions from the electrical grid that will be used to charge electric trucks. Lifecycle emissions analysis is becoming the established methodology for understanding the upstream and downstream impacts of the transportation sector and can be used to predict the overall environmental impact of policy decisions. [EPA-HQ-OAR-2019-0055-1320-A1, p.28]

To illustrate the relative NOx inventory contribution of battery electric trucks compared to their near-zero combustion counterparts, we relied on U.S. EPA's eGrid average annual NOx emission values for in-state electricity production. We took into account renewable energy targets (e.g., California has renewable energy targets of 44% in 2024 to 60% in 2030) and manufacturer claimed electric efficiencies from marketing materials. In our conservative approach, transmission and charging losses were not included, nor were smart charging strategies. Furthermore, fuel economy values of 7 mpg were approximated for Class 8 trucks using U.S. DOE and industry publications for diesel vehicles, even though these are lower than required by HD Phase 2 GHG regulations. Upstream fuel related NOx emissions from refining of 20% were also added. [EPA-HQ-OAR-2019-0055-1320-A1, pp.28-29]

On a gram-per-mile basis, a MY 2027 and later class 8 low NOx diesel truck will emit approximately 0.1 g/mile at full useful life. The grid emissions from the same weight class battery electric truck will lead to upstream emissions of 0.25 g/mile in 2024 and 0.18 g/mile in 2030 as the grid continues to incorporate higher percentages of renewable sources of energy. This analysis is not meant to suggest that one truck technology is cleaner than another since only NOx emissions were considered. It simply illustrates that crediting battery electric trucks as zero NOx in the ABT program is not warranted. Since EPA's Clean Trucks Rule starts in MY 2027, we encourage the agency to follow CARB and remove the ability for ZEV to generate NOx credits. [EPA-HQ-OAR-2019-0055-1320-A1, p.29]

EPA staff should reconsider the generous credit provisions with respect to NOx credits and ZEV credit multipliers in light of the numerous OEM announcements of market introductions of EV trucks. Furthermore, stringent CO2 standards being adopted in other global markets, such as Europe, will drive electric truck technology in the US into the market. All of these factors should be considered when revising the Phase 2 vehicle GHG limits and credit considerations. An underestimation of the EV penetration in light of generous credits could significantly increase emissions of NOx and CO2 from combustion powered trucks. Our industry is prepared to do its part and deliver cost-effective and durable advanced emission control and efficiency technologies to the heavy-duty sector to assist in simultaneously achieving lower GHG and NOx emissions, while also meeting other criterial pollutant standards. [EPA-HQ-OAR-2019-0055-1320-A1, p.34]

Organization: *Motor & Equipment Manufacturers Association (MEMA)*

MEMA encourages EPA to not issue NOx credits for battery electric vehicles or fuel cell electric vehicles to avoid unintended backsliding and lowering of technology deployment on internal combustion engine heavy-duty vehicles. [EPA-HQ-OAR-2019-0055-1322-A1, p. 4]

Organization: *Moving Forward Network (MFN)*

Given the myriad risks posed by EPA's proposed averaging scheme, if EPA refuses to adopt more stringent standards that reflect the feasibility of achieving significant emissions reductions through the application of ZE truck technologies, EPA must remove ZEV credits from the NOx compliance calculations. The current proposal fails to properly account for the on-going transition to ZEVs and the feasibility of ZEVs as NOx reduction technology, while allowing ZEV to undermine an already weak combustion engine standard. Consequently, the combustion engine standard will weaken over time as more ZEV are sold due to state policies and market economics. EPA cannot defend the inclusion of these credits with either Option 1 or Option 2 as meeting the requirements of the Act. Unless EPA intends to accelerate ZEV adoption, ZEV credits must be excluded from the NOx compliance calculation. [EPA-HQ-OAR-2019-0055-1277-A1, p. 21]

As noted in Section II, zero-emission trucks are projected to reach a much greater degree of market penetration than EPA's projections. However, the best way of driving the adoption of these vehicles is to require their sale. [EPA-HQ-OAR-2019-0055-1277-A1, p. 46]

By crediting the sale of these zero-emission solutions without considering them when setting the average requirements, EPA has created a perverse situation where the sale of a zero-emission truck results in the sale of a dirtier diesel vehicle. This is untenable for the communities suffering from freight pollution, particularly when the dirtiest vehicles on the road are likely to end up in those overburdened communities.178 [EPA-HQ-OAR-2019-0055-1277-A1, p. 46]

> 178. See Chernova 2018 (https://digitalcommons.law.ggu.edu/cgi/viewcontent.cgi?article=1150&context=gguelj) and references contained therein.

EPA's best option is to consider and drive the sale of these vehicles separately, as outlined in Section II.A. If EPA insists on retaining zero-emission trucks in a vehicle NOx standard, EPA must lower the NOx standard to reflect the greatest degree of emission reductions achievable across the entire truck fleet based on the feasibility of widespread transition to zero-emission trucks, as outlined in Section II.B. [EPA-HQ-OAR-2019-0055-1277-A1, p. 46]

ZEV credits from Omnibus states were considered in the 2024-2026 timeframe under the Omnibus average stringency, since manufacturers can earn ZEV credits toward their requirements in that timeframe. However, nationwide sales in the 2024-2026 period still yield

ZEV credits. As zero-emission trucks approach even just an 11 percent marketshare in 2030, credits from these vehicles surpass 13,000 metric tons—by 2035, at a projected share of just 17 percent this is doubled to 26,000 owing to increased FUL as well as marketshare. [EPA-HQ-OAR-2019-0055-1277-A1, p. 55]

Organization: *National Association of Clean Water Agencies (NACWA)*

NACWA supports EPA's efforts to incentivize zero emissions vehicle (ZEV) and near-zero emission vehicle (NZEV) development while reducing nitrogen oxides (NOx), particulate matter, and greenhouse gas emissions. This is important for publicly owned treatment works (POTWs) that are major stationary sources and located in nonattainment air basins, since these utilities may face significant penalties. POTWs have no option to reduce or stop their operations – they must operate continuously to provide reliable wastewater treatment and protect public health and the environment. [EPA-HQ-OAR-2019-0055-1343-A1, p.1]

Organization: *Northeast States for Coordinated Air Use Management (NESCAUM)*

In particular, if heavy-duty ZEV sales exceed the sales projections that EPA assumed in the NPRM, substantial heavy-duty engine NOx credits would be available in the ABT program. The projections for heavy-duty ZEV sales in the NPRM relied on data from 2016 or earlier and significant technical and policy developments have occurred since those studies were published. Examples are reductions in battery cell and pack costs, improvements in range, and reductions in battery weight. In addition, the policy landscape has changed with the finalization of the CARB Advanced Clean Trucks (ACT) and Advanced Clean Fleets regulations and the adoption of ACT in five Clean Air Act Section 177 states. [EPA-HQ-OAR-2019-0055-1249-A1, pp. 14 - 15]

44. 87 Fed. Reg. 17414 (March 28, 2022), at 17550.

Organization: *Oshkosh Corporation*

Oshkosh supports EPA's proposal to allow all heavy-duty EVs (including BEVs and FCEVs) to generate NOx credits. See Proposed Rule, 87 Fed. Reg. at 17,556. EPA requests comment on its proposed approach to limit the use of NOx emission credits generated from BEVs or FCEVs to the averaging sets in which they are generated. Id. at 17,558. In response to this request, Oshkosh submits that EPA should encourage maximum penetration of heavy-duty EVs by adopting an approach that would allow BEV-generated credits to be used in any heavy-duty engine or vehicle family. Not only would this approach provide crucial incentives for heavy-duty EV production at an important stage of market and technological development, but the approach is warranted given the high bar that EPA proposes to set through new testing, useful life, warranty, and durability requirements for credit generating BEVs and FCEVs. [EPA-HQ-OAR-2019-0055-1226-A1, p. 5]

To provide further incentives for EV development, Oshkosh also requests that EPA ensure harmonization of NOx and CO2 credit programs for heavy-duty vehicles. In general, we request that EPA modify existing credit ABT programs to (1) allow credit transport across all heavy-duty engine/vehicle families; (2) allow a credit life of 10 years for credits generated by EV, FCEV and hybrid technologies; and (3) guard existing credit banks to enable carry over of legacy credits to future programs. [EPA-HQ-OAR-2019-0055-1226-A1, p. 6]

Organization: *Ozone Transport Commission (OTC) and Mid-Atlantic/Northeast Visibility Union (MANE-VU)*

In addition, if heavy-duty ZEV sales exceed EPA's projections, substantial heavy-duty engine NOx credits would be available in the ABT program. The projections for heavy-duty ZEV sales in the NPRM rely on data from 2016 or earlier. Significant technical and policy developments have occurred since those studies were published. Because of this, we believe heavy-duty ZEV sales will be significantly greater than the 1.5 percent of heavy-duty vehicle sales in 2027 and subsequent model years that EPA assumed. [EPA-HQ-OAR-2019-0055-1250-A1, p.16]

40 87 Fed. Reg. 17414 (March 28, 2022), at 17550.

Organization: *PACCAR, Inc (PACCAR)*

PACCAR supports EPA's initiative to offer NOx credits to incentivize ZEV adoption. See proposed 1037.616 (NOx credits for electric vehicles and fuel cell vehicles). Promulgating a NOx ABT program provides manufacturers with the needed flexibility to plan investments and manage product costs, while also providing time to overcome technical or lead-time challenges. Although we support starting the NOx credit bank for ZEVs and early credit in MY 2024, we do not support using NOx credits from earlier technology engines (i.e., pre-MY 2024) because EPA should further incentivize producing new low NOx and ZEV technologies. PACCAR also supports establishing a NOx FEL cap to avoid backsliding if ZEVs proliferate, and a reasonable NOx cap would support manufacturers' technological investments and provide manufacturers additional product planning flexibility to meet the NOx standard, while allowing them to focus research and development engineering resources toward future products. [EPA-HQ-OAR-2019-0055-1346-A1, p.35]

PACCAR summarizes below the major issues that EPA should take into account as it moves forward with this rulemaking: PACCAR supports EPA's initiative to allow NOx credit generation from ZEVs. [EPA-HQ-OAR-2019-0055-1346-A1, p.60]

Organization: *Rivian Automotive, LLC (Rivian)*

Because of the important and growing role of ZEV technology in reducing NOx emissions, Rivian generally supports EPA's proposal to allow ZEVs to earn credits toward NOx standard compliance. Even if the agency finds that the standards are feasible using conventional engine technologies alone, recognizing the development and sale of zero-emission trucks and buses on a one-for-one basis with their emissions abatement is valuable for accelerating the growth of the MHD ZEV industry to the point of economical and profitable scale. To the extent that concerns arise about the potential for backsliding on individual conventional engine performance due to the salutary effects of including ZEVs in the averaging set, Rivian encourages EPA to explore a more stringent emissions standard that expressly accounts for ZEV technology in its development. Rivian supports ZEVs earning NOx credits that recognize the zero tailpipe emissions. [EPA-HQ-OAR-2019-0055-1229-A1, p.4]

Organization: *Southern Environmental Law Center (SELC)*

Moreover, to advance these goals, the credit systems used in the nitrogen oxides (NOx) and GHG emissions standards must be properly tailored to ensure the regulations result in cleaner internal combustion engines and meaningful deployment of ZEV technology beyond the forecasted baseline. [EPA-HQ-OAR-2019-0055-1247-A1, pp.1-2]

EPA notes that proposed Option 1 is feasible without the use of credits.41 Yet the agency proposes to maintain the averaging, banking, and trading of credits and early adoption incentives to offer compliance flexibility for manufacturers. If these flexibilities are retained, it is critical that they do not unnecessarily dilute the effectiveness of the standards. Getting ZEVs on the road should be a priority, but efforts to incentivize their deployment cannot erode improvements intended for the internal combustion engines that will be sold during the period of the proposed rule. [EPA-HQ-OAR-2019-0055-1247-A1, p.7]

41 Id. at 17550.

For this reason, EPA should reconsider whether NOx emissions credits should be provided for ZEVs at all.42 If ZEVs are permitted to offset NOx emissions from other vehicles in manufacturers' fleets, manufacturers will be able to continue to sell highly polluting internal combustion vehicles that contribute to the significant public health and environmental impacts in communities. This is especially true given the fact that ZEV technology is not currently included in baseline compliance modeling due to EPA's artificially low ZEV market penetration projection discussed above. If EPA maintains the use of NOx credits, we support the agency's efforts to minimize backsliding of emissions reductions from internal combustion engine vehicles through credit restrictions and caps. EPA's proposed early incentive credit multipliers, however, should be scaled back or eliminated. [EPA-HQ-OAR-2019-0055-1247-A1, p.7]

42 Additionally, the elimination of ZEV credits would better align the standards with the Omnibus Regulation, which phases out ZEV credits after model year 2026. Id. at 17557.

EPA should also adjust the NOx and CO2 emissions credit systems to ensure that these compliance flexibilities do not unnecessarily dilute the stringency of the standards. [This comment can also be found in section 28.2 of this comment summary.] [EPA-HQ-OAR-2019-0055-1247-A1, p.8]

Organization: *South Coast Air Quality Management District*

Further, South Coast AQMD supports rapid deployment of HD ZEVs, but opposes NOx crediting for ZEV beyond MY 2026. A recent report issued by the International Council on Clean Transportation, which echoes information found in the Omnibus Final Statement of Reasons, analyzed the emissions impact from ZEV NOx credits and concluded that overly generous NOx crediting for ZEVs is less likely to incentivize additional ZEV deployment but rather would lead to a small NOx dis-benefit from engines with higher NOx emissions.44 [EPA-HQ-OAR-2019-0055-1201-A1, p.11]

44 International Council on Clean Transportation (ICCT), Impacts of Crediting Zero-Emission Vehicles in the Upcoming Federal Regulation for Criteria Pollutants from Heavy-Duty Engines and Vehicles (January 2022), available at https://theicct.org/wp-content/uploads/2022/02/us-ze-hdvs-pollutant-credits-feb22.pdf, pgs. 7-8; FSOR at 197.

We also support not permitting HD ZEV credits to be transferred to other vehicle weight classes. This might permit manufacturers to opt to produce lighter weight class ZEVs (Class 4-6) and use the credits to sell higher emitting HD diesel engine families which could result in further delay of the development and deployment of low NOx technologies. [EPA-HQ-OAR-2019-0055-1201-A1, p.11]

Organization: *States of California, et al. (The States)*

The States are enthusiastic about the significant potential of HD ZEVs to reduce NOx emissions and fully support rewarding early market entry of HD ZEVs. But conventional heavy-duty diesel engines and HD ZEVs will coexist on roads for a significant transition period.92 Thus, stringent federal emission limits must continue to control conventional engines' emissions effectively even as the market share of HD ZEVs grows. While the States support the generation of NOx credits from HD ZEVs, EPA should carefully calibrate this feature so that NOx standards for conventional diesel engines remain binding. In particular, the States urge EPA to:

- Limit the credit life to at most five years
- Sunset the generation of NOx credits from HD ZEVs in model year 2026
- Set FEL caps to match those in California's Omnibus Rule93 [EPA-HQ-OAR-2019-0055-1255-A1, p. 21]

92. The most recent projections by the National Renewable Energy Lab (NREL) for HD ZEV adoption, modeling only economic factors, show 42 percent adoption by 2030, but greater than 99 percent adoption only after 2035 (for light- to medium-duty trucks), 2046 (for medium-duty trucks), and 2042 (for heavy-duty trucks). C. Ledna et al., NREL, Decarbonizing Medium- & Heavy-Duty On-Road Vehicles: Zero-Emission Vehicles Cost Analysis, at 2, 20-22, 25 (Mar. 2022), https://doi.org/10.2172/1854583, attached as Exhibit 9 ("NREL Cost Analysis").

93. See 87 Fed. Reg. at 17,552 (discussing FEL caps in Omnibus Rule); 17,561 (discussing five-year credit life and sunset of credit generation).

First, because credits are best used to facilitate the transition to current, more effective NOx control technologies, a limited credit life commensurate with this transition period is appropriate. A five-year credit life, or even a shorter life such as three years, ensures credits are available to ease the transition to model year 2027 and later standards and reward early adoption of the most current NOx aftertreatment systems and HD ZEVs, without reducing or delaying widespread implementation of the standards in later years. Second, as EPA discusses, battery-electric trucks are expected to reach cost parity with conventional engines between 2025 and 2030.94 Sunsetting HD ZEV credit generation in model year 2026 would therefore incentivize early adoption and simultaneously prevent excess credit generation once market factors start to make them unnecessary. Third, lowering FEL caps prevents a surplus of credits from undermining the stringency of the proposed standards. [EPA-HQ-OAR-2019-0055-1255-A1, pp. 21 - 22]

94. Id. at 17,562.

The above limits on the ABT program ensure that early adoption of HD ZEVs remains attractive for manufacturers and operators, without compromising the environmental benefits expected under the proposed standards. Notably, States and the federal government alike already undertake numerous other incentives for HD ZEVs that are both more meaningful and less environmentally costly, including initiatives to deploy charging infrastructure for HD ZEVs, alternative fuel corridors, purchase rebate programs, and government fleet electrification.95 These initiatives enhance the market conditions that are projected to make HD ZEVs more attractive purchases than conventional trucks within the next decade.96 [EPA-HQ-OAR-2019-0055-1255-A1, p. 22]

Hall & N. Lutsey, International Council on Clean Transportation, Estimating the Infrastructure Needs and Costs for the Launch of Zero-Emission Trucks, at pp. 20-23, 25 (Aug. 2019) (predicting cost advantage for most HD ZEVs by 2030), EPA-HQ-OAR-2019-0055-0148.

Organization: *Tesla, Inc. (Tesla)*

In 2021, Tesla generated almost $1.5 billion in revenue selling zero-emission regulatory credits to other manufacturers.133 Proceeds from such sales go towards building new factories to produce BEVs – including in the heavy-duty sector - that will continue to displace ICE vehicles and their tailpipe emissions. For the U.S. to meet its decarbonization goals and to mitigate the public health and welfare impacts from climate change and criteria air pollutant emissions, EPA's proposal should allow heavy duty BEVs to generate NOx credits and be amended to meet increasingly more stringent regulatory requirements that support medium and heavy-duty manufacturers rapidly scaling up delivery of high-quality BEVs. [EPA-HQ-OAR-2019-0055-1219-A1, p.15]

133 Tesla, SEC Form 10-K (Jan. 26, 2022) at 37.

In Tesla's view, agency proposals that would prevent or reduce the role of BEVs in compliance are misguided, as heavy-duty BEVs represent the best NOx mitigation strategy, and should be recognized as such through the crediting provisions. NOx credits generated by BEVs under the NOx rule can also help further deploy BEVs by creating additional value that can be passed onto prospective buyers in the form of lower prices. While it is common practice today for internal combustion engine vehicle manufacturers to purchase regulatory credits from other companies (such as Tesla) to offset their total CO2 and other emissions, Tesla recognizes that in the long-term it is not a sustainable strategy. Accordingly, providing NOx crediting should be time limited to provide some near-term compliance flexibility while supporting much more stringent regulations and a full transition to BEV technology. [EPA-HQ-OAR-2019-0055-1219-A1, p.15]

Finally, Tesla supports sunsetting the use of NOx credits generated by ZEVs beyond MY 2031.139 This sunset provision would ensure that many of the credits generated in the program will have only a limited timeframe within which they can be generated, traded, and used to offset emissions deficits. As BEV penetration will grow rapidly Tesla supports a sunset date that will prevent overall emissions backsliding and ensure complete electrification of the medium- and heavy-duty sectors. [EPA-HQ-OAR-2019-0055-1219-A1, p.16]

139 87 Fed. Reg. at 17561

Organization: *Toyota Motor North America, Inc. (Toyota)*

Toyota appreciates EPA's concerns of credits impeding deployment of cleaner technologies on certain classes of vehicles. However, we think limiting the use of NOx emission credits generated from BEV or FCEV to the class, or "primary intended service," to which they were generated is unnecessarily inflexible. We believe credits should be transferrable across vehicle classes, with appropriate adjustments to account for differences in annual mileage and other factors to ensure emission tons-equivalence. This would allow flexibility to heavy HD vehicles as cleaner, longer-range technologies in the HD space are introduced to the fleet. Additionally, it would encourage HD vehicle OEMs to use BEV and FCEV powertrains when feasible across the classes that can be electrified more rapidly, leading to lower emissions overall. [EPA-HQ-OAR-2019-0055-1224-A1, p.2]

Organization: *Truck and Engine Manufacturers Association (EMA)*

As discussed above, ZEVs are beginning to emerge in the medium- and heavy-duty trucking industry, yet many significant challenges remain for manufacturers, fleets, utilities, governments, and other stakeholders before we can point to the beginning of a broad-based transition of the industry to ZEVs. While aspirations are quite high right now, a great deal of work remains before trucking fleets will be willing to make the significant and long-term investments needed to begin transitioning to ZEVs in a meaningful way. At this time, most medium- and heavyduty ZEVs in service are prototypes or demonstration units that are a long way from providing trucking businesses with the competitive total cost of ownership that they need to justify beginning the process of converting to ZEVs. [EPA-HQ-OAR-2019-0055-1203-A1, p. 109]

The NPRM proposes to reduce the barriers to ZEV adoption by allowing BEVs and FCEVs to generate NOx credits beginning in model year 2024. EMA endorses that strategy as a way not only to incentivize ZEVs, but also to provide manufacturers additional product planning flexibility to meet the NOx standard. [EPA-HQ-OAR-2019-0055-1203-A1, p. 109]

Organization: *Valero Energy Corporation*

The current HD engine and vehicle regulations do not allow electric HD vehicles to generate NOx or particulate matter ('PM') emission credits.7 Ignoring upstream emissions associated with electricity generation based on the rationale that these emissions are subject to regulation at the source of generation, EPA now proposes to allow BEVs and FCEVs to generate tailpipe NOx emission credits. [EPA-HQ-OAR-2019-0055-1328-A2, p.6]

7 40 CFR 86.016-1(d)(4)

EPA does not describe how allowing EVs to generate NOx emission credits for the first time is consistent with its statutory authority. [EPA-HQ-OAR-2019-0055-1328-A2, p.6]

Organization: *Westport Fuels Systems (WFS)*

As policymakers create frameworks to both encourage and support the deployment of new technologies, RNG and Hydrogen ICEs should be given equal footing to Fuel Cell Electric Trucks and battery electric trucks. [This comment can also be found in section 3.10 of this comment summary.] [EPA-HQ-OAR-2019-0055-1278-A1, p.1]

Organization: *Wisconsin Department of Natural Resources (WDNR)*

Incentivizing accelerated adoption of heavy-duty ZEV’s will have a positive impact on air quality; however, it is also important to ensure that combustion engines, which will remain a significant portion of the heavy-duty vehicle fleet for many years, are also required to reduce emissions. EPA’s NOx credit trading program in the proposal allows NOx credits generated by ZEVs to be traded with those generated by combustion engines with no backstop. If the market share of ZEVs accelerates more quickly than EPA estimates in this proposal, it is possible that high emitting internal combustion engines will continue to be produced without stringent emission controls. EPA should adopt a reasonable sunset date for NOx credits to ensure internal combustion engines are required to include technically feasible emission controls. [EPA-HQ-OAR-2019-0055-1162-A1, pp. 3 - 4]

Organization: *Zero Emission Transportation Association (ZETA)*

ZETA supports EPA’s proposal to allow manufacturers to earn credits for achieving lower NOx emissions than EPA sets as the standard via HDEV deployment. Because HDEVs do not have tailpipe emissions and therefore do not emit NOx or any other tailpipe pollution, it stands to reason that HDEVs should be counted as vehicles that emit 0 grams of NOx per mile. HDEVs are the best available technological mechanism for mitigating NOx emissions, and

manufacturers should receive credits for increasing their production share of HDEVs. [EPA-HQ-OAR-2019-0055-1283-A1, p.8]

We appreciate the arguments that giving credits for HDEV deployments could obscure the true NOx emissions of HDVs with tailpipes and, therefore, 'dilute' the standard. **We contend that EPA should mitigate this problem by both increasing the baseline MY2027 NOx standard and increasing its ratcheting process through MY2030.** [EPA-HQ-OAR-2019-0055-1283-A1, p.8]

<u>**EPA Summary and Response**</u>

As described in preamble Section IV.G, we are not finalizing the proposed allowance for manufacturers to generate NO_X emissions credits from heavy-duty zero emissions vehicles (ZEVs). Numerous commenters provided feedback on EPA's proposal to allow manufacturers to generate NO_X emissions credits from ZEVs. The majority of commenters oppose allowing manufacturers to generate NO_X emissions credits from ZEVs. Several additional commenters oppose ZEV NO_X emissions credits unless there were restrictions on the credits (e.g., shorter credit life, sunsetting credit generation in 2026). Other commenters support allowing manufacturers to generate NO_X emissions credits from electric vehicles. Arguments from each of these commenter groups are summarized immediately below. Further below in this Section 12.6, we discuss EPA's response to those comments, which includes our rationale for our approach to ZEVs NO_X credits in the final rule.

<u>Summary of Comments Opposing **NO_X emissions credits for ZEVs:**</u>

Commenters opposing NO_X emissions credits for ZEVs present several lines of argument, including the potential environmental impacts of NO_X emissions credits for ZEVs, impacts on improvements in conventional engine technologies, impacts on ZEVs and other technologies, and legal authority. Each of these topic areas is discussed further immediately below in this Section 12.6.1. Stakeholders opposing NO_X emissions credits from ZEVs were generally environmental or state organizations, or suppliers of heavy-duty engine and vehicle components.

Environmental Impacts and Legal Authority

Commenters state that NO_X emissions credits for ZEVs would diminish the environmental benefits expected from the rule. Some of these commenters argued that the credits would result in standards that fail to "achieve the statute's requirement for the greatest emissions reductions achievable." One commenter further stated that EPA did not describe how allowing manufacturers to generate NO_X emissions credits from ZEVs is consistent with its statutory authority.

Commenters stated that EPA underestimated ZEV adoption rates, and that higher ZEV adoption rates would result in larger impacts on the expected emissions reductions than EPA estimated in the proposal. One commenter provided an extensive list of references to information suggesting higher ZEV adoption rates would be likely (e.g., number of models available today, number of state regulatory and non-regulatory actions). Several of these commenters provided analyses showing the potential emissions impacts of higher ZEV adoption rates than assumed in EPA's proposal analysis; commenters used different metrics (e.g., tons of NO_X reduced in 2045, emission rates of internal combustion engines, increase in tons of NO_X emitted) but results consistently showed substantial impacts on the emissions reductions expected from the proposed rule due to higher ZEV adoption rates, leading to greater magnitudes of NO_X emissions credits than projected in the proposal. Other commenters also argued that EPA should consider emissions of criteria pollutants that occur upstream of the vehicle (e.g., from power plants providing electricity to ZEVs). One commenter estimated gram-per-mile NO_X emissions rates of a MY2027 diesel-fueled truck compared to a BEV when accounting for upstream emissions; results of their analysis suggested a diesel truck meeting MY 2027 and later requirements could produce slightly lower g/mile NO_X in 2030 than a battery-electric truck from same weight class. The commenter stated that the analysis is not intended to suggest that one truck technology is cleaner than another since only NOx emissions were considered, but rather that NO_X credits for ZEVs is not warranted.

Numerous commenters also stated that the higher NO_X emissions resulting from ZEV NO_X emissions credits would lead to higher emissions in some communities (e.g., those located near power plants) than others (e.g., those with higher numbers of ZEVs), which could result in disproportionate impacts in disadvantaged communities already overburdened with pollution. Commenters argue that EPA has not justified the need to allow the increased emissions that would result from allowing ZEVs to generate NO_X emissions credits. At least one commenter further argues that the credits do not support NO_X emissions reductions, and thus are misaligned with the environmental goals of the rule.

Impacts on ICE improvements

Commenters further state that the credits would result in a lack of improvement in conventional engine technologies. Commenters argue that cost-effective technologies exist to reduce emissions from heavy-duty engines and that the standards should be achieved with conventionally-fueled vehicles.

Impacts on ZEVs and other technologies

Several commenters argue that ZEVs will be cost-competitive with internal combustion engine technologies in the 2025 timeframe and thus emissions credits are not needed as incentives. Commenters state that ZEVs already planned for production would be used to generate NO_X emissions credits, and thus the credits would not incentivize additional ZEV production. Rather, commenters argue, the credits would only serve to allow higher emissions from internal combustion engines. At least one commenter noted that other State and federal actions are providing more meaningful and less environmentally costly HD ZEV incentives (e.g., deploying charging infrastructure, purchase rebate programs). Some commenters further argue that the allowing ZEVs to generate NO_X emissions credits favors one technological approach over another; commenters state that the credits would stifle innovation and use of non-ZEV decarbonization technologies.

Restrictions on NOx Emissions Credits for ZEVs

Many commenters provided input on the types of restrictions that would be necessary, in their view, if EPA were to allow manufacturers to generate NO_X emissions credits from ZEVs. First, several commenters stated that EPA should include ZEVs when setting the level of the numeric standard. Other commenters urged EPA not to allow ZEVs sold to meet state policies such as the California Advanced Clean Trucks (ACT) rule, to generate federal NO_X emissions credits. Many of these commenters urged EPA not to allow ZEVs to generate NO_X emissions credits beyond 2026; other commenters suggested different sunset dates for ZEV NO_X emissions credits (e.g., 2030). In contrast, one commenter stated that EPA should only allow ZEVs to generate NO_X emissions credits starting in 2027 in order to avoid large credit values that would result from the current standard and zero; the commenter stated if EPA allowed ZEVs to generate NO_X emissions credits prior to 2027, then the value of the credits should be calculated based on the difference between zero and the 2027 and later standards.

Numerous commenters also stated that the Family Emission Limit (FEL) cap should be lower than proposed; several commenters suggested a FEL cap of 0.05 g/hp-hr, which would be consistent with the CARB Omnibus program NO_X emissions standard for MYs 2024 – 2026. Some commenters supported EPA's proposed credit life of five years, while others urged EPA to shorten the credit life for ZEVs to three years based on data suggesting that BEVs will reach cost parity with internal combustion engines in the 2025 to 2030 timeframe. At least one commenter supported EPA's proposed restriction not to allow ZEV NO_X credits to be transferred between vehicle weight classes; however, another commenter, who supports allowing ZEVs to generate credits, argued ZEV NO_X credits should be allowed to be used in any vehicle weight class as a way to incentivize ZEV production. Finally, one commenter urged EPA to only allow ZEVs to generate NO_X or GHG credits, not both; the commenter stated this approach would only credit ZEVs produced beyond the volume of ZEVs needed to show compliance with revised GHG standards.

Summary of Comments Supporting **NO_X emissions credits for ZEVs**:

In contrast, several commenters support allowing manufacturers to generate these credits. Many of these commenters are heavy-duty engine and vehicle manufacturers. These comments are summarized immediately below as they relate to: 1) environmental impacts, 2) impacts on ICE improvements, and 3) Impacts on ZEVs and other technologies.

Environmental Impacts

Some commenters state that it is appropriate for EPA to allow manufacturers to generate NO_X emissions credits from ZEVs because doing so recognizes the zero-emissions tailpipe performance of the technologies, and because these technologies help meet emissions reductions and air quality goals. One commenter stated that incentivizing ZEVs and near-zero emissions vehicles is important for stationary sources that must operate in nonattainment areas.

Impacts on ICE improvements

Several commenters stated that concerns about NO_X emissions credits from ZEVs resulting in higher emissions from internal combustion engines were not warranted because FEL caps would prevent ICE backsliding. One commenter noted that the difference between MY2027 and later standards and the proposed FEL would mean only a small fraction of manufacturers' fleets could certify near the FEL cap. Other commenters argued that the FEL cap combined with a stringent standard would prevent backsliding of internal combustion engines. One commenter agreed with commenters opposing ZEV emissions credits and stated that EPA could address concerns about backsliding by considering ZEVs when setting the NO_X emissions standards. Finally, one commenter argued that compliance flexibilities such as the NO_X credit program would be essential to the achievability of the standards.

Impacts on ZEVs and other technologies

Some commenters further argue that NO_X emissions credits for ZEVs would allow manufacturers to manage investments across different products and ultimately result in increased ZEV deployment. One commenter noted that using credits to incentivize ZEV production is warranted based on the proposed requirements for ZEVs (e.g., testing, useful life, warranty). Another commenter stated that EPA should allow ZEVs to generate NO_X emissions credits in this final rule, and then could revisit that decision in a later rulemaking. One commenter stated that allowing a credit life of 10 years for ZEV credits would further incentivize EV development. Finally, one commenter stated that President Biden encouraged the EPA Administrator to consider ZEVs when setting emissions standards for 2027 and later.

In Section 12.6.1 of this document, we discuss our responses to the comments summarized in this Section and our decision not to finalize at this time the allowance for manufacturers to generate NO_X emissions credits from heavy-duty ZEVs. See Sections 12.6.2 through 12.6.6 of this document for additional details on comments received and EPA responses to comments on the proposal to allow manufacturers to generate NO_X emissions credits from and ZEVs, including: emission credit multipliers for ZEV credits, vehicle certification for ZEVs, testing requirements for ZEVs generating NO_X emissions credits, and useful life and warranty requirements for ZEVs generating NO_X emissions credits.

Response to Comments and Rationale for Approach to ZEV Credits in Final Rule:

As discussed in preamble Section IV.G, we are not finalizing the proposed allowance for manufacturers to generate NO_X emissions credits from heavy-duty ZEVs. In this Section 12.6 of this document, we provide additional discussion of the three considerations on which we based our decision not to finalize the allowance for manufacturers to generate NO_X emissions credits from ZEVs.

First, the standards in the final rule are technology forcing, yet achievable for MY2027 and later engines without the flexibility for manufacturers to generate NO_X emissions credits from ZEVs. CAA section 202(a)(3)(A) requires EPA to set emission standards for NOx, PM, HC, and CO that reflect the greatest degree of emission reduction achievable through the application of technology that the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology. As described in preamble Section III, after further consideration, including consideration of public comments, we are finalizing standards that our assessment and data show are feasible in the MY 2027 timeframe. We therefore disagree with the commenter who stated that compliance flexibilities such as the ability for manufactures to generate NO_X emissions credits from ZEVs would be essential to the achievability of the proposed standards. Nevertheless, as described in preamble Section IV.G, the ABT program in the final rule balances providing manufacturers with flexibility in their product planning and encouraging the early introduction of emissions control technologies with maintaining the expected emissions reductions from the program. We expect that the final standards, including the final ABT program, will result in meaningful emissions reductions in all communities, including in disadvantaged communities already overburdened with pollution.

Second, since the final standards are not based on projected utilization of ZEV technology, and given that we believe there will be increased penetration of ZEVs in the HD fleet by MY 2027 and later, we are concerned that allowing NO_X emissions credits from ZEVs would result in fewer emissions reductions than intended from this rule. We therefore generally agree with commenters who provided analyses suggesting that rapid growth in ZEV penetration rates could result in NO_X credits from ZEVs impacting the emissions reductions expected from the final standards. This is particularly true in light of other, recent Federal programs that may result in additional HD ZEVs leading up to and following MY 2027.[36] Thus, while we agree with some commenters that ZEV technologies can provide zero-emissions tailpipe performance, and accordingly proposed an allowance to generate NOx credits from ZEVs as compliance flexibility, we have determined that the potential for the flexibility to reduce the expected emissions reductions from the rule outweighs the potential benefits of additional flexibility to meet the standards.[37]

Third, we continue to believe that testing requirements to ensure battery and fuel cell performance over the useful life of a ZEV are important to ensure the zero-emissions tailpipe performance for which they are generating NO_X credits; however, after further consideration, including consideration of public comments, we also believe it may be appropriate to take additional time to work through specific test procedures and other specifications for ZEV battery and fuel cell performance over the useful life period of the ZEV. These three considerations, including the relationship between the second and third considerations, supports our decision not to allow manufacturers to generate NO_X emissions credits from ZEVs in this final action (see Sections 12.6.4 and 12.6.5 of this document for additional detail on comments and EPA responses to comments on the proposed ZEV testing and useful life and warranty requirements).[38]

We note that one commenter stated that EPA had not described how our proposal to allow EVs to generate NO_X emission credits is consistent with our statutory authority. While we are choosing not to finalize at this time the proposed allowance for manufacturers to generate NO_X emissions credits from ZEVs, doing so would be consistent with our statutory authority.

---

[36] For example, the recently passed Inflation Reduction Act (IRA) has many incentives for promoting zero-emission vehicles, see Sections 13403 (Qualified Clean Vehicles), 13404 (Alternative Fuel Refueling Property Credit), 60101 (Clean Heavy-Duty Vehicles), 60102 (Grants to Reduce Air Pollution at Ports), and 70002 (United States Postal Service Clean Fleets) of H. R. 5376.

[37] One commenter suggested that EPA could ensure only ZEVs produced beyond the volumes required to meet GHG standards would generate NOx emissions credits by allowing ZEVs to generate NOx or GHG credits, but not both. EPA did not propose or ask for comment on this approach and since we are not allowing NOx ZEV credits we are not including this approach in the final rule. We also note that if we were to include an approach that allowed ZEVs to generate NO_X or GHG credits but not both, then that approach may lessen the potential concerns of the second consideration, but it would not fully address the three considerations on which we based our decision not to allow NOx ZEV credits.

[38] We note that our approach for ZEV NO_X credits differs from our approach to hybrid engines and hybrid powertrains in the final rule. While the first consideration discussed in this response is the same for any emission control technology that can comply with the final standards, the second consideration is more pronounced for ZEVs than for hybrids given the greater number of potential credits that could be generated by ZEVs. This difference is then compounded by the third consideration for ZEVs, whereas our approach for hybrid engines and hybrid powertrains relies on an accurate test procedure for quantifying NO_X emissions (see preamble Section III.A for details). The uncertainty in appropriate test procedures to validate the NO_X emission credits generated for ZEVs combined with additional uncertainty in the potential for allowing ZEV NO_X emissions credits to result in fewer emissions reductions than intended from this rule, leads us to finalize a different approach for ZEVs than hybrids at this time.

Finally, as noted at the start of this Section 12.6, many commenters provided input on the types of restrictions that would be necessary, in their view, if EPA were to allow manufacturers to generate NO_X emissions credits from ZEVs. Since we are not allowing NO_X ZEV credits, we are not including the suggested restrictions in the final rule.

12.6.2 Multipliers for NOx Emissions Credits Generated by Electric Vehicles

Comments by Organizations

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

Commenters also agree that EPA should not adopt any emission credit multipliers, 87 Fed. Reg at 17,562 (requesting comments on whether emission credit multipliers should be included in the final rule). [EPA-HQ-OAR-2019-0055-1302-A1, p.54]

Organization: *California Air Resources Board (CARB)*

On page 17562 of the NPRM, U.S. EPA asks for comments regarding the applicability of NOx credit multipliers for BEVs and FCEVs. [EPA-HQ-OAR-2019-0055-1186-A2, p.21]

CARB staff supports U.S. EPA’s position for not allowing credit multipliers for electric vehicles. It should be noted that these vehicles are currently unable to generate any NOx credits. The proposed rule introduces a new incentive to this market segment by allowing these vehicles to accrue credits. Addition of multipliers would lead to double counting of these credits and would be detrimental to the overall program benefits. [EPA-HQ-OAR-2019-0055-1186-A2, p.21]

CARB staff also agrees with U.S. EPA that the current state of technology development and implementation of electric vehicles, while still relatively nascent compared to combustion engines, are mature enough not to warrant emission credit multipliers. It should also be noted that in addition to California, the ACT regulation has also been adopted by five other states (Washington, Massachusetts, Oregon, New Jersey, New York). [EPA-HQ-OAR-2019-0055-1186-A2, p.21]

Organization: *Daimler Truck North America LLC (DTNA)*

As noted above in Section II.A, incentivizing ZEV market penetration should be a guiding principle for EPA in this and all other Agency rulemakings related to vehicle emission standard-setting. While EPA correctly determines in the Proposed Rule that ZEVs should generate NOx credits, the Agency does not go far enough to incentivize them in its proposal. A simple analysis shows that ZEVs contribute to the NOx inventory reductions and can balance out NOx emissions from higher-emitting diesel vehicles. Offering credit multipliers for ZEVs would only serve to enhance production incentivizes for these vehicles, which in turn would increase their emission reduction benefits. [EPA-HQ-OAR-2019-0055-1168-A1, pp.80-81]

EPA notes that in developing the proposal, it considered whether to provide NOx credit multipliers for ZEVs, but ultimately decided against it ‘due to the potential emission impacts of the use of credit multipliers.'105 Paradoxically, however, EPA does propose to apply credit multipliers (and accordingly, enhance incentives) for early adoption of new low-NOx diesel engines.106 In this manner, EPA proposes to incentivize low-NOx diesel vehicles, which do emit NOx, over ZEVs, which do not emit NOx. [EPA-HQ-OAR-2019-0055-1168-A1, p.81]

105 Proposed Rule, 87 Fed. Reg. at 17,557.

106 See id. at 17,554.

EPA's logic on credit incentives should be applied consistently; ZEVs are a nascent technology, and EPA should seek to spur ZEV adoption wherever possible. Increased ZEV adoption today has a carry-on effect far greater than its direct effect to the NOx inventory implies, as widespread ZEV adoption will drive increased market acceptance. This increased demand will enable further manufacturer investment and new technologies, and it will drive demand for ZEV infrastructure, which, in turn, enables further ZEV penetration later on. [EPA-HQ-OAR-2019-0055-1168-A1, p.81]

We recommend that EPA apply emission credit multipliers for ZEVs of at least 2.0; since the Agency proposes to grant this credit to low-emission diesels that meet the MY 2031 emissions standards early. ZEVs, by comparison, are even cleaner than diesel engines that meet the proposed MY 2031 emission standards, and should be entitled to at least as much credit: [EPA-HQ-OAR-2019-0055-1168-A1, p.81]

EPA requests comments on whether the Agency should limit ZEV emission credits to particular vehicle classes or categories. Daimler Truck believes that all ZEVs are equally deserving of incentive programs, as penetration rates are not guaranteed for any class. However, if EPA must limit NOx multiplier eligibility to any particular category, we believe that ZEVs that replace heavy-heavy duty conventional vehicles are the least likely to have significant adoption rates of mature technology without proper incentives. EPA could thus limit these credits to Class 6-8 trucks and tractors. [EPA-HQ-OAR-2019-0055-1168-A1, p. 81]

Organization: *Environmental Defense Fund (EDF)*

However, if EPA retains these credits in any form, it is critically important that the agency not adopt any credit multipliers and that EPA substantially strengthen the FEL cap to help ensure remaining diesel vehicles are not able to certify to higher emission levels based on the availability of ZEV credits. [EPA-HQ-OAR-2019-0055-1265-A1, p.23]

Organization: *Fuel Cell and Hydrogen Energy Association (FCHEA)*

The hydrogen and fuel cell industry supports the proposal to provide early adopter incentives, as well as credit multipliers for longer-range FCEVs able to travel 300 miles between fuelings and ability to fuel in less than twenty minutes. This would provide greater incentive for adoption of these zero-emission technologies. [EPA-HQ-OAR-2019-0055-1187-A2, p. 2]

Organization: *Lion Electric Co. USA Inc. (Lion)*

To encourage OEMs to meet these standards, we strongly support providing opportunities for manufacturers to generate NOx emission credits, along with the use of credit multipliers, at least in the first few years of the proposed changes. This is an excellent way to encourage more OEMs to manufacture ZEVs, bringing the electric vehicle market closer to cost parity with ICE vehicles and accelerate long-term ZEV adoption. Lion believes that these credit allowances will boost ZEV production and adoption, and can always be revisited in future rulemaking once the market has advanced. [EPA-HQ-OAR-2019-0055-1151-A2, p. 2]

We disagree with the proposal to "provide a multiplier for longer-range BEVs" as many of the market segments that most need ZEVs have the lowest range needs. This accounts for school buses, refuse trucks, and delivery trucks, which may not travel long distances, but have multiple stops in neighborhoods and communities that may already be overburdened by air pollution. Also, while Lion does not oppose the generation of credits for hybrid vehicles, we encourage the EPA to offer higher credits to manufacturers of all-electric vehicles. [EPA-HQ-OAR-2019-0055-1151-A2, p. 2]

Organization: *Natural Gas Vehicles for America (NGVAmerica)*

NGVAmerica and its members submit the following recommendations for policies and programs that the EPA and other federal agencies can advance to encourage the use of cleaner trucks.

2) Adopt the regulatory safeguards EPA has proposed with respect to electric vehicle credits since electric vehicles are already heavily subsidized and benefit from recently adopted sales mandates in California and other states; this includes support for the safeguards proposed for the use of credits to limit emissions from engines and vehicles that rely on credits for compliance, and the decision not to extend sale credit multipliers to electric vehicles; [EPA-HQ-OAR-2019-0055-1330-A1, pp.12-13]

Organization: *Rivian Automotive, LLC (Rivian)*

At the same time, consistent with our position in GHG programs, Rivian opposes ZEV credit multipliers in the criteria emissions program and finds EPA's initial proposal in this regard appropriate. Generally, multipliers are intended to encourage the development and use of advanced technologies that otherwise face substantial barriers to market entry and proliferation. While EPA offers certain narrow HD segments as examples of where this might still be the case, Rivian believes that industry has amply demonstrated its ability to develop and commercialize advanced technology vehicles in all classes.11 Rivian supports NOx credits commensurate with zero tailpipe emissions but not credit multipliers. [EPA-HQ-OAR-2019-0055-1229-A1, p.4]

> 11 Baha Al-Alawi, Owen MacDonnell, Ross McLane, and Kevin Walkowicz, CALSTART, Zeroing in On Zero-Emission Trucks: The Advanced Technology Truck Index: A U.S. ZET Inventory Report (January 2022), available at www.calstart.org/zeroing-in-on-zero-emission-trucks/.

Organization: Zero Emission Transportation Association (ZETA)

EPA should not issue multipliers for these NOx credits. As more HDEVs become available, auto manufacturers will no longer need external incentives baked into these emissions standards to build more HDEVs. Manufacturers should be encouraged to maximize their HDEV production; credit multipliers would have the adverse effect of encouraging manufacturers to produce a limited number of HDEVs in order to inequitably write off the emissions of their most polluting vehicles. Multipliers would undermine the intention of this rulemaking. Once HDEVs make up the majority of the market, these credits should be removed to more stringently regulate the emissions of remaining fossil fuel-powered vehicles. Similarly, EPA should eliminate all credit multipliers for vehicles in the current draft. We are agnostic to the mechanism for removing these credits. [EPA-HQ-OAR-2019-0055-1283-A1, pp.8-9]

EPA Summary and Response

Summary:

A subset of commenters opposing the proposal to allow manufacturers to generate NO_X emissions credits from ZEVs also stated that they opposed providing emissions credits multipliers for ZEV emissions credits. Commenters stated that multipliers would lead to double counting of the credits and would be detrimental to the program benefits. Commenters further stated that ZEV technologies are mature enough that they do not need multipliers; this rationale is consistent with one commenter who supported the proposal to allow manufacturers to generate NO_X emissions credits from ZEVs but opposed credit multipliers. Another commenter stated that the multipliers would encourage manufacturers to produce a limited number of ZEVs.

In contrast, a subset of commenters support emissions credit multipliers for ZEVs emissions credits; these commenters are a subset of those who supported the proposal to allow manufacturers to generate NO_X emissions credits from ZEVs. One commenter stated that EPA should apply emissions credit multipliers of at least 2.0 to incentivize ZEVs and provide level playing field with low-emissions diesel products that meet MY 2031 standards early; the commenter noted that, if needed, EPA could restrict multipliers to Class 6-8 trucks and tractors. Another commenter stated that EPA should incentivize adoption of FCEVs by providing multipliers for FCEVs with a range of 300 miles and ability to fuel in less than 20 minutes.

Response:

As discussed in Section 12.6.1, EPA is not finalizing the proposed allowance for manufacturers to generate NO_X emissions credits from ZEVs. Since we are not allowing NO_X emissions credits from ZEVs, we are also not allowing emissions credits multipliers for ZEV emissions credits. As described in preamble Section IV.G, we are also not finalizing the proposed Early Adoption Incentive Program, and in turn we are not including emissions credit multipliers in the final program. Rather, we are finalizing a revised version of the transitional credit program under the ABT program that provides four pathways to generate straight NO_X emissions credits (i.e., no credit multipliers) that are valued based on the extent to which the engines generating credits comply with the requirements we are finalizing for MY 2027 and later (e.g., credits discounted at a rate of 40% for engines meeting a lower numeric standard but none of the other MY 2027 and later requirements) (see Section 12.4 of this document and preamble Section IV.G.7 for more details).

12.6.3 Vehicle Certification for ZEVs

Comments by Organizations

Organization: *Allison Transmission, Inc. (Allison)*

EPA has proposed that HEVs, BEVs and FCEVs be allowed to generate NOx emission credits starting in MY 2024.57 In doing so, EPA is proposing to allow vehicle manufacturers to generate the credits using certification pathways that have already been established pursuant to the Phase 2 rule. Given existing CARB rules in this area concerning powertrain certification, however, it is probable that EPA will receive comments advocating broader use of powertrain certification method and/or targeted use in vehicle categories that EPA believes will move more rapidly towards electrification. Again, Allison's view is that EPA should explore and utilize simpler methods for certification. Allison comments regarding the generation of NOx emission credits are contained below in Section XVII. [EPA-HQ-OAR-2019-0055-1231-A1, pp.27-28]

57 Id. at 17,556-7.

Organization: *Cummins Inc. (Cummins)*

EPA proposes to allow vehicle manufacturers, rather than powertrain manufacturers, to generate NOx credits from battery electric vehicles (BEV) and fuel cell electric vehicles (FCEV). EPA proposed this approach "because the vehicle certification pathway is already utilized for certifying BEV and FCEV to GHG standards, and thus would require fewer resources to implement and carryout for both manufacturers and EPA's certification program" (87 FR 17557). However, it is unclear how the resources and burden are reduced with EPA's proposed approach. The default procedures in §1037.552 and §1037.554 for determining inputs for calculating ZEV NOx credits and for determining initial useable battery energy (UBE) for a BEV or initial fuel cell voltage (FCV) for a FCEV are powertrain tests. It is unclear how a zero emission powertrain manufacturer would experience more burden in completing a test of their own powertrain compared to a vehicle manufacturer completing a test of a powertrain which may or may not be their own. [EPA-HQ-OAR-2019-0055-1325-A1, p. 10]

As proposed, a zero emission powertrain manufacturer such as Cummins who does not manufacture vehicles would be prevented from generating ZEV credits of their own. Since EPA's rule sets new NOx standards and other requirements for engine (powertrain) certification applicable to the engine (powertrain) manufacturer, it is more appropriate for zero emission credits brought into the engine program to be earned by the zero emission powertrain manufacturer, rather than the zero emission vehicle manufacturer. This change would provide consistency with NOx and greenhouse gas credit ownership in existing engine regulations, continue to foster a level playing field among manufacturers, and provide incentive for powertrain manufacturers, including vertically-integrated manufacturers who manufacture both the powertrain and the vehicle, to invest in and develop zero emission powertrain technology. If

EPA chooses to finalize provisions that allow the generation of ZEV NOx credits, those credits should belong to the zero emission powertrain manufacturer. Note too that CARB recently finalized MY 2024 regulations that prescribe that ZEV NOx credits are generated by the certifying powertrain manufacturer. [EPA-HQ-OAR-2019-0055-1325-A1, p. 10]

Organization: *Daimler Truck North America LLC (DTNA)*

Daimler Truck supports EPA's proposal that such NOx credits should accrue to the vehicle manufacturer. While CARB grants NOx credits from ZEVs to the manufacturer of the 'Zero Emissions Powertrain,' Daimler Truck has argued that the concept of a 'powertrain manufacturer' does not apply well to ZEVs. For example, Daimler Truck currently manufactures ZEVs whose 'powertrains' have one manufacturer for the battery, another manufacturer for the electric motor, and many other manufacturers for other components that CARB considers part of the 'zero emissions powertrain.' Ultimately, Daimler Truck is responsible for the system integration, validation of the system, and service and warranty of the vehicle, and the Company is the face of the ZEV experience to the customer. Therefore, the Company believes it is appropriate for the credits generated to accrue to the vehicle manufacturer. Most importantly, it is Daimler Truck that must take on the financial obligation of making the ZEV attractive for customers to buy, and is therefore the only organization in the production chain that needs to be incentivized to market these products. Suppliers are incentivized to develop and market the components because vehicle manufacturers will buy them. [EPA-HQ-OAR-2019-0055-1168-A1, p.80]

Any rule that EPA adopts to set ZEV certification standards should:

1. Minimize added cost and manufacturer uncertainty for ZEVs, which will serve only to slow their adoption.

2. Seek opportunities to incentivize ZEV adoption wherever possible by allowing judicious use of credits, etc.

3. Ensure a level playing field for manufacturers regardless of their NOx credit status, to avoid creating a splintered market with two tiers of products.

4. Limit useful life, warranty, and durability standards to those in the vehicle GHG standards in 40 CFR 1037 today.

5. Base useful life, warranty, and durability requirements on total system energy throughput to recognize non-motive forms of operation that age ZEVs.

6. Set clear requirements for useful life, a concept which does not neatly apply to ZEVs. ZEVs will emit zero emissions forever, so EPA must directly identify what requirements manufacturers are certifying their products to for the defined useful life period.

7. Study the effect of infrastructure and charging, especially high charge-rate systems, on ZEV durability and longevity, and account for it during standard setting.

8. Develop test procedures in concert with OEMs to ensure repeatability, practicality, and effectiveness; if EPA must test battery capacity, it should be done at the battery pack or fuel cell level, and not at the vehicle or powertrain level, which is expensive and impractical, and does not provide additional information about the battery or fuel cell. DTNA recommends the Static Capacity Test (Constant Current Method)' set forth in Society of Automotive Engineers (SAE) J1798, 'Recommended Practice for Performance Rating of Electric Vehicle Battery Modules.'

9. Avoid adding unnecessary requirements that do not serve EPA's mission to reduce emissions. EPA requests comments on various aspects of potential standards for ZEVs, including diagnostic requirements from CARB's Zero Emission's Powertrain procedure, communication requirements, proposed signals manufacturers would need to make available, and more. None of these requirements have any effect on emissions, and serve only to add development cost and burden to manufacturers, delaying ZEV introduction and increasing prices.

10. Ensure that manufacturers have adequate lead-time to develop systems, and the market can develop organically, by delaying new standards for ZEVs to at least MY 2031. [EPA-HQ-OAR-2019-0055-1168-A1, pp.124-125]

Organization: *Motor & Equipment Manufacturers Association (MEMA)*

MEMA encourages EPA to not issue NOx credits for battery electric vehicles or fuel cell electric vehicles to avoid unintended backsliding and lowering of technology deployment on internal combustion engine heavy-duty vehicles. In addition, NOx credits have traditionally only gone to engine certifiers. Opening this up to additional parties could result in a fundamental change to the NOx credit program with significant unintended consequences. Not many companies make both batteries and internal combustion engines to be able to transfer credits within one company. This generates more questions than answers and may open the door to backsliding. [EPA-HQ-OAR-2019-0055-1322-A1, p. 8]

Organization: *Toyota Motor North America, Inc. (Toyota)*

We request that the EPA allow manufacturers of HD ZEV powertrains (such as HD-BEV and HD-FCEV) to generate credits, rather than only allowing credit generation by vehicle manufacturers. Toyota appreciates the ability of vehicle manufacturers to generate NOx credits from ZEV HD vehicles and believes this is an important incentive for wider adoption of ZEV technologies that lead to emissions benefits. However, development of ZEV powertrain technologies for HD vehicles requires significant investments and risks. Allowing powertrain manufacturers to generate credits would be a powerful incentive to encourage more widespread investment from manufacturers in the development of ZEV technologies. We suggest EPA establish a credit allowance for the ZEV powertrain manufacturers to generate credits for the powertrain. The powertrain credits would be a portion of the total credits the vehicle generates, split between the vehicle and powertrain manufacturers. [EPA-HQ-OAR-2019-0055-1224-A1, p.2]

EPA Summary and Response

Summary:

Several commenters provided perspectives on EPA's proposal for manufacturers to certify ZEVs through a vehicle certification pathway, and therefore generate vehicle credits when choosing to participate in the NOx ABT program with ZEVs. One commenter opposes the proposal and urged EPA to allow powertrain manufacturers, not vehicle manufacturers, to generate NO_X emissions credits from ZEVs; this commenter stated that vehicle certification would prohibit powertrain manufacturers who do not manufacturer vehicles from generating ZEV credits on their own. Another commenter supported EPA's proposal and argued vehicle manufacturers were the more appropriate owner of ZEV NO_X emissions credits because the vehicle manufacturer is responsible for integrating and validating systems from multiple component manufacturers (e.g., battery, electric motor). Another commenter stated that EPA should allow both vehicle and powertrain manufacturers to own credits from ZEVs, with the powertrain manufacturer owning a portion of the vehicle credits. The remaining two commenters did not clearly support or oppose the proposed vehicle certification approach; one commenter urged EPA to simplify the process without providing specific suggestions, and the other commenter stated that allowing parties other than engine manufacturers to generate NOx credits could lead to backsliding and uncertainty since not many companies make both batteries and internal combustion engines to transfer credits within one company.

Response:

As discussed in Section 12.6.1 of this document, and Section IV.G of the preamble, EPA is not finalizing the proposed allowance for manufacturers to generate NO_X emissions credits from ZEVs. However, as proposed, we are finalizing requirements for ZEVs to certify to criteria pollutant standards under 40 CFR 1037. We are finalizing the vehicle certification pathway as proposed, which allows manufacturers to use the same compliance pathway for certifying ZEVs to both criteria and GHG standards. We believe this approach also minimizes added costs for manufacturers and provides manufacturers with certainty on a criteria pollutant certification pathway for ZEVs, which address additional factors that one commenter raised. EPA agrees with the commenter who stated that the vehicle manufacturer is responsible for system integration and validation, as well as vehicle service and warranty; therefore, we continue to believe the vehicle certification pathway is the most appropriate.

The remaining considerations that the commenters provide pertain to ownership of ZEV NO_X emissions credits and the proposed requirements for ZEVs that generate NO_X emissions credits, which are not at issue in this rule as finalized.

12.6.4 Testing Requirements for Electric Vehicles Generating NOx Emissions Credits

Comments by Organizations

Organization: *Alliance for Automotive Innovation (Auto Innovators)*

40 C.F.R. 1037.552 Multicycle powertrain test for battery electric vehicles.

We request that the requirement to measure DC energy during AC recharge be removed from the test procedure requirements. DC energy measured during the AC recharge is not required for the test result calculations and introduces additional test burden to laboratories. AC recharge energy is measured upstream of the charger and includes any charger losses. Measurement of DC energy during AC recharge may require modification of charge monitoring systems and additional intrusive current sensor(s) on the vehicle/powertrain if the recharge cable is separate from the drive cables. [EPA-HQ-OAR-2019-0055-1303-A1, pp.4-5]

Subsection (c)

Auto Innovators proposes that 'Charge the powertrain for the duration of the soak period measuring the DC recharge energy, EDCRC , and do not end the soak period prior to reaching full charge' be revised to 'Charge the powertrain for the duration of the soak period and do not end the soak period prior to reaching full charge.' [EPA-HQ-OAR-2019-0055-1303-A1, p.5]

Subsection (f)(ii)

Regarding the statement 'Immediately apply the brake and decelerate the powertrain to a stop within 15 seconds once the test termination criteria have been met[,]' Auto Innovators suggests that EPA consider increasing the time requirement for HD vehicles from 15 seconds to 20 or 30 seconds. Decelerating high mass vehicles from 55 mi/hr to 0 mi/hr in 15 seconds can be challenging given the lower coefficient of friction on a dynamometer. [EPA-HQ-OAR-2019-0055-1303-A1, p.5]

Subsection (g)

Auto Innovators proposes that 'Place the powertrain on-charge within 3 hours of completing the MCT and charge the battery to full capacity to measure the total AC recharge energy, EACRC, and DC recharge current per hour, CRC' be revised to 'Place the powertrain on-charge within 3 hours of completing the MCT and charge the battery to full capacity to measure the total AC recharge energy and EACRC.' [EPA-HQ-OAR-2019-0055-1303-A1, p.5]

Auto Innovators recommends that EPA remove section (g)(6) referring to Charge Recovery. Charge recovery verification is not typically an issue for BEV vehicles. Significant issues with charge recovery can be detected from the AC recharge energy. [EPA-HQ-OAR-2019-0055-1303-A1, p.5]

Organization: *California Air Resources Board (CARB)*

CARB staff recommends that U.S. EPA modify the greenhouse gas emission model to include the ability to calculate work performed by electric motors. Such an approach would establish an industry-wide, standardized procedure for calculating the electric vehicle credits. [EPA-HQ-OAR-2019-0055-1186-A2, p.22]

The HD electric vehicle market is quite diverse and includes small volume manufacturers and large, vertically integrated manufacturers. Given such a landscape, establishing a simple tool to standardize the calculations could lead to the establishment of a level playing field for estimating electric vehicle credits. [EPA-HQ-OAR-2019-0055-1186-A2, p.22]

In response to U.S. EPA's request for comment on the proposed approach to BEV and FCEV powertrain testing, CARB staff supports U.S. EPA's proposal to require manufacturers to measure work produced as well as usable battery energy and fuel-cell voltage for BEV and FCEV powertrains, respectively, via the multicycle test (MCT) because it better reflects real-world operation compared to other common battery and fuel-cell test methodologies (e.g., bench testing). Requiring such testing would provide reliable information about a powertrain's work capabilities when new as well as a verifiable baseline value for either usable battery energy or fuel-cell voltage, as applicable, to facilitate the implementation of the proposed durability requirements for BEVs and FCEVs. Furthermore, because of the value of the information provided by this testing to potential purchasers of BEVs and FCEVs, CARB staff recommends that all BEV and FCEV powertrains, regardless of whether or not they generate NOx emission credit, be subject to the same testing requirements. [This comment can also be found in sections 15.1 and 15.2 of this comment summary.] [EPA-HQ-OAR-2019-0055-1186-A2, p.22]

However, CARB staff recommends that in later model years, manufacturers be required, as part of the durability demonstration, to age/cycle the batteries and/or fuel cells to simulate real-world operation prior to performing the MCT. In addition, CARB staff recommends that the durability of BEV and FCEV powertrains be demonstrated through the same process, regardless of whether these vehicles generate NOx credits. Durable BEVs and FCEVs will be needed to provide a viable secondary market. A robust secondary market is necessary to ensure success of these new technologies because many fleets only operate new vehicles for a few years and rely on vehicle asset residual value in the secondary market to fund future new vehicle purchase. Also, some fleets only buy reliable second market vehicles to reduce upfront costs and so BEVs and FCEVs success requires them to be reliable through their useful lives. This aspect is critically important because purchasers of used vehicles tend to be small businesses and owner-operators who often reside in historically underserved communities. CARB staff believes the success of the secondary market will depend on transparency to understand the status of a used vehicle and its battery health or fuel stack voltage performance when purchasing these vehicles. [EPA-HQ-OAR-2019-0055-1186-A2, p.23]

Organization: *Cummins Inc. (Cummins)*

Cummins manufactures a broad range of technologies for on-highway vehicles – from internal combustion engines to hybrids to zero emission powertrains. We strive to provide durable and reliable products to our customers who rely on them for their livelihood. In principle, we support durability testing for zero emission powertrains, along with appropriate useful life and warranty requirements that are on par with requirements for other types of powertrains. Those requirements are important to ensure acceptance by customers, so that adoption increases, and to provide a level-playing field for manufacturers of competing technologies. However, just as with conventional powertrains, any test procedures for durability demonstration should not create undue cost or a lengthy test burden for the manufacturer. Similarly, useful life and warranty requirements should not be so extreme as to significantly increase the cost of the zero emission powertrains further and inhibit their adoption. EPA should work with manufacturers to strike the right balance in the final rule. [EPA-HQ-OAR-2019-0055-1325-A1, p. 10]

1036.510(d)-(e)

When the CD mode is covered in EV and the charge sustaining mode has one FTP/SET cycle, the GHG emission will be elevated based on the current calculation approach. Cummins suggests running more than one CS cycle to account for cold warm operations:
• The current method defined in NPRM can be used to calculate GHG emission in CD mode.
• The first cycle in CS mode should be treated as cold cycle and the next cycle as warm. Calculate composite CS mode emission using 1/7 and 6/7 weighting factors for cold and warm cycles.
• Then apply UF based calculation to get the combined CO2. [EPA-HQ-OAR-2019-0055-1325-A1, p. 25]

Organization: *Daimler Truck North America LLC (DTNA)*

EPA's proposed method for calculating ZEV NOx credits is overly onerous and not practical. [EPA-HQ-OAR-2019-0055-1168-A1, p.82]

Under the Proposed Rule, manufacturers would calculate vehicle emission credits using a powertrain test cycle that measures work produced over a defined duty-cycle test, and either useable battery energy for battery-electric vehicles (BEVs) or fuel cell voltage for fuel cell electric vehicles (FCEVs). EPA proposes to use the measured work to define the number of credits a ZEV would generate. [EPA-HQ-OAR-2019-0055-1168-A1, p.82]

EPA has not, however, considered the feasibility of performing such a test for all electric vehicle configurations. Issues related to the technical feasibility of this test are elaborated in Section VI of these comments, but in short, each powertrain configuration will require approximately 40 hours of chassis-dyno testing to complete this test procedure. [EPA-HQ-OAR-2019-0055-1168-A1, p.82]

Since EPA envisions this testing will be performed on a powertrain level, it is not clear how many configurations a manufacturer must test—but the work produced over the defined duty-cycle test will vary based on number of factors not related to the NOx emissions emitted by these vehicles (which is, of course, zero). These factors include, among others:

- Axle ratio of the drivetrain
- Vehicle transmission characteristics
- Control strategies and driver-selectable options
- Battery capacity, configuration, controls
- Power rating of the powertrain
- Power consuming accessories [EPA-HQ-OAR-2019-0055-1168-A1, p.82]

As EPA does not specify how powertrains should be categorized for this testing, we assume that EPA expects manufacturers to run this test for each configuration that could result in a different cycle power measurement. [EPA-HQ-OAR-2019-0055-1168-A1, p.82]

Each of these factors will have an effect on the measured cycle power, and therefore manufacturers could be expected to test many configurations. Even with a reasonable categorization strategy—per vehicle family as defined in Part 1037, for example—manufacturers could be required to demonstrate many configurations at great expense, and vehicle families already contain several different ZEV architectures today. [EPA-HQ-OAR-2019-0055-1168-A1, pp.82-83]

Ultimately, this test intends to measure how much NOx credit a vehicle should generate— but by definition, a ZEV generates no NOx at all. The amount of work that a powertrain outputs on a cycle test is not indicative of the NOx savings that vehicle will accrue over its life, and it is not reasonable to assume that the vehicle it replaces would output the same amount of work. Diesel engine credits are not affected, today, by the axle ratio, gearing, shift strategies, or control strategies of the vehicles they are installed in; nor is the work done by those engines reduced by the losses in their associated powertrains. By extension, ZEV NOx credits should not be affected by these factors either. This is very significant expense and an impractical amount of testing with no tangible benefit. [EPA-HQ-OAR-2019-0055-1168-A1, p.83]

Lastly, this is a new test procedure that EPA proposes – manufacturers have little experience performing the testing, few accessible test cell facilities that can perform the test, and no time with which to develop these capabilities. It is impractical to expect manufacturers to certify new products, with which we have little experience, to a new test cycle, with which we have no experience, and to complete that testing in less than one year from the time the rule is finalized. [EPA-HQ-OAR-2019-0055-1168-A1, p.83]

Daimler Truck recommends that EPA assign a specific NOx credit value for each ZEV, based on vehicle weight class. Credits could be assigned without cycle work testing, since the amount of NOx the vehicle will emit is known (it is zero), and the amount of NOx the vehicle will offset cannot be determined from this testing. [EPA-HQ-OAR-2019-0055-1168-A1, p.83]

EPA could set the credits so that a Class 8 ZEV would offset the typical NOx credits consumed by a typical conventional Class 8 vehicle. EPA could similarly categorize credits for Class 6-7 vehicles, and other categories that the EPA could reasonably bin together. Such an approach would drastically reduce manufacturers' test burdens, EPA's certification review load, and credit-related unpredictability and risk—all without any trade-offs in emission reductions. [EPA-HQ-OAR-2019-0055-1168-A1, p.83]

While the Proposed Rule contains new test standards for both battery electric vehicles and hydrogen fuel cells in this rule, before finalizing its proposal EPA must work with manufacturers and testing experts to determine practical testing procedures that make sense. [EPA-HQ-OAR-2019-0055-1168-A1, p.121]

Daimler Truck has analyzed EPA's proposed Multicycle Test (MCT) from proposed 40 C.F.R. 1037.552 and believes it is not a practical or reasonable test for the following reasons:

- EPA's test procedure takes approximately 40 hours of testing to complete, per configuration
- EPA's test procedure will not be able to be completed as envisioned by some configurations (particularly with high power ratings relative to their battery size) since the vehicles will be left with <10% of their battery capacity after the second HDTC/LLC/SET test sequence. In fact, it is likely the test will only be able to be completed by vehicles with the largest battery capacities relative to their power outputs.
- EPA's abrupt speed/grade/load changes in the HDTC/LLC/SET test sequence are unsafe— the high torque and instant torque capability of ZEVs cause extreme stresses to the dyno couplings and test equipment. This is a real safety risk and could damage the powertrain, the dyno, or any couplings in the system.
- Truck control strategies (such as low-power derates) might cause the test to end earlier than battery capacity alone would dictate.
- EPA's test procedure would require production high-voltage cabling to be removed, since shielded high voltage cables cannot be adequately measured with current probes. This will mean that to perform EPA's proposed testing, manufacturers will have to modify the high voltage cabling in a potentially unsafe manner.
- Very few test facilities in the U.S. are even capable of performing the test EPA proposes, as complete powertrain testing that meets EPA's testing requirements has not typically been used by manufacturers to any great degree. Manufacturers will have to build up this test equipment and the expertise needed to use it.
- EPA's test procedure requires ambient temperatures to be maintained throughout the cycle, but most existing powertrain test facilities may not be conditioned with enough capability to hold temperature throughout the entire test. [EPA-HQ-OAR-2019-0055-1168-A1, p.121]

Daimler Truck would be happy to review its analysis of the MCT in a confidential setting, but firmly believes that the EPA must develop any test procedure with adequate input from manufacturers and test facilities before incorporating it into the federal regulations. [EPA-HQ-OAR-2019-0055-1168-A1, p.122]

Additionally, as discussed in Section III of these comments, EPA's test procedure represents an inappropriate burden for manufacturers. Since EPA envisions this testing will be performed on a powertrain level, it is not clear how many powertrain configurations a manufacturer must test, but the test results will vary based on number of factors not related to the energy capacity or durability of the powertrain. These factors include, among many others:

- Axle ratio of the drivetrain
- Vehicle transmission characteristics
- Control strategies and driver-selectable options
- Battery capacity, configuration, controls
- Power rating of the powertrain
- Power-consuming accessories [EPA-HQ-OAR-2019-0055-1168-A1, p.122]

Since EPA does not specify how powertrains should be categorized for this testing, we assume that the Agency expects manufacturers to run this test for each configuration that could result in a different outcome; therefore manufacturers could be expected to test many configurations. Even employing a reasonable categorization strategy—per vehicle family as defined in Part 1037, for example—manufacturers could be required to demonstrate many configurations at great expense, particularly given that today's typical vehicle families already contain several different ZEV architectures.136 [EPA-HQ-OAR-2019-0055-1168-A1, p.122]

> 136 This increased expense and the attendant compliance burden should be weighed heavily in OMB's review and decision whether to approve the information collection components of the Proposed Rule, in accordance with the Paperwork Reduction Act. Each test takes about 40 hours to run (per vehicle). Given the many configurations that manufacturers may have to test, it is difficult to approximate exactly how much cost and how many personnel hours would be involved, but Daimler Truck expects that the burden would be significant.

Ultimately, EPA's proposed test is intended to measure how much capacity is available in the battery pack. It is unclear why factors outside of the battery should be part of the test. While the drive motor, accessories, control strategies, etc. might change the rate at which power is consumed from the battery, they have no effect on the total amount of energy stored in the battery pack (and by extension, the total amount of energy expended during the MCT, since the test ends when the battery is depleted). The proposed test will need to be repeated many times—one for each configuration that affects the test—with no significant additional information to be gained about the capacity of the battery pack. [EPA-HQ-OAR-2019-0055-1168-A1, p.122]

Daimler Truck recommends that EPA consider a battery-only test to determine battery capacity. Such a test reduces the number of configurations a manufacturer must test, and provides detailed information about the capacity of the battery in a useable, repeatable manner. The industry already uses such a test for this purpose—the 'Static Capacity Test (Constant Current Method)' set forth in Society of Automotive Engineers (SAE) J1798, 'Recommended Practice for Performance Rating of Electric Vehicle Battery Modules,' which is incorporated by reference in CARB's 'California Standards and Test Procedures for New 2021 and Subsequent Model Heavy- Duty Zero Emission Powertrains.' [EPA-HQ-OAR-2019-0055-1168-A1, p.122]

Organization: *General Motors LLC (GM)*

EPA proposes to incorporate by reference regulations and test procedures in many cases that are unclear, duplicative, or are not yet final. [EPA-HQ-OAR-2019-0055-1246-A1, p.5]

In " § 1037.102 Exhaust emission standards for NOx, HC, PM, and CO", EPA proposes that, for battery electric vehicles to qualify for averaging, banking, and trading programs, "Useable battery energy must remain at or above 70 percent throughout the useful life." with the Initial capacity determined by "§ 1037.552 Multicycle powertrain test for battery electric vehicles." These proposed test procedures are new, and duplicative with and distinct from United Nations and CARB proposals to estimate and regulate battery capacity over the useful life of the vehicle.

None of the procedures are yet finalized with final regulations. [EPA-HQ-OAR-2019-0055-1246-A1, p.6]

Incorporating standards by reference that are not finalized, unclear, or duplicative adds uncertainty to what is expected in a finalized regulation, and often increases the burden to industry to comply with standards. GM encourages EPA to not incorporate by reference regulations and test procedures that are unclear, potentially duplicative, or not finalized. [EPA-HQ-OAR-2019-0055-1246-A1, p.6] [[This comment can also be found in section 7.5 of the comment summary]]

Organization: *Truck and Engine Manufacturers Association (EMA)*

However, the NPRM also proposes to impose on credit-generating ZEVs a suite of excessively complex, burdensome, and expensive certification, durability, useful life, and warranty requirements. In that regard, the NPRM includes entirely new certification and compliance requirements that, as written, appear to be impossible to implement. Even if a manufacturer could meet all the proposed regulatory requirements, the certified ZEV would be so expensive that no fleet would be willing to invest in it. The proposed requirements are likely to end up creating two distinct classes of medium- and heavy-duty ZEVs. Credit-generating ZEVs would be burdened with excessive certification, durability, useful life, and warranty provisions, making them commercially non-viable. Conversely, manufacturers would be free to customize non-credit generating ZEVs to meet their customers' needs most efficiently. That unlevel competitive playing field would splinter and hamstring the nascent medium- and heavy-duty ZEV market, rather than promote ZEV sales. [EPA-HQ-OAR-2019-0055-1203-A1, p. 109]

EPA has developed the proposed new ZEV certification, durability, useful life, and warranty provisions without any consultation with the manufacturers that are expected to implement them. History has shown that such unilateral development of complex vehicle certification procedures rarely leads to implementable and successful regulatory requirements. Although it is unfortunate that industry would be starting with the unilateral proposal included in the NPRM, we request that EPA commit to collaborating with manufacturers to identify a workable path forward for the certification and compliance requirements for credit-generating ZEVs. Considering the limited time before a final rule, and the complexity and novelty of ZEV certification and compliance requirements, we believe an interim approach may be the only realistic path forward. An interim solution could be fashioned to meet EPA's needs while not burdening ZEVs with excessive costs and regulatory requirements. If we can identify an appropriate interim approach, a long-term solution could then be developed as part of the Phase 3 GHG rulemaking. That rulemaking is a more appropriate forum for the in-depth data analyses and technical discussions needed to establish workable and effective long-term ZEV certification and compliance requirements. [EPA-HQ-OAR-2019-0055-1203-A1, p. 109]

In medium- and heavy-duty applications, BEVs and FCVs can be used in emissions reducing applications that do not accumulate mileage. For instance, a vehicle may be used as a source of electricity in remote applications, or at a job site, replacing a generator and powering jobsite equipment. A zero-emission vehicle may be used to temporarily power a building, replacing a generator. In advanced applications, a vehicle or a fleet of vehicles may be used to supplement electricity grid services, such as through load-leveling. These example applications have the potential to create societal value using advanced transportation technologies to reduce emissions traditionally associated with other sectors. NESCAUM19, Union of Concerned Scientists (UCS)20, Environmental Defense Fund (EDF)21, International Council on Clean Transportation (ICCT)22, Rocky Mountain Institute (RMI)23, Sierra Club24, the State of California, and the United States Department of Energy25 have all recognized the potential value from zero-emissions vehicles, and especially from medium-duty and-heavy duty zero emissions vehicles, through their deployment in innovative applications. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 135 - 136]

CARB, EPA, and the United Nations are all proposing regulations requiring manufacturers to report on or meet battery durability, UL, and warranty requirements, as measured by different test and certification procedures. Those multiple requirements are duplicative, and burdensome, and possibly counter-productive to accelerating the deployment of zero-emissions vehicles, and the realization of the attendant emissions reductions. CARB is proposing to regulate battery durability through Advanced Clean Cars II26; EPA has proposed new test procedures for energy storage devices in this NPRM27; and the United Nations Economic Commission for Europe has finalized a Global Technical Requirement (UN GTR) for light-duty vehicle battery durability28 (Heavy-Duty in-vehicle battery durability development was started in 2022). EPA should work with those regulating bodies to coalesce around a single harmonized standard. The UN GTR process has incorporated feedback from manufacturers, more so than the CARB or EPA rulemakings. The Society of Automotive Engineers J1979 and J1939 standards may be excellent references as the topic matures as well. Complying with multiple regulations, having different requirements and test procedures, has the potential to slow manufacturers’ ability to bring zero emissions vehicles into the market and could prevent the realization of economies of scale. As with any emerging market, regulations can have unintended consequences. For example, mileage based warranties and ULs could preclude zero-emission vehicles from participating in innovative applications, such as electricity grid services. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 136 - 137]

EPA Summary and Response

Summary:

Several commenters provided perspectives on EPA's proposed testing requirements for ZEVs that manufacturers were choosing to generate NO_X emissions credits from. One commenter (CARB) suggested that EPA modify GEM to calculate work performed by electric motors; the commenter stated that doing so would allow a standardized approach to calculate credits and create a level playing field for manufacturers to calculate NO_X emissions credits. One commenter (CARB) supports proposed approach to use the multicycle test (MCT) to measure work produced since it better reflects real-world operation compared to other test methods (e.g., battery bench testing). The commenter recommends that EPA require the same testing for all ZEVs, regardless of whether or not they generate NOx emissions credits because the information would be valuable. They further recommend that in later program years EPA require manufacturers to age the batteries or fuel cells prior to conducting MCT, and again that, the same requirement should apply to all ZEVs regardless of if they generate NOx emissions credits. The commenter asserted that testing information is critical to support durability and transparency on the state of battery or fuel cell stack performance when purchasing vehicles in the secondary market, and noted that secondary market users can often be those who live in underserved communities. Finally, the commenter stated that test procedures should not create undue costs or lengthy test burden for manufacturers.

One commenter (DTNA) opposing the proposed test requirements stated that EPA hasn't considered the feasibility of performing MCT for all electric vehicle configurations. They noted that each powertrain configuration will require approximately 40 hours of chassis-dyno testing based on their evaluation and stated that the considerable test burden should be considered relevant to Paperwork Reduction Act. They further stated that it is unclear how many configurations would need to be tested and that the work produced will vary based on factors unrelated to NOx emissions (e.g., axle ratio of drivetrain, battery capacity). They also noted that diesel credits are not affected by factors that impact work produced by ZEV powertrain. They further stated that manufacturers don't have experience with the test procedure, and it is impracticable for them to complete the testing in less than one year from when rule is finalized. The commenter (DTNA) recommends that EPA assign a specific NOx credit value for each ZEV based on vehicle weight class with no testing required (e.g., set Class 8 ZEV credits equal to typical NOx credits consumed by Class 8 vehicle). The commenter provided a list of specific concerns with the test procedure (e.g., some vehicles would be unable to complete the test due to insufficient battery energy) and suggested EPA consider a battery-only test to determine battery capacity; they noted that industry is already using SAE J1798.

Other commenters opposing the proposed test procedures state that the test procedures are new and duplicative with and distinct from UN and CARB proposals to estimate and regulate battery capacity over useful life of a vehicle. Commenters stated that incorporating standards by reference that are not finalized, unclear, or duplicative adds uncertainty regarding what to expect in the final rule and can increase industry burden to comply with standards. Commenters encouraged EPA not to incorporate by reference regulations and test procedures that are unclear, potentially duplicative, or not finalized. Commenters stated that mileage-based useful life and warranty requirements could discourage the use of HD ZEVs in applications that don't accumulate mileage, such as supplying energy back to the grid. Finally, commenters stated that EPA should work with other entities such as the United Nations, CARB, and SAE to develop a harmonized test procedure(s) and set of requirements.

<u>Response</u>:

Since we are not finalizing the proposed allowance for manufacturers to generate NOx emissions credits from ZEVs (see Section 12.6.1 of this document and preamble Section IV.G), we are also not finalizing the testing requirements we proposed for ZEVs to generate NOx emissions credits.

We recognize that one commenter urged EPA to require the same durability demonstration process for all ZEVs, regardless of whether they generate NOx emissions credits; however, we did not propose that the testing and performance requirements for battery and fuel cells over the useful life would apply to all ZEVs and thus are not finalizing such an approach at this time. We note that the final requirements result in consistent requirements for manufacturers certifying ZEVs to criteria and GHG emissions standards. We intend to continue to consider the perspectives included in this comment and the other comments in this Section 12.6.4 when developing future rulemakings relevant to heavy-duty ZEVs.

12.6.5 Useful Life and Warranty Requirements for Electric Vehicles Generating NOx Emissions Credits

<u>Comments by Organizations</u>

Organization: *American Automotive Policy Council (AAPC)*

Given the early stage of commercialization of zero emissions vehicles in medium- and heavy-duty applications, it is appropriate for EPA to collect battery data as the market develops prior to regulating a useful life. EPA should consider exempting ZEVs from useful life requirements in the 2027-2030 timeframe until more real-world battery data is available to inform rulemaking. When EPA does choose to regulate the useful life of ZEVs, EPA should reconsider the restrictive definition of useful life that has been proposed. EPA "mileage or years" based useful life standards should be updated to include, "mileage or year or hours or kWh delivered" to better consider ZEV emissions reducing applications. For instance, hours could accumulate any time the battery is productively discharging. The "kWh delivered" metric would consider wear and tear batteries frequently discharged at high rates and provide some incentive to install packs with larger capacity. Alternatively, the "kWh delivered" metric could be normalized to initial battery pack capacity to effectively sum discharge cycles, without biasing the regulation away from smaller capacity battery packs in affordable applications. EPA should consider harmonizing the "hours or kWh delivered" metrics between classes (for instance light-heavy, and medium-heavy) to ease certification burdens. BEVs and FCVs are technologies that can reduce criteria emissions and GHG emissions; including ZEVs in an ABT program appropriately recognizes how these vehicles can contribute to meeting ambitious air quality goals. [EPA-HQ-OAR-2019-0055-1293-A1, p. 3]

Additionally, we recommend including a provision that partial NOx credits be available for Zero-Emission Vehicles with a declared full useful life below the designated full-useful of the particular engine service class. EPA should consider updates to the Warranty and Useful Life requirements for the final rule to recognize innovative applications for battery electric vehicles (BEVs) and fuel cell vehicles (FCVs). For instance, BEVs and FCVs may be used in emissions reducing applications that do not accumulate mileage. Identical BEV and FCV powertrains may be installed in different vehicle classes and would therefore be subject to different, conflicting warranty and useful life requirements. With some simple changes that align the Warranty and Useful Life requirements, EPA could increase the likelihood that zero emissions vehicles will qualify for NOx ABT without precluding innovative applications. Including zero emissions vehicles in the NOx ABT program appropriately recognizes the potential of these vehicles to reduce emissions and improve air quality. [EPA-HQ-OAR-2019-0055-1293-A1, pp. 3 - 4]

In medium- and heavy-duty applications, BEVs and FCVs add significant new use capabilities that will be used in emissions reducing applications that do not accumulate mileage. For instance, a vehicle can be used as a source of electricity in remote applications, or at a job site, replacing a generator and powering jobsite equipment. The vehicle could be used to power a building for a time, replacing a generator. In advanced applications, the vehicle, or a fleet of vehicles may be used for electricity grid services, such as load leveling. These example applications have the potential to create societal value and use transportation technology to reduce stationary emissions traditionally associated with other sectors. NESCAUM,4 Union of Concerned Scientists (UCS),5 Environmental Defense Fund (EDF),6 International Council on Clean Transportation (ICCT),7 Rocky Mountain Institute (RMI),8 Sierra Club,9 the State of California, and the United States Department of Energy10 have all recognized the potential value zero emissions vehicles, and especially medium duty and heavy-duty zero emissions vehicles, to be used in innovative applications. The referenced U.S. Department of Energy report correctly states that, “V2G adds uncertainty related to battery life and capacity”, which is particularly relevant for useful life requirements measured in mileage or years, as EPA proposes. In innovative zero emissions vehicle applications, battery packs may accumulate cycles unrelated to mileage, and the EPA should consider this when finalizing standards for useful life and warranty. Considering age of the equipment, in years, is also insufficient. Battery cycles, and wear and tear for innovative applications may be unrelated to mileage or years. [EPA-HQ-OAR-2019-0055-1293-A1, pp. 4 - 5]

6 EDF supported research through the NC Clean Energy Technology Center (NCCETC) in coordination with Roanoke Electric Cooperative (REC) to demonstrate vehicle-to-grid smart chargers. “Preliminary findings from a demonstration of two-way, vehicle-to-grid

(V2G) technology in North Carolina show the economic potential for using bidirectional charging technologies to feed energy stored in electric vehicle batteries back to charging sites, especially when the grid is experiencing high demand.", NC Cooperative Demonstration of Vehicle-to-Grid Smart Charger Shows Economic Value. https://nccleantech.ncsu.edu/2021/09/21/nc-cooperative-demonstration-of-vehicle-to-grid-smart-charger-shows-economic-value/

7 "EVs could potentially benefit the grid through additional services that help utilities manage load. For example, an EV that is plugged in all day could be used to store excess electricity during off-peak hours; the utility could later withdraw that electricity from the EV battery to supply peak load, avoiding some inefficient cycling of generators." ICCT recommends that policy makers "Create or amend rules to allow participation by EVs in electricity markets, so EVs can provide and be compensated for ancillary services." (pages 3-4), Electric Vehicle Grid Integration in the U.S., Europe, and China. https://theicct.org/wp-content/uploads/2021/06/ICCT_Briefing_EV-grid_integration_20130923.pdf

8 "Actions on the demand side, such as improved energy efficiency (and appliance efficiency), demand response, community scale RE and battery storage systems, vehicle-grid systems, etc. can benefit the system by smoothening peak loads, mitigating grid power shortfalls, and sustaining critical services during power outages." (page 19) Powering Through: A Climate Resilient Future. https://rmi.org/insight/powering-through-a-climate-resilient-future/

9 "Vehicle-to-grid (V2G) technology allows EVs to absorb electricity from the grid when it's plentiful, and then provide electricity back to the grid when – and where – it's needed most. Heavy-duty electric vehicle fleets are particularly attractive energy resources." Electric Vehicles are Indispensable for California's Climate Resiliency, Even During a Power Outage. https://www.sierraclub.org/articles/2020/09/electric-vehicles-are-indispensable-for-californias-climate-resiliency-even-during

10 "The current availability of plug-in electric vehicles (PEVs), and their projected penetration of the private transportation market in the coming years, introduces the possibility of feeding the energy stored in the vehicle batteries back to the electric grid." (page 1), Vehicle-to-Grid (V2G) Power Flow Regulations and Building Codes Review by the AVTA. https://www.energy.gov/sites/prod/files/2014/02/f8/v2g_power_flow_rpt.pdf

The EPA proposal includes warranty and useful life requirements that vary by regulatory class, and this unnecessarily complicates certification, especially for zero emissions vehicles. For instance, the proposed mileage requirement for useful life of medium heavy- duty is nearly 1.5 times that of light heavy-duty, in 2027-2030. Ideally, requirements would be similar for similarly equipped powertrains, or similarly capable vehicles. The additional weight of batteries on zero emissions vehicles often increases curb weight, and subsequently gross vehicle weight rating (GVWR). As a result, zero emissions vehicles with high-capacity batteries, designed for lighter applications, may be subject to warranty and useful life regulations that historically were tailored for internal combustion engine vehicles with higher capabilities and uses. [EPA-HQ-OAR-2019-0055-1293-A1, p. 5]

The California Air Resources Board (CARB), EPA, and the United Nations are all proposing regulations requiring manufacturers to report on or meet battery durability, useful life, and warranty requirements, as measured by different test and certification procedures. Knowing that OEMs are ultimately responsible for customer satisfaction, these requirements are duplicative and burdensome, and possibly counter-productive to accelerating the adoption of zero emissions vehicles, and their emissions reductions. Durability and warranty requirements for ICE vehicles have developed over many years, but the knowledge of how ZEV technology works in numerous heavy-duty use cases requires further analysis and more time to mature. CARB is proposing to regulate battery durability through Advanced Clean Cars II,11 EPA has proposed new test procedures for energy storage devices in this notice,12 and United Nations Economic Commission for Europe has finalized Global Technical Requirement (UN GTR) for light-duty vehicle battery durability13(Heavy-Duty in-vehicle battery durability development started in 202214). EPA should work with these regulating bodies to form one national standard for the U.S. The UN GTR incorporates significantly more feedback from manufacturers than the current drafts of other proposals. Society of Automotive Engineers J1979 and J1939 standards may be excellent references as the topic matures, as well. Many different regulations, with different requirements and test procedures, has the potential to slow manufacturers' ability to bring zero emissions vehicles to market and reduce economies of scale. As with any emerging market, regulations may have unintended consequences; for instance, a mileage based standard alone may preclude participation in innovative zero emissions vehicles applications, like supplying electricity grid services. [EPA-HQ-OAR-2019-0055-1293-A1, pp. 5 - 6]

14 (EVE) Latest EVE #54 Meeting including Heavy-Duty UN GTR development on battery durability. https://wiki.unece.org/display/trans/EVE+54th+Session

Organization: *California Air Resources Board (CARB)*

CARB staff supports U.S. EPA's proposal to require manufacturers of BEVs and FCEVs that choose to generate NOx credits certify their configurations to the same useful life (UL) requirements as conventional engines and powertrains. This would provide assurance to owners and operators that BEVs and FCEVs are designed to be as durable as their conventional vehicle counterparts. Such requirements would ensure that real-world emission reductions resulting from the use of BEVs and FCEVs are realized and would align with the level of NOx emission credits generated. Additionally, CARB staff agrees with U.S. EPA's proposal to use a phased in approach for earlier model years to allow adequate time for BEV and FCEV manufacturers to transition to these more stringent requirements. [EPA-HQ-OAR-2019-0055-1186-A2, pp.22-23]

In response to U.S. EPA's request for comment on the proposed approach for warranty requirements applicable to BEVs or FCEVs that generate NOx emission credits, CARB staff supports U.S. EPA's proposal to subject said BEVs and FCEVs to the warranty periods corresponding to an engine-based primary intended service class, as specified in the proposed 1037.120(b). [EPA-HQ-OAR-2019-0055-1186-A2, p.23]

CARB staff appreciates U.S. EPA's acknowledgement of the work to develop the Zero-Emission Powertrain (ZEP) certification procedure for medium and HD vehicles. In response to U.S. EPA's request for comments on the proposed approach that only batteries and fuel cells in BEVs and FCEVs, respectively, are covered under warranty for manufacturers choosing to generate NOx emission credits, CARB staff recommends that covered components include, at minimum, not only the battery or fuel cell, but all powertrain components. In ZEP Certification,44,45,46 a ZEP includes (as applicable) the electric traction motor, system controller, generator, on-board charger, battery management system, thermal management systems, energy storage system (batteries, capacitors, and flywheels), inverter, fuel-cell stack, and the interface at which electrical power is converted to (or from) tractive mechanical power. System design and component selection are both critical in ensuring the function of a ZEP, and inappropriate design or components could cause catastrophic failure along the driveline. Therefore, CARB staff does not believe that the current proposal would adequately protect purchasers from the potential problems that could occur in BEVs and FCEVs. [EPA-HQ-OAR-2019-0055-1186-A2, pp.23-24]

44 https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2019/zepcert/fsoraddendum.pdf

Organization: *Cummins Inc. (Cummins)*

Durability, useful life, and warranty are especially important in the context of ABT. EPA proposes to allow the generation of ZEV NOx credits that can be used by diesel engines to comply with the engine NOx standards and to require ZEV to meet the same useful life requirements as diesel engines. This parity in useful life is needed to ensure that the ZEV is fully offsetting the higher emissions of the credit-using diesel engine. EPA further proposes to require that UBE and FCV must remain at least 70% and 80%, respectively, throughout UL. Alternatively, EPA should consider allowing manufacturers to calculate ZEV credits based on reduced UL periods if the UBE and FCV minimums can't be met for the full UL. [EPA-HQ-OAR-2019-0055-1325-A1, pp. 10 - 11]

Organization: *Daimler Truck North America LLC (DTNA)*

EPA has not adequately demonstrated feasibility of their proposed ZEV durability standards, especially in the timelines EPA proposes. We believe that it is impossible for manufacturers to validate and certify their vehicles to durability standards for MY 2024, when such certification would need to start less than one year from now. Any ZEV requirements that increase uncertainty, cost, or risk will serve to dis-incentivize their production and adoption, which is the opposite of EPA's intention. Requiring different standards for ZEVs that generate NOx credit, as compared to those that do not, could create a splintered ZEV market, with two tiers of ZEVs at different price points, creating an unlevel playing field and confusing or misleading customers—ultimately dissuading further adoption of ZEVs. Each of these issues is discussed in more detail in Section VI of these comments. [EPA-HQ-OAR-2019-0055-1168-A1, pp.81-82]

Further, the emissions benefits of ZEVs—and the knock-on effects of incentivizing ZEVs now—outweighs the small risk that ZEVs will not offset as much NOx as their credits enable. The same risk exists for clean diesels, which may not generate as much credit as predicted (particularly if they are not used as much as their statutory useful lives imply, or are damaged in an accident or otherwise removed from service). The public benefit is best served by an aggressive and dramatic shift towards ZEVs as soon as possible. We urge EPA not to slow the adoption of ZEVs with unnecessary requirements tied to the generation of NOx credits. [EPA-HQ-OAR-2019-0055-1168-A1, p. 82]

EPA proposes useful life and durability requirements for credit-generating HD ZEVs far in excess of what the Agency has demonstrated to be feasible.131 The only materials that EPA presents in support of feasibility are several press articles claiming 'transit buses show BEVs are capable of operating more than 10 million miles and over 30 years of normal service,' and that the Department of Energy has set a durability *target* for HD FCEVs as part of DOE-sponsored research program to develop a one-off demonstrator vehicles.132 The sources do not adequately support the Agency's claims that its proposed ZEV useful life and durability requirements are feasible for the following reasons:

1. The articles that EPA cites are not controlled studies. Rather, EPA provides a collection of press releases from manufacturers and magazine articles, which are intended to sell vehicles.

2. The cited articles only focus on city buses, which are prime candidates for electrification in light of their controlled and predictable charging practices. These vehicles should be expected to have better durability than other ZEV applications, since their loads are light, their total energy throughput is small in comparison to Class 8 vehicles, and they will not be exposed to aging factors like high charge rates.

3. The cited articles mostly focus on the length of the warranty: 12 years in these cases. However, since they are press pieces, they are presented in brief and do not focus on the limitations of the warrantees. Many warrantees expressly limit the number of cycles or the total energy throughput the battery is guaranteed for, and these limits are often not in line with EPA's proposals. The articles do not even provide a mileage limit— which, in any case, would not translate from city buses to other ZEV applications that target much higher mileage.

4. One of EPA's cited articles even explicitly states that the battery will need to be replaced at mid-life, specifically because it will not meet durability targets.133 As the most expensive component of a ZEV, the cost of a battery pack must be accounted for in the purchase price of the ZEV if a replacement is required.

5. The DOE target that EPA cites is a development target for the Super Truck 3 program. This program is intended to research the feasibility and develop demonstrator vehicles. While the value of government investment in ZEV research cannot be understated, a research program target should not be assumed as evidence of feasibility for production vehicles. In addition, no products have been completed or demonstrated to meet the targets of Super Truck 3 to date; it is an in-progress research program, but EPA uses it to justify a requirement which will take effect in MY2024. [EPA-HQ-OAR-2019-0055-1168-A1, pp.117-118]

131 We request that EPA keep in mind its statutory directive to ensure that criteria pollutant emission standards for heavy-duty vehicles reflect the 'greatest degree of emission reduction achievable' through the application of technology that EPA

determines will be available for the model year to which such standards apply, giving 'appropriate consideration to cost, energy, and safety factors associated with the application of such technology.' 42 U.S.C. §7521(a)(3)(A)(i). Compliance flexibilities such as the NOx credit program are essential to the achievability of the very stringent NOx standards that EPA has proposed, thus the considerations in CAA Section 202(a)(3)(A)(i) are relevant to appropriateness of the requirements that EPA has proposed for credit-generating ZEVs.

132 See Proposed Rule, 87 Fed. Reg. at 17,502.

133 See id. (citing 'Idaho's YRT to add Proterra battery-electric buses, charging infrastructure,' Metro Magazine, (Oct. 25, 2019) ('The performance warranty also includes a requirement for Proterra to install new batteries on the buses at mid-life to help ensure the batteries always have plenty of energy to meet their route needs and hedge against future replacement battery costs.')).

EPA's own sources in fact support the *in*feasibility of the Agency's proposals. City bus manufacturers are offering warrantees, which are limited in terms of cycles, energy throughput, or mileage—and even in these cases, may require battery pack replacements. It can be inferred that other applications may struggle even more with EPA's proposed requirements, with higher loads, greater energy throughput, large accessory loads, and potential exposure to higher charge rates. [EPA-HQ-OAR-2019-0055-1168-A1, p.118]

The ZEV market is still developing, and factors will emerge bearing on feasibility that EPA has not considered during its assessment. For example, high-speed charging (megawatt charging or more) will almost certainly become a market necessity, which will enable further penetration of ZEVs, but will likely have some effect on battery life that manufacturers cannot predict at the time of certification. Similarly, the state of hydrogen infrastructure and the quality and purity of the supplied hydrogen could affect fuel cells in ways that are not well understood today. [EPA-HQ-OAR-2019-0055-1168-A1, p.118]

Additionally, EPA's proposal does not consider the widespread adoption of Vehicle-to- Grid operations (which Daimler Truck has already successfully deployed today) or for auxiliary power draws in the form of so-called 'ePTO' applications. Both of these technologies could draw as much or more power from the vehicle as driving will, but EPA's proposals do not account for them in their calculation of useful life. Any useful life requirement should be based on total energy throughput, which accurately represents the work done by the powertrain over its life. [EPA-HQ-OAR-2019-0055-1168-A1, pp.118-119]

Daimler Truck's experience as one of the leaders in ZEV deployment suggests that ZEV equipment specifications for battery and fuel cells may not match EPA's proposed useful life targets for credit-generating ZEVs. The Company will share further relevant technical details on the state of development of BEVs and FCEVs with the EPA in a confidential setting. [EPA-HQ-OAR-2019-0055-1168-A1, p.119]

Finally, it would be impossible for manufacturers to validate products to the useful life values that EPA proposes, especially in the timeframe EPA proposes. Traditional diesel vehicles are operated twenty-four hours a day, for years ahead of production, to ensure their performance over EPA's useful life targets. ZEVs cannot be operated as aggressively, since they need downtime for charging. Using Daimler Truck's most aggressive validation programs, it takes about twice as long to validate a ZEV to full useful life than it does for a conventional vehicle. It would take more than 4 years to even accumulate the mileage necessary to validate a single truck to EPA's proposed useful life, given the charging requirements. EPA proposes its requirements would take effect as early as MY 2024; products for that year have already been developed and validated, and there is about one year between now and when certification efforts begin for those products. Thus, certifying these products to the proposed useful life values in the timeframe given is not practical or reasonable. [EPA-HQ-OAR-2019-0055-1168-A1, p.119]

All of these factors must be considered by EPA when it determines whether or not its proposed durability and useful life requirements for NOx credit-generating ZEVs are in fact feasible. [EPA-HQ-OAR-2019-0055-1168-A1, p.119]

Our customers are aware that ZEV products are ideal for some applications, but not appropriate for others. In their current forms, ZEVs are not well-suited for long-haul, sleeper applications that have extremely high energy usage, high mileage, and little downtime. Daimler Truck works with its customers to determine appropriate applications for their needs, and customers' expectations regarding range, durability, and longevity are well-defined before they invest in the technology. Typical use cases involve regional pick-up and delivery, short-haul tractors, trucks, school buses, walk-in-vans, and other applications that generally accumulate fewer miles over their life. However, EPA is proposing to set 'one size fits all' useful life and durability targets for manufacturers to generate NOx emission credits from these vehicles, on the assumption that there will be adequate ZEV replacements for *all* types of diesel vehicles on the road today. This assumption fails to account for the wide variety of applications and duty cycles that customers demand. [EPA-HQ-OAR-2019-0055-1168-A1, p.119]

It is likely true that an average ZEV will accumulate fewer miles over its life than a diesel-powered, long-haul truck. EPA argues that therefore it might not be appropriate for it to generate the same number of NOx credits. EPA makes no attempt, however, to rationalize the same inconsistency in the diesel market today—namely, that a manufacturer may generate NOx credits for producing a HD engine used in a short-haul vehicle, and use them to meet emissions compliance obligations for a HD engine that powers a long-haul vehicle. [EPA-HQ-OAR-2019-0055-1168-A1, pp.119-120]

Customers will adopt ZEVs in the applications that make business and technical sense for them. In these applications, ZEVs will replace trucks that would have been conventionally diesel powered—and therefore, these vehicles deserve to generate NOx credit because their adoption will lead to actual NOx emissions reductions. Even if a ZEV is not destined to be used in the most extreme applications that its diesel counterpart would be, it is still being used as a replacement for a diesel-powered vehicle, and this should be reflected in the crediting provisions of EPA's regulatory program. [EPA-HQ-OAR-2019-0055-1168-A1, p.120]

Instead, EPA proposes to impose durability targets that would make ZEVs capable of meeting the durability of the longest-lived, highest mileage diesels in order to generate NOx emission credits; this will necessarily add cost. EPA admits as much in the Proposed Rule, explicitly recommending approaches for meeting battery and fuel cell durability requirements that would add significant cost to these vehicles: 'For instance, manufacturers could choose to design the battery or fuel cell in their product to have a larger capacity at the start of the vehicle life and limit the extent to which the initial capacity is available for use […] Alternatively, a manufacturer could choose to include battery or fuel cell maintenance or replacement as part of critical emission-scheduled maintenance.'134 [EPA-HQ-OAR-2019-0055-1168-A1, p.120]

134 Proposed Rule, 87 Fed. Reg. at 17,559.

In other words, EPA's proposal would amount to a requirement that manufacturers:

1. Install a larger battery or fuel cell;

2. Limit the capability of the vehicle by restricting its available energy; and/or

3. Replace the battery or fuel cell during its useful life. [EPA-HQ-OAR-2019-0055-1168-A1, p.120]

Each of these actions would necessarily add very significant cost, or reduce the effectiveness of the vehicle at a given cost point. EPA's proposal is geared towards guaranteeing capability that fleets might not need, by adding very significant cost or reducing product capability. This serves to undermine the principles of variability in use and customer needs discussed above, and will directly reduce the adoption of ZEVs in the market place. [EPA-HQ-OAR-2019-0055-1168-A1, p.120]

Regarding EPA's request for comment on whether manufacturers should be required to pay for battery / fuel cell replacement,135 ultimately, that cost will be passed on to the customer, either as a maintenance replacement that they pay for, or an up front cost reflected in the purchase cost of the vehicle. If manufacturers are obligated to take on liability for replacements, this will add further uncertainty and risk, making manufacturers less likely to aggressively pursue new technologies and increase ZEV penetration. [EPA-HQ-OAR-2019-0055-1168-A1, p.120]

135 See id. at 17,560.

Ultimately, manufacturers want to build products that customers want to buy. EPA's proposal threatens to disrupt the supply-demand dynamics of the ZEV marketplace by effectively impeding manufacturers' ability to design and build products with the capacity, range, and durability that fleets demand. EPA's proposal, if finalized, would mandate the optimum product that manufacturers must produce to the detriment of customers' ability to choose. The likely outcome would be to dampen the ZEV market and impose significant and unnecessary costs, serving to slow ZEV adoption. [EPA-HQ-OAR-2019-0055-1168-A1, pp.120-121]

EPA states its belief that the proposed battery and fuel cell durability requirements for BEVs and FCEVs would ‘help to ensure consistency in product quality as these technologies become increasingly available in larger portions of the heavy-duty fleet.’137 As noted above, manufacturers are sufficiently motivated to ensure product quality. Manufacturers want to sell the products that fleets want to buy—and with ZEVs, fleet motivations are already well-aligned with environmental benefits. The requirements of the Proposed Rule would only serve to stifle market forces, add cost, and ultimately slow adoption of these technologies. [EPA-HQ-OAR-2019-0055-1168-A1, p.123]

137 Id. at 17,559.

EPA’s proposed requirements for generating NOx credits would in fact undermine the notion of consistency in the ZEV market by specifically creating two different ‘classes’ of ZEVs. ZEVs that are produced to generate NOx credits will be subject to much stricter requirements for longer periods of time, while non-credit-producing ZEVs will be subject to no durability requirements, and be held to much shorter useful life and warranty periods. This will create two tiers of ZEVs:

- Credit-producing ZEVs with long, expensive warranty periods, long certified useful lives, and (as discussed above) oversized batteries which are intentionally capacity-limited
- Non-credit-producing ZEVs with shorter warrantees, shorter useful life periods, and much more freedom and flexibility regarding their power source—and no EPA-guaranteed durability. [EPA-HQ-OAR-2019-0055-1168-A1, p.123]

This will necessarily lead to market confusion and uncertainty. Fleets will not be aware or, nor be interested in, the certification strategies that manufacturers used to generate credits or not, but they will know that they can buy cheaper products, or more expensive, less-flexible products. [EPA-HQ-OAR-2019-0055-1168-A1, p.123]

Not only will this lead to inconsistency in the marketplace for ZEVs, it will create an uneven playing field for manufacturers. Manufacturers that produce a significant legacy portfolio of conventionally-powered vehicles will need to generate NOx credits—since, as we have demonstrated, EPA’s proposed diesel regulations are not feasible. Smaller manufacturers, who can afford to sell only ZEVs in targeted markets where ZEVs are most likely to be successful, will not face such challenges and will offer ZEVs without these expensive EPA requirements. [EPA-HQ-OAR-2019-0055-1168-A1, p.123]

The upshot will be that manufacturers who are best positioned to develop the long-term solutions for difficult ZEV applications will be forced to significantly reduce sales in markets that are not technically ripe for ZEV adoption. Meanwhile, smaller ZEV-only manufacturers will have an advantage in ZEV-ripe applications, since they won’t be burdened by onerous EPA requirements for longevity, warranty, and useful life. The market impacts of such a situation are dramatic. EPA will not realize its goals of consistent product quality, and may disrupt the entire market as no legacy products will be available. Such an uneven approach, which gives so much advantage to non-traditional OEMs, cannot be tolerated. While Daimler Truck is aggressively pursuing a

ZEV future, we cannot do so competing against companies playing by different rules. EPA must assure a level playing field. [EPA-HQ-OAR-2019-0055-1168-A1, pp.123-124]

Daimler Truck has also investigated EPA's proposed test procedure for hydrogen fuel cells and discussed this proposed test with our fuel cell suppliers, and find similar concerns with the proposed test procedures. EPA's test procedures must be developed in concert with truck, battery, and fuel cell manufacturers to adequately capture the degradation modes of these vehicles. [EPA-HQ-OAR-2019-0055-1168-A1, p.123]

Organization: *Ford Motor Company (Ford)*

However, given the uncertainty in the heavy-duty commercial truck segment about the durability of ZEV high-voltage batteries and fuel cells, we recommend that partial NOx credits be available for ZEVs with a declared full useful life below the designated full-useful life of the particular engine service class. This regulatory flexibility is appropriate in light of the emissions reductions achieved and will be vital to ensuring broader deployment of heavy-duty ZEVs. [EPA-HQ-OAR-2019-0055-1300-A1, p. 4]

Organization: *General Motors LLC (GM)*

In medium- and heavy-duty applications, BEVs and FCVs may be used in emissions reducing applications that do not accumulate mileage, such as providing electricity to a job site. [EPA-HQ-OAR-2019-0055-1246-A1, p.6]

GM encourages EPA to exempt ZEVs from the useful life requirement to participate in the ABT program, or to reform the useful life metrics to better account for innovative emissions reducing applications of ZEVs. [EPA-HQ-OAR-2019-0055-1246-A1, p.6]

Organization: *Navistar, Inc. (Navistar)*

A well-structured credit system is critical to providing compliance flexibility for manufacturers, and can be accomplished without sacrificing emission reductions or causing backsliding. In the proposed rule, EPA is seeking to impose battery life requirements in order for NOx credits to issue. Specifically, for vehicles generating NOx credits, EPA would require that for electric vehicles ("EVs") useable battery energy must remain at or above 70 percent throughout the useful life, and for fuel cell vehicles ("FCVs") fuel cell voltage must remain at or above 80 percent throughout the useful life as a requirement of the NOx emission credit calculation. 87 Fed. Reg. at 17814. These remaining useful life percentages are based on the engine useful life warranty requirements in 40 CFR §§ 1037.102 and .120. EPA should not use the engine useful life requirements as the basis for battery and fuel cell durability requirements. The modes of operation of batteries and fuel cells are much different from engines. For example, batteries and fuel cells will likely be used as back-up power or for peak shaving. These modes of operation are unique to EVs and FCVs, and the durability of batteries and fuel cells should not be subjected to the same requirements as engines for purposes of generating NOx credits. Indeed, EPA has acknowledged that EV and FCV technologies "are in relatively nascent periods of development." 87 Fed. Reg. at 17559. Navistar urges EPA to adopt lower percentages than 70 and 80 percent, respectively, for the required percentage of battery energy and fuel cell voltage remaining at the end of the useful life period in order to generate NOx credits. [EPA-HQ-OAR-2019-0055-1318-A1, p. 5]

Organization: *NC Commerce*

We are also concerned about the proposed rules attempts to add new certification, warranty, and useful life requirements to zero-emission vehicles. This will add cost to ZEV and delay their deployment to the business community. Nearly half (49 percent) of U.S. commercial trucks are now powered by the newest generation, near-zero emissions diesel technology. It is imperative we do not impede continued progress on this front. [EPA-HQ-OAR-2019-0055-1434]

Organization: *North Carolina Assembly House of Representatives, John Faircloth*

We are also concerned about the proposed rules attempts to add new certification, warranty and useful life requirements to zero emission vehicles. This will add cost to ZEV and delay their deployment. [EPA-HQ-OAR-2019-0055-2446, p. 1]

Organization: *Tesla, Inc. (Tesla)*

Under EPA's proposal, to participate in the NOx trading provisions, manufacturers face an eligibility threshold whereby manufacturers must attest that their vehicles retain 70% useable battery energy (UBE) for a useful life of 10 years and/or 435,000 miles (and greater after MY 2027), whichever comes first.140 For reasons elaborated below, the durability requirements should be removed or substantially amended. [EPA-HQ-OAR-2019-0055-1219-A1, p.16]

140 87 Fed. Reg. at 17557-17559.

Tesla shares EPA's interest in building BEV customer assurance and increasing BEV adoption. Indeed, Tesla maintains overwhelming customer satisfaction with all its vehicles.141 As drafted, the durability requirements, however, provide no NOx emission reduction benefit, encourage a lack of customer transparency, and will harm electric vehicle uptake by imposing substantial new costs by inviting designs with hidden battery capacity. EPA should eliminate the threshold and defer any such requirement until at least the Phase 3 GHG regulations when manufacturers have adequately acquired data from the deployed BEV fleets. [EPA-HQ-OAR-2019-0055-1219-A1, p.17]

141 J.D. Power, Making Electric Vehicle Leap of Faith is Highly Satisfactory to New Owners, J.D. Power Finds (Jan . 27, 2022) (Tesla Model 3 and Model Y rank highest); Consumer Reports, The Most and Least Liked Car Brands: Rankings based on Consumer Reports' owner satisfaction survey (Feb. 1, 2022) ('This year Tesla again tops our brand-level satisfaction ranking.')

First, as a threshold to participation the durability requirement provides no additional emissions benefit. Under potential BEV inclusion in the NOx program, a heavy-duty vehicle would be able to generate early action credits from MY 2024-27 and post-MY 2027 program credits through

MY 2031. Manufacturers have only a short credit generation window and are incentivized to ensure a good initial customer experience. Indeed, the entire seven-year crediting period is far shorter than a proposed BEV useful life period. In other words, when manufacturers cease to able to generate credits the first deployed BEVs in the program will still not have reached useful life and data as to durability performance will still be sparse. Furthermore, whatever the retained UBE in any of these vehicles after 10 years/435,000 miles these deployed heavy-duty BEVs will still have emitted no NOx over their useful life. [EPA-HQ-OAR-2019-0055-1219-A1, p.17]

Second, Tesla is not aware of evidence from any OEM that heavy duty BEV battery packs can maintain the proposed 70% UBE retention over 10 years for all customer use cases. In the heavy-duty space, BEVs will borrow directly from light-duty battery chemistry (unlike moving from a gas light duty vehicle to a heavy- duty diesel). On the light-duty side, few Tesla vehicles (or any EVs) have been on the road for 10 years (Tesla's oldest Model S vehicles are just reaching such an age) and/or 435,000 miles. Furthermore, the heavy-duty cycling use case is substantially more aggressive than the light duty use case (more throughput/day, more fast charging, etc.). Allowing greater BEV deployment now via NOx program participation without requiring a durability pre-requisite would empower manufacturers to begin to deploy BEVs without regulatory risk, accumulate significant durability data, and as noted above, do so without any direct NOx emission implications. [EPA-HQ-OAR-2019-0055-1219-A1, p.17]

Third, EPA suggests that manufacturers can overcome the durability threshold by either creating larger batteries with hidden capacity that can slowly be accessed142 or by declaring a lower UBE during testing and certification than is present.143 Encouraging either of these approached is fundamentally flawed. BEV customers, just like other heavy-duty customers, will have guarantees of performance from the manufacturer. In adding new product specifications, the agency is just adding cost for more performance than what the customer/company wanted in the vehicle. Further, compelling oversized battery packs will also significantly and unnecessarily raise BEV prices and dampen deployment of the best NOx reduction technology currently available. In addition to cost and range, the hidden capacity approach negatively impacts other product performance metrics (such as range recovered during a fast-charging event), which may be more important for the heavy-duty application than battery lifetime. To that end, hiding capacity does not actually change much about the battery itself. All it does it take away utility, and further NOx emission reductions, at the beginning of life to give customers a manufactured sense of stability. Allowing full access to the battery (with reliable energy estimation) allows for maximum utility of deployed products over the entire life - something that is fundamental to the Tesla customer experience and should be present in good public policy. [EPA-HQ-OAR-2019-0055-1219-A1, p.17]

142 87 Fed. Reg. at 17559.

143 Id. at fn. 695 (allowing manufacturer to declare UBE lower than measured value in order account for degradation over useful life.).

Organization: *Toyota Motor North America, Inc. (Toyota)*

Growing the market for HD ZEV is crucial as these emerging technologies, particularly FCEVs, have promising uses in long distance transportation. However, further study is needed to determine the long-term performance of these powertrains under the new operating conditions they will encounter in heavy-duty service. Toyota supports EPA's incorporation of UNECE durability requirements of 70% usable battery energy (UBE) for BEV and 80% for fuel cell voltage (FCV) for FCEV. However, Toyota disagrees with the proposal to align BEV and FCEV useful life periods with those for an engine-based service class to generate NOx emission credits. BEV and FCEV powertrain durability is impacted by multiple factors, including duty cycles. Variations in duty cycles are likely to result in variations in ZEV powertrain performance and longevity. [EPA-HQ-OAR-2019-0055-1224-A1, p.2]

We request EPA specify a limited set of duty cycles and/or vehicle use cases, such as drayage, long haul, regional haul, local delivery, etc., and establish an appropriate durability requirement for each duty cycle to generate credits. Additionally, while early data from ZEV HD applications show good durability, and we expect future trends to be similar, the technology is still evolving. Therefore, we propose EPA begin with a lower durability requirement for the various duty cycles and reassess in three to five years' time. This will allow both EPA and manufacturers to collect data on the appropriate durability for ZEV powertrains as the technology evolves and improves. [EPA-HQ-OAR-2019-0055-1224-A1, p.2]

Toyota also finds EPA's potential requirement to provide maintenance free-of-charge as part of emission-related maintenance to be extremely burdensome. As EPA has stated, the battery or fuel cell is guaranteed to be one of the highest-cost components as part of a BEV/FCEV. Powertrain manufacturers and HD OEMs have contractual agreements and warranty coverage [EPA-HQ-OAR-2019-0055-1224-A1, p.3] which includes certain parts, performance standards, and maintenance arrangements. This proposal exceeds those agreements and would be extremely costly. [EPA-HQ-OAR-2019-0055-1224-A1, p.2]

Organization: *Volvo Group*

EPA should not apply useful life and emissions warranty requirements to ZEVs
The Volvo Group supports the EMA comments regarding useful life and warranty requirements for ZEVs generating NOx credits ("11. The Proposed Certification and Compliance Provisions Would be a Barrier to the Adoption of Medium- and Heavy-Duty ZEVs", EMA comments, pg. 106). Further, we are opposed to any application of useful life or emissions warranty to zero-emission vehicles. [EPA-HQ-OAR-2019-0055-1324-A1, p. 8]

Battery and fuel cell durability is highly dependent on loading of the power source, depth of discharge, operation, and environmental factors. Thus, warranty and durability will be highly variable and may change dependent on a specific application, or even from customer to customer within an application, based on average load, daily mileage, terrain, climate, etc. As a result, a standardized determination of durability is not feasible. [EPA-HQ-OAR-2019-0055-1324-A1, p. 8]

Additionally, the Volvo Group does not have sufficient in-use data to determine what battery or fuel cell state of health (SOH) is achievable at the current 435,000-mile useful life, let alone at the increased 600,000- and 800,000-mile proposed values. Nor do we expect to have this data available for approximately five to eight years. [EPA-HQ-OAR-2019-0055-1324-A1, p. 8]

As a result, we urge EPA not to apply useful life criteria to zero-emission vehicles. Barring EPA's acceptance of this request, EPA must work with manufacturers to evaluate actual in-use durability achievements prior to setting any level of useful life or required emissions warranty. [EPA-HQ-OAR-2019-0055-1324-A1, p. 9]

EPA Summary and Response

Summary:

Several commenters provided perspectives on the proposed useful and warranty periods, as well as the proposed requirements for battery and fuel cell performance over the useful life period (referred to as "durability requirements" in the proposal). [39] Commenters supporting the proposed requirements stated that the proposal would provide assurance to owners and operators that ZEVs are designed to be as durable as conventional vehicles, as well as ensure real-world emissions reductions. They further stated that durable ZEVs are necessary to ensure success of the technologies and support robust secondary market since some fleets only buy second market vehicles. Commenters suggested that EPA require the same durability demonstration process for all ZEVs, regardless of whether they generate NOx emissions credits, and, in later years of program, require manufacturers to age/cycle the batteries and/or fuel cells prior to conducting the proposed multicycle test procedure. One commenter supports EPA adopting the UNCE percentages for remaining battery useable energy and fuel cell voltage, as proposed, but would like EPA to start with lower requirements and reassess in three to five years. Other commenters who didn't specifically support or oppose the proposed requirements suggested simply that EPA adopt percentages lower than the proposed 70 and 80 for remaining battery useable energy and fuel cell voltage, respectively. Commenters also stated that EPA should not use engine useful life periods as the basis for battery or fuel cell useful life since ZEVs are used in different applications than conventionally fueled vehicles (e.g., supplying power to the grid) and therefore shouldn't be held to the same requirements as engines for the proposes of generating credits.

Some commenters opposing the proposed useful life and warranty requirements stated that they are unreasonable. They further argued that EPA should not apply useful life and warranty requirements to ZEVs, while other commenters suggested that EPA allow partial NOx credits for useful life less than what's required for particular engine service class. Commenters urged EPA to consider ZEV applications that do not accumulate mileage when setting useful life requirements. They noted that the same ZEV powertrain may be used in different vehicle classes,

[39] We proposed that manufacturers who choose to generate NO_X emission credits from BEVs or FCEVs would certify to the emission standards, useful life values, and warranty periods of an engine-based primary intended service class, as specified in proposed 40 CFR 1037.102(b). We further proposed that manufacturers choosing to generate NO_X emissions credits from ZEVs would be required to meet battery or fuel cell performance requirements over the useful life of the vehicle, where throughout useful life, useable battery energy (UBE) would remain at 70 percent or greater and fuel cell voltage (FCV) would remain at 80 percent or greater of the initial value of a BEV or FCEV, respectively, that was used to generate NO_X emissions credits.

and therefore subject to different useful life and warranty requirements. Commenters were generally concerned with the variety of duty-cycles that HD ZEVs could be used in and how those different duty-cycles would impact battery and fuel cell durability, or performance over the useful life period. Commenters opposing the proposed requirements for battery and fuel cell performance over useful life further argued that the requirements do not provide NO_x emission reduction benefit and could encourage a lack of customer transparency. They also stated that the proposed requirements could result in larger batteries or hidden battery capacity, these and other commenters expressed concerns about the proposed requirements adding costs to ZEVs, which they stated would then decrease ZEV purchases. They noted that based on the variety of use cases in heavy-duty industry, manufacturers prioritize different characteristics (e.g., ability to charge quickly vs. longer range driving) and customers should have full access to the battery with reliable energy estimation. Commenters also argued that there is insufficient data available to set performance requirements for battery useable energy and fuel cell voltage, and therefore EPA should allow manufacturers to deploy HD ZEVs without regulatory requirements to acquire durability data. Finally, commenters stated that EPA's proposal for manufacturers to provide battery or fuel cell maintenance free of charge as part of emissions-related maintenance is overly burdensome and would be extremely costly because it would exceed current contracts and warranty coverage between powertrain manufacturers and vehicle manufacturers.

<u>Response</u>:

As discussed in Section 12.6.1, EPA is not finalizing the proposed allowance for manufacturers to generate NO_X emissions credits from ZEVs. Since we are not allowing NO_X emissions credits from ZEVs, we are also not finalizing the proposed useful life and warranty periods, or the proposed durability requirements for battery and fuel cells to meet certain performance requirements over the useful life, for ZEVs used to generate NO_X emissions credits.

We recognize that one commenter urged EPA to require the same durability demonstration process for all ZEVs, regardless of whether they generate NO_x emissions credits; however, we did not propose that the testing and performance requirements for battery and fuel cells over the useful life would apply to all ZEVs and thus are not finalizing such an approach at this time. We note that the final requirements provide consistent requirements for manufacturers certifying ZEVs to criteria and GHG emissions standards. We intend to continue to consider the perspectives included in this comment and the other comments in this Section 12.6.5 when developing future rulemakings relevant to heavy-duty ZEVs.

12.7 Production volume allowance

<u>Comments by Organizations</u>

Organization: *Alliance for Vehicle Efficiency (AVE)*

In the Proposal, EPA discusses "Other Flexibilities Under Consideration" 12 Here, EPA is considering providing additional flexibilities that will allow for the production of engines with much higher in-use emissions through the year 2032. These flexibilities would allow over 5% of heavy-duty trucks to emit NO_x and PM at levels 10 times higher than what Option 1 proposes to take effect in 2031. This flexibility will unnecessarily subject the public, particularly those in high-risk areas, to additional decades of high NOx emissions and related adverse health effects. AVE asks EPA to reconsider the offering of these flexibilities. [EPA-HQ-OAR-2019-0055-1280-A1, p. 6]

12. Federal Register / Vol. 87, No. 59 / Monday, March 28, 2022, at 17563

Organization: *Allison Transmission, Inc. (Allison)*

As proposed, beginning with MY 2027, more stringent GHG and NOx standards would apply for all heavy-duty vehicle OEMs. Limited exceptions apply, but most heavy-duty vehicles are addressed in this rulemaking.65 EPA, however, indicates that they will consider flexibility for engine manufacturers to certify up to 5 percent of their total production volume to pre-MY 2027 standards where the vehicles involved would be low-volume specialty vocational vehicles such as fire trucks.66 [EPA-HQ-OAR-2019-0055-1231-A1, p.31]

65 Proposed 40 C.F.R. §1036.5.

66 87 Fed. Reg. at 17,565.

- In addition to such flexibility, EPA should consider additional means to ease regulatory burdens for smaller OEMs. For example, the CARB Advanced Clean Trucks Low Volume Exemption allows small OEMs with fewer than 500 average annual vehicle sales in the state over the past three model to be able to generate ZEV credits, but vehicle sales do not generate the accompanying ZEV deficits.67

67 13 CCR §§1963- 1963.5(c). See also Definitions 21(e).

- CARB also allowed for exemptions within the Heavy-Duty Omnibus Rule for certain vocations such as for transit agencies, motorcoach, refuse and heavy-haul given the need for specialized capabilities, along with lower volumes. EPA should consider allowing for similar, specialized exemptions or extensions in the context of this rulemaking for applications which will require additional time to cost-effectively control emissions.[EPA-HQ-OAR-2019-0055-1231-A1, p.31]

Organization: *California Air Resources Board (CARB)*

- CARB opposes the provisions for ‘Other flexibilities under consideration’ and ‘Production volume allowance for model years 2027 through 2029’ as described in pages 17563 through 17565 of the Federal Register. [EPA-HQ-OAR-2019-0055-1186-A1, p.2]

U.S. EPA is seeking comments on considering providing additional flexibilities that would allow manufacturers to certify up to 5 percent of their total production volume of 2027 through 2029 MY medium and heavy HDEs to the current federal pre-MY 2027 engine provisions. [EPA-HQ-OAR-2019-0055-1186-A2, p.56]

Again, CARB staff opposes U.S. EPA finalizing a flexibility that would allow engine manufacturers to certify up to 5 percent of their production volume in a given MY in MY 2027 through 2029 medium and heavy HDEs to the current federal standards for the MY. The justification provided for considering this flexibility is to provide engine and vehicle manufacturers additional lead time to redesign low sales volume products to accommodate the technologies needed to meet the proposed more stringent engine emission standards. CARB staff does not agree with the justification provided by U.S. EPA. CARB staff believes there is enough lead time between now and 2027 to develop the technologies and overcome any packaging challenges. Since HDEs last for many years before they are scrapped, these flexibilities together with the other flexibilities mentioned above could result in significant emissions impacts for many years to follow creating extreme difficulty for California and other impacted states to achieve air quality goals. If U.S. EPA decides to move forward with this flexibility, and with the described restrictions, then CARB staff recommends that those engines emissions should be offset with ABT emission credits to protect our vulnerable impacted communities. [EPA-HQ-OAR-2019-0055-1186-A2, p.56]

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

EPA has requested comment on exempting a portion of engines from compliance with its updated emissions standards by allowing them to instead comply with pre-MY 2027 requirements through MY 2029. Id. at 17,565. That exemption is unnecessary, and EPA should not adopt it. The Proposal states that EPA is considering an allowance for up to 5% of a manufacturer's production volume within the Medium HDE or HHDE families that manufacturers show would be used in low volume, specialty vocational vehicles. Id. The purported reason for such an allowance would be to provide 'lead time and flexibility to redesign' those vehicles. Id. EPA's Proposal provides more than adequate lead time to meet requirements in MY 2027. See Comments of CARB, to be filed in Docket EPA-HQ-OAR-2019- 0055 on May 16, 2022. And to the extent that some vehicles present unique design difficulties, manufacturers can and should generate cleaner engines to compensate for those few nonconforming engines through the standards' ABT provisions. See Section IV.E, supra (noting likely excess of credits). But if EPA does adopt an exemption, it should identify the specific vocational categories for which redesigns will be infeasible, and limit any exemption to those categories alone. [EPA-HQ-OAR-2019-0055-1302-A1, p.63]

Organization: *Cummins Inc. (Cummins)*

Cummins also recommends a low-volume legacy engine flexibility for the most challenging applications. EPA requested comment on a 5% annual sales flexibility to address specialty vehicle applications. Specifically, Cummins recommends EPA's suggested 5% annual sales cap for current NOx level engines. Cummins recommends further constraining this flexibility to the following engines and vehicles: ≥525 hp engine family sales into any vehicle application or any engine sales that are directed for installation in the following Part 1037 vehicle categories: heavy-haul tractors and custom chassis motor homes, concrete mixers, and emergency vehicles. All those engine and vehicle categories have clear EPA definitions, and most have very low average annual vehicle miles traveled. Therefore, a 5% of sales cap would be enforceable and constrained and would lead to a much lower percentage of additional emissions inventory. [EPA-HQ-OAR-2019-0055-1325-A1, p. 9]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

The credit program that EPA proposes is not, however, sufficiently flexible to allow manufacturers to spread their investments and their limited development resources adequately. Under EPA's proposal (and in concert with EPA's other proposals), regardless of a manufacturer's credit balance, they will be required to implement, in MY 2027:

- Emissions systems with a maximum family emission limit (FEL) cap of 0.15 g/hp-hr NOx. o It should be assumed most engines today, regardless of their certification values, could not be certified with an FEL cap of 0.15 g/hp-hr NOx, or manufacturers would do so to generate credit under the existing programs.
- New closed crankcase ventilation systems.
    - This will require, in some cases, dramatic and expensive redesign efforts, up to and including changes to the casting of the engine blocks
- New OBD and inducement requirements.
    - This will require significant software development, and may include changes to vehicle to display signals that EPA envisions.
- New useful life requirements.
    - This could require the redesign of critical emissions relevant components for greater longevity.
- New standards for criteria pollutants besides NOx.
- Many other requirements that could require development beyond the proposed low-NOx standards. [EPA-HQ-OAR-2019-0055-1168-A1, p.84]

So while manufacturers may use NOx credits to reduce the NOx FELs that they must certify to in later model years, they are still required to engage in expensive and time-consuming engine development programs to meet all of the other, non-NOx requirements. In fact, developing new engines that meet all of the above standards—and then, some years later, developing again to further reduce NOx—is very likely to be more expensive than a single development step without any NOx credits. In effect, such an approach creates an 'extra step,' which Daimler Truck believes is not cost effective or beneficial to the manufacturers or the environment. [EPA-HQ-OAR-2019-0055-1168-A1, p.84]

What manufacturers need is a program that will enable them to carry over some of their existing MY 2026 engines and vehicles entirely into MY 2027 and beyond, at least for a few years. This is necessary so that manufacturers can adequately manage their investments, and prioritize technology adoption in the applications that make the most sense—during the transition to new UL NOx technologies, but more importantly, during the transition to ZEVs. [EPA-HQ-OAR-2019-0055-1168-A1, p.84]

For example, manufacturers may decide that certain classes are ripe for ZEV adoption: school buses, walk-in vans, etc. A manufacturer may wish to subsidize small volumes of existing diesel engines using NOx credits to support these applications with the intention to never develop a next-generation UL NOx engine for these applications, but rather, to ramp up ZEV penetration in these applications and obviate the need for diesels in these categories altogether. EPA's proposal does not allow this approach, since manufacturers would be required to develop new engines, with new reduced emissions, new closed-crankcase architectures, longer useful life periods, etc. Under EPA's proposal, manufacturers would be required to engage in a significant, expensive development program regardless of their NOx credit positions. This is money that could be better spent on enabling those ZEV platforms. [EPA-HQ-OAR-2019-0055-1168-A1, pp.84-85]

Similarly, EPA's proposal prevents manufacturers from delaying engine development programs for the purposes of spreading development costs, and managing their human and capital resources. If a manufacturer wished to delay development for a high-horsepower, low-volume, vocational application to manage this R&D investment wisely, he may have sufficient NOx credits to do so, but EPA's other rules prevent such a strategy. [EPA-HQ-OAR-2019-0055-1168-A1, p.85]

Effectively, EPA's proposed NOx credit strategy only serves to manage risk associated with very low NOx levels. It does not allow a manufacturer to adequately manage its investment, or to prioritize technology adoption—since manufacturers will have to engage in costly development and validation for all platforms for MY2027. [EPA-HQ-OAR-2019-0055-1168-A1, p.85]

EPA should consider alternate credit program options that can be used to truly manage investment and to prioritize appropriate applications by allowing manufacturers to leverage credits to stage development programs. CARB has developed similar (although overly complicated) provisions in its Omnibus rule by providing a certification path for so called 'legacy engines,' and additionally by providing an alternative certification path for emergency vehicles and for low-volume high horsepower engines. [EPA-HQ-OAR-2019-0055-1168-A1, p.85]

To enable manufacturer flexibility, EPA must delay the implementation of the other standards in the Proposed Rule for engines that are certified using NOx credits, at least for a transitional period. Delaying such standards to MY 2031 for engines that use NOx credits would be a reasonable compromise and would allow manufacturers to plan to transition all of their products to UL NOx in a manageable and affordable fashion, or, where possible, transition some of them straight to ZEVs. [EPA-HQ-OAR-2019-0055-1168-A1, p.85]

Organization: *Moving Forward Network (MFN)*

The current program has not resulted in the emissions reductions originally promised, owing in large part to shortcomings in the certification procedures on the books today. These are detailed extensively in the NPRM in the agency's justifications for the low-load cycle, increases in warranty and useful life, and updates to the off-cycle program, and more. [EPA-HQ-OAR-2019-0055-1277-A1, p. 33]

As detailed in the section on credit provisions (Section IV.D), particularly the transitional credit program, there is no need for additional flexibility for the dirty diesel engines held to today's weak standards. In fact, there is already far too much flexibility in the proposal which undermines the standards and will eat away at the proposed reductions in damaging NOx emissions this rule is purported to target. [EPA-HQ-OAR-2019-0055-1277-A1, p. 33]

It is abhorrent that EPA would consider further weakening the rule by giving credits to legacy engines certified to 20-year-old standards. Furthermore, the engines found in these vehicles are generally produced by the same large-volume manufacturers that are found in the highest mileage vehicles, Class 8 tractors. In fact, the largest engine manufacturer, Cummins, boasts of one of the identified applications that "more firefighting and EMS professionals depend on Cummins than any other diesel engine."137 [EPA-HQ-OAR-2019-0055-1277-A1, pp. 33 - 34]

137. https://www.cummins.com/engine-applications/fire-and-emergency

The proposed 5 percent exemption is patently absurd—from Cummins alone, such a target could mean that over 10,000 vehicles could be exempted from the proposed standards. Factor in Detroit Diesel and Ford engines, two other high-volume vocational engine manufacturers, and that would mean 20,000 vehicles in 2027-2029 could be exempted at standards that emit nearly 6 times more NOx emissions on the FTP cycle than the already-weak proposed Option 1, a number that is larger when you consider the differences in off-cycle certification and other protections which strengthen real-world emissions reductions compared to the current program. [EPA-HQ-OAR-2019-0055-1277-A1, p. 34]

The proposed exemption is so large that these vehicles could easily represent 20-25 percent of the total NOx emissions from 2027-2029 vehicles. This proposal is as though EPA were creating a loophole comparable to the glider vehicle provisions it limited in the Phase 2 regulations. Moreover, because these vehicles are certified to a different crediting process, whose credits are not eligible to be transferred according to the proposal (87 FR 17553), it is not even clear that these vehicles will be credited against a manufacturer's annual average requirements, which means those emissions will not be made up for in gains elsewhere. At least if such engines were credited against EPA's already too-high FELs, there would be some attempt at recovering those lost emissions! [EPA-HQ-OAR-2019-0055-1277-A1, p. 34]

Finally, 100 percent of diesel engines certified since 2019 have been certified at or below the current average requirement. There is no indication that manufacturers need the added flexibility provided, and the Omnibus standards in effect in 15 percent of the market for new vehicles already require engines below the current standard. This argument is further detailed in Section III.B.6.1 above, in the technical justification opposing a high FEL. [EPA-HQ-OAR-2019-0055-1277-A1, p. 34]

Even under the limited low-volume constraints supposed by EPA, it is possible to achieve a standard much reduced from the current levels, and EPA should eliminate any exemption to such reductions in its finalization of the rule, particularly those that would further the unprotective standards currently on the books. [EPA-HQ-OAR-2019-0055-1277-A1, p. 34]

Organization: *National Association of Clean Air Agencies (NACAA)*

NACAA does not support the inclusion of manufacturer production volume allowances for specialty vocational products or any other engine categories.[EPA-HQ-OAR-2019-0055-1232-A1, p. 14]

Another flexibility on which EPA seeks comment is production volume allowances for MY 2027 through 2029 medium HD engines and heavy HD engines. Based on EPA's description of this option manufacturers would be allowed to continue to certify up to 5 percent of their total production volume of medium and heavy HD diesel engines in each of MYs 2027 through 2029 to "pre-MY 2027 engine provisions"; that is, these engines would be exempt from the new emission standards and allowed to continue to comply with the 21-year-old 200-mg NOx standard. [EPA-HQ-OAR-2019-0055-1232-A1, p. 14]

EPA says this exemption from the new emission standards for the first three MYs "may" be necessary to allow manufacturers lead time and flexibility to redesign some low sales volume specialty vocational products to accommodate the technologies needed to meet the new emission standards. EPA offers as its only example fire trucks, for which, the agency contends, not being subject to the new emission standards during the first three MYs would be "appropriate" because of potential challenges to engine, chassis and body manufacturers of packaging new emission controls. [EPA-HQ-OAR-2019-0055-1232-A1, p. 14]

Not only is this flexibility unwarranted, it would undermine the effectiveness of the rule to reduce emissions and protect public health. Allowing 5 percent of a manufacturers' total production volume of HD engines to meet a 200-mg/hp-hr NOx standard means that one in every 20 engines would be allowed to emit NOx at a level that is an order of magnitude higher than the standard NACAA recommends for MYs 2027-2029, with excess emissions of 180 mg/hp-hr, and to do so with no requirement for mitigating the increased emissions. The result would be an inventory increase of up to 45 percent for each applicable model year's production from a manufacturer with products in a single useful life and power rating category. However the excess NOx inventory could be even greater if a manufacturer elects to satisfy the 95 percent of production with low-rated power and short-useful-life engines while using the 5-percent allowance for engines with a much longer useful life and higher rated power output (such as the large engines that are typically used in EPA's own example). Useful life can vary by a factor of three or four and power rating by a factor of two or three, depending on the details of the engine models involved, but could multiply the excess NOx inventory beyond the 45-percent simplest case above. [EPA-HQ-OAR-2019-0055-1232-A1, p. 14]

The agency also asks whether an exemption from the new emission standards for an interim period should be "limited to specific vocational vehicle regulatory subcategories and the engines used in them" or allowed for others as well. [EPA-HQ-OAR-2019-0055-1232-A1, p. 14]

The only fair evaluation of the emissions impact of this "flexibility" is one based on the assumption that manufacturers will use their full 5-percent allowance and apply the allowance to an engine mix of the largest, longest-lived engines. Assuming actual sales will be less than the allowed 5 percent would be highly imprudent and imperil the NOx reduction program. [EPA-HQ-OAR-2019-0055-1232-A1, p. 14]

EPA should not exempt any engines from complying with the adopted new emission standards for any amount of time and, therefore, should not adopt a production volume allowance option. [EPA-HQ-OAR-2019-0055-1232-A1, p. 15]

Organization: *PACCAR, Inc (PACCAR)*

PACCAR supports the following EMA comment: EPA has also requested comment on a 5% annual sales flexibility to address specialty vehicle applications. In that regard, EMA recommends a low-volume ‘legacy engine’ flexibility provision that a manufacturer could utilize for the most challenging applications. Specifically, EMA recommends that the final rule provide that a manufacturer may sell US 10-compliant engines in volumes up to 5% of their total annual sales volume in the same primary intended service class for a period of 3 years. EMA recommends further limiting this flexibility provision to include only engines that have low annual average miles traveled, thereby minimizing the emissions inventory consequences of this flexibility allowance. This can be achieved by allowing legacy engine sales only from the following engine and vehicle applications:

1) ≥525 hp engine family sales into any vehicle application [PACCAR respectfully submits that this lower threshold should be 510 hp]; and

2) any engine sales that are directed for installation in the following 40 CFR Part 1037 vehicle categories: heavy-haul tractors, custom chassis motor homes, concrete mixers, and emergency vehicles. All those engine and vehicle categories have very low average annual vehicle miles traveled. EMA supports EPA’s proposal to allow for limited sales of previous-Tier engines according to the limitations as described. [EPA-HQ-OAR-2019-0055-1346-A1, p.39]

EMA Comments at 132. PACCAR also proposes to add the following provision to those above:

3) Low Volume highly specialized vocational applications that will not support the installation of these Low NOx systems due to severe packaging constraints. These applications are to be reviewed and approved by EPA on a case by case basis.’ This would protect manufacturers from unforeseen issues that might arise with very specialized products. [EPA-HQ-OAR-2019-0055-1346-A1, p.39]

Organization: *Truck and Engine Manufacturers Association (EMA)*

EPA also has requested comment on a 5% annual sales flexibility to address specialty vehicle applications. In that regard, EMA recommends a low-volume “legacy engine” flexibility provision that a manufacturer could utilize for the most challenging applications. Specifically, EMA recommends that the final rule provide that a manufacturer may sell US10-compliant engines in volumes up to 5% of their total annual sales volume in the same primary intended service class for a period of 3 years. EMA recommends further limiting this flexibility provision to include only engines that have low annual average miles traveled, thereby minimizing the emissions inventory consequences of this flexibility allowance. This can be achieved by allowing legacy engine sales only from the following engine and vehicle applications: 1) ≥525 hp engine family sales into any vehicle application; and 2) any engine sales that are directed for installation in the following 40 CFR Part 1037 vehicle categories: heavy-haul tractors, custom chassis motor homes, concrete mixers, and emergency vehicles. All of those engine and vehicle categories have very low average annual vehicle miles traveled. EMA also supports EPA's proposal to allow for limited sales of previous-Tier engines according to the limitations as described. [EPA-HQ-OAR-2019-0055-1203-A1, p. 135]

Organization: *Volvo Group*

The Volvo Group appreciates the following EPA specialty vocational comments and requests that EPA consider a specialty vehicle definition that considers applications where aftertreatment is mounted off the frame rails. "We are considering a flexibility allowing engine manufacturers, for model years 2027 through 2029 only, to certify up to 5 percent of their total production volume of heavy-duty highway compression-ignition (CI) engines in a given model year to the current, pre-MY 2027 engine provisions of 40 CFR part 86, subpart A. The allowance we are considering would be limited to Medium HDE (Heavy Duty Engine) or Heavy HDE engine families that manufacturers show would be used in low volume, specialty vocational vehicles." (87 FR at p. 17563.) [EPA-HQ-OAR-2019-0055-1324-A1, p. 6]

Organization: *Wisconsin Department of Natural Resources (WDNR)*

In addition to the technical program elements included in Options 1 and 2 of the proposal, EPA is taking comment on several "other flexibilities under consideration", including production volume allowances. As described in the proposed rule, this provision would allow engine manufacturers, for model years 2027 through 2029 only, to certify up to 5 percent of their total production volume at pre-MY 2027 engine standards. [EPA-HQ-OAR-2019-0055-1162-A1, p. 4]

EPA should not finalize the production volume allowance described in this proposal without further justification. Finalizing this provision would allow manufacturers to produce engines that emit significantly more NOx (as much as five times more) for MY's 2027 through 2029, greatly reducing the benefits of the proposed standards. These provisions are intended to allow manufacturers time to understand and address in-use deterioration of engines; however, due to the importance of the NOx emission reductions from this rulemaking, EPA should work with manufactures to ensure these issues are analyzed and addressed prior to the implementation of this rule in MY 2027 wherever possible. If EPA intends to finalize any volume allowance provision, it must provide strong technical justification for each engine category subject to the provision. [EPA-HQ-OAR-2019-0055-1162-A1, p. 4]

EPA Summary and Response

See preamble Section IV.G for EPA's summary and response to comments on the request for comment on a potential flexibility to allow engine manufacturers, for model years 2027 through 2029 only, to certify up to 5 percent of their total production volume of heavy-duty highway CI engines in a given model year to the currently existing, pre-MY 2027 engine provisions of 40 CFR part 86, subpart A.

16 General engine and vehicle testing provisions under 40 CFR parts 1065 and 1066

16.1 Measuring catalyst temperature for vanadium-based SCR systems

Comments by Organizations

Organization: *Cummins Inc. (Cummins)*

EPA is proposing to codify EPA Guidance CD-16-09 “Certification of Diesel Engines Equipped with Vanadium-Based SCR Catalyst” by adding requirements to the standard-setting parts for on- and off-highway engines to prevent vanadium sublimation and to protect the catalyst from high temperatures. The proposal also adds a procedure for identifying the sublimation threshold temperature, specified in §§1065.1113 through 1065.1121. Cummins supports the intent of those proposed additions, but we recommend the following improvements. [EPA-HQ-OAR-2019-0055-1325-A1, p. 18]

First, it is possible for vanadium-based catalyst wash-coat materials to mechanically shear from the substrate and result in a false-positive detection of sublimated vanadium, when in fact it was only physically transported in the solid phase within the experimental setup. Cummins recommends that the test procedures should be modified to either prevent such a false-positive detection, or EPA should allow for such false-positive results to be voided if physical transport of solid phase vanadium is known to have occurred. To minimize shear stress differences between different lab-to-lab experimental setups, EPA should restrict the allowable sample length to be 2 – 3 inches, instead of EPA’s proposed 1 – 3 inches. At a constant space velocity, restricting the sample length to 2 – 3 inches decreases the shear stress differences by a factor of two, versus EPA’s proposed 1 – 3 inch specification. Cummins supports EPA’s prescribed test procedure space velocity of 35 k/h, but Cummins recommends that the detection limit unit of measure should be a gaseous sample volume normalized concentration, in μg/m3, not a solid sample mass normalized concentration (e.g., pg/g) that includes the mass of the recovered alumina, a portion of the ground quartz tube and the quartz wool. Combining the constant space velocity requirement with Cummins' recommended μg/m3 limit of detection unit of measure unambiguously specifies the procedure and detection limit. In contrast, the total mass-based approach could lead to false negatives if the denominator is sufficiently large, due to a large fraction of the mass merely being part of the experimental setup. [EPA-HQ-OAR-2019-0055-1325-A1, p. 18]

Cummins also requests the addition of an option in Part 1065 for manufacturers to request EPA approval of alternative vanadium sublimation test procedures that involve a system-level test with the complete aftertreatment system and potentially involve higher exhaust temperatures to demonstrate durability and feasibility under representative conditions. We request EPA clarification on whether §1065.10(c)(1) already clearly provides that option, or whether it would be more appropriate for EPA to specify that alternative test procedures may be approved by EPA in advance, in the chapeau paragraph of §1065.1113. [EPA-HQ-OAR-2019-0055-1325-A1, p. 18]

Organization: *Navistar, Inc. (Navistar)*

In particular, we support: EPA's continued support of innovation and flexibility regarding the potential use of different catalysts in SCR processes, including vanadium-based SCR catalysts; [EPA-HQ-OAR-2019-0055-1318-A1, p. 3]

In the proposed rule, EPA is proposing to codify the vanadium SCR requirements currently included in EPA's 2016 guidance (CD 1609). The 2016 guidance clarified EPA's expectations for manufacturers using vanadium-based SCR catalysts and summarized EPA's recommendations on steps manufacturers could take to protect against excessive loss of vanadium from these SCR systems. Navistar supports EPA's proposal to codify the 2016 guidance as regulatory requirements for using vanadium-based SCR catalysts. 87 Fed. Reg. at 17626. [EPA-HQ-OAR-2019-0055-1318-A1, p. 5]

Organization: *Truck and Engine Manufacturers Association (EMA)*

EPA is proposing to codify the Vanadium SCR requirements currently included in Guidance CD 1609. The proposed provisions of §§ 1065.1113 through 1065.1121 are reflective of that long-standing guidance, and provide reasonable requirements related to the determination of sublimation temperatures for the catalyst formulations proposed for certification. Manufacturers would be required to demonstrate that exhaust gas temperatures would not exceed the critical threshold temperatures, and that the system has the capability to detect upstream failures that might lead to high exhaust temperature. [EPA-HQ-OAR-2019-0055-1203-A1, p. 118]

EMA supports the proposed Vanadium SCR provisions, as applicable to HDOH, non-road and other market sectors. Those catalysts have been shown to be effective for NOx reduction and may be a key part of OEM strategies to comply with stringent tailpipe emissions requirements. The proposal provides clear methodologies to validate and certify a highly effective SCR catalyst. That said, EMA requests the addition of a provision in Part 1065 that would allow manufacturers to request EPA approval for alternative test procedures. For example, a manufacturer could propose a system-level test with the complete aftertreatment assembly, and potentially include higher exhaust temperatures to demonstrate representative durability and feasibility. [EPA-HQ-OAR-2019-0055-1203-A1, p. 118]

EPA Summary and Response

Three commenters provided perspectives on the proposed requirements to prevent vanadium sublimation and to protect the catalyst from high temperatures, as well as the proposed procedure to identify the sublimation threshold temperature for vanadium catalysts. Commenters were supportive of the proposed requirements, but two commenters suggested some adjustments for EPA to consider.

Specifically, one commenter suggested that EPA modify the measurement procedure to prevent detection of vanadium-based catalyst wash-coat materials that are physically transported in the solid phase within the experimental setup, or allow for results to be voided if physical transport of solid phase vanadium is known to have occurred. The commenter further stated that EPA should restrict the allowable sample length to be 2 – 3 inches, instead of 1 – 3 inches as proposed; the commenter stated that doing so would minimize sheer stress differences between lab environments. The commenter also stated that the detection limit unit of measure should be a gaseous sample volume normalized concentration, in μg/m3, not a solid sample mass normalized concentration (e.g., pg/g); they stated that the total mass-based approach could lead to false negatives if the denominator is sufficiently large. Finally, two commenters asked EPA to clarify whether the proposal allows manufacturers to request EPA approval of alternative vanadium sublimation test procedures.

EPA agrees with commenters that the proposed requirements for vanadium-based SCR catalysts provide important clarity for manufacturers who wish to use this type of SCR catalyst. We agree that physical transport of solid phase vanadium should be discarded from test results as it is likely that any solid vanadium present in the capture bed is a result of the test method. While the loss of vanadium catalyst could result in environmental concerns whether it is due to physical transport of solid phase or sublimated, any solid vanadium present as a result of the 1065 test procedure is very likely due to the test method itself. We do note, however, this means that when EPA is evaluating an ambient air sample of vanadium (e.g., near a construction site where V-SCR catalysts could be in use), we would collect all inhalable vanadium and consider it relevant for human health evaluation, regardless of size or indication of whether it was sublimated or abraded from the catalyst surface. EPA agrees that a 2- to 3-inch sample may help minimize shear stress differences between lab-to-lab environments; however, loss of sample due to abrasion or sheer stress is already accounted for in the procedure by measuring titanium in 40 CFR 1065.1115(f). The presence of titanium would be an indication of solid vanadium loss. The vanadium correction then takes into account the vanadium-to-titanium ratio of the catalyst. We are also aware that many labs have been testing 1-inch samples for many years and have built up a database of sample and blank test results based on this sample size. While we understand the possibility of loss of sample from the core due to sheer stress, we have not received concerns regarding this from other labs carrying out this testing as abrasion is already accounted for as described above. Therefore, we are not revising the length from what was proposed in the final test procedure. EPA agrees that the detection limit unit of measure should be a gaseous sample volume normalized concentration, rather than solid mass volume, as this will address concerns with the variable impact of dilution effect based on sample size. We are finalizing a recommended method detection limit of 15 μg/m^3 based on a target mass-based method detection limit of 2 ppm, a 60 g capture bed mass, a 0.0129 L (1" long x 1" diameter core) catalyst volume, an SV of 35,000, and an 18-hour test duration. We also agree that the units in EPA guidance document CD-16-09 have been inaccurate and that the units should be in μg instead of pg to reflect a detection limit of ppm. As described in preamble Section XII, we have clarified that manufacturers can request EPA approval of alternative vanadium sublimation test procedures as described in existing 40 CFR 1065.10(c)(7) for test procedures in part 1065. Therefore, no clarification in 40 CFR 1065.1113 is needed.

16.2 Real-time PM corrections based on gravimetric PM filter measurement

Comments by Organizations

Organization: *Alliance for Automotive Innovation (Auto Innovators)*

40 C.F.R.1065.190 PM-stabilization and weighing environments for gravimetric analysis.

We support these proposed changes remove the recommendation to measure the static change of the filter. This test is not typically performed and also not required. [EPA-HQ-OAR-2019-0055-1303-A1, p.5]

EPA Summary and Response

Thank you for your comment.

16.3 NIST-traceability

Comments by Organizations

Organization: *Alliance for Automotive Innovation (Auto Innovators)*

40 C.F.R.1065.301 Overview and general provisions.

Auto Innovators also supports the proposed changes to this section as they appear to be in line with revisions previously requested by Auto Innovators. [EPA-HQ-OAR-2019-0055-1303-A1, p.5]

EPA Summary and Response

Thank you for your comment.

16.4 Engine mapping

Comments by Organizations

Organization: *Truck and Engine Manufacturers Association (EMA)*

Numerous revisions are proposed for GEM modeling in Part 1037. GEM powertrain mapping is an incredibly complex process. To improve the understanding for all, the Agency should provide step-by-step flow charts of the powertrain mapping procedure for ICE, PHEV, and BEV powertrains. Flowcharts would greatly clarify the process, reducing confusion, avoiding wasteful errors, and saving time for both manufactures and the Agency. Similarly, we support the added regulatory flexibility to test hybrid and plug-in hybrid vehicles on either an engine dynamometer or a powertrain dynamometer. [EPA-HQ-OAR-2019-0055-1203-A1, p. 116]

One additional recommendation concerns the engine mapping procedures under §1065.510(b)(5)(ii). The preamble reads: Specifically, our proposed update to 40 CFR 1065.510(b)(5)(ii) would require manufacturers to disable any electronic controls that they report to EPA as an auxiliary emission control device (AECD) that would impact peak torque during the engine mapping procedure. Yet, in proposed §1065.510(b)(5)(ii), there is no such revision. EPA should correct this omission in the final rule. [EPA-HQ-OAR-2019-0055-1203-A1, p. 116]

EPA Summary and Response

EPA agrees with the commentor that the addition of a flow chart to 40 CFR 1037.550 will be useful, but not a necessity at this time, thus we will propose a flow chart in a future rulemaking. Regarding the requirement to disable any electronic controls reported as AECDs that would impact peak torque during the engine mapping procedure, the preamble inadvertently cited the wrong paragraph in 1065.510. This update was added to proposed 40 CFR 1065.510(a), not proposed 40 CFR 1065.510(b)(5)(ii) and is included in the final rule.

16.5 Miscellaneous engine testing amendments

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

CARB staff supports the proposal to add requirements of zero and span verification frequency, and range, zero, and span verification and following actions for 'PEMS gas analyzers used to determine bin emission values' in 1065.935(d)(4)(ii) and 1065.935(g)(5), respectively. However, CARB staff strongly recommends U.S. EPA to add language requiring email notification to the agencies (U.S. EPA and CARB) prior to any retests due to range, zero, and/or span invalidation, so that CARB and U.S. EPA staff know about the retest, including the reasons for the retest. With that notification, U.S. EPA and CARB staff can decide to ask for data of the invalidated test and the retest in a timely manner. Otherwise, we would not see any data of the invalidated test, which are not needed to be submitted unless U.S. EPA or CARB staff asks, and would only have the retest results when they submit their in-use testing report and data for their assigned engine families, which could be more than a year before U.S. EPA or CARB staff would even know about it as it should be described that a retest had to be done in the comment field of the report as in 1036.430, Reporting requirements. In addition, regarding zero- and span-drift verification in 1065.935(g)(5)(iii), CARB staff recommends U.S. EPA to clarify the consequences when PEMS gas analyzers (used to determine bin emission values) do not meet zero- and/or span-drift criteria. CARB staff assumes all the test data would be considered invalid while drift criteria are not met, but it is not clearly stated in paragraph 1065.935(g)(5)(iii). [EPA-HQ-OAR-2019-0055-1186-A2, pp.129-130]

Organization: *Cummins Inc. (Cummins)*

1065.935(g)(4)(ii)

Invalidation criteria should be as follows: Invalidate any data that does not meet the drift criterion in § 1065.550. For HC, invalidate any data if the difference the difference between the uncorrected and the corrected brake-specific HC emission values are not within ±10 % of the uncorrected results or the applicable standard, whichever is greater. [EPA-HQ-OAR-2019-0055-1325-A1, p.24]

1065.935(g)(5)(ii)

Invalidation criteria should be as follows: For HC, invalidate data if the difference between the uncorrected and the corrected brake-specific HC emission values are not within ±10 % of the uncorrected results or the applicable standard, whichever is greater. [EPA-HQ-OAR-2019-0055-1325-A1, p.24]

Organization: *Outdoor Power Equipment Institute (OPEI)*

Section 1065.650 – Emission calculations OPEI is seeking clarification, if the new parts will also affect the sub calculations before reaching the reporting value. Additionally, if a reporting value is negative will it be set to zero? (E.g. this can happen during the THC correction on CH_4 – Sub calculation.) [EPA-HQ-OAR-2019-0055-1205-A1, p.4]

EPA Summary and Response

40 CFR 1065.935

One commentor supports the proposal to add requirements of zero and span verification frequency, and range, zero, and span verification and following actions for 'PEMS gas analyzers used to determine bin emission values' in 1065.935(d)(4)(ii) and 1065.935(g)(5), respectively. EPA thanks you for your comment.

One commentor strongly recommends EPA add language requiring email notification to the agencies (EPA and CARB) prior to any retests due to range, zero, and/or span invalidation, so that CARB and EPA staff know about the retest, including the reasons for the retest. EPA does not agree with the commentor. Tests are occasionally voided due to equipment issues and EPA does not need the manufacturer to notify EPA of a voided test prior to receiving the data from the “official” in-use test; EPA receiving information about the voided tests at the same time as receiving the “official” in-use test data is sufficient.

One commentor recommends EPA to clarify in 40 CFR 1065.935(g)(5)(iii) the consequences when PEMS gas analyzers (used to determine bin emission values) do not meet zero- and/or span-drift criteria. The commentor assumes all the test data would be considered invalid while drift criteria are not met. EPA agrees with the commentor and has revised 40 CFR 1065.935(g)(5)(iii) to invalidate data for the entire shift-day if any of the NOx analyzer drift limits in paragraphs 1065.935(g)(5)(iii)(A) and (B) are exceeded. This intent was implied in the changes proposed to 40 CFR 1065.935(g)(5)(iii) and the revision for the final rule makes this clear.

1065.935(g)(4)(ii)

One commentor stated that the invalidation criteria should be “…**not** within ±10 % of the uncorrected results or the applicable standard, whichever is greater.” EPA agrees with the commentor as the intent is to invalidate the data where the difference between the corrected and uncorrected result is greater than 10 %. Therefore, we have added “not” to 40 CFR 1065.935(g)(4)(ii).

1065.935(g)(5)(ii)

One commentor stated that the invalidation criteria should be “…**not** within ±10 % of the uncorrected results or the applicable standard, whichever is greater.” EPA agrees with the commentor as the intent is to invalidate the data where the difference between the corrected and uncorrected result is greater than 10 %. Therefore, we have added “not” to 40 CFR 1065.935(g)(5)(ii).

40 CFR 1065.650(a)

One commentor requested clarification on if the new sentences added to paragraph (a) of 1065.650 will affect the sub calculated value prior to calculating the reporting value. EPA would note that negative values resulting from sub calculations should never be set to zero unless specified elsewhere in 40 CFR part 1065 or the standard setting parts. The additional language added to paragraph (a) of 40 CFR 1065.650(a) makes it clear that negative values should be carried forward until the final emission calculation, with the exception of the chemical balance where values may need to be set to zero to obtain convergence. 40 CFR 1065.650(g) then make it clear that any negative mass or mass rates should be set to zero for calculating brake-specific emissions, but should be left negative for drift validation.

One commentor asked: If a reporting value is negative, will it be set to zero? (e.g., this can happen during the THC correction on CH_4 – Sub calculation). EPA is not clear on exactly what the commentor’s example is intending to cover. In regards to a reporting value for compliance with an emission standard, this is governed by 40 CFR 1065.650(g) where it states “If a measured mass (or mass rate) is negative, set it to zero for calculating composite brake-specific emissions, but leave it unchanged for drift validation.”

16.6 Other comments on general engine and vehicle testing provisions under 40 CFR parts 1065 and 1066

Comments by Organizations

Organization: *National Propane Gas Association (NPGA) and Propane Education & Research Council (PERC)*

We suggest the following modifications to the Proposed Option 1:

- 4. **Fuel Quality Changes to Propane**: We urge the agency to modify the butanes standard for propane as detailed at Part 1065.720.12 Table 1 includes a butanes standard at a maximum value of 0.05 m3/m3 as per ASTM D2163.13 We ask that the maximum value for butanes is revised to 0.1 m3/m3. There are multiple advantages presented with a modified butanes maximum. First, it slightly lowers the vapor pressure for propane, which makes it more conducive to direct liquid injection. Additionally, butane has a lower light off temperature and therefore this will further aid in mitigating Carbon Monoxide (CO) and Hydrocarbon (HC) emissions from propane vehicles. [EPA-HQ-OAR-2019-0055-1263-A1, p.3]

12 40 C.F.R. 1065.720(a) (2022); see also supra note 1, at 17867.

13 40 C.F.R. 1065.720(a) (2022).

EPA Summary and Response

EPA disagrees with NPGA and PERC. We did not propose a change to the butane value in 40 CFR 1065.720. While the commentor states that there are multiple advantages to increasing the maximum butane limit on the certification fuel, NPGA and PERC did not provide any data on what effect this change would have on the stringency of the emission standards other than stating it would help lower CO and HC emissions. Further, they did not provide any data showing what the typical butane values are of “in-use” fuels and how these values compare to the current certification fuel butane content and their requesting new butane maximum. If the intent of their change is to help reduce CO and HC, then the change in certification fuels also needs to translate to real world butane values at the pump to ensure real world emission reductions.

Organization: *Outdoor Power Equipment Institute (OPEI)*

Section 1065.720 – Liquefied petroleum gas Today’s Section 1065.720 is named ‘Liquefied petroleum gas’. With the Amendment package, it is intended to rename the section to ‘Data requirements’. Section 1065.695 is currently also named ‘Data requirements’. OPEI believes the renaming of Section 1065.720 may be an oversight (same as 1065.695) and recommends no change to Section 1065.720 title – ‘Liquefied petroleum gas’. [EPA-HQ-OAR-2019-0055-1205-A1, p.4]

EPA Summary and Response

EPA agrees with the commentor. We did not intend to propose to change the title of section 1065.720 to "Data Requirements". This was a publication error in the proposed rule amendatory text and we are not finalizing a change to the title in the final rule. Section 1065.720 will continue to be titled "Liquefied petroleum gas."

17 Rulemaking process, analysis, and legal requirements

17.1 Rulemaking Procedures for Small Businesses

Comments by Organizations

Organization: *American Truck Dealers (ATD)*

Importantly, the COVID-19 pandemic and related supply-chain shortages, inflation, and strong freight volumes have resulted in high new and used CMV prices for now and the foreseeable future.11 Given that the majority of ATD members are small businesses and that almost all (98%) of U.S. fleet owners are small businesses, current and foreseeable market conditions are especially concerning. Thus, when evaluating the potentially dramatic market impacts of its NOx proposal, it is incumbent upon EPA to fully evaluate potential impacts on small business dealerships and their small business customers. [EPA-HQ-OAR-2019-0055-1321-A1, p. 4]

11. Equipment Radar, New & Used Medium & Heavy-Duty Truck Prices Will Likely Continue Rising Amid Components Shortages (Sept.2021); Fleet Equipment, Commercial Vehicle Industry Faces An 'Everything' Shortage (Dec. 2021).

Organization: *American Trucking Associations (ATA)*

ATA has established 12 fleet Guiding Principles that should be considered in the development of HD2027 including:

• Impacts on the 97% of trucking companies classified as small business must be considered. [EPA-HQ-OAR-2019-0055-1326-A1, p. 5]

Organization: *National Association of Chemical Distributors (NACD)*

Moreover, it can be reasonably inferred that the EPA's estimated economic impact underestimates how the rule will affect small businesses. … Also, while the proposed rule did not predict a significant impact on a substantial number of small entities, this analysis only considered ***manufacturers*** of heavy-duty vehicles to be affected. There are a wide range of other entities, a substantial number of them small businesses, that will also be impacted. Nearly all stakeholders in the supply chain use heavy-duty trucks to deliver their products to their customers, be it from ports, rail yards, warehouses, or intermodal transportation facilities. The

EPA's economic analysis in its final rule should reflect the entire universe of affected entities so the full economic impact of this regulation can be appreciated. [EPA-HQ-OAR-2019-0055-1279-A1, p. 2]

Organization: *Owner-Operator Independent Drivers Association (OOIDA)*

Furthermore, OOIDA disagrees with EPA's certification that this action will not have a significant economic impact on a substantial number of small business entities under the Regulatory Flexibility Act. [EPA-HQ-OAR-2019-0055-1266-A1, p.2]

As currently proposed, both option 1 and option 2 introduced in the NPRM fail to provide adequate production timelines to ensure vehicle affordability for motor carriers or other truck buyers. During an EPA Virtual Public Hearing on the NPRM held in April, the Truck and Engine Manufacturers Association stated, "EPA's proposed rule is not technologically feasible, cost-effective or customer acceptable."2 This and other initial responses from heavy-duty truck manufacturers indicate that EPA has not learned from previous rulemakings and that this proposal will undoubtedly lead to higher costs for truckers. [EPA-HQ-OAR-2019-0055-1266-A1, p.3]

2 https://www.epa.gov/system/files/documents/2022-04/hd-2027-stds-public-hearing-transcript-2022-04-12-day1.pdf

In recent years, the trucking industry has been subjected to numerous federal and state regulations relating to environmental emissions. Some of these standards were necessary and have been helpful in reducing NOx vehicle emissions by as much as 98%. However, many were short-sighted and have been difficult to implement, especially for smaller motor carriers. The influx of regulations has contributed to higher costs for new trucks with the average price increasing almost 49 percent since 2001.3 Meanwhile, the cost of used trucks has remained relatively the same. In some cases, these dramatic cost increases can limit the environmental benefits of the regulations by forcing truckers to maintain older vehicles longer than they otherwise would or compelling truckers to purchase used vehicles. On average, OOIDA members have stated that emissions and environmental equipment represented approximately $5,700 of their annual maintenance costs.4 53 percent of OOIDA members indicated they did not get a return on investment for installing and using environmental/emissions technologies such as exhaust gas recirculation (EGR) / selective catalytic reduction (SCR) systems and diesel particulate filters (DPF).5 For small carriers operating on the slimmest of margins, these costs can be a major deterrent to purchasing newer, cleaner trucks. [EPA-HQ-OAR-2019-0055-1266-A1, pp.3-4]

3 Owner-Operator Member Profile Survey 2020, OOIDA Foundation (2020).

4 Ibid.

5 Ibid.

Small-business truckers also remember EPA's track record from previous emissions rulemakings. Dating back to the 1970's, the agency has a history of well-intentioned attempts at reducing air pollutants and increasing fuel efficiency. However, the unrealistic expectations of engine manufacturers' capabilities, the underestimation of costs, the failure to anticipate risk aversion from buyers, and a lack of understanding about the trucking industry have undermined the environmental goals of the agency as well as intensified the mistrust of the agency.6 In order to avoid similar results, the NOx proposal must be amended to achieve the desired reduction in emissions. [EPA-HQ-OAR-2019-0055-1266-A1, p.4]

6 EPA's Myopic Cost Benefit Analysis, OOIDA Foundation (2014).

Any final rulemaking must better prioritize affordability for owner-operators drivers who will be required to purchase and install new equipment. This rulemaking must ensure that drivers and carriers who are investing in new vehicles are getting a fair deal and will not be constantly sidelined from their profession due to costly and repeated breakdowns. OOIDA members have encountered various problems with emissions systems which have had a dramatic impact on their business. These challenges include expensive visits to dealers, lost productivity, poor efficiency, and towing costs that can quickly escalate into the tens of thousands of dollars. For small carriers, hefty maintenance expenses coupled with the loss of income resulting from downed trucks, can severely jeopardize their ability to remain viable. [EPA-HQ-OAR-2019-0055-1266-A1, p.4]

For these reasons, EPA must conduct a more comprehensive RFA analysis that addresses the impact the Rule would have upon small-business vehicle purchasers, including OOIDA members, whom EPA has acknowledged are integral stakeholders in this rulemaking proceeding. [EPA-HQ-OAR-2019-0055-1266-A1, p.5]

While EPA has included a Regulatory Flexibility Act certification in the NPRM (id. at 17640), it has only addressed the impact the Rule would have on certain small-business manufacturers. The certification did not address the impact the Rule would have on small-business truckers or owner-operators such as OOIDA's members. Therefore, OOIDA requests that the EPA comply with the Regulatory Flexibility Act, 5 U.S.C. 601-611, by alleviating the detrimental impact the Rule will have on OOIDA's small-business independent owner-operators. [EPA-HQ-OAR-2019-0055-1266-A1, p.8]

The Regulatory Flexibility Act (RFA), 5 U.S.C. § 601, et seq. (1980), requires an agency issuing a final rule to either conduct "an analysis of the rule's impact on small businesses," Nat'l Tel. Co-op. Ass'n v. F.C.C., 563 F.3d 536, 538 (D.C. Cir. 2009), or to "certify" that there will be "no impact for those small businesses that are subject to the regulation," Cement Kiln Recycling Coal. v. E.P.A., 255 F.3d 855, 869 (D.C. Cir. 2001) (internal quotation marks omitted). See 5 U.S.C. § 605. [EPA-HQ-OAR-2019-0055-1266-A1, p.8]

In addition to, and separate and apart from, EPA's obligation to consider costs of compliance under the Clean Air Act, EPA is required to consider the impact of regulations to small businesses under the RFA. Here, EPA has published an RFA certification in the NPRM, but the certification only referenced the impact on "heavy-duty alternative fuel engine converters, heavy- duty electric vehicle manufacturers, a heavy-duty conventional vehicle manufacturer, and heavy-duty secondary vehicle manufacturers." Id. at 17640. EPA should conduct a complete RFA analysis and certification with respect to OOIDA owner-operators whom EPA has forthrightly acknowledged to be integral stakeholders in this rulemaking proceeding. [EPA-HQ-OAR-2019-0055-1266-A1, p.9]

OOIDA's members meet the definition of small businesses under the RFA. The RFA defines "small entities" as having the same meaning as the terms "small business," "small organization," and "small governmental jurisdiction," as defined in the RFA. 5 U.S.C. § 601(6). Section 601(3), "Definitions" provides:
(3) the term "small business" has the same meaning as the term "small business concern" under section 3 of the Small Business Act, unless an agency, after consultation with the Office of Advocacy of the Small Business Administration and after opportunity for public comment, establishes one or more definitions of such term which are appropriate to the activities of the agency and publishes such definition(s) in the Federal Register; [EPA-HQ-OAR-2019-0055-1266-A1, p.9]

Section 3 of the Small Business Act states that such a concern is "one which is independently owned and operated and which is not dominant in its field of operation." 15 U.S.C. § 632(a)(1). [EPA-HQ-OAR-2019-0055-1266-A1, pp.9-10]

It should be noted that EPA has separately defined small businesses as follows: A small business is a person, corporation, partnership, or other entity that employs 100 or less individuals (across all facilities and operations owned by the small business). Small Business Compliance Policy, 65 Fed. Reg. No.70 at 19632 (EPA April 11, 2000). [EPA-HQ-OAR-2019-0055-1266-A1, p.10]

OOIDA members readily satisfy each of the foregoing "small business" definitions for purposes of the RFA. A majority of OOIDA's 150,000 members are small trucking businesses with one to five trucks that are "independently owned and operated and which [are] not dominant in [their] field of operation." [EPA-HQ-OAR-2019-0055-1266-A1, p.10]

Again, the Regulatory Flexibility Act certification only addressed small-business manufacturers. However, EPA has separately recognized OOIDA's importance as a stakeholder in this proceeding in responding to OOIDA's prior ANPRM comments as follows:

- EPA received comments from trade organizations representing very large trucking fleets (e.g., the American Trucking Associations, ''ATA''), small fleets (e.g., National Association of Small Trucking Companies, ''NASTC''), and owner operators (e.g., Owner-Operator Independent Drivers Association, ''OOIDA''), as well as from independent commenters, indicating that serviceability issues are one of the top concerns when operating trucks with advanced emission control systems. See NPRM at 17514.
- OOIDA commented that their members have encountered various problems with emissions systems which have had a dramatic impact on their businesses including expensive visits to dealers, lost productivity, poor efficiency, and towing costs. See NPRM at 17514.

- We are keenly aware of significant discontent expressed by owners concerning their experiences with emission systems on engines compliant with EPA 2010 standards. … OOIDA commented that some of its members have experienced emission technology failures that caused their engines to quickly derate, placing truckers and other motorists in unsafe situations. See NPRM at 17515.
- In response to the ANPRM, EPA received numerous comments on difficulties associated with repairs of emission control systems. … OOIDA commented that according to a 2018 survey, 73 percent of their members perform repairs and maintenance on their own trucks. OOIDA added that being able to diagnose problems and repair equipment outside of dealerships is important for owner-operators and allows them to save time, avoid downtime, and reduce operating costs; however, they believe that restrictions built into existing trucks are preventing this practice. OOIDA supported an emphasis on serviceability improvements so that professional drivers can independently identify and repair problems with their engines and after treatment as much as possible. See NPRM at 17515.
- Commenters stated that, despite their continued diligence to use high-quality DEF, they have repeated experiences with inducements resulting in very onerous costs. Some commenters noted they were subject to the most severe restrictions multiple times per year even though DEF tanks were properly filled. OOIDA commented that inducement related costs can severely jeopardize owner-operators' ability to stay in business, citing costs that included towing and lost income from downtime in addition to diagnosis and repair. See NPRM at 17538-39. [EPA-HQ-OAR-2019-0055-1266-A1, pp.10-11]

While OOIDA appreciates that EPA has acknowledged its concerns in the NPRM, the response is simply insufficient in alleviating the detrimental impact the Rule will have on OOIDA's small-business truck owner-operators. [EPA-HQ-OAR-2019-0055-1266-A1, p.11]

Based on the foregoing, OOIDA requests that EPA comply with the Regulatory Flexibility Act including, but not limited to, the following requirement in 5 U.S.C.A. § 604 (a)(6):

(a) *** Each final regulatory flexibility analysis shall contain—

***

(6) a description of the steps the agency has taken to minimize the significant economic impact on small entities consistent with the stated objectives of applicable statutes, including a statement of the factual, policy, and legal reasons for selecting the alternative adopted in the final rule and why each one of the other significant alternatives to the rule considered by the agency which affect the impact on small entities was rejected;

Id. [EPA-HQ-OAR-2019-0055-1266-A1, p.11]

The Regulatory Flexibility Act analysis required under this rule related to small-business truck owners and purchasers would include an examination of:

- the costs of the proposed equipment (and installation where required) to truck owners; ï,· the new costs of ongoing maintenance of the proposed equipment,
- the reduction in truck efficiency caused by the proposed equipment,
- the predictable costs of new equipment unreliability caused by more frequent breakdowns, costly towing to the locations qualified to do such repairs, lengthy shop time (due to mechanics' unfamiliarity with new equipment and the wait for scarce parts delivery) and the loss of business and productivity each day the truck is in the shop, and
- the cost of equipment failures on the highway that create the opportunity for collisions and damage to roads and property. [EPA-HQ-OAR-2019-0055-1266-A1, p.12]

The analysis must also consider the regulatory options that may reduce the economic burden of the new equipment:

- the requirement that purchasers of the new equipment are given the ability to diagnose problems with and maintenance needs of equipment,
- the provision of adequate manuals, diagrams, instructions, troubleshooting guides and QR codes for truck owners to be able to repair the new equipment, and
- the requirement for adequate warranties to protect small businesses from the cost of repairs (labor and parts) of new equipment. [EPA-HQ-OAR-2019-0055-1266-A1, p.12]

The economic analysis of these and other issues is critical for EPA to perform an adequate Regulatory Flexibility Act analysis to determine how EPA may be able to achieve its goals in a way that reduces the burdens on small-business truck owners to the greatest extent possible. [EPA-HQ-OAR-2019-0055-1266-A1, p.12]

EPA Summary and Response

Summary:

The four comments reproduced above, from ATD, ATA, NACD, and OOIDA, each of which represent the owners and/or operators of regulated equipment (trucks), note that most (97%, according to ATA) owner/operators are small companies that should be included in EPA's Regulatory Flexibility Act analysis for this rule. ATA referred to the recent COVID-19 pandemic and several other economic factors as contributing to higher commercial motor vehicle prices, and noted those higher prices are especially concerning for small businesses. NACD also noted that many other small entities in the supply chain will be impacted, and they should also be considered. OOIDA commented that EPA's recognition of the concerns of owner/operators in the NPRM is insufficient, and EPA must consider the economic burden on these entities in the RFA analysis. The commenter stated that this would include the costs to truck owners of the equipment itself, its maintenance, any reduction in efficiency and reliability, and equipment failures including costs of collisions and damage to roads and property. The commenter stated that, pursuant to the RFA, EPA must also consider regulatory options to reduce those burdens including giving the purchasers the ability to diagnose maintenance and repair issues, adequate manuals to be able to repair those issues, and adequate warranties to protect small businesses from the cost of repairs.

Response:

Our assessment of small business impacts prepared to support EPA's certification that the rule will not have a significant economic impact on a substantial number of small entities was appropriately limited to small entities that would be regulated under the proposed rulemaking (i.e., engine and vehicle manufacturers). Other than those entities discussed in the final RIA Chapter 11, the rule does not impose any requirements on small businesses (for example, small trucking firms are not regulated entities under the final rule's requirements). The impacts on small businesses to which the commenters refer would not be effects of the rule on regulated entities, and thus are not impacts that we are required to analyze. See *Cement Kiln Recycling Coal. v. EPA*, 255 F.3d 855, 869 (D.C. Cir. 2001) (noting that "this court has consistently rejected the contention that the RFA applies to small businesses indirectly affected by the regulation of other entities" and citing cases), *Mid-Tex Elec. Coop. v. FERC*, 773 F.2d 327, 342-43 (D.C. Cir. 1985) ("An agency may properly certify that no regulatory flexibility analysis is necessary when it determines that the rule will not have a significant economic impact on a substantial number of small entities that are subject to the requirements of the rule. . . . Congress did not intend to require that every agency consider every indirect effect that any regulation might have on small businesses in any stratum of the national economy."); see also *Coalition for Responsible Regulation v. EPA*, 684 F. 3d 102, 129 (D.C. Cir. 2012).

Even though EPA is not required to include owner/operators in our Regulatory Flexibility Act analysis since they are not regulated entities under the rule, the Agency considered concerns from owner/operators in developing both our proposed program, as noted by OOIDA, and this final rule. As explained in the final rule preamble, including Sections IV and V, we expect that all truck owner/operators will benefit from several provisions being adopted in this rule, including longer useful life, longer warranty periods, and improved serviceability. These provisions are expected to lead to improved engine durability, reduced repair costs, and more consistent maintenance over the life of the engines. Our technology demonstration shows that the final standards can be achieved without a reduction in truck efficiency (see RIA chapter 3). Further, manufacturers have the option of meeting the standards using technologies that differ from our demonstrated technology package and that may have less costs than the technology pathway we anticipated. Overall, the final regulations being adopted in this rule will be helpful toward ensuring that new MY 2027 and later HD trucks purchased and used by all owner/operators, including small owner/operators, will perform more reliably while reducing their emission impacts on human health and the environment. As noted in our response to the American Farm Bureau in section 18.9 of this Response to Comments document, we hope, as everyone does that the current economic conditions – inflation, the pandemic, etc. – and any associated impact on businesses, including small businesses, are alleviated by the time the new standards are being implemented.

17.2 Request for Extension of Comment Period

Comments by Organizations

Organization: *American Bus Association (ABA) (1070 and 1308)*

As a preliminary matter, EPA has not provided sufficient time for the public or stakeholder community to review the Proposal. As ABA is small organization, it has limited resources and this is especially true in the wake of the COVID-19 pandemic. In March 2020 and throughout the period, nearly a quarter of the motorcoach businesses in operation closed, with industry revenue losses exceeding $8.4 billion in 2020 alone (https://home.treasury.gov/news/press-releases/jy0395). In turn, as the industry representative, ABA has also suffered economic losses and downsized to fit the needs of the industry it serves. ABA's abilities to review the highly complex, technical and lengthy Proposal are severely constrained, particularly given the short amount of time provided for the comment period. Because ABA lacks both in-house technical expertise and the capacity to obtain such assistance in a short time span, it has placed the motorcoach industry at a distinct disadvantage in responding to the Proposal. This benefits neither EPA or the motorcoach industry in terms of meeting the goal to better control air pollution from heavy duty vehicles. [EPA-HQ-OAR-2019-0055-1308-A1,pp.1-2]

On behalf of the motorcoach industry, ABA, along with many other stakeholders, petitioned EPA for a reasonable extension of time to appropriately review the Proposal, as done on prior occasions with similarly complex rulemakings (EPA–HQ–OAR–2014–082, Sept. 2015; 80 FR 53756). Considering the Notice is 475 pages in length, including various complex tables and formulas, along with a docket of additional supplemental materials ranging in the thousands of pages, it is unrealistic for small stakeholders to properly review and prepare comments in response to the Agency's proposed action. The EPA's grant of a 3-day extension, particularly after being forced to extend the public hearing schedule and conduct additional outreach/briefings, appears misguided, in terms of providing sufficient opportunity for public participation in a significant rulemaking. Proposed rules of this size and scope require, and the public is generally afforded, a minimum of 60 to 120 days to review and formulate comments. It is unfortunate EPA is limiting the process for a rulemaking proposal of this scope as it will result in costly, unintended consequences that will diminish anticipated benefits and hinder future cooperation between the public and private sectors. [EPA-HQ-OAR-2019-0055-1308-A1, p.2]

We do appreciate the letter sent to ABA from Principal Deputy Assistant Administrator Joseph Goffman regarding our request for an extension of time for the comment period and explaining the Agency's position in denying the request for additional time. We do find it hard to understand how the Agency could consider an issuance of the pre-publication version of the proposal as part of the review timetable, when it is well known that those pre-publication versions can change (and in this case did change, as additional dates were added to the announced public hearing), and in this specific case between March 15 and May 4, nearly 450 new supplementary materials were added to the docket. That is a tremendous amount of material to review, consider and digest in addition to the lengthy proposal. As stated in the response letter, it is very clear that the EPA is committed to their timeline in getting a final rule out before the end of the year, and very few suggestions for modifications to this rule proposal will be evaluated or considered very seriously. [EPA-HQ-OAR-2019-0055-1308-A1, p.2]

Nonetheless, in the interest of ensuring EPA is aware of the interest, and to the best of our abilities, the concerns of the motorcoach industry in relation to this rulemaking, ABA submits the following comments for the record. Please be advised, however, ABA will file supplementary comments, as appropriate, as we continue to work through the Proposal.[EPA-HQ-OAR-2019-0055-1308-A1, p.2]

The EPA is moving far too quickly with this technically complex rulemaking and ABA again requests the agency extend its comment period deadline to allow for necessary and appropriate input. [EPA-HQ-OAR-2019-0055-1308-A1, p.12]

On behalf of the American Bus Association (ABA), I petition the US Environmental Protection Agency (EPA) to request a 60-day extension of time for filing comments on the notice published in the Federal Register on March 28, entitled Control of Air Pollution From New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards [EPA–HQ–OAR–2019–005] (Notice). Currently, the comment period is set to close on May 16, 2022. [EPA-HQ-OAR-2019-0055-1070-A1, p.1]

ABA's request for a 60-day extension is based on the following: 1) the length and complexity of responding to the proposed rule; 2) the need to review and obtain technical assistance as part of the review; and 3) the hinderance of limited public outreach and engagement. The ABA requests this action to ensure the public has a fair opportunity to provide meaningful comment. As precedent, we note an extension was requested and granted for the similarly complex Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles - Phase 2 proposed rule in 2015 (EPA–HQ–OAR–2014–082, Sept. 2015; 80 FR 53756). [EPA-HQ-OAR-2019-0055-1070-A1, p.1]

The Notice, as published in the Federal Register, is over 450 pages long and the docket, which continues to expand, includes a number of supplementary documents. In order to fairly analyze and address the Notice and the supplementary material, even just the materials added to the docket between March 15 and the present, totaling thousands of pages, more time is needed. As of today, there are at least 445 documents in the docket related to this proceeding, which requires review and analysis, if not even just a cursory review – this equates to thousands of pages. Although there may be some nonrelevant or unrelated supplementary materials within the whole, there is insufficient time to even make this distinction and to focus only on the relevant material necessary to prepare comments. [EPA-HQ-OAR-2019-0055-1070-A1, p.1]

Further, much of the Notice and supplementary materials are of a highly technical nature, requiring technical expertise and resources to interpret, understand and assess. These type of resources are not readily available to small industries such as the motorcoach industry, particularly in the wake of the unprecedented economic fallout from the COVID-19 pandemic. Additionally, as referenced and relied upon by EPA in this rulemaking proceeding, the California Air Resources Board (CARB) recently completed a similar rulemaking effort. Based on the close nexus between these two respective proceedings, we need additional time to review the materials and supporting documentation from the CARB proceeding. [EPA-HQ-OAR-2019-0055-1070-A1, p.2]

It is unreasonable for a federal agency to expect businesses affected, both directly and indirectly, by a sweeping, complex rule to be in a position of providing thoughtful and accurate comments within this short of a time period, particularly if these businesses have not been included in prior discussions. In fact, based on an initial cursory review of the Notice, it appears EPA only minimally considered motorcoaches, if at all, in this proceeding. Significant rulemakings such as this, involving a high level of complexity, depth and length, and affecting such a broad swath of operating industries, at a minimum provide a 120-day comment period. Even if the original proposed period was only 60 days, it is not unusual or unreasonable for agencies to grant extensions well beyond the original proposal. [EPA-HQ-OAR-2019-0055-1070-A1, p.2]

The motorcoach industry is a relatively small industry, in terms of the entire surface transportation sector. However, motorcoach vehicles use the same engines used by the commercial property-carrying industry. The motorcoach industry is not subsidized on any significant scale by the Federal Government. Of the approximately 1800 motorcoach companies currently in operation in the U.S. following the COVID pandemic, over 90% are small fleets or operating 10 vehicles or less. The pandemic hit the industry considerably hard, and its effects continue to plague the industry. More than 40% of the operating companies went out of business and vehicle development and sales came to a complete standstill. Recovery to pre-COVID levels is not projected to until late 2023, or longer. While various public transportation modes (e.g., Amtrak, transit and aviation) received significant federal support to sustain their operations through the pandemic, this is not the case for the motorcoach industry. The industry is currently struggling to recover, and resources are in short supply. As a result, the industry is at a distinct disadvantage to participate in this rulemaking, as access to resources to assist in reviewing the complex rule proposal is limited. [EPA-HQ-OAR-2019-0055-1070-A1, p.2]

Further, motorcoach manufacturers are in one of the best positions to provide technical assistance to the motorcoach industry in evaluating this rulemaking and identifying the unique operational impacts on motorcoach operations. Yet, these equipment manufacturers are a step removed from engine manufacturers, who design and produce engines universally for trucks, buses and other heavy-duty diesel vehicles. Based on the size of the motorcoach industry, in comparison to the truck industry, the motorcoach manufacturers do not have the same amount of contact, bearing or input into the engine manufacturing process. However, there is only a limited number of motorcoach manufacturers, and they also are struggling with resources in the wake of the pandemic. The motorcoach industry needs more time to obtain their assistance on this proceeding. [EPA-HQ-OAR-2019-0055-1070-A1, p.2]

The preamble of the proposal includes numerous statements regarding the close working relationship of EPA and CARB in developing this proposal. However, there is little mention of EPA's interaction with stakeholders beyond the public hearing. The public hearing, which occurred after the publication of the Notice, limited EPA's ability to engage and provide a proper briefing to the public on a very complex rule. This in turn resulted in a hearing where, with very little time to prepare, speakers scrambled to read the lengthy, complex proposal and had even less time to understand it and develop thoughtful feedback for the hearing. [EPA-HQ-OAR-2019-0055-1070-A1, p.3]

Although there may very well be a limited number of stakeholders better versed and more engaged with EPA, who were in a better position to participate, this is not the case for a vast majority of the stakeholders will be affected by this proceeding. It is unclear what efforts EPA engaged in to ensure stakeholders, including not only the engine manufacturers, but all those who use and rely on these engines, were provided sufficient time to digest the complex Notice in advance of a public hearing. It is only at this late breaking stage of this comment period that EPA is now undertaking outreach in the nature of a briefing to these constituencies, many of whom are small industries like the motorcoach industry. There should be better and broader outreach and recognition that the stakeholder community for this rulemaking goes far beyond engine manufacturers. [EPA-HQ-OAR-2019-0055-1070-A1, p.3]

Further, it appears EPA has not given much consideration, if at all, to the motorcoach or coach bus industry. In the fact sheet posted to the website related to this rulemaking, motorcoaches do not even appear in the graph categorizing mobile source GHG, unless being swept up in descriptions like “other transportation sources”. The Notice, as currently written, mentions trucks over 300 times, whereas coach bus or motorcoach are mentioned less than 10 times, in terms of the NOx standards. Even worse, there is no recognition of the positive environmental benefits that motorcoach operations provide in removing cars from the road, serving socially and economically disadvantaged communities, reducing congestion, and conveying essential as well as emergency services. One plausible outcome of this reading is to deduce the Notice or parts of it do not apply to bus operations, which also illustrates the need for time to dive deep enough into the proposal to make the appropriate connections. Also, although we do appreciate the outreach efforts at this late stage, many stakeholders are not prepared or are ill-equipped to participate meaningfully in the comment period now due to the abbreviated time frame of the comment period. While these stakeholders could provide meaningful input to assist EPA in reaching its goals, because of the short comment period they instead risk the imposition of significant, costly requirements that will end up impeding their business operations. This is not the intended outcome of the Administrative Procedures Act (APA) for significant rulemakings. If EPA wishes this rulemaking to be successful in meeting its goals, it will provide more time and opportunity for all stakeholders to be fully apprised and knowledgeable of this federal action and provide sufficient opportunity to provide meaningful input. [EPA-HQ-OAR-2019-0055-1070-A1, p.3]

For these reasons, ABA urges EPA to extend the comment period deadline, for at least 60 days. The Notice repeatedly notes that it is EPA’s goal to “work with stakeholders,” therefore we urge the agency to provide sufficient time, and conduct and engage in broad stakeholder outreach, to accommodate the needs of all affected stakeholders and particularly smaller businesses. It is not simply engine manufacturers who will bear the burden of the changes proposed in the Notice, and this should be taken into consideration by EPA. [EPA-HQ-OAR-2019-0055-1070-A1, pp.3-4]

Organization: *Coach USA, Inc. (Coach USA)*

The relatively short comment period allowed for the EPA’s massive (475-page) and technically-complex proposed rules was grossly insufficient to allow Coach USA to adequately analyze all of the implications of the proposed rules on its business and its customers. [EPA-HQ-OAR-2019-0055-1307-A1, p. 3]

Organization: *Navistar, Inc. (Navistar)*

As an initial matter, the 49-day public comment period, which currently ends on May 16, 2022, does not provide sufficient time to stakeholders to meaningfully evaluate the regulatory intricacies to provide comprehensive comments on the proposed rule. We respectfully urge EPA to extend the public comment period on this important rulemaking, in which EPA's actions will have profound ramifications on the future development of the next generation of low-NOx heavy-duty engines and vehicles, and zero-emission commercial trucks. [EPA-HQ-OAR-2019-0055-1318-A1, p. 1]

Organization: *New Flyer of America Inc. (New Flyer) and Motor Coach Industries, Ltd. (MCI)*

To allow for complete review of the detailed rule, and in order to fully understand what impact the new standards would have on our suppliers, New Flyer / MCI requests for the EPA to extend the NPRM comment period by an additional 30 days beyond the current May 16th deadline. Such an extension would afford us a chance for proper analysis and provide more meaningful feedback. [EPA-HQ-OAR-2019-0055-1064-A1, p.1]

Organization: *Pennsylvania Motor Truck Association (PMTA)*

Finally, we believe it important to point out that 34 business days is a wholly inadequate public comment period for a highly technical, 475-page proposed regulation, especially for these small businesses who struggle every day to manage the challenges of a supply chain crisis, record high-diesel prices, and a workforce shortage to deliver freight for their customers and keep the American economy afloat. Understanding the impact of this regulation on their business is itself a challenge, much less putting it into words in time to meet the May 13 deadline. We would ask that EPA consider these limitations as it assesses the comments (or lack thereof) that are submitted within the timeframe given. [EPA-HQ-OAR-2019-0055-1202; this is an additional comment provided by PMTA included with their State Trucker Associations (2) letter.]

EPA Summary and Response

Summary:

The five entities listed above stated that the comment period for this rule was too short. Two of these entities, American Bus Association (ABA) and New Flyer of America, sent letters specifically requesting EPA Administrator Regan to extend the comment period. In addition, Coach USA and Navistar, as well as ABA and PMTA, mentioned the length of the comment period in their written comments, and Navistar urged EPA to extend the comment period.

In their formal request letter, ABA noted that an extension was needed for three reasons:

1. The length and complexity of responding to the proposal;
2. The need to review and obtain technical assistance as part of the review; and

3. The hinderance of limited outreach to the public.

ABA reminded the Administrator that an extension was granted for EPA's Phase 2 GHG rule. They also stated that significant rules often provide a 60-120-day comment period and that extensions are often granted even when the original comment period was 60 days. Finally, they noted their concern that the Agency did not give much attention to the motorcoach industry when preparing the rule.

In their subsequent written comments, ABA expressed disappointment in EPA's formal response to their request for an extension of the comment period. While the Agency noted that a pre-publication version of the proposal had been available since March 7, ABA observed that pre-publication versions of rules often change, that additional materials were added to the docket after March 7 (nearly 450 documents), and they would also need to review the materials associated with CARB's actions that were added to the docket. ABA noted their concern about "limiting the process for a rulemaking proposal of this scope as it will result in costly, unintended consequences that will diminish anticipated benefits and hinder future cooperation between the public and private sectors." ABA also commented that their organization and the motorcoach industry are experiencing resource limitations as they recover from economic impacts of the recent pandemic.

Response:

EPA responded to the two formal requests for extension of the comment period by letter dated May 13, 2022, denying the requests (see EPA-HQ-OAR-2019-0055-1152 and 1153). As we explained in that response, we continue to believe that the comment period length was appropriate and provided a meaningful opportunity to comment on the proposed rulemaking. Four of these commenters joined hundreds of others in submitting detailed comments on the rule before the end of the comment period. In addition, we posted a copy of the pre-Federal Register publication of the notice of proposed rulemaking on the EPA website on March 7th, when we issued the press release for the proposed rule. Finally, we conducted three days of public hearings (April 12, 13, 14, 2022) for stakeholders to provide oral presentation of data, views, and arguments. Because we held a third day of public hearing for the proposed rule, we also extended the public comment period to 49 days.

Our response letter to the request for extension of comment period indicated that we intended to issue a final rule later in 2022, and that further extending the comment period would likely preclude that timeline. We did not say that "very few suggestions for modifications to this rule proposal will be evaluated or considered very seriously" as indicated by ABA in their comment above. The Agency has been, is, and will continue to be committed to considering timely comments received on proposed rules. The compressed final rule schedule is necessary to finalize the standards this year to ensure that these important emission reductions occur as soon as possible. However, EPA still fully considered timely submitted comments in this final action.

Finally, the vast majority of the provisions contained in the pre-publication version of the notice of proposed rulemaking were not changed in the publication version, and the commenters failed to indicate any significant changes apart from the addition of another day for the public hearing and an extension of the comment period.

We agree that the motorcoach industry plays an important role. As noted in our response to the American Farm Bureau in section 18.9 of this Response to Comments, we understand ABA's concerns regarding the economic factors impacting their industry, but we are acting on our authority under Clean Air Act section 202(a)(3)(A). We hope, as everyone does, that the current economic conditions – inflation, the pandemic, etc. – are alleviated by the time the new standards are being implemented.

17.3 Information Collection Request (ICR)

<u>Comments by Organizations</u>

Organization: *Daimler Truck North America LLC (DTNA)*

This is to inform you that Daimler Truck North America ("DTNA") is developing comments on the U.S. Environmental Protection Agency ("EPA") "Control of Air Pollution From New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards; Proposed Rule," 87 Fed. Reg. 17,414 (March 28, 2022) (the "Proposed Rule"). DTNA's comments will address in detail EPA's burden and cost estimates for the Proposed Rule, including some of the information requested in the Information Collection Request ("ICR") that is under review by the Office of Management and Budget ("OMB"). DTNA notes that the ICR for the Proposed Rule (EPA ICR Number 2621.01) has not been posted to the regulatory docket and that EPA's "Supporting Statement" for the ICR was only posted to the OMB ICR Dashboard on April 19, 2022. [EPA-HQ-OAR-2019-0055-1045, p.1]

Under these circumstances, there has not been sufficient time for review and meaningful comment on the ICR in advance of the April 27, 2022 OMB comment deadline. DTNA thus plans to address EPA's cost and burden estimates in its comments on the Proposed Rule and will submit a copy of these comments to OMB in addition to EPA. We appreciate your consideration of these comments, which DTNA plans to submit on or before the EPA deadline of May 13, 2022. [EPA-HQ-OAR-2019-0055-1045, p.1]

[Daimler Truck North America LLC subsequently provided a comment in a footnote to their main comments; see EPA-HQ-OAR-2019-0055-1168-A1, p.11]

> 9 While Daimler Truck focuses primarily here on increased incremental technology, warranty, and other direct/indirect compliance costs, we also note that paperwork burdens would increase under EPA's proposal. The Proposed Rule implicates a number of information collection activities, all of which will significantly increase compliance burdens and costs for manufacturers. Daimler Truck has reviewed EPA's 'Supporting Statement for Information Collection Request' (EPA ICR Number 2621.01) (April 19, 2022) and notes that EPA's summary—in particular the respondent burden and cost estimates in Table 3 of

> the 'Supporting Statement'—captures some but perhaps not all of the information collection burdens and costs accompanying implementation of the Proposed Rule. These costs should not only be factored in to OMB's consideration of the Proposed Rule under the Paperwork Reduction Act, but should also be accounted for in evaluating whether EPA's proposal reflects adequate consideration of costs as required under CAA Section 202.

Since EPA does not specify how powertrains should be categorized for this testing, we assume that the Agency expects manufacturers to run this test for each configuration that could result in a different outcome; therefore manufacturers could be expected to test many configurations. Even employing a reasonable categorization strategy—per vehicle family as defined in Part 1037, for example—manufacturers could be required to demonstrate many configurations at great expense, particularly given that today's typical vehicle families already contain several different ZEV architectures.136 [EPA-HQ-OAR-2019-0055-1168-A1, p.122]

> 136 This increased expense and the attendant compliance burden should be weighed heavily in OMB's review and decision whether to approve the information collection components of the Proposed Rule, in accordance with the Paperwork Reduction Act. Each test takes about 40 hours to run (per vehicle). Given the many configurations that manufacturers may have to test, it is difficult to approximate exactly how much cost and how many personnel hours would be involved, but Daimler Truck expects that the burden would be significant.

EPA Summary and Response

Summary:

EPA received only one comment pertaining to the draft Supporting Statement for Information Collection Request, Proposed Changes to Certification and Compliance Requirements for Heavy-Duty Engines and Vehicles (Proposed Rule) – EPA ICR Number 2621.01; OMB Control Number 2060-NEW. DTNA indicated in their April 27, 2022, letter that they intended to provide comments to OMB and EPA on EPA's cost and burden estimates. However, in DTNA's subsequent comments on the proposal (EPA-HQ-OAR-2019-055-1045), the cost and burden information they provided was specific to direct manufacturing costs of the expected technologies or indirect costs of longer warranty periods; they did not provide additional information related to implementing test procedures, keeping records, or reporting to EPA.

Response:

We did not revise our ICR burden estimates after consideration of this comment, given that DTNA did not provide detailed comments about their concerns. However, some of the data used to calculate the burden were revised for the final ICR to reflect the Agency's current knowledge with respect to the number of respondents, adjustments due to changes in the final requirements as compared to the proposal, and the number of hours required to assemble and submit data to EPA.

In addition, DTNA commented that there would be increased expense and compliance burden for manufacturers choosing to generate NOX emissions credits from ZEVs due to the proposed test procedures for ZEVs; as discussed in preamble Section IV.G and section 12 of this Response to Comments document, we are not finalizing the proposal to allow manufacturers to generate NOX emission credits from ZEVs, and thus have removed these estimates from the ICR for the final rule.

18 Costs

18.1 Individual technology piece costs

Comments by Organizations

Organization: *California Air Resources Board (CARB)*

U.S. EPA has estimated the projected costs of compliance for the proposed emission standards associated with both Option 1 and Option 2. Although the incremental technology costs for the Option 1 emission standards are generally higher than the corresponding technology costs for the Option 2 emission standards, the difference in such costs is minor (the maximum difference in technology costs between Options 1 and 2 is $716 in technology costs for a Class 8 heavy heavy-duty vehicle), and the largest incremental costs associated with the Option 1 standards only constitute a fraction of the base technology costs of new vehicles,90 thereby falling within the range of allowable cost increases. [EPA-HQ-OAR-2019-0055-1186-A2, p.38]

90 For example, the incremental cost of the Option 1 2031 MY standards for Class 8 heavy heavy-duty diesel vehicles is $3931; the base price of a Class 8 heavy heavy-duty diesel vehicle is $8465 (NPRM at 17570).

Furthermore, it is especially notable that U.S. EPA has also determined that the total technology and operating costs associated with Option 1 are lower than the costs associated with Option 2. 91 The total technology and operating costs associated with Option 1 and Option 2's criteria pollutant standards are similar in the early years, but overall (during the 2027 to 2045 time period) the costs for Option 1 are lower than the costs for Option 2 over the 2027 though 2045 time period by $2 to $3 billion dollars.92 [EPA-HQ-OAR-2019-0055-1186-A2, pp.38-39]

91 Compare Table V-16, (Option 1 costs), 17576, with Table V-17 (Option 2 costs), 17577.

92 Discounted at 3 and 7 percent rates, ($2017)

CARB staff believes the following assumption U.S. EPA made is incorrect and should be amended: 'Note the direct manufacturing costs for proposed Options 1 and 2 are equivalent because we expect the same technologies would be needed to meet the standards in each option.'186 Although the type of technology driven by the two options would be similar, as described in greater detail above in section 5.a.B., Option 2 would not encourage full use of technically feasible and cost -effective NOx reduction technologies that have been demonstrated. Indeed, the design and material of technologies would differ in cost due to unique elements directly related to optimizing for the different target emission standards such as aftertreatment sizing and catalyst loading. For example, for LHDD, MHDD, and HHDDs through IUL Option 1 has a 60 percent lower emissions limit for NOx when compared to Option 2. The large difference in the two options would be expected to cause a proportional change in direct manufacturing costs. For example, CARB's Omnibus regulation has a 2024 MY standard identical to Option 2, however, with a 435,000 mile UL. The technology package for meeting the 2024 standards did not include technologies, such as the addition of a light-off SCR or CDA to meet the standard. Increasing the UL to the Option 2 NPRM UL of 600,000 miles would require consideration for additional catalyst degradation such as enlarging catalyst size or using improved catalyst substrate but would not drive the need for adding additional aftertreatment technologies. The Omnibus regulation did recognize the need for additional aftertreatment technologies to meet the more stringent 2027 MY 20 mg/bhp-hr NOx standards to assure effective emission control with significantly improved thermal management. CARB staff believes that U.S. EPA's Option 1 2027 MY 35 mg/bhp-hr NOx standard would require these added technologies, consistent with the NPRM Option 1 technology cost estimates. Thus, CARB staff recommends that U.S. EPA reevaluate the technology cost for Option 2 and only identify the technology changes need to meet the 50 mg/bhp-hr NOx standard. In fact, U.S. EPA will be able to obtain more accurate information from manufacturers designing engines to meet the Omnibus upcoming 2024 MY standards. [EPA-HQ-OAR-2019-0055-1186-A2, p.122]

186 NPRM at 17566.

Organization: *Ingevity Corporation (Ingevity)*

EPA estimated the average cost of adding ORVR to HHDGVs at $25 per vehicle for a 70-gallon fuel tank volume. This average cost was based on an unspecified mix of single and dual fuel tanks, use of either an enlarged single canister or two existing canisters, and use of either liquid or mechanical seals. The retail price equivalent (RPE) mark-up in Chapter 7 of EPA's draft RIA is 1.36, yielding an average per vehicle cost of $34.3 Ingevity believes these estimates are conservative, as a 70-gallon tank is towards the upper range of the distribution of HHDGV product offerings4. [EPA-HQ-OAR-2019-0055-1213-A1, p. 3]

3. See Table 7-10 of US EPA draft RIA "Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards, EPA-420-D-22-001, March 2022.

4. A review of 2022 HHDGV product offerings on the OEMs commercial and medium-duty truck web pages indicates that fuel tank volumes fall into two categories. For single tank HHDGVs, the tank volumes range from 35-40 gallons; for dual tank vehicles the total volume is nominally 80 gallons. Low production volume school bus chassis may have total fuel tank volumes of about 100 gallons.

We note that EPA's cost estimate does not include a cost for increased vapor vent hose diameter between the fuel tank outlet and the canister inlet as was done in previous EPA analyses.5 It may be that with a Tier 3 HHDGV there is no net vapor line hardware cost increase when going from a Tier 3 evaporative configuration to a Tier 3 evaporative plus ORVR configuration. It would be helpful if EPA would clarify this point in any future analysis. [EPA-HQ-OAR-2019-0055-1213-A1, p. 3]

5. More detail can be found in Table 5.1, US EPA, "Final Regulatory Impact Analysis: Refueling Emission Regulations for Light Duty Vehicles and Trucks and Heavy-Duty Vehicles," January 1994.

Organization: *Manufacturers of Emission Controls Association (MECA)*

MECA agrees with EPA's cost analysis conducted to support this rulemaking. Similar to EPA, our estimates of the incremental technology costs to meet the Proposed Option 1 show that the technology packages on MY 2027 trucks would yield cost effective NOx reductions. In support of cost-benefit analyses funded by CARB and conducted by NREL as part of the development of the Omnibus, MECA estimated the costs (in 2019$) of the technologies employed in current trucks to meet today's emission standards as well as the technologies projected to be employed on trucks in future years to meet the requirements proposed in the Omnibus. In our cost analysis, we first estimated a cost range of current heavy-duty emission controls systems based on meeting today's FTP-limit of 0.2 g/bhp-hr over a useful life of 435,000 miles. The hardware included the DOC, DPF and SCR catalysts along with the DEF dosing system and OBD sensors and controllers necessary to comply with current OBD requirements. We estimated costs for two engine sizes, 6-7L and 12-13L. The former is often found in Class 4-6 heavy-duty vehicles while the latter is found in Class 7-8 vehicles. [EPA-HQ-OAR-2019-0055-1320-A1, pp.25-26]

The direct hardware cost estimate for a current aftertreatment system on a vehicle with a 6-7L engine is about $2,600 to $3,500. This is similar to the costs estimated by the ICCT ($2,807) in their most recent cost analysis [37]. For a Class 8 line-haul tractor with a 12-13L engine, we estimate a direct hardware cost of the engine and aftertreatment hardware to be in the range of $3,500 to $4,600 per truck. Similar to the 6-7L engine above, our cost is in-line with ICCT's latest estimate ($4,365) [37]. An older ICCT report estimated the cost of a 2015 exhaust emission control system (not including EGR) in the U.S. or Europe was about $5,068 or 3% of the cost of the average retail truck price reported as $157,000 [38]. It is important to note that the average price of a heavy-duty line-haul truck has historically increased by about 1% per year [38] due to safety, operational and other customer demanded enhancements that truck manufacturers have made to trucks. At the same time, emission control technology suppliers are typically expected to reduce the costs of their components through manufacturing improvements and other optimization by about 2-3% per year [37]. The year-over-year supply chain reductions can account for much of the cost difference between recent cost estimates compared to those reported by ICCT in 2016. Given declining emission control system costs and increases in the average price of a heavy-duty truck, the emission control system cost has become a smaller portion of the total truck price. [EPA-HQ-OAR-2019-0055-1320-A1, p.26]

[37] F. Posada, A. Isenstadt and H. Badshah, 'Estimated cost of diesel emissions-control technology to meet the future California low NOx standards in 2024 and 2027,' 2020.

[38] F. Posada, S. Chambliss and K. Blumberg, ‘Costs of Emission Reduction Technologies for Heavy-Duty Diesel Vehicles,’ International Council on Clean Transportation, Washington, DC, 2016.

The second part of our analysis involved estimating the cost of meeting an FTP certification standard of 0.02 g/bhp-hr and proposed LLC certification standard in 2027 with an emission control system that includes a close-coupled SCR combined with a traditional aftertreatment system. To meet these tighter standards, the technology evolution (discussed in our white papers referenced herein) includes incremental improvements to substrates and catalysts as well as the addition of a close-coupled SCR and dual dosing system with one heated doser, additional NOx sensors and an ammonia sensor in an upgraded OBD system. In addition, this analysis assumed the use of CDA and an EGR cooler bypass system. All of these technologies have been demonstrated by SwRI. Two cost estimates were prepared – one that assumed today's durability and warranty requirements, and one assuming one million mile useful life (FUL) and 800,000 mile warranty for class 8 and 550,000 mile FUL and 440,000 mile warranty for Class 4-7 starting in 2027. These durability and warranty levels were chosen because they were initially proposed by CARB during the Omnibus rulemaking [39]. Given EPA's Proposed Option 1 includes lower durability and warranty requirements than assumed in our cost analysis, we expect the cost estimate for longer FUL and warranty provided below to represent a worst-case scenario. [EPA-HQ-OAR-2019-0055-1320-A1, p.26]

[39] CARB, ‘Heavy-Duty Low NOx Program Workshop: HD UL & Step 2 warranty,’ 23 January 2019. [Online]. Available: https://www.arb.ca.gov/msprog/hdlownox/files/workgroup_20190123/04-HD_UL_&_Step_2_warranty_WS01232019.pdf.

For a vehicle with a 6-7L engine, the incremental hardware improvements needed to meet a 0.02 g/bhp-hr certification limit on the FTP cycle and future LLC standard at today's durability and warranty requirements were estimated to add about $1,300 to $1,800 to the cost of the engine efficiency and emission control technologies. For a Class 8 tractor with a 12-13L engine similar incremental improvements were estimated to add about $1,500 to $2,050 (less than 1.2%) to the cost of a MY 2027 truck, projected to be approximately $177,000, based on a historical 1% annual rate of MSRP increase reported by ICCT. The estimated incremental costs to meet the above referenced increased durability and warranty requirements for a 6-7L engine and 12-13L engine were $1,800 to $2,450 and $2,000 to $2,750, respectively. The estimated total additional emission control cost in 2027, including a 0.02 g/bhp-hr FTP tailpipe limit, LLC limit, 1-million-mile durability requirement and 800,000 mile warranty, would be $3,100 to $4,250 for 6-7L engines and $3,550 to $4,800 for 12-13L engines. If a Class 8 truck with 12-13L engine is assumed to sell for an average price of $177,000 in 2027, based on the historical 1% annual rate of increase reported previously, the additional cost of emission controls on this truck will account for roughly 2-2.7% of the total vehicle price. It is important to reiterate that these cost estimates are biased high since they are based on more stringent requirements than those included in Propose Option 1. [EPA-HQ-OAR-2019-0055-1320-A1, pp.26-27]

The ICCT recently conducted an analysis that estimated the cost of diesel emissions control technology to meet CARB's Omnibus standards [37]. Their study included direct manufacturing costs and indirect costs for two engine sizes, but costs of proposed longer warranty requirements were excluded. The methodology follows the steps outlined in previous ICCT cost studies where both in-cylinder technology aftertreatment costs are estimated and scaled to account for engine size [38]. In order to meet the proposed MY 2027 standards (similar to EPA Proposed Option 1), ICCT estimated both low-cost and high-cost durability cases. The resulting incremental cost range estimated to meet the Omnibus requirements was $1,800 to $2,500 for a 7L engine and $2,200 to $3,200 for a 13L engine. The ICCT results are roughly 10-20% lower than those estimated by MECA, and this may be explained by differences in assumptions for useful life and baseline year for cost between the two analyses. [EPA-HQ-OAR-2019-0055-1320-A1, p.27]

[37] F. Posada, A. Isenstadt and H. Badshah, ‘Estimated cost of diesel emissions-control technology to meet the future California low NOx standards in 2024 and 2027,’ 2020.

[38] F. Posada, S. Chambliss and K. Blumberg, ‘Costs of Emission Reduction Technologies for Heavy-Duty Diesel Vehicles,’ International Council on Clean Transportation, Washington, DC, 2016.

It should be noted that the cost estimates developed by NREL included the costs due to the extended warranty requirements, despite a lack of adequate information available from suppliers or OEMs to estimate these. Similarly, costs analyses conducted by ACT Research and Ricardo made assumptions for significant warranty costs due to the new regulation based on confidential surveys. NREL and CARB acknowledged that the cost estimates for extended warranty are very uncertain. CARB subsequently conducted its own analysis of costs needed to meet extended warranty requirements, and these are substantially lower than those estimated in the NREL report as well as those estimated by ACT Research and Ricardo. After the Omnibus was approved by its Board, CARB staff convened a working group of OEMs, EMA, and MECA to review warranty costs. This working group resulted in a final report in which CARB staff concluded that the methodology used to support the Omnibus Regulation warranty-related cost estimates is reasonable and defensible and they did not believe changes to those estimates were needed [45]. As stated above, this uncertainty in costs estimated to meet extended durability and warranty provides an opportunity for future collaborative work in the form of a study that includes fleets, industry stakeholders, CARB and EPA staff. [EPA-HQ-OAR-2019-0055-1320-A1, pp.27-28]

Organization: *RV Industry Association (RVIA)*

As we understand the proposal, the cost increases that will be realized by gas and diesel motorhome chassis suppliers in MY27 will be as follows:

Note: The cost shown below are the so-called 'Option 1' costs, not the more expensive 'Option 2 costs.'

Diesel motorhomes

• Class B diesel motorhomes (8501-14000 lbs. GVWR - class 2b/3 trucks): $7,952.3
• Class C diesel motorhomes (14,001-19,500 lbs. GVWR - class 4/5 trucks): $8,032.4
• Class C diesel motorhomes (19,501-33,000 lbs. GVWR – class 6/7 trucks): $8,358.5
• Class A diesel motorhomes (>33,000 lbs. GVWR – class 8 trucks): $13,382.6 [EPA-HQ-OAR-2019-0055-1270-A1, p. 2]

3. Table 7-14: MY2027 Technology Costs for LHD2b3 Diesel, Average per Vehicle, 2017 Dollars, Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards, Draft Regulatory Impact Analysis, US EPA, EPA-420-D-22-001, March 2022, page 328.

4. Table 7-16: MY2027 Technology Costs for LHD45 Diesel, Average per Vehicle, 2017 Dollars, Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards, Draft Regulatory Impact Analysis, US EPA, EPA-420-D-22-001, March 2022, page 328.

5. Table 7-18: MY2027 Technology Costs for HHD67 Diesel, Average per Vehicle, 2017 Dollars, Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards, Draft Regulatory Impact Analysis, US EPA, EPA-420-D-22-001, March 2022, page 329.

6. Table 7-20: MY2027 Technology Costs for HHD8 Diesel, Average per Vehicle, 2017 Dollars, Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards, Draft Regulatory Impact Analysis, US EPA, EPA-420-D-22-001, March 2022, page 329.

Gas motorhomes

• Class A and C motorhomes (14,001-19,500 lbs. GVWR – class 4-8 trucks): $1,944.7 [EPA-HQ-OAR-2019-0055-1270-A1, p. 3]

7. Table 7-24: MY2027 Technology Costs for LHD45, MHD67 & HHD8 Gasoline, Average per Vehicle, 2017 Dollars, Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards, Draft Regulatory Impact Analysis, US EPA, EPA-420-D-22-001, March 2022, page 330.

Separate from the increased engine costs listed above are the additional costs that would be directly incurred by manufacturers of gasoline motorhomes. These costs are associated with changing manufacturing or other process to accommodate compliant refueling emission control systems. EPA has projected these costs will be $2,528 per company in the first year of the new program. [EPA-HQ-OAR-2019-0055-1270-A1, p. 3]

As indicated above, EPA is projecting that this regulation will add $7,952 to $8,358 per vehicle for the cost of the diesel engines used in motorhomes < 33,000 lbs. GVWR. For motorhomes > 33,000 lbs. GVWR, the cost increase is projected to be $13,382 per vehicle. As we understand it, these are cost increases that will be seen by the buyer of the engine (i.e., the motorhome chassis supplier). Because the chassis supplier must make some profit, the motorhome manufacturer is likely to see cost increases 1.2 times the cost seen by the chassis supplier. A similar markup could be seen by the motorhome retailer and then again by the motorhome customer. Thus, an $8000 cost increase imposed by the engine manufacturer will likely result in a $9600 price increase for the chassis supplier. This will lead to a $11,520 price increase for the motorhome manufacturer, a $13,824 price increase for the motorhome retailer, and finally, a $16,588 price increase to the motorhome customer. In effect, the ultimate end user is likely to see twice the cost increase levied by the engine manufacturer. [EPA-HQ-OAR-2019-0055-1270-A1, p. 3]

EPA Summary and Response

We thank CARB and MECA for their detailed comments on the proposal. In general, MECA's estimates for emissions control system costs are comparable to the costs used by EPA within our analyses for the final rule. As explained in preamble Sections III, IV, and V, the final emission standards and useful life provisions are feasible, giving appropriate consideration to the cost associated with the application of technology EPA determined will be available for the model year the final standards apply (i.e., cost of compliance for the manufacturer associated with the application of such technology) and other statutory factors. EPA's assessment of the relevant statutory factors in CAA section 202(a)(3)(A) justify the final emission standards. As explained in preamble Section IV, the final warranty periods are appropriate. We also evaluated additional factors, including factors to comply with E.O. 12866; our assessment of these factors lend further support to the final rule. See responses in the remainder of this section 18 of this documents for additional responses regarding our cost estimates, including for warranty.

With respect to specific cost difference issues raised by CARB, EPA believes that the direct manufacturing costs that we have developed for the final rule based upon the FEV "tear-down" studies of valvetrain systems and diesel emission control systems provide the most accurate and up-to-date assessment of direct manufacturing costs for these systems. The FEV "tear-down" studies used a highly detailed bill-of-materials methodology for determining direct manufacturing costs that was both completely transparent and independently peer-reviewed. See RIA Chapter 3.1 for more information on the FEV "tear-down" study.

Ingevity Corporation commented on EPA's costs estimates associated with ORVR stating that Ingevity considered the estimates to be conservative but that EPA had also failed to consider the cost for increased vapor vent hose diameter between the fuel tank outlet and the canister inlet as was done in previous EPA analyses. The previous analysis to which the commenter referred was a 1994 EPA Regulatory Impact Analysis. EPA notes that our ORVR cost estimate was meant to reflect the "needed" new hardware on a modern system. Many new vehicles have canisters directly mounted to the tank assembly to minimize the need for extra lines/connections that are ultimately unnecessary costs and present durability/leakage concerns.

RV Industry Association (RVIA) commented about the costs of engines installed in motor homes. However, the costs pointed to by RVIA were actually the total technology costs of the baseline plus the proposed rule, not the incremental increase in technology costs associated with the proposal. RVIA simply misunderstood the tables presented in the proposed preamble and/or RIA. One such table is shown below, Table 7-20 from the draft RIA.

Table 7-20 MY2027 Technology Costs for HHD8 Diesel, Average per Vehicle, 2017 Dollars

Scenario	DMC	Warranty	R&D	Other	Profit	Tech Cost Sum
Baseline	$6,457	$194	$323	$1,873	$323	$9,169
Baseline+Proposed Option 1	$8,668	$1,170	$598	$2,514	$433	$13,382
Baseline+Proposed Option 2	$8,668	$910	$648	$2,514	$433	$13,172
Option 1 increase from Baseline	$2,210	$976	$275	$641	$111	$4,213
Option 2 increase from Baseline	$2,210	$716	$325	$641	$111	$4,003

In their comment, RVIA states that the cost increase of the proposed Option 1 would be "Class A diesel motorhomes (>33,000 lbs. GVWR – class 8 trucks): $13,382.6." As shown in the second row of the above, reprinted table, $13,286 is the "Baseline+Proposed Option 1" cost. However, the increased cost due to the proposed Option 1 was estimated to be $4,213 (see row 4 of the table above), much lower than the value noted by RVIA. RVIA had this same misunderstanding with the other values they noted in their comments.

18.2 Direct manufacturing costs and learning effects

Comments by Organizations

Organization: *Advanced Engine Systems Institute (AESI)*

Each independent and government study of the potential incremental cost of the 2027 standards have projected hardware and durability costs that are a small fraction (20% or less) of the $38,000 estimate offered by truck manufacturers. [EPA-HQ-OAR-2019-0055-1281-A1, p. 2]

Organization: *Agricultural Retailers Association (ARA) (1241 and 1421)*

These new federal standards attempt to match those implemented by the state of California last year. However, the trucking industry and manufacturers have maintained that it is not technically feasible to meet the new standards and have never demonstrated that to be the case. It has been reported in December 2021 that the Truck and Engine Manufacturers informed the White House that no manufacturer has said they can produce a complying product. The result of this mandate going into effect means equipment manufacturers will spend hundreds of millions of dollars chasing an impossible standard rather than strategically deploying scarce financial resources on proven technologies. [EPA-HQ-OAR-2019-0055-1251-A1, p. 3]

Organization: *American Bus Association (ABA) (1070 and 1308)*

Although ABA has insufficient time to fully analyze the cost data included in the Proposal to meet the comment deadline, these comments will address cost concerns on a broad basis. From a fundamental standpoint, the Proposal will increase costs significantly for engine manufacturers, and in turn for heavy-duty vehicle users. There will be increased costs associated with research and development necessary to achieve the proposed new standards, costs to produce the new

technology, costs to improve the durability of components to meet the proposed extended useful life of the engine and to support the proposed extended warranty time period. These costs will in inevitably be passed on to customers, in other words heavy-duty vehicle purchasers.
EPA suggests these costs will be minor, in terms cost increases, but estimates of the actual costs associated with the Proposal suggest the cost increases for a heavy-duty engine could exceed $42,000 per vehicle per other commenters such as the Truck & Engine Manufacturers Association. [EPA-HQ-OAR-2019-0055-1308-A1,pp.5-6]

Organization: *American Farm Bureau Federation (Farm Bureau)*

Farm Bureau also believes discrepancies must be addressed regarding the proposal's forecasted compliance costs. In short, there is an enormous disparity—approximately an order of magnitude— between EPA's compliance cost estimates and those projected by engine manufacturers, which are forecast to be up to $35,000 per truck. If EPA's cost estimates are too low, then other key factors influencing the proposal will be affected in turn. [EPA-HQ-OAR-2019-0055-1163-A1, p.1]

Organization: *American Truck Dealers (ATD)*

The current average cost of a new MY 2022 Class 8 CMV is $140,826.8 ATD suggests that EPA has underestimated what the average cost of similar CMVs will be in MYs 2027-2030. Analyses conducted by Ricardo Strategic Consulting (RSC) found that the incremental costs for Option 1 will be $42,051,9 which contrasts with EPA's prediction that incremental costs will be $16,750. [EPA-HQ-OAR-2019-0055-1321-A1, p. 4]

8. NADA, ATD Data 2021 (Midyear Report), p.8 (2021).

9. Includes increased operating costs. Ricardo, Review of EPA NRPM and Compliance Cost Assessment Study, p.32 (Apr. 25, 2022). An earlier cost study conducted by the National Renewable Energy Laboratory (NREL) on NOx standards being considered by the California Air Resources Board (CARB) reached similar conclusions. NREL, On-Road Heavy-Duty Low-NOx Technology Cost Study, p. 60 (May 2020).

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

Daimler Truck has undertaken its own analysis of incremental compliance costs for Class 8 diesel engines and trucks under the Proposed Rule, and it has consulted the available cost impact studies for achieving EPA's 'next-tier' standards and the similar requirements of CARB's Omnibus Low-NOx Regulations. Based upon this review, EPA's cost projections underestimate both direct and indirect costs that manufacturers would necessarily incur to achieve compliance. Further, the Agency's estimates differ significantly from the figures published in a number of recent third-party cost impact studies, without explanation of what factors account for the differences. Finally, EPA's operator cost estimates do not include the potentially significant expenditures that vehicle owners would have to make to maintain critical emissions components after the warranty period expires, which could chill fleet owner investment in next-generation vehicles produced to comply with the Proposed Rule. These issues are discussed in turn below. [EPA-HQ-OAR-2019-0055-1168-A1, p.11]

Direct Manufacturing Costs. Based upon an internal study of direct costs that the Company would incur on a per-unit basis to comply with the Proposed Rule, Daimler Truck believes that EPA significantly underestimates per-vehicle direct manufacturing costs (DMC) for Class 8 diesel vehicles. In the Proposed Rule, EPA estimates the incremental DMC increase for such vehicles in MY 2027 to be **$2,210** to achieve compliance with the Agency's proposed Options 1 and 2. 11 This estimate is based upon EPA's itemized material cost estimates in the draft RIA. 12 [EPA-HQ-OAR-2019-0055-1168-A1, pp.11-12]

11 See Proposed Rule, 87 Fed. Reg. at 17,566, Table V-1 (providing estimated MY 2027 incremental diesel technology package direct manufacturing costs associated with Proposed Options 1 and 2 in 2017 dollars).

12 See Draft RIA at Tables 3-26 and 3-27. Daimler Truck notes that in certain categories, EPA's itemized cost estimates align to a certain extent with its 0\¥ 11. For example, EPA estimates the cost of NOx sensors that would be part of the technology package used to meet the new standards under Options 1 or 2 at around $170 (or 3 sensors for a total of $510). This is not far off of Daimler Truck's estimate that the material cost would be around [redacted] per NOx sensor. Other estimates in the draft RIA rule unrealistically low, however. For instance, EPA estimates selective catalytic reduction (SCR) canning costs at around $834 for the SCR system, whereas Daimler Truck's estimate is closer to $ [redacted].

In marked contrast to this figure, Daimler Truck conservatively estimates material costs for Class 8 diesel vehicles at $ [redacted] 13 for the first year of implementation under either Option 1 or Option 2 for the Proposed Rule, accepting EPA's premise that the same technologies would be used to meet the standards in each option. 14 Based upon this figure, Daimler Truck believes that actual per-unit incremental costs of first-year compliance with the Proposed Rule would be **approximately [redacted] % greater** than EPA's $2,210 per-vehicle DMC estimate. [EPA-HQ-OAR-2019-0055-1168-A1, p.12]

13 Daimler Truck has redacted its material cost estimates from these comments, as they are based upon confidential business info1mation. The Company will make these estimates available to EPA in a confidential setting.

14 See Proposed Rule, 87 Fed. Reg. at 17,566.

Given the confidential nature of this information, Daimler Truck is not able to specify in these comments the particular technology package that it believes would be best to achieve the proposed standards for Class 8 diesel trucks, other than to note that the technology solution under consideration is based upon a combination of new engine hardware, improved catalyst formulations and layouts, including close-coupled selective catalytic reduction (CCSCR), and vehicle-side improvements to accommodate engine and aftertreatment system changes. The package under consideration would also include a thermal management system to accelerate warmup of the aftertreatment system for improved emissions performance during cold-start. 15

The above estimate is based upon the technology package that, using sound engineering judgment, Daimler Truck believes would best achieve the proposed standards without compromising performance and safety. Notably, the Company's direct cost estimates incorporate only material costs and do not include labor costs, as EPA's DMC estimates did. 16 Further, they are in present-day dollars and do not reflect adjustments for inflation. [EPA-HQ-OAR-2019-0055-1168-A1, p.12]

15 At a high level, Daimler Truck's $ [redacted] DMC cost estimate is comprised of several categories of material costs, including $ [redacted] for engine upgrades, $ [redacted] for the the1mal management system, $ [redacted] for ATS improvements, and $ [redacted] for vehicle-side costs necessa1y to inco1porate these new systems. As noted above, Daimler Truck will make the detailed breakdown available to EPA in a confidential setting.

16 See id. at 17,565.

Discussed immediately below are more holistic cost assessments set forth in the numerous published cost studies prepared in anticipation of EPA’s proposed rule and the similar proposal by CARB in its Omnibus rulemaking. [EPA-HQ-OAR-2019-0055-1168-A1, p.15]

Comparison of EPA Estimates to Other Cost Studies. As EPA notes in the draft RIA, there are a number of available studies that analyze anticipated incremental cost increases associated with next-tier NOx compliance and associated regulatory requirements. These studies, based upon extensive OEM, trade group, and supplier input, are largely consistent with one another as far as what the main cost drivers will be and what individual program components will cost. Yet EPA does not fully explain why its DMC and indirect cost assessments diverge—in some cases, quite significantly—from the estimates in these studies. Below is a summary of the principal conclusions on estimated compliance costs for Class 8 diesel trucks from four different studies: (1) the Ricardo Cost Study; (2) the NREL Cost Study; (3) a 2020 Cost Study prepared by ACT Research (the ‘ACT Cost Study’); and (4) a 2020 Cost Study prepared by the International Council on Clean Technology (the ‘ICCT Cost Study’). [EPA-HQ-OAR-2019-0055-1168-A1, p.15]

Ricardo Cost Study. The Ricardo Cost Study was prepared for the Truck and Engine Manufacturers Association (EMA) in April 2022, in support of EMA’s analysis of the Proposed Rule, and examines the impacts of EPA’s proposed Option 1 and Option 2 on the cost of heavy-duty diesel engines (HDDEs). The Ricardo Cost Study assumed that the Southwest Research Institute (SWRI) Stage 3 prototype technology package would be sufficient to attain EPA’s proposed low-NOx targets and related requirements, and its estimates encompass incremental costs associated with new hardware, extended warranty and useful life periods, in-use compliance, R&D, engineering, and testing.26 Relative to a MY 2021 baseline, the study estimates that the total incremental cost per HDDE for meeting anticipated regulatory requirements under Option 1 is approximately **$18,650** in MY 2027 and **$31,246** in MY 2031, and under Option 2 is approximately **$16,091** starting in MY 2027.27 These figures reflect *only* the Ricardo Cost Study estimates of direct and indirect incremental costs to manufacturers (in 2017$) and do not include the significant incremental operating costs that are also provided in the study.28 [EPA-HQ-OAR-2019-0055-1168-A1, pp.15-16]

26 Ricardo Cost Study at 24.

27 Id. at 32, Table 26. The figures provided here were calculated by subtracting the operating cost estimates in Table 26 from the 'Total' figures provided in 2017$ that table. Using this calculation method, the corresponding cost estimates in 2021$ would be $20,702 in MY 2027 and $34,682 in MY 2031 under Option 1, and $17,861 starting in MY 2027 under Option 2.

28 Notably, the Ricardo Cost Study estimates incremental per-engine operating costs to be around $11,993 under Proposed Rule Option 1, and $7,176 under Option 2 (in 2021$). See id.

NREL Cost Study . The NREL Study was commissioned by CARB in support of its Omnibus rulemaking and was published in May 2020. The study included a review of engine and exhaust afte1treahnent technologies that could achieve 0.02 g/bhp-hr NOx on certification test cycles, including a low-load cycle. 29 For Class 8 diesel applications, NREL surveyed trade organizations, Tier 1 suppliers, and OEMs, requesting that they provide incremental cost estimates on two unique diesel engine technology packages (charge air, exhaust gas recirculation (EGR), and turbine cooler bypass vs. cylinder deactivation) combined with two unique aftertreatment technology packages. 30 From the responses, NREL constructed proposed low-, average-, and high-cost combined engine and aftertreatment technology packages, generating cost ranges for each package.31 The survey assumed 0.02 g/bhp-hr NOx regulation beginning MY 2027 and included FTP and SET-RMC steady-state test cycles, as well as a proposed new LLC cycle. It also considered an extended full useful life of 1,000,000 miles/15 years, and a regulatory warranty period of 800,000 miles/12 years. The study encompassed California production volumes only. The survey responses provide an illustrative range of the low, average, and high cost estimates for each of the three categories of technology packages considered (i.e. , low-, average-, and high-cost) and reflect that increased warranty costs are a key driver of incremental cost increases under CARB 's proposed regulato1y framework, as illustrated below: [EPA-HQ-OAR-2019-0055-1168-A1, p.16]

29 NREL Cost Study at vii.

30 Id. at 12.

31 Id.

ACT Cost Study . ACT Research prepared an analysis for EMA of costs associated with CARB's proposed Omnibus rule in March 2020.35 The analysis focused on CARB's proposed standards and requirements for the Omnibus rule in both 2027 and 2031 , and concluded the following with respect to incremental costs for heavy HDVs on a per-unit basis: [EPA-HQ-OAR-2019-0055-1168-A1, pp.16-17]

35 See ACT Research, Cost Study: Proposed Heavy-Duty Engine and Vehicle Emissions Regulations (March 19, 2020) ('ACT Cost Study').

Adding these incremental cost estimates together, the ACT Cost Study concludes that the total cost increase per unit to meet CARB 's proposed combined MY 2027 and MY 2031 vehicle standards on a nationwide basis would be **$25,963** applying a 7% discount rate and **$37,079** applying a 3% discount rate. As found in the other cost studies referenced herein, the ACT Cost Study concludes that the extended warranty and useful life requirements in the CARB Omnibus rule were key drivers of incremental cost increases.[EPA-HQ-OAR-2019-0055-1168-A1, p.17]

ICCT Cost Study. Finally, the ICCT Cost Study was published in May 2020 and estimates the costs of technology required to meet CARB's proposed regulato1y changes for the Omnibus rule in 2024 and 2027. 38 While the ICCT Cost Study did review the anticipated impact of increased useful life requirements, the effect of lengthened regulatory warranty periods was outside of the scope of the analysis. A principal conclusion of the study is that meeting CARB's MY 2027 targets39 ‘would require significant changes in current technology and costs, driven by 90% lower FTP NOx targets, LLC requirements, and long use useful life mandates. ‘40 The ICCT Cost Study assumes that cylinder deactivation and EGR bypass would need to be added to future engines to achieve the projected CARB MY 2027 requirements.41 It also assumes that aftertreatment changes would include the addition of CCSCR and changes to the urea dosing system, and it assumes changes to catalyst volume and wash coat fo1mulations, as well as sensor replacement to meet the extended regulat01y useful life requirement. 42 Based upon these assumptions, the ICCT Cost Study estimates the total incremental cost of meeting the CARB MY 2027 standards to be **$5,919 - $6,013** as the ‘low-cost durability case’ and **$6,864 - $6,988** as the ‘high-cost durability case.’43 While these figures purport to include account for direct and indirect costs associated with meeting the CARB MY 2027 proposal, they do not include a number of key cost inputs, including the indirect costs that would be associated with CARB’s extended warranty requirement. Further, it is important to note that ICCT’s estimates are based upon available literature, trade publications, and expert reviews and not actual cost data from manufacturer or supplier surveys. The absence of these crucial inputs may account for the relatively low estimates in the ICCT Cost Study as compared to other studies with more robust data inputs. [EPA-HQ-OAR-2019-0055-1168-A1, pp.17-18]

38 See Posada et al., International Council on Clean Transportation, White Paper, 'Estimated Cost of Diesel Emissions-Control Technology to Meet Future California Low-NOx Standards in 2024 and 2027' (May 2020) (the 'ICCT Cost Study').

39 The ICCT Cost Study is based upon the following proposed requirements for MY 2027 in the CARB Omnibus proposed rule (which, except for the NOx limits, closely resemble EPA Option 1 in the Proposed Rule): NOx FTP limit of 0.02 g/bhp-hr, LLC limit of 1-3 times the FTP limit, 600,000 mile useful life in MY 2027 and 800,000 miles by MY 2031. See id. at Table 1.

40 Id. at 2.

41 Id.

42 Id.

43 Id., Table ES-2.

Comparison to EPA Total Technology Cost Per Vehicle Numbers. EPA estimates total per-vehicle technology costs (in 2017 dollars) for Class 8 diesel trucks as follows:44

- Option 1:
    - MY 2027: $4,213
    - MY 2031: $3,931
- Option 2:
    - MY 2027: $4,003
    - MY 2031: $3,215 [EPA-HQ-OAR-2019-0055-1168-A1, p.18]

44 See Proposed Rule, 87 Fed. Reg. at 17,571, Table V-11. As EPA explains in the Proposed Rule, these figures reflect incremental cost increases over a baseline or 'no action' case consisting of engine or emission control systems meeting 2019-era criteria emission standards. Id. at 17,565, n. 726.

Considering EPA's total technology cost estimates alongside Daimler Truck's direct material and warranty cost estimates discussed above, alongside the cost estimates in the Ricardo, NREL, ACT, and ICCT cost studies, it is clear that EPA underestimates what actual costs of compliance with its Proposed Rule standards and requirements would likely be.45 EPA's per unit estimate range of **$3,215 - $4,213** (in 2017 dollars) is far lower than even the most conservative ICCT estimates of **$5,919 - $6,988** (in 2019 dollars) and Daimler Truck's partial-cost estimates of $ [redacted] (in today's dollars). EPA's ranges are well off the mark when compared to the more realistic Ricardo Cost Study range of **$16,091 - $31,246** (in 2017 dollars) the NREL Cost Study range of **$10,697 - $50,846** (in 2018 dollars), and the ACT Cost Study range of ***$25,963 - $37,079*** (in 2019 dollars). The fact that EPA's estimates differ so dramatically from the other leading cost studies warrant re-visiting its methods and assumptions to account for the vast disparities, particularly given that EPA has not explained how it can justify such a departure. [EPA-HQ-OAR-2019-0055-1168-A1, p.18]

45We note that while the details and assumptions of each of the above-cited cost studies are slightly different (e.g., 2017$ vs. 2019$, the assumed applicable NOx standard, the assumed applicable regulatory useful life and warranty periods), these studies generally considered very similar technology packages and their premises are roughly similar, such that they provide reasonable benchmarks for the expected program costs on a per-vehicle basis.

EPA cost projections have historically undercounted the effects of its rulemakings, as compared to sales data and pricing information gathered by analysts working directly with the manufacturing sector to gather cost data. A 2012 study published by American Truck Dealers (ATD) examined EPA cost projections for 1997, 2000, and 2001 HD truck rules that phased in new emission standards between MY 2004 and 2010, specifically the degree to which—and possible reasons why—EPA's RIA for these standards dramatically underestimated real world costs of the regulations. 46 The ATD Study concluded that EPA underestimated compliance costs by a factor of 2-5, and that these higher-than-projected costs resulted in significantly lower-than projected new truck sales, reducing the environmental benefits associated with the standards reviewed.47 The figure below, taken from the ATD Study, reflects that actual manufacturing cost increases for MY 2010-compliant heavy HD trucks were around three times higher than the costs that EPA had projected during the rulemaking process:48 [EPA-HQ-OAR-2019-0055-1168-A1, pp.18-19]

46 See Calpin et al., American Truck Dealers, 'A Look Back at EPA's Cost and Other Impact Projections for MY 2004-2010 Heavy-Duty Truck Emissions Standards' (February 13, 2012) (the 'A.TD Study').

47 Id. at 2.

48 See id. at 9, Figure 3. As explained by A.TD, this figure reflects truck OEMs and year of invoice on the X-axis, as well as per-vehicle regulatory compliance premiums on the Y-axis. Dollars are standardized to 2010 with surcharges adjusted for inflation. The EPA estimate is a MY 2009 projection made in December 2000, inflation adjusted.

EPA should revisit its cost projections made in support of the Proposed Rule, and utilize the wealth of information available on *actual* manufacturing cost increases that accompanied implementation of EPA's previous-generation emission standards, as well as the numerous available studies on the currently-proposed next-tier standards and requirements. [EPA-HQ-OAR-2019-0055-1168-A1, p.19]

Organization: *International Council on Clean Transportation (ICCT)*

The total cost to meet a standard is traditionally split between direct and indirect cost of manufacturing. Direct manufacturing cost (DMC) covers in broad terms the hardware; indirect costs (IMC) cover warranty, R&D, profit, and other cost elements that would impact the cost depending on how many units are sold. Figure 5 shows estimates of the incremental direct manufacturing costs derived from meeting the standards, including estimates from ARB’s Low NOx Omnibus and EPA’s NPRM (Option 1). The deviation is relatively small compared to the deviation found in the total costs table. The DMC values are close to $2,000 for EPA NPRM and ICCT costs. ARB’s cost for the Low NOx Omnibus rule is based on NREL's OEM survey, which explains the agreement in values. ARB’s values corrected by volume to better represent national HDV sales reduce DMC by ~30% and are close to DMC values reported by Ricardo under contract for EMA in 2021. However, EMA-Ricardo’s values and NREL values were obtained from surveying vehicle manufacturers and provide few details to explain how the numbers were derived. Cost surveys among regulated entities tend to generate values well above those found via bottom-up cost analysis, as detailed by ICCT and EPA. [EPA-HQ-OAR-2019-0055-1211-A1, p. 13]

Additional sources from the industry also confirm the DMC range. Eaton’s analysis shows that the total incremental cost to meet the proposed regulation while reducing GHG emissions ranges from $1,700 to $2,900 and includes cylinder deactivation, e-heater, LO-SCR, and a 48V, and supports a 25-35% full-time NOx compliance margin to 435k miles useful life. [EPA-HQ-OAR-2019-0055-1211-A1, p. 13]

Organization: *National Association of Chemical Distributors (NACD)*

This severe cost to the chemical distribution industry and American economy would not only harm those directly impacted, but it would also make it more difficult to take future steps to reduce emissions. This loss in jobs and economic output would also burden manufacturers of heavy-duty engines and vehicles as there would be fewer purchases of their vehicles. Since the 1970s, the EPA and trucking industry have successfully reduced the emissions of particulate matter (PM) and nitrogen oxide (NOx) by 98%. With the emissions of PM and NOx from heavy-duty trucks already reduced to such a small fraction of where they were previously, pushing for an even lower amount will be less cost-effective than previous rules and will force manufacturers to reallocate resources that are currently being dedicated towards the research and development of zero emission vehicles. [EPA-HQ-OAR-2019-0055-1279-A1, p. 2]

The proposed rule estimates an increase in each vehicle of only about $4,000; however, research from the Truck and Engine Manufacturers found that a more realistic increase in the cost of vehicles is $42,000, roughly ten times that of EPA estimates.1 [EPA-HQ-OAR-2019-0055-1279-A1, p. 2]

> 1. Truck & Engine Manufacturers Association, 'By the Numbers: Unintended Consequences of EPA's Proposed Truck Emissions Rule,' https://cleantruckfacts.org/, EMA, https://drive.google.com/file/d/1XD8yHIgfkoFbCdmXJLM_ZXfgBMxofCcb/view

Organization: *New York Farm Bureau (NYFB)*

NYFB also believes discrepancies must be addressed regarding the proposal's forecasted compliance costs. In short, there is an enormous disparity—approximately an order of magnitude— between EPA's compliance cost estimates and those projected by engine manufacturers, which are forecast to be up to $35,000 per truck. If EPA's cost estimates are too low, then other key factors influencing the proposal will be affected in turn. [EPA-HQ-OAR-2019-0055-1268-A1, p. 1]

Organization: *PACCAR, Inc (PACCAR)*

In particular, PACCAR agrees with the following aspects of EMA's comments: The proposed extended useful life (UL), and durability demonstration testing requirements, coupled with the increased recall liability, could result in manufacturers building-in assumptions regarding the need to replace the aftertreatment systems at approximately 500,000 miles (or sooner), which would cause substantial price increases for new HDOH vehicles. [EPA-HQ-OAR-2019-0055-1346-A1, p.2]

Organization: *Truck and Engine Manufacturers Association (EMA)*

EMA retained Ricardo to conduct a comprehensive assessment of the direct and indirect costs, as assessed on a per-vehicle basis, that likely will result from EPA's implementation of the low-

NOx regulations, particularly with respect to new regulations centered around Option 1. The Ricardo compliance cost assessment (Exhibit “B” hereto) is based on its exhaustive review of public data sources, evaluation of recommended cost-estimation methods, and a detailed survey and analysis of the HDOH vehicle and engine manufacturing industry, which Ricardo completed in mid-2021 and then updated in 2022. Table 26 from the Ricardo report, reproduced below, summarizes Ricardo’s findings regarding the aggregated per-vehicle cost impacts from EPA’s Option 1 and Option 2 proposals: [EPA-HQ-OAR-2019-0055-1203-A1, pp. 148 - 149]

As reflected above, Ricardo estimates that the per-vehicle incremental costs for HHD vehicles under EPA’s Option 1 will total $42,051 (in 2017 dollars) as of 2031, including increased operating costs. When Ricardo’s per-vehicle cost number is compared against EPA’s estimated per-vehicle cost number ($3,931 for HHD vehicles in 2031), it is clear (again) that EPA has understated the per-vehicle costs of its proposed rulemaking by an order of magnitude. The same conclusion holds when comparing Ricardo’s calculation of likely per-vehicle HHD warranty, UL and component replacement costs in 2031 ($26,376) with EPA’s calculation of those indirect costs ($1,458).32 [EPA-HQ-OAR-2019-0055-1203-A1, p. 149]

32. It is worthy of note that EPA significantly underestimated the costs of its last HDOH rulemaking by at least a factor of four (4). See ATF Report, Feb. 2012, “A Look Back At EPA’s Cost And Cyber Impact Projections For MY 2004- 2010 Heavy-Duty Truck Emission Standards.”

Unlike EPA’s cost assessment, Ricardo conducted an actual comprehensive survey of all leading OEM’s to assess the likely direct and indirect cost impacts of the Option 1 standards, and so was able to make detailed determinations of the per-vehicle direct and indirect cost impacts that will result from EPA’s proposal as of 2027 and 2031. As explained in the Ricardo Report, the cost-assessment that Ricardo utilized is inherently more reasonable and robust than the assumption driven and extrapolation-based approach that EPA has taken. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 149 - 150]

From the foregoing comparisons of cost estimates, it is clear that the main differences between EPA’s estimates and Ricardo’s relate to the direct costs for CDA systems, and the indirect costs associated with the proposed extensions of emissions warranty and UL periods. More specifically, EPA assumes that the all-in per-vehicle costs associated with the deployment of the required complex CDA systems will be only $206, a number that EPA derived from assessing costs at the component-supplier level. Ricardo, on the other hand, based its assessments of all of the relevant CDA-integration costs at the OEM level, and has calculated those per-vehicle costs to be $1,512. (See Ricardo Report, p. 20.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 150]

Beyond that. the more significant cost differentials stem from how EPA and Ricardo have estimated the per-vehicle costs associated with EPA’s proposals to extend the regulatory UL and emissions warranty periods. EPA’s estimate of those costs (as adjusted upward by Ricardo) — based on the Agency’s assumption that aftertreatment components will not need to be replaced during the extended UL period — amounts to just $2,373 per vehicle, a figure that is inherently unrealistic and that is less even than CARB’s much shorter “Step 1” warranty, as discussed further below. Ricardo, on the other hand, based on real data from OEMs, and on the OEMs’ direct confirmation that ERCs will need to be replaced if an 800,000 mile UL is mandated, has calculated that the actual incremental per-vehicle UL and warranty costs will be $26,376. Here too, EPA has under-estimated the actual incremental costs of Option 1 by more than an order of magnitude. Ricardo's Report explains these critical differences with greater particularity, and demonstrates that EPA's cost projections are unreasonable, which means that they are an insufficient basis for this rulemaking. [EPA-HQ-OAR-2019-0055-1203-A1, p. 150]

A side-by-side comparison of the cost elements of EPA's Option 1 and 2 proposals, as estimated by EPA and by Ricardo is set forth below: [EPA-HQ-OAR-2019-0055-1203-A1, p. 150]

As already discussed, EPA's order-of magnitude miscalculations of cost are rooted in large part in the Agency's unsupported assumption that manufacturers will not fully adjust the costs of their HHD and MHD vehicles to recoup the full projected costs that will result from EPA's proposals to extend emission warranties and regulated FULs, and from the increased compliance liabilities that will stem from the substantially expanded list of emissions-related components that will be covered under the lengthened warranties. But it is fundamentally unreasonable to assume that manufacturers will choose to absorb the quantumly increased costs and risks of the low-NOx regulations, and so will not attempt to fully recoup those costs through corollary vehicle price increases. Based on consistent historical experience, and as a matter of sensible business practice, manufacturers will calculate and fully recoup those regulatory costs through corollary per-vehicle price increases. [EPA-HQ-OAR-2019-0055-1203-A1, p. 151]

Organization: *Truck Renting and Leasing Association (TRALA)*

In its proposed rule, the EPA has asked the public to comment on two options for reducing Nitrogen Oxides (NOx) emissions. Option 1 would lead to a 90% reduction of NOx from the current 0.2 g/bhp-hr standard to an ultra-low .02 standard in 2031, which would be in line with the California Air Resources Board's (CARB) Heavy-Duty Engine and Vehicle Omnibus Regulation that was finalized on December 22, 2021. The new NOx standard that CARB has set will lead to a substantial increase in the cost of a new Heavy-Duty vehicle, as well as significantly disrupt the new truck market. After discussions with several OEMs, TRALA is not confident this level of NOx reduction is even possible by the target date, and therefore, TRALA opposes Option 1 as it is currently not technologically feasible. [EPA-HQ-OAR-2019-0055-1180-A1, p. 2]

As noted in the comments of the Truck and Engine Manufacturer Association (EMA) that were submitted to CARB on August 27, 2020, an independent study was performed by Americas Commercial Transportation Research Company (ACT Research), which found that CARB's NOx regulation would result in a $58,000 increase in the cost of a new Model Year 2031 heavy heavy-duty vehicles and a $51,000 increase for medium heavy-duty vehicles. Since those cost estimates were made prior to the inflationary period that the economy is going through now, TRALA believes the actual cost of this regulation on a per-vehicle basis may be higher than $58,000. These costs cannot simply be absorbed by TRALA members, and a requirement for a 90% reduction in NOx will ultimately result in higher lease payments for TRALA customers. [EPA-HQ-OAR-2019-0055-1180-A1, p. 2]

The majority of TRALA customers are small businesses who need trucks to operate a segment of their business and they are inclined to lease instead of purchase a fleet of trucks. The typical customer will lease two or three trucks for a period of four to six years, and at the end of their lease contract they will turn in their truck to the lessor and enter into a new lease on a new truck. The lessor will either keep that truck as a part of their rental fleet or sell the truck on the secondary market. This model has reduced the overall cost of ownership for small businesses, while also putting new trucks out on the road faster than other segments of the trucking industry. Increasing the cost of new diesel trucks by a significant amount will lead to customers opting into longer lease contracts, or in many cases, opting to renew their current vehicle lease instead of leasing a newer, more environmentally friendly truck. Longer lease terms and renewals of current leases will significantly slow the velocity of new trucks entering the marketplace once these new rules go into effect. [EPA-HQ-OAR-2019-0055-1180-A1, p. 2]

Organization: *U.S. Chamber of Commerce*

EPA openly acknowledges that the proposed rule's impacts on the cost of new medium- and heavy-duty trucks, and the impacts of its associated unprecedented and untested useful life and warranty requirements, are highly uncertain. Indeed, there is an enormous and troubling disparity—approximately an order of magnitude—between EPA's compliance cost estimates and those projected by engine manufacturers. Such factual issues merit very careful attention and consideration by the agency.

Specifically, a detailed April 2022 analysis by Ricardo Strategic Consulting forecasts that EPA's Option 1 would impose incremental compliance costs of $42,000 per truck.12 The report concluded that, based on historical cost data, "most OEMs do not experience the steep cost reductions that EPA uses in its analysis of the introduction of new emission-control technologies." [EPA-HQ-OAR-2019-0055-1245-A1, p. 5]

> 12. Review of EPA NRPM and Compliance Cost Assessment, April 25, 2022. Available at https://drive.google.com/drive/folders/1PdGgvJMGBLNM8pFLd3SXuD8ZS0VcNh-g

EPA Summary and Response

The comments summarized above focus primarily on assertions about:

- EPA's costs being too low, largely because EPA did not consider aftertreatment replacement costs in its cost analysis; and,
- EPA's cylinder deactivation costs being too low when compared to estimates by manufacturers generated via surveys; and,
- EPA's cost reductions resulting from the learning-by-doing phenomenon being too aggressive.

Several commenters stated that costs would be much higher than estimated by EPA, as high as $42,000 per HHD8 engine (Advanced Engine Systems Institute, American Bus Association, American Farm Bureau Federation, American Truck Dealers (ATD), Daimler Truck North America LLC (Daimler), National Association of Chemical Distributors (NACD), PACCAR, Truck and Engine Manufacturers Association (EMA), New York Farm Bureau (NYFB), U.S. Chamber of Commerce, Truck Renting and Leasing Association (TRALA)). The source of these cost estimates is the EMA comments which included a study done for EMA by Ricardo which estimated costs as high as $42,000 per engine. The primary difference between EPA's cost estimates and the higher cost estimates from commenters was a difference in approach associated with the proposal's Option 1, particularly for the Heavy HDE NOx standards and useful life values for MY 2031, which the EMA/Ricardo study and comments argued would require aftertreatment system replacement during the useful life of the vehicle at a cost of as much as $20,000. As explained in preamble Sections III and IV, the useful life values under the proposal's Option 1 in MY 2031 for Heavy HDE are not part of the final rule, and the final useful life values for Heavy HDE are both shorter and associated with higher numeric emission standards (i.e., less stringent levels of NOx control) than proposed Option 1 in MY 2031. More specifically, 1) EPA's final rule does not require the longer useful life considered in the EMA/Ricardo study (800,000 miles), 2) the EPA final numeric NOx standards are not as stringent as the values considered in the EMA/Ricardo study, and 3) as explained in preamble Sections III and IV, the EPA final NOx standards for the HHD8 engines explicitly include consideration of compliance margin, which was one of the primary technical concerns identified by EMA as driving the asserted need for the projected aftertreatment replacement requirements in the EMA/Ricardo study. In addition, EPA's final rule does not include the 600,000 mile emissions warranty for the HHD8 engine class which was considered in the EMA/Ricardo study. These factors, plus EPA's analysis and determination that the final standards and useful life values are technically feasible for MY 2027 and later engines, obviate the need to replace aftertreatment systems to maintain compliance during the useful life and thus make a comparison of the EPA final cost estimate and the EMA/Ricardo study an apples-to-oranges comparison.

Another area of significant difference, in EPA's view, is EPA's reliance on a very detailed set of bottom-up cost estimates, including tear-down efforts for CDA system costs. The EPA final rule cost estimates for the aftertreatment system and the CDA system rely upon peer-reviewed, externally commissioned, detailed and transparent cost estimates. In contrast, the EMA/Ricardo study estimates are based on manufacturer surveys with little to no detail behind what survey respondents may have included or not included in their estimated costs. ICCT noted in their comments that, "Cost surveys among regulated entities tend to generate values well above those found via bottom-up cost analysis," and EPA shares that concern. A possible source of difference between EPA estimates and typical manufacturer survey estimates has to do with assumptions about how some or all indirect costs are recovered. In the HD2027 analysis, EPA estimates that indirect costs continue indefinitely at a multiple of the direct manufacturing costs. In contrast, it is possible that manufacturer respondents, or some respondents, may have assumed that indirect costs would have to be recovered over a short time frame, amortizing those costs over one or only a few model years of sales. The limited detail provided in the EMA/Ricardo study estimates makes it difficult for EPA to evaluate whether that is in fact the case.

EMA also commented on the "substantially expanded list of emissions-related components that will be covered under the lengthened warranties." As we describe in Section 4.1, we did not intend to expand the list of components covered under warranty and we are revising the proposed warranty provisions in the final rule to clarify that emission-related warranty covers components listed in 40 CFR part 1068, appendix A, consistent with current requirements.

The U.S. Chamber of Commerce also commented on the rate of cost reductions in the EPA cost analysis, stating that "most OEMs do not experience the steep cost reductions that EPA uses in its analysis of the introduction of new emission-control technologies." This appears to be a reference to the EMA/Ricardo study comments and, specifically, the Ricardo study. In section 5.6 of that Ricardo study, Ricardo mistakenly claims that EPA used certain learning curves that EPA did not actually use in the proposal (or this final rule). Ricardo did not provide a source for the learning curves they attribute to EPA.[40]

Importantly, Ricardo did not make clear that EPA also applies learning effects to the baseline technology costs, although at an appropriately lower rate. Since EPA's primary focus is on the incremental costs associated with standards, the costs under the standards versus those under the baseline is of most relevance. Without learning in the baseline, the baseline cost would not decrease while the action case cost would continue to decrease downward toward the baseline cost, thereby decreasing the marginal cost much more rapidly than the approach used by EPA. Therefore, EPA believes that this claim of EPA having used inappropriately high rates of learning is simply not accurate, especially when combined with the fact that learning is also applied in the baseline. EPA is using the same approach to learning in the final analysis (see Chapter 7.1.1 of the final RIA for all of the learning effects applied in the final analysis).
At least one manufacturer provided more detailed cost estimates but redacted those estimates in their comments to the public docket. These estimates, while higher than EPA's proposal, included costs for replacement of parts during the useful life based on the manufacturer's views of the EPA proposed Option 1. However, as explained further in preamble Sections III and IV, EPA is not finalizing the complete Option 1 standards, useful life values, and warranty periods as proposed and, as explained above, the final standards are feasible without replacement of aftertreatment systems to maintain compliance during the final regulatory useful life values. In three key drivers of costs (emission standards, emissions warranty, and regulatory useful life) the EPA final rule has less stringent numeric requirements than considered by this manufacturer and is thus similarly an apples-to-oranges comparison for the same reasons explained above with regard to the EMA/Ricardo study cost estimates.

The National Association of Chemical Distributors (NACD) commented that so much has already been done through the years to clean up heavy-duty trucks that this rule will be less cost-effective than those prior efforts. NACD also commented, as did the Agricultural Retailers Association, that this rule is requiring R&D expenditures that could be focused on zero emission vehicles. In EPA's judgment, despite the evolution of zero emission technology, as discussed in preamble Sections VII and VIII, the projected emissions and negative impacts on public health and welfare from internal combustion engine trucks cannot be ignored. Clean Air Act section 202(a)(3)(A) requires EPA to set emission standards for NOx, PM, HC, and CO for heavy duty engines that reflect the greatest degree of emission reduction achievable through the application of technology that the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology. CAA section 202(a)(3) neither requires that EPA consider all the statutory factors equally nor mandates a specific method of cost analysis;

[40] The approach used by EPA in estimating learning effects is explained in the final RIA Section 7.1.1 and was derived from "Cost Reduction through Learning in Manufacturing Industries and in the Manufacture of Mobile Sources, Final Report and Peer Review Report," EPA-420-R-16-018, November 2016.

rather EPA has discretion in determining the appropriate consideration to give such factors. See, e.g., Sierra Club v. EPA, 325 F.3d 374, 378 (D.C. Cir. 2003) (explaining that similar technology forcing language in CAA section 202(l)(2) ‘‘does not resolve how the Administrator should weigh all [the statutory] factors in the process of finding the ‘greatest emission reduction achievable’ ’’); Husqvarna AB v. EPA, 254 F.3d 195, 200 (D.C. Cir. 2001) (explaining that under CAA section 213’s similar technology-forcing authority that ‘‘EPA did not deviate from its statutory mandate or frustrate congressional will by placing primary significance on the ‘greatest degree of emission reduction achievable’ ’’ or by considering cost and other statutory factors as important but secondary). As explained in preamble Sections I, III and V, in setting the final emission standards, EPA appropriately assessed the statutory factors specified in CAA section 202(a)(3)(A), including giving appropriate consideration to the cost associated with the application of technology EPA determined will be available for the model year the final standards apply (i.e., cost of compliance for the manufacturer associated with the application of such technology). EPA’s assessment of the relevant statutory factors in CAA section 202(a)(3)(A) justify the final emission standards. We also evaluated additional factors, including factors to comply with E.O. 12866; our assessment of these factors lend further support to the final rule. This rule is projected to result in a significant reduction in heavy-duty truck emissions which, as described in the final rule preamble and final RIA, is projected to reduce air pollution and improve public health and welfare. In addition, we note that EPA’s analysis demonstrates that the rule is cost beneficial to society in that its benefits outweigh its costs. Given these considerations, how this rule’s cost-effectiveness compares to prior emission control regulatory programs is not germane.

NACD also commented that loss in jobs and economic output would burden manufacturers of heavy-duty engines and vehicles, as there would be fewer purchases of their vehicles. We respond to these comments in sections 25 through 26 of this document.

TRALA also commented with respect to what we call low-buy, where truck purchasers may decrease purchases of new trucks due the to the final program thereby reducing the benefits of the program. We respond to such comments in section 25 of this document.

18.3 Indirect costs – Warranty

Comments by Organizations

Organization: *Allison Transmission, Inc. (Allison)*

In order to calculate the cost of longer warranty and useful life periods, EPA relied on one analysis (the Fleet Advantage study) over another (the American Transportation Research Institute (ATRI) study.30 EPA’s rationale for relying on the first study was that it was centered on “both short-haul and long-haul combination trucks.”31 EPA theorized that the ATRI study would “suggest a higher weighting of older vehicles with higher repair and maintenance costs/mile relative to the weighting of costs/mile in the Fleet Advantage study.”32 For this reason, EPA apparently chose the Fleet Advantage study over the ATRI study with its concomitant lower costs (10.48 cents/mile versus 17.1 cents/mile). [EPA-HQ-OAR-2019-0055-1231-A1, p.14]

30 Draft RIA at 342.

32 Id.

Organization: *American Trucking Associations (ATA)*

One of the more controversial potential cost increases under HD2027 is the requirement to significantly extend mandatory warranties paid for by the initial vehicle purchaser. Warranty pricing is not a stand-alone operational cost line-item. It is wrapped into the category of truck lease or purchase payments complete with a 12% Federal Excise Tax tacked on. A potential sixfold increase in warranty coverage will not come cheap. [EPA-HQ-OAR-2019-0055-1326-A1, p. 11]

Many factors determine equipment turnover cycles for fleets including the financial health of the economy and the company, depreciation, type of operation, maintenance levels, and trade-in values. There is no need for a company that has a short fleet turnover cycle to purchase an extended warranty package. These fleets already have the lowest emission profiles in the industry given they routinely purchase the newest equipment on the market. It is these fleets that will be disproportionally impacted financially if they are required to purchase warranties that exceed their mileage needs. Requiring the purchase of extended warranties not normally needed may potentially have the unintended consequence of fleets holding onto their current trucks longer thereby decreasing the introduction of new ultra-low NOx trucks into the secondary marketplace. [EPA-HQ-OAR-2019-0055-1326-A1, p. 11]

Fleets have widely varied approaches to their purchase of extended warranties depending on their business models and financial means. The one common factor that exists is that fleets purchase extended warranties based upon their specific needs and costs. The following five real life examples illustrate this point and are based upon today’s technologies, not those involving the next generation of more highly complex and expensive pathways: [EPA-HQ-OAR-2019-0055-1326-A1, p. 11]

Example #1

Fleet A is a large Less-Than-Truckload (“LTL”) fleet that purchases new Class 8 trucks and uses them for the life of the truck which is roughly 1.6 million miles or 15 years. Fleet A has emission control/maintenance work that typically costs $10,000 at around 400K mile intervals. They purchase the longest extended warranties available in the market. Emission control equipment falling outside the warranty period is typically repaired at dealerships. [EPA-HQ-OAR-2019-0055-1326-A1, p. 11]

Example #2

Fleet B is a large Truckload (“TL”) fleet that purchases new Class 8 trucks and uses them for around 400-450K miles before reselling their vehicles. Fleet B pays over $4,000 above the standard 100K mile/5-year warranty for extra emission systems coverage (i.e., they purchase a 5-year 450K mile aftertreatment extended warranty). Their extended warranty purchases align with their expected use of their equipment. Fleet B notes that they must purchase an extended engine warranty package (i.e., 4-year 450K mile engine extended warranty) to purchase the extended aftertreatment warranty package therefore both costs are reflected in their $4,000+ figure. Both warranty packages cover different aspects of the emission control system. Fleet B also noted that given their large volume of orders, they are able to negotiate a substantially lower extended warranty package per power unit compared to fleets that are not able to leverage economies of scale. Given Fleet B's consistent fleet turnover cycles, there is no need to purchase warranties beyond their period of ownership which is the case for all similarly situated fleets. [EPA-HQ-OAR-2019-0055-1326-A1, p. 12]

Example #3

Fleet C is a small trucking company that conducts LTL, TL, and drayage operations. Fleet C purchases new Class 8 trucks that include the standard 100K mile/5-year manufacturers' warranty. They do not purchase extended warranties and they operate their trucks for their entire operational life. Major repair work outside the standard warranty period is conducted at dealerships. [EPA-HQ-OAR-2019-0055-1326-A1, p. 12]

Example #4

Fleet D is a medium-sized trucking company that operates flatbeds. Fleet D purchases new Class 8 trucks and they also purchase the extended warranty packages that cover 500k miles including clutch and towing. Their additional cost beyond the standard 100K mile/5-year warranty (excluding their clutch and towing warranty cost) costs $7,000 for an additional 500,000 miles of warranty coverage. They operate their fleet until the end of their equipment operational life, sometimes as much as 2 million miles. Major repair work outside their warranty periods is undertaken at dealerships. [EPA-HQ-OAR-2019-0055-1326-A1, p. 12]

Example #5

Fleet D is a small trucking company that operates 10 Class 8 trucks. Their operations include TL, dry van, temperature-controlled, and flatbed. Fleet D only purchases used trucks and operates them for the remainder of their operational life, typically 800,000 to 1,000,000 miles. Fleet D buys used trucks having between 300,000 to 400,000 miles but that may change given the tremendous escalation in used truck prices that have now exceeded $100,000 per tractor – the highest prices on record for used Class 8 trucks.8 They do not normally purchase extended warranties on their used equipment due to high warranty prices. In addition, they noted that they are charged between $500 to $1,000 per vehicle up-front per vehicle for pre-inspections for extended warranty applications whether they decide to buy an extended warranty or not. [EPA-HQ-OAR-2019-0055-1326-A1, pp. 12 - 13]

8. "March's Average Used Class 8 Retail Price Breaks $100,000," Transport Topics (April 26, 2022).

There is an exceptionally wide variation in projected warranty cost estimates between CARB, the U.S. Department of Energy's National Renewable Energy Laboratory ("NREL"), EPA, and the OEMs – a matter that is creating great concern amongst fleets as they anticipate their future equipment purchasing paths. Depending on where extended warranties are set, the cost of such warranties paid for up-front by the initial vehicle purchaser – whether they need such coverage or not – could potentially cost more than the technology needed to achieve compliance. This would be a historical first in our industry. [EPA-HQ-OAR-2019-0055-1326-A1, p. 13]

As an example, CARB estimated the cost increase of raising the minimum emissions warranty from 100,000 miles to 350,000 miles would range from $285 - $413 on a per-vehicle basis.9 According to a sampling of ATA member companies, the cost of purchasing a CARB-certified vehicle with the minimum 350,000 mile warranty added more than $1,000 to the vehicle purchase price when compared to the same federally-certified vehicle without this added warranty.10 [EPA-HQ-OAR-2019-0055-1326-A1, p. 13]

9. California Air Resources Board, Public Hearing To Consider Proposed Amendments To California Emission Control System Warranty Regulations and Maintenance Provisions for 2022 and Subsequent Model Year On-Road Heavy-Duty Diesel Vehicles And Heavy-Duty Engines with Gross Vehicle Weight Ratings Greater Than 14,000 Pounds and Heavy-Duty Diesel Engines in such Vehicles, p. IX-6 (May 8, 2018).

10. See Appendix A.

These member companies have indicated that, while their minimum manufacturer's emission warranty is closer to 250,000 miles, on average, many do purchase extended warranties to cover their expected mileage during their ownership period. The cost of these extended warranties was reported to be roughly $1,000 per 100,000 miles of warranty. [EPA-HQ-OAR-2019-0055-1326-A1, p. 13]

These real-world warranty costs are in sharp contrast to the previous regulatory cost estimates that have been presented by CARB. EPA should take note of these differences and ensure that their warranty cost estimates are thoroughly evaluated and vetted. [EPA-HQ-OAR-2019-0055-1326-A1, p. 13]

The proposed increases in coverage as well as the complexity of the technologies being covered have raised concerns within the trucking industry. Cost estimates prepared by truck manufacturers have consistently projected significantly higher warranty costs for future increases. These cost disparities, which are as much 8 times higher than the EPA estimates, highlight the need to get it right. As we have experienced with the CARB 2022 warranties, adding thousands of dollars to the cost of a new truck, especially when a return-on-investment is not apparent, will result in fleets reevaluating the purchase decisions and could result in adverse purchase impacts. [EPA-HQ-OAR-2019-0055-1326-A1, p. 13]

Additionally, nearly every fleet sampled indicated they did not receive a residual value from any unused portion of their emissions warranty when they resold a truck. This may partly explain why fleets that purchase extended warranties attempt to purchase coverage for only the mileage they accrue under ownership. It should be noted that secondary buyers still have the ability to purchase additional warranty coverage through the secondary market should they want such coverage. [EPA-HQ-OAR-2019-0055-1326-A1, pp. 13 - 14]

Warranties are intended to cover defects in materials and workmanship which cause the failure of a warranted part to be identical in all material respects to that part as described in the vehicle or engine manufacturer's application for certification. Warranties are not intended to cover failure of parts that are not designed properly. In the simplest of terms, CARB contends in its December 2021 "California Air Resources Board Staff Report on the Warranty Cost Study for 2022 and Subsequent Model Year Heavy-Duty Diesel Engines" that components fail because manufacturers are not properly engineering their performance within their useful life – a rather simplistic and absurd response. Manufacturers invest millions of dollars in research and development to ensure components function and perform properly. The relationships between manufacturers and fleets are built over decades with performance, price, and quality tied to continued brand loyalty. Equipment that continually breaks down or is constantly in service bays does a fleet no favors. We have a saying in the trucking industry that a non-moving truck is an un-productive truck. [EPA-HQ-OAR-2019-0055-1326-A1, p. 14]

Extended warranties, durability, and vehicle downtime are all interconnected. As useful life increases, the theory is that components will become more durable and in turn lead to fewer repairs and less downtime for fleets. Extended warranties are not free. They can best be compared to insurance in guaranteeing different degrees of coverage for repairs. A useful life figure never guarantees the performance of a part or system. What extended warranties do not cover are towing fees and downtime after a breakdown. Between hook-up and mileage fees, it is not unusual for a fleet to receive a $5,000 bill for a 100-mile tow. Once at a repair shop, fleets will likely experience parts and technician shortages. It is not uncommon for a truck to be out of circulation for days, weeks, and even more than a month. For these reasons, downtime costs frequently exceed repair costs – even under different warranty packages. Monthly payments on equipment not in use remain the same as payments for equipment actively hauling freight. Extended warranties are not the end-all solution in making timely repairs and keeping the nation's supply chain connected. [EPA-HQ-OAR-2019-0055-1326-A1, p. 14]

When lower NOx standards take effect and longer useful life and warranty requirements are phased-in, expect increased repair costs due to higher unit prices for parts due to longer useful life and the introduction of premature new technologies likely to have elevated failure rates. Manufacturers have no choice but to substantially increase warranty prices -- including extra margins -- to cover cost and frequency of repair uncertainties. Such technologies were aged in the lab, not under actual on-road operating conditions. Again, the financial burdens fall squarely on the shoulders of fleets, not manufacturers. [EPA-HQ-OAR-2019-0055-1326-A1, p. 14]

Organization: *California Air Resources Board (CARB)*

Option 2 matches CARB's less stringent Step 1 warranty, which took effect with model year 2022 and which was intended only as an intermediate step to the longer warranty periods in the Omnibus Regulation (termed Step 2 warranty). Although the small incremental Step 1 represents was appropriate as an intermediate step toward the longer warranty periods of Omnibus

Regulation, it is inadequate as an endpoint for 2027 MY and later engines. As discussed in comment b of this section, the voluntarily purchased longer warranties should be considered as part of the regulatory warranty baseline. Using California State University, Sacramento survey data and information shared by the manufacturers and third-party warranty providers, CARB staff more accurately accounted for current warranty buying practices by fleets and owner/operators, and hence CARB staff's warranty baseline is higher than in the other analyses. [EPA-HQ-OAR-2019-0055-1186-A2, pp.109-110]

The incremental change of warranty coverage of Option 2, which is equivalent to CARB's Step 1 warranty, is small especially after voluntarily purchased longer warranties are considered. In CARB staff's analysis in the Step 1 warranty rulemaking, heavy HD vehicles are estimated to travel about 316,000 miles on average under warranty in the baseline condition prior to Step 1 warranty because of the significant uptake of voluntary longer warranties beyond the regulatory 100,000 miles. For example, 40 percent of vehicle owners who voluntarily purchased 5 years/500,000 miles warranties already would not be affected by Step 1 warranty, which lowered CARB staff's estimated incremental costs. The miles covered under warranty was estimated to increase to 348,100 miles under Step 1 warranty, which means the warranty coverage, on average, only increased by about 10 percent. [EPA-HQ-OAR-2019-0055-1186-A2, p.110]

CARB staff have concerns regarding the 'Vehicle miles traveled based scaling factors' used in U.S. EPA's calculation of warranty cost. The warranty calculation method assumes the warranty cost of a HD diesel engine is 3 percent of the direct manufacturing cost of diesel technology package multiplied by the corresponding scaling factor. For example, the scaling factor of heavy HD vehicles for MY 2031 and later is assumed to be six because the current mileage of the regulatory warranty is 100,000 miles, and Option 1 proposes to extend warranty to 600,000 miles. This assumption can overstate the relative cost impact of longer warranty periods for two reasons:

1. **The estimated warranty cost includes the cost of voluntary longer warranties currently purchased by the majority of vehicle owners.** As noted in page 17507 of the proposed rule, nearly 50 percent of new HD Class 8 vehicles are sold with a 500,000 mile extended warranty. In California's Step 1 warranty rulemaking, CARB staff estimated based on survey data that only 15 percent of Class 8 vehicles rely on the 100,000 mile warranty period, with the remainder having an extended warranty to 250,000 miles (45 percent) or 500,000 miles (40 percent).173 As specified in 40 CFR 86.004-2 as well as in the proposed section 1036.120 (b), the emission warranty period should not be less than the basic mechanical warranty period that the manufacturer provides with or without additional charge to the purchase of the engine. Therefore, the current purchase practice of extended warranty should be considered as part of the regulatory baseline to reflect the average real cost fleets will encounter when purchasing vehicles with the proposed longer warranty period.

173 Appendix C Economic Impact Analysis / Assessment, page C-3, https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2018/hdwarranty18/appc.pdf?_ga=2.65626670.1089019171.1648488649-859068364.1628622434

2. **The warranty cost method overestimates the total mileages accumulated by all the vehicles** because it assumes every vehicle reaches the mileage limit before reaching the hour or year limit (e.g., reaching 600,000 miles limit before 10 years or 30,000 hours for HHDD). Although the different usage patterns of different vehicles categories are accounted for in the calculation of repair costs (section 7.2.3), this difference is not considered in the warranty cost. In other words, the repair cost analysis accounts for different usage patterns of different vehicle categories through the vehicle's service life, but the upfront warranty cost estimate does not. This assumption can exaggerate the warranty cost increase of low-mileage vehicles that can reach the hour or year limit before the mileage limit. To account for the different limiting factors of warranty periods, i.e., mileage, years, or hour limit, CARB staff used the 'miles covered under warranty' in estimating the incremental change of usage due to the longer warranty periods of Step 1 warranty and Omnibus warranty. A similar analysis using U.S. EPA's Motor Vehicle Emission Simulator should be considered to represent the appropriate warranty cost more accurately for low-mileage vehicle categories. Revising the analysis as recommended would lower the cost of warranty Option 1, which provides another rationale for supporting the stronger, more effective Option 1. [EPA-HQ-OAR-2019-0055-1186-A2, pp.110-111]

It is important to note that the same factors significantly contributed to the difference in warranty cost estimates of CARB's Omnibus Regulations presented by CARB staff compared to those prepared by industry stakeholders. Detailed analysis is available in the final report of the Board-Directed HD Warranty Cost Study Working Group.174 [EPA-HQ-OAR-2019-0055-1186-A2, p.111]

174 See section IV.E (page 43-44) of the final report regarding CARB's analysis of the difference between CARB and other warranty cost estimates, https://ww2.arb.ca.gov/sites/default/files/2022-01/warranty_cost_study_final_report.pdf

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

Indirect Costs. EPA's indirect cost estimates are similarly inaccurate and are well below what Daimler Truck estimates will be the actual costs of implementing the Proposed Rule under either Option 1 or 2. As explained in Section IV.A of these comments, and as acknowledged by EPA in the Proposed Rule, the proposed extension of useful life and emission warranty periods will be the main drivers of indirect cost increases for manufacturers. EPA does not acknowledge the magnitude of these cost increases, while providing estimates that understate the compliance burdens associated with these aspects of the proposal. [EPA-HQ-OAR-2019-0055-1168-A1, p.12]

As explained in Section IV.A, it is widely expected that to meet the more stringent numerical standards for the extended useful life timeframes under Option 1 of the Proposed Rule, it may be necessary to repair and/or replace the aftertreatment system and related components during the useful life of the vehicle and likely during the emission warranty period. In the draft RIA, EPA acknowledges the National Renewable Energy Lab (NREL) technology cost study conducted in conjunction with the development of CARB's Low-NOx Omnibus rule, in which NREL factors in to its cost scenarios the need to replace the aftertreatment system at one or more times during the useful life of the vehicle to meet the 0.02 g/bhp-hr NOx standard adopted by CARB in the Omnibus rule.17 Similarly, a recent Ricardo Strategic Consulting analysis of incremental increased costs associated with the Proposed Rule assumes replacements of existing and new emission-related components throughout the extended emission warranty periods and takes these into account in estimating indirect costs.18 Both the NREL and Ricardo Cost Studies are based upon extensive input by manufacturers and reflect a reasonable assumption (which is explained in more detail in Section IV.A) that aftertreatment system and/or component replacement will likely be necessary at some point during the extended regulatory useful life and potentially the warranty period, given the stringent standards that EPA is proposing. [EPA-HQ-OAR-2019-0055-1168-A1, pp.12-13]

17 See NREL, On-Road Heavy-Duty Low-NOx Technology Cost Study (May 2020) at (the ‘NREL Cost Study’).

18 See Ricardo Strategic Consulting, Review of EPA NPRM and Compliance Cost Assessment, prepared for Truck and Engine Manufacturers Association (April 25, 2022) at 28-30 (the ‘Ricardo Cost Study’) (submitted with Truck and Engine Manufacturers Association comments on EPA-HQ-OAR-2019-0055[-1203]).

Yet EPA rejects this reasonable assumption without full explanation, stating simply that it assumes ‘that manufacturers would not pursue such an approach’ (i.e., complete system replacement at some point during the useful life of the engine/vehicle), pointing to what it characterizes as industry practice ‘by and large since emission controls were introduced in the 1970s and 1980s.’19 EPA thus rejects a central component of the NREL and Ricardo cost impact studies and a key driver of indirect costs to manufacturers. This is not reasoned decision-making20 and reflects that the Agency’s proposal does not acknowledge what compliance with significantly more stringent standards for the increased regulatory useful life periods, as well as the increased costs associated with longer warranty periods, will actually cost under Option 1.21 Daimler Truck provides a detailed technical explanation for why and how these costs are likely to be incurred in Section IV.A, which supports the conclusion that EPA’s assumption is unreasonable. [EPA-HQ-OAR-2019-0055-1168-A1, p.13]

19 Draft RIA at 327.

20 Cf. FCC v. Fox Television Stations, Inc., 556 U.S. 502, 515, 129 S.Ct. 1800, 173 L.Ed.2d 738 (2009) (noting ‘the requirement that an agency provide reasoned explanation for its action’).

21 Because the Agency’s cost-benefit analysis does not account for the likelihood of aftertreatment system replacements, it also fails to address the inherent inefficiencies of such replacements, where a fully-functional emission control system must be traded out for a marginally more effective one to ensure that EPA’s stringent standards are met for full useful life. For a complete evaluation of costs and benefits associated with the Proposed Rule, particularly under Option 1, it is recommended that EPA conduct an

assessment of the significant cost of aftertreatment system replacements in comparison to their marginal environmental benefits.

As noted above, Daimler Truck has undertaken its own internal study of incremental cost increases associated with the Proposed Rule, including indirect costs attributable to the extended warranty periods in the proposal. Table 2 below reflects the Daimler Truck's warranty cost estimates in comparison to EPA's under proposed Option 1 and Option 2: Table 2 reflects the large disparity between EPA and Daimler Truck warranty cost estimates, the latter of which are more in line with industry expectations based upon many years of service and emission warranty experience. As reflected in the table, the most costly phase of EPA's proposal would start in MY 2031 under Option 1, where manufacturers of Class 8 Trucks would have to meet very stringent NOx standards for an unprecedented 800,000 mile useful life, including a 600,000 mile emission warranty period. Daimler Truck estimates that during this time, per-vehicle warranty costs would be **upwards of $ [redacted]**, many times more than EPA's incremental cost projection of $1,210 per vehicle.25 EPA's warranty cost estimates under Option 2 ($716 for MY 2027-2030 and $641 for MY 2031 +) are similarly inaccurate and are well below Daimler Truck's more realistic $ [redacted] cost estimate. Daimler Truck's cost estimate under Option 2 is suppo1ied by real-world data from the first phase of implementation of CARB's 'Step 1 ' warranty period extension for Class 8 bucks under the Omnibus rule, which imposed a 350,000 mile/5 year warranty period for MY 2022-2026. Due to Daimler Truck's actual average production cost increases, vehicle prices in fact increased during CARB's 'Step 1' phase by **$ [redacted]** (depending upon the vehicle). Notably, this phase has not required the installation of additional engine or afte1ireatment technology as compared to MY 2021 builds, in contrast to EPA' s proposal. [EPA-HQ-OAR-2019-0055-1168-A1, pp.13-14]

25 The Ricardo Cost Study estimates incremental costs associated with extended emission warranties as high as $9,942 strut ing in MY 2027 and $16,268 starting in MY 2031 under Proposed Rule Option 1, and $5,800 under Proposed Rule Option 2. Daimler Truck's figure is thus reasonably aligned with the warranty costs estimated in the Ricardo Cost Study, which is based upon industry expe1t input and OEM responses to a confidential survey. See Ricardo Cost Study at 28.

On the basis of the cost estimates presented above, Daimler Truck conservatively estimates that incremental material and warranty costs alone will total:

- $ [redacted] per MY 2027-2030 Class 8 truck under Option 1.
- $ [redacted] per MY 2031+ Class 8 truck under Option 1.
- $ [redacted] per MY 2027+ Class 8 truck under Option 2. [EPA-HQ-OAR-2019-0055-1168-A1, p.15]

Again, it is important to note that Daimler Truck estimates only direct material costs and indirect costs associated with extended warranty periods. It has not taken into account other factors such as markup, R&D, or profit margins for the service centers that perform warranty work. Thus, Daimler Truck's estimates should be considered a starting point for cost increases that would be incurred under the Proposed Rule. [EPA-HQ-OAR-2019-0055-1168-A1, p.15]

EPA estimates that, for MY 2031 Class 8 HHD trucks, its proposed warranty periods in Option 1 will add only $1,227 in incremental warranty costs, and that Option 2 would add only $641 in incremental warranty costs.97 These figures conflict with readily and widely available information. For instance, CARB's recently enacted 'Step 1 Warranty' standards in the Omnibus rule extended the warranty period for heavy HDVs to 350,000 miles (as compared to the federal 100,000 mile requirement) but did not require the addition of more complicated emissions hardware and associated warranty costs. Pricing differences between 'EPA-certified' and 'CARB-certified' vehicles with the exact same powertrains are readily available to the public, and illustrate the cost of CARB's extended warranty products. As noted in Section II.B.1 of these comments, for Daimler Truck Class 8 trucks, the extended CARB warranty has added as much as $ [redacted] to the price of a vehicle—and nearly $ [redacted] to the price of a high-volume on-highway engine like the Detroit DD15. These increased costs are solely attributable to the extended warranty terms under the CARB Omnibus rule, thus are a benchmark of the likely cost increases that will be associated with EPA's warranty period proposal. [EPA-HQ-OAR-2019-0055-1168-A1, p.72]

97 See Draft RIA at 330, Table 7-21.

Organization: *International Council on Clean Transportation (ICCT)*

The largest source of cost variability comes from indirect cost assessments. The values reported on indirect costs from each study are summarized in Figure 6. The root of this wide range of values are assumptions and methods to evaluate the cost impact of increasing emission control system useful life (UL) and warranty requirements. [EPA-HQ-OAR-2019-0055-1211-A1, pp. 13 - 14]

Two different UL and warranty requirement evaluation methodologies were used by the different authors of the reports presented here. The first group (EPA, ICCT and ARB) assumed that suppliers and manufacturers have several years to make production-ready the next generation of control technology to comply with the CARB proposal for NOx limits, UL and warranties. Most would increase the size of some components to meet the new requirements. As the cost impact of the size increases is already accounted for in the DMC values, the impact on IMCs is minimized. [EPA-HQ-OAR-2019-0055-1211-A1, p. 14]

In addition, EPA reflected the warranty and UL costs in the IMC by including Retail Price Equivalent (RPE) multipliers. RPEs are one of the main methods EPA has used to estimate IMCs. Warranty costs that traditionally have a RPE of 0.02 were increased by a factor derived from the mileage increase to meet the MY2027 and MY2031 warranty, i.e., a VMT-based scaling factor. The warranty-RPE scaling factor ranged from 4.5 to 6.0. The UL requirement costs were accounted for in the R&D component of the IMC. RPEs for R&D were increased by a VMT-based scaling factor of 1.33 to 1.38. [EPA-HQ-OAR-2019-0055-1211-A1, p. 14]

The second group relied on surveys of engine and truck manufacturing OEMs. This approach was adopted by NREL under contract to ARB, and by Ricardo under contract to EMA. The main assumption these make is that an average truck would experience a complete system replacement during the warranty period covering the useful life of the vehicle. By oversimplifying, this approach implies thousands of dollars of additional increased warranty costs per vehicle that exceed those over other estimates. [EPA-HQ-OAR-2019-0055-1211-A1, p. 14]

Given that emission control system manufacturers have historically been able to meet their UL and warranty requirements since the inception of emission standards in the 70's, that the bulk of the technology required is an incremental improvement on existing technology, and that the industry still has 8 years to develop durable and reliable technology, it would be wrong to assume that complete system replacements would be required to meet more ambitious UL and warranty requirements. [EPA-HQ-OAR-2019-0055-1211-A1, p. 14]

Organization: *Manufacturers of Emission Controls Association (MECA)*

It should be noted that the cost estimates developed by NREL included the costs due to the extended warranty requirements, despite a lack of adequate information available from suppliers or OEMs to estimate these. Similarly, costs analyses conducted by ACT Research and Ricardo made assumptions for significant warranty costs due to the new regulation based on confidential surveys. NREL and CARB acknowledged that the cost estimates for extended warranty are very uncertain. CARB subsequently conducted its own analysis of costs needed to meet extended warranty requirements, and these are substantially lower than those estimated in the NREL report as well as those estimated by ACT Research and Ricardo. After the Omnibus was approved by its Board, CARB staff convened a working group of OEMs, EMA, and MECA to review warranty costs. This working group resulted in a final report in which CARB staff concluded that the methodology used to support the Omnibus Regulation warranty-related cost estimates is reasonable and defensible and they did not believe changes to those estimates were needed [45]. As stated above, this uncertainty in costs estimated to meet extended durability and warranty provides an opportunity for future collaborative work in the form of a study that includes fleets, industry stakeholders, CARB and EPA staff. [EPA-HQ-OAR-2019-0055-1320-A1, pp.27-28]

> [45] CARB, 'California Air Resources Board Staff Report on the Warranty Cost Study for 2022 and Subsequent Model Year Heavy-Duty Diesel Engines,' 2021.

Two cost estimates were prepared – one that assumed today's durability and warranty requirements, and one assuming one million mile useful life (FUL) and 800,000 mile warranty for class 8 and 550,000 mile FUL and 440,000 mile warranty for Class 4-7 starting in 2027. These durability and warranty levels were chosen because they were initially proposed by CARB during the Omnibus rulemaking [39]. Given EPA's Proposed Option 1 includes lower durability and warranty requirements than assumed in our cost analysis, we expect the cost estimate for longer FUL and warranty provided below to represent a worst-case scenario. [EPA-HQ-OAR-2019-0055-1320-A1, p.26]

> [39] CARB, 'Heavy-Duty Low NOx Program Workshop: HD UL & Step 2 warranty,' 23 January 2019. [Online]. Available: https://www.arb.ca.gov/msprog/hdlownox/files/workgroup_20190123/04-HD_UL_&_Step_2_warranty_WS01232019.pdf.

For a vehicle with a 6-7L engine, the incremental hardware improvements needed to meet a 0.02 g/bhp-hr certification limit on the FTP cycle and future LLC standard at today's durability and warranty requirements were estimated to add about $1,300 to $1,800 to the cost of the engine efficiency and emission control technologies. For a Class 8 tractor with a 12-13L engine similar incremental improvements were estimated to add about $1,500 to $2,050 (less than 1.2%) to the cost of a MY 2027 truck, projected to be approximately $177,000, based on a historical 1% annual rate of MSRP increase reported by ICCT. The estimated incremental costs to meet the above referenced increased durability and warranty requirements for a 6-7L engine and 12-13L engine were $1,800 to $2,450 and $2,000 to $2,750, respectively. The estimated total additional emission control cost in 2027, including a 0.02 g/bhp-hr FTP tailpipe limit, LLC limit, 1-million-mile durability requirement and 800,000 mile warranty, would be $3,100 to $4,250 for 6-7L engines and $3,550 to $4,800 for 12-13L engines. If a Class 8 truck with 12-13L engine is assumed to sell for an average price of $177,000 in 2027, based on the historical 1% annual rate of increase reported previously, the additional cost of emission controls on this truck will account for roughly 2-2.7% of the total vehicle price. It is important to reiterate that these cost estimates are biased high since they are based on more stringent requirements than those included in Propose Option 1. [EPA-HQ-OAR-2019-0055-1320-A1, pp.26-27]

Organization: *Motor & Equipment Manufacturers Association (MEMA)*

The proposed standards will result in increased warranty costs. Some OEMs don't even return parts to suppliers. Even if parts are returned, they only provide data on failed parts, with little or no data on surviving components. Different components have dramatically different service lifetimes. Considering this, MEMA recommends an interim review before the second phase. Suppliers have real concerns about the longevity of DEF sensors, and other electronic sensors. EPA should designate certain replaceable parts as maintenance service items rather than as warranty service items. Having such a long warranty on new vehicles, will drive significant additional costs into the vehicle purchase price for additional warranty coverage due to the lack of data as well as known additional costs based on part life. This may result in pre-buys of older technology or owners keeping their trucks for extended times versus buying new vehicles. [EPA-HQ-OAR-2019-0055-1322-A1, p. 7]

Organization: *Navistar, Inc. (Navistar)*

EPA's extended warranty cost estimates are understated by an order of magnitude. Navistar provided EMA with actual data regarding the warranty costs incurred when customers purchased extended warranty packages. We support EMA's comments on this issue, which reflect the cost data Navistar provided to EMA. [EPA-HQ-OAR-2019-0055-1318-A1, p. 6]

Organization: *New York Farm Bureau (NYFB)*

Specifically, NYFB is concerned that the agency's projection of extremely modest technology and warranty costs associated with the rule will result in a significant overestimation of future fleet turnover and underestimation of the negative emissions consequences associated with large-scale 'pre-buys' prior to compliance deadlines. To its credit, EPA openly admits that its projections are guesswork, but it does not quantitatively explore how underestimating costs could drive higher pre-buy behavior that could significantly delay and undermine emissions reductions benefits that are the central purpose of the rule. So, before finalizing this rule, NYFB urges EPA to work collaboratively with industry, states, and other affected stakeholders to resolve discrepancies related to technology costs and achievability, warranty impacts, corresponding fleet turnover and environmental impacts of the proposal. [EPA-HQ-OAR-2019-0055-1268-A1, p. 2]

Organization: *PACCAR, Inc (PACCAR)*

In particular, PACCAR agrees with the following aspects of EMA's comments: The increase in manufacturers' costs to cover the proposed extended warranty requirements will be substantial, and necessarily will be passed on to purchasers at the point of sale. [EPA-HQ-OAR-2019-0055-1346-A1, p.2]

Organization: *Small, George (OOIDA)*

it is my hope that the cost for clean air is affordable for small businesses and that those emissions components are very reliable and come with a strong warranty in the pass some emissions components were not under warranty and these systems are very expensive to replace and that affects my bottom line. [EPA-HQ-OAR-2019-0055-1266-A2, p.3]

Organization: *Truck and Engine Manufacturers Association (EMA)*

The proposed Option 1 requirements also likely would be cost-prohibitive, principally because of the incremental costs that would result from the proposed mandates for extended emissions warranty and full useful life ("FUL") periods. [EPA-HQ-OAR-2019-0055-1203-A1, p. 12.]

One of the consequences of that reality is that the Option 1 proposal cannot be implemented in a cost-effective manner. In that regard, EPA's Regulatory Impact Analysis (RIA) has not factored-in manufacturers' anticipated costs of having to replace and pay for the multiple "Stage 3" catalyst systems. More specifically, at page 327 of the RIA, EPA concedes that its cost estimates – unlike the detailed cost analyses prepared by Ricardo and the National Renewable Energy Laboratory (NREL) (discussed infra) – do not include a scheduled replacement of the new envisioned multi-component aftertreatment systems, notwithstanding that EPA's proposal will, in effect, extend the useful life requirements for those systems out to 650,000 miles or even to 800,000 miles, for HHD engines. On that point, EPA states as follows: Our understanding is that, while the costs associated with warranty and useful life are quite high [in the NREL study], they were estimates associated with complete system replacement at some point during the extended useful life of the engine/vehicle. We have assumed that manufacturers would not pursue such an approach and would, instead, include upfront (i.e., at the point of end user purchase) [sic] with the expectation that the parts would last the full useful life without a mandatory replacement. For that reason, we have chosen not to use the warranty and useful life cost estimates presented by NREL [or by Ricardo], and have instead used [our own] approach. (RIA, p. 327.) (Emphasis added.) [EPA-HQ-OAR-2019-0055-1203-A1, pp. 12 - 13]

EPA's assumption in that regard is neither reasonable nor correct. HDOH engine and vehicle manufacturers have expressly and repeatedly informed EPA that they will be compelled to include a replacement of aftertreatment systems in their design and cost calculations to ensure that low-NOx emissions performance can remain stable and compliant out to the significantly extended useful life periods. EPA's decision to disregard the information provided by manufacturers has led to the Agency's inaccurate estimates of the overall costs of its proposal. On that point, the Agency likely has underestimated costs by an order of magnitude. For example, while EPA estimates that the per-vehicle incremental cost of its Option 1 proposal will amount to approximately $4,000 for HD vehicles (see 87 FR at p. 17571, Tables V-10 and V-11; RIA, p. 329, Tables 7-19 and 7-20), Ricardo's cost estimate, in line with NREL's, is that those per-vehicle incremental costs will be closer to $42,000, including increased operating costs. The net result is that EPA's proposal, as it stands, is not based on sound assumptions and is not cost-effective. [EPA-HQ-OAR-2019-0055-1203-A1, p. 13]

Notwithstanding the foregoing, EPA claims that extending the useful life and warranty periods as proposed actually will lead to lower costs, and that the Option 1 proposal, even though more stringent than Option 2, will be less costly than Option 2 because the shorter Option 2 warranties will result in higher net emissions-related repair costs than under the Option 1 proposal. (87 FR at p. 17428.) That too is not correct. It assumes, incorrectly, that engine and vehicle manufacturers would not fully account for their increased emissions-related repair obligations under Option 1's extended useful life and warranty requirements in setting their increased purchase prices for Option 1-compliant products. In fact, EPA itself has rebutted that assumption: "Manufacturers include warranty repairs in the price of an engine or vehicle." (87 FR at p. 17511.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 13.]

Independent experts at Ricardo and the National Renewable Energy Laboratory (NREL) have conducted a comprehensive cost study regarding the proposed low-NOx requirements and have determined that regulations centered around Option 1 would result in an approximate $42,000 per-vehicle cost increase (in 2017 dollars – the metric EPA has used) for heavy heavy-duty (HHD) vehicles, when factoring in increased operating costs. [EPA-HQ-OAR-2019-0055-1203-A1, p. 144]

EPA's cost assessment, as presented in the RIA, stands in sharp contrast to the detailed cost assessments that Ricardo and NREL have prepared. The primary difference between EPA's cost "teardown" assessment, which did not rely on input from HDOH engine and vehicle manufacturers, and those that Ricardo and NREL developed, which did utilize manufacturers' input, relates to whether the extended Option 1 UL periods would compel manufacturers to factor in the costs of a replacement aftertreatment system (or multiple aftertreatment system components) at or before the 500,000 mile point. Ricardo and NREL, based in part on direct input from manufacturers, concluded that the replacement of aftertreatment system components likely would be required within the Option 1 extended UL period. EPA has assumed otherwise. In the NPRM, EPA offers only the following conclusory statement for its contrary position: We believe our proposed useful life periods are feasible and would not require manufacturers to adopt component replacement as part of critical emission-related maintenance strategies. (87 FR at p. 17496.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 144]

EMA fundamentally disagrees. The known degradation of catalyst substrates and related components, including as observed with EPA's Stage 3 prototypes, creates material risks of noncompliance with the proposed Option 1 requirements, especially if the UL period is extended out to 800,000 miles. Manufacturers will have to account for and mitigate those risks in developing their compliance and maintenance strategies, and likely will include aftertreatment component replacements as manufacturer-covered maintenance at or before 500,000 miles. The risk of recall liability – which liability can amount to several hundred million dollars – is simply too high to rely on a different strategy. Assuming that all SCR systems can maintain better than 99.5% conversion efficiencies and can maintain steady NOx levels no higher than 0.04 g/bhp-hr all the way out to 800,000 without aftertreatment component replacement is not reasonable. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 144 - 145]

The cost to the manufacturer to schedule replacement of the aftertreatment system is significant. If EPA were to misjudge whether manufacturers will have to bear the cost of scheduled aftertreatment systems within the extended UL periods (and pass that cost on to customers at the time of purchase), it will have a significant bearing on the benefits-to-costs ratio. [EPA-HQ-OAR-2019-0055-1203-A1, p. 145]

EMA acquired actual cost data from four manufacturers reflecting what they pay in total to a dealer when a current HHDDE US10 aftertreatment package is replaced under warranty. Those costs, including labor, ranged from approximately $6,500 to $17,750.31 Again, those are costs associated with current aftertreatment configurations. Ricardo estimates the cost of aftertreatment systems consistent with the Stage 3 solution will further increase by $2,588, with labor costs potentially impacted significantly due to the additional time required to access, extract and replace the LO-SCR packaged as close to the turbocharger as physically practical. Thus, in total, EPA is dismissing as much as $20,000 in costs with its unsupported assumption that those systems would not require replacement within the extended ULs. That assumption is wholly incorrect. [EPA-HQ-OAR-2019-0055-1203-A1, p. 145]

> 31. Labor consistently represented well less than $1,000 within these costs. Costs did not include ECU's, wiring harnesses, DEF injectors, or pressure or temperature sensors.

In its assessment of this critical cost issue, EPA has acknowledged that its assumption is contrary to the data-driven assessment that NREL made when it conducted a cost analysis of CARB's version of Option 1. In its RIA, EPA has offered the following explanation of its disagreement with NREL: We are aware of a recent study conducted by the National Renewable Energy Lab (NREL) for the California Air Resources Board (CARB). In that study, NREL surveyed parts suppliers and engine/vehicle manufacturers regarding estimated costs associated with the [Stage 3] technologies being considered within the context of CARB's Heavy-Duty Low NOx program. As part of that study, NREL considered costs associated with increased warranties and increased useful life periods being considered by CARB. Our understanding is that, while the costs associated with [Option 1] warranty and useful life are quite high, they were in fact estimates associated with complete system replacement at some point during the extended useful life of the engine/vehicle. We have assumed that manufacturers would not pursue such an approach and would, instead, include upfront (i.e., at the point of end user purchase) with the expectation that the parts would last the full useful life without a mandatory replacement [sic]. For that reason, we have chosen not to use the warranty and useful life estimates presented by NREL and have instead used [our own] approach. (RIA, p. 327.) (Emphasis added.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 145]

The foregoing explanation makes it clear that EPA's disagreement with NREL (and Ricardo) is based more on opinions and assumptions than data. That is not sufficient to support a rulemaking of this magnitude. [EPA-HQ-OAR-2019-0055-1203-A1, p. 145]

Notwithstanding EPA's choice, in effect, to disregard NREL's work, the NREL cost study that CARB commissioned is, in fact, very instructive. As an initial matter, it confirms that, when attempting to assess indirect costs, such as the potential impacts of expanded warranty and UL requirements, OEMs are the entities best positioned to estimate those costs, which implicitly confirms that EPA's indirect "teardown" cost-assessment method – i.e., scaling from previously established "RPE factors" for warranty costs and R&D (RIA, p. 325) – is not an optimal approach. NREL's specific conclusions on that point is as follows: "Engine OEM participation was crucial, as only they could provide estimates for indirect costs that represented a significant portion of the total cost. Incremental costs are largely driven by indirect costs associated with engineering research and development costs and warranty costs. Indirect costs are highly dependent on production volumes over which to amortize research and development costs. Indirect costs due to warranty are high, reflecting high uncertainty with new technologies and the introduction timeframes." (NREL Report, p. vii,) [EPA-HQ-OAR-2019-0055-1203-A1, p. 146]

The NREL Report is most telling, of course, in the bottom-line results it presents. Specifically, the NREL Report concludes that for HHD vehicles, the per-vehicle cost for compliance with CARB's version of Option 1 would range from $28,868 to $47,042, with the higher range being the more likely outcome. That number is an order of magnitude greater than the per-vehicle costs that EPA has posited (i.e., $4,213 per-vehicle for HHD vehicles; see RIA, p. 329, Tables 7-19 and 7-20), and is consistent with the detailed cost analysis that Ricardo has prepared based on nationwide HHD sales volumes (discussed infra). [EPA-HQ-OAR-2019-0055-1203-A1, p. 146]

With respect to the incremental per-vehicle costs associated with Option 1-like extended emission warranties and ULs, NREL concluded that, on average, those aggregate indirect costs would range from $23,424 to $38,898. (See NREL Report, pp. vii-viii, 40, and Table 20.) That too is largely consistent with Ricardo's findings, and confirms that the majority of the incremental costs that would result from the implementation of Option 1 would stem from the proposed significant increases in ULs and emission warranties. As discussed in more detail below, Ricardo concluded that the indirect incremental costs associated with the Option 1 ULs and warranties would be as high as approximately $27,000 (in 2017 dollars) per-vehicle, within the range posited by NREL. (See Ricardo Report, Table 26.) In contrast, EPA has posited that the incremental per vehicle costs stemming from the Option 1 extended UL and emission warranties will only amount to approximately $1,300 for vehicles. (See RIA, pp. 329-330.) Once again, the EPA cost estimates differ markedly from NREL's and Ricardo's more reasonable and data-based conclusions by at least an order of magnitude. [EPA-HQ-OAR-2019-0055-1203-A1, p. 146]

In addition to dismissing the need to account for aftertreatment replacements, and, as a result, substantially understating the UL and warranty costs at issue, EPA's cost assessment also relies on an under-inclusive and inapt estimation method for indirect costs. At pages 323-325 of its RIA, EPA describes its use of previously established "retail price equivalent (RPE) multipliers" to calculate the indirect costs that can be derived from the ratio of revenues-to-direct costs. As EPA explains it, "using RPE multipliers [ranging from 1.28 to 1.5] implicitly assumes that incremental changes in direct manufacturing costs produce common incremental changes in all indirect cost contributors as well," including the costs associated with substantially extended UL and emissions warranty periods. (RIA, p. 323.) EPA applies this proportional methodology notwithstanding the Agency's recognition that, "[t]he use of RPEs, with their assumption that all technologies have the same proportion of indirect costs, is likely to overestimate the costs of less complex technologies and underestimate the costs of more complex technologies." (RIA, p. 323.) [EPA-HQ-OAR-2019-0055-1203-A1, pp. 146 - 147]

This rulemaking clearly involves a whole suite of new "more complex" technologies. Nonetheless, and despite its own admonition, the Agency has proceeded to rely on the implicit assumption that all of the quantumly increased indirect costs at issue will remain uniformly proportional to the increased direct costs at issue. Applying this "implicit assumption," EPA then accounts for the cost of the proposed extended UL and warranty periods by applying additional "VMT-based scaling factors" to the R&D and Warranty costs derived from the underlying RPE based calculations of indirect costs. (RIA, p. 325.) For example, when assessing the indirect cost impacts from extending the current warrant periods from 100,000 miles initially to 450,000 miles, and then to 600,000 miles under Option 1, EPA offers the following explanation of its VMT-scaled RPE-based methodology: Proposed Option 1 would extend the required warranty period for a Class 8 diesel to 7 years or 450,000 miles for MYs 2027 through 2030, and then extend further to 10 years or 600,000 miles for MY 2031 and beyond. As such, in our analysis of proposed Option 1 for Class 8 diesel trucks we applied a scaling factor of 4.5 (450/100) to the 0.03 [RPE-based] warranty cost contribution factor for MYs 2027 through 2030, and applied a scaling factor of 6.0 (600/100) for MYs 2031 and later. The same approach is followed for the other regulatory classes (RIA, p. 325.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 147]

There are multiple concerns with EPA's VMT-based RPE-derived scaling approach to assess UL and warranty costs. At its core, EPA's analysis assumes that the indirect costs attributable to the significantly extended UL and warranty periods will increase on a linear VMT weighted basis from the previously-derived RPEs that the Agency "used in prior rule-makings setting new greenhouse gas standards for heavy-duty trucks." (RIA, p. 324.) That is not a sound assumption, as detailed in Ricardo's Report. [EPA-HQ-OAR-2019-0055-1203-A1, p. 147]

EPA's low-NOx proposal will require manufacturers to develop and rely on the types of innovative highly-complex and multi-component aftertreatment systems that have been used in EPA's Stage 3 RW prototype. Those advanced and complex integrated systems, including CDA, are entirely new for HDOH engines, as are the combinations and configurations in which they are being deployed at SwRI. Manufacturers have no prior experience using or packaging those new multi-component systems in the field, and do not know how they will age and whether they can consistently make it out to the substantially extended Option 1 ULs without needing to be replaced. Thus, using linear VMT-based extrapolations from old RPE-based factors to assess the indirect costs associated with these entirely new highly-complex systems and configurations, which will have compliance obligations far beyond any previously proven points of component durability, is not a sound or reasonable methodology. [EPA-HQ-OAR-2019-0055-1203-A1, p. 147]

Manufacturers do not have prior experience with these new “Stage 3” systems. Thus, there is no basis to assume that the resultant indirect costs associated with the extended ULs and emission warranties will be uniformly proportional to the direct manufacturing costs associated with those Stage 3 systems. Simply stated, there is not sufficient data to support the Agency’s assumption that future warranty and UL costs will amount to a VMT-based linearly-scaled increase from previously calculated RPEs, and that no separate considerations need to be given to whether the magnitude of those indirect costs should include the costs of replacement aftertreatment components. Consequently, the indirect cost estimates that EPA has derived from its extrapolation method are not reasonable. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 147 - 148]

The net result is that EPA’s assessment of the aggregate per-vehicle incremental cost impacts from its Option 1 proposal are significantly understated – most likely by an order of magnitude. Focusing on Class 8 vehicles, EPA estimates that the total incremental per-vehicle costs from implementing Option 1 will be $4,213 in MY 2027, and $3,931 in MY 2031. With respect to the indirect-cost portion of that total incremental cost amount, the Agency estimates that for the extended ULs (treated as R&D costs) and emission warranties at issue, those indirect costs will amount to $1,251 per-HHD-vehicle in 2027, and $1,458 per-HHD-vehicle in 2031, as reflected below in Tables 7-20 and 7-21 from the Agency’s RIA (RIA, pp. 329-330): [EPA-HQ-OAR-2019-0055-1203-A1, p. 148]

As noted, these per-vehicle incremental cost estimates are more than an order of magnitude lower than those derived by NREL and Ricardo. They also utilize an unrealistic “learning curve” to derive even lower estimates for the overall MY 2031 cost projections. In addition, they assume that the more stringent requirements for 2031 MY products will result in lower incremental costs than the less stringent requirements for MY 2027 products. Simply stated, EPA’s cost estimates are not reasonable. [EPA-HQ-OAR-2019-0055-1203-A1, p. 148]

As detailed next, Ricardo has developed a far more robust assessment of the cost impacts of EPA’s Option 1 proposal, including the indirect costs attributable to EPA’s proposed extended ULs and emission warranties. The Agency will need to account for Ricardo’s detailed analysis and data-driven conclusions (as well as Ricardo’s critique of the Agency’s cost assessment) before finalizing this rulemaking. [EPA-HQ-OAR-2019-0055-1203-A1, p. 148]

EPA has tied the cost-effectiveness of its Option 1 proposal to the unsupported assumption that the replacement of aftertreatment components will not be necessary, and that the incremental indirect costs associated with extending the HHD UL period from 435,000 miles to 800,000 miles, along with extending the emissions warranty period from 100,000 miles to 600,000 miles as of 2031, will only total $1,458 per-vehicle. (See RIA pp. 329-330.) That is well off the mark. [EPA-HQ-OAR-2019-0055-1203-A1, p. 151.]

Currently available market data and pricing information show that the incremental costs associated with CARB's "Step 1" extended emission warranties — which went into effect this year, and which extend those warranties for HHD vehicles from 100,000 miles to just 350,000 miles — amount to approximately $2,500 per-vehicle. That is what the extended "Step 1" warranty requirements actually add to the cost of HHD vehicles that are actually being bought and sold in the market today. What this shows, therefore — and, in fact, proves — is that EPA is unreasonably assuming that an emission warranty that is more than 70% longer than CARB's "Step 1" warranty as of 2031 will cost approximately 25% less than the actual cost of the much shorter "Step 1" warranty today. EPA's assumption in this regard is obviously and fundamentally wrong, as further underscored by Ricardo's (and NREL's) analyses. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 151 - 152]

EMA took additional steps to evaluate EPA's emissions warranty cost projections, turning to two sources of actual warranty cost data for warranties that extend long beyond the current baseline regulated emission-related component ("ERC") warranties, and also beyond manufacturers' "base" powertrain warranties (that also cover emissions-related components). The first additional analysis is based on pricing rates of aftermarket warranty packages, and the second is based on HHDDE manufacturers' actual warranty costs incurred when customers purchase extended warranty packages. Both of these additional analyses show (again) that EPA's cost projections related to the proposed extended emissions warranty coverage requirements are grossly understated. [EPA-HQ-OAR-2019-0055-1203-A1, p. 152]

EMA consulted with one of the largest aftermarket warranty companies in the U.S. to understand the warranty products they offer and the pricing structure for them. Those warranty packages include certain component groupings, such that ERCs (including aftertreatment systems) can be segregated for comparison against the company's price sheet. Pricing was set up based on the included component packages, the age and mileage of the vehicle to be covered, and the years and mileage of extended the warranty coverage. It was therefore possible to estimate the subscription price to cover an additional warranty period from today's ERC warranty coverage (which we assumed to be 5 years/250,000 miles to account for the combination of the 5 year/100,000 mile regulated ERC warranty and the typical manufacturer's warranty of 2 years/250,000 miles) to EPA's proposed Option 1 extended warranty period of 10 years/600,000 miles. [EPA-HQ-OAR-2019-0055-1203-A1, p. 152]

The aftermarket warranty provider's business model involves relying on OEM dealer networks and provider-approved independent repair centers to perform warranty repairs that are subsequently billed to the provider. This means that the warranty provider does not operate any vehicle repair centers, and does not employ or train any repair technicians. Instead, the provider simply reviews repair invoices and pays the OEM dealers and repair centers from the funds accumulated from the customers' extended warranty subscriptions. Under this model, EMA assumed a 20% profit margin should be subtracted from the pricing model to estimate the actual costs of the ERC warranty repairs. [EPA-HQ-OAR-2019-0055-1203-A1, p. 152]

Using this information, it was a relatively straightforward mathematical exercise to draw parallels between the aftermarket extended emissions component warranty coverage costs, and EPA's extended warranty costs. The aftermarket warranty costs included in this additional analysis were limited to the ERCs in current US10-compliant products. Future warranties, however, will also be compelled to cover any new emissions-related components deployed by manufacturers to comply with the proposed 2027 and 2031 emissions standards. To estimate those warranty costs, EMA multiplied the aftermarket warranty costs by the ratio of future emissions-related component costs to current emissions-related costs. Current ERC costs were estimated to be $10,000 for a HHDDE, and future costs were estimated at approximately $4,000 (See Ricardo Report, Table 22). For the new ERC's, the warranty costs from 0 miles to today's ERC warranty coverage was estimated by the same component cost ratio approach. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 152 - 153]

The resultant warranty cost increase to engine manufacturers calculated from this analysis process was approximately $11,900 per HHDDE. There are two other factors that should be considered in this analysis. The first is the impact that the extremely stringent proposed NOx standards may have on warranty costs of existing (US10-compliant engine) components. This factor can manifest itself in the following ways: (1) the cost of various components could increase to support longer UL requirements, (2) the OBD system may more often trigger the MIL due to faults of the existing component set due to the overall greater complexity of the Stage 3 system, increasing frequency of repair, (3) EPA's new requirements in §1036.120(c) will expand the current ERC list to include "all components whose failure would increase emissions," and (4) the inspection and maintenance programs being implemented by various states will increase repair frequency. (See Ricardo Report, Tables 22 and 30.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 153]

The second factor that could increase the cost of emissions warranties beyond the estimation from this analysis stems from the fact that new technologies (e.g., CDA, EGR cooler bypass, heated DEF doser, and NH3 sensors, which have seen only limited use to date) or new applications of existing technologies (e.g., close coupled SCR) can experience higher failure rates in the early years of production than those of more mature components. Recall that the warranty cost projection for the new (Stage 3-based) ERCs in this analysis was based on the cost ratio of the new ERCs to the existing ERCs, where the existing ERCs are mature components with mature failure rates. An adjustment would be required to account for the historical, and unavoidable, elevated failure rates for new components. [EPA-HQ-OAR-2019-0055-1203-A1, p. 153]

For the purpose of this analysis, if we assume an increase in warranty costs for existing components of 20% for the first factor described above, and a 20% elevated failure rate for new technologies and new applications of existing technologies as described for the second factor, the estimated increase to warranty costs relative to today's products is approximately $14,900. [EPA-HQ-OAR-2019-0055-1203-A1, p. 153]

While admittedly a somewhat crude analysis, this estimation has its basis in real-world expenses that are being incurred today. There may be some elements in the analysis that could be revised, but the point is not to use the process to get a precise estimation of warranty costs for rulemaking purposes; rather, it is to check the scale of EPA's estimates against actual data available today. In that regard, EPA's warranty cost estimates ($976 to $1,227) are, once again, clearly understated by an order of magnitude. Indeed, if EPA's estimates reflected a more accurate assessment of extended warranty costs, that would imply that purchasers of aftermarket warranties are paying multiple times the value they get from those coverages, an outcome highly unlikely given how astute most trucking companies are when it comes to controlling costs and managing their businesses. [EPA-HQ-OAR-2019-0055-1203-A1, p. 153]

The second analysis EMA conducted offers a more direct assessment of extended warranty costs. EMA obtained from OEMs actual data reflecting the warranty costs that those OEMs have incurred when customers purchased extended warranty packages. Three manufacturers culled their warranty expense databases to collate the warranty coverage expenses incurred from the time a vehicle passed the point of a standard warranty (combination of regulated ERC warranty and the manufacturer's base warranty) to the end of the purchased extended warranty period. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 153 - 154]

The graph below shows the range of extended warranty costs incurred on emissions-related components by these three HHDDE manufacturers. To be clear, this is a data-capture of actual costs incurred from extended emissions warranty repairs, not how much the manufacturers charged the customer for the extended warranty. Most of the data is based on purchased extended warranties to approximately 5 years and 500,000 miles, though some included longer warranty coverage periods. Each manufacturer's input is shown in the graph as a shaded area. The analysis was based on average per-vehicle costs from a population of covered vehicles. The data is represented as a range through the shaded areas because each manufacturer had his own way of sharing the data depending on how their tracking systems were structured. (For example, one OEM provided three consecutive model years of data, while another tracked the figures by low-HP range and high-HP range within a platform.) In total, data from more than 250,000 engines is included in the following graph: [EPA-HQ-OAR-2019-0055-1203-A1, p. 154]

Once again, it is clearly evident from this actual ERC incremental cost data – incremental to base warranty costs -- that EPA's incremental cost estimates attributed to the proposed extended warranty requirements are significantly understated. Importantly, the data presented above is based on today's ERCs installed in US10-compliant engines. Even though the data above does not include the additional ERCs that will be required to comply with the new low-NOx emissions standards, the costs as captured are nonetheless significantly greater than EPA's projections that do include those additional components. [EPA-HQ-OAR-2019-0055-1203-A1, p. 154]

It is instructive to apply the cost ratio techniques used in the aforementioned aftermarket warranty analysis to these real-world actual cost-data to project what the "all-in" incremental warranty costs could be. Considering the graph below, we might conservatively assume that the line indicated by the circled marker "1" is a conservative projection of warranty costs that would be incurred on today's existing ERC's if subject to a 10year/600,000 mile warranty. If we apply the cost ratio technique of the aftermarket warranty data analysis to estimate the warranty cost coverage on existing and the new ERCs, that would move the estimation to the level indicated by the "2" marker as shown. This second estimation includes the estimated cost of the warranty to cover the new ERCs from mile 0 to today's emissions warranty. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 154 - 155]

Also noted on the graph above, for reference, is the Ricardo estimate of incremental ERC warranty costs resulting from the EPA proposal, which aligns very well with the extrapolated cost estimation. Finally, the EPA estimate of $1,227, an order of magnitude lower, is noted. [EPA-HQ-OAR-2019-0055-1203-A1, p. 155]

It is very safe to conclude from these two additional analyses – the aftermarket warranty analysis and the actual purchased extended warranty costs analysis – both of which are based on real-world experience, that EPA's projection of incremental ERC warranty costs is grossly understated. While the detailed underlying cost information used to conduct these analyses is not included in these comments for confidentiality reasons, EMA is open to discussing these analyses in more detail with EPA. In that regard, it is imperative for EPA to correct its cost assessment in order to fashion a final rule that can be implemented in a cost-effective manner. [EPA-HQ-OAR-2019-0055-1203-A1, p. 155]

On top of that, the significant direct and indirect costs that are to be borne by the trucking industry, and thereby consumers, to meet those new UL standards will be impacted even more by the additional costs associated with the proposed 6-fold increase in the required emission warranties. [EPA-HQ-OAR-2019-0055-1203-A1, p. 171]

Perhaps even more concerning are the necessary data-generation projects that are completely unplanned at this time. More specifically, EPA intends to complete this rulemaking without having access to the following: It appears that EPA will not undertake any effort to resolve the considerable discrepancy between the Agency's cost estimates and those of NREL and Ricardo. Cost impacts are extremely important to justifying the many onerous requirements included in this rulemaking. Further, there has been no effort to understand the benefits/cost ratio of any of the individual elements of this multi-faceted rulemaking package, such as whether the extended warranty requirements will yield emissions benefits commensurate with the very considerable costs to be incurred by customers. [EPA-HQ-OAR-2019-0055-1203-A1, p. 172]

Organization: *Truckload Carriers Association (TCA)*

An incremental cost would also reflect manufacturers' added stringency for emissions and an increase in useful life and warranties for emission-related components. One report found that if the proposed standards go into effect, the price of heavy-duty diesel engines would increase between $18,000 to $35,000 per vehicle, depending on the level of requirement4. [EPA-HQ-OAR-2019-0055-1160-A1, p. 2]

> 4. Ricardo Strategic Consulting, "Cost Impact Study for Potential Next-Tier EPA HDOH Emission Regulations", January 14, 2022, 360b6600755b47/t/625cbec8f7aef559cbc4c9a7/1650245321849/Ricardo.pdf

Organization: *U.S. Chamber of Commerce*

EPA openly acknowledges that the proposed rule's impacts on the cost of new medium- and heavy-duty trucks, and the impacts of its associated unprecedented and untested useful life and warranty requirements, are highly uncertain. Indeed, there is an enormous and troubling disparity—approximately an order of magnitude—between EPA's compliance cost estimates and those projected by engine manufacturers. Such factual issues merit very careful attention and consideration by the agency. [EPA-HQ-OAR-2019-0055-1245-A1, p. 5.]

Similarly, and as EPA notes in the proposal, there is considerable uncertainty surrounding the feasibility of and cost impacts associated with dramatically extended useful life and warranty requirements under the rule. As EPA acknowledges, key technical assumptions in the rule pertain to performance and durability data for engines and emissions control systems that have yet to be operated on a broad scale for an extended length of time. Without detailed real-world performance data, such technical assumptions should remain conservative (i.e., they should not be unduly optimistic) and should be expressed in terms of a range. [EPA-HQ-OAR-2019-0055-1245-A1, pp. 5 - 6.]

Instead, the rule applies extremely aggressive assumptions for these technologies that raise serious questions about feasibility and practical achievability. For example, the proposal would nearly double useful life mileage expectations for heavy-heavy duty engines (HDE)—from 435,000 miles to 800,000 miles. The factual basis for proposing such a vast increase seems unclear. [EPA-HQ-OAR-2019-0055-1245-A1, p. 6]

The ultimate cost of corresponding warranty requirements is unknown, and while EPA seeks feedback on "uncertainty in how the emissions control technologies would deteriorate in the field and across different vehicle applications," even the most informed estimates necessarily involve a high degree of uncertainty due to the unprecedented and untested nature of the requirements. [EPA-HQ-OAR-2019-0055-1245-A1, p. 6]

According to the Ricardo report, "EPA's warranty cost estimation methodology grossly underestimates the expected incremental warranty costs…due to fundamental weaknesses in the Agency's warranty estimation approach." This is in large part because EPA assumes that warranty costs rise linearly with mileage, when in fact it is commonly accepted that product and technology failures tend to rise exponentially with increased mileage, particularly in the later years of a vehicle's operational life. [EPA-HQ-OAR-2019-0055-1245-A1, p. 6]

We also recommend that EPA undertake a sensitivity analysis that considers the potential for modest variations in cost inputs to influence the overall economic and emissions impacts of the rule. For example, even if EPA concludes after further analysis that warranty costs would indeed remain linear throughout an 800,000-mile warranty period, the Agency should undertake a sensitivity analysis estimating cost impacts under an exponential warranty cost distribution. [EPA-HQ-OAR-2019-0055-1245-A1, p. 6]

EPA Summary and Response

The comments summarized above focus primarily on assertions about:

- EPA's estimated warranty costs being too low in part because EPA failed to consider necessary emission-control system replacements needed to comply with the long warranty and useful provisions of proposed Option 1; and,
- EPA failed to consider the number of extended warranties on engines in today's fleet in its estimates of warranty costs in the baseline; and,

- Longer warranties often fail to benefit second and subsequent purchasers of HD vehicles.

Allison commented on our use of the Fleet Advantage Whitepaper to estimate warranty and emission-related repair costs. EPA has developed a new approach to estimating warranty costs as described below and further in Chapter 7.1.2 of the final RIA, after consideration of and in response to comments from EMA and others. As for use of the Fleet Advantage Whitepaper in estimating emission-related repair costs, we respond to these comments from Allison in section 18.6 of this response to comments document.

The American Trucking Association (ATA) commented on several aspects of the proposed longer warranty provisions. First, they raise the issue of upfront warranty costs coming under the 12 percent Federal Excise Tax. Currently, longer warranties, or extended warranties, are purchased separately from the new vehicle purchase and, therefore, do not incur the 12 percent excise tax that is applied to the new vehicle purchase.[41] EPA is not accounting for the excise tax in our cost analyses. Because the tax is paid by purchasers of vehicles, as opposed to manufacturers, the tax is not part of the manufacturers' costs of compliance. In addition, taxes, being a transfer payment from one entity to another, are also generally excluded from social cost analyses.[42] EPA thus generally excludes taxes in our cost analyses that are geared toward estimating social costs, such as those undertaken to comply with E.O. 12866.

ATA also commented that different users/purchasers currently make different decisions regarding whether to purchase extended warranties depending on their unique business and use case. ATA provided several examples but, in short, they argued that a purchaser that keeps trucks for short periods, maybe only 2 to 3 years, is less likely to purchase an extended warranty than one that purchases a vehicle with the intention of operating for its full operational life and would be less likely to get the full benefit from paying the increased purchase price of a longer federal warranty. To the extent that fleets currently base their turnover cycle of 2-3 years on the time at which today's warranty periods expire, we expect they would consider adjusting their current business model to accommodate the longer warranties in this final rule. ATA also noted that their members report to them that they receive very little residual value for extended warranties when they resell a truck. We think this is understandable when extended warranty contracts vary from purchaser to purchaser and may be difficult to transfer to subsequent owners, but that would not be the case with the warranty provisions under the final rule. All second or subsequent purchasers will know the remaining warranty period and will know whether and to what extent they would be covered by that remaining warranty.

The California Air Resources Board (CARB) suggested that any voluntarily purchased extended warranties should be considered in the baseline costs. Because many heavy-duty vehicles are sold with extended warranties, we agree with this suggestion and have done so in our updated analysis for this final rule. CARB also expressed concerns regarding EPA's use of mileage scalers applied to the warranty contribution to indirect costs as a means of estimating warranty

[41] See IRS form 510: Excise Taxes (July 2021), Chapter 6: Retail Tax on Heavy Trucks, Trailers, and Tractors.

[42] See, e.g., Guidelines for Preparing Economic Analyses, U.S. EPA, December 2010, updated March 2016 at page 1-5; Circular A-4 from the Office of Management and Budget, available at https://obamawhitehouse.archives.gov/omb/circulars_a004_a-4/#e (providing guidance to Federal agencies in measuring and reporting benefits and costs of Federal regulatory actions to comply with E.O. 12866).

costs. EPA has moved away from that approach in the updated analysis for this final rule, as explained in Chapter 7 of the final RIA. CARB also commented that EPA had considered only the mileage provisions and not the age or hours provisions when estimating warranty duration. This is not correct for the proposed rule, nor for the approach EPA has used for this final rule. While EPA did not use the hours provisions in the proposed analysis, the ages were used and served as the limiting factor for several vehicle types (those with lower mileage accumulations such as refuse trucks, etc.) For the updated final analysis, EPA has included the hours provisions in addition to miles and ages.

Daimler, Navistar, PACCAR, EMA, TCA and the U.S. Chamber of Commerce commented on the disconnect between the EMA-sponsored cost study and EPA with respect to warranty costs. These commenters suggested warranty costs ranging from $5,000 to $15,000, depending on model year and option, for a Class 8 diesel truck. EPA has reanalyzed the costs for the final rule and has taken into consideration the data provided by EMA regarding real-world warranty claims data (see pages 148 through 152 of the EMA comments). For the final rule, EPA has used the EMA data to estimate warranty costs on a $1,000 per year of coverage basis. There are three important additional factors applied to that $1,000 per year of warranty coverage: (1) since the data were specific to heavy heavy-duty engines, EPA has scaled the warranty cost for non-heavy heavy-duty engines (e.g., light-heavy and medium-heavy engines) by the ratio of the non-heavy heavy-duty engine's emission control system direct costs to the heavy heavy-duty engine's emission control system costs; (2) EPA applies the warranty cost per year not to the mandated length of the warranty but to the estimated length of the warranty based on estimates of the miles and speeds driven by different vehicles and estimating the age at which warranty would be reached (the minimum of the 3 possible ages based on required years, required miles or required hours); and, (3) unlike in the proposal, where EPA calculated warranty costs assuming that engines were covered only by the mandated warranty period, for the final rule EPA has considered that many engines are sold today with extended warranty coverage and, therefore, are already incurring some extended warranty costs. We present a discussion of our updated methodology in Chapter 7 of the final RIA and we believe that our updated approach is consistent with the data provided by EMA.

DTNA commented that EPA did not acknowledge the magnitude of the cost increases associated with longer warranty and useful life provisions. This is not correct. While EPA understands that most industry commenters found our proposed cost estimates to be low, it is not true that EPA did not acknowledge their costs. We estimated costs associated with longer useful life as part of our research and development estimates. Importantly, the EMA/Ricardo study estimates did not call into question EPA's estimates of R&D costs and actually used the EPA costs in their summation of costs. The primary difference between industry and EPA, as discussed in Section 18.2 of this document, is with respect to aftertreatment system replacement costs, which EPA believes will not occur under the final program because, as explained further in preamble Sections III and IV, EPA is not finalizing the complete Option 1 standards, useful life values, and warranty periods as proposed. As described in the preamble and RIA for this final rule, EPA's technical analysis demonstrates that next generation aftertreatment systems can achieve the EPA final rule NOx standards at the final rule useful life with compliance margins and thus we do not believe based on the available data and the standards and requirements contained in this final rule that manufacturers would need to include a full aftertreatment system replacement as part of their compliance approach.

EMA also commented on additional warranty cost factors associated with a 20 percent increase in warranty costs for existing components due to the stringent new standards, and a 20 percent increase in failure rates for new technologies and new applications of existing technologies. After considering these comments, we do not believe it is appropriate to apply any such factors. As noted above, EMA provided warranty data showing that warranty costs were roughly $1,000 per year of warranty coverage. Further, EMA showed data extending over an eight-year timeframe. EPA believes that over an eight-year period certainly some if not many of the engines reflected in the data included new technology and new applications of existing technology. In other words, it seems reasonable to assume that the warranty costs of any such increased failure rates are included in the data and are, therefore, included in the $1,000 per year value. In addition, because in the final rule's analysis we now apply warranty costs on a cost per year basis, we carry the increased warranty cost per year for more years relative to the baseline. In the end, we consider our updated methodology to provide a robust, thorough and reasonable accounting of the costs associated with the final warranty provisions.

The Motor & Equipment Manufacturers Association (MEMA) commented that having such a long warranty on new vehicles will drive significant additional costs into the vehicle purchase price. MEMA was not clear as to whether they meant any warranty longer than the mandated 100,000 miles or if they were referring specifically to the NPRM's Option 1 warranty period of 600,000 miles (for Class 8 diesel engines). Nonetheless, EPA agrees the longer warranty periods will increase purchase costs and we have estimated those costs for the final warranty periods, though we note that EPA has not finalized the proposed Option 1 600,000 mile warranty period for Class 8 heavy-heavy diesel engines.

George Small commented in favor of the longer warranty provisions given that emission control systems are expensive to replace. EPA expects that, with the final standards, more emission-control system repairs will be done during the warranty period and will, therefore, be paid by the OEM. However, it is expected that those costs will be borne at vehicle purchase, so EPA does not attempt to claim that the longer warranty provisions will result in lower costs overall. As explained above in this section, EPA does not expect that emission control systems will be replaced to meet the final new standards.

18.4 Indirect costs - R&D

Comments by Organizations

Organization: *International Union, United Automobile, Aerospace & International Union, United Automobile, Aerospace & Agricultural Implement Workers of America - UAW Region 1A*

To be effective, the final rule must be: A bridge to a zero-emissions future. The final rule must not prevent continued progress toward zero-emissions commercial vehicles by forcing excessive, costly redesigns of traditional combustion engines at the expense of investments in the research and development of zero emissions vehicles, nor add cost to these new technologies. [EPA-HQ-OAR-2019-0055-1062-A1, pp.1-2]

EPA Summary and Response

The International Union, United Automobile, Aerospace & International Union, United Automobile, Aerospace & Agricultural Implement Workers of America - UAW Region 1A commented that the final rule must not prevent continued progress toward zero-emission commercial vehicles by forcing R&D on conventional vehicles. However, EPA must keep in mind that, despite the evolution of zero emission technology, the projected emissions from conventional engines cannot be ignored. EPA's final standards, useful life values, and warranty periods are consistent with EPA's authority under the CAA, as explained in the preamble of the final rule and sections 3 and 4 of this document, and include appropriate consideration of costs. In setting the final emission standards, EPA appropriately assessed the statutory factors specified in CAA section 202(a)(3)(A), including giving appropriate consideration to the cost associated with the application of technology EPA determined will be available for the model year the final standards apply (i.e., cost of compliance for the manufacturer associated with the application of such technology). EPA's assessment of the relevant statutory factors in CAA section 202(a)(3)(A) justify the final emission standards. We also evaluated additional factors, including factors to comply with E.O. 12866; our assessment of these factors lends further support to the final rule (see, e.g., Section IX of the preamble, which explains that this rule is cost beneficial to society in that its benefits outweigh its costs).

18.5 Indirect costs – Other

Comments by Organizations

Organization: *Taxpayers Protection Alliance (TPA)*

This last category is particularly important, given the rampant price inflation experienced by consumers over the past year. The Consumer Price Index (CPI) increased by 8.5 percent for the year ended March 2022, the most significant increase since 1981.4 Supply chain difficulties are a key contributor to this price increase and stringent fuel/pollution controls will have a further upward pressure on CPI. Manufacturers of compression ignition engines will likely respond to new, required laboratory tests (i.e., 'a new low- load cycle (LLC) test procedure to demonstrate that emission controls are meeting proposed LLC standards when the engine is operating under low-load and idle conditions') by passing costs along to companies further downstream in the supply chain (e.g., e-commerce companies) who may in turn raise prices on consumers. [EPA-HQ-OAR-2019-0055-1102-A1, pp.1-2]

4 Jeanna Smialek, 'Inflation Hits Fastest Pace Since 1981, at 8.5% Through March,' The New York Times (Apr. 12, 2022).

These inflationary pressures not only harm consumers, they also pose significant environmental consequences. The current structure of the supply chain in the U.S. tends to reduce emissions by reducing the amount of energy required to transport each product unit to reach consumers' doorstep.5 The increased integration of the supply chain has resulted in a proliferation of heavy-duty vehicles willing to take products all (or most) of the way to their final destination. But, if heavy-duty vehicle deliveries are 'taxed' by an onerous regulatory regime, it may become more economical for these fleets to travel shorter distances and deliver products at stores rather than going the last mile to households. This reduction in e-commerce would result in increased consumer trips to stores to pick up their orders, resulting in increased emissions via roadway congestion. Given that the EPA's estimated net benefits ($8-9 billion in 2045) are small, introducing these unintended consequences into the equation could result in large net costs for the proposed rulemaking. [EPA-HQ-OAR-2019-0055-1102-A1, p.2]

5 Prologis, Inc., 'Logistics Real Estate and E-Commerce Lower the Carbon Footprint of Retail' (Jan. 14, 2021).

TPA urges the agency to take all costs into account when promulgating rulemaking. [EPA-HQ-OAR-2019-0055-1102-A1, p.2]

EPA Summary and Response

The Taxpayers Protection Alliance (TPA) commented that inflationary pressures to date, with an "onerous" regulatory regime on top, will cause costs to increase, fleets to stop delivering to households, and consumers to make more store trips to pick up orders. EPA agrees that costs will increase but does not believe it will disrupt the trends of household deliveries, particularly because the cost increase is only a small part of the overall cost of shipping. TPA has not provided data on past EPA actions that could shed light on possible outcomes associated with the final standards.

18.6 Operating costs – Repair

Comments by Organizations

Organization: *Allison Transmission, Inc. (Allison)*

Allison first questions EPA's reliance on the Fleet Advantage study in measuring this crucial element of EPA's cost analysis. For one, it seems inapposite EPA's rationale for extending useful life and warranty periods to utilize a study based on a seven-year average of costs of vehicles from 0 to 7 years of age versus a study that utilized vehicles ranging in age from 4.4 years to 8.5 years old. As proposed, EPA would extend useful life and warranty periods for all vehicles in all weight classes and the time period(s) that extend beyond those currently utilized. Thus, it would appear more directly relevant to EPA's analysis to use data from a more diverse fleet of different ages versus a study which averaged out the cost of older vehicles with newer vehicles when costs for older vehicles sharply increased in later years.33 [EPA-HQ-OAR-2019-0055-1231-A1, p.14]

> 33 In the first year of operation, costs were 2.07 cents/mile versus 19.82 cents/mile at year 7.

Second, EPA also appears to have “flat-lined” costs at 8 years.34 EPA’s rationale in doing so is that the vehicles are “beyond useful life.” However, this assumes that all vehicles will be beyond useful life periods based on mileage. While this may be so with long- and short-haul fleet vehicles, this analysis certainly does not extend to all vehicles, particularly many vocational vehicles which may not accumulate large amounts of daily mileage or be used daily as is typical in the freight-hauling sector. See Table 1 below.35 Allison has provided mileage accumulation data to represent 70% of various vocational application’s annual accumulation which shows a low end of range of 10,800 miles for fire, pumper application to high end of range 72,000 miles annually for intercity coach application, demonstrating that vocational usage differs significantly from tractor usage. Many vocational applications vary between 15,600 miles to 48,000 miles annually. For such vehicles, hours of operation may be the operative factor with respect to the extent of warranty coverage, not mileage. Again, EPA’s assumption tends to slant the cost data in a direction that is not reflective of the broader HDV sector.[EPA-HQ-OAR-2019-0055-1231-A1, pp.14-15]

34 Draft RIA, Figure 7-2 at 345.

35 Table values were derived from Allison Transmission, Inc. warranty data.

Third, it is likely that more “stop-and-go” operation of a vehicle and increased transient operation is likely to put different kinds of demands on vehicle components than the steady-state operation that appears to dominate the Fleet Advantage data. Solely by the selection of vehicles involved, the Fleet Advantage data reflects relatively longer periods of time spent on highways, in high-speed operation. But EPA does not account or adjust this data to account for the operational characteristics of other vehicles that may not predominantly handle freight, or may be used in many varied applications. Different demands will be placed on an automobile that completes a 50-mile commute each day on the interstate versus a 5-10 mile creep through heavy traffic to a downtown area. These obvious differences are only accentuated in the commercial, vocational vehicle sector where vehicles are not only used in vastly different ways from line-haul, but developed and constructed in a manner so as to service discrete commercial needs. EPA’s cost data is inherently biased against such vehicles. [EPA-HQ-OAR-2019-0055-1231-A1, p.15]

Allison has decades of experience serving vocational markets and designing our products to accommodate the work demanded of such vehicles. To a much greater extent in its cost analysis, EPA should consider and/or develop additional information for this segment of the heavy-duty fleet due to its combined market size representing roughly 190,000 vehicles sold annually across CL6/7/8.36 While vocational markets are fragmented across a variety of applications for specific customer uses, in aggregate vocational applications including bus and straight truck which may serve construction, municipal, heavy haul, refuse, emergency response, utility, pick-up and delivery, etc., account for over 90% of Class 6 & 7 and approximately 25% of Class 8 builds on an annual basis. See Table 2 below. [EPA-HQ-OAR-2019-0055-1231-A1, pp.15-16]

Footnote 36 was not included in comment.

As demonstrated by the data presented above, EPA should also consider that in smaller, fragmented, more diverse market segments in the vocational vehicle sector, the costs that will be incurred for research and development activities will be different. In general, the relative research and development costs will be greater to validate the technology needed to serve these markets if only for the fact that such costs will need to be spread over lesser numbers of vehicles in discrete sub-categories and markets. Testing that will be required will also vary from that which we would expect in the short- and long-haul sector. A variety of diverse duty cycles and operating environments will need to be considered, again likely resulting in greater costs than vehicles which may be expected to "age out" based on mileage accumulation. For vocational applications that accumulate miles more gradually, the emissions maintenance cost ratio for manufacturers to operators is likely higher than what EPA has assumed in the seven-year repair cost analysis based on 75,000-144,000 annual mileage accumulation on Fleet Advantage data. [EPA-HQ-OAR-2019-0055-1231-A1, pp.16-17]

In sum, Allison believes that research and development and indirect costs are undercounted for Option 1 and should also be better reflected in both Options to consider a more diverse array of vehicles. Higher costs will lead to higher initial prices for vehicles under Option 1 (as well as for vehicles under the Alternative) which is likely to result in reduced emissions benefits in the near- and middle-term since the higher costs will affect the "pre-buy" and "low-buy" impacts than EPA assumes elsewhere in its analysis.[EPA-HQ-OAR-2019-0055-1231-A1, p.17]

Organization: *Agricultural Retailers Association (ARA) (1241 and 1421)*

ARA recommends that EPA propose modest and achievable nitrogen oxide (NOx) emissions standards that are affordable, dependable, durable, fuel efficient and meet the needs of agricultural retailers, trucking companies, and all other impacted industries. It is our understanding that the current costs for the maintenance and repairs of emissions-related equipment is at least $5,000 annually. The new proposal will make those average annual maintenance and repair costs soar even higher. [EPA-HQ-OAR-2019-0055-1251-A1, pp. 2 - 3]

Organization: *American Bus Association (ABA) (1070 and 1308)*

Additionally, there will also be added costs for vehicle purchasers associated with operating engines with more complex emissions control systems, such as increased maintenance intervals, replacement component products, supply chain issues, and ease in diagnosing and facilitating repair. Although EPA suggests the Proposal would actually lower emission system repair costs, by extending the useful life of the engine and the warranty period, these changes would still come at a cost as engine manufacturers will be taking on more liability – and these costs will be reflected in the purchase price of a new vehicle and some components may end up being in short supply as censors and chips are currently. Also, EPA makes assumptions on future repair costs in the Notice; however, the motorcoach industry already bears a costly burden under the current heavy-duty emissions regulations as a result of EPA's inducement policy and design strategy. Perhaps unanticipated in the initial emissions control rulemaking, it is a very real and costly burden to the heavy-duty vehicle industry, and it is not fully addressed in terms of cost analysis in the Proposal, as it will likely increase even with EPA's proposed inducement provisions. EPA includes discussion of the cost burden in the Notice under Section IV. D, based on comments from the Advanced Notice of Proposed Rulemaking in this proceeding. These comments identify a number of real world, burdensome costs to truck and motorcoach operators, including unnecessary repair expenses for replacing non-faulty parts, towing costs, lost time and schedule impacts, reimbursement costs for passenger tickets, and cost to reputation as a result of inducements or derates. However, above and beyond these costs is the largest cost risk for motorcoach operators: the risk to human life by placing in peril stranded passengers, as a result of this design strategy. ABA cannot sufficiently underscore the hazard created by EPA's inducement policy and the fear within the industry because of the increased risk o human life caused by the Proposal's potential to increase derate occurrences. [EPA-HQ-OAR-2019-0055-1308-A1,p.7]

In sum, ABA believes EPA underestimates the cost impacts of the Proposal, in terms of the cost to manufacture an engine with an emissions control system to meet the proposed standards and testing, along with the added cost to extend the useful life and warranty periods. These costs will lead to an increase in vehicle purchase price and maintenance and repair costs for vehicle purchasers. ABA also, again, points out that EPA has not fully accounted for or undervalued the benefits of travel by motorcoach and the importance of encouraging such travel, rather than making motorcoach operations prohibitively and unreasonably expensive, slowing down fleet turnover and making motorcoach operations unviable. [EPA-HQ-OAR-2019-0055-1308-A1, p.8]

Organization: American Trucking Associations (ATA)

Trucking companies meticulously track their business costs. The American Transportation Research Institute ("ATRI") has prepared and issued annual trucking operational cost reports since 2008. ATRI's latest report, An Analysis of the Operational Costs of Trucking: 2021 Update, analyzed calendar year 2020 industry data and concludes once again what our industry already knew – it is becoming more and more costly to own and operate trucking businesses -- especially for the 97% of the industry which are small businesses. 4 [EPA-HQ-OAR-2019-0055-1326-A1, p. 9]

4. American Transportation Research Institute. An Analysis of the Operational Costs of Trucking: 2020 Update, November 2021.

The most recent survey presents data representing 138,930 truck-tractors. Additionally, the data includes 418,520 trailers of varying types, and represents over 12 billion vehicle miles traveled. As shown in Figure 2, a majority of respondents (53%) represent fleets of 100 or fewer power units. [EPA-HQ-OAR-2019-0055-1326-A1, p. 9]

The ATRI survey found that for most trucking companies, labor is again their top operating expense per mile (45%), followed by fuel (19%), and truck payments (16%). Since 2011, marginal operating costs per mile for truck/trailer payments have increased 43% while labor costs per mile have increased by 21% (See Table 2). [EPA-HQ-OAR-2019-0055-1326-A1, p. 10]

Organization: *Daimler Truck North America LLC (DTNA) (1045 and 1168)*

Operator Costs. Daimler Truck notes that EPA also underestimates operator costs in the draft RIA and in the Proposed Rule, in particular the potential costs of critical emissions maintenance after the warranty period expires. This is particularly so if manufacturers require scheduled maintenance for replacing after treatment components, which will be covered by the manufacturer during useful life but not after. [EPA-HQ-OAR-2019-0055-1168-A1, p.19]

Further, EPA does not account for higher upfront costs for operators related to the extended emission warranty. As explained in the NREL Cost Study, 'because aftertreatment package repair costs are either paid by the vehicle owner or the vehicle manufacturer through the warranty (if applicable), one may expect the higher upfront cost incurred to the vehicle owner for an aftertreatment package with extended full useful life and extended warranty.'49 NREL further explains that while these higher upfront costs may be offset to a certain degree by the aftertreatment repair cost savings over the life of the vehicle, incremental upfront purchase costs 'would be significantly higher than the repair cost savings that vehicle owners would realize.'50 [EPA-HQ-OAR-2019-0055-1168-A1, pp.19-20]

49 NREL Cost Study at 50.

Organization: *Engine and Truck Organizations*

Based on our assessment, EPA's "Option 1" rule as proposed will be:

- Disruptive of business. The additional costs and downtime associated with increased repairs and maintenance will directly impact our customers' day-to-day operations and inhibit their ability deliver goods and services. [EPA-HQ-OAR-2019-0055-1177-A1, p.1]

Organization: *Esler, Bob (OOIDA)*

"A friend of mine bought a new cat engine when all new emissions controls. That engine was in the shop more than it was on the road. It was a very expensive experience. The EPA was successful in putting one engine maker out of business. Who are they after next." [EPA-HQ-OAR-2019-0055-1266-A2, p.3]

Organization: *Motor & Equipment Manufacturers Association (MEMA)*

EPA is interested in stakeholder input on their approach for estimating emission reductions from lengthening useful life and warranty periods and on their estimate of repair costs for emission control system components. MEMA would suggest that the analysis is very mileage focused. Data from a minimum of 75,000 miles/year and a maximum of 144,000 miles/year was used to make all repair model estimates. The effects of continued usage outside of that range is unknown. In addition, significantly more repair is required for many vocational applications being performed in rough environments. [EPA-HQ-OAR-2019-0055-1322-A1, p. 8]

Organization: *Sell, Richard (OOIDA)*

I have seen 10 Freightliners of ours go down with one box faults. Every time one goes down it cost approximately $20,000 to fix. This cost is bad enough, now you want to add a new program on emissions that manufacturers cannot meet. The deadline you're setting is unacceptable with the current and in the foreseeable future advances in technology. We now have record high fuel prices coupled with high truck prices. We cannot afford this. The trucking industry moves this nation. The cost of this program would need passed onto the consumer. The consumer will not be able to pay the increase. Most families are struggling just to make ends meet. This is being caused by high gas prices, grocery prices caused by inflation. These problems need to get rectified before any new rules are implemented. [EPA-HQ-OAR-2019-0055-1266-A2, p.3]

Organization: *United Motorcoach Association (UMA)*

Currently, a typical new motorcoach will cost $500,000 to $600,000. The cost and maintenance of these vehicles is amortized over the life of the vehicle, expected to be 20-plus years, through sales of the various services bus and motorcoach companies offer. Safety technologies, artificial intelligence, semi-automated driving is rapidly coming to market; however, these safety technologies are very expensive and any savings from predicted crash reductions may only be realized many years after the acquisition and implementation. [EPA-HQ-OAR-2019-0055-1311-A1, p.2]

Another layer of mandated emissions reductions will add more cost to the bus and motorcoach. Considering there are limits the consumers of bus and motorcoach services can absorb, providers will be less likely to adopt safety technologies. EPA must consider the unintended consequences of displacing safety technologies and the subsequent adverse cost of bodily injury, property damage, and fatalities when mandating additional engine technologies. [EPA-HQ-OAR-2019-0055-1311-A1, p.2]

EPA Summary and Response

The comments summarized above focus primarily on assertions about:

- EPA's use of a Fleet Advantage Whitepaper to estimate emission-related repair costs rather than the more established and annual ATRI study; and,
- EPA having underestimated emission-related repair costs; and,
- EPA's focus on miles driven rather than operating hours in estimating emission-related repair costs.

Allison Transmission, Inc. (Allison), commented with respect to EPA's use of the Fleet Advantage study over the American Transportation Research Institute (ATRI) study in developing a repair cost estimate. In short, EPA used the Fleet Advantage study to estimate emission-related repair costs and how those would change in the event of longer warranty and useful life periods. That said, the Fleet Advantage and ATRI costs were not dissimilar. The Fleet Advantage costs ranged from roughly 2.7 cents per mile in the first year of life to 19.6 cents per mile by age 6 or 7. This increasing cost with age allowed for development of a cost curve as a function of age. In contrast, the ATRI study developed a cost per mile value, 17.1 cents per mile, for every age. We used the former in the proposal since it seemed reasonable that repair costs would increase in some manner with age. That said, the most recent release of the ATRI study includes data spanning 10 years, making for a nice dataset upon which to base a cost per mile estimate. Further, the ATRI study includes a repair and maintenance cost per operational hour value and Allison also argued that certain vehicle types, such as vocational vehicles, tend to have repair costs more closely aligned with operating hours than with operating miles due to slower speeds and/or stop-and-go type operation. After careful consideration of these facts, and as described in Chapter 7.2.3 of the final RIA, the final cost analysis makes use of the ATRI study and of both its repair and maintenance cost per mile and cost per hour estimates.

Allison also questioned EPA's use of a maximum cost per mile value for vehicles beyond their useful life. This aspect of Allison's comment seems to be contrary to their prior point in their comment, just discussed, which seemed to argue for a constant cost per mile value of 17.1 cents per mile for all ages in a vehicle life. EPA used a maximum cost per mile value beyond useful life because the Fleet Advantage data did not extend beyond around 7 years of vehicle age. As noted above, the final cost analysis makes use of the ATRI study, as also suggested by Allison, and scales upward the emission-related repair cost per unit (mile or hour) value based on the direct manufacturing costs of the given HDE in the action scenario relative to its baseline. This scaling approach is described in Chapter 7.2.3.

Allison also commented that vocational vehicles may experience more stop-and-go operation than do the combination vehicles upon which the Fleet Advantage data were based. This is a valid point and we agree it is possible that stop and go operation could result in higher annual repair costs than would otherwise be estimated using a cost per mile approach. However, while providing good qualitative arguments, Allison did not include a better estimate of emission-related repair costs for those vehicles. While pointing out what Allison considered to be flaws in the EPA approach, Allison did not provide sufficient data such as typical hours of operation for various vehicle types that could be used for an emission-repair cost estimation approach based on hours of operation. Allison provided estimated miles driven per year for several vocational vehicle types, but EPA used Federal Highway Administration's (FHWA) Highway Statistics series, as well as Annual Energy Outlook (AEO2018), for vehicle miles travelled for both inventory and cost analyses to maintain internal consistency.[43] That being said, EPA has added to the methodology a check of hours of operation in the estimation of the age at which warranty and useful life would be reached. That estimation process now considers the required age, the age at which the miles provision is estimated to be reached, and the age at which the hours provision is estimated to be reached. The methodology assumes that all vehicles within a MOVES source type are operated at the average speeds within MOVES (see Chapter 7 of the final RIA for more detail). Had Allison provided more detail regarding hours of operation for each vehicle type, we would have considered using it, and we would have considered using repair costs per hour had such data been provided. Note that the ATRI study provides a repair and maintenance cost per hour, but that number is simply a conversion from the repair and maintenance cost per mile value along with an assumed average speed of roughly 40 miles per hour. We have used that value when determining repair costs for most vocational vehicles,

[43] Sonntag, Darrell. Population and Activity of Onroad Vehicles in MOVES_CTI_NPRM. Attachment to Memorandum to Docket EPA-HQ-OAR-2019-0055: "Updates to MOVES for Emissions Analysis of the HD 2027 NPRM." May 2021.

calculating their repair costs based on estimated hours of operation rather than miles of operation.

The Agricultural Retailers Association (ARA) and the American Trucking Associations (ATA) commented that the rule would result in soaring maintenance and repair costs. EPA has estimated the impact on emission-related repair costs associated with the more costly emission control systems expected to be employed to comply with the new standards. We present our methodology and results in Chapter 7 of the final RIA.

The American Bus Association (ABA) commented about the increased costs of emission controls, the increased repair costs, safety concerns surrounding derates and an assertion that EPA has not considered the benefits of bus travel. EPA acknowledges that the final program will result in costs on the regulated industry, and may result in new operating costs and savings for owner/operators of new MY2027 and later HD vehicles. However, EPA finds those costs are associated with significant net benefits to society as explained in Sections VIII and IX of the preamble.

Daimler argued that EPA had underestimated operator costs associated with emission-related repairs. However, EPA estimated emission-related repairs for a diesel long-haul tractor of over $40,000 over the first 18 years of the tractor's lifetime. The marginal costs during those 18 years were over $6,000 for each of the proposed options. EPA is not sure if the commenter considered those costs as too low, or if the commenter may have been unclear about what costs had been estimated in the proposed rule's presentation of emission-related repair costs. Note that the EMA comments and associated Ricardo study failed to properly reflect EPA's estimated emission-related repair costs, which suggests commenters may have been unclear about the presentation in the draft RIA. EPA has tried to make the presentation clearer in Chapter 7 of the final RIA. Daimler also commented on EPA's warranty costs, which have been updated for the final analysis as discussed in more detail in Section 18.3 of this document.

The Engine and Truck Organizations stated that proposed Option 1 would result in additional costs and downtime associated with increased repairs and maintenance and will directly impact our customers' day-to-day operations and inhibit their ability to deliver goods and services. As explained further in preamble Sections III and IV, EPA is not finalizing the complete Option 1 standards, useful life values, and warranty periods as proposed. We also touch upon how our final standards do not incorporate some of the provisions of most concern to some commenters in section 18.2 of this document.

Bob Esler suggested that EPA had put Caterpillar out of business. To the extent that the commenter is referring to past EPA actions, the comment is beyond the scope of this rulemaking. In any event, EPA has not put Caterpillar out of business, as Caterpillar continues to be a large manufacturing firm that produces and sells a wide range of construction, mining, marine, power generation and other industrial equipment. The commenter may be referring to the decision by Caterpillar to exit the on-highway diesel engine market more than ten years ago in 2010. The commenter provides no basis for the assertion that Caterpillar made this decision in response to an EPA action. EPA does not believe this comment is relevant to this rulemaking, and the commenter does not provide an explanation of why this claim regarding Caterpillar is relevant to this rulemaking. The commenter implies that EPA standards have the effect of putting an engine manufacturer out of business. EPA disagrees with this comment, and our detailed feasibility and cost analysis for this rulemaking demonstrates there are technologies available for the engine industry to develop and produce that will meet the standards established in this final rule.

MEMA commented on EPA's request for input regarding the emission-related repair cost estimates in the proposal. MEMA expressed a concern about the EPA methodology, stating that it was very focused on mileage. MEMA's primary concern appeared to be that data from a minimum of 75,000 miles/year and a maximum of 144,000 miles/year was used to make all repair model estimates. MEMA also stated that the effects of continued usage outside of that range is unknown and that significantly more repair is required for many vocational applications being performed in rough environments. Regarding the mileage focus, this was true in the proposed analysis, but EPA has updated the final analysis to use operating hours for vocational vehicles (rather than miles driven). EPA does not understand MEMA's comment that EPA used data from 75,000 to 144,000 miles for all repair estimates. A cost per mile approach was used, but the miles driven (in the proposal) and/or hours operated (in the final analysis) are unique to each vehicle and do not use a static 75,000 or 144,000 mile per year value. Regarding the costs for vocational vehicles in rough environments, MEMA did not provide data that EPA could consider for the final analysis.

Richard Sell suggested that high gas prices and grocery prices due to inflation had to be rectified before any new rules are implemented. Clean Air Act section 202(a)(3)(A) requires EPA to set emission standards for NOx, PM, HC, and CO that reflect the greatest degree of emission reduction achievable through the application of technology that the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology. EPA is finalizing this rule consistent with this authority. See also our response to similar comments in section 18.7 of this document.

The United Motorcoach Association (UMA) argues that the rule and its costs may displace the introduction of safety technologies and that EPA must consider this possibility. EPA does not believe that the new emission standards would conflict with regulatory safety standards that apply to any highway vehicle, including motorcoaches. The UMA makes a hypothetical argument that, because the EPA standards will increase the costs of a motorcoach, which they acknowledge in their comments can cost $500,000, the final standards would discourage vehicle purchasers from buying safety equipment. However, UMA failed to provide data or analysis demonstrating that this effect would occur. EPA does not agree with this hypothetical argument and believes it is unlikely that the marginal costs are high enough to create this result for a $500,000 vehicle.

18.7 Operating costs – Fuel

Comments by Organizations

Organization: *Agricultural Retailers Association (ARA) (1241 and 1421)*

Advanced and cellulosic biofuels have been proven to provide low-cost and low emission alternative based fuel that EPA can help promote by reducing the regulatory backlog stifling fuel technologies that can allow the nation to harness cleaner, renewable energy available from agricultural residue, corn fiber, and waste. ARA supports the EP A's lifting of the restrictions on the sale of E 15 for the 2022 summer driving season, but this policy decision needs to be made permanent in order to allow consumers access to E15 on a year-round basis. According to Growth Energy, the lifting of E 15 restrictions for this summer will save drivers as much as 50 to 60 cents a gallon. [EPA-HQ-OAR-2019-0055-1251-A1, p. 3]

Organization: *American Trucking Associations (ATA)*

Over the past 10 years, both vehicle-based and driver-based costs per mile have fluctuated. Slight variability of individual cost components year-over-year may appear to be insignificant, but overall financial impacts on a fleet can be substantial. [EPA-HQ-OAR-2019-0055-1326-A1, p. 10]

For example, fuel costs for one truck travelling 100,000 miles per year in 2020 at $2.56 per gallon averaging 6.2 miles per gallon would equate to an annual fuel expense increase of $41,290.5,6 A fleet running 100 vehicles would recognize a $4.1 million annual fuel bill upcharge. [EPA-HQ-OAR-2019-0055-1326-A1, p. 10]

5. U.S. Department of Transportation, U.S. Federal Highway Administration Highway Statistics 2020.

6. U.S. Department of Energy, U.S. Energy Information Administration, U.S. On-Highway Diesel Fuel Prices, Gasoline and Diesel Fuel Update - U.S. Energy Information Administration (EIA), (May 9, 2022).

Using today’s diesel price of $5.62 per gallon -- a 220% increase from the average diesel fuel price in 2020 -- the fuel bill for one truck is now $90,645, an increase of nearly $49,355 per year.7 That 100 vehicle fleet would expect an annual fuel bill of over $9.1 million a year, a $5 million dollar increase compared to only two years ago. In an industry that operates on razor thin profit margins, many trucking companies continue to teeter on the edge of insolvency. [EPA-HQ-OAR-2019-0055-1326-A1, pp. 10 - 11]

7. Id.

While not reflected in Table 2, significant cost increases in 2022 resulting from record inflation, parts and equipment shortages, historically high fuel and labor costs, and rising insurance premiums, will likely set new fleet operating expense records in next year’s ATRI operational cost report. These costs, along with the additional financial impacts that will be created under HD2027, must all be considered in that increased costs associated with any one individual rule by any state or federal agency may very well lead to trucking companies shuttering their operations. [EPA-HQ-OAR-2019-0055-1326-A1, p. 11]

Organization: *Booth, Norman (OOIDA)*

"I know that this is all a scam I have a 2021 389 Pete my close friend has a 2017 389 Pete glider We have on several occasions ran together and he will get 2 miles better fuel economy than I do (loaded) and even better than that empty And we are comparing apples to apples We both pull tankers and had the same weight of 45000. His truck does not put out no more black smoke that my new one does. Thanks." [EPA-HQ-OAR-2019-0055-1266-A2, p.2]

Organization: *Ingevity Corporation (Ingevity)*

On an ORVR-equipped vehicle, refueling emission vapors are captured in the activated carbon canister, purged during driving, and used as fuel. In the draft RIA, EPA estimated that 1.48 ml of gasoline would be recovered as fuel for each gram of vapor purged from the canister. [EPA-HQ-OAR-2019-0055-1213-A1, p. 3]

It is useful to compare the monetary value of this recovered fuel over an HHDGV lifetime period in miles (e.g., 150,000) to the suggested $34 RPE cost estimate. Four values are needed to calculate total gallons recovered: the uncontrolled refueling emission rate (g/gal), the control efficiency of ORVR, the vehicle fuel economy (miles/gal), and the adjustment for energy density since refueling emissions are mostly butane. Using a 150,000-mile driving lifetime, a 4.1 g/gal refueling emission rate (assuming a mechanical seal), a 98% control efficiency of ORVR6, 11 miles/gallon fuel economy,7 and a 1.117 energy density adjustment factor (as per the EPA draft RIA), yields a total fuel recovery of 22.4 gallons over the HHDGV life. In the draft RIA, EPA used the AEO 2018 $/gal gasoline price projections.8 For the period 2027-2038 this value is about $3.40, which gives an undiscounted fuel recovery value of about $76 over the vehicle life. [EPA-HQ-OAR-2019-0055-1213-A1, p. 4]

6. Passavant G., 2017 Summary and Analysis of 2000-2015 Model Year IUVP Evaporative and Refueling Emission Data, SAE Technical Paper 2017-01-5008

7 The 11-mpg projection for 2027+ for HHDGV fuel economy is based on information on page 8-8 and Table 5-15 for vocational vehicles as found in EPA's RIA entitled "Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles - Phase 2," EPA-420-R-16-900, August 2016.

8 Energy Information Administration (U.S. EIA). 2020. Annual Energy Outlook 2020 with Projections to 2050. January. www.eia.gov/aeo.

While the cost of ORVR is incurred at the time of purchase, the recovery credits are accrued over the years as the vehicle is driven. In previous documents, EPA based its mobile source emission inventories on annual vehicle miles travelled (VMT) with the VMT for any given vehicle decreasing each year after it enters the fleet.9 Using the "mileage accumulation rate per vehicle" in Table 1.4.4 of reference 9, a given vehicle will accumulate 150,000 miles in 12 years.

Applying a 3 percent discount rate to the stream of fuel recovery credits in years 1 through 12 (calculated as a function of annual mileage) yields an adjustment factor of 0.888 for a discounted recovery credit value of about $67 for the 150,000-mile use period. [EPA-HQ-OAR-2019-0055-1213-A1, p. 4]

9. See Table 1.4.4 of US EPA "Compilation of Air Pollutant Emission Factors Highway Mobile Sources, EPA 460/3-81-005, March 1981. Data for the "mileage accumulation rate per vehicle" for heavy duty gasoline vehicles used.

This discounted $67 recovery credit is much greater than the $34 RPE price-adjusted estimate. The VOC cost effectiveness on a $/ton basis is -$550/ton. This analysis does not include the additional environmental and health benefits that would be realized from the recovery of the fuel vapor, as evaporated fuel vapors are a precursor to the formation of ozone and secondary particulate matter (PM 2.5). [EPA-HQ-OAR-2019-0055-1213-A1, p. 4]

Organization: *Starnes, Elvin (OOIDA)*

"I own a 2014 Prostar and I have had numerous problems with the EGR coolers and DPF problems at a cost of $3,700 to as much of $9,500 at least once a year. The fuel economy is worse than my older truck that didn't have any emissions on it also I wish that I never got rid of the older truck." [EPA-HQ-OAR-2019-0055-1266-A2, p.1].

Organization: *Streenstrup, Hank (OOIDA)*

Every Diesel vehicle I have has been negatively affected by updating the emissions systems. My current heavy truck is a Glider kit with a pre-emissions, re-built engine in order to avoid the downtime and reduced fuel economy that I experienced with my previous truck. I do not go to any "emissions regulated" areas in my class 8. I also own a 1ton Mercedes Sprinter that had the emissions update this January. This has resulted in a reduction in fuel economy, resulting in more fuel expense during these times of very high fuel costs anyway. I'm all for being "environmental", but it makes no sense to burn 20-40 percent more fuel………and this results in fewer emissions?????? I also operate a HD pickup that is currently consuming excessive fuel because of the emissions systems. These costs must be passed on through higher rates to my customers. I am slowly retiring early because of the increased costs. I have become VERY SELECTIVE with what loads that I contract, because of costs and loss of flexibility in operating my business." [EPA-HQ-OAR-2019-0055-1266-A2, p.2]

Organization: *Zero Emission Transportation Association (ZETA)*

Finally, the economic benefits of electrifying HDVs are significant. The total cost of ownership of HDEVs is lower than that of fossil fuel-powered HDVs (as explained in detail in the following section), especially amidst record-high gasoline and diesel prices. A new ZETA report found that gas-powered vehicles are 3-5 times more expensive to drive per mile than EVs,9 and those effects are multiplied in low-efficiency gas-powered vehicles like HDVs. [EPA-HQ-OAR-2019-0055-1283-A1, p.3]

EPA Summary and Response

The Agricultural Retailers Associated (ARA) stated support for a permanent lifting of restrictions on the sale of E15. This is outside the scope of this rulemaking.

The American Trucking Associations (ATA) commented that the recent upswing in fuel costs, combined with increased costs associated with the new standards, must be considered in estimating costs of the rule. We understand the concern, but our cost analysis is intended to estimate the incremental costs on regulated entities. Since there are almost no diesel fuel consumption impacts associated with the new standards (there is a small fuel savings associated with captured fuel during refueling events for gasoline vehicles), there is no incremental cost impact associated with fuel prices since they would be, except for gasoline vehicles, the same in the no-action and the final rule scenarios. See also our response to a similar comment in section 18.6 of this document.

Norman Booth, Elvin Starnes, and Hank Streenstrup provided anecdotes regarding their truck's fuel consumption compared to a friend's truck and/or a prior owned truck, but there did not appear to be a comment with respect to any portion of our proposal in the anecdotes.

Ingevity Corporation (Ingevity) provided a detailed accounting of costs and fuel savings associated with the ORVR requirements on gasoline engines. The comment was supportive of the proposal.

The Zero Emission Transportation Association (ZETA) commented that electrified heavy-duty vehicles have a more favorable total cost of ownership than fossil fuel-powered heavy-duty vehicles. EPA has not looked closely at total cost of ownership in the analysis for the proposal or the final rule because the rule is focused on criteria emission control, not ownership costs. Note also that we didn't evaluate costs of electric vehicles for the criteria emission standards since the final standards are not based on projected utilization of electric vehicle technology, as explained further in preamble Section III, and we are not taking final action at this time on the GHG standards portion of the proposal.

18.8 Operating costs - Diesel Exhaust Fluid (DEF)

Comments by Organizations

Organization: *Champion Auto Carriers*

Having been in the transportation industry for over 35 years I have witnessed what the DEF regulations has cost my business and drivers since 2012. Down time for DEF issues account for 90% of my overall downtime and driver expense. Maybe the EPA should be looking at better technology or systems to reduce NOx but allow for better performance and uptime. We can't afford any extra truck costs or maintenance costs and still deliver the goods and services trucking provides. [EPA-HQ-OAR-2019-0055-2733, p.1]

Organization: *CSM Trucking*

Emission control devices on heavy commercial vehicles are non effective in business use and environmental use. They cost consumers more money in parts and maintenance, and generate more waste to public landfills as def jugs contribute tons of plastic containers to landfills also. [EPA-HQ-OAR-2019-0055-2131, p.1]

Trucks running def are unreliable and not cost effective. More waste is produced using said emissions control vs not using them. Lastly many trucks get worse mpg than older motors not using def units. [EPA-HQ-OAR-2019-0055-2131, p.1]

Clean burning trucks are can be generated in cleanly or accurately tuned vehicles. [EPA-HQ-OAR-2019-0055-2131, p.1]

EPA Summary and Response

Champion Auto Carriers and CSM Trucking commented that EPA should be looking at better technology or systems to reduce NOx but allow for better performance and uptime. EPA does not mandate the technology to be used by industry for compliance with EPA emission standards – the standards are performance standards. EPA does not understand the argument that the SCR and DEF systems are causing reduced performance (by which EPA assumes the commenter means fuel consumption performance) for today's heavy-duty vehicles. While we understand there was some decrease in fuel consumption with the introduction of the model year 2007 diesel engines which added particulate filters for the first time for majority of the Class 8 truck market, those impacts were reversed with the introduction of the 2010 SCR-catalyst technologies, and with the implementation of the EPA GHG standards in 2014, today's highway heavy-duty Class 8 tractors are the most fuel efficient vehicles the industry has ever produced. The EPA GHG Phase 2 standards in 2024 and 2027 require further reductions in CO_2 emissions. As discussed in Section III of the preamble, EPA expects those products will continue the trend of improved fuel consumption and lower fuel operating costs while also complying with the final program.

18.9 Other comments on costs

Comments by Organizations

Organization: *Agricultural Retailers Association (ARA) (1241 and 1421)*

The proposed rule must protect the continued use of the internal combustion engine and promote the use of low-emission biofuels. The EP A's push towards zero-emission vehicles and support for efforts to ban the internal combustion engine, which this latest proposal is designed to do, will cause major job losses, decrease farm income, cause a decline in the U.S. GDP, and adversely impact corn and soybean prices. In October 2020, before the nation's started to see record high inflation, ARA released a commissioned study that analyzed the impact of increased electric vehicle penetration on U.S. biofuels, agriculture, and the economy. Proposals to ban internal combustion engine vehicles, which is a goal of this proposal, by 2035 and 2050 served as the economic models for the study, along with a base case provided by the U.S. Energy Information Administration's Annual Energy Outlook. Key findings of the 'Economic Impacts to U.S. Bio fuels, Agriculture, and the Economy from Subsidized Electric Vehicle Penetration'1 include the following:

- U.S. light-duty and freight vehicle consumption of ethanol and biodiesel could decline up to 90 percent to 1.1 billion gallons and up to 61 percent to 0.8 billion gallons, respectively
- Corn and soybean consumption decrease by up to 2.0 billion bushels and up to 470 million bushels, respectively
- Corn prices fall up to 50 percent to $1.74 per bushel
- Soybean prices fall up to 44 percent to $4.92 per bushel
- U.S. Net Farm Income decreases by up to $27 billion
- U.S. GDP declines by up to $26.4 billion, resulting in cumulative GDP losses of up to $321 billion
- U.S. job losses could reach up to 255,300 in the year 2050 [EPA-HQ-OAR-2019-0055-1251-A1, p. 2]

Organization: *Allison Transmission, Inc. (Allison)*

As EPA notes, costs are imposed both directly (e.g., through the cost of new emission technology) and indirectly (e.g., through the need of a manufacturer to account for the risks and potential financial exposure from extended useful life and warranty periods). At least in some cases, the direct technology costs for new emission control technology to address Options 1 and 2 may be similar due to the need under both options to substantially reduce NOx emissions. In such an instance, however, the indirect cost of extended useful life and warranty periods may be substantially different and realistically impact the prices paid by the ultimate purchaser. This is especially true under Option 1, where manufacturers will need to assess the risks (and uncertainties) of being financially responsible for recalls and/or warranty repairs for extended periods, in some cases up to 6 times the length of current periods.24 [EPA-HQ-OAR-2019-0055-1231-A1, p.12]

> 24 EPA’s proposed Option 1 would implement an emissions warranty period of 600,000 miles in MY 2031 for Heavy HDE vehicles as compared with current standards requiring 100,000 miles.

Organization: *American Bus Association (ABA) (1070 and 1308)*

However, the Proposal does not really address motorcoach operations, or the benefits derived from travel by motorcoach. Because of EPA’s emphasis on trucks or freight carrying services, ABA believes the assumptions and analyses EPA relies upon for support are either inaccurate or incomplete. Passenger carrying transport, and specifically motorcoach operations, differ significantly from freight transport. For example, the impacts on air quality from bus and motorcoach operations should not be solely evaluated in the context of engine emissions but must also take into account the number of the other vehicles removed from the road by virtue of providing mass transportation. Motorcoach operations can take up to 50 personal vehicles off the road (MJ Bradley & Associates (Ed.). (2019, June). Updated Comparison of Energy Use & Emissions from Different Transportation Modes - https://www.buses.org/assets/images/uploads/general/2019%20UPDATE%20Comparative%20Fuel%20CO2%20FINAL-July%202019.pdf). When you consider the potential removal of 600 million passengers worth of personal vehicles from our roadways, we believe that the motorcoach industry should receive some special considerations under this rulemaking and should certainly be acknowledged for their positive impact on the environment. It is short-sighted and inaccurate to entirely discount the benefits to air quality from removing other vehicles from the road in terms of both emissions as well as congestion. At the same time, if conducting motorcoach operations becomes cost prohibitive or untenable, it will cause the demise of the motorcoach industry, leading to an increase of vehicles on the road and increased congestion for urban areas, reversing the strides made to limit pollution and improve air quality. [EPA-HQ-OAR-2019-0055-1308-A1, p.4]

Further, the proposed rule leaves major open questions about its impact on engine size and weight. Any significant increase in either the size or weight of engines could counter-productively serve to potentially reduce the number of passengers that could be transported on a motorcoach. For example, both under federal and state laws buses are subject to strict weight limits (23 USC 127). However, the proposed rule contains no useful analysis of its bus weight implications. Vehicle redesign costs to accommodate any increased weight to the engine or emissions control system components should have also been considered in the Regulatory Impact Analysis. [EPA-HQ-OAR-2019-0055-1308-A1, pp.4-5]

The EPA needs to incorporate more data on the motorcoach industry, motorcoach services and the role motorcoaches play in the national transportation system, into its analysis and assumptions for this rulemaking. Motorcoach transportation provides a significant benefit to air quality by removing other vehicles from the road. If motorcoach operations in this country were to decline, it will have a negative impact on air quality, and effect the economy through job loss and by limiting transportation options, particularly for undeserved communities who rely heavily on motorcoach transportation, in addition to the military and emergency response network. [EPA-HQ-OAR-2019-0055-1308-A1,p .5]

As previously noted, the private motorcoach industry suffered consequential economic losses as a result of the COVID-19 pandemic. Motorcoach operations, overall, were running at 5-10% of capacity throughout 2020, and only recovered to about 45-50% in 2021. Many of the motorcoach operators who survived and continue in operation today were forced to defer payments on their heavy-duty equipment fleets for months. Even now these operators are still trying to recover from the financial hole caused by these deferments. As well, the motorcoach equipment market was flooded with excess equipment from foreclosures and abandonment during this time period, sinking the value of both equipment and businesses overall. Motorcoach manufacturers were particularly hard hit, with so much excess capacity as new motorcoach sales plummeted down from an average of 2,200 units annually (2016-2220) to less than 1,000 in 2021 (https://www.buses.org/aba-foundation/research-summary/quarterly-sales-data). The industry is experiencing an unprecedented driver shortage, leaving equipment sitting idle. All to say, the motorcoach industry, economically, remains in an unstable position for the foreseeable future, and equipment costs plays a major role in business decisions. [EPA-HQ-OAR-2019-0055-1308-A1, pp.7-8]

ABA believes EPA underestimates the cost impacts of the Proposal, in terms of the cost to manufacture an engine with an emissions control system to meet the proposed standards and testing, along with the added cost to extend the useful life and warranty periods. These costs will lead to an increase in vehicle purchase price and maintenance and repair costs for vehicle purchasers. ABA also, again, points out that EPA has not fully accounted for or undervalued the benefits of travel by motorcoach and the importance of encouraging such travel, rather than making motorcoach operations prohibitively and unreasonably expensive, slowing down fleet turnover and making motorcoach operations unviable. [EPA-HQ-OAR-2019-0055-1308-A1, p.8]

Organization: *American Farm Bureau Federation (Farm Bureau)*

Finally, heavy-duty trucks are the lifeblood not only of farms and ranches, but also throughout the entire supply chain. Increasing costs, decreasing availability and potentially encouraging negative environmental impacts through public policy should always be avoided. Yet, this proposed rule would multiply the supply chain, inflationary and input pressures American farmers, ranchers and consumers are already facing. [EPA-HQ-OAR-2019-0055-1163-A1, p.2]

Specifically, we are concerned that the agency’s projection of extremely modest technology and warranty costs associated with the rule will result in a significant overestimation of future fleet turnover and underestimation of the negative emissions consequences associated with large-scale 'pre-buys' prior to compliance deadlines. To its credit, EPA openly admits that its projections are guesswork, but it does not quantitatively explore how underestimating costs could drive higher pre-buy behavior that could significantly delay and undermine emissions reductions benefits that are the central purpose of the rule. So, before finalizing this rule, we urge EPA to work collaboratively with industry, states, and other affected stakeholders to resolve discrepancies related to technology costs and achievability, warranty impacts, corresponding fleet turnover and environmental impacts of the proposal. [EPA-HQ-OAR-2019-0055-1163-A1, p.2]

Organization: *American Trucking Associations (ATA)*

ATA has established 12 fleet Guiding Principles that should be considered in the development of HD2027 including:

• Cost impacts must include warranty upcharges, downtime, operation and maintenance, research and development recoupment, profit margins, and training expenses. [EPA-HQ-OAR-2019-0055-1326-A1, p. 5]

Organization: *Coach USA, Inc. (Coach USA)*

EPA has failed to provide sufficient study or data concerning the safety, operational and cost implications of its proposed rules on the bus industry, which has been economically devastated by the COVID pandemic and which can scarcely afford any regulations that will significantly increase the cost of new buses and possibly impose a significant weight issue that could make bus travel less efficient. [EPA-HQ-OAR-2019-0055-1307-A1, p. 3]

Given the economic challenges still facing the motorcoach industry, any rules that will increase the cost of a new bus by over $40,000, as proposed here (and that will likely also increase vehicle maintenance and repair costs) will counterproductively encourage the continued use of older, less emissions-efficient motorcoaches. Such rules could also have the perverse effect of forcing some motorcoach operators to abandon the business altogether, as many have already done in recent years. The impact could well be more personal cars on the highway, and higher emissions. To prevent these results, EPA needs to be more mindful of the role of motorcoaches in the nation's transportation system and develop emissions rules that balance reasonable emissions goals with the constraints facing our industry. [EPA-HQ-OAR-2019-0055-1307-A1, p. 3.]

Finally, Coach USA urges EPA to obtain information from engine manufacturers to assess implications from the added weight and increased temperatures associated with SCR and derate-related equipment. As noted above, interstate buses are subject, throughout the country, to heavily-enforced weight restrictions; any exceedance caused by SCR or derate-related equipment that causes a bus to be overweight would be unacceptable to sustaining interstate bus operations. Likewise, any increased temperatures caused by such equipment – which may cause buses to be less reliable or otherwise potentially impair driver/passenger safety – would also be unacceptable to Coach USA. [EPA-HQ-OAR-2019-0055-1307-A1, p. 7]

Organization: *International Council on Clean Transportation (ICCT)*

The implementation of the proposed standards and new certification and in-use NOx requirements will require technology changes in HDVs sold in MY2027 and beyond. These technologies would have an impact on costs. For the past 10 years, the ICCT has been publishing detailed cost information to ensure that national regulators in countries where we work can have access to that type of information. EPA's NPRM presents a careful revision and update of emission control technologies for diesel and gasoline HDVs in the U.S., and the proposal presents a detailed analysis of the expected cost to meet the proposed targets. The draft RIA often refers to ICCT's work as the basis for its cost assessment. Our detailed review of the cost numbers shown in the draft RIA agrees with our own analysis. The RIA provides an even deeper look into the cost elements that influence the total incremental cost to meet the proposed standards. [EPA-HQ-OAR-2019-0055-1211-A1, p. 12]

The California Air Resources Board (CARB) recently adopted a new rule, referred throughout this document as the HDV omnibus, to significantly reduce real-world nitrogen oxide (NOx) emissions from new on-road heavy-duty engines sold in the state beginning in 2024. The cost information from that process is relevant in this discussion as the current EPA NPRM is closely linked to the CARB regulation. [EPA-HQ-OAR-2019-0055-1211-A1, p. 12]

Six studies were published that analyzed the cost to manufacturers of the low-NOx regulation between 2019 and 2021: one by the ICCT, one from the Manufacturers of Emissions Control Association (MECA); one by the California Air Resources Board; one by the National Renewable Energy Laboratory (NREL); and two by the Truck and Engine Manufacturers Association (EMA). [EPA-HQ-OAR-2019-0055-1211-A1, p. 12]

The table below shows what each of the six studies found to be the incremental 12L–13L engine cost to the manufacturer of full compliance with the final step of CARB’s regulation and EPA’s NPRM. The estimates range from $2,200 (the lowest, from ICCT’s study) to $80,821 (the highest, from EMA-ACT Research)—a huge difference. These can be compared to EPA’s estimated $3,200 to $3,900 compliance cost to meet the HHDV regulatory requirements for MY 2031, depending on the regulatory option adopted. We find that the highest estimates are inaccurate largely due to their overestimation of indirect costs, as discussed below. For reference, the MSRP of a leading MY2022 Class 8 tractor-trailer model, the Freightliner Cascadia, is listed today at $168,274. 14 [EPA-HQ-OAR-2019-0055-1211-A1, p. 12]

14. Source: Price Digests https://app.pricedigests.com/login. Accessed 4 May 2022.

Organization: *Labor Network for Sustainability (LNS)*

The Proposed Rule does not appear to take into account the reality of the independent contractor/owner operator model and the significant risk of unjustly increasing the costs that truck drivers will bear as a consequence of its implementation. The Proposed Rule breaks down the costs associated with getting compliant vehicles on the road into three categories: Technology Package Costs, Operating Costs, and Program Costs. Without further action by the EPA, these costs will worsen the already inequitable burdens shouldered by misclassified truck drivers. As we show more fully below, this omission jeopardizes the efficacies of the Proposed Rule itself. [EPA-HQ-OAR-2019-0055-1257-A1, p.7]

Technology Package Costs, comprise both the direct costs of new technology and the indirect costs of bringing those technologies to market.31 EPA projects that these costs, ‘while first incurred by manufacturers of new engines, are presumed to be passed on to the consumers of those engines (i.e., heavy-duty truck manufacturers and, ultimately, their purchasers/owners).’32 Operating Costs are the costs ‘associated with the truck and bus operation that are projected to be impacted by the proposal.’33 EPA acknowledges that these costs will also be ‘incurred by truck and bus purchasers/owners.’34 Program Costs are the sum of the Technology Package Costs and the Operating Costs taken together representing EPA’s best estimate of the Proposed Rule’s ‘costs to society.’35 [EPA-HQ-OAR-2019-0055-1257-A1, p.8]

31 EPA, Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards: Draft Regulatory Impact Analysis 313 (2022), https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10144K0.pdf

32 Ibid.

33 Ibid.

34 Ibid.

35 Ibid.

At an informational meeting hosted by EPA on April 18th, 2022, EPA officials presented an overview of the Proposed Rule. When questioned about the regulation's impacts on misclassified truck drivers, one EPA official answered that EPA estimated a 2% - 3% increase on the purchase price of a new compliant vehicle. Since the purchase prices of heavy-duty vehicles are already high (on average $150,000 36), this increase is significant given the major costs that have been shifted to truck drivers described above. The increased costs of regulation will further push drivers to the economic edge. [EPA-HQ-OAR-2019-0055-1257-A1, p.8]

36 Sarah Harris, How Much Does a Semi Truck Cost?, FreightWaves, (Nov. 16, 2021), https://ratings.freightwaves.com/how-much-does-a-semi-truck-cost/

As EPA expects essentially all of the cost increases associated with the Proposed Rule to be borne by the end-purchasers, drivers that purchase their own trucks but also drivers that lease their trucks from trucking firms will likely have these costs passed through to them. [EPA-HQ-OAR-2019-0055-1257-A1, p.8]

This is highly inequitable and should and can be addressed. This is not pure speculation. California has faced this very issue in connection with its heavy-duty regulation. Analysts who have studied the impact of that regulation have concluded that '[a]dded expenses are truly company overhead and should not be the responsibility of the driver.'37 [EPA-HQ-OAR-2019-0055-1257-A1, p.8]

37 Sears, supra note 23 at 42.

Moreover, we strongly support the comments and recommendations of others, including the more than 50 organizations that make up the Moving Forward Network (MFN), that the Proposed Rule inadequately addresses the public health and environmental dangers of continued use of fossil-fuel powered vehicles; we need to embark sooner and faster on a road to full electrification of medium and heavy duty vehicles. But, electrification carries with it additional equity considerations especially to workers who currently manufacture diesel powered trucks and to communities who rely on the tax income generated by factories that make these products. [EPA-HQ-OAR-2019-0055-1257-A1, p.8]

We support the comments made during the public hearings by UAW representative Josh Nassar that the cost impacts of greening the transportation sector should not be borne by the workers least able to afford them. Since our Comments here primarily address the impacts on workers of the Proposed Rule as currently written, we do not elaborate on the additional implications of full vehicle electrification. [EPA-HQ-OAR-2019-0055-1257-A1, p.9]

Organization: *Marathon Cheese Transport*

Perhaps our government should subsidize the heavy duty truck cost increases by finally eliminating the onerous Federal Excise Tax already being added to each piece of equipment fleets have to purchase. Another example of political parties pushing agendas without proper research at the expense of trucking companies who are already fighting an uphill battle with higher labor costs, insurance premiums, fuel costs, shipper detention times, time/cost delays due to traffic, and safety programs. [EPA-HQ-OAR-2019-0055-2516, p.1]

Organization: *Natural Gas Vehicles for America (NGVAmerica)*

NGVAmerica and its members submit the following recommendations for policies and programs that the EPA and other federal agencies can advance to encourage the use of cleaner trucks.

9) Ensure that federal funding provided under the CMAQ Program and the DERA Program and other programs enacted as part of the Bipartisan Infrastructure Law are competitively awarded for projects that provide the most cost-effective emission reductions and offer increased funding levels for engines and vehicles that are certified to more demanding standards in advance of EPA's adoption of such standards; [EPA-HQ-OAR-2019-0055-1330-A1, p.14]

13) Work with Congress to amend the federal excise tax on new trucks to reduce the impediment to fleets and businesses purchasing cleaner new trucks by either eliminating the tax altogether since it discourages new purchases or amend the tax so that it does not penalize more costly, lower polluting technologies (i.e., eliminate the excise tax on the incremental cost). [EPA-HQ-OAR-2019-0055-1330-A1, p.14]

EPA Summary and Response

The Agricultural Retailers Association (ARA) commented about the proposal's goals being to push towards zero-emission vehicles and provide support for efforts to ban the internal combustion engine. EPA's goal with these standards is to reduce air pollution from highway heavy-duty engines and vehicles to improve public health and welfare. Congress has given EPA that responsibility via the Clean Air Act and has directed EPA to promulgate standards that are technology-forcing and feasible after giving appropriate consideration to certain listed factors. The standards promulgated are performance-based standards that do not require a specific technology and are not based on projected utilization of electric vehicle technology. The analyses that EPA has done show that the final standards fall within EPA's authority under Clean Air Act. The commenter also focuses on the Annual Energy Outlook's findings of possible economic impacts to the U.S. biofuels industry associated with a subsidized electric vehicle penetration without also presenting possible economic benefits. Regardless, a subsidized electric vehicle penetration program is outside the scope of the proposal or final rule.

Allison Transmission, Inc. (Allison) commented that the costs of longer warranty and useful life periods must be considered. EPA has done so and has provided our best cost estimates for those new provisions. EPA notes that the final analysis makes use of many suggestions by industry for improving the final analysis. EPA notes these changes largely in section 18.3 above in this document and in Chapter 7 of the final RIA.

The American Bus Association (ABA) commented that EPA should have considered weight impacts on motor coaches associated with the standards. It is true that we have not considered the very small weight impacts in our cost analysis. The technology teardown work we had done by FEV suggests that the new aftertreatment systems may weigh from 40 to 80 kilograms more than current aftertreatment systems. This is the weight of a single passenger or a few suitcases, and EPA believes these small changes are not sufficient to disrupt the motorcoach industry. ABA also commented with respect to the motor coach industry and the difficult economic times during the pandemic. EPA has no desire to limit or discourage motor coach ridership and we do not believe that this final rule will do so. Regarding economic hardships, EPA understands that the U.S. economy has experienced such hardships. EPA has updated the cost analysis in the final rule and believes that the costs are properly characterized, and that the reduction in heavy-duty emissions and air pollution that will result from this final rule are significant, and that EPA has given appropriate consideration of the costs of this rulemaking. EPA agrees with ABA that the motor coach industry provides a valuable service to society and that its emissions per passenger mile are likely less than would be the case were those passengers to travel by personal vehicle. EPA disagrees that the costs associated with the final standards are likely to push people out of motor coach travel and into personal vehicles because travel by motor coach will almost certainly remain less costly in comparison.

The American Farm Bureau Federation (Farm Bureau) also commented with respect to the challenging economic times brought on by the pandemic. The Farm Bureau argues that increasing costs and decreasing availability would multiply the supply chain, inflationary and input pressures American farmers, ranchers and consumers are already facing. EPA understands the concern, but Clean Air Act section 202(a)(3)(A) requires EPA to set emission standards for NOx, PM, HC, and CO that reflect the greatest degree of emission reduction achievable through the application of technology that the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology. In other words, the Clean Air Act requires the criteria pollutant standards for heavy duty engines set by EPA to be technology forcing and the CAA does not require that EPA consider all the statutory factors equally, rather EPA has discretion in determining the appropriate consideration to give such factors as costs.[44] EPA has updated the cost analysis in the final rule and believes that the costs are properly characterized, and that the reduction in heavy-duty emissions and air pollution that will result from this final rule are significant, and that EPA has given appropriate consideration of the costs of this rulemaking. As explained elsewhere in this document and the final rule preamble, EPA's final standards were determined after consideration of the required factors and are within EPA's authority and appropriate. EPA also notes that EPA conducted additional analyses that demonstrate the impacts of the final program to be cost-beneficial to society (i.e. the benefits

[44] See, e.g., Sierra Club v. EPA, 325 F.3d 374, 378 (D.C. Cir. 2003) (explaining that similar technology forcing language in CAA section 202(1)(2) ''does not resolve how the Administrator should weigh all [the statutory] factors in the process of finding the 'greatest emission reduction achievable' ''); Husqvarna AB v. EPA, 254 F.3d 195, 200 (D.C. Cir. 2001) (explaining that under CAA section 213's similar technology-forcing authority that ''EPA did not deviate from its statutory mandate or frustrate congressional will by placing primary significance on the 'greatest degree of emission reduction achievable' '' or by considering cost and other statutory factors as important but secondary).

outweigh the costs). EPA hopes, as everyone does, that the current economic conditions – inflation, the pandemic, etc. – are alleviated by the time the final program is being implemented.

The American Farm Bureau Federation (Farm Bureau) and the New York Farm Bureau (NYFB) stated that "EPA openly admits that its projections are guesswork." It is not clear where these commenters got this impression, but EPA wants to make clear that the EPA proposed costs projections, as well as the cost projections in this final rule, are not guesswork – and in fact, EPA's cost estimates are based on detailed engineering studies, modeling work and proven estimation approaches as we have detailed throughout our regulatory documents (both for the proposal and this Final Rule). Regarding the Farm Bureau's comments on pre-buy, we respond to those comments in Section 25 of this document.

Regarding the comments from the American Trucking Associations (ATA), EPA believes that it has estimated all the costs that should be considered in setting the new standards. EPA has estimated costs for new technology, including the indirect costs (including profits and R&D) to be incurred by engine and truck manufacturers (i.e. regulated entities for the new standards). EPA has also conducted additional analyses, and estimated increased operating costs consisting of repair, DEF consumption and fuel consumption impacts.

Coach USA expressed concerns regarding the increased weight associated with the new exhaust aftertreatment systems. As noted above in response to the ABA, EPA believes that weights may increase from 40 to 80 kilograms, depending on the regulatory class. EPA acknowledges that no accounting of this weight increase is included in our cost analysis, but EPA believes that the increase is not large enough for weight restrictions to suddenly become a problem for motor coach operators. The temperature impacts associated with the new systems are responded to in Section 3. Coach USA also suggested that a rule that imposes $40,000 in costs is too much for the motorcoach industry to handle given Covid and its effects on the industry. As noted throughout this section 18, EPA disagrees with the claims of $40,000 in costs expressed by Coach USA and other commenters.

EPA appreciates the comments from the International Council on Clean Transportation (ICCT). We have updated our analysis for the final rule and present our updated cost analysis in Chapter 7 of the final RIA.

The comments from the Labor Network for Sustainability (LNS) appear to be directed not so much at the cost estimates or the methodology, but instead on who pays those costs. The concern is over contracted drivers and those drivers not being treated as employees of the companies that should bear the burden of the rule (in the commenter's opinion). This issue is outside the scope of the regulation or the analysis supporting it. EPA has estimated the costs and noted that the costs will be borne, largely, by purchasers of the engines and vehicles (i.e., the owner/operators). By whom those owner/operators are employed is outside EPA's scope, as is how some operators are compensated by the owners of the vehicles.

Marathon Cheese Transport suggests that the Federal Excise Tax be eliminated. This is outside the scope of this EPA rulemaking.

Natural Gas Vehicles for America (NGV America) suggested that EPA ensure that federal funding under the CMAQ and DERA programs be competitively awarded and that EPA work with Congress to amend the federal excise tax. Both of these comments are outside the scope of this action.

19 Inventory impacts

19.1 MOVES model

Organization: *Retail Industry Leaders Association (RILA)*

The estimated cost and benefits that are anticipated because of a proposed rule are important to assess the effectiveness and viability of the changes it contains. Such estimates are typically based on advanced models that rely on a set of forecasted assumptions. In the case of EPA's proposed rule focused on heavy-duty engine emissions, forecasted impacts appear to be at least in part based on an updated Motor Vehicle Emissions Simulator (MOVES) model. The documentation for this analytical model is included in the rulemaking's docket,1 providing a detailed view of the depth and breadth that the model encompasses. [EPA-HQ-OAR-2019-0055-1189-A2, p.4]

1 'MOVES_CTI_NPRM', May 2021. https://www.regulations.gov/document/EPA-HQ-OAR-2019-0055-0594

Although the model's soundness is not in question, the published documentation is unclear regarding some of EPA's modeling assumptions. For example, the model appears to rely on the data from the U.S. Energy Information Agency's (EIA) 'Annual Energy Outlook 2018' 2 (AEO2018) as an input to its projected vehicle populations (Section 4.2 of MOVES_CTI_NPRM documentation, 'Projected Vehicle Populations (2017-2060)'). The AEO2018 document forecasts a considerable increase in electricity and natural gas as a transportation fuel when forecasting anticipated fuel mix out to 2050. However, there are several areas within MOVES_CTI_NPRM documentation that appear to indicate a forecasted fuel-mix through 2060 that does not include much (if any) electricity of natural gas. [EPA-HQ-OAR-2019-0055-1189-A2, pp.4-5]

2 'Annual Energy Outlook 2018', Feb 6, 2018.
https://www.eia.gov/outlooks/archive/aeo18/pdf/AEO2018.pdf

Although EPA's modeling assumptions and inputs will not have a direct impact on the actual real-world costs and benefits if the proposed rule is implemented, the use of consistent and accurate assumptions is critical to promote confidence in the proposed rule's projected costs and benefits. Although such figures are not being questioned here, EPA is urged to include additional context and transparency around modeled assumptions, especially in areas where the documentation may appear to indicate inconsistencies. [EPA-HQ-OAR-2019-0055-1189-A2, p.5]

There are also additional factors that EPA might not have currently incorporated in its forecasting fuel mix or vehicle quantity. For example, consumer preferences have shifted recently (over the past 5-10 years) for many products away from as many in-person purchases to making more purchases online for home delivery. It's therefore possible that EPA's forecasting assumptions underestimates the magnitude of this increase 'last-mile' delivery truck operations, which typically happen at low-speed and idle in areas of higher population density. Another example is the potential shift towards lighter vehicle classes being used more commonly in last-mile delivery of goods than currently assumed, especially in denser population centers. Such shifts would likely be too recent or insignificant for inclusion in EPA's modeling, but it is worth reviewing EPA's assumptions around such trends in future rulemakings.[EPA-HQ-OAR-2019-0055-1189-A2, p.5]

EPA Summary and Response

Retail Industry Leaders Association (RILA) commented on some of the modeling assumptions and inputs in the EPA’s MOVES_CTI_NPRM model (which was used for the inventory analysis for the proposed rule). An example they mentioned was a potential inconsistency in EPA’s use of the Annual Energy Outlook (AEO) 2018 data from the U.S. Energy Information Agency (EIA), particularly about the projected numbers of electric and natural gas vehicles. RILA also commented on the importance of properly accounting for the “shifts” in heavy-duty fleet characteristics and the activity patterns, such as the increases in “last-mile” delivery truck operations.

EPA thanks Retail Industry Leaders Association (RILA) for their comments on the underlying assumptions in the MOVES model. As described in the MOVES_CTI_NPRM documentation, we used AEO 2018 primarily to project future vehicle population for the conventional vehicles with internal combustion engines.. Since the standards in the proposed rule, as well as the final rule, are not based on the projected utilization of zero-emission vehicles (ZEVs), such as battery-electric/fuel cell-electric vehicles, we assumed no electric vehicles in the heavy-duty fleet for both the baseline and control scenarios of the inventory analysis. Natural-gas-powered vehicles are included as part of the MOVES national default heavy-duty vehicle fleet.

EPA agrees with RILA’s comment related to the importance of properly accounting for the “shifts” in heavy-duty fleet characteristics and the activity patterns. For the final rule analysis[45], EPA used an updated version of the MOVES model (“MOVES3”) which takes into account more recent information on the heavy-duty vehicle fleet characteristics and activities (such as FHWA Highway Statistics Series 1990-2017, AEO 2019 and other supplementary data sources). MOVES3 also includes updated fuel type and regulatory class distributions for each MOVES sourcetype based on IHS2014 data.

19.2 Comments presenting emissions inventory analyses

[45] For details, refer to Chapter 5 of the Regulatory Impact Analysis (RIA) document of the final rule.

Organization: *Elders Climate Action*

The two scenarios tested are the emission reductions achieved by applying the proposed NOx standards for HDVs in Option 1 to OOS trucks operating in the AQMDs, and a scenario that reduces emissions from those trucks to zero based on a zero emission standard. [EPA-HQ-OAR-2019-0055-1218-A1, p. 13]

Figures 1 and 2 show the portion of the SIP inventory that would benefit from the proposed federal rule for both the South Coast and San Joaquin Valley air basins. Although the state will be able to reduce NOx emissions from light and medium duty trucks, heavy duty truck emissions in both severe nonattainment areas will eventually plateau by 2024. [EPA-HQ-OAR-2019-0055-1218-A1, p. 14]

In calculating baseline emissions benefits, the EMFAC 2021 model was used to identify emission factors for California vehicles in state and subject to the California Heavy Duty omnibus rule and other CA regulations. The emission factors for model years 2027+ were used to develop the emission profile. A baseline modeling run for 2035 was conducted for Class 8 trucks assuming current California regulations were in place for heavy duty trucks and no new federal NOx regulations were promulgated. The baseline inventory also includes the ZEV requirements associated with CARB's Advanced Clean Truck Rule. [EPA-HQ-OAR-2019-0055-1218-A1, p. 15]

In developing the adjusted baseline that incorporates the emissions reductions associated with the federal Heavy Duty Vehicle Low NOx Rule, it was assumed that any vehicle meeting the federal NOx standard would have an emissions profile similar to a California vehicle meeting the California Omnibus Standard in that year. Class 8 vehicles are a combination of in-state and out-of-state purchased vehicles. Out-of-state vehicles are identified by EMFAC Categories T7 NNOOS Class, T7 NOOS Class and T7 CAIRP Class 8 in the EMFAC model. It was assumed that all NNOOS and NOOS are purchased out of state and that In-State Tractors, Port and CAIRP vehicles include both in-state purchased vehicles and out-of-state vehicles which vary by the age of the fleet in the first column of Table 1 below. [EPA-HQ-OAR-2019-0055-1218-A1, p. 15]

To calculate the adjusted baseline, these "California-specific" low NOx emission factors were then substituted back into the EMFAC emission inventory for out-of-state Class 8 trucks in model years 2027 to 2036. [EPA-HQ-OAR-2019-0055-1218-A1, p. 15]

As shown in Table 2, the baseline NOx inventory for the South Coast and San Joaquin Air Basins is predicted to 32.2 and 29.6 tons per day, respectively. The Adjusted Baseline Scenario that adds the promulgation of the federal Heavy Duty Vehicle Low NOx Rule would reduce daily NOx emissions from Class 8 Long Haul OOS vehicles in the South Coast and San Joaquin Air Basins to 21.7 and 19.3 tons, respectively. The accelerated implementation of 2027+ ZEV would further reduce both NOx inventories to 13.4 and 10.8 tons per day, respectively. [EPA-HQ-OAR-2019-0055-1218-A1, p. 16]

In addition to analyzing the impact of an accelerated Federal ZEV requirement in 2027 (that would apply to both CA and OOS trucks), the emissions that would be avoided from these 3 model years were also evaluated by isolating a portion of the inventory for the NOx and CO2 emissions from trucks from only these 3 model years. The CO2 emissions were extrapolated to 2050 assuming that these trucks would remain in service 20 years or until 2050. [EPA-HQ-OAR-2019-0055-1218-A1, p. 16]

EPA Summary and Response

Elders Climate Action estimated the impact of the EPA's proposed rule on the NOx emissions from out-of-state Class 8 heavy duty vehicles operating in the State of California using the EMFAC model. The analysis predicts a significant reduction in NOx inventory for the South Coast and San Joaquin Air Basins areas with the adoption of EPA's HD2027 standards for the out-of-state Class 8 fleet in California. Additional analysis showed that an accelerated federal ZEV requirement would result in further reductions of NOx inventories for the areas studied, as well as substantial reductions of CO_2 emissions.

EPA thanks Elders Climate Action (ECA) for the helpful analysis they provided on the impacts of the proposed rule on the out-of-state Class 8 vehicle fleet emissions in California. Their analysis indicates that the proposed Option 1 standards would produce substantial improvements in controlling mobile source emissions of the areas studied, which is consistent with the findings from EPA's analyses as documented in the draft RIA. See preamble Section III for discussion on the technology pathway we evaluated for complying with the final standards, and the ability for manufacturers to use other technology pathways to comply with the performance-based final standards (e.g., electrification, including plug-in hybrid electric vehicles, battery-electric or fuel cell electric vehicles).

19.3 Comments related to upstream or other non-tailpipe emissions

Organization: *Alliance for Vehicle Efficiency (AVE)*

AVE urges EPA to move beyond tailpipe only definitions for ZEVs and integrate lifecycle analysis for future standards. [EPA-HQ-OAR-2019-0055-1280-A1, p. 5]

Defining ZEVs only at the tailpipe distorts the environmental gains of vehicles with known upstream emissions. Relying on the current definition of ZEVs serves as a barrier to automotive technologies that can deliver significant real-world emission reductions. For example, hydrogen combustion engines can deliver significant emission reductions, and when compared to other vehicles on a lifecycle basis, can match the environmental impact of vehicles currently defined as ZEVs. [EPA-HQ-OAR-2019-0055-1280-A1, p. 5]

Continuing to focus solely on tailpipe emissions for future standards also ignores President Biden's January 25, 2021, Executive Order, in which he stressed the need for environmental standards to account for all greenhouse gas emissions. [EPA-HQ-OAR-2019-0055-1280-A1, p. 5]

“Sec. 5. Accounting for the Benefits of Reducing Climate Pollution. (a) It is essential that agencies capture the full costs of greenhouse gas emissions as accurately as possible, including by taking global damages into account. Doing so facilitates sound decision-making, recognizes the breadth of climate impacts, and supports the international leadership of the United States on climate issues.” 10 [EPA-HQ-OAR-2019-0055-1280-A1, p. 5]

> 10. 7040 Federal Register / Vol. 86, No. 14 / Monday, January 25, 2021 / Presidential Documents

Congress is also encouraging EPA to assess lifecycle emissions when setting future vehicle standards: [EPA-HQ-OAR-2019-0055-1280-A1, p. 5]

Vehicle Emissions Lifecycle Analysis. — The Committee believes it is essential that when setting future standards for reducing greenhouse gas emissions, the Agency fully evaluate emission impacts of vehicle technologies and transportation fuels (including electricity used as a fuel) from well to wheel, and the vehicle cycle through material recovery and vehicle disposal in order to capture the full impacts of greenhouse gas emissions as accurately as possible. The Committee encourages the Agency to develop standardized modeling to evaluate the full lifecycle of vehicle technologies and transportation fuels, as new standards to reduce pollutants are being developed, and to coordinate as necessary, with other federal agencies that are conducting similar models for vehicles in an effort to accurately determine the full impact of reducing greenhouse gas emissions when conducting cost-benefit analyses of regulatory and other actions. 11 (Emphasis added) [EPA-HQ-OAR-2019-0055-1280-A1, p. 5]

> 11. See, H. Rept. 117-83 – Dept. of the Interior, Environment, & Related Agencies Appropriations Bill, 2022 at P. 84.

Organization: *BorgWarner*

BorgWarner supports lifecycle analysis for all future vehicle regulations. We support the transition from a tailpipe-based standard (i.e., tank-to-wheel) to a more holistic assessment (e.g., well-to-wheel emissions, or more completely, full lifecycle emissions) as the proper metric for determining the environmental impact of the vehicle as a product. This approach is consistent with technology neutrality, global carbon neutrality goals, and a holistic environmental impact assessment. [EPA-HQ-OAR-2019-0055-1234-A1, p. 3]

Organization: *National Association of Small Trucking Companies (NASTC)*

Moreover, the reputed “clean” technologies this rulemaking apparently aims to advantage over diesel may well fall short. “In a study, the American Transportation Research Institute found the process of extracting the materials used in lithium-ion batteries for battery electric vehicles creates a significant amount of emissions. Lithium-ion battery production generates more than six times the carbon of diesel truck production, ATRI officials said in a press release.”1 [EPA-HQ-OAR-2019-0055-1130-A1, p. 4]

1. Heavy Duty Trucking Staff, “ATRI: Zero-Emissions Trucks Still Generate Significant Emissions,” Trucking Info, May 4, 2022. https://www.truckinginfo.com/10169798/atri-zeroemissions- trucks-still-generate-significant-emissions

Organization: *Motor & Equipment Manufacturers Association (MEMA)*

As we have advocated in the past, it would also be beneficial to look at the entire lifecycle rather than just “tailpipe” emissions. As vehicles become significantly more fuel efficient, both upstream and downstream emissions become much more important when attempting to truly compare them. Significant infrastructure requirements would also come along with these rules, so if EPA were to try to match CARB there would need to be significant coordination with DOE in terms of planning for the national electric grid. [EPA-HQ-OAR-2019-0055-1322-A1, p. 8]

Organization: *State Soybean Associations*

Additionally, the proposal overemphasizes the benefits of EVs while overlooking their negative impacts. Specifically, EPA fails to adequately account for the lifecycle emissions associated with EVs, including the significant upstream emissions resulting from charging batteries. [EPA-HQ-OAR-2019-0055-2035-A1, p.3] [Also included in Section 28.5 of this document]

Organization: *Valero Energy Corporation*

Before allowing electric vehicles to generate any emission credits, EPA should consider upstream emissions of criteria pollutants in its analysis of costs and benefits associated with allowing BEVs, FCEVs, and HEVs to generate NOx emission credits as zero- or near-zero NOx generating technologies. [EPA-HQ-OAR-2019-0055-1328-A2, p.6]

EPA's eGRID2020 data show the NOx Output Emission Rate for the U.S. Average Grid as 0.509 lb/MWh (equal to 172 mg/hp-hr),8 while EPA is considering 35 mg/hp-hr or 50 mg/hp-hr as the baseline against which credits would be given for BEVs. EPA should consider the NOx emissions associated with stationary source emissions at the power plant, and should take into consideration the losses that occur during electricity transmission and charging. [EPA-HQ-OAR-2019-0055-1328-A2, p.6]

8 https://www.epa.gov/egrid, accessed March 8, 2022

Further, because these emissions will result in localized increases at power plants, these potential adverse impacts must be considered in EPA's environmental justice analysis. EPA only accounted for reduced highway emissions; it did not account for increased emissions of all pollutants from the power plants in the communities where the power is generated. [EPA-HQ-OAR-2019-0055-1328-A2, p.6]

In the final LD GHG standards, in response to comments, EPA said that upstream emissions would be accounted for in standards for MY 2027 and later. EPA should be consistent and account for upstream emissions for criteria pollutants and GHG emissions in these standards for MY 2027 and later HD vehicles and engines. [EPA-HQ-OAR-2019-0055-1328-A2, p.7]

EPA Summary and Response

Several commenters stated that the EPA should account for the lifecycle emissions associated with heavy-duty vehicles, particularly heavy-duty electric vehicles, when conducting analyses for the final rule. Many commenters urged EPA to evaluate upstream emissions from charging or refueling heavy-duty zero emissions vehicles (ZEVs); one commenter pointed to Executive Order 13990 as, in the commenter's view, supportive of evaluating upstream emissions from ZEVs. Some commenters further stated that EPA should conduct life cycle analysis (LCA) to fully understand the emissions and potential exposures from actions related to generating electricity and mining battery materials. One commenter also urged EPA to move beyond tailpipe only definitions for ZEVs and integrate lifecycle analysis for future standards; the commenter pointed to language in a report accompanying a 2022 Appropriations Bill as an indication that Congress supports the use of LCA when setting GHG standards. A subset of these commenters focused on the GHG emissions impacts that occur across the vehicle lifecycle. For instance, one commenter stated that producing lithium-ion batteries creates emissions and those emissions are greater than the emissions from producing diesel vehicles.

Other commenters argued that EPA should consider emissions of criteria pollutants that occur upstream of the vehicle (e.g., from power plants providing electricity to ZEVs) when conducting an analysis of costs and benefits, and that the analysis should be conducted before allowing HEVs and ZEVs to generate NO_X emissions credits. Commenters cited data from an EPA database on NO_X emissions rates from power plants across the U.S., as well as a press release announcing an ARTI study on the carbon emissions impacts of mining lithium for batteries.

EPA acknowledges commenters' suggestions to evaluate upstream emissions or otherwise conduct lifecycle analysis for the final rule. As an initial matter, the cost and benefit analyses we conduct evaluate the impacts of the final standards and requirements in a rulemaking. This final rule does not require the production or use of ZEVs, and the final standards are not premised upon increased ZEV penetration. As such, lifecycle analysis for GHGs and ZEVs is outside the scope of this final rule and of the cost and/or benefit-cost analysis of this final rule. We explain this further in the two points below:

1. As discussed in preamble Section I and Section 28 of this Response to Comments document, EPA is not taking final action at this time as part of this final rule on any changes to the HD GHG Phase 2 regulations. It appears that many of the comments regarding upstream emissions were in response to that aspect of the proposal. Since EPA is not finalizing that aspect of the proposal in this action, any comments regarding that aspect of the proposal are accordingly beyond the scope of this final rule.

2. The final standards in this rule are not based on the projected utilization of ZEV technology, though manufacturers may choose to comply with the standards by using ZEV technology. Moreover, while we believe there will be increased penetration of ZEVs in the HD fleet by MY2027 and later,[46] we are also not including in the final rule an allowance for

[46] For example, the recently passed Inflation Reduction Act (IRA) has many incentives for promoting zero-emission vehicles, see Sections 13403 (Qualified Clean Vehicles), 13404 (Alternative Fuel Refueling Property Credit), 60101

manufacturers to generate NO_X emissions credits from ZEVs under ABT, see preamble Section IV.G for details. That is, any actual increased ZEV adoption will not reduce the environmental benefits associated with this rule.

More generally, EPA also disagrees that it is required to perform a lifecycle analysis of vehicle and fuel production before setting engine and vehicle emission standards, or to treat emissions of air pollutants attributable to electricity generation, or the mining, production or disposal of batteries for electric vehicles, as emissions “from” new motor vehicles under CAA section 202(a). The Clean Air Act’s entire structure evidences a clear divide between stationary sources (regulated under other sections of the Act, especially Title I) and mobile sources (regulated under Title II). There may be indirect impacts of stationary source regulation on mobile sources and vice versa, and it may be appropriate to consider those impacts in some circumstances. But it would be inappropriate and contrary to the plain text of the Clean Air Act to conflate the consideration of indirect impacts, when appropriate, with actually treating stationary source emissions as mobile source emissions. Cf. Coal. for Responsible Regul., Inc. v. E.P.A., 684 F.3d 102, 128–29 (D.C. Cir. 2012), aff'd in part, rev'd in part sub nom. Util. Air Regul. Grp. v. E.P.A., 573 U.S. 302 (2014), and amended sub nom. Coal. for Responsible Regul., Inc. v. Env't Prot. Agency, 606 F. App'x 6 (D.C. Cir. 2015) (“EPA was not arbitrary and capricious by not considering stationary-source costs in its analyses”). EPA interprets the Clean Air Act as generally directing EPA to consider regulation of emissions for each sector according to the applicable statutory requirements for each program. While EPA may also elect to consider upstream emissions in certain appropriate circumstances, such consideration is not required by statute. Nor is such consideration appropriate here, for the reasons stated further above.

EPA also disagrees with commenters that we should consider upstream emissions of criteria pollutants from HEVs as part of our analysis of costs and benefits before allowing HEVs to generate NOx emission credits.[47] We are not projecting an increase in PHEVs in response to the final standards and the final standards are not based on projected utilization of PHEV technology; thus, the same number of PHEVs are included in our baseline and control scenarios. The lack of a delta between baseline and control scenarios precludes including PHEVs in our analysis of costs or benefits in the final rule (see preamble Section III for additional discussion on the basis of the final standards). We note that we are not assuming a zero-emissions tailpipe performance of HEVs in the final rule; as discussed in preamble Section III, manufacturers must declare their family emissions limit (FEL) for HEVs based on testing both the charge depleting and charge sustaining operations (see preamble Section III.B.2 for details on testing hybrid powertrains). As such, the final rule only allows manufacturers to generate NO_X emissions credits from HEVs that are reflective of their tailpipe NO_X emissions performance.

(Clean Heavy-Duty Vehicles), 60102 (Grants to Reduce Air Pollution at Ports), and 70002 (United States Postal Service Clean Fleets) of H. R. 5376.

[47] Note that the term hybrid electric vehicles (HEVs) refers to vehicles that are propelled by both an on-board engine using a consumable fuel (e.g., diesel internal combustion engine, hydrogen fuel cell) and an energy storage device (e.g., battery, capacitor). For a subset of HEVs, the energy storage device can be recharged by either the on-board engine or by plugging a charging cable into an external electrical source (i.e., plug-in hybrid electric vehicles, PHEVs). Since the commenter focuses on upstream emissions from HEVs (i.e., emissions that would occur from plugging in a PHEV), we focus on PHEVs in this response.

20 Air quality impacts

20.1 Modeling of Inventory and Air Quality Contribution

Comments by Organizations

Organization: *Lake Michigan Air Directors Consortium (LADCO)*

U.S. EPA's March 28, 2022 proposed rule to reduce pollution from highway diesel vehicles targets a source of pollution that recent work by my organization identifies as a significant contributor to ground level ozone in the Great Lakes region. The Lake Michigan Air Directors Consortium (LADCO) conducted air quality modeling of the year 2016 that used emissions tracers to quantify the contributions of different air pollution sources to ground level ozone at receptors in the eastern United States1. [EPA-HQ-OAR-2019-0055-1034-A1, p. 2]

> 1. LADCO 2016 Base and Future Year Modeling Protocol. Available for download at: https://www.ladco.org/wp-content/uploads/Modeling/2016/CAMx/LADCO_2016-Platform_Air-Quality-Modeling-Protocol_06May2021.pdf

The figures on the next page summarize the emissions tracer results of the LADCO 2016 air quality modeling. Figure 1 shows that the model attributed approximately 10% of the surface ozone at key monitors in the eastern half of the U.S. to roadway diesel emissions sources (or_diesel). Similarly, Figure 2 illustrates that the model indicates that roadway diesel emissions contribute 9% of the ozone concentrations on average across all surface ozone monitors in U.S. EPA Region 5. [EPA-HQ-OAR-2019-0055-1034-A1, p. 2]

LADCO's modeling shows that relative to other source types, emissions from roadway mobile sources are the largest contributors to surface ozone in the Great Lakes region. Regulatory actions that result in emissions reductions from roadway mobile sources will impact a major source of ozone precursor emissions in this region. [EPA-HQ-OAR-2019-0055-1034-A1, p. 2]

Organization: *Manufacturers of Emission Controls Association (MECA)*

MECA recently co-funded an emission inventory and air quality modeling analysis based on the emission limit values and durability requirements proposed by CARB to quantify the air quality benefits if a national standard were set by U.S. EPA under the Clean Trucks Rule to align with the CARB proposed limits and implementation dates [1] [2]. The analysis did not incorporate the compliance program changes or warranty revisions into our model assumptions. [EPA-HQ-OAR-2019-0055-1320-A1, p.2]

[1] MECA, 'MOVES Inventory Modeling of a Potential Cleaner Trucks Initiative Scenario,' 2020. Online at https://www.meca.org/wp-content/uploads/2022/01/CTI-MOVESInventoryModelingProjectSummary-0122Finalrev.pdf.

[2] Alpine Geophysics, 'Air Quality Model Analysis of a Potential Cleaner Trucks Initiative Scenario,' 2020.

The foundation of the evaluation was the current U.S. EPA inventory projection for 2028. The 2028 inventory projection is that of the 2016v1 emissions modeling platform. It is a product from the agency's National Emissions Inventory Collaborative and includes a full suite of the base year (2016) and the projection year (2023 & 2028). This part of the analysis is referred to as the '2028 Base Case' inventory in this study and corresponds closely with a 2027 implementation date for the Clean Trucks Rule. From that inventory foundation, two new inventory scenarios were developed as follows.

- The '2035 Base Case' inventory was developed to include an on-road fleet projection to 2035 with no change in the underlying regulatory context.
- The '2035 Control Case' inventory was developed to include both the 2035 fleet projection and the impacts of adoption of federal FTP standards for heavy-duty trucks of 0.05 g/bhp-hr beginning with MY 2024 and 0.02 g/bhp-hr beginning with MY 2027, as proposed by CARB, on on-road vehicle emissions. [EPA-HQ-OAR-2019-0055-1320-A1, p.3]

The 2035 on-road fleet projection estimated hours, VMT and vehicle populations at the county, roadway type, fuel type and vehicle class level. The resources used to create the fleet projection were U.S. EPA's 2023 and 2028 activity projections (used to capture trends at the desired resolution by county, roadway type, fuel type and vehicle class level) and the current version of the Energy Information Administration (EIA) Annual Energy Outlook 2019 (used for national-level vehicle and VMT projections on which the trends were renormalized to match the national growth rate estimated by the EIA). The fleet-turnover impacts included in the 2035 inventories – both with and without the impacts of the Clean Trucks Regulation – were modeled with U.S. EPA's MOVES2014b model (MOVES2014b-20181203, which includes the December 2018 technical update). Fleet-turnover effects were modeled relative to the 2028 Base Case with MOVES at the national scale. Inputs into this modeling included U.S. EPA's 2028 age distribution data aggregated to the national level – assumed unchanged for 2035 – and emission factor updates to include the impacts of the Clean Trucks Rule. [EPA-HQ-OAR-2019-0055-1320-A1. p.3]

Results from the inventory analysis show that the new modeled FTP limits would result in a nationwide reduction of 330,000 tons per year of NOx in 2035. On a state-by-state level, the NOx inventory reductions from the heavy-duty fleet are about 60-70% below the 2028 base case. When taking a more refined look at the location of the NOx benefits at the county level, those counties currently in nonattainment or maintenance with the 2015 ozone NAAQS will receive some of the highest NOx reductions (e.g. > 145 tons NOx in 2035) from a 0.02 g/bhp-hr heavy-duty engine FTP standard. In addition to the modeled NOx reductions, our preliminary analysis suggests reductions of 2,300 tons of VOCs and 83,000 tons of carbon monoxide in 2035. Both NOx and VOC contribute to ozone formation. [EPA-HQ-OAR-2019-0055-1320-A1, p.3]

The modelled 2028 base year 8-hour ozone design values were found to be above the 70 ppb NAAQS for 75 monitoring locations. Applying the California Omnibus standards to the 2028 base year eliminates ozone nonattainment everywhere east of the Rockies, while several monitoring sites (mostly in California) are projected to have reduced ozone levels that yet remain in nonattainment. The greatest ozone reduction impact of the strategy is seen in urban areas and along highway corridors with reductions of up to 6.5 ppb seen in the west (San Bernardino) and 4.9 ppb seen in the east (Atlanta). It is important to note that even though the 2015 ozone NAAQS was finalized at 70 ppb, EPA's Clean Air Scientific Advisory Committee (CASAC) in 2015 supported a range of 60-70 ppb for the 8-hour primary ozone standard. Without a federal HD low NOx regulation, nearly 300 monitoring sites are projected to have 8-hour ozone design values between 60 and 70 ppb, and standards consistent with Proposed Option 1 will reduce these by an average of 2.35 ppb and up to a max of 5 ppb. [EPA-HQ-OAR-2019-0055-1320-A1, pp.3-4]

Organization: *Midwest Ozone Group (MOG)*

In these comments MOG will not only offer its support for the CTI and relative contribution findings generated by others, but also offer the results of air quality modeling data performed for MOG by Alpine Geophysics that assess the contribution that mobile sources make to ozone concentration at various monitors in the East. This data confirms the significant role that mobile sources play in determining the quality of our air and the importance of the rule that EPA has proposed and is consistent with the findings of EPA published with this proposed rule. [EPA-HQ-OAR-2019-0055-1272-A1, p.2]

The air quality analysis prepared by Alpine Geophysics offers ozone source apportionment data relative contribution calculations for the various source sectors from multiple upwind states to downwind receptors5 which continues to demonstrate that local source emissions from mobile categories have the greatest relative contribution to projected ozone concentrations in the domain. [EPA-HQ-OAR-2019-0055-1272-A1, p.3]

5
http://www.midwestozonegroup.com/files/Ozone_Modeling_Results_Supporting_GN_SIP_Obligations_Final_Dec_2017_.pdf

Figure 1 provides recent ozone source apportionment results for the Queens County, New York monitor (360810124) in the 2023 projection year. The figure shows geographic, source category-based relative contribution to the 2023 ozone design value predicted at the monitor. In the figure, the height of each bar represents the relative contribution to other geographic (state or region) sources of category-based emissions (individual colors within each bar). Of importance in this figure, the bars for New York and adjacent state New Jersey dominate the list of anthropogenic emission contributions and within that bar, the blue (onroad mobile) and orange (nonroad mobile + area + marine/rail/air) are of greatest relative modeled contribution. [EPA-HQ-OAR-2019-0055-1272-A1, p.3]

When we look at the aggregate of all categories, regardless of geography (Figure 2), we also see that motor vehicles (15%) and nonroad mobile + area + marine/rail/air (33%) dominate the relative contribution to projected ozone concentrations. [EPA-HQ-OAR-2019-0055-1272-A1, pp.3-4]

Similar results are seen in Figure 3 at the coastal Connecticut site at Fairfield (090010017) with emissions from New York, New Jersey, and Connecticut dominating the geographic contributions. Again, like the Queens County, New York monitor, emissions from the blue (onroad mobile) and orange (nonroad mobile + area + marine/rail/air) combine for over 56% of the modeled ozone concentrations. This is also seen in Figure 4 when geography is removed from the equation. [EPA-HQ-OAR-2019-0055-1272-A1, p.4]

This pattern is also seen across most of the eastern U.S. and as seen in Figure 5, motor vehicle emissions (red piece of each pie) are a significant percentage of relative contribution to 2023 ozone concentration predictions from U.S. anthropogenic sources at most monitors. [EPA-HQ-OAR-2019-0055-1272-A1, p.5]

Through the sponsorship of MECA, Oak Leaf Environmental Inc. (Oak Leaf) completed a 48-state emissions impact analysis of a possible CTI scenario that would result from EPA aligning their final CTI rule to the 90% NOx emission reduction levels as proposed by the California Air Resources Board (CARB) and implemented and phased-in through fleet turnover assumed in MOVES through 2035. This Oak Leaf technical support document is attached to these comments and identified as Exhibit A. The report is also available on the MOG web site.6 The basis for the CTI scenario was the most recent information – available at project commencement – from CARB (September 26, 2019 workshop proposal) with the understanding that EPA and CARB are working on a nationally uniform regulatory framework. [EPA-HQ-OAR-2019-0055-1272-A1, pp.6-7]

6 Modeling Inventory of Potential Heavy-Duty Cleaner Trucks Initiative Scenario Final Report, Prepared By: Jeremy G. Heiken Oak Leaf Environmental, Inc, June 2020 (http://www.midwestozonegroup.com/files/OakLeaf_Report_June_2020.pdf); Appendix A - National & State CTI Scenario Summary (http://www.midwestozonegroup.com/files/Appendix_A_-_National_State_CTI_Scenario_Summary.xlsx); Appendix B - National & State Activity Summary (http://www.midwestozonegroup.com/files/Appendix_B_-_National_State_Activity_Summary.xlsx).

The foundation of the evaluation was the EPA inventory projection for 2028fh7. The ‘2035 Base Case’ inventory was developed to include an on-road fleet projection to 2035 with no change in the underlying regulatory context. The ‘2035 Control Case’ inventory was developed to include both the 2035 fleet projection and the impacts of the proposed CTI on onroad vehicle emissions. Accordingly, the emissions impacts of the CTI are defined by the difference between the 2035 Control Case and 2035 Base Case inventories. [EPA-HQ-OAR-2019-0055-1272-A1, p.7]

7 https://www.epa.gov/air-emissions-modeling/2016v1-platform

This is a consistent methodology for the development of the modeling platform compared to EPA’s proposal in that both analyses maintain the 2028fh projection for non-mobile categories and updating projections for mobile sources. EPA’s modeling for this proposed rule uses a 2045 projection for mobile sources, whereas Oak Leaf has projected to 2035. The Oak Leaf product also differs from the EPA proposal in that Oak Leaf’s estimates assume NOx standards begin in

MY 2024 compared to EPA's action that sets NOx standards beginning in MY 2027. [EPA-HQ-OAR-2019-0055-1272-A1, p.7]

The modeled year of 2035 was chosen to allow as much phase-in of low NOx trucks meeting the future modeled CTI emission limits while still providing adequate confidence from the air quality perspective. Given that the new truck regulations begin implementation in 2024 and heavy-duty trucks last 20-30 years on the road, the 2035 timeframe represents an intermediate level of CTI truck penetration. It is expected that further NOx reductions will be realized beyond the 2035 modeled year as the heavy-duty truck fleet continues to turn over to the cleanest technology vehicles. [EPA-HQ-OAR-2019-0055-1272-A1, p.7]

Figure 6 presents the relative, annual NOx benefit of the potential CTI scenario in 2035 at a county-level resolution. The percent benefit is estimated as a reduction in the total on-road NOx inventory (both light and heavy-duty vehicles). The range in benefit, by county, is between 4 and 60 percent. [EPA-HQ-OAR-2019-0055-1272-A1, p.7]

Working with this 2035 scenario, Alpine Geophysics, LLC (Alpine) through the sponsorship of MOG, merged the onroad emissions data with a 2028 'base case' modeling simulation already completed The Technical Support Document related to Alpine's 2028 'base case' is attached and identified as Exhibit B and is available on the MOG web site.8 [EPA-HQ-OAR-2019-0055-1272-A1, p.8]

8 Air Quality Modeling Technical Support Document for 12km Modeling of EPA 2028fh Base Case Technical Support Document Prepared by: Alpine Geophysics, LLC, May 2020 (http://www.midwestozonegroup.com/files/Alpine_Geophysics_-_CTI_Scenario_Modeling_TSD_-_June_2020.pdf)

Alpine then ran photochemical grid modeling (PGM) with the Comprehensive Air Quality Model with Extensions (CAMx) model to generate future CTI scenario concentrations of ozone and PM2.5. This modeling of the CTI scenario is described in a Technical Support Document that is attached to these comments and identified as Exhibit C and is available on the MOG web site.9 [EPA-HQ-OAR-2019-0055-1272-A1, p.8]

9 Cleaner Trucks Initiative Scenario Modeling Using EPA 2028fh Modeling Platform Technical Support Document Prepared by: Alpine Geophysics, LLC, June 2020 (http://www.midwestozonegroup.com/files/Alpine_Geophysics_-_CTI_Scenario_Modeling_TSD_-_June_2020.pdf)

Together, this work assesses how the change in mobile source emissions between the 2028 base case and the CTI scenario would change the ozone and PM2.5 ambient air quality projections at receptors in the continental United States. [EPA-HQ-OAR-2019-0055-1272-A1, p.8]

As illustrated in Figure 7, the modeled 2028 base year 8-hour ozone design values were found to be above the 70 ppb NAAQS in the states of California, Utah, Colorado, Texas and Connecticut. [EPA-HQ-OAR-2019-0055-1272-A1, pp.8-9]

As shown in Figure 8, applying the 90% NOx emission reduction CTI scenario to the 2028 base year eliminates ozone nonattainment everywhere east of the Rockies and in Denver and leaves only the states of California and Utah with 70 ppb 2015 ozone NAAQS nonattainment areas. Multiple monitors in California and in Salt Lake County, Utah also show modeled attainment with the CTI strategy. [EPA-HQ-OAR-2019-0055-1272-A1, p.9]

As shown in Figure 9, the greatest ozone impact of the strategy is seen in urban areas and along highway corridors with reductions of up to 6.5 ppb seen in the west (San Bernardino) and 4.9 ppb seen in the east (Atlanta). [EPA-HQ-OAR-2019-0055-1272-A1, p.9]

The CTI strategy impacts on the annual PM2.5 design value nationwide are shown in Figure 9 with modeled attainment changes occurring at monitors in Madera, San Joaquin, and Stanislaus counties in California. The greatest annual PM2.5 impacts are reductions of 0.64 μg/m3 (4.1%) seen in the west (Kern County, CA) and 0.21 μg/m3 (2.3%) reduction in the east (Chicago). [EPA-HQ-OAR-2019-0055-1272-A1, p.10]

From a daily (24-hour) PM2.5 perspective, Figure 11 shows daily PM2.5 design values nationwide. As with the annual PM2.5 modeling, areas shown to move to modeled attainment as a result of the CTI strategy include Madera, Merced, and San Joaquin counties in California. The greatest daily PM2.5 impacts are reductions of 4.5 μg/m3 (9.8%) seen in the west (Tulare County, CA) and 0.9 μg/m3 (4.5%) reduction in the east (Chicago). [EPA-HQ-OAR-2019-0055-1272-A1, p.10]

This modeling is consistent with EPA's proposed rule modeling10 of 2045 with the Community Multiscale Air Quality (CMAQ) model in both geography and magnitude for ozone and PM concentrations with the implementation of the control program. [EPA-HQ-OAR-2019-0055-1272-A1, p.11]

10 Air Quality Modeling for the HD 2027 Proposal, Draft Technical Support Document (TSD), EPA-420-D-22-002, February 2022 (https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P101481P.pdf)

The modeling data provided in these comments illustrates the need for measurable improvements to environmental conditions in communities that are heavily impacted by dense traffic. Ambient improvements to PM, PM2.5, and ozone represented by this proposed rule will serve to facilitate the development of implementation outcomes of local environmental benefits attributable to controls on mobile sources like heavy duty trucks. EPA's burden is to effectively implement this rule per Executive Order 12898, 'Federal agencies must identify and address, as appropriate, disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority populations and low-income populations.' [EPA-HQ-OAR-2019-0055-1272-A1, p.11]

Given the technical availability and cost effectiveness of achieving a 90% reduction of NOx emissions from heavy duty trucks by 2035 as established by MECA and by 2045 as demonstrated by EPA and given the remarkable improvement in air quality as demonstrated by the Alpine and EPA modeling, MOG urges that EPA finalize a rule calling for a 90% reduction in NOx emissions from heavy duty trucks. [EPA-HQ-OAR-2019-0055-1272-A1, p.11]

Organization: *Ozone Transport Commission (OTC) and Mid-Atlantic/Northeast Visibility Union (MANE-VU)*

To address the region's persistent air quality problems, reducing NOx from heavy-duty truck engines is of the utmost importance due to its role in local and regional ground-level ozone formation, as well as its contributions to PM2.5 and to winter-time visibility impairment at Class 1 areas. The year-round benefits of measures that reduce heavy-duty vehicle NOx emissions are substantial. [EPA-HQ-OAR-2019-0055-1250-A1, p.4]

An OTC analysis, shown in Figure 2, illustrates that onroad diesel vehicles, including heavy-duty vehicles (HDVs), are projected to be the third largest NOx emissions source in the OTR in 2023.8 Emissions from highway trucks are estimated to comprise 20 percent of the region's total NOx emissions. [EPA-HQ-OAR-2019-0055-1250-A1, pp.4-5]

> 8 National Emissions Inventory Collaborative (2019). 2016v1 Emissions Modeling Platform. Retrieved from http://views.cira.colostate.edu/wiki/wiki/10202.

To estimate the impact of onroad diesel emissions – the lion's share of which is emitted by HDVs – the OTC modeled the contribution (ppb) of onroad diesel to 8-hour maximum ozone concentrations at monitors in the OTR.10 An example is provided in Figure 3, which shows the modeled contribution to total ozone from onroad diesel vehicles at each monitor in the OTR for which future-year 2023 photochemical modeling predicts continued nonattainment or maintenance challenges. [EPA-HQ-OAR-2019-0055-1250-A1, p.5]

> 10 OTC, 'Ozone Transport Commission/Mid Atlantic Northeastern Visibility Union 2011 Based Modeling Platform Support Document – October 2018 Update,' 2nd Version, October 18, 2018. Available at https://otcair.org/upload/Documents/Reports/OTC%20MANE-VU%202011%20Based%20Modeling%20Platform%20Support%20Document%20October%202018%20-%20Final.pdf. The modeling evaluated the 8-hour maximum ozone on the 4th highest day, which is the metric EPA uses to evaluate compliance with the ozone NAAQS.

Table 3 lists the percent contribution to total ozone from onroad diesel emissions at additional monitors in the OTR. Onroad diesel emissions are projected to contribute up to 10 ppb to total ozone and the projected contribution makes up between 10 and 17 percent of controllable ozone contributions on these days. Table 3 also shows the onroad diesel category's ranking in terms of the top emissions sectors that contribute total ozone at these monitors. Onroad diesel emissions are consistently projected to be the second, third, or fourth largest contributing sector to ozone, typically only behind area/nonpoint, onroad gasoline vehicles, and in some cases, electric generating units. [EPA-HQ-OAR-2019-0055-1250-A1, p.6]

The OTR had been making progress for over a decade at addressing its regional ozone problem, with ozone levels trending downward due to the adoption of measures that reduce emissions of ozone precursors. In recent years, however, air quality monitoring data no longer show a declining trend. Figure 5 shows the number of days in Connecticut where maximum 8-hour ozone was measured above the 2008 and 2015 ozone NAAQS for each year from 1976 to 2018. After significant improvements in the earlier years, the number of high ozone days in Connecticut has remained level or has slightly increased since 2011. Similar patterns have been recorded in other OTC states, as can be seen in Figure 6. [EPA-HQ-OAR-2019-0055-1250-A1, p.9]

Figure 5 also includes an extensive list of requirements that have been adopted in Connecticut and other OTC states to reduce emission of the ozone precursors from stationary sources, area sources, fuels, mobile sources, and consumer products. Imposing further control requirements on many of these source categories would be more costly than controlling heavy-duty engine emissions and would create disproportionate economic burden for those sources. The OTC estimated that the cost of additional NOx controls for industrial, commercial, and institutional boilers (100 million British Thermal Units per hour in size) ranges from $2,700 to $21,000 per ton of NOx reduced, as compared to a cost range of $1,000 to $5,000 per ton of NOx reduced from HDVs.18,19 [EPA-HQ-OAR-2019-0055-1250-A1, p.10]

> 18 OTC/Lake Michigan Air Directors Consortium (LADCO), ‘Evaluation of Control Options for Industrial, Commercial and Institutional (ICI) Boilers,’ May 2010.
>
> 19 Manufacturers of Emission Controls Association, ‘Technology Feasibility for Heavy-Duty Diesel Trucks in Achieving 90% Lower NOx Standards in 2027,’ February, 2020. Available at https://www.meca.org/wp-content/uploads/resources/MECA_2027_Low_NOx_White_Paper_FINAL.pdf. Accessed May 4, 2022.

As noted previously, the New York-Northern New Jersey-Long Island ozone nonattainment area consistently fails to meet its attainment deadlines for the 2008 8-hour ozone NAAQS (0.075 ppm), and EPA has now proposed to re-classify this area to severe nonattainment status for the NAAQS. [EPA-HQ-OAR-2019-0055-1250-A1, p.10]

Not only have ozone design value improvements stalled, the region has experienced unusually high peak ozone concentrations in recent years. In July of 2018, the New York City metropolitan region saw a 1-hour ozone average of 143 ppb, a peak level not seen in this area in more than 10 years. [EPA-HQ-OAR-2019-0055-1250-A1, p.10]

The satellite imagery in Figure 7 readily shows visible nitrogen dioxide (NO2) pollution (a major component of NOx) along the Northeast Corridor, with the highest concentrations of NO2 in the New York City area. The figure shows the NO2 vertical column concentration measured during daily overpasses by the TROPOMI satellite for weekdays (Monday-Friday) during May through September in 2018. Much of the NO2 pollution is near the surface close to its emission sources. High density ground level NOx emissions in large urban areas not only react to create low elevation ozone, but also mix upward into higher altitudes, which is shown in the NO2 vertical column measurements. Power plants in some locations enhance the vertical column measurements as many of them inject their emissions into higher altitudes. As a result, low-level emissions such as those from HDVs are an important component to local ozone production while power plant emissions have a greater relative tendency to contribute to downwind ozone production. [EPA-HQ-OAR-2019-0055-1250-A1, pp.10-11]

Figure 8 shows satellite imagery of NO2 concentrations during the winter in the Northeast and Mid-Atlantic on February 18, 2019, a day with particularly severe haze. NO2 concentrations are abundant and dominant along the I-91/95 corridor from Virginia to Massachusetts, suggesting a strong mobile source NOx contribution. These are major arteries where goods are being transported by truck from the ports of Baltimore, Philadelphia, and New York. Note how clearly defined the area of red is along I-91 in central Connecticut and Massachusetts. In addition to region-wide stagnation on this particular day, the strength of the NO2 signal also reflects the longer NO2 lifetime in winter. [EPA-HQ-OAR-2019-0055-1250-A1, p.11]

Because of its role in secondary particulate formation, reducing HDV NOx emissions will improve visibility in MANE-VU federal Class I areas. There are seven federal Class I areas in the region that have historically faced some of the worst visibility in the nation. Analyses of monitoring data from the Interagency Monitoring of Protected Visual Environment (IMPROVE) network show the increasing importance of nitrate formation on visibility impairment, in particular at the Brigantine Wilderness Area in the Edwin B. Forsythe National Wildlife Refuge in New Jersey.20 In addition, as was shown in Figure 2, HDVs are the third largest source of NOx emissions in the region. Because of this, the MANE-VU states, through the MANE-VU Regional Planning Organization process, requested that EPA implement a program to reduce NOx emissions from HDVs.21 [EPA-HQ-OAR-2019-0055-1250-A1, p.12]

EPA Summary and Response

Summary:

The commenters support the NOx reductions proposed in the rule and provided results of inventory and air quality modeling analyses that assess the contribution that mobile sources make to ozone and $PM_{2.5}$ concentrations and the impact of the proposal on air quality. Further detail on the assumptions and inputs used in these analyses is included within the comments and references to the comments. There are some differences from EPA’s analysis but overall, the different analyses all indicate that mobile sources are an important contributor to ozone and $PM_{2.5}$ concentrations, and those that represented a hypothetical HD control program are consistent with EPA's air quality modeling analysis.

Lake Michigan Air Directors Consortium (LADCO) commented on their modeling analysis showing that the emissions from roadway mobile sources are leading contributors to the ground level ozone in the eastern United States. LADCO mentioned that EPA’s proposed rule on heavy-duty vehicle emissions would have a major impact with respect to controlling the future ozone level in that region.

Manufacturers of Emission Controls Association (MECA) presented an emission inventory and air quality modeling analysis, also referenced by Midwest Ozone Group (MOG), based on adoption of federal FTP standards for heavy-duty trucks of 0.05 g/bhp-hr beginning with MY 2024 and 0.02 g/bhp-hr beginning with MY 2027. The analysis showed decreases in ozone and $PM_{2.5}$ concentrations in 2035.

Also, OTC and MANE-VU note that NOx reductions from heavy duty trucks are important for addressing the ozone transport region’s (OTR) persistent air quality problems, including ozone concentrations, $PM_{2.5}$ concentrations and wintertime visibility at federal Class I areas. The commenter provides an Ozone Transport Commission (OTC) analysis illustrating that onroad diesel vehicles (including HD vehicles) are projected to be the third largest NOx emissions source in the OTR in 2023. The commenter conducted modeling to project how much ozone comes from on-road diesel vehicles at OTR monitors and on-road diesel is one of the largest contributors. The commenter also mentions that ozone reductions have plateaued in some places and that in some places peak concentrations have been going up recently. The commenter asserts that OTC states have adopted lots of requirements for other NOx emissions sources and further controls would be more costly than controlling HD engines. The commenter states that satellite data shows average NO_2 concentrations during the summer, with maximum concentrations around the NYC area. The commenter asserts that ground level NO_2 emissions (e.g., from HD vehicles) are more likely to contribute to local ozone while NO_2 emissions that are higher aloft are more likely to contribute to ozone concentrations downwind. The commenter states that satellite imagery of a day in wintertime also shows higher NO_2 along major roadways when NO_2 has a longer lifetime. The commenter analyzed IMPROVE data and found that nitrates are becoming increasingly important for visibility in federal Class I areas in the OTR.

Response:

EPA appreciates this evidence that corroborates the modeling analysis undertaken for the proposed rule. EPA agrees that emissions from heavy duty trucks are significant contributors to concentrations of ozone and $PM_{2.5}$ and reducing NOx from this source will help many areas improve their air quality. More information on EPA’s air quality modeling analysis can be found in Chapter 6 of the RIA and the AQM TSD.

20.2 Biofuels would be beneficial for air quality

Comments by Organizations

Organization: *American Soybean Association (ASA)*

The growth of the biodiesel industry, and more recently the renewable hydrocarbon diesel industry, has been spurred by strong federal and state-level policies that promote cleaner, lower-carbon energy sources. Increased utilization of biomass-based diesel over the past several years has had a marked impact on the rural economy. Domestic markets use over 2.5 billion gallons of biomass-based diesel which supports over 65,000 jobs—many in rural America—and creates an economic impact of $17 billion1. Looking ahead, the biomass-based diesel industry is poised for significant growth with the expansion of renewable diesel. The EPA has an opportunity to play a critical role in supporting this industry—not only through the Renewable Fuel Standard, but through emissions rules that continue to allow a pathway for low carbon liquid fuels. [EPA-HQ-OAR-2019-0055-1309-A1, p.1]

> 1 LMC International, 2019. The Economic Impact of the Biodiesel Industry on the U.S. Economy. National Biodiesel Board.

Of note, government and corporate entities around the country are already utilizing biomass based diesel as an opportunity to achieve lower emissions now. For example, New York City requires all 11,000 city fleet vehicles to use biomass-based diesel—from the police department and fire department to the department of sanitation and off-road equipment vehicles. Other cities, like Washington, D.C., are also transitioning their fleets to biomass-based diesel. In 2018, D.C. used 120,000 gallons of biomass-based diesel in their vehicle fleet, which resulted in 1,000 fewer tons of greenhouse gas emissions. In 2020, the D.C. Department of Public Works announced that they would begin running 17 garbage trucks on B100, or 100% biomass-based diesel—an 86% greenhouse gas emissions reduction from a traditional petroleum-fueled garbage truck. The results are so clear that the city plans to double the size of its B100 vehicles in the next year. Through funds granted by EPA's Diesel Emissions Reduction Act program, DC Water Authority is expanding their use of B100 to 31 vehicles where it also benefits worker health. [EPA-HQ-OAR-2019-0055-1309-A1, p. 2]

Soy farmers are proud of the success of biomass-based diesel—not only for the new market opportunities the fuel created for farmers, but also for being able to grow a clean energy solution right in soybean fields. In fact, many soybean growers are using biomass-based diesel in their own farming equipment. Soybean oil represents about half of the feedstock used to produce biomass-based diesel and, according to the analysis of Clean Fuels Alliance America, biomass based diesel has led to a savings of 143.8 million metric tons of carbon since 2010. Further, according to the most recent update to the Greenhouse Gases, Regulated Emissions, and Energy Use in Technologies (GREET) model, it is estimated that the current U.S. biomass-based diesel feedstock mix reduces emissions by approximately 74% compared to traditional petroleum diesel.3 [EPA-HQ-OAR-2019-0055-1309-A1, pp. 2-3]

> 3 Wang, M., A. Elgowainy, U. Lee, A. Bafana, S. Banerjee, P. Benavides, P. Bobba, A. Burnham, H. Cai, U. Gracida- Alvarez, T. Hawkins, R. Iyer, J. Kelly, T. Kim, K. Kingsbury, H. Kwon, Y. Li, X. Liu, Z. Lu, L. Ou, N. Siddique, P. Sun, P. Vyawahare, O.

Winjobi, M. Wu, H. Xu, E. Yoo, G. Zaimes, G. Zang, 2021. Summary of Expansions and Updates in GREET 2021. https://greet.es.anl.gov/publication-greet-2021-summary

The rise of renewable diesel in the United States, in addition to our existing biodiesel capacity, appears poised to help meet the growing need for low-carbon fuels as drivers on our country's roads move to reduce their environmental footprint. American soybean farmers stand ready to support the continued growth of biomass-based diesel to meet our nation's carbon reduction goals. [EPA-HQ-OAR-2019-0055-1309-A1, p. 3]

ASA is eager to continue working with the EPA to support the role of agriculture in diversifying the fuel supply and supporting cleaner fuel options. On behalf of America's soybean farmers, we appreciate this opportunity to comment, and look forward to working with EPA, its partner agencies, and other relevant stakeholders to enact policies that will address climate change while expanding the use of soy-based biofuels and market opportunities for soybean farmers. [EPA-HQ-OAR-2019-0055-1309-A1, p. 3]

Organization: *Clean Fuels Alliance America (Clean Fuels)*

These new proposed Heavy-Duty Engine and Vehicle Standards are an important part of our country's continued push for cleaner air and a cleaner environment. The new Ultra-Low Emissions Diesel Engines (ULEDEs) produced under these regulations will be substantially cleaner than New Technology Diesel Engines (NTDE) in the market today and will approach near-zero regulated emissions of PM, NOx, unburned hydrocarbons, and carbon monoxide. [EPA-HQ-OAR-2019-0055-1248-A1, p.3]

Organization: *Valero Energy Corporation*

There are several critical deficiencies in the data and analysis on which the proposed rule revisions rely. In addition to these specific deficiencies identified below, Valero incorporates as part of these comments a report prepared by Ramboll U.S. Consulting, Inc. for Western States Petroleum Association that evaluates CARB's Heavy Duty Truck strategy1 and concludes that CARB's approach does not deliver results as early and as cost-effectively as an approach that incorporates low-nitrogen oxides ('NOx') emission vehicles coupled with increased introduction of renewable liquid and gaseous fuels. Since EPA's proposal relies heavily on analysis performed by CARB, the conclusions in the Ramboll study are relevant to EPA's proposal. EPA must not blindly follow CARB, but should take these comments, including the Ramboll study, into account. [EPA-HQ-OAR-2019-0055-1328-A2, p.3]

1 'Multi-Technology Pathways to Achieve California's Air Quality and Greenhouse Gas Goals: Heavy-Heavy-Duty Truck Case Study,' prepared for Western States Petroleum Association by Ramboll U.S. Consulting, Inc. (February 1, 2021).

EPA Summary and Response

Summary:

Commenters note that increased biofuel requirements would bring larger GHG reductions more quickly than the proposed program. One commenter cites an ATRI life-cycle analysis done using the Greenhouse Gases, Regulated Emissions, and Energy Use in Technologies (GREET) model, which found that the most realistic approach to decreasing carbon dioxide in ICE vehicles is through alternative fuels like biofuels. Another commenter points to a recent update to the GREET model that shows the current U.S. biomass-based diesel feedstock mix reduces emissions by approximately 74% compared to traditional petroleum diesel. Finally, one commenter refers to an analysis done by Ramboll focusing on California that indicates emissions reductions are greater and happen more quickly if biofuel requirements are also included.

Response:

EPA is not taking final action at this time on the portion of the HD 2027 NPRM regarding proposed changes to HD GHG Phase 2 standards. EPA intends to undertake a separate rulemaking regarding more stringent HD GHG standards in the future (i.e., HD GHG Phase 3 standards). Comments related to additional technology pathways, such as alternative fuels, are addressed in section 3.10 of this Response to Comments document. Related to the Ramboll analysis one commenter points to, our response is included in section 3.1 of this document.

20.3 Ozone Transport from Asia

Comments by Organizations

Organization: *American Trucking Associations (ATA)*

A recent study regarding ozone transport from Asia and its impacts on the U.S. found that Asia contributed as much as 65% of the increase in Western ozone in recent years.13 China and India, where many consumer products are manufactured, are the worst offenders. Scientists say that since Asian NOx emissions have tripled since 1990, they will continue to impact gains in U.S. air quality. The research, which was conducted by the National Oceanic and Atmospheric Administration and EPA, was published in the journal of Atmospheric Chemistry and Physics. The study, which analyzed levels of ground-level ozone between 1980 through 2014, concluded that the spike in man-made emissions in Asia "is the major driver" of the rise in ozone levels in the western U.S. for both spring and summer in recent decades.14 [EPA-HQ-OAR-2019-0055-1326-A1, p. 16]

> 13. Lin, M., Horowitz, L. W., Payton, R., Fiore, A. M., and Tonnesen, G.: US surface ozone trends and extremes from 1980 to 2014: quantifying the roles of rising Asian emissions, domestic controls, wildfires, and climate, Atmos. Chem. Phys., 17, 2943–2970, https://doi.org/10.5194/acp-17-2943-2017, 2017.
>
> 14. Id. at 2964.

Aside from Asian ozone transport, EPA’s 2015 National Ambient Air Quality Standard for Ozone projected only 14 counties outside of California will not meet the revised standard of 70 parts per billion (ppb) averaged over 8-hours by 2025 (See Figure 3).15 Yet every trucking company in the U.S., regardless of where they operate, is being asked to pay higher prices for equipment and warranties. IHS Markit data from the end of 2021 indicates that 53% of commercial vehicles are MY 2011 or newer meaning they are powered by engines meeting EPA's most stringent NOx engine emission standards. As the 47% of legacy vehicles gets rotated out of use, the industry's NOx emission profile will continue to decrease. [EPA-HQ-OAR-2019-0055-1326-A1, p. 16]

> 15. Regulatory Impact Analysis of the Final Revisions to the National Ambient Air Quality Standards for Ground-Level Ozone, EPA-452/R-15-007, Page ES-8, September 2015.

Fleets being operated solely in attainment areas question why they will be required to pay such a high price to improve air quality deemed healthy by EPA. These operations, like many others, will assess the anticipated technological and financial impacts of HD2027 on their purchase and operating decisions and adjust accordingly. [EPA-HQ-OAR-2019-0055-1326-A1, p. 17]

Organization: *National Association of Small Trucking Companies (NASTC)*

The proposed NOx and GHG reduction goals and the timetable for achieving them in this NPRM are quite ambitious, especially in light of the remarkable reductions our trucking sector has already achieved. Effectively, post-2010 heavy-duty trucks release cleaner air into the atmosphere than they take in. [EPA-HQ-OAR-2019-0055-1130-A1, p. 4]

The EPA has certainly played a role in the gains that have helped clean our air. Regrettably, the EPA and other government agencies have been party to increasing a substantial regulatory burden on American industry and erecting high hurdles to advancements such as building new, cleaner oil refineries and adequate truck parking. Meanwhile, China continues to use Diesel 2, the precatalytic converter-grade diesel fuel that has long been in disuse in the United States. We note that the current, cleaner-grade diesel fuel used in the United States costs trucking roughly $1 more per gallon than would Diesel 2. To be sure, U.S. diesel fuel today is better for the environment. Presumably, our country's citizens regard the more expensive U.S. diesel fuel and the costs it adds to their cost of living worth the extra money. Yet, China not only benefits economically from cheaper, dirtier diesel fuel, its polluted air reaches the West Coast of the United States. There seems to be a disconnect here. Americans pay dearly to clean our air, which flows eastward, and China sends back its dirty air. [EPA-HQ-OAR-2019-0055-1130-A1, p. 4]

EPA Summary and Response

Summary:

Two commenters noted that ozone transport from Asia is contributing to U.S. ozone concentrations, especially in the Western U.S. One commenter specifically questioned why fleets operating in attainment areas would need to increase their costs to reduce their emissions.

Response:

EPA agrees that ozone and ozone precursors, both from within the U.S. and from outside the U.S., can be transported and contribute to downwind ozone concentrations in the U.S. and beyond. Transport of ozone and ozone precursors also means that emissions from trucks operating in areas attaining the NAAQS can still be impacting downwind areas, and those downwind areas might not be in attainment. In addition, people experience health effects at concentrations below the level of the NAAQS, and reductions in NOx emissions will help areas maintain the ozone and $PM_{2.5}$ NAAQS and help prevent future nonattainment. Overall, reducing NOx emissions across the country will result in improved health outcomes attributable to lower ozone and particulate matter concentrations in communities across the United States.

Our air quality modeling analysis includes emissions within the country and coming in from outside the country. The air quality results, presented in Chapter 6 of the RIA, indicate that this rule will help reduce ozone across the U.S., including in areas that are impacted by long range transport of ozone from outside the country.

20.4 Air Quality Impacts of Buses

Comments by Organizations

Organization: *American Bus Association (ABA) (1070 and 1308)*

However, the Proposal does not really address motorcoach operations, or the benefits derived from travel by motorcoach. Because of EPA's emphasis on trucks or freight carrying services, ABA believes the assumptions and analyses EPA relies upon for support are either inaccurate or incomplete. Passenger carrying transport, and specifically motorcoach operations, differ significantly from freight transport. For example, the impacts on air quality from bus and motorcoach operations should not be solely evaluated in the context of engine emissions but must also take into account the number of the other vehicles removed from the road by virtue of providing mass transportation. Motorcoach operations can take up to 50 personal vehicles off the road (MJ Bradley & Associates (Ed.). (2019, June). Updated Comparison of Energy Use & Emissions from Different Transportation Modes - https://www.buses.org/assets/images/uploads/general/2019%20UPDATE%20Comparative%20Fuel%20CO2%20FINAL-July%202019.pdf). When you consider the potential removal of 600 million passengers worth of personal vehicles from our roadways, we believe that the motorcoach industry should receive some special considerations under this rulemaking and should certainly be acknowledged for their positive impact on the environment. It is short-sighted and inaccurate to entirely discount the benefits to air quality from removing other vehicles from the road in terms of both emissions as well as congestion. At the same time, if conducting motorcoach operations becomes cost prohibitive or untenable, it will cause the demise of the motorcoach industry, leading to an increase of vehicles on the road and increased congestion for urban areas, reversing the strides made to limit pollution and improve air quality. [EPA-HQ-OAR-2019-0055-1308-A1, p.4]

Organization: *United Motorcoach Association (UMA)*

Additionally, buses and motorcoaches significantly reduce emissions by removing private passenger automobiles. Consumers that cannot afford the inevitable fare and charter cost increases will select less efficient means of travel, counterproductive to EPA's goals of reducing overall emissions. [EPA-HQ-OAR-2019-0055-1311-A1, p.2]

Another consideration is the general havoc mandated by the earlier rounds of NOx emissions reductions. [EPA-HQ-OAR-2019-0055-1311-A1, p.2]

EPA Summary and Response

Summary:

Two commenters noted that ridership on buses and motorcoaches can reduce emissions from private passenger automobiles. They also noted that if buses and motorcoaches are not cost-effective to operate for the operators, or are too expensive for riders, then consumers will select less efficient means of travel which runs counter to EPA's goal with this rule. The commenters ask for the positive impact of buses and motorcoaches to be acknowledged and suggest that the industry should receive special considerations.

Response:

EPA agrees that buses and motorcoaches can decrease the need for individual passenger vehicles, which can decrease emissions from the light-duty passenger vehicle sector. Emissions from both light-duty passenger vehicles and heavy-duty buses or motorcoaches contribute to air pollution and its associated health and environmental effects. EPA believes that the increased costs due to this rule would not be enough to have a meaningful impact on the industry; more information on this is provided in Section 25.3 of this document. In addition, responses to comments on special considerations, including inducements related to motorcoaches, are addressed in Section 8 of this document.

21 Criteria pollutant health benefits

21.1 EPA's Benefits Methods are Flawed

Comments by Organizations

Organization: *Truck and Engine Manufacturers Association (EMA)*

Accordingly, and as confirmed by independent expert analyses and reports (see infra at Section 16 of these comments), it is expected that the monetized costs of a program centered around the Option 1 proposal would exceed the potential monetized health-related benefits. [EPA-HQ-OAR-2019-0055-1203-A1, p. 12]

On the benefits side, independent experts at NERA Economic Consulting ("NERA") previously have determined through a "scoping study" that the range of potential monetized health benefits from the implementation of the proposed low-NOx regulations, when focusing primarily on potential reductions in secondary PM2.5 and ozone, as EPA is doing in its benefits analysis, and without accounting for exposure-extrapolation uncertainties, could be as high as approximately $4,500 per-vehicle. [EPA-HQ-OAR-2019-0055-1203-A1, p. 144]

Turning to the potential health-related benefits from EPA's proposal, NERA's expert reports (Exhibit "C" hereto) estimate and quantify those potential benefits. In that regard, NERA conducted a prior "scoping study" to delineate the potential quantitative benefits from the types of low-NOx regulations at issue, and, as a supplement to that, NERA also has prepared a critical review of the portions of the RIA that include the Agency's quantitative risk assessment. [EPA-HQ-OAR-2019-0055-1203-A1, p. 159]

NERA's earlier "scoping study" includes two parts: a conceptual summary of methods and results; and a more detailed technical analysis. As explained in its conceptual summary, NERA conducted a comprehensive "scoping" analysis to estimate, on a per-vehicle basis, the likely maximum range of monetized health benefits that could result over time from the implementation of the envisioned low-NOx standards. The relevant findings and conclusions from NERA's report as they relate to the monetized benefits potentially attributable to reductions in NOx-related secondary PM2.5 and ozone are described below. [EPA-HQ-OAR-2019-0055-1203-A1, p. 159]

NERA focused its benefits calculations on the value of projected health-risk reductions from the projected reductions in ambient ozone and secondary PM2.5 that could result from reduced HDOH truck NOx emissions due to the implementation of substantially tighter HDOH NOx standards. Based on a long history of such benefits calculations (by EPA and many other entities), NERA assumed that approximately 98% of the estimated health benefits from reductions in ozone and PM2.5 would be due to reductions in mortality risks. Thus, NERA focused its benefit-per-truck estimates by estimating only mortality risk benefits, having confidence that this method would have no meaningful impact on any quantified conclusions. [EPA-HQ-OAR-2019-0055-1203-A1, p. 160]

In order to obtain per-truck benefit estimates, NERA first calculated the tons of NOx emissions reductions from an average new truck that would be purchased in 2027 meeting the tighter low-NOx standard, accounting for a potential truck-life of up to 30 years. NERA made that calculation for each of the 8 truck types covered by the assumed low-NOx standards. That computation was carried forward for each year of a truck's operational life. NERA also assessed the average truck's continued operation in each future year based on truck survival rates over time. The emissions reductions in each future year were then translated into a dollar estimate of each year's health benefits using a "reduced form" method in which the precursor emissions changes were multiplied by a "benefit per ton" value. [EPA-HQ-OAR-2019-0055-1203-A1, p. 160]

NERA's methodology generated a time-line from 2027 through 2057 of annual benefits per-truck in each year of the average 2027-vintage truck's operating life, varying across time (generally declining) as the truck ages. NERA discounted that stream of benefits to obtain the present value of benefits per-truck for each of the 8 truck types. Those 8 values were then combined into a single sales-weighted average benefit-per-truck estimate. [EPA-HQ-OAR-2019-0055-1203-A1, p. 160]

The most important input to NERA's benefit-per-ton estimates, and hence the benefit-per truck estimates, is the assumption about the increase in mortality risk per unit change (reduction) in ozone and secondary PM2.5 concentrations. That assumption is usually based on a statistically-derived association between mortality risk and observed pollutant concentrations or exposures, called a concentration-response (C-R) coefficient. The assumed C-R coefficient typically is derived from one or more of many existing epidemiological studies and associated peer-reviewed papers. EPA tends to change the mortality risk assumption as new epidemiology papers are published and as each NAAQS-review cycle is conducted. NERA reviewed statements in EPA's Policy Assessments for PM2.5 and ozone (EPA, 2020 and 2019b) to attempt to anticipate which assumptions EPA might ultimately adopt in the RIA for its rulemaking. Without commenting on the appropriateness of any such studies, NERA decided it would be reasonable to provide a range of estimates for the secondary PM2.5 benefits-per-ton at issue. The lower end of the range is based on a C-R coefficient for all-cause mortality risk derived from the Krewski et al. (2009) study, and the higher end of the range is based on a C-R coefficient estimate for all-cause mortality risk from the Di et al. (2017) study. [EPA-HQ-OAR-2019-0055-1203-A1, p. 160]

There are significant scientific uncertainties when using statistical associations from epidemiological studies to predict risks for different populations and under different air quality concentrations and conditions in the future. At the same time, there are methods for identifying how the uncertainties may be reduced or scaled to derive benefits estimates that have a higher degree of confidence. [EPA-HQ-OAR-2019-0055-1203-A1, p. 160]

More specifically, any use of the derived unit risk estimate from an epidemiology study to predict changes in risks in different locations and under different levels of ambient pollution exposure necessarily involves extrapolation outside of the original range of the study's data. Extrapolation always introduces uncertainties that are not included in any of the original study's statistical measures of confidence. The more extreme is the extrapolation that a risk analysis requires with respect to exposure and population conditions not representative of the original study, the less qualitative confidence one would have in the derived risk estimate. [EPA-HQ-OAR-2019-0055-1203-A1, p. 161]

Such extrapolation can be a particular problem when using studies of associations between ambient air pollutant and health outcomes, even from the relatively recent past, to predict risk in a future year because of the steady declines in ambient pollutant concentrations that have taken place, especially with respect to PM2.5, and that are projected to continue in the future. For example, the average concentrations of PM2.5 experienced by the individuals studied in Krewski et al. (2009) fell by 30% during the period from 1980 to 2000, over which their mortality risk levels were being observed. Furthermore, the EPA dataset that NERA used to project average PM2.5 levels in 2035 are another 50% lower (before any reductions due to a tightened HDOH low- NOx standard) than the average exposures occurring at the end of the Krewski et al. study period (i.e., in 2000). Thus, the uncertainties due to extrapolation issues in this case are significant. Yet EPA did not take them into account at all. [EPA-HQ-OAR-2019-0055-1203-A1, p. 161]

It is possible to adjust the calculated risk estimates from the relevant epidemiology studies to exclude the portions of the estimates that involve the most extreme amounts of extrapolation from the exposure levels at issue in the original studies. As the amount of extrapolation from the original exposure and health-benefits estimates is reduced, confidence in the resulting estimate is qualitatively improved. This creates a "sliding-scale" of benefits estimates from least confident to most confident. [EPA-HQ-OAR-2019-0055-1203-A1, p. 161]

EPA introduced such a sliding confidence scale for its PM2.5 co-benefits estimates in a recent RIA (EPA, 2019a), which employed a health risk estimate for all-cause mortality from the Krewski et al. (2009) epidemiology study. On that sliding scale, the "more confident" end of the spectrum of mortality risk estimates was calculated by excluding those portions of the underlying exposure and risk calculations that applied the original study's risk factor to PM2.5 pollutant exposures below the 25th percentile of the originally-observed range of PM2.5 exposures. The 25th percentile of a data set is generally viewed as the point where sparseness of exposure observations begins to undercut the ability to determine if an average C-R slope detected over the entire set of originally-observed exposure levels still remains at those lower and less frequently experienced exposure levels. [EPA-HQ-OAR-2019-0055-1203-A1, p. 161]

NERA applied that sliding-scale approach in the calculation of benefits that could be ascribed to the type of HDOH low-NOx standards at issue. In doing so, by requiring more confidence in the benefit-per-truck estimates, the estimates declined somewhat, since they exclude benefits that are in areas with projected baseline PM2.5 concentrations that are below various percentile levels of the pollutant observations in the original study (e.g., below the 25th percentile of exposures). [EPA-HQ-OAR-2019-0055-1203-A1, p. 161]

There is no way to select a single "best" cut-off point for limiting extrapolation uncertainties. In its last PM2.5 NAAQS decision (i.e., the 2013 rulemaking), the EPA Administrator discussed how insufficient confidence in the continued existence of health risk associations would arise somewhere between the 10th to 25th percentiles of a study's range of observations. She chose to set the standard near the lowest of the 25th percentiles of available studies. NERA made an even more conservative choice in its analysis in this instance, and set its "best estimate" values at the 10th-percentile cut-off point of exposures from the underlying epidemiological studies. [EPA-HQ-OAR-2019-0055-1203-A1, pp. 161 - 162]

In addition, in recognition of the significant differences in the projected PM2.5 concentration distributions that exist between California and the rest of the country, NERA recomputed its benefits-per-truck for California and for the "Rest of the U.S.," separately. NERA's results, including the effects of the sliding-scale confidence-adjustments, are provided for PM2.5 in Tables 4 and 5 of NERA's Report, which are reproduced below: [EPA-HQ-OAR-2019-0055-1203-A1, p. 162]

It should be noted that the benefits estimates in NERA's scoping study reports are conservative or, stated differently, weighted to the high side. That conservative approach stems from the fact that in conducting its analyses, NERA assumed, among other things, that: there is no exposure threshold to PM2.5 or ozone below which mortality effects are no longer evident; the slope of the relative risk function for mortality is linear all the way down to zero exposure; and (as noted) it is appropriate to assess quantified benefits values at the 10th percentile of the exposure levels at issue in the underlying epidemiological studies, as opposed to utilizing a cut-point at the 25th percentile of exposures. Applying different assumptions regarding any of the foregoing points would lead to a reduction in the calculated benefits estimates. (NERA Report pp. 3-6, 9, 11, and 14-15.) [EPA-HQ-OAR-2019-0055-1203-A1, pp. 162 - 163]

As noted earlier, if confidence-adjusted values are not used, the potential benefits from the Agency's low-NOx proposal could be as high as approximately $4,500 per vehicle. On the other hand, based on NERA's confidence-adjusted analysis, and excluding only up to the 10th-percentile of the exposure data from the underlying epidemiology studies, and also applying a 3% discount rate as opposed to a 7% discount rate, the national per-truck benefits that could be derived from the types of HDOH low-NOx regulations at issue range from approximately $4,300 on the high-side to $3,100 on the low-side, for an average per-truck benefit of $3,700. Comparing that confidence-adjusted average per-truck benefit against the average per-HHD-truck cost as determined by Ricardo ($42,000) yields a costs-to-benefits ratio for HHD trucks (or a negative benefits-to-costs ratio) of approximately 10:1, which indicates that the proposed regulations, if not revised, will be cost-prohibitive. [EPA-HQ-OAR-2019-0055-1203-A1, p. 163]

More recently, as a follow-up to its scoping study, NERA has conducted a critical review of the Agency's methodology for estimating the potential quantitative health benefits associated with the rulemaking proposal at issue, as spelled out in the Agency's RIA. A copy of NERA's technical comments on the Agency's benefits estimates is included in Exhibit "C." [EPA-HQ-OAR-2019-0055-1203-A1, p. 163]

NERA's detailed critique demonstrates that EPA's RIA has a number of significant methodological flaws leading to a significant over-estimation of potential health-related benefits. The principal methodological flaws in the Agency's estimation of benefits include the following: EPA has elected to base its estimates of ozone-related mortality risks on a 2016 study by Turner, et al. that derived an unrealistic C-R factor for chronic ozone exposures. As a consequence of its unreasonable reliance on the Turner, et al. C-R factor, EPA has estimated high-end mortality ozone risks that are higher than the estimated mortality risks for PM2.5, a result that is completely at odds with the established scientific consensus regarding the relative magnitude of the potential mortality risks associated with PM2.5 exposures. As NERA explains, "risk estimates for ozone-related respiratory mortality using the Tuner, et al. (2016) study are theoretically and technically unreliable." (NERA Critique, p. 22.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 163]

The principal methodological flaws in the Agency's estimation of benefits include the following: The Turner, et al. (2016) study is flawed principally because it: applies an incorrect exposure window to the underlying data set, thereby underestimating exposures (which biases risks upward); applies a year-round exposure metric, as opposed to an ozone-season metric; and fails to account for the threshold of effects for longterm mortality that emerged from the underlying data, which threshold for ozone was approximately 56 ppb. The net result from that flawed analyses is the derivation of a risk ratio for ozone mortality that "has completely upended the long established history of multi-pollutant air quality benefits assessments in which ozone mortality benefits are substantially smaller than PM2.5 benefits." (NERA Critique, pp. 6, 14.) Accordingly, NERA assigns "zero reliability to estimates based on the Turner, et al. C-Rs" (id at p. 13), and concludes that the study "should be removed from the benefits analysis" (Id. at pp. 9, 17.) NERA further recommends that EPA should "omit long-term respiratory mortality from the Draft RIA altogether." (NERA Critique, p. 13.) [EPA-HQ-OAR-2019-0055-1203-A1, pp. 163 - 164]

The principal methodological flaws in the Agency's estimation of benefits include the following: Significantly, the Agency's RIA is at odds with the Agency's own 2020 NAAQS review process where the Agency-drafted Integrated Science Assessment (ISA) found inconsistent associations between ozone and respiratory mortality, did not ascribe confidence in any quantitative estimates of ozone respiratory risks, and so included no quantitative estimates of such risks. (See also NERA Critique, pp. 10- 13.) Thus, the Agency – the same Agency that has issued the draft RIA for this rulemaking – has expressly concluded that the evidence is suggestive of, but not sufficient to infer, a causal relationship between long-term ozone exposure and cardiovascular effects, respiratory mortality or total mortality. (See ISA, Tables 4- 2 and 6-2, pp. 4-65, 6-30, 6-43), and has specifically stated (citing the Tuner study) that there is "little evidence for an association between long-term exposure and total mortality." (ISA, p. 6-28.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 164]

Importantly, the scientific consensus on that point has not changed. Indeed, very recently, on April 29, 2022, and as a part of the pending reconsideration of the 2020 NAAQS, EPA issued a review draft of its Policy Assessment (PA) for ozone. In that PA, EPA specifically concludes that the newer available studies "do not materially change the findings of the 2020 ISA or warrant reopening of the air quality criteria" for ozone. (See EPA Staff Presentation to CASAC, slide 6, April 29, 2022.) Significantly, in that just-released PA for ozone, EPA chose not to rely on Turner, et al. (2016), noting that the "air quality data are not described [in the PA/ISA] for that study as it relied on estimated O3 concentrations for the years 2002-2004 as surrogates for study population O3 concentrations during the 1982- 2004 period." (See PA, p. 3B-33.) (See also NERA Critique, pp. 10-11.) Thus, the EPA staff with the greatest expertise in this area have actually agreed with NERA that the Turner, et al. (2016) study relies on an incorrect exposure window, and so should not be used to derive C-Rs. EPA's draft RIA flies in the face of its own more robust scientific conclusions, and so is patently unreasonable. [EPA-HQ-OAR-2019-0055-1203-A1, p. 164]

The principal methodological flaws in the Agency's estimation of benefits include the following: The Agency has failed to provide for any confidence-weighting to its benefits estimates. That has led to highly overestimated benefits due to the inherent unsupported assumption that the derived C-R relationships continue to hold fully, well below the ranges of exposure observations on which those C-R relationships were based. (NERA Critique, pp. 2-3.) When appropriate confidence-weighting factors are applied, it is clear that the Agency's RIA has substantially overestimated the health-related benefits at issue, most likely by more than an order of magnitude. (Id., Tables 1 and 2, pp 2-3, 18-30.) [EPA-HQ-OAR-2019-0055-1203-A1, p. 164]

EPA Summary and Response

Summary:

The above commenter asserts, for various reasons, that EPA's benefits methodology is flawed. In the response immediately below we provide some additional information on the comments included in this section, with additional details available in the comment excerpts above (Section 21.1).

Response:

We disagree with the premise that our benefits methodology is flawed. EPA's analysis is consistent with applicable guidance and best practices for conducting benefit-cost analyses, including OMB Circular A-4 and EPA's Guidelines for Preparing Economic Analyses. Guidance in both Circular A-4 and EPA's Guidelines directs the Agency to quantify and monetize all impacts associated with a particular rulemaking to the extent feasible. We consider our analysis consistent with the guidance, methodologically rigorous, and a best estimate of the projected societal benefits and costs associated with the final program. In the proposal, we found that the benefits of both scenarios we analyzed, Option 1 and Option 2, far outweighed the costs associated with those same scenarios. We have considered the comments and we have retained our approach to estimating benefits and have not made any changes to the analysis for the final rule.

In Chapter 18 of this document, EPA responds to the claim that EPA's cost estimates should be higher, finding that the primary difference between EPA's cost estimates and the higher Ricardo cost estimates was a difference in approach associated with the proposal's Option 1. Please refer to that section for more detail.

Furthermore, and as explained in Sections I and III of the preamble, EPA is promulgating the final emission standards pursuant to its authority under CAA section 202(a)(3)(A). In setting the final emission standards, EPA appropriately assessed the statutory factors specified in CAA section 202(a)(3)(A), including giving appropriate consideration to the cost associated with the application of technology EPA determined will be available for the model year the final standards apply (i.e., cost of compliance for the manufacturer associated with the application of such technology). EPA's assessment of the relevant statutory factors in CAA section 202(a)(3)(A) justify the final emission standards. We also evaluated additional factors, including factors to comply with E.O. 12866; our assessment of these factors lends further support to the final rule, including that the benefits of the proposed options outweigh their costs.

We do not agree with the basis for the commenter's claim that the proposed options are "cost-prohibitive" based on a comparison of per-truck benefits and costs (as described in the "Scoping Study"). EPA has based its estimation of the health-related benefits attributable to the proposed and final program using analytical tools, methods and assumptions that have been peer reviewed and are consistent with best practices and analytical guidance. EPA has estimated the full suite of spatially and temporally allocated emissions impacts associated with the multiple components of the standards (RIA Chapter 5 describes EPA's emissions modeling methods and assumptions). We have conducted full-scale photochemical air quality modeling that accurately projects levels of criteria and air toxic pollutants and captures the complex atmospheric chemistry related to ambient concentrations of $PM_{2.5}$, ozone, and air toxics (RIA Chapter 6 describes EPA's air quality modeling methodology and assumptions). Reductions in ambient $PM_{2.5}$ and ozone attributable to the standards are used as inputs to the health benefits analysis, which quantifies and monetizes improvements in human health due to avoided premature deaths and avoided non-fatal illnesses (RIA Chapter 8 describes EPA's benefits methodology and assumptions). The Scoping Study assumed a hypothetical emission reduction scenario that was different from the form of the proposed regulatory program. As the basis for a comparison of the costs and benefits of the proposed and final program, EPA's analysis is appropriate and its tools and methods peer reviewed. We also note that many of the responses we provide below, related to the commenter's critical review of the Agency's methodology for estimating the quantitative health benefits associated with the NPRM, also apply to methodological critiques we have with the Scoping Study.

As a first step in quantifying $PM_{2.5}$- and ozone-related human health impacts, the Agency consults the most recent Integrated Science Assessments (ISA) for each pollutant.[48,49,50] These documents synthesize the toxicological, clinical and epidemiological evidence to determine whether PM and ozone are causally related to an array of adverse human health outcomes associated with either short-term (i.e., hours or days-long) or long-term (i.e., years-long) exposure; for each outcome, the ISA reports this relationship to be causal, likely to be causal, suggestive of a causal relationship, inadequate to infer a causal relationship or not likely to be a causal relationship. Historically, the Agency estimates the incidence of air pollution effects for those health endpoints that the ISA classified as either causal or likely-to-be-causal. The focus on categories identified as having a "causal" or "likely to be causal" relationship with the pollutant of interest allows for the estimation of pollutant-attributable human health benefits in which the Agency is most confident.

Though we begin with studies identified in ISAs, the goals of an ISA differ greatly from those of benefits assessments. ISAs evaluate the overall state of the science and develop overarching conclusions regarding the relationship between exposure to the pollutant of interest and adverse health effects. The ISA considers the potential for some groups of people, such as people with pre-existing conditions, to experience risks that may not be generalizable to the entire U.S. population. For a benefits analysis, EPA systematically reviews the body of available epidemiological studies and risk estimates identified in the ISAs using explicit criteria to identify which studies and risk estimates are a best fit for use in a benefits analysis. These criteria include factors such as study design, geographic coverage, demographic populations, and health

endpoints. EPA's systematic review process and study selection criteria are presented in its Technical Support Document, "Estimating $PM_{2.5}$- and Ozone-Attributable Health Benefits" (Benefits TSD).[51]

The commenter states a principal flaw in the Agency's estimation of benefits is that the Agency's RIA is at odds with the Agency's own 2020 NAAQS review process where the Agency-drafted Integrated Science Assessment (ISA) found inconsistent associations between ozone and respiratory mortality. This is incorrect for both the short- and long-term causality determination for ozone exposure and respiratory outcomes, including respiratory mortality.

The 2020 Ozone ISA determined that there exists a "causal" relationship between short-term ozone exposure and respiratory outcomes (U.S. EPA, 2020b). The short-term exposure causality determination "was made on the basis of a strong body of evidence integrated across controlled human exposure, animal toxicological, and epidemiologic studies, in addition to established findings from previous [Air Quality Criteria Documents], demonstrating respiratory effects due to short-term exposure to ozone." While the ISA found that "recent epidemiological evidence for respiratory mortality is limited, …there remains evidence of consistent, positive associations, specifically in the summer months." The ISA also found that "when recent evidence is considered in the context of the larger number of studies evaluated in the 2013 O3 ISA, there remains consistent evidence of an association between short term ozone exposure and respiratory mortality." Due to the strength of the ISA evidence relating short-term exposures to respiratory mortality, estimates of respiratory mortality impacts are included in the main benefits assessment of ozone-attributable health impacts.

Regarding the selection of which study and risk estimate to use to quantify long-term ozone-related mortality benefits, the 2020 Ozone ISA determined that there exists a "likely to be causal" relationship between long-term ozone exposure and respiratory outcomes (U.S. EPA, 2020b). The overall "likely to be causal" determination for long-term exposures "was based on epidemiologic evidence of associations between long-term ozone exposure and asthma development, respiratory symptoms in children with asthma, and respiratory mortality." More specifically, the ISA found that "there is strong coherence between animal toxicological studies of changes in lung morphology and epidemiologic studies reporting positive associations between long-term ozone exposure and new onset asthma, respiratory symptoms in children with asthma, and respiratory mortality" and the "several multicity studies and a multi-continent study reported associations between short-term increases in ozone concentrations and increases in respiratory mortality." Overall, the 2020 Ozone ISA concluded there was "some evidence that long-term ozone exposure is associated with respiratory mortality, but the evidence is not consistent across studies." Due to the strength of the ISA evidence relating long-term exposures to respiratory mortality, we included estimates of respiratory mortality impacts when estimating benefits attributable to changes in ozone exposure associated with the proposal.

---

[51] U.S. Environmental Protection Agency (U.S. EPA). 2021. Estimating PM2.5- and Ozone-Attributable Health Benefits. Technical Support Document (TSD) for the Final Revised Cross-State Air Pollution Rule Update for the 2008 Ozone Season NAAQS. EPA-HQ-OAR-2020-0272. March. Available at: https://www.epa.gov/sites/default/files/2021-03/documents/estimating_pm2.5-_and_ozone-attributable_health_benefits_tsd_march_2021.pdf.

The study and risk estimate EPA identified as most suitable to quantify long-term ozone-related mortality benefits was Turner et al., 2016, which examined the relationship between long-term ozone exposure and mortality (all-cause, cause-specific) in American Cancer Society Cancer Prevention Study-II participants (aged 30-99 years). We found that the Turner study provides strong evidence that demonstrates positive associations between long-term ozone exposure and respiratory mortality. Compared to alternative long-term ozone mortality studies such as Jerrett et al., 2009, the Turner study has a larger study size, more U.S. study locations, and a different exposure estimation technique. EPA's Technical Support Document, "Estimating PM2.5- and Ozone-Attributable Health Benefits" describes the study and criteria used in its selection in more detail.[52]

The commenter took issue with the selection and use of the Turner study in the proposal claiming several deficiencies: that it applies an incorrect exposure window to the underlying data set; that it applies a year-round exposure metric, as opposed to an ozone-season metric; and that it fails to account for a long-term mortality threshold. We address each of these claims in turn.

We acknowledge that there is uncertainty whenever temporal misalignment exists between pollutant exposure and outcome data in the air pollution health effects literature. That uncertainty also applies to the exposure window assumptions Turner et al. used to derive the risk estimate we applied in the proposal's high-end estimate of ozone-related benefits. The Turner study acknowledged this uncertainty but observed that "[t]hough we lacked historical ozone data, there was little difference in respiratory mortality HRs in previous work when researchers examined specific exposure time windows or ozone exposures matched more closely in time. Recent ozone concentrations are correlated with past estimates. Correlations between 1998–2000 concentrations and those from 1988–1990 and 1978–1980 were 0.80 and 0.58, respectively." Despite this uncertainty, the rigorous study review and study selection criteria we apply (described earlier in this response) identified the Turner et al. study as the most suitable to quantify long-term ozone-related respiratory mortality benefits. We qualitatively address this source of uncertainty in the Benefits TSD.

Regarding the comment that we erroneously applied a year-round exposure metric instead of an ozone-season metric, this is incorrect. Turner et al., 2016, provided a warm-season specific hazard ratio of 1.08 (1.06-1.11) per 10 ppb increase in seasonal average of daily 8-hour maximum ozone concentrations, which we used with air quality surfaces for the summer season (April – September). Notably, the study compared annual mortality with warm-season ozone exposures, so full-year baseline incidence rates were used with risk estimates from this study. We therefore appropriately quantified annual cases of ozone-related respiratory mortality attributable to the seasonal average change in ozone associated with proposal.

The commenter also faulted the Agency for failing to account for a threshold of effects in its estimation of long-term mortality benefits. The 2020 final Ozone ISA evaluated many studies

[52] U.S. Environmental Protection Agency (U.S. EPA). 2021. Estimating PM2.5- and Ozone-Attributable Health Benefits. Technical Support Document (TSD) for the Final Revised Cross-State Air Pollution Rule Update for the 2008 Ozone Season NAAQS. EPA-HQ-OAR-2020-0272. March. Available at: https://www.epa.gov/sites/default/files/2021-03/documents/estimating_pm2.5-_and_ozone-attributable_health_benefits_tsd_march_2021.pdf.

examining the shape of the concentration-response relationship for long-term ozone exposure and mortality using various different statistical techniques, including linear models and restricted cubic splines, which were used to inform the long-term ozone-attributable respiratory mortality relationship (U.S. EPA, 2020b). The ISA concluded that:

> Generally linear, no-threshold relationships exist down to 35−40 ppb, although the results were not entirely consistent. Some studies observed a sublinear relationship, indicating larger changes in risk for higher ozone concentrations compared with lower ozone concentrations. Several studies also included threshold analyses and support the possibility of a threshold near 35 to 40 ppb. (U.S. EPA, 2020b, section 6.2.7)

The ozone ISA also found that:

> Recent multicity studies continue to support a linear [concentration-response] relationship with no evidence of a threshold between short term ozone exposure and mortality over the range of ozone concentrations typically observed in the U.S. Studies that used different statistical approaches and ozone averaging times (i.e., 24 hour avg and 8 hour max) provide evidence of a linear concentration-response relationship, with less certainty in the shape of the curve at lower concentrations [i.e., 40 ppb for 24 hour avg and 30 ppb for 8 hour max]. An examination of whether a threshold exists in the ozone mortality concentration-response relationship provided no evidence of a concentration below which mortality effects do not occur when examining 5 μg/m3 (~2.55 ppb) increments across the range of 1 hour max concentrations reported in the U.S. and Canadian cities included in [a large cohort]. (U.S. EPA, 2020b, section 6.1.8)

Collectively, these results continue to support the conclusion of the 2006 Ozone Air Quality Criteria Document that "if a population threshold level exists in ozone health effects, it is likely near the lower limit of ambient ozone concentrations in the U.S." and thus we assume linear, no-threshold relationships exist between ozone and health impacts in the benefits that were estimated for the proposal.

The Turner study did not provide threshold models or find evidence supporting a threshold associated with warm-season effects, which is the hazard ratio we selected from the study. The Turner study did find "some evidence that a threshold model improved model fit for respiratory mortality at 35 ppb (P = 0.002) compared with a linear model using year-round but not summertime O3 (HR per 10 ppb using threshold ozone indicator at 35 ppb for respiratory mortality, 1.17; 95% CI, 1.11–1.22)." We believe the no-threshold assumption continues to be appropriate for both the high-end estimate of long-term ozone mortality benefits (based on Turner et al.), and the low-end estimate of short-term ozone mortality benefits (based on Katsouyanni et al., 2009).

The commenter takes issue with the fact that EPA estimates the number and value of respiratory mortality associated with long-term exposure to ozone as a high-end estimate of ozone-related benefits, and note that by monetizing those benefits, we have "completely upended the long-established history of multi-pollutant air quality benefits assessments in which ozone mortality benefits are substantially smaller than $PM_{2.5}$ benefits." This statement ignores the possibility that scientific progress allows for the expansion of benefits quantified and monetized by the Agency along with the fact that different air quality regulations reduce ambient $PM_{2.5}$ and ozone exposures in different scales and proportions. It is not unexpected that a rule predominantly controlling NO_X emissions would yield large ozone-related health benefits.

The commenter also alleges that the Agency substantially overestimated benefits in the proposal because we did not apply a confidence-weighting approach to account for declining confidence in the relationship between pollution exposure and health response. We believe this confidence-weighting approach is not consistent with the approach to estimating benefits recommended by the National Academy of Sciences' National Research Council (NRC) and the Science Advisory Board (SAB),[53,54] and is not supported by the literature upon which our primary estimate of benefits for the proposal was based.

EPA has long acknowledged that there are multiple sources of uncertainty present in its benefits analyses that may bias benefits in either a downward or upward direction. To demonstrate the uncertainty associated with air pollution exposures observed in health studies compared to exposures modeled in the proposal, we provided a stylized graphic that makes the point that we are more confident in the magnitude of the risks we estimate from simulated pollutant concentrations that coincide with the bulk of the observed concentrations in the epidemiological studies that are used to estimate the benefits. The graphic is not meant to convey any certainty about where along that spectrum a cut-off (or threshold) exists below which there would be no health benefit from reduced exposure. EPA does not view the lower end of the distribution of concentration levels reported in the mortality studies as a threshold below which we would not quantify the health benefits of air quality improvement, nor do we believe that cut-offs exist at arbitrary percentiles of the distribution or even at the level of the NAAQS. Rather, the benefits estimates reported in the proposal were the most appropriate estimates because they reflect the full range of air quality concentrations associated with the emission reduction program that was evaluated. In fact, as demonstrated in Figure 8-2 of the proposal, the range of baseline $PM_{2.5}$ pollution concentrations are almost entirely above the lowest recorded PM levels in the studies, the population-weighted mean concentration of the distribution is between 7 and 8 ug/m3, and the distribution of concentrations is skewed more toward the level of the NAAQS than the lowest recorded concentration levels.

Regarding the commenter's specific assertion that EPA has overestimated $PM_{2.5}$-related benefits due to "the inherent unsupported assumption that the derived C-R relationships continue to hold fully, well below the ranges of exposure observations on which those C-R relationships were based," we reject this premise. As detailed in the 2019 PM ISA and previous assessments in support of the PM NAAQS, EPA's review of the science has consistently found no evidence of a threshold below which exposure to $PM_{2.5}$ yields no health response. Specifically, the 2019 PM ISA found that "extensive analyses across health effects continues to support a linear, no-threshold concentration-response (C-R) relationship." This conclusion in the 2019 PM ISA is

[53] NRC (2002). Estimating the public health benefits of proposed air pollution regulations. 0309086094. National Academies Press; NRC (2008). Estimating the Mortality Risk Reduction and Economic Benefits from Controlling Ozone Air Pollution.
[54] U.S. Environmental Protection Agency—Science Advisory Board (U.S. EPA-SAB). 2010. Review of EPA's Draft Health Benefits of the Second Section 812 Prospective Study of the CAA.

supported by the more recent evaluation of the health effects evidence detailed in the recently released Draft Supplement to the PM ISA which found "continued evidence of a linear, no-threshold concentration-response (C-R) relationship."

Based on the evidence and lack of nonlinear relationships between long-term $PM_{2.5}$ exposure and health impacts, we continue to assume a linear, no-threshold relationship and do not quantitatively assess uncertainties related to the shape of the concentration-response relationships, either through a so-called "confidence weighting" approach or otherwise. We instead address this uncertainty qualitatively.

In summary, we believe that the primary estimate of benefits presented in the proposal for both Option 1 and Option 2 is based on methods and assumptions that are consistent with applicable guidance and best practices for conducting benefit-cost analyses and reflect a best estimate of the total health-related benefits from the proposed program that we are able to quantify and monetize. The benefits of both scenarios, Option 1 and Option 2, far outweigh the costs associated with those same scenarios. See Preamble Section VIII for the benefits estimates for the final program and Preamble Section IX for a comparison of benefits and costs of the final program. Like the proposed options, these estimates are based on methods and assumptions that are consistent with applicable guidance and best practices for conducting benefit-cost analyses and reflect a best estimate of the total health-related benefits from the final program that we are able to quantify and monetize, and the benefits outweigh the costs.

21.2 EPA Should Clarify its Economic Assumptions

Organization: *Institute for Policy Integrity at New York University School of Law (Policy Integrity)*

EPA should clarify its economic assumptions to better explain its choices in its methodology. In particular, EPA should provide additional discussion regarding how the agency incorporates income changes into the value of a statistical life, considers the cost of illness, and accounts for learning-by-doing in calculating compliance costs. [EPA-HQ-OAR-2019-0055-1256-A1, p. 2]

In the Proposed Rule, EPA has adjusted the value of statistical life ("VSL") over time for an increase in GDP per capita84 consistent with its own most recent guidelines.85 We applaud the agency for taking this theoretically and empirically correct choice.86 However, to strengthen the Final Rule, EPA should further clarify its reasoning and process in adjusting VSL over time. [EPA-HQ-OAR-2019-0055-1256-A1, p. 15]

84. DRIA, supra note 41, at 379.

85. EPA Guidelines, supra note 35, at App'x B.

86. See W. K. Viscusi & C. J. Masterman, Income Elasticities and Global Values of a Statistical Life, 8 J. BENEFIT-COST ANALYSIS 226–50 (2017); C. J. Masterman & W. K. Viscusi, The Income Elasticity of Global Values of a Statistical Life: Stated Preference Evidence, 9 J. BENEFIT-COST ANALYSIS 407–34 (2018).

Currently, the RIA states that it discusses how "evidence and theory suggest that one's willingness-to-pay (WTP) for health and environmental improvements should increase as real income increases" in the accompanying Technical Support Document ("TSD").87 However, Policy Integrity was unable to identify this discussion in the TSD. Critically, as the quantity of life is limited (i.e., individuals have only one life) in comparison to most consumption goods, the relative value of a statistical life increases over time as GDP rises over time. In other words, as consumption goods become less scarce relative to non-market goods such as the environment and health goods and services, the relative price of these non-market goods and services rises in contrast to the more abundant market goods.88 [EPA-HQ-OAR-2019-0055-1256-A1, pp. 15 - 16]

87. DRIA, supra note 41, at 379 (referencing Sections 5.4 and 6.4.3 of the TSD)

88. M. Hoel & T. Sterner, Discounting and Relative Prices, 84 CLIMATIC CHANGE 265–80 (2007); T. Sterner & U. M. Persson, An Even Sterner Review: Introducing Relative Prices into the Discounting Debate, 2 REV. ENV'T ECON. & POL'Y 61 (2008).

EPA should also discuss more clearly its calculation of the VSL in the RIA. EPA lays out the source for income (i.e., GDP per capita) growth calculations and extends "income growth adjustment factors out to 2045" as growth is expected to increase into the future leading to a rise in the VSL.89 However, EPA does not introduce the magnitude of the income elasticity and its corresponding source. Presumably, it uses the central value of 0.4 given in Appendix B of EPA's Guidelines for Preparing Economic Analyses.90 However, recent research finds a higher value for the United States between 0.5 to 0.7 with a best estimate of 0.55.91 Accordingly, EPA should clarify why it selected its current value of 0.4, particularly given that it has previously used a value of 0.55.92 EPA should conduct a literature review to determine the most appropriate value. It should also explain its reasoning for not including sensitivity analysis with respect to this parameter given that EPA's guidelines specify a wide range between 0.08 to 1.0.93 This empirical question is important because a higher income elasticity will increase the benefits of reducing air pollution. 94 [EPA-HQ-OAR-2019-0055-1256-A1, p. 16]

89. DRIA, supra note 41, at 379.

90. EPA Guidelines, supra note 35, at B-4.

91. Viscusi & Masterman (2017), supra note 86; Masterman & Viscusi (2018), supra note 86.

92. 85 Fed. Reg. 24,174, 24,827 (April 30, 2020).

93. EPA Guidelines, supra note 35, at B-4.

94. EPA correctly adjusted VSL for rising GDP per capita, but not individuals or sub-populations within the United States. This is consistent with Appendix B of EPA's

Guidelines for Preparing Economic Analyses, supra note 35. It is also consistent with the United States's use of a uniform VSL applied to all individuals equally within the United States.

EPA should also consider addressing the impact of the rising relative value of statistical life on household decisions. Specifically, a rise in the real value of a statistical life should lead the household to take more protective action for air quality. In other words, as households become richer and place more value on reducing risk, we should see more defensive behavior on the extensive and intensive margins. For example, households should buy more air purifiers, cleaners, or filters and run them more frequently, as well as take other actions such as wearing face masks and staying indoors until their marginal benefit equals their marginal cost.95 Ideally, the agency would quantitively calculate the impact of rising income on the baseline and alternative scenarios, as well as the cost of this defensive behavior. As the cost differences between these scenarios are likely to be small, this could reasonably be addressed with a qualitative discussion. [EPA-HQ-OAR-2019-0055-1256-A1, pp. 16 - 17]

95. Ruth Dittrich & Stuart McCallum, How to Measure the Economic Health Cost of Wildfires—A Systematic Review of the Literature for Northern America, 29 INT'L J. WILDLAND FIRE 961–73 (2020).

EPA underestimates the true economic value of air pollution reduction as it uses the cost of illness approach ("COI") instead of society's willingness-to-pay for changes in risk of a given health effect. EPA should discuss the type of impacts omitted from valuing morbidity impacts using this approach and the potential magnitude of these omissions. [EPA-HQ-OAR-2019-0055-1256-A1, p. 17]

For example, a COI approach omits many important impacts of illness, including the lower quality of life that individuals experience from illness. Beyond the suffering associated with morbidity, which the EPA briefly mentions,96 the COI approach also excludes lost productivity from workers facing higher air pollution. At a minimum EPA should address this qualitatively, ideally in conjunction with a sensitivity analysis using willingness-to-pay estimates from the existing literature.97 [EPA-HQ-OAR-2019-0055-1256-A1, p. 17]

96. See DRIA, supra note 41, at 387 ("These cost-of-illness (COI) estimates are typically a lower bound estimate of the true value of reducing the risk of a health effect because they reflect the direct expenditures related to treatment, but not the value of avoided pain and suffering.")

97. Dittrich & McCallum (2020), supra note 95.

In using the COI approach, the EPA does not clearly state whether its estimates include opportunity costs such as income losses due to absence from work, which a willingness-to-pay approach is more likely to reflect. This is critical, as the COI approach "only looks at direct costs from morbidity: it sums the resource and opportunity costs from being sick – the treatment cost and lost wages – without considering the disutility associated with pain, discomfort, and lower quality of life... The cost of the preventative action taken to avoid becoming sick is also not taken into account (e.g. the cost of buying an air cleaner)."98 [EPA-HQ-OAR-2019-0055-1256-A1, p. 17]

98. Id.

EPA states in the RIA that its cost estimates account only for direct treatment costs99—excluding the lost wages recommended in the literature. If EPA's COI approach does not go beyond direct treatment costs, the agency is underestimating morbidity costs in its COI calculations. As the COI approach is already an underestimate as compared to the willingness-to-pay approach, only accounting for direct treatment costs would represent a significant underestimation of the morbidity impacts. This is concerning and should be addressed qualitatively at a minimum. [EPA-HQ-OAR-2019-0055-1256-A1, p. 17]

99. DRIA, supra note 41, at 398 ("cost-of-illness (COI) estimates…reflect the direct expenditures related to treatment").

Regardless, the EPA's use of the COI approach and its potential underestimation implies that the net benefits of regulation are potentially significantly higher. EPA should explicitly take this into account when selecting between alternatives. [EPA-HQ-OAR-2019-0055-1256-A1, p. 17]

EPA Summary and Response

Summary:

The commenter provided input and recommendations for improving the documentation of methodological assumptions related to income growth adjustment, the VSL, COI estimates, and the impact of rising income on household decisions to avert risk.

Response:

EPA acknowledges the commenter's input and recommendations for improving the documentation of methodological assumptions related to income growth adjustment, the VSL, COI estimates, and the impact of rising income on household decisions to avert risk. We may consider these suggestions in future rulemakings.

For more information on the derivation of income elasticity estimates EPA uses to develop income growth adjustment factors, please refer to the memorandum available here: https://www3.epa.gov/ttnecas1/regdata/Benefits/IncomeElasticityUpdate_Recommendationswithappendices.pdf. We note that a quantitative sensitivity analysis of income growth adjustment factors is included in the Benefits TSD. We also note that EPA has consistently applied the central income growth adjustment (or the "mid" value) to the WTP for each corresponding health endpoint, as referenced in the Benefits TSD. EPA may consider the suggestion to conduct a literature review for future rulemakings.

For more information on the estimation of the Value of a Statistical Life (VSL), please refer to Appendix B of EPA's Guidelines for Preparing Economic Analyses (Guidelines), which can be downloaded here: https://www.epa.gov/environmental-economics/guidelines-preparing-economic-analyses. As stated in RIA Chapter 8, the Agency is committed to using scientifically sound, appropriately reviewed evidence in valuing changes in the risk of premature death and continues to engage with the Science Advisory Board to update its mortality risk valuation estimates.

Chapter 5 of the Benefits TSD provides detail on what is and is not included in the Cost-of-Illness valuation estimates for each endpoint. Chapter 7 of the Guidelines also describe Cost-of-Illness (COI) valuation estimates in more detail. We agree that there are additional human health and environmental benefits associated with reductions in exposure to ambient concentrations of $PM_{2.5}$, ozone, and NO_2 that EPA has not quantified due to data, resource, or methodological limitations, including the limitations of the COI approach to capture the value of avoiding non-fatal health endpoints. The estimated benefits of the proposal and the final rule would be larger if we were able to monetize all unquantified benefits. We do not expect that the monetization of unquantified benefits would modify our consideration of alternatives.

The approach used by EPA in estimating learning effects is explained in the final RIA Section 7.1.1 and was derived from, "Cost Reduction through Learning in Manufacturing Industries and in the Manufacture of Mobile Sources, Final Report and Peer Review Report," EPA-420-R-16-018, November 2016.See our response in section 21.2 of this document regarding the factors EPA assessed in setting the final standards and in promulgating the final rule.

21.3 NO_2-related Health Benefits

Organization: *Various Academic Researchers*

NOx emissions are precursors to PM2.5 and ozone, which contribute tens of thousands of premature deaths each year in the U.S. Heavy-duty trucks and buses are responsible for a substantial share of PM2.5- and ozone-attributable premature deaths. Traffic-related air pollution is responsible for an estimated 22,000 premature deaths in the U.S. each year, about 19% of all PM2.5- and ozone-attributable deaths in the U.S.1 On-road diesel vehicles contribute an estimated 43% of these traffic-related air pollution deaths. The vast majority of diesel vehicles in the U.S. are the heavy-duty vehicles that would be affected by the proposed emissions standards. [EPA-HQ-OAR-2019-0055-1220-A1, p. 1]

> 1. Anenberg, S. C.; Miller, J.; Henze, D. K.; Minjares, R.; Achakulwisut, P. The Global Burden of Transportation Tailpipe Emissions on Air Pollution-Related Mortality in 2010 and 2015. Environ. Res. Lett. 2019, 14 (9), 094012. https://doi.org/10.1088/1748-9326/ab35fc.

Health impacts from NO2 pollution were not accounted for in the Regulatory Impact Analysis (RIA) for this proposed rule. Our research has revealed that NO2 pollution could be responsible for a large fraction of new onset of pediatric asthma in U.S. cities.2 For example, we estimated that NO2 was responsible for about 33% of new pediatric asthma cases in Los Angeles and New York City, and about 25% in Washington, DC.4 The proposed strengthening of NOx emissions limits for HDVs would substantially reduce NO2 pollution, with important benefits for children’s respiratory health and development. These health benefits are not just statistics; asthma affects children throughout their entire lives. The exclusion of NO_2-attributable health impacts leads to underestimated benefits in the RIA. [EPA-HQ-OAR-2019-0055-1220-A1, pp. 1 - 2]

4. Achakulwisut, P.; Brauer, M.; Hystad, P.; Anenberg, S. C. Global, National, and Urban Burdens of Paediatric Asthma Incidence Attributable to Ambient NO_2 Pollution: Estimates from Global Datasets. The Lancet Planetary Health 2019, 3 (4), e166–e178. https://doi.org/10.1016/S2542-5196(19)30046-4.

Improved methods are needed to estimate health and environmental justice benefits from reduced NO_2 concentrations

The RIA for this proposed rule estimates that the emissions standards would avoid up to 2,100 premature deaths and 6,700 hospital admissions and emergency department visits from reduced $PM_{2.5}$ and ozone, among other health benefits. The RIA discusses how communities of color disproportionately live near high-volume roads. It also includes a demographic analysis of air quality changes resulting from the standards, finding that “the largest predicted improvements in both ozone and $PM_{2.5}$ are estimated to occur in areas with the worst baseline air quality, where a substantially larger number of people of color are expected to reside.” [EPA-HQ-OAR-2019-0055-1220-A1, p. 2.]

The Justice40 Initiative is aimed at ensuring that 40% of the benefits of governmental programs accrue to overburdened communities. The proposed HDV NO_x emissions standards are likely to dramatically narrow the inequities in traffic-related air pollution exposure and associated health risks across the U.S. and within individual U.S. cities. But the current RIA, as well as traditional methods EPA uses to estimate health benefits of improved air quality, are unable to capture the distributional benefits, particularly for rules that have the potential to dramatically narrow inequities, like rules affecting NO_x emissions from vehicle tailpipes. [EPA-HQ-OAR-2019-0055-1220-A1, p. 3.]

In particular, several key limitations preclude the RIA for these proposed standards from revealing which communities could experience the greatest improvements in air quality and associated health benefits. First, the chemical transport model simulations were conducted at 12km x 12km spatial resolution, too coarse to capture neighborhood-scale impacts. Second, the RIA did not include a demographic analysis of the health benefits of the rule. Finally, the analysis focused only on ozone and $PM_{2.5}$, and did not include NO_2, a pollutant that is one of the most inequitably distributed in U.S. cities and that is also most affected by HDV NO_x emissions standards. Thus, while this proposed rule could dramatically narrow inequities in air pollution-attributable health risks across the U.S., particularly for NO_2, the demographic distribution of the rule's air quality and health benefits is currently unknown. [EPA-HQ-OAR-2019-0055-1220-A1, p. 3.]

Improved methods are therefore needed to estimate health and environmental justice benefits from reduced PM2.5, ozone, and NO2 concentrations resulting from this proposed rule. This should include high spatial resolution chemical transport modeling to estimate neighborhood-scale changes in air pollution concentrations; considering NO2 concentrations as well as PM2.5, ozone, and NO2 health impacts; and population and disease rates that are spatially disaggregated. [EPA-HQ-OAR-2019-0055-1220-A1, p. 3.]

EPA Summary and Response

Summary:

The commenter notes that the proposed standards would bring about substantial health benefits, including to those who live near roads and to those who live in communities with EJ concerns. The commenter also suggests that the Agency should consider methods to better estimate the health and environmental justice benefits from reduced NO2 concentrations like those that would be achieved by the proposed and final program.

The commenter specifically noted three key limitations to our analysis: the spatial resolution of our photochemical air quality modeling, the absence of a demographic analysis of health benefits, and the omission of quantified and monetized NO2 health impacts.

Response:

Thank you for your comments. We agree that the proposed standards would bring about substantial health benefits, including to those who live near roads and to those who live in communities with EJ concerns. We also agree that the Agency should consider methods to better estimate the health and environmental justice benefits from reduced NO_2 concentrations like those that would be achieved by the proposed and final program. EPA intends to continue to consider how to better reflect NO_2-related benefits as well as the overall distributional implications of future regulatory actions.

The commenter specifically noted three key limitations to our analysis: the spatial resolution of our photochemical air quality modeling, the absence of a demographic analysis of health benefits, and the omission of quantified and monetized NO_2 health impacts. We will address the first and third of these limitations here and refer the reader to Section 22 of this document for a response to comments regarding demographic analyses of health benefits.

We agree that the chemical transport model simulations that were conducted at a 12km x 12km grid cell spatial resolution are too coarse to capture neighborhood-scale impacts. EPA is considering how to better estimate the near-roadway air quality impacts of its regulatory actions and how those impacts are distributed across populations. Because the heavy-duty standards apply nationally and will be implemented consistently across roadways throughout the U.S., we can still make useful observations of demographic trends at a national scale using the air quality modeling data at a 12km x 12km resolution. The Agency continues to research highly resolved air quality data and intends to incorporate new methods and modeling techniques after they become available.

Regarding the quantification and monetization of NO_2-related health impacts, the Integrated Science Assessment for Oxides of Nitrogen makes clear that given the current literature, it is difficult to disentangle the effects of other pollutants, such as PM and ozone, from NO_2 to specifically estimate health effects such as premature mortality.[55] There is, however, evidence that NO_2 can be associated with asthma incidence, and the Agency intends to continue to consider how best to quantify this endpoint in future regulatory actions. Such consideration could apply the same systematic process for selecting, quantifying, and monetizing NO_2-related health impacts as it has for $PM_{2.5}$ and ozone. This process includes: applying criteria for identifying and selecting studies and risk estimates most appropriate to inform a benefits analysis for an RIA; identifying pollutant-attributable health effects for which the ISA reports strong evidence and that may be quantified in a benefits assessment; collecting baseline incidence and prevalence estimates and demographic information; developing appropriate economic unit values; and characterizing uncertainty with quantified benefits estimates.

21.4 General Comments About the Benefits of the Proposal

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

According to EPA's own analysis, Option 1 would produce at least $11 billion and up to $50 billion more in present-value monetized benefits than Option 2 (depending on the discount rate and other factors) due to reduced mortality and avoided illnesses. See DRIA at 403–04 & Table 9-1. And those figures do not account for the additional unquantified but valuable human health and environmental benefits that Option 1 would create. 87 Fed. Reg. at 17,428, 17,590. [EPA-HQ-OAR-2019-0055-1302-A1, p.50]

Organization: *International Council on Clean Transportation (ICCT)*

The human health costs are high and will increase each year the U.S. fails to reduce pollutants from the most-polluting vehicles on the road. An ICCT study showed in 2015, the U.S. lost 2,982 lives to premature death caused by on-road diesel vehicle NOx emissions, largely from heavy-duty vehicles that were shown to have 10 times the impact of light-duty diesel cars.xl Given that the travelled mileage from heavy-duty trucks in the U.S. is rising – about 13 percent from 2010 to 2020xli – more stringent NOx standards for HDTs that pollute at disproportionately high levels are a crucial piece of protecting public health. [EPA-HQ-OAR-2019-0055-1310-A1, p.7]

> xl ICCT, New Study Quantifies Global Health, Environmental Impacts of Excess Nitrogen Oxide Emissions from Diesel Vehicles, May 15, 2017, https://theicct.org/new-

[55] U.S. EPA (2016). Integrated Science Assessment for Oxides of Nitrogen – Health Criteria. U.S. Environmental Protection Agency. Washington, DC. Office of Research and Development. EPA/600/R-15/068. Available at: https://cfpub.epa.gov/ncea/isa/recordisplay.cfm?deid=310879.

study-quantifies-global-health-environmental-impacts-of-excess-nitrogen-oxide-emissions-from-diesel-vehicles/

xli U.S. Department of Transportation, Bureau of Transportation Studies, 'Single-Unit 2-Axle 6-Tire or More Truck Fuel Consumption and Travel (metric), https://www.bts.gov/content/single-unit-2-axle-6-tire-or-more-truck-fuel-consumption-and-travel-0.

Previous ICCT research has shown that achieving a 90% NOx reduction for model year 2027 and later diesel engines could avoid more than $1 trillion in air pollution-related health damages cumulatively from 2027–2050. [EPA-HQ-OAR-2019-0055-1211-A1, p. 7]

The EPA analysis shows the adoption of Option 1 will result in substantial air quality benefits. Annual NOx reductions in 2030 and 2040 are 16.4 and 55.9 percent. PM2.5 emissions are reduced 3.4 and 23.7 percent. And benzene, an air toxic, is reduced 4.1 and 23.1 percent. Reducing the health impacts of exposure to these pollutants is especially important to residents of communities located close to high truck traffic. [EPA-HQ-OAR-2019-0055-1211-A1, p. 14]

EPA's analysis of health benefits indicates the proposed Option 1 standards when fully implemented in 2045 will reduce premature deaths by about 3,000 per year. The average monetized value of all health benefits of Option 1 (at a 7 percent discount) is 5.3 times the total cost of compliance. Option 2 provides lower benefits and higher costs with a less favorable benefit/cost ratio of 3.8. [EPA-HQ-OAR-2019-0055-1211-A1, p. 15]

Organization: *Public Citizen and Healthy Port Communities Coalition (HPCC)*

We support the Proposal's inclusion of a health benefits analysis that demonstrates Option 1's significant health savings of $12 to $33 billion (3% discount rate) or $10 to $30 billion (7% discount rate). Many of these benefits will be delivered to communities that are overburdened by pollution from sources beyond transportation-related emissions. Some of these communities may also lack adequate access to health insurance and health care services, so prevention of pollution and resulting disease could provide much needed relief to those harmed by pollution from heavy-duty vehicles. [EPA-HQ-OAR-2019-0055-1417-A2, p. 1]

Our own work shows that vehicle turnover and electrification can reduce health and financial burdens on the public. In 2017, Public Citizen and our partners at the Healthy Port Communities Coalition worked with University of Houston researchers to better understand the benefits that cleaning up transportation-related pollution would have on the greater Houston region in terms of the amount and distribution of air pollution and health benefits. The study found over $1.5 billion in monetized health benefits from aggressive electrification where 70% of the fleet in Greater Houston (both light- and heavy-duty vehicles) is electrified in model year 2040. This scenario would prevent nearly 200 premature deaths per year.1 [EPA-HQ-OAR-2019-0055-1417-A2, pp. 1 - 2]

1. https://www.citizen.org/wp-content/uploads/migration/public-citizen-air-quality-transportation-houston-report-october-2018.pdf

Organization: *Zero Emission Transportation Association (ZETA)*

According to the American Lung Association, the widespread transition to zero-emission transportation by 2050 can annually produce up to $72 billion in avoided health costs, save approximately 6,300 lives, and prevent more than 93,000 asthma attacks and 416,000 lost workdays.6 These positive health impacts will be most significant among frontline communities, whose members are disproportionately likely to live near highways and suffer from poor air quality.7 This higher exposure burdens underserved residents with negative health outcomes and higher healthcare costs. [EPA-HQ-OAR-2019-0055-1283-A1, p.2]

6 https://www.lung.org/ getmedia/99cc945c-47f2-4ba9-ba59-14c311ca332a/electric-vehicle-report.pdf

7 https://www.smithsonianmag. com/history/how-federal-government-intentionally-racially-segregated-americancities-180963494

Beyond its negative health impacts, transportation-based pollution damages the environment in myriad ways. The VOCs and NOx emitted by diesel vehicles react to form dangerous ground-level ozone, which forms smog and leaves agricultural crops and forests particularly susceptible to stunted growth and a decreased ability to sequester CO_2. Likewise, nitric acid, another tailpipe pollutant, forms acid rain that leaches into the ground and waterways. Perhaps the most dramatic effect of diesel burning is its emission of global warming-causing GHGs. Global warming, in turn, causes extreme weather patterns, reductions in air quality, a rise in sea levels, and leads to widespread species extinction.8 [EPA-HQ-OAR-2019-0055-1283-A1, p.2]

EPA Summary and Response

Summary:

The commenters noted that the health benefits of the regulatory options analyzed in the proposal are significant and meaningful both to the U.S. population as a whole and to communities currently overburdened by pollution, and that Option 1 yielded higher benefits than Option 2. Commenters also noted the potential benefits of electrification.

Response:

Thank you for your comments. EPA agrees that the health benefits of the regulatory options analyzed in the proposal are significant and meaningful both to the U.S. population as a whole and to communities currently overburdened by pollution. We also agree that the benefits of the proposed program outweigh their costs, as they also do for the final program. See RIA Chapter 8 for a complete description of the benefits analysis conducted for the final program. In response to comments on the potential benefits of electrification, the final standards are not based on the projected utilization of ZEV technology; however, manufacturers may choose to comply with the standards by using other technologies, including ZEV technologies (see preamble Section III.A for discussion).

22 Demographic Analysis of Air Quality

Comments by Organization

Organization: *Alliance for Vehicle Efficiency (AVE)*

AVE supports incentives to accelerate the adoption of technologies that lower NOx and PM to improve air quality for at-risk communities. [EPA-HQ-OAR-2019-0055-1280-A1, p. 7]

On-road Heavy Duty trucks account for close to 60% of this country's annual NOx emissions which serves as the leading factor of ozone. EPA has an opportunity to improve the air quality and reduce ground level ozone for millions of Americans living in projected Ozone Nonattainment areas. [EPA-HQ-OAR-2019-0055-1280-A1, p. 7]

As of December 2020, approximately 50% of all commercial diesel trucks in operation, nationwide, were purchased after MY 2010 or later, while 50% of the heavy-duty trucks now on the roads continue to operate without the benefit of NOx and PM emissions control technologies. New heavy-duty trucks will be operational for decades. Incentives for compliant trucks, not just ZEVs, purchased prior to the MY 2027 will bring tremendous health benefits to at-risk communities and the nation. [EPA-HQ-OAR-2019-0055-1280-A1, p. 7] [Also in Section 13.4 of this document]

Although states are required to develop and follow pathways to comply with National Ambient Air Quality Standards (NAAQS), NOx emission from on-road heavy duty trucks is a national problem. As heavy-duty trucks travel long distances and often across state lines, a strong and robust federal emissions program is vital to meeting Ozone NAAQS while, at the same time, providing regulatory certainty to the industry and state air regulators across the country. As shown in the chart below, urban areas across the country suffer from significantly unhealthy levels of NOx and PM. [EPA-HQ-OAR-2019-0055-1280-A1, p. 7]

13.6 million Americans living in 11 large and small urban areas and rural counties experienced over 100 days of ozone pollution at levels above what the EPA considers "good" in 2020. [EPA-HQ-OAR-2019-0055-1280-A1, p. 8]

An additional 57.3 million Americans living in 90 large and small urban areas and rural counties experienced between 31 and 100 days of elevated ozone pollution. [EPA-HQ-OAR-2019-0055-1280-A1, p. 8]

Air pollution levels are uneven within cities, contributing to persistent health disparities between neighborhoods and population sub-groups. Highly spatially resolved information on pollution levels and disease rates is necessary to characterize inequities in air pollution exposure and related health risks.14 [EPA-HQ-OAR-2019-0055-1280-A1, p. 8]

14. https://pubmed.ncbi.nlm.nih.gov/34765851/#:~:text=We%20find%20that%20PM2.5,(between%202014%20and%202018).

Organization: *Institute for Policy Integrity at New York University School of Law (Policy Integrity)*

EPA should revise and expand its distributional analysis to better reflect the impacts of the Proposed Rule on vulnerable subpopulations. EPA should conduct a more geographically granular analysis and reconfigure its subpopulation analysis. In addition, EPA should conduct a distributional analysis of all regulatory alternatives under consideration in order to evaluate incremental distributional benefits among alternatives. [EPA-HQ-OAR-2019-0055-1256-A1, p. 1]

EPA Summary and Response

Summary:

Commenters noted that people who live in both urban and rural areas experience elevated exposures to pollution from the heavy-duty engines that would be regulated by the proposed standards.

Commenters also suggested that EPA conduct a more "spatially resolved," "geographically granular" demographic analysis.

The commenter also suggested that EPA conduct a distributional analysis of all regulatory alternatives under consideration in order to evaluate incremental distributional benefits among alternatives.

Response:

We agree with the commenter that people who live in both urban and rural areas experience elevated exposures to pollution from the heavy-duty engines that would be regulated by the proposed standards. The proposed and final standards would bring about substantial health benefits, including benefits to those who live near roads and to those who live in communities with EJ concerns.

The commenters suggest that EPA conduct a more "spatially resolved," "geographically granular" demographic analysis. For the proposal, we conducted chemical transport model simulations at a 12km x 12km grid cell spatial resolution. A limitation of this analysis is the 12km x 12km horizontal grid spacing of the air quality modeling domain. Such resolution is unable to capture the heterogeneity of human exposures to pollutants within that area, especially pollutant concentration gradients that exist near roads. EPA is considering how to better estimate the near-roadway air quality impacts of its regulatory actions and how those impacts are distributed across populations. Because the heavy-duty standards apply nationally and will be implemented consistently across roadways throughout the U.S., we can still make useful observations of demographic trends at a national scale using the air quality modeling data at a 12km x 12km resolution.

The commenter also suggested that EPA conduct a distributional analysis of all regulatory alternatives under consideration in order to evaluate incremental distributional benefits among alternatives. EPA considers computational efficiency when conducting national analyses of policy-relevant air quality scenarios. Conducting full-scale photochemical modeling for all scenarios was not feasible. Furthermore, because the scope of each policy scenario was national, the reductions in secondarily-formed $PM_{2.5}$ and ozone were regional, and the form of the standards did not fundamentally affect the spatial allocation of emissions changes, we believe the demographic analysis we conducted for the proposal was a representative characterization of the distribution of air quality impacts. See RIA Chapter 6 for a description of the demographic analysis of air quality.

23 Environmental Justice

23.1 EPA Needs More Detailed Environmental Justice Analysis

Comments by Organizations

Organization: *Moving Forward Network (MFN)*

The Freight Transportation System Imposes Unacceptable Levels of Cumulative Impacts on Environmental Justice Communities. People who live near freight hubs or "diesel death zones"—including ports, highways, warehouses, and rail and intermodal yards—are disproportionately exposed to high concentrations of pollution from the combined activity of diesel-fueled heavy-duty trucks, equipment, rail, and vessels.10 Countless studies show that diesel-powered vehicles emit fine particulate matter (PM2.5) and nitrogen oxides (NOx), which lead to numerous adverse health outcomes and even premature death. Additionally, heavy-duty trucks and buses are also a major source of climate-warming greenhouse gas (GHG) emissions. [EPA-HQ-OAR-2019-0055-1277-A1, p. 7]

> 10. See, e.g., Loma Linda University, Report, Project ENRRICH: A Public Health Assessment of Residential Proximity to a Goods Movement Railyard, available at http://www.aqmd.gov/docs/default-source/clean-air-plans/clean-communitiesplan/enrrich_final_report_29may2014.pdf.

Unfortunately, a huge number of people in the U.S. are affected by this pollution every day. For example, in 2016, EPA estimated that approximately 39 million people in the United States—mostly low-income people of color—live close to ports and are exposed to elevated levels of diesel pollution.11 Another 45 million people live within 300 feet of a highway.12 People of color and low-income households are disproportionately exposed to elevated levels of diesel pollution.13 Indeed, our health, air pollution, and climate crises are among the most urgent environmental justice issues of our time. [EPA-HQ-OAR-2019-0055-1277-A1, p. 7]

Today, a person's zip code remains the most significant predictor of health and wellbeing. In fact, low income neighborhoods and communities of color breathe in an average of 28 percent more NOx pollution than higher-income and majority white neighborhoods.14 For residents of environmental justice communities, this means that their lives can be 10-20 years shorter because of environmental pollution, compared to residents in wealthy white communities.15 [EPA-HQ-OAR-2019-0055-1277-A1, pp. 7 - 8]

The science behind cumulative impacts is substantial and growing.29 In fact, MFN and its members have long pressed the federal government to acknowledge the multiple and thus cumulative environmental threats environmental justice communities face and their heightened vulnerability to those threats. Specifically, these cumulative impact analyses recognize not only that some individuals and communities face more pollution than others, but also that the same amount of pollution can result in more harm to people facing additional and compounded stressors than to people who do not face such stressors. It also recognizes that these multiple stressors are too often interrelated in their origins. The results are clear— people of color and people with low incomes face some of the highest levels of pollution, and are least equipped to ward off the consequences of this pollution.30 [EPA-HQ-OAR-2019-0055-1277-A1, pp. 10 - 11]

For example, a new study released in March 2022 examines the link between port-related traffic and hospital visits for respiratory, heart-related, and psychiatric issues, and concludes that people of color are more vulnerable to health impacts as a result of increased goods movement operations.31 Adding just one vessel or increasing overall vessel tonnage in a nearby port leads to more than 3 additional hospital visits per year per thousand Black residents, compared to about 1 visit per thousand for white residents in the same area.32 Relatedly, the study also found that reducing fossil fuel use in ports would significantly reduce air pollution concentration, and have an acute and positive benefit to local Black residents. Yet, despite all these well-documented harms, the freight industry continues to grow rapidly in the very communities that are already overburdened, making it more urgent than ever that we fully and properly address our air pollution and climate crises. In fact, over the last three years, more people in the U.S. have experienced “very unhealthy” or “hazardous” air quality than in the last two decades, and people of color are now 3.6 times more likely than white people to live in a county with failing air quality, according to the American Lung Association.33 [EPA-HQ-OAR-2019-0055-1277-A1, p. 11]

33. American Lung Association, 2022 State of the Air, Key Findings, (last visited May 5, 2022), https://www.lung.org/research/sota/key-findings.

Likewise, truck traffic at ports, railyards, and warehouses is on the rise due to historic levels of online shopping, e-commerce, and congestion associated with the COVID-19 pandemic. According to the California Air Resources Board (CARB), during the second half of 2021, truck pollution associated with a surge in cargo volumes at the Ports of Los Angeles and Long Beach contributed almost 2 tons of additional NOx pollution every single day, on top of the existing emissions associated with business-as-usual cargo volumes prior to the pandemic.34 Other freight-impacted communities have also seen spikes in activity as the e-commerce industry expands. The American Lung Association found that in the last three years, more US residents experienced “very unhealthy” or “hazardous” air quality than in the last two decades, with people of color 3.6 times more likely than white people to live in a county with failing air quality.35 [EPA-HQ-OAR-2019-0055-1277-A1, p. 11]

35. American Lung Association, 2022 State of the Air, Key Findings, (last visited May 5, 2022), https://www.lung.org/research/sota/key-findings.

Moreover, critically, the COVID-19 pandemic has escalated the negative consequences from living in a “diesel death zone” or a region with poor air quality. Numerous studies now show that long-term exposure to air pollution makes people more vulnerable to complications and death from COVID-19.36 That neighborhoods with high proportions of Black and Latinx residents experience disproportionately high levels of air pollution may help explain why these groups have suffered disproportionately from the COVID-19 pandemic.37 Indeed, a recent study found that Los Angeles neighborhoods with the worst air pollution have experienced a 60 percent increase in mortality from COVID-19 compared to Los Angeles neighborhoods with the best air quality.38 COVID-19 infections have been known to be more severe for people who are already diagnosed with asthma. A recent study from Harvard University found that a small increase in long-term exposure to PM2.5 leads to a large increase in the COVID-19 death rate.39 One of the reasons that BIPOC (Black, Indigenous, and people of color) communities, are dying at higher rates from COVID-19 is because of the underlying health conditions like diabetes, heart disease, and asthma, all of which are linked to the disportionately high levels of air pollution in these communities. As Dr. Sacoby Wilson says, “Context matters. Place matters.”40 For EJ communities, place matters, and EPA should only be proposing regulations that guarantee health benefits and emission reductions for overburdened communities, especially as we now have the increased threat from COVID-19. EPA documented some of the connections between this rulemaking and environmental justice in the NPRM164, but it needs a more detailed analysis if it is going to actually reduce harms in environmental justice communities. Environmental racism in the impacts from heavy-duty truck pollution shows up in multiple ways—not limited to disproportionately high exposure to pollution, already elevated incidence rates of health risks such as asthma and premature mortality, and amplified effects of environmental exposures from social vulnerabilities such as cumulative physiological “wear and tear” and stress.165 We recommend that EPA further consider the disparate impacts of the rule and alternatives through analyzing race/ethnicity-stratified health benefits. This is already being done in other EPA rulemakings, and would more accurately capture the distribution of health impacts to environmental justice communities and result in a more accurate total health benefit as well. [EPA-HQ-OAR-2019-0055-1277-A1, p. 41]

Environmental Health Perspectives 129, no. 12 (December 2021): 127004. https://doi.org/10.1289/EHP9001.

Analyzing race/ethnicity-stratified health benefits is the next logical step from the existing analysis in the RIA. EPA's demographic analysis of air quality impacts of the rule shows that in the 2045 baseline, nearly double the number of people of color live in areas with the worst air quality compared with non-Hispanic Whites. These areas are also where the largest PM2.5 and ozone reductions occur due to Option 1. This is an important analytical step, and it is also important to outline how the resulting health risks are affected by these changes in exposures. As noted above, capturing the differences in exposure and exposure reductions from the rule only captures one part of its environmental justice impacts. A stratified health benefit analysis provides a view on how these exposure reductions are ultimately felt by different groups. These disparities in health impacts are often magnified when compared to disparities in exposure reductions, given the overlay of elevated incidence rates of health risks and the amplified health effects due to other vulnerabilities in communities of color (i.e., "cumulative impacts" as discussed elsewhere in these comments). Lastly, stratified health risk analyses can help communicate the impacts of the rule to stakeholders and promote meaningful involvement.166 [EPA-HQ-OAR-2019-0055-1277-A1, pp. 41 - 42]

166. A goal noted in EPA's definition of environmental justice and "Guidance on Considering Environmental Justice During the Development of a Regulatory Action." Environmental Protection Agency, https://www.epa.gov/environmentaljustice/guidance-considering-environmental-justice-during-development-action

EPA has shown strong documented support for analyzing health impacts by race/ethnicity within their rulemaking. Most notably, the 2019 PM2.5 Integrated Science Assessment (ISA) and draft supplement cite extensive evidence supporting racial and ethnic differences in PM2.5 exposure and health effects, especially within Hispanic and non-Hispanic Black populations.167 EPA's

2016 “Technical Guidance for Assessing Environmental Justice in Regulatory Analysis” recommends analysts to “present information on estimated health and environmental risks, exposures, outcomes, benefits and other relevant effects disaggregated by income and race/ethnicity”, while acknowledging context-specific data limitations, time and resource constraints, and analytic challenges.168 EPA has already conducted such an analysis in its Policy Assessment for the Reconsideration of the National Ambient Air Quality Standards for Particulate Matter (External Review Draft – October 2021), where it analyzed the effects of race/ethnicity-stratified health impact functions and baseline incidence data on mortality risk rate reductions from a number of different NAAQS modeling scenarios. This stratified analysis was reviewed favorably by the Clean Air Scientific Advisory Committee (CASAC), and its methods can be useful in other air quality rulemakings. [EPA-HQ-OAR-2019-0055-1277-A1, p. 42]

Showing the distributional effects of the rule is a small additional step in light of the tremendous amount of work done in the rest of the RIA.169 In this case, the health benefit analysis already includes spatially distributed modeled health impact results, and matching this to the projected population distribution by race/ethnicity is a small effort. EPA’s Environmental Justice Strategy and Executive Order 12898 make clear the necessity for distributional analyses to ensure EPA policies and programs do not exacerbate environmental injustices, but it is also important to document where policies have the potential to mitigate disparities, and assess to what extent it does. There are a few caveats when doing this, notably that it is based on modeled exposures and projected population distributions, where populations in each grid cell are assumed to experience the same pollution.170 [EPA-HQ-OAR-2019-0055-1277-A1, p. 42]

169. Banzhaf, H Spencer. “Regulatory Impact Analyses of Environmental Justice Effects,” National Center for Environmental Economics Working Paper Series, 10–08 (2010). https://www.epa.gov/sites/default/files/2014-12/documents/regulatory_impact_analyses_of_environmental_justice_effects.pdf at 17.

170. Post, Ellen S., Anna Belova, and Jin Huang. “Distributional Benefit Analysis of a National Air Quality Rule.” International Journal of Environmental Research and Public Health 8, no. 6 (June 1, 2011): 1872–92. https://doi.org/10.3390/ijerph8061872.

Including racially-specific health benefits can also more accurately assess the total health benefits of the rule. Spiller et al. (2021) has shown that including race/ethnicity-specific mortality incidence rates or health impact functions (HIFs) can both change the distribution of health benefits as well as increase total premature mortality estimates by 9%.171 Similarly, in the case of Proposed Option 1 of this rule, not using race/ethnicity-specific health impact functions underestimates the total PM2.5 premature mortality reduction by around 16%. This translates to a $1.2 billion underestimation of health benefits from PM2.5 premature mortality reduction alone. Notably, benefits to Black populations are underestimated by 64%, benefits to Hispanic populations are underestimated by 36%, and benefits to White populations are overestimated by 16%. Table 3 below shows the full distribution of results from an illustrative stratified analysis. [EPA-HQ-OAR-2019-0055-1277-A1, pp. 42 - 43]

171. Spiller, Elisheba, Jeremy Proville, Ananya Roy, and Nicholas Z. Muller. "Mortality Risk from PM2.5: A Comparison of Modeling Approaches to Identify Disparities across Racial/Ethnic Groups in Policy Outcomes." Environmental Health Perspectives 129, no. 12 (December 2021): 127004. https://doi.org/10.1289/EHP9001.

The benefits in the stratified analysis above are modest compared to the thousands of deaths from diesel pollution across the country every year.173 The use of race/ethnicity stratified HIFs avoids underestimation of total health benefits as well as provides a more accurate portrayal of health benefits by race/ethnicity. This is just an illustrative analysis, and we encourage EPA to conduct its own, acknowledging difficulties in data collection, certainty, and health impact function availability for other health endpoints. Further analysis should situate these policies within a holistic cumulative impacts framing that guarantees reduction of harms in environmental justice communities. [EPA-HQ-OAR-2019-0055-1277-A1, p. 43]

173. https://www.catf.us/deathsbydiesel/

It is critical that, in this rulemaking, USEPA sends a strong signal to the market and regulators that longstanding burdens to communities and increasing disparities in burdens from heavy-duty trucks cannot continue. While Section 202 of the Clean Air Act itself does not on its face address the spatial/geographic distribution of heavy-duty trucks and other vehicles once manufactured and sold, USEPA has obligations under the Clean Air Act and Title VI of the Civil Rights Act to ensure that state agency receiving funds for their air programs address disparities in burdens from heavy duty trucks through their State Implementation Plans (SIPs).174 [EPA-HQ-OAR-2019-0055-1277-A1, pp. 43 - 44]

174. USEPA also may have civil rights obligations to ensure that localities receiving federal funds similarly do not create or perpetuate disparities in pollution and/or cumulative impacts from the logistics sector, as does its federal counterpart the Department of Housing and Urban Development. See 42 U.S.C. § 2000d-1 and 40 C.F.R. 7.15 ("This part applies to all applicants for, and recipients of, EPA assistance in the operation of programs or activities receiving such assistance" (emphasis added).)

USEPA can and should help support states doing so by setting a standard under Section 202 that ensures robust availability of the cleanest trucks across the country, in all states, cities and other municipalities facing the heavy and disparate toll of the logistics industry. [EPA-HQ-OAR-2019-0055-1277-A1, p. 44]

President Biden has directed the entire federal government and the Environmental Protection Agency (EPA) to prioritize protecting and investing in overburdened and underserved communities across America. EPA plays a leading role in delivering environmental and public benefits for communities with environmental justice (EJ) concerns through our policies, programs, and activities.198 [EPA-HQ-OAR-2019-0055-1277-A1, p. 59]

198. https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10144Y3.pdf

EPA Summary and Response

Summary:

The commenter noted that a large portion of the U.S. population is affected by the pollution from heavy-duty vehicles and engines. The commenter also noted that people of color and low-income households are disproportionately exposed to elevated levels of diesel pollution.

The commenter specifically requested that the Agency consider the disparate impacts of the rule through the analysis of race/ethnicity-stratified health benefits. The commenter also noted the impacts of COVID on underserved communities.

Response:

Thank you for your comments. We agree that the proposed standards would bring about substantial health benefits, including benefits to those who live near roads and to those who live in communities with EJ concerns. We also agree that the Agency can improve its methods to better estimate the health and environmental justice benefits associated with pollution reductions like those that would be achieved by the proposed and final rulemaking. There is considerable scientific evidence that specific populations and lifestages are at increased risk of $PM_{2.5}$- and ozone-related health effects. EPA is working to consider how to better reflect the overall distributional implications of future regulatory actions to improve air quality and public health. Nevertheless, we believe that our analysis for the proposed and final rulemaking is appropriate and informative in the context of the policy decisions being considered in this action

The commenter specifically requested that the Agency consider the disparate impacts of the rule through the analysis of race/ethnicity-stratified health benefits. In the proposal, the Agency provided an analysis that examined the racial and ethnic composition, as well as poverty status, of areas with the worst baseline air quality in 2045 and then considered whether those with the worst air quality were likely to benefit more from the proposed rule. We found that in the 2045 baseline, nearly double the number of people of color live within areas with the worst ozone and $PM_{2.5}$ air pollution compared to non-Hispanic Whites (NH-Whites). We also found that (in absolute terms) the largest predicted improvements in both ozone and $PM_{2.5}$ are estimated to occur in areas with the worst baseline air quality, where a substantially larger number of people of color are expected to reside. We did not expand this analysis to health benefits for a few reasons.

For our primary estimate of national-level PM and ozone-related health benefits, EPA systematically reviews the body of available epidemiological studies and risk estimates using explicit criteria to identify which studies and risk estimates are a best fit for use in a national analysis. These criteria include factors such as study design, geographic coverage, demographic populations, and health endpoints.[56] Using these criteria, the Agency selects risk estimates from epidemiologic studies that may be generalized to the population that is affected by the policy. Following this approach, EPA found that a risk estimate drawn from a national study of long-term exposure $PM_{2.5}$ mortality would more reliably estimate the number of $PM_{2.5}$-attributable deaths than would risk estimates stratified by individual race.

Furthermore, the Agency does not yet possess the race- or ethnicity-stratified baseline rates of death and disease for each endpoint it quantifies. Other data limitations include confidence in projections of population counts and population distribution (out to year 2045 for the proposal analysis) and the lack of race/ethnicity-stratified baseline health incidence projected into the future. Given the analytical limitations of the underlying literature and data to support a race/ethnicity stratified benefits analysis, we believe analyzing the distributional impacts of improvements in air quality is a fair surrogate for how benefits are distributed, while making the important observation that, qualitatively, there are specific populations and lifestages that may benefit more or less due to the distribution of pollution reductions projected to be achieved by the proposal. EPA will continue to work to improve how we characterize the distributional implications of future regulatory actions to improve air quality.

EPA is committed to taking decisive action to advance environmental justice and civil rights as part of its FY2022-2026 Strategic Plan. This rulemaking advances that strategic goal by setting stronger national emission standards for heavy duty engines and vehicles.

EPA acknowledges comments from many stakeholders on the impacts of COVID on underserved communities. While we were not able to incorporate COVID 19 into our modeling, we have evaluated the impacts we expect the rule to have on communities overburdened by pollution; this analysis is included in preamble Section IV.H, with additional discussion on environmental justice in preamble Sections II and XII.

23.2 General Comments About Environmental Justice

Comments by Organizations

Organization: *350Marin*

Air pollution from trucks to date is a major public health problem. According to EPA, more than 45 million people in the U.S. live within 300 feet of a major roadway or transportation facility, and 72 million people live within 200 meters of a truck freight route. People of color and those with lower income are most affected. [EPA-HQ-OAR-2019-0055-2474, p.1]

In addition, many vulnerable populations including children, the elderly, and communities of color are both more exposed to air pollution, and more at risk of health problems caused by air pollution. [EPA-HQ-OAR-2019-0055-1244; see also Section 2.1]

> 6. Ozone causes asthma attacks, is as bad for progression of emphysema as 29 pack-years of cigarettes(https://doi.org/10.1001/jama.2019.10255). Ozone likely contributes to children developing asthma, and contributes to heart disease in adults. Ozone causes excess deaths in Medicare recipients, this effect is more pronounced in black people (https://doi.org/10.1056/NEJMoa1702747). [EPA-HQ-OAR-2019-0055-1244]
>
> 8. Demetillo and colleagues found that diesel traffic is the dominant source of NO2 disparities(https://doi.org/10.1029/2021GL094333). Lane and colleagues found that historical redlining maps from the 1930s still cause current day disparities in PM2.5 and NOx, with the placement of highways as one of the main contributing factors (https://doi.org/10.1021/acs.estlett.1c01012). Houston and colleagues found that Black and Asian-American/Pacific Island people were more exposed to diesel truck traffic near the Port of Los Angeles (https://doi.org/10.2105/AJPH.2012.301120). [EPA-HQ-OAR-2019-0055-1244]

Because air pollution from trucks and other heavy duty vehicles is so damaging to health, and especially to vulnerable populations such as children, the elderly, pregnant women, and communities of color, because of the structural inequities in our built environment placing more highways, ports, and railyards in communities of color, and because climate change is the biggest health threat we face, I support this rule. I encourage EPA to make it much stronger to fully protect the health of the most vulnerable populations. [EPA-HQ-OAR-2019-0055-1244]

Organization: *Carreras Tours, LLC (2033)*

Improving these standards will improve health outcomes for communities hardest hit by diesel pollution: communities near ports and freight corridors. [EPA-HQ-OAR-2019-0055-2033, p.1]

Organization: *Center for Climate and Energy Solutions (C2ES)*

Diesel-powered vehicles produce climate-polluting greenhouse gas emissions, as well as harmful air pollutants including PM2.5 particulate pollution and nitrous oxides (NOx), which produce smog and are hazardous to human health, especially to children, the elderly, pregnant people, and others with pre-existing respiratory conditions.3 Yet often the emissions from idling trucks, delivery vans, and other medium- and heavy-duty vehicles are concentrated in the very communities with populations most vulnerable to them. Delivery vans travel through neighborhoods, while highway and urban truck routes often pass through vulnerable communities and low-income communities. The burdens of pollution are often borne by communities disproportionately made up of people of color.4 [EPA-HQ-OAR-2019-0055-1165-A1, p.2]

Air pollutants, including PM2.5 and NOx, are hazardous to human health; prolonged or excessive exposure can contribute to conditions like asthma, high blood pressure, chronic stress, and chronic respiratory diseases.12 Exposure to poor air quality is also correlated at the community level with significantly higher rates of COVID-19 infections and poorer health outcomes following infection.13 Burdens of air pollution and poor air quality are disproportionately borne by historically marginalized communities, including majority-Black communities, majority-immigrant communities, and low income communities, as well as children, the elderly, and other population with heightened health vulnerability.14 [EPA-HQ-OAR-2019-0055-1165-A1, p.4]

Importantly, given that MHDVs are the largest source of nitrogen oxides (NOx) in the transportation sector, it is critical to strengthen the proposed NOx standards. Disadvantaged communities, located near highways, ports and distribution centers, have long borne the brunt of negative health and air quality impacts from truck pollution, and it is necessary to reduce this pollution as quickly as possible during the transition to electrification (which in turn, will have additional health benefits). Accordingly, EPA should adopt a strengthened Option 1, requiring a 90% reduction in NOx by 2027, and phase out advanced technology credit multipliers for NOx as soon as feasible. [EPA-HQ-OAR-2019-0055-2714-A1, p.2]

Further, given that medium- and heavy-duty vehicles are the largest source of nitrogen oxides (NOx) in the transportation sector, it is critical to strengthen the proposed NOx standards, which were last updated twenty years ago. Disadvantaged communities have long borne the brunt of negative health and air quality impacts from truck pollution, and we need to reduce these pollutants to the maximum extent possible. [EPA-HQ-OAR-2019-0055-2714-A2, p.1]

Further, given that MHDVs are the largest source of NOx in the transportation sector, it is critical to strengthen the standards to the maximum extent possible in order to reduce air pollution from MHDVs during the transition, which disproportionately increases health and air quality risks in disadvantaged communities located near truck routes, ports, and distribution centers. [EPA-HQ-OAR-2019-0055-2714-A3, p.2]

Organization: *Chesapeake Bay Foundation, Inc. (CBF)*

Emissions from heavy-duty trucks—including NOx and particulate matter—cause numerous, well-documented negative health impacts, including exacerbation of existing respiratory and cardiovascular conditions, increased asthma attacks and new cases of asthma, difficulty breathing, inflammation and irritation of the lungs, and decreased cardiac function, among many others.5 These negative health impacts are particularly damaging for communities and individuals who live, work, or attend school close to major roadways.6 Many of these communities are home to lower-income and/or minority populations who are already burdened by industrial air and water pollution sources located nearby.7 [EPA-HQ-OAR-2019-0055-1295-A1, p.3]

One recent study found that communities of color and lower-income neighborhoods are disproportionately impacted by NOx emissions.8 Communities that are primarily composed of people of color and lower-income households experience, on average, 28 percent more nitrogen dioxide pollution than communities that are majority-white and higher income. Furthermore, millions of U.S. citizens live in areas burdened by high levels of ozone pollution fueled by NOx emissions,9 and lower-income and minority communities are disproportionately impacted by ozone pollution.10 [EPA-HQ-OAR-2019-0055-1295-A1, p.3]

These trends are seen in communities throughout the Chesapeake Bay watershed. The Chesapeake Bay watershed is traversed by major interstate highways running up the Eastern Seaboard on which heavy-duty trucks regularly operate. Many of these major roadways are located directly adjacent to or within residential communities. According to 2014 National Emissions Inventory data, in Maryland and Washington, D.C., 74 and 75 percent of NOx emissions are due to transportation, respectively.11 In Virginia, 67 percent of NOx emissions are due to transportation.12 The Bay watershed also hosts all or part of three nonattainment areas for the 2015 Ozone National Ambient Air Quality Standard: Philadelphia-Wilmington-Atlantic City, PA-NJ-MD-DE (Marginal Nonattainment); Washington, DC-MD-VA (Marginal Nonattainment); and Baltimore, MD (Marginal Nonattainment).13 [EPA-HQ-OAR-2019-0055-1295-A1, pp.3-4]

Figure 1 uses EJSCREEN, the 2017 National Air Toxics Screening Assessment, and the 2015-2019 American Community Survey to compare census block groups exposed to the highest amounts of diesel particulate matter, with those block groups that are largely comprised of minorities. The communities exposed to large amounts of diesel particulate matter are generally communities with large numbers of people of color. [EPA-HQ-OAR-2019-0055-1295-A1, p.4]

The same study that found communities of color and lower-income neighborhoods experience as much as 28 percent more NOx pollution also found, of the 52 cities examined, that diesel trucks contributed up to half the nitrogen oxide emissions despite comprising 5 percent or less of all traffic.14 Furthermore, a 60 percent reduction in diesel-related pollution would lead to a 40 percent decline in 'air pollution inequality'.15 Reducing diesel-related pollution is an incredibly effective way to ensure all communities, but particularly those that suffer the most, are able to breathe clean air. [EPA-HQ-OAR-2019-0055-1295-A1, p.5]

14 Pollution from Freight Traffic Disproportionately Impacts Communities of Color Across 52 U.S. Cities, American Geophysical Union (Oct. 7, 2021), https://news.agu.org/press-release/pollution-from-freight-traffic-disproportionately-impacts-communities-of-color-across-52-u-s-cities.

Since 1990, EPA has repeatedly asserted the objective of addressing environmental justice concerns through the reduction of air pollution that disproportionately harms or cumulatively impacts such communities.16 EPA's Office of General Counsel, the Environmental Law Institute, and the National Environmental Justice Advisory Council have all observed that the Clean Air Act gives EPA ample authority to address such concerns through rulemaking.17 We therefore urge EPA to swiftly fulfill its mission and reduce heavy duty truck emissions to decrease negative health impacts to historically disadvantaged communities. Of Envtl. Just., EPA, Technical Guidance for Assessing Environmental Justice in Regulatory Analysis in Regulatory Analysis, June 2016 1 (2016).

Organization: *Christopher Lish*

I am glad that, after 20 years of delay, the Environmental Protection Agency has finally proposed stronger tailpipe toxic pollution standards for heavy-duty diesel trucks.

However, while these rules are a good start, they don't go far enough. Now is the time to eliminate toxic tailpipe emissions from trucks. Black, Latino, Asian American, and other marginalized communities living in highly trafficked areas have suffered the health impacts of diesel trucks for far too long. To deliver on the Biden Administration's environmental justice, public health, and climate goals, the Environmental Protection Agency must make the rules stronger and finalize a strong heavy-duty vehicle rule this year that sets us on a rapid path to cleaning up and electrifying the most polluting vehicles on the roads—our trucks and buses—by 2035, if not sooner. [EPA-HQ-OAR-2019-1147; see also Section 1.2/2.4]

Diesel pollution kills. Smog and soot air pollution caused by trucks and buses are among the greatest threats to public health for the more than 45 million people in the U.S. living within 300 feet of a major roadway or transportation facility. Nearly 10,000 people in the United States die each year from exposure to diesel emissions from the transportation sector, and hundreds of thousands of others face heart attacks, asthma, and respiratory conditions that damage their wellbeing and quality of life. Diesel emissions most severely harm communities of color and working class communities, and cleaning up dirty diesel pollution helps to create a more just society. Improving these standards will improve health outcomes for communities hardest hit by diesel pollution. The Environmental Protection Agency should adopt requirements to address disproportionate health impacts so that those who are most harmed by diesel pollution can find relief quickly. Even with strong heavy-duty emissions standards in place, it will take years for the benefits to reach the people who need them most. That's why we also need a zero-emissions truck mandate. [EPA-HQ-OAR-2019-1147]

Organization: *City Council District 8, Pittsburgh, PA, Erika Strassburger*

We know that diesel pollution from heavy duty trucks and buses is a massive public health threat. Diesel pollution worsens asthma and is particularly dangerous to children’s developing lungs. Of course, dangerous nitrogen oxides and other pollution that heavy duty vehicles like trucks and buses spew into our air hurt communities of color and low wealth communities first and worst. With more than 13 million people (including 3.5 million children) living near major marine and inland ports or rail yards, an additional 45 million individuals living within 300 feet of a highway or close to large distribution centers where diesel emissions are particularly dangerous, and that these individuals are disproportionately low-income communities of color, this is truly an environmental justice issue. [EPA-HQ-OAR-2019-0055-2233, p.1]

We urgently need cleaner heavy-duty vehicles on the road, especially in underserved communities that are overburdened with truck pollution due to their proximity to highways and high-traffic corridors. [EPA-HQ-OAR-2019-0055-2233, p.1]

I urge the EPA to adopt these standards as soon as possible. Families in diesel death zones have suffered long enough. [EPA-HQ-OAR-2019-0055-2233, p.1]

Organization: *City of Seattle, Office of Sustainability & Environment*

The City of Seattle agrees with the EPA that the current EPA 2010 standards are inadequate to protect public health from dangerous pollutants like NOx emissions from Heavy Duty Vehicles. We encourage you to go further with the proposed rule to protect environmental justice and port-adjacent communities, like Seattle’s Beacon Hill and Duwamish Valley neighborhoods, which are continuously exposed to sources of pollution from diesel trucks and other transportation emissions. Specifically, Beacon Hill, Georgetown, and SouthPark rank higher in both air pollution levels and child asthma rates and on average have a life expectancy that is eight years lower than other neighborhoods in Seattle. [EPA-HQ-OAR-2019-0055-1287-A1, p.1]

Please use this opportunity to finalize a rule that puts communities first and aggressively pursues the targets necessary to address the climate crisis. The public health crisis across the country, particularly for communities near highways, warehouses, and ports cannot wait. Together, we can both tackle the climate and air-quality crisis and address the problem of the price-differential between a typical, used truck ($20-30k), and a new zero-emission electric vehicle ($300-400k) for those who will most struggle to adopt this critical new technology. By adopting firm standards that protect communities and incentivizing the transition, the U.S. can create a stronger, more efficient, and healthier economy. [EPA-HQ-OAR-2019-0055-1287-A1, p.2]

Organization: *Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, and Sierra Club*

Environmental justice, energy justice, and equity considerations are central to the Proposal, given the vast history of disproportionate environmental and public-health burdens placed on communities of color and low-income communities.19 Communities that are overburdened with pollution from sources such as major roadways, industrial sites, and agriculture are predominantly low-income, and a large percentage of residents of these communities are people of color and non-English speakers.20 With the improvements described later in these comments, this rulemaking could bring about significant air-quality and health improvements in communities that are disproportionately burdened with air pollution from trucking and overburdened from pollution more broadly.21 [EPA-HQ-OAR-2019-0055-1302-A1, pp.14-15]

19 For more information on the history and definition of the environmental justice movement, see Initiative for Energy Justice, Section 1—Defining Energy Justice: Connections to Environmental Justice, Climate Justice, and the Just Transition (Dec. 23, 2019), https://iejusa.org/section-1-defining-energy-justice/.

20 See Gina M. Solomon et al., Cumulative Environmental Impacts: Science and Policy to Protect Communities, 37 Annual Review of Public Health (Jan. 6, 2016), https://pubmed.ncbi.nlm.nih.gov/26735429/.

21 See EPA, ISA for Particulate Matter at Ch. 12: Populations and Lifestages Potentially at Increased Risk of a Particulate Matter-Related Health Effect; Section 5: Sociodemographic Factors, https://www.epa.gov/isa/integrated-science-assessment-isa-particulate-matter.

EPA must set strong emissions standards to meet the obligations established by presidential directives on environmental justice. Under Executive Order 12,898, EPA 'shall make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations.' 59 Fed. Reg. 7,629 (Feb. 11, 1994). And Executive Order 14,008 directs EPA to develop 'programs, policies, and activities to address the disproportionately high and adverse human health, environmental, climate-related and other cumulative impacts on disadvantaged communities, as well as the accompanying economic challenges of such impacts.'' 86 Fed. Reg. 7,619, 7,629 (Jan. 27, 2021). It also establishes the Administration's policy ''to secure environmental justice and spur economic opportunity for disadvantaged communities that have been historically marginalized and overburdened by pollution.'' Id. [EPA-HQ-OAR-2019-0055-1302-A1, p.15]

This rulemaking presents a critical opportunity to mitigate the adverse health impacts plaguing communities that are overburdened by air pollution from HDVs and other sources. As noted by the ALA's 2022 State of the Air report, which grades counties on daily and long-term measures of particle pollution and daily measures of ozone, 'Close to 19.8 million people live in the 14 counties that failed all three measures. Of those, 14.1 million are people of color. People of color were 61% more likely than white people to live in a county with a failing grade for at least one pollutant, and 3.6 times as likely to live in a county with failing grades for all three pollutants.'22 As described in Section II.C.1 above, all 14 of these counties are located in the vicinity of at least one major highway that overburdens county residents with pollution from trucks. [EPA-HQ-OAR-2019-0055-1302-A1, p.15]

22 See ALA, State of the Air 2022 Key Findings, https://www.lung.org/research/sota/key-findings.

According to the ALA's report, more than 137 million Americans live in places that received failing grades for unhealthy levels of ozone or PM in their air. In addition to the disproportionate impact on people of color noted above, ALA outlines other 'high-risk' groups that are impacted by the pollution in these regions. For example, low-income communities are particularly vulnerable and at risk of health impacts from pollution. More than 15.9 million people whose incomes meet the federal definition for living in poverty reside in counties that received a failing grade on at least one of ALA's pollutant indicators, while over 2.6 million people living in poverty reside in counties that received failing grades on all three pollutant measures. In addition, around 31 million children (under age 18) and almost 21 million older adults (age 65 or older) live in counties that received a failing grade on at least one pollutant.23 [EPA-HQ-OAR-2019-0055-1302-A1, pp.15-16]

23 See ALA, State of the Air 2022 at 18.

A new paper, titled 'Pollution from Freight Trucks in the Contiguous United States: Public Health Damages and Implications for Environmental Justice' and currently undergoing peer review, explores the spatial implications of pollution from freight trucks in the United States.24 The authors find evidence that the negative health impacts of emissions from freight trucking are disproportionately distributed across the country and are disproportionately likely to impact certain racial and ethnic groups. In particular, they find that pollution from freight trucking is more likely to occur in counties and census tracts with higher proportions of Black and Hispanic residents. [EPA-HQ-OAR-2019-0055-1302-A1, p.16]

24 Priyank Lathwal et al., Pollution from Freight Trucks in the Contiguous United States: Public Health Damages and Implications for Environmental Justice, arXiv:2204.06588 (2022), https://arxiv.org/abs/2204.06588.

In fact, it is well established that communities of color and economically disadvantaged communities are disproportionately exposed to environmental burdens from a variety of sources.

The White House Council on Environmental Quality (CEQ) recently released a preliminary Climate and Economic Justice Screening Tool, which identifies communities around the country that are 'marginalized, underserved, and overburdened by pollution'25 and would therefore qualify for Justice4026 investments (President Biden's key environmental justice initiative). The Screening Tool identifies census tracts as 'disadvantaged' if they are above the threshold for one or more environmental or climate indicators (e.g., exposure to diesel PM or PM2.5, traffic proximity and volume, or proximity to hazardous waste sites) *and* above the threshold for socioeconomic indicators related to income and education.27 A recent analysis found that 64% of the population in census tracts the Screening Tool identifies as disadvantaged are Hispanic/Latino, Black or African American, or American Indian or Alaskan Native. Overall, 50% of Hispanic/Latino, Black or African American, and American Indian or Alaskan Native individuals in the country reside in disadvantaged communities, compared to just 17% of White, Non-Hispanic/Latino individuals.28 [EPA-HQ-OAR-2019-0055-1302-A1, p.16]

cument.pdf.

28 Emma Rutkowski et al., Justice40 Initiative: Mapping Race and Ethnicity, Rhodium Group (Feb. 24, 2022), https://rhg.com/research/justice40-initiative-mapping-race-and-ethnicity/.

These findings show the critical need for EPA to minimize the harmful emissions from the HDV sector. Doing so will not only improve a significant public-health and environmental issue, but will also decrease air pollution and improve well-being in overburdened communities. [EPA-HQ-OAR-2019-0055-1302-A1, p.16]

A 2019 study by ICCT found that, on average, trucks traveling at speeds below 25 miles per hour emitted NOx at more than five times EPA's certification limit.234 That study also found that, on average, trucks only achieved NOx emissions at or below the certification limit when traveling at highway speeds above 50 mph.235 For each mile of urban driving, a single 'line-haul' truck used in long-distance shipping can emit *one hundred times* the NOx pollution that a car would emit.236 Even when traveling on highways in populated urban areas, trucks will often be moving at lower speeds due to congestion. The Federal Highway Administration's 2020 list of 'major freight highway bottlenecks and congested corridors' shows that many of the most congested highways in the United States are near densely populated urban areas that are also ozone nonattainment areas, such as Chicago, New York City, Los Angeles, California's Bay Area, Dallas/Fort Worth, and Denver.237 As EPA's Proposal notes, 72 million Americans live within 200 meters of freight routes, and people of color and those with lower incomes are disproportionately likely to live near freight truck routes and to live in urban areas. 87 Fed.

Reg. at 17,451. Studies have consistently found that environmental hazards such as air pollution are more prevalent in areas where people of color and low income populations represent a higher fraction of the population compared with the general population, and a recent study found that PM2.5 pollution from HDVs disproportionately impacts people of color. 87 Fed. Reg. at 17,452. It is crucial that these overburdened near-road communities do not continue to experience disproportionate levels of air pollution due to high levels of emissions from HDVs traveling at lower speeds. See Section II.C, supra. [EPA-HQ-OAR-2019-0055-1302-A1, pp.55-56]

Organization: *Clean Energy (CE)*

The benefits of accelerating adoption of near-zero vehicles will be most closely felt in environmental justice communities. These neighborhoods are commonly adjacent to industrial areas with heavy truck traffic and need relief now. Near-zero trucks provide tangible results whereas EV heavy-duty trucks are, at the present date, technological speculation. In a 2017 article, Jason Morgan of Fleet Equipment Magazine wrote, '*…Tesla unveiled its electric Class 8 truck, dubbed the Semi. Fully loaded, the Tesla Semi consumes less than two kilowatt-hours of energy per mile and is capable of 500 miles of range at GVW and highway speed…10*' But in 2022, five years later, orders for these trucks have not been filled. Conversely, earlier this year, Amazon deployed its 1,000th near-zero truck running on RNG. [EPA-HQ-OAR-2019-0055-1350-A1, p.3]

10 https://www.fleetequipmentmag.com/tesla-semi-electric-class-8-truck/

Therefore, in order to address the air quality issues in environmental justice communities today and in the foreseeable future near-zero trucks, deployable now, must be encouraged. They will provide the air quality benefits these communities deserve which include not only NOx reductions of 95 to 98 percent but also virtual elimination of particulate matter emissions. The new heavy-duty truck rule must support near-term solutions in addition to long-term strategies and aspirations. [EPA-HQ-OAR-2019-0055-1350-A1, pp.3-4]

Organization: *CleanAirNow (CANKC)*

CANKC believes the time for purposeful action is now, the Armourdale neighborhood in Kansas City Kansas is already experiencing a shorter life expectancy by 22 years as compared to other nearby neighborhoods. KCK is not siloed in this large and impactful discrepancy; our nation has overburdened environmental justice (EJ) communities by having them bear the brunt of systemic racism with a legacy of redlining, zoning and dumping practices that have left families without access to clean air, water, and land. We ask, how many more lives is this lack of ruling going to cost us? How many more preterm babies, developmental disorders, cognitive disorders, asthma attacks, heart disease, lung disease or cancer will occur in our communities as a result of poisonous diesel emissions? [EPA-HQ-OAR-2019-0055-1239-A1, p.1]

Environmental Justice communities and frontline workers are being buried day in and day out with a multitude of polluting sources from the transportation freight sector. This is NOT accounting for the coal plants, toxic release inventory sites, and scrap metal facilities all primarily located in BIPOC and low-income communities. EJ communities are at the fenceline and are inhaling the mixture of dirty air, compromising their immunity and resulting in higher risks for health problems. As we have seen firsthand during this pandemic, they are the same communities with higher hospitalizations and deaths from COVID-19. [EPA-HQ-OAR-2019-0055-1239-A1, pp.1-2]

In the creation of zero emission infrastructure and zero emission solution, we must prioritize environmental justice communities. The implementation of these regulations must take into account the lifecycle of pollution, from source to manufacturing to tailpipe to waste and all of the potential impacts throughout that system. We need innovative and comprehensive policy from the EPA that ensures a reduction in harms to EJ communities. [EPA-HQ-OAR-2019-0055-1239-A1, p.2]

The answer is zero actually meaning zero, it’s a win win for the climate and for the hardworking people of this nation. Because as we know, justice delayed is justice denied and haven’t we faced enough injustice? [EPA-HQ-OAR-2019-0055-1239-A1, p.2]

Organization: *CleanEarth4Kids*

Pollution from heavy-duty trucks is a racial justice issue as they mostly harm communities of color. [EPA-HQ-OAR-2019-0055-1208-A1, p.1]

Communities of color are paying a heavy price for this pollution and need a rapid transition to zero-emitting trucks and a clear path towards 100% electrification of big rigs, trucks, and buses. [EPA-HQ-OAR-2019-0055-1208-A1, p.1]

Frontline communities are being poisoned and they can not afford to wait for cleaner air. [EPA-HQ-OAR-2019-0055-1208-A1, p.1]

Organization: *Coalition for Clean Air*

Emissions from vehicle tailpipes are the greatest barrier to clean air in California. Fine particulate matter produced by diesel trucks is particularly health-threatening. It is responsible for about 95 percent of pollution-related health impacts in the world. In California, communities of color are most burdened by this diesel truck pollution. [EPA-HQ-OAR-2019-0055-1139-A1, p.1]

Organization: *Colorado Energy Office, et al.*

Of note, cleaner trucks on the roads are especially important for our residents who live in close proximity to freight routes and bear a disproportionate impact from truck emissions. These communities cannot be left behind in the transition to clean transportation. [EPA-HQ-OAR-2019-0055-1297-A1, p.2]

Organization: *Consumer Reports (CR)*

Long-term exposure to ozone and PM2.5 increase the risk of premature death from respiratory and cardiovascular diseases. Exposure to PM2.5 is also linked with increased incidences of childhood asthma.10 These health impacts more significantly affect the estimated 72 million people living within 200 meters of a truck freight route. Communities living near these routes are disproportionately people of color and those with lower incomes.11 A recent study conducted by the Union of Concerned Scientists showed that Asian-American, Black, and Latinx communities face, respectively, 34%, 24%, and 23% higher exposures to diesel pollution compared to their white counterparts.12 Stringent NOx emission standards are vital to reducing these adverse health impacts and to addressing historic environmental inequities. [EPA-HQ-OAR-2019-0055-1285-A1, p.3]

Organization: *Creation Justice Ministries*

Even though these trucks account for only 4 percent of vehicles on the road, they are responsible for 25 percent of total transportation sector greenhouse gas emissions. Those emissions are destroying our climate and communities, degrading God’s planet and God’s people, with a disproportionate and absolutely unjust impact on communities of color. [EPA-HQ-OAR-2019-0055-2482, p.1]

Organization: *Dave Arndt*

[*From Hearing Testimony, April 12, 2022*] Unfortunately, by plan, all of this injustice is burdened on Black, Brown and low- income areas. Let me repeat that – this was and is all done by design.

I sorry to say, just five years ago I did not know this. Sure, I knew that air pollution and environmental and social in justice was bad, but I never saw the design. My eyes have been opened; however, we need to open everyone's eyes. This hearing is a good start in doing that, thank you for your work and this opportunity.

Let's take a look at the Brooklyn, Cherry Hill, Curtis Bay neighborhoods of Baltimore. They have two incinerators within 5 miles. Now add a few more layers, 3 RMP facilities, a chemical factory which is a large emitter of carcinogens. That is just the start. There is a working port which drives heavy duty truck traffic through the neighborhoods. Plus, several very large distribution centers which amplifies the truck traffic. Next add in the diesel emission from trains and the large ships themselves. And for convenience several major interstates cutting through the neighborhoods transporting thousands of trucks through the I-95 corridor. This would be a good design if it was isolated, however it was all placed in a Black, brown and low-income neighborhood by design. All having a cumulative effect.

The Baltimore region ranks among the worst in the U.S. for air pollution. A study by the Chesapeake Bay Foundation in 2017 found air quality in the region was ranked moderate or worse one of every three days, according to the EPA's own Air Quality Index. Little wonder then that children in Baltimore City have asthma at twice the rate of the rest of the country.

I would recommend you go to your own EPA's Environmental Justice Screening and Mapping Tool and see how bad it is.

I would like to end with a quote from Richard Moore, the National Co-Coordinator of the Environmental Justice Health Alliance: "You can't separate health from environmental justice, because environmental justice is health. And you can't separate issues of climate change and global warming because environmental justice and economic justice is addressing global warming and climate change. And so those intersections are very crucial." [EPA-HQ-OAR-2019-0055-2867; see also EPA-HQ-OAR-2019-0055-0994]

Organization: *Delaware Department of Natural Resources and Environmental Control (DNREC)*

Cleaning up truck emissions is long overdue for the communities living adjacent to the I-95 Corridor, the Port of Wilmington, and freight hubs who disproportionately suffer from harmful air pollution. [EPA-HQ-OAR-2019-0055-1200-A1, p.2]

Air pollution from HD vehicles disproportionately harms underserved and lower income communities. To achieve environmental justice goals and provide equitable access to clean air across the state, Delaware needs options for reducing vehicle pollution. [EPA-HQ-OAR-2019-0055-1200-A1, p.3]

Organization: *District of Columbia Department of Energy and the Environment (DOEE)*

DOEE acknowledges that the District's urban and natural environments are constructed and managed in ways that have not benefitted the capital's communities equally. District residents that continue to suffer the effects of environmental hazards—and their compounding impacts—are disproportionately people of color and people experiencing poverty. These hazards manifest as air pollution, inequities in access to clean water and nutritious food, lack of proximate green space, proximity to industrial toxins, racial disparities in life expectancy, and increased vulnerability to extreme weather events and climate change. By addressing racial inequity in the systems we manage and influence, we create opportunities for more communities to benefit from and participate in the process of identifying and implementing environmental solutions. [EPA-HQ-OAR-2019-0055-1299-A1, p. 4]

Communities adjacent to congested highways in particular experience heavy truck traffic. These communities in the District, located near the highways that run through the Southeastern portion of the District experience the worst asthma rates in Washington. Data from the Centers for Disease Control and Prevention shows that, nationally, Black and indigenous people have statistically significant higher asthma rates than their counterparts in other races.5 In the District, children who live in predominately Black communities have 20 to 25 times more asthma-related emergency department visits than their counterparts in majority White communities.6 [EPA-HQ-OAR-2019-0055-1299-A1, p. 4]

Recent evidence, especially research conducted during the Covid-19 health emergency, has shown the strong negative impact of NOx emissions on health, affecting environmental justice communities in particular. One such study conducted by researchers at George Washington University found the reduction in NOx pollution during the Covid-19 lockdown was twice as large in Black, indigenous, people of color, and Latinx communities as it was in White communities, providing further evidence that reducing NOx pollution is an environment justice issue.7 Another study conducted specifically to look at health discrepancies in the District found that communities of color in the Southeastern portion of the District had disproportionally higher rates of negative health outcomes related to air pollution exposure.8 Strong heavy-duty NOx standards are an important part of the solution to the health disparities that result from exposure to truck emissions. [EPA-HQ-OAR-2019-0055-1299-A1, p. 4]

Organization: *Edwin J. Ward*

It’s no secret that the health effects of air pollution from heavy-duty vehicles have disproportionately impacted historically marginalized communities over the last century and continue to do so.1 In Syracuse, NY, I lived for years in the shadow of the infamous I-81 viaduct, a highway constructed in the 1950s that destroyed the thriving black neighborhood of the 15th Ward. 2 As a result, black residents in Syracuse today face significantly higher rates of asthma than white residents.3 What happened in Syracuse is no anomaly; it is a microcosm of the United States as a whole. And while heavy- duty vehicle emissions standards might seem like an odd place to start ameliorating historical environmental injustices, heavy-duty vehicles are responsible for a disproportionate amount of air pollution impacts and GHG emissions. Despite accounting for only 5% of vehicles on the road, trucks generate over 25% of GHG emissions from the transportation sector.4 Even more concerning, a recent study by the University of Toronto found that someone living near a road that serves as a major trucking route experiences the same levels of air pollution as someone who lives near a highway with ten times as much traffic.5 If sufficiently stringent, EPA’s heavy-duty vehicle emissions standards have the opportunity to right historic wrongs, mitigate air pollution, and reduce greenhouse gas emissions. [EPA-HQ-OAR-2019-1050]

Organization: *Energy Innovation, LLC*

In addition, air pollution has an adverse impact on public health and quality of life for nearly all Americans, but communities of color, lower-income individuals, and frontline communities remain disproportionately impacted. [EPA-HQ-OAR-2019-0055-1310-A1, p.1]

We know that air pollution from transportation disproportionately impacts people of color, who are three times more likely than white people to live in the most polluted counties in the U.S.xxxix [EPA-HQ-OAR-2019-0055-1310-A1, pp.6-7]

Organization: *Environmental Community Advocates of Galena Park*

I live in the port community of Galena Park. The 18 wheelers rule our main street of Clinton Dr. Monday thru Friday we live in a world of dust and particulate matter. When will be free of these trucks? [EPA-HQ-OAR-2019-0055-2825,p.1]

Organization: *Environmental Defense Fund (EDF) (1265 and 2855)*

The health burden from truck and bus pollution is substantial, causing adverse health impacts in utero, in infants and children, and in adults and the elderly – with those who live closest to our nation’s roads and highways, ports, distribution centers, freight depots, and other well-known sources of truck pollution facing the greatest harms.6 EPA has estimated that 72 million people live within 200 meters of a truck freight route, and relative to the rest of the population, people of color and those with lower incomes are more likely to live near truck routes.7 [EPA-HQ-OAR-2019-0055-1265-A1, p.4]

Despite making up only about 4 percent of vehicles on the road,8 the buses, trucks, and tractor trailers that distribute our people and goods are the largest contributor to ozone-forming oxides of nitrogen (NOx) emissions from all highway vehicles and will be one of the largest mobile source contributors to ozone in 2025.9 They are also responsible for a significant amount of health-harming fine particulate matter (PM2.5) and more than 420 million tons of climate pollution – nearly a quarter of all transportation sector emissions and more than the entire country of Australia.10 [EPA-HQ-OAR-2019-0055-1265-A1, p.4]

It is estimated that more than 15,000 Americans die prematurely every year as a result of the motor vehicle pollution on our roads and highways.11 As a result of housing discrimination and other unjust policies, communities of color and low-income communities constitute a higher percentage of the population near our roads and highways and therefore suffer disproportionately from this harmful pollution.12 According to the American Lung Association’s 2022 State of the Air report, people of color are more than three and a half times more likely to breathe the most polluted air when compared to white people.13 A report by Moving Forward Network found that, on average, Asian and Black Americans are exposed to PM2.5 pollution that is 56 and 44 percent higher, respectively, than white Americans.14 And an EDF analysis of the Bay Area in California found that neighborhoods with higher percentages of residents of color experienced double the rate of asthma from nitrogen dioxide (NO2) –a pollutant often used as a marker for transportation-related pollution.15 [EPA-HQ-OAR-2019-0055-1265-A1, p.5]

Heavy-duty diesel vehicle emissions are often identified as among the largest source of disparity, disproportionally affecting racial-ethnic minorities across geographies and demographics.16 A recent analysis by The Real Urban Emissions (TRUE) Initiative finds that people of color living in New York City are exposed to 5 percent more PM2.5 attributable to diesel trucks operating in the city than average, while non-Latino white residents are exposed to 10 percent less.17 TRUE concludes, '[t]hese inequities in air pollution exposure contribute to racial disparities in health outcomes.'18 [EPA-HQ-OAR-2019-0055-1265-A1, p.5]

Recent work using satellite data to assess the health burdens from NO2 pollution in 52 cities found diesel traffic is the dominant source of disparities—across race, ethnicity, and income—and that a 62 percent reduction in on-road diesel traffic would decrease these inequalities by 37 percent, noting that heavy-duty diesel vehicle emissions, specifically, contribute to the majority of these NO2 inequalities.19 [EPA-HQ-OAR-2019-0055-1265-A1, pp.5-6]

19 Demetillo, M. A. G., Harkins, C., McDonald, B. C., Chodrow, P. S., Sun, K., & Pusede, S. E. (2021). Space-based observational constraints on NO2 air pollution inequality from diesel traffic

in major US cities. Geophysical Research Letters, 48, e2021GL09433. https://doi.org/10.1029/2021GL094333

Analysis by scientists at EDF, Harvard Chan School of Public Health and University of North Carolina, using state of the art fine scale air quality modeling and health impact assessment methods, found that electrification of medium- and heavy-duty diesel vehicles will have significant benefits in New York City at a census tract scale.20 Full electrification of the sector in New York area would **prevent $2.4 billion in health damages** every year by 2040 (248 deaths, 173 childhood asthma emergency department (ED) visits), much of it directly due to the nitrogen dioxide (NO2) reduction health benefits. Many minority and low-income neighborhoods with high baseline asthma ED visits also have elevated diesel truck and bus traffic and pollution and therefore face disproportionate impacts. Census tracts with 97 percent minority populations bear > 35 percent of total childhood asthma ED visits attributable to medium- and heavy-duty vehicles, despite being only 19 percent of the population. [EPA-HQ-OAR-2019-0055-1265-A1, p.6]

20 Presentation by Jonathan Buonocore, Chet France, Rick Rykowski, Brian Naess, Komal Shukla, Catherine Seppanen, Dylan Morgan, Frederica Perera, Katie Coomes, Ananya Roy, Sarav Arunachalam. 2022. 'Distribution of Air Quality Health Benefits of MHEV policies: New York,' University of North Carolina, Harvard Chan School of Public Health, Columbia University Mailman School of Public Health and Environmental Defense Fund.

This also means that these communities in New York City will potentially experience significant benefits of medium- and heavy-duty electrification. Up to 68 percent of childhood asthma ED visits reduced will be accrued in census tracts with >85 percent minority populations if full electrification takes place by 2040. (See Attachment D for full details of the analysis and results) [EPA-HQ-OAR-2019-0055-1265-A1, p.6]

Heavy-duty vehicles are also responsible for significant NOx, PM2.5, and black carbon emissions around ports, railyards, distribution centers, airports, and other places where trucks congregate and idle.21 Warehouses and distribution centers where trucks pull in and out, and often idle, are also concentrated sources of risk. Again, many discriminatory policies have led to the siting of these facilities near communities of color who face higher rates of underlying health conditions as a result of the cumulative burden from air pollution and other factors.22 In Houston's Fifth Ward, diesel trucks that come and go from the cluster of metal recyclers and concrete processing plants, drive up NO2 levels by 48 percent relative to the rest of the city. Residents are largely people of color (more than 90 percent), 40 percent live below the federal poverty line and life expectancy is almost a decade lower than the rest of the region (69 compared to 78 years).23 [EPA-HQ-OAR-2019-0055-1265-A1, p.6]

Commercial diesel trucks also take an especially heavy toll on neighborhoods along their routes. A years-long study in Canada confirms large trucks to be the greatest contributors to black carbon emissions near major roadways.24 A study in Oakland, California found that transportation-related air pollution (e.g., black carbon and NOx) was much higher—in some cases double—on a freeway that is a designated truck route (I-880) compared to another freeway in the same city where trucks are prohibited (I-580).25 Another study near the Port of Oakland also found that black carbon levels measured along truck routes were higher compared to measurements at most other sites, including those near industrial facilities, other highways and on residential streets.26 Studies have combined these fine scale assessments with electronic health records in the health care systems serving the population in Oakland (Sutter Health and Kaiser Permanente) and find that these elevated levels of NO2 and black carbon are associated with higher rates of cardiovascular events,27 asthma emergency room visits and hospitalizations,28 as well as adverse pregnancy outcomes.29 Estimated effects of NO2 and black carbon on preeclampsia were highest among non-Latina Black mothers.
