Sample Results Being Sent to Homeowners River Valley Ground Water Contamination Site, North Platte, Nebraska

INTRODUCTION

The U.S. Environmental Protection Agency (EPA) Region 7 was in the North Platte community sampling private drinking water wells during the week of June 21, 2004. This sampling was part of a removal assessment that looked for volatile organic compounds (VOCs). EPA worked closely with the state of Nebraska and the City of North Platte to conduct this effort.

The area sampled covered most of the city of North Platte. Sample results showed most of the private drinking water wells were clear of any contamination. However, some wells showed high levels of VOCs. This area is generally north of 4th Street (Hwy 30) and east of Popular Street (Hwy 83), extending out to the city limits on the north and east.

EPA will send the results of laboratory testing of these samples to all residents that were sampled. For residents who have wells with VOCs in excess of the EPA Safe Drinking Water Act maximum contaminant level, EPA will work with the city, state, and the homeowner to determine the best strategy for preventing exposure to the contamination.

In addition, EPA will conduct a second sampling effort in the area where contamination was found to determine whether or not other residences have been impacted.

SUPERFUND PROGRAM

Congress established the Superfund program in 1980 in response to growing concerns over human health and environmental risks posed by hazardous waste sites. Superfund locates, investigates and cleans up hazardous waste sites.

SITE BACKGROUND

A Nebraska Department of Health public water supply sampling program (1988) initially detected volatile organic compound (VOC) contamination in some of the seventeen municipal wells that serve the City of North Platte. Since then, several VOCs have been identified in groundwater samples collected during subsequent site investigations, including an EPA investigation in 2002. That investigation confirmed the detection of PCE in soil at one location, and that the groundwater had been impacted by VOC contamination beneath the site.

The chemicals present at the site include tetrachloroethene (PCE), trichloroethene (TCE), and other VOCs. PCE and TCE are the only VOCs to have been detected above EPA Safe Drinking Water Act maximum contaminant level.

CURRENT INVESTIGATIONS

The focus of the June sampling effort was on private wells, as opposed to the municipal wells that were been sampled in the past. The sampling was intended to

determine whether or not the contamination found in the municipal wells previously has also occurred in private drinking water wells.

Since the sampling results showed contamination in several private drinking water wells, EPA will work with City officials to ensure that citizens are protected from exposure to this contamination. In addition, a second sampling effort will be conducted to find additional private drinking water wells that may be contaminated, and to determine the extent of the contamination in the area previously sampled.

FOR MORE INFORMATION

If you live in the general area, have a private well on your property that you drink from, and want to have it sampled, please contact:
