#### PREFACE

This report on health effects of methanol was prepared by Midwest Research Institute (MRI) on Task No. 7 under Contract No. 68-03-2928, "Health Effects Support for the Emission Control Technology Division" for the U.S. Environmental Protection Agency.

Health effects literature primarily related to inhalation exposures to methanol has been collected, evaluated, tabulated, and summarized so that this report can be used to derive a range of concern for human exposure to vehicular atmospheric emissions of methanol. Because of the possible use of methanol as a fuel, a brief summary of the health effects from ingestion and skin absorption has been included.

Task activities were coordinated by the project leader, Mrs. Bonnie L. Carson, Senior Chemist, and task leader, Ms. Joy L. McCann, Assistant Scientist. Documents were rated and summarized by senior pharmacologists, Drs. Harry V. Ellis III, and Betty L. Herndon, of MRI, and epidemiologist, Larry H. Baker, M.D., MRI consultant, who is Associate Professor of Community Health at the University of Kansas Medical Center. Data were tabulated and the annotated bibliography prepared by Ms. McCann and Mrs. Carson. This study was performed under the general supervision of Dr. Edward W. Lawless, Head, Chemical Impact Assessment Section.

Mr. Robert J. Garbe was the project officer for the Emission Control Technology Division, U.S. Environmental Protection Agency, and Ms. Colleen DeMeyer served as Branch Technical Representative.

#### SUMMARY

# GOALS AND METHODS

The purpose of this compilation of data on methanol (MeOH)\* inhalation exposures is to assist the Emissions Control Technology Division (ECTD) of the U.S. Environmental Protection Agency (EPA) to establish the ranges of exposure conditions that are of concern for MeOH in exhausts from vehicles equipped with catalytic converters and to be able to advise automobile manufacturers thereof. The situations of concern are during malfunctions and during exposures in traffic jams, parking and home garages, and other situations where little dilution of the exhaust is expected before inhalation. Most of the report is, as directed by ECTD, in the form of tables based on the literature reviewed. Data from exposures at levels higher than those of primary concern are included because strictly relevant information was scarce and these related data might prove helpful in assessing health effects at lower levels.

In addition to MeOH inhalation data, literature related to oral ingestion and skin absorption was also retrieved and reviewed for this task. Brief summaries of the toxicity and range of concern associated with these two routes of exposure are included. These were included because of the recognition by ECTD that MeOH is being proposed as an alternative fuel in automobiles, and such usage would result in skin absorption from spills during handling and possible ingestion from siphoning or other careless handling.

Documents relevant to this study of health effects from exposure to MeOH were identified from manual and computerized literature searches and then rated in a two-step process by the project pharmacologists and epidemiologist. First, the document received an A, B, C, or D rating according to its applicability for deriving a range of concern for MeOH inhalation exposure. Second, if the paper was not a low-rated, foreign language document,\*\* a theoretical paper, a review, or a nontoxicology experimental paper, it received a numerical score based on itemized features that should be present in an ideal report. For the most part, only A- and B-rated documents were tabulated; but when data were limited as with MeOH, C- and D-studies were also tabulated when it was felt they contributed some useful information to the overall evaluation of health hazards. Blanks in the tables should be construed as denoting missing information in the documents.

<sup>\*</sup> Chemical formula CH<sub>3</sub>OH. Also called methyl alcohol and wood alcohol.

\* Most foreign language articles rated C and D were usually not translated.

Each foreign language document tentatively rated A or B from an English language abstract or brief examination of the paper was translated in sufficient degree to judge the experimental design and details. These papers were numerically scored from the translation.

# BACKGROUND INFORMATION ON METHANOL TOXICITY

Methanol is a well-known poison, discussed today in most standard reference works on toxic chemicals (such as Gosselin et al., 1976). In the past, MeOH's toxicity was debated, and, as late as 1936, doubts existed as to the toxicity of pure MeOH. The toxicity of wood alcohol was attributed to its impurities by some early authorities (Bennett et al., 1953). A 1904 report by Wood and Buller documented the earliest cases of MeOH poisoning; it stated that 275 cases of blindness or death attributable to wood alcohol were reported between 1856 (when the first scientific report of toxicity was made) and 1904. Nevertheless, MeOH was a frequent component of liniments, toilet articles, perfumes, and some patent medicines well into this century (Wood, 1912).

Practically all the MeOH toxicity data involve its ingestion with, or as a substitute for, ethanol (ethyl alcohol). The immediate symptom is an inebriation, indistinguishable from that from ethanol ingestion. After 12 to 18 h, the characteristic MeOH toxicity appears, presumably caused by its metabolites, formaldehyde and formic acid. Symptoms include headache, weakness, leg cramps, and vertigo; nausea and vomiting sometimes with violent abdominal pain; back and leg pain; vision defects; rapid, shallow breathing from metabolic acidosis; and weak, rapid pulse with hypotension; progressing to apathy and coma, or to excitement, mania, and convulsions. Death, if it occurs, is usually from respiratory failure. In nonfatal cases, convalescence is often protracted and complicated by debility, blindness, and kidney problems.

Relatively few experimental studies on MeOH toxicity have been published, and most of them involved very large doses, mechanistic studies of the retinal toxicity, or both. Most human reports are case studies, with little exposure data. Toxicity has occurred from ingestion, inhalation, contact, and confounded exposure through two or all three routes (Wood and Buller, 1904; McLean et al., 1980).

Methanol's toxicity (especially its ocular effects) is generally believed to be caused by its metabolites, although its metabolism is not fully understood. In humans and other primates, MeOH is first oxidized to formaldehyde by the enzyme catalase, but in lower animals this oxidation is effected by alcohol dehydrogenase. The highly reactive formaldehyde quickly disappears from the tissue but was formerly believed to be the cause of toxic effects. More recently, the further metabolites, formic acid or formate esters, have been proposed to be the toxic products. Tephly et al. (1974; 1979) have reviewed the available information on the metabolism of MeOH.

# BIOASSAY STUDIES

The broassay data were limited in applicability to human toxicity, but did demonstrate that in the animal  $\underline{in}$   $\underline{vitro}$  systems studied, MeOH is not very toxic and not mutagenic. In the one respiratory tissue study, 0.4 to

1.4 mg MeOH in aerosol at the rate of 27 mL/s inhibited ciliary activity in the esophageal tract of the leopard frog. Another study found low concentrations of MeOH,  $\leq 0.02$  mMol increased release of lung prostaglandins; higher MeOH levels decreased rate of release.

# INHALATION STUDIES

Chao (1959) exposed rats 12 h/day for 8 weeks. He found definite toxicity (respiratory tract irritation, liver degeneration, cortical neuropathy) at 50 mg/m³, but not at 1.77 mg/m³. Ubaydullayev (1968) found minor toxicity in rats exposed continuously for 90 d to 5.31 mg/m³, but none at 0.57 mg/m³. Sayers et al. (1942) exposed dogs (including pups bred and born during the exposure) to about 600 mg/m³ for 8 h/d, 7 d/wk for over a year. Although blood MeOH levels were typically 7 to 15 mg/dL after a daily exposure, no adverse effects were noted.

Human case reports (e.g., Wood and Buller, 1904; Tyson, 1912) have shown toxicity from MeOH in lacquer thinner and similar products. Although some skin contact would have occurred, this exposure is presumably primarily from inhalation.

Several human experimental studies have determined an odor threshold for MeOH. The highest reported value was 7,800 mg/m $^3$  (May, 1966). Leonardos et al. (1969) reported identification of MeOH odor at 133 mg/m $^3$ , while Hellman and Small (1974) reported the same results at 70 mg/m $^3$ . Minimum detectable thresholds include 4.3 to 11 mg/m $^3$  (Chao, 1959); 4.5 mg/m $^3$  (Ubaydullayev, 1968); and 5.7 mg/m $^3$  (Hellman and Small, 1974). The discrepancy may be due to the purity of the MeOH used in testing.

Two groups studied the effects of MeOH on nervous system reflexes. Chao (1959) found that 3.3 to 3.7 mg/m³ was the threshold for degradation of light sensitivity (dark adaptation), with 1.8 to 2.4 mg/m³ having no effect. Ubaydullayev (1968) found EEG changes, of dubious significance at 1.17 mg/m³, but not 1.01 mg/m³, in subjects selected for olfactory sensitivity.

The reports of studies involving occupational exposure to MeOH are not very useful for our purposes. Several studies were confounded by the presence of other chemicals, were poorly controlled, or the reports lack necessary information. Kingsley and Hirsch (1954-1955) found that office workers complaining of recurrent headaches were exposed to ~ 22 to 500 mg MeOH/m³ from spirit duplicating machines and those workers actually operating the machines had more severe symptoms. One study (Barmann and Angerer, 1979) found a significant increase of formic acid (a MeOH metabolite) in the blood and urine of print shop workers exposed to 113 to 178 mg MeOH/m³. Another study (Dutkiewicz and Blockowicz, 1967) found that workers exposed to 45 to 1,640 mg MeOH/m³ had levels of MeOH in their urine (during the work shift and immediately afterwards) ranging from 0.09 to 36.4 mg/L, the level varying according to level of exposure.

# INGESTION STUDIES

These usually involved overwhelming doses, since most animal studies were prompted by fatal or near-fatal human accidents. The classic case report is the Atlanta epidemic of 1951 (Bennett et al., 1953), involving 323 patients and 41 deaths from 90 gal. of contaminated moonshine whiskey. Very notable is the extreme variability in individual sensitivity. One patient died from ingesting 6 mL of MeOH, while another survived 200 mL. Cooper and Kini (1962) cite contrasting reports in which one man consumed 540 mL without irreversible toxicity, while blindness occurred with ingestion of 15 mL and death from ingestion of 30 mL in another case.

#### SKIN ABSORPTION

All inhalation exposures (except mask tests) involve the possibility of skin absorption. McCord (1931) showed that skin absorption and inhalation exposures produced similar effects in animals. Yant and Schrenk (1937) observed similar results in dogs given MeOH by inhalation, stomach tube, or subcutaneously. Dutkiewicz et al. (1980) reported similar results in humans given MeOH orally or on the skin. They calculated a dermal absorption rate of  $0.192 \, \text{mg/cm}^2/\text{min}$ , but did not report toxicity from doses of  $1.7 \, \text{mL}$ .

#### ENVIRONMENTAL CONTRIBUTIONS TO HUMAN EXPOSURE

Cigarette smoking is a source of MeOH exposure for humans. One gas phase analysis of cigarette smoke found 180  $\mu g$  MeOH/cigarette (Grob, 1965); another study found 13 and 10  $\mu g$  MeOH/40 mL puff of smoke from unfiltered and filtered cigarettes, respectively (Newsome et al. 1965). Newsome and Keith were reported to have found a range of 100 to 200  $\mu g$  MeOH/cigarette (Maddox and Mamenta, 1977).

Alcoholic beverages may contribute to an individual's exposure and accumulation of MeOH in the blood. Levels of 3.9 to 105.5 mg MeOH/L have been reported in commercial alcoholic beverages (Schneck, 1979; Majchrowicz and Mendelson, 1971; Carroll, 1970). Alcoholics with high blood ethanol levels (> 100 mg/100 mL) tend to accumulate MeOH in their blood at levels up to 2.7 mg/100 mL after an 11-d intoxication (Majchrowicz and Mendelson, 1971). Some of the MeOH accumulated by alcoholics is believed to be derived from endogenous sources and accumulated due to ethanol's disruption of MeOH oxidation and elimination. That some MeOH is endogenously produced is supported by studies finding MeOH levels of 0.06 to 0.49  $\mu$ g/L and 0.3 to 3.4 ppm in normal human breath (Eriksen and Kulharni, 1963; Jansson and Larson, 1969). Another study of 54 healthy nonsmoking adults found only 3.6% of 387 breath samples to contain MeOH; the mean concentration when found was 0.549 mg/m³ (Krotoszynski et al., 1979).

Certain foods have been reported to contain MeOH. Brussels sprouts, celery, onions, parsnips, potatoes, and swede (rutabaga) were vegetables that contained "large" or "very large" levels (unquantified) of MeOH after boiling for 30 min. Frozen peas and corn and instant coffee contained little or no MeOH after cooking (Self et al., 1963). Eriksen and Kulharni (1963) found that levels of MeOH in human breath tended to increase 1 to 2 h after eating.

A potential contribution to human exposure would be the exhaust of vehicles fueled by MeOH or MeOH/gasoline mixtures. Review of the numerous literature data on MeOH levels in vehicular exhaust was beyond the scope of this task.

# INTERNATIONAL RECOMMENDATIONS AND STANDARDS

Several U.S. agencies and professional associations have regulations and recommendations concerning the level of MeOH in different situations. The Occupational Safety and Health Administration standard for MeOH exposure in the workplace is 200 mg/m³ for a ceiling level. The American Conference of Governmental Industrial Hygienists suggests 260 mg MeOH/m³ as the time-weighted-average threshold limit value (TLV) and 310 mg/m³ as the short-term-exposure limit (ACGIH, 1978). The American National Standard Institute (ANSI) listed a ceiling concentration of 600 ppm ( $\sim$  798 mg/m³) MeOH with the provision that the 8-h time-weighted average concentration of MeOH is at or below 200 ppm ( $\sim$  260 mg/m³) (AIHA, 1978).

In the U.S.S.R., the Maximum Allowable Concentrations (MAC) in air for 1972 were 5 mg MeOH/m³ in the workplace, and 1 mg/m³ as the one-time limit and 0.5 mg/m³ as the average limit in populated places (U.S.S.R., 1972). The Czechoslovakian normal workplace MAC for 1970 was 100 mg/m³ with 500 mg/m³ as the short-term, single exposure permitted level (ILO, 1970).

#### RECOMMENDED RANGE OF CONCERN

MeOH is rapidly absorbed by <u>all</u> exposure routes, and is notorious for the wide range of human susceptibility to it. The range of response for oral ingestion varies from recovery after doses of 200 to 500 mL to death and blindness after doses of only 6 to 60 mL. That a dose of 6 mL (approximately 1 teaspoon) could cause death appears surprisingly low, the report is from Bennett et al. (1953), a relatively recent case study involving hospital observation and treatment of poison victims. Dutkiewicz et al. (1980) reported no toxicity from ingestion of 1.67 g (~ 2 mL). These data suggest a range of concern of 0.1 to 1 mL for ingestion of MeOH while handling it as an automotive fuel.

For inhalation, the TLV is currently set at 260 mg/m³, but at that level, a workperson inhaling 10 m³ of air over an 8-h period would have an intake of 26 g/d or 32.5 mL/d. This is well above the upper limit of the ingestion range of concern. Chao (1959) recommended a TLV limit of 1.5 mg/m³ after a study finding eye sensitivity unaffected by 1.8 to 2.4 mg/m³. The data of Ubaydullayev (1968) tend to support this level; eye sensitivity was unaffected at 3.1 mg/m³. Changes in cerebral cortex activity were detected at 1.17 and 1.47 mg/m³ but not at 1.0 mg/m³. In an isolated case, Humperdinck (1941) reported one worker had vision problems from exposure to 1.6 to 10.9 mg/m³. For inhalation of MeOH, a range of concern of 1.0 to 3.0 mg/m³ is suggested. (An 8-h exposure would result in intake of 10 to 31 mg/d or 0.013 to 0.039 mL/d.)

MeOH is readily absorbed through the skin, and cases have been reported of death, blindness, and other injury from MeOH either spilled on clothes or applied to the skin. A rate for skin absorption of MeOH by humans of  $0.192~\text{mg/cm}^2/\text{min}$  has been reported (Dutkiewicz et al., 1980). Immersing a whole hand ( $\sim 440~\text{cm}^2$ ) in MeOH for 2 min would result in the absorption of 170 mg (0.2~mL) of MeOH or within the range of concern for ingestion. Long or repeated skin contact with a solution of 1% or above of MeOH would give exposures in the range of concern and should be avoided. Appropriate personnel protective equipment, such as rubber gloves, to prevent skin contact is suggested for handling MeOH fuel.

#### SECTION I

#### INTRODUCTION

This report on methanol (MeOH)\* was compiled as the seventh task under Contract No. 68-03-2928, "Health Effects Support for the Emission Control Technology Division (U.S. Environmental Protection Agency, Ann Arbor, Michigan)." The goal of the project is to evaluate health effects literature on specific compounds emitted from automobiles equipped with emission-control devices (specifically catalytic converters), not for the purpose of creating a criteria document but to identify a range of concern or a no-observable-effect level for each compound to serve as guidance to automobile manufacturers in their development of future emission-control devices. This particular report also contains a brief review of the health effects of exposure to MeOH by ingestion and skin absorption as might occur in handling MeOH if it is adopted as an alternative automobile fuel.

The present report was meant to be largely a series of charts or tables of pertinent data with the tests logically ordered according to exposure levels. The narrative summary was not meant to describe again each paper in detail. There are admittedly some disadvantages in not doing so; e.g., some of the graduations in effect that the authors of a particular paper observed may be diluted or lost when the details are spread throughout an exceptionally large table, or between several tables. Papers described in a largely narrative fashion, however, often are difficult to compare. Results that appear within their source paper to be quite definitive may appear less so or even anomalous when juxtaposed in tabular format with other results from similar studies. Hence, the present format was designed to facilitate comparisons.

Literature related to health effects of MeOH exposure was collected mainly by computer search of TOXLINE and TOXBACK and manual search through the NIOSH criteria document on MeOH. Approximately 160 papers and other documents were evaluated, but only about 25 contained original data suitable for tabulation.

Experimental animal and human exposure studies were evaluated and summarized by a senior Ph.D. pharmacologist. Occupational exposures were rated by an epidemiologist with an M.D. degree. Figure I-1 is the form used for rating documents by the project pharmacologist and epidemiologist. Each

<sup>\*</sup> Also called methyl alcohol and wood alcohol. The chemical formula is CH<sub>3</sub>OH.

- a. Clearly, directly applies/assists in establishing a range of concern (Chronic human studies; acute exposure of humans if minimal effects.)
- Research requires major inferences; potentially applicable.
   (Chronic animal studies; acute human, maximal effect; acute animal, minimal effects.)
- c. Useful hints or suggestions; tentatively applicable. (Acute animal, lethal effects; studies in above categories but effects reported not appropriate.)
- d. Not directly applicable (peripheral useful information).

Figure I-1. Form for report rating.

document was rated in a two-step procedure according to the applicability of its subject matter and to the quality of the experimental methodology. The letter assigned in rating the document A, B, C, or D was derived from the corresponding lower case letters under item 7 in Figure I-1. Thus, a study was rated A if it directly applies to or assists in establishing a level of concern for exposure to MeOH. The second part of the rating is the methodology score. The document reviewer checked off which score should be given for each of the first six items in Figure I-1, and the total was written at the top of the pages along with the letter that rated the paper's applicability. In some cases, such as reviews, theoretical papers, and low-rated foreign language documents, a paper may have received an applicability rating (generally C or D), but none on methodology.

Data, including the MRI-assigned rating, from the papers were tabulated by mid-level scientists. Information for each topic heading was carefully sought; so if blanks appear in the table, the reader can generally assume the data were not given. Sometimes a group published several papers that described the same tests. To avoid redundancy, all pertinent papers were cited and the test was described as well as possible from all the papers' descriptions.

The final written summary of the tabulated data was also performed by a senior pharmacologist. This summary attempts to reflect objectively the scientific community's thought as a whole and does not reflect the tabular material by weight. The <u>tables</u> reflect the amount of data generated, and the <u>summary</u> puts the evaluated data in perspective with the overall scientific community's opinions.

The references are cited in an annotated bibliography that includes not only each document's rating, but also a brief comment on its pertinence (or lack of same) to the study. English titles are given for foreign language documents. An abbreviation of the language is given in parentheses at the end of the citation.

The report is organized into the following chapters: II - Bioassay Tests; III - Experimental Animal Inhalation Exposures; IV - Experimental Human Inhalation Exposures; and V - Occupational Exposures and Human Case Reports. The Summary precedes the entire report.

#### SECTION II

# **BIOASSAYS**

Broassay studies involving MeOH are limited. A brief summary of the literature is presented here rather than a tabulation of the limited data. These  $\underline{\text{in}}$   $\underline{\text{vitro}}$  studies contribute little in our understanding of the mechanisms of activity or toxicity of the chemical in man that would be useful to the task of determining a range of concern for human exposure to MeOH in automobile exhaust.

Mazur et al. (1969) noted the gut contraction that occurred in rabbits exposed to MeOH, defined the fraction or metabolite responsible, and measured its effects on the contraction amplitude and coronary output of the isolated rabbit heart. Methanol (and formic acid), 0.0001 M, decreased both rate and cardiac output while formaldehyde at that concentration had no effect.

Thomas et al. (1980) measured prostaglandin ( $PgE_2$ ) released from rat isolated perfused lungs exposed to varying concentrations of aliphatic alcohols. MeOH in increasing concentrations, up to 0.02 mM, caused increased  $PgE_2$  release; higher concentrations caused a decrease.

In the one bioassay study involving respiratory tissue, Tremer et al. (1959) found that 0.4-1.4 mg MeOH in aerosols at the rate of 27 mL/s for 2 s inhibited mucus flow of ciliated epithelium from the esophageal tract of the leopard frog.

Gotterer (1969) showed that rat liver beta-hydroxybutyrate dehydrogenase enzyme assay required 4,600 mM MeOH to produce 50% inhibition. For comparison, quinine produced 50% inhibition with 0.11 mMol.

Hohne and Patsch (1969) studied bacterial inhibition by several alcohols. Two percent MeOH had no effect on Staphylococcus aureus, Escherischia coli, and Klebsiella pneumoniae were unaffected by 1% MeOH. It was less toxic to these organisms than was isopropyl or isomeric butyl alcohols.

Khan (1969) showed that the microsomes of the common housefly produced an epoxide with the cyclodiene aldrin, and that MeOH at high concentrations stimulated this microsomal epoxidation.

Obe and Ristow (1977) found no sister chomatid exchange (SCE) following 7- to 8-d treatment of Chinese hamster ovary cells in culture with 0.1% (by volume) MeOH daily.

# SECTION III

# EXPERIMENTAL ANIMAL INHALATION EXPOSURES

This chapter presents the essential parameters of the studies involving animal inhalation experiments. Relatively few studies were found in the literature and a number of these involve rather high-level exposures (from 55,214 to 5,320 mg/m³); effects reported range from a 6-h LD $_{50}$  for mice of 54,530 mg/m³ to no illnesses when dogs inhaled MeOH at 13,300 mg/m³ for 3 min, 8 times/d for 160 d. Changes were reported in the nervous systems of rats and rabbits, with repeated and chronic doses of 5 to 5.3 mg/m³. No effects reported at 1.7 mg/m³ for 12 h/d for 90 d or to 0.57 mg/m³ continuously for 90 d.

The primary organization of data is by species, in order of increasing weight (mice to monkeys in this case). Within a species, studies are divided by dosing duration: acute exposure ( $\leq 24$  h), repeated exposure, and chronic exposure ( $\geq 90$  d). Within a single table, reported results are listed in order of decreasing exposure level.

In the animal exposure tables in this section (Tables III-1 through III-10), the column headed "Total length of experiment" includes not only the total length of exposure to MeOH but also any recovery time observed in the study. This recovery time was included to note the endurance or reversibility of the toxic effects.

TABLE III-1 MICE--ACUTE EXPERIMENTAL EXPOSURE TO MOOH

Compound(s) and concentration(s) in mg/m³ (ppm)	Humidity/ temp	Mode of exposure	Species/ strain/ age/weight	No of test animals	No of controls	Duration and frequency of exposure	Total length of exporiment	Fffects	Reference and rating
MeOH ~ 55,214 (41,514)		2 1-L inha- lation cham- ber with only head exposed	Mice, Swiss- Webster	8 N	Served as own controls	10 min	10 min	RD <sub>50</sub> value calculated from mice responses, RD <sub>50</sub> is defined as the concentration of chemical that produces a 50% decrease in respiration rate	Kane et al (1980) C-11
MeOH ~ 54,530 (41,000)	22-25°C	28-L inha- lation cham- ber	Mice			6 h, once	30 h (all deaths 24 h after exposure counted)	Calculated 6-h LC <sub>50</sub> Livers of exposed animals had a significant degree of centrilobular fatty metamorphosis. Eyes had acute keroconjunctivitis characterized by an infiltrate of neutrophils into the cornea and conjunctiva	Scott (1978) B-9

TABLE III-2. MICE--REPEATED DOSE EXPERIMENTAL EXPOSURE TO MECH

Compound(s) and concentration(s) in mg/m³ (ppm)	Humidity/ temp	Hode of exposure	Species/ strain/ age/weight	No of test animals	No of controls	Duration and frequency of exposure	Total length of experiment	Effects	Reference and rating

MeON 6,650 (5,000)		250-L inha- lation cham- ber	Rats, Sprague- Dawley 200-450 g	≧ 6	≥ 6	1 h	9 h	No change in carboxyhemoglobin levels at 2 or 4 h postexposure	Ciuchta et al (1979) C-8

TABLE 111-4 RATS--REPEATED DOSF EXPERIMENTAL EXPOSURE TO MOOH

Compound(s) and concentration(s) in mg/m³ (ppm)	Humidity/ temp	Mode of exposure	Species/ strain/ age/weight	No. of test animals	No of controls	Duration and frequency of exposure	Total length of experiment	Effects	Reference and
MeOH 50			Albino rats	10	10	12 h/d ex- cept for days off for 3 mo	≥ 18 wk (1 mo habituation to test conditions plus 3-wk recovery period)	A slight change of the ratio of the chronaxy of the muscle antagonists was seen in the 2nd wk which became more expressed in the 4th wk Starting from the 8th wk of poisoning, the values of the chronaxies of the flexors and extensors converged, but by the end of poisoning they had diverged. The ratio returned to normal in the recovery period.  The histopathological examination revealed catarrhal-desquamative tracheitis, bronchitis, hyperplasia of the tracheal submucous glands, whose infiltrates were of a slightly lymphoid character. Changes in the trachea	Chao Chen-Ts; (1959) A-8 (human) B-8 (anımal)
								were somewhat more expressed than in the bronchi and lung tissue  Swelling, hypertrophy of the muscle layer of some medium- and low-caliber arteries of the lungs, and very weakly expressed degernative changes in the liver (nonuniform staining of the nuclei and granularity of the protoplasm were sometimes observed  Dendrites of the neurons of the brain cortex were distinctly deformed and their branches had disappeared The top dendrites of the pyrimidal cells were more affected	
МеОН 1 77			Albino rats	10	10	12 h/d except for days off for 3 mo)	≥ 18 wk (1 mo habitu- ation to test con- ditions plus 3 wk recovery period)	The concentration was lower than the human odor threshold (2 4 mg/m³) or the threshold of reflex action on light sensitivity of the eye  At the end of poisoning, all rats were healthy and active and had gained weight No classical toxic symptoms (irritation or nervous system affection). The average chronaxy of the muscle extensors was significantly higher than the average chronaxy of the flexors, as it was in the control group.	Chao Chen-Tsi (1959) A-8 (human) B-8 (animal)

TABLE III-6 RABBITS--CHRONIC EXPERIMENTAL EXPOSURE TO MeOH

Compound(s) and concentration(s) in mg/m³ (ppm)	Humidity/ temp	Mode of exposure	Species/ strain/ age/weight	No of test animals	No of controls	Duration and frequency of exposure	Total length of experiment	Effects	Reference and rating
MeOH ~ 5 ("near the 1968 MAC")			Rabbits, mature	6	6	4 h/d, 6-7	6-7 mo, animals killed by air embolism and eyes immediately enucleated	General nervous system changes were observed for other animals exposed to hexanol, heptanol, nonanol, and decanol as well as methanol The reactions of the retina were of the same type after exposure to all the alcohols at the levels of their MACs. The structure and functional capacity of the retina, optic nerve, optic chiasm, optic tract, anterior corpora quadrigemina, and cerebral optic lobe were damaged. The retinal changes resembled those reported from oral dosing at MeOHpathological changes at the ganglionic cells and proliferation of the glial elements.  Irritation of the nerve fibers of the optic nerve, optic chiasm, and optic tract was expressed in "corkscrew" twisting of the fine nerve fibers and protoplasm leakage along the path of the thick fibers. Proliferation of the glia, hyperemia of the vessels, and dilation of the perivascular space also occurred. The optic nerve was	Fel'dman and Vendilo (1973) C-5
								Degenerative phenomena in the neurons and proliferative phenomena in the glia were also observed in the visual region of the brain cortex  The histological results agree with those	

TABLE 111-7 DOGS--ACUTE EXPERIMENTAL EXPOSURE TO MEON

Compound(s) and concentration(s) in mg/m³ (ppm)	Humidity/ temp	Mode of exposure	Species/ strain/ age/weight	No of test animals	No of controls	Duration and frequency of exposure	Total length of experiment	Effects	Reference and rating
MeOH ~ 19,950 (15,000)			Dogs	3		22-24 h	22-24 h for two dogs, re- covery pe- riod of 48 h for one dog	Blood levels of MeOH were 1,390-1,470 mg/100 g at end of exposure but dropped to 335 mg/100 g 48 h later in the one dog Levels in tissue were in the 500-1,000 mg/100 g range at end of exposure but dropped to 200-400 mg/100 g 48 h later. The distribution of MeOH to tissues and fluids was closely related to the amount of water in the various body fluids and tissues.	Yant and Schrenk (1937) C-7
MeOH ~ 5,320 (4,000)			Dogs	2		12 h	12 h	Blood level of MeOH was 100 mg/100 g Levels in tissue ranged from 95 mg/100 g in kidneys to 17 mg/100 g in adipose tissue. The distribution of MeOH to tissues and fluids was again closely related to the amount of water in the tissue or fluid.	Yant and Schrenk (1937) C-7
MeOH 390-720		Inhalation through nose mask while anesthetized	Dogs, mongrel, 8-22 kg	≥ 5		Not re- ported	Not re- ported	Retention of MeOH by respiratory tract increased with increased exposure concentration but was not affected by tidal volume	Egle and Gochberg (1975) D-11
NeOH 400-600		Inhalation through tracheotomy while anes- thetized	Dogs, mongrel, 8-22 kg	≧ 5		Not re- ported	Not re- ported	Lower respiratory tract NeOH retention rate was 64 6-68 2% with no relationship to ventilatory rate. Upper respiratory tract retention was 63 0-66 1% and related to ventilatory rates, with increased retention as the ventilatory rate increased.	Egle and Gochberg (1975) D-11
MeOH 400-600		Inhalation through nose mask while anesthetized	Dogs, mongrel, 8-22 kg	≧ 5		Not re- ported	Not re- reported	Total respiratory tract retention of MeOII was 81 2-88 4% over a range of ventilatory rates of 7-30/min. There was a statistically significant relationship between increased retention and higher ventilatory rates.	Egle and Gochberg (1975) D-11

# SECTION IV

# EXPERIMENTAL HUMAN INHALATION EXPOSURE

This chapter describes acute laboratory human exposures to MeOH. A number of the studies presented in Table IV-1 are odor threshold determinations. Reported odor thresholds range from a high of 7,800 mg/m³ to a much lower 4.3 mg/m³, with values in between of 71, 133, and 1,500 mg/m³. Varying levels of impurities in the MeOH samples tested may account for the discrepancy in results, since odor thresholds of compounds of low odor are greatly influenced by the presence of odorous impurities. Two studies measured urinary levels of MeOH during inhalation; another, cerebral cortex reflex activity; two investigated eye responses. Effects on eyes were found at 3.3 to 6.5 mg/m³ levels but not at 1.8 to 2.4 mg/m³, all far below the TLV limit of 260 mg/m³ but above the upper limit of this report's recommended range of concern of 3.0 mg/m³.

TABLE IV-1 HUMANS--ACUTE AND REPEATED DOSE EXPERIMENTAL INHALATION EXPOSURE TO MEON

Compound and concentration in mg/m³ (ppm)	Mode of exposure	No of test subjects	No of controls	Duration and frequency of exposure	Total length of experiment	Effects	Reference and rating
MeOH 11,700	Inhalation by "sniffing" flask of MeOH	8 M, 8 F, ages 31-63		Tests repeated up to 5 X/d for an unspec- ified number of d for sev- eral mo	Not given	Clearly perceptible odor threshold measured at 760 torr and 20°C	May (1966) D-5
МеОН 7,800	Inhalation by "sniffing" flask of MeOH	8 M, 8 F, ages 31-63		Tests repeated up to 5 X/d for an unspec- ified number of d for sev- eral mo	Not given	Just perceptible odor threshold measured at 760 torr and 20°C	May (1966) D-5
MeOH ~ 1,995 (1,500)	Inhalation from air blender	3		Not given		Odor threshold	Scherberger et al (1958) D-10
MeOH 1,430	Small sealed room, 22 9 m <sup>3</sup>	1 (G L ), same sub- ject also exposed to 1,350, 732, and 700 mg/ m³ levels at unknown intervals	Served as own control	1 6 h - 1st ex- posure, 2 9 h - 2nd exposure	~ 4 5 h	Urinary MeOH level increased steadily during both exposures, was 2 00 mg/100 mL at end of 1st exposure During 2nd exposure, level at 1 6 h was 1 88 mg/100 mL, and 2 56 mg/100 mL at 2 5 h	Leaf and Zatman (1952) A-7
МеОН 1,350	Small sealed room, 22 9 m <sup>3</sup>	1 (G L ), same sub- ject also exposed to 1,430, 732, and 700 mg/ m³ levels at unknown intervals	Served as own control	3 h	~ 3 3 h	Urinary MeOH level increased steadily during exposure, was 1 46 mg/100 mL** at 1 6 h and 2 06 mg/100 mL at 2 5 h	Leaf and Zatman (1952) A-7

<sup>\*</sup> Subject's initials
\*\* Urinary MeOH levels reported by Leaf and Zatman (1952) are corrected for the control value, the level found on entry into the exposure room prior to any MeOH exposure (continued)

IABLE IV-1 (continued)

Compound and concentration in mg/m³ (ppm)	Mode of exposure	No of test subjects	No of controls	Durition and frequency of exposure	Total length of experiment	F(fects	Reference and rating
MeOH 1,230	Small sealed room, 22 9 m <sup>3</sup>	i (I J Z ), same sub- ject also exposed to 655 and 732 mg/m³ levels at unknown intervals	Served as own control	2 5 h	~ 3 h	Urinary McOH level increased steadily during exposure, was 1 90 mg/100 mL at 1 6 h, and 2 54 mg/100 mL at 2 5 h	Leaf and Zatman (1952) A-7
МеОН 732	Small scaled room, 22 9 m <sup>3</sup>	1 (L J 2 ), same subject also exposed to 1,230 and 655 mg/m³ levels at unknown intervals	Served as own control	4 h	4 h	Urinary MeOH level increased steadily during exposure, was 0 94 mg/100 mL at 1 6 h, 1 32 mg/100 mL at 2 5 h, and, at the end of the exposure, $\sim$ 2 2 mg/100 mL	Leaf and Zatman (1952) A-7
НеОН 732	Small sealed room, 22 9 m <sup>3</sup>	1 (G L ), same sub- ject also exposed to 1,430, 1,350, and 700 mg/m <sup>3</sup> levels at unknown intervals	Served as own control	4 h	4 h	Urinary MeOH level increased steadily during exposure, was 0 77 mg/100 mL at 1 6 h, 1 05 mg/100 mL at 2 5 h, and, at the end of exposure, ~ 1 8 mg/100 mL	Leaf and Zatman (1952) A-7
НеОН 700	Small sealed room, 22 9 m <sup>3</sup>	1 (G L ), same sub- ject also exposed to 1,430, 1,350, and 732 mg/m <sup>3</sup>	Served as own control	3 1 h	~ 3 1 h	Urinary McOH level increased steadily during exposure, was 0.56 mg/100 mL at 1.6 h, and 0.78 mg/100 mL at 2.5 h	Leaf and Zatman (1952) A-7

TABLE IV-1 (continued)

Compound and concentration in mg/m³ (ppm)	Mode of exposure	No of test subjects	No of controls	Duration and frequency of exposure	Total length of experiment	Effects	Reference and rating
MeON 655	Small sealed room, 22 9 m <sup>3</sup>	I (L J Z ), same sub- ject also exposed to 1,230 and 732 mg/m <sup>3</sup> levels at unknown intervals	Served as own control	3 3 h	~ 3 5 h	Uninary MeOH level increased steadily during exposure, was 0.76 mg/100 mL at 1.6 h, 1.03 mg/100 mL at 2.5 h, and, at the end of the exposure, $\sim$ 1.4 mg/100 ml	Leaf and Zatman (1952) A-7
MeOH 298-337	Room, 64 3 m <sup>3</sup>	3 M, ages 31-56		8 h/d for 4 consecutive d (urine col-lected at 2-h intervals)	~ 96 h	No accumulation of MeOH in the body, urine levels returned to normal before the next exposure	Sedivec et al (1981) A-10
МеОН 300	Room, 64 3 m <sup>3</sup>	4 M, ages 31-56	17 M 14 F	8 h, once	24 h	Lung retention independent of lung ventilation and duration of exposure. Urine MeOH level increased from norm of $\sim 0.7$ mg/L to $9.5$ mg/L at $8$ h and returned to normal $16$ h after end of exposure.	Sedivec et al (1981) A-10
МеОН 231-251	Room, 64 3 m <sup>3</sup>	5 M, ages 31-56		4 h/8 h, in 2-h periods with exposures chosen to cover all possible combinations of early, late, and alternate expo- sure/nonexposure		MeOH in urine was affected by "pauses" in exposure - level dccreased Short-term urine samples did not accurately reflect level of total exposure in this type of intermittent exposure	Sedivec et al (1981) A-10
<b>М</b> еОН 205	Room, 64 3 m <sup>3</sup>	4 M, ages 31-56	17 M 14 F	8 h, once	24 h	Lung retention independent of lung ventilation and duration of exposure. Urine MeOH level increased from norm of $\sim$ 0.7 mg/L to 6.6 mg/L at 8 h and returned to normal 16 h after end of exposure.	Sedivec et al (1981) A-10
MeOH 200 Ethanol 514	Room, 64 3 m <sup>3</sup>	3 M, ages 31-56		8 h		No inhibitory effect from ethanol on level of MeOH in urine	Sedivec et al (1981) A-10

TARIE IV-1 (continued)

Compound and concentration in mg/m³ (ppm)	Mode of exposure	No of test subjects	No of controls	Duration and frequency of exposure	Total length of experiment	Effects	Reference and rating
NeOH 199	Room, 64 3 m <sup>3</sup>	4 M, ages 31-56, 2 limited liq- uid intake, 2 increased it, subjects switched roles 2nd wk		8 h, once/wk	2 uk	McOH in urine remained the same regardless of volume excreted. (Indicates rate of excretion of MeOH from the body is dependent on intake of liquids.)	Sedivec et al (1981) A-10
MeOH 133 (100)	500 ft <sup>3</sup> in- halation chamber	Four trained odor panelists	None	Duration not given, ≥ 20 min bytween tests	Not given	Odor threshold determined as level at which panelists recognized the odor	Leonardos et al (1969) A-11
HeOH 118	Room, 64 3 m <sup>3</sup> , 19 5-min exer- cise periods on a bicycle ergometer	4 н		8 iı		Jung ventilation increased on avg of 2.56 X during exercise. The total air volume inspired during the 8-h test was 1.45 X higher than normal. The basic correlation between MeOH dose and MeOH concentration in whole workshift urine (derived at resting lung ventilation) was also valid where subjects performed physical work and had enhanced lung ventilation.	Sedivec et al (1981) A-10
МеОН 103	Room, 64 3 m <sup>3</sup>	4 M, ages 31-56	17 M 14 F	8 h, once	24 h	Lung retention independent of lung ventilation and duration of exposure. Urine MeOH level increased from norm of $\sim 0.7$ mg/L to $3.2$ mg/L at $8h$ and returned to normal $10h$ after end of exposure	Sedivec et al (1981) A-10
MeOH 99 Ethanol 996	Room, 64 3 m <sup>3</sup>	3 M, ages 31-56		8 h (14 d af- ter exposure to 200 mg MeON/m <sup>3</sup> level)		No inhibitory effect from ethanol on level of MeOH in urine	Sedivec et al (1981) A-10
MeOH 70.9 (53 3)	Odor fountain	Trained odor panel with un- reported number of subjects	Not given	20 min	20 min	Odor recognition threshold, concentration at which 100% of the odor panel defined the odor as being representative of the odorant being studied	Hellman and Small (1974) A-3

#### SECTION V

#### OCCUPATIONAL EXPOSURES AND HUMAN CASE REPORTS

This chapter describes studies of occupational exposure to MeOH and contains a brief review of the numerous human case histories reported in the literature. The occupational studies (Table V-1) are not particularly useful in establishing a range of concern for MeOH exposure because of poor control, lack of health effect information, or confounded exposure. One study found 11 workers who developed vision defects from exposure to 1.6 to 10.9 mg MeOH/m³, but this is an isolated case. Headaches were reported by office workers exposed to 20 to 500 mg MeOH/m³, and also by two workers in another office where the MeOH exposure was much lower (~ 3.2 to 6.5 mg/m³) but confounded by the presence of toluene and CO.

Almost all of the case histories are early publications that give limited information, especially as to level of exposure. Because of the limited data, these cases are difficult to tabulate and contribute little toward quantifying a range of concern, but are of interest in that they definitely establish the toxicity of MeOH to humans through all routes of exposure.

Some of the earliest inhalation cases involved occupational exposure of workmen shellacking the interiors of beer vats. Wood and Buller (1904), Wood (1912), Carhart (1908), Herbert (1902), Jelliffe (1905), Tyson (1912), and Hamilton (1925) all report cases of workmen entering poorly ventilated beer vats and using varnish made with MeOH. These reports indicate that a number of workmen collapsed and either died or were left partially or totally blind as a result. These papers—as well as ones by De Schweinity (1901), Stricker (1908), and Hawes (1905) that reported other cases of painters and varnishers harmed by MeOH exposure—established the toxicity of MeOH by inhalation years ago. Descriptions of cases are limited; but, in general, the initial signs of toxicity were delayed until 1 day or more after the initial exposure when the workmen experienced various symptoms such as headaches, nausea, and failing vision.

Tyson (1912) reports the cases of two women who worked polishing lead pencils using varnish made with MeOH. Both had failing vision and other symptoms that cleared somewhat when leaving the workplace and getting fresh air.

The hat stiffeners were another early occupation in which workers suffered from MeOH exposure. Baskerville (1913) reported the cases of 15 such workers who had various health effects and diminished vision from MeOH exposure while working from 6 months to 32 years with MeOH. The testimony of

Danburg, Connecticut, hatters before Congress that 75 of their number had suffered health effects and/or impairment of sight contributed to the passage of a measure that made revenue-free denatured grain alcohol available for industrial use.

Another case of toxic occupational exposure to MeOH involved workers manufacturing artificial flowers. Twenty women were reported to have conjunctivitis and skin inflammation from their use of dyes dissolved in MeOH. Other occupational cases involved a man using a liquid shoe dye (Robinson, 1918), a worker in a nitrocellulose plant, and a chemical-pharmaceutical factory worker (NIOSH, 1976).

A few case histories clearly involving skin absorption have been reported, although some inhalation may have occurred in each case. One involved a painter who spilled a gallon of MeOH down his leg soaking his clothes and shoe. He let them dry on him and within a few days blindness developed (Hamilton, 1925). Wood and Buller (1904) report the case of a woman who bathed her head and face daily with MeOH for weeks. Her vision diminished until the MeOH applications were discontinued. Other cases involved 21 children who had cloths soaked in MeOH applied to their abdomens and held in place by rubber pants. Signs of intoxication developed in 1 to 13 h; 12 died, the others recovered without any permanent damage (NIOSH, 1976).

Literally hundreds of cases of poisoning by ingesting MeOH have been reported. By 1913, Baskerville had listed a series of 720 reported cases of which ~ 50% were fatal and ~ 25% resulted in permanent impairment of vision or blindness. Most of these cases involved drinking bootleg or cheap alcoholic beverages that had been adulterated with the cheap, readily available wood alcohol. Dose information is limited, but Baskerville reports a case where total blindness resulted from drinking 0.5 fluid ounce wood alcohol (~ 15 mL) and another case of death from 0.75 ounce (~ 22 mL). These case histories also indicate that extreme variability of individual sensitivity to MeOH exists as other cases were reported of individuals consuming four or more ounces of MeOH and recovering completely (Baskerville, 1913).

Cooper and Kini (1962) report that during the prohibition period in the United States there were 400 fatalities due to MeOH ingestion in 7 months. They also quote a 1950 report by Zohl that estimates 6% of all blindness in the Armed Forces during World War II was caused by MeOH ingestion. Other papers that detail later case histories but with limited dose information are Menne (1938), Closs and Solberg (1970), McLean et al. (1980), and McMartin et al. (1980).

Several major outbreaks of MeOH poisoning have been reported. Kane et al. (1968) reported on 18 cases in Kentucky. Cooper et al. (1952), Benton and Calhoun (1953), and Bennett et al. (1953) reported on the Atlantic epidemic of 323 cases with 41 deaths. Individuals had consumed illicit whiskey of 30 to 40% MeOH. Onset of symptoms varied from 40 min to 72 h and included visual disturbances, headache, and gastrointestinal disturbances. Again, great individual variable was evidenced—one individual died from ingesting 15 mL, another individual survived 500 mL.

TABLE V-1 STUDIES OF OCCUPATIONAL EXPOSURE 10 MeOH

Compound(s) and Concentration(s)	Population Group					Reference and
ın mg/m³ (ppm)	Description	Exposed	Controls	Effects	Remarks	Rating
leOH 754-1,640 hand unloading ind crushing of holesterol, 1 heach shift)	Workers in a plant manufacturing emul- gents from choles- terol	2	None	Urine sampled during work shift and 8 h afterwards at 2-h intervals  MeOH in urine during work shift ranged from 14 4-36 4 mg/L, with 1st level of one worker at only 4 8 mg/L. After work, levels ranged from 0 36 to 3 96 mg/L with highest levels 6 and 8 h after work shift	No health effects measured Useful, however, for correlation of environmental exposures to physiologic measurements in exposed persons. Inadequate numbers to be convincing and no real controls are present.	Dutkiewicz and Blochowicz (1967) C-6
MeOH 45-894 (short-term exposures for 0 25-5 h during certain processes in production cycle)		5		Urine MeOH levels during work shift ranged from 0 83 to 22 5 mg/L After work levels ranged from 0 046-1 37 mg/L	No health effects measured Useful, however, for correlation of environmental exposures to physiologic measurements in exposed persons Inadequate numbers to be convincing and no real controls are present	Dutkiewicz and Blochowicz (1967) C-6
MeOH 59-270 (longer-term ex- posures during regular produc- tion for most of 8 h shift)		6		Urine MeOH levels during work shift ranged from 0 09-12 3 mg/L with most < 4 mg/L; after work levels ranged from 0 07-1.37 mg/L with most < 1 mg/L	No health effects measured Useful, however, for correlation of environmental exposures to physiologic measurements in exposed persons Inadequate numbers to be convincing and no real controls are present	Dutkiewicz and Blochowicz (1967) C-6
MeOH ~ 20-499 (15-375)	Office workers	Not given	None	Workers reported frequent, recurrent, persistent headaches, especially in cooler weather when windows were closed Workers closer to the spirit duplicating machines and those actually operating them had most severe symptoms	No quantification of health effects nor numbers of persons affected Air measurements taken are not re- lated to any measure of physiologic parameters. It rates as an anecdotal case report	Kingsley and Hirsch (1954–1955) D-3

## TABLE V-1 (continued)

Compound(s) and Concentration(s) in mg/m³ (ppm)	Population Group					Reference and
	Description	Exposed	Controls	Łſſects	Remarks	Rating
MeOH ~ 113-178 (85-134) Mean of air concentration in three locations in shop, range over 16 5-h sampling period was < 10 to 650 ppm	Workers in printing shop	20	15-36	Blood and urine levels of formic acid were compared between workers and controls  In blood, mean value of controls in the morning was 5 6 ± 4 5 mg/L, and, in the afternoon, 4 9 ± 4 2 mg/L. In the workers, the mean value in the morning was 3 2 ± 2 4 mg/L, and, in the afternoon, 7 9 ± 3 4 mg/L. The controls had either lower or slightly higher (0 6 mg/L) afternoon values compared to morning values, whereas all the workers had higher afternoon values. Both the increased level in the afternoon and the differences between the control and workers' afternoon values are significant.  In urine, the mean value of controls in the morning was 11 9 ± 6 4 mg/L, and, in the afternoon, 11 7 ± 5 6 mg/L. In the workers, the mean morning value was 13 1 ± 3 9 mg/L, and, in the afternoon, 20 2 ± 7 0 mg/L. Same significant increase as with blood in workers' afternoon values over morning or control values.  Analysis of MeOH content of alveolar air of exposed worker showed slightly significant increase between morning and afternoon levels.  Angerer et al (1977) compared air levels of MeOH in the three locations to mean workers' formic acid levels in urine and MeOH in alveolar air and found no dose relationship to measured levels	Cross-sectional study of measured air exposure to MeOH and effect as measured by blood and urine formic acid level. No health effects were measured. Controls revealed wide variability of formic acid concentrations in blood (0 to 20 mL) and urine. Unfortunately, information was not obtained on factors which influence formic acid levels (i.e., diet, cigarette smoking status, etc.). Stratification on these parameters may have permitted a better understanding of the use of these measures in epidemiological or occupational studies. Useful since, although no correlation was present between air exposure levels, there was a significant difference over time (i.e., beginning at end of shift) as compared to controls.	Baumann and Augerer (1979), Angerer and Lehnert (1977), Angerer et al (1977) B-9

TABLE V-1 (continued)

Compound(s) and Concentration(s)	Population Group					Reference and
in mg/m³ (ppm)	Description	Ехрочед	Controls	Fffects	Remarks	Rating
HCHO 5-78 MeOH 2 1-7 5 EtOH 47 5-110	Workers in the for- malin department of a sheepskin dyeing factory	99 F, 25- 40-y-old, worked for 5-20 y	84 F in other shops, Iree of HCHO vapors	Complaints of persistent headache, vertigo, irritability, and tendency to weep. Skin temperature was measured on the forehead, chest, and forearm, and the variations between the left and right sides of the body reported. The incidence of physiological thermal asymmetry (a difference of 0.1-0.5°C) before work was 43.3% in the exposed group and 27.2% in the controls. The incidence of pathological thermal asymmetry (0.6-2.2°C) before work was 48.4% in the test group and 3.0% in the controls. After work, the physiological asymmetry was about equal in both groups (3.3% versus 34.5% in the controls), and the pathological asymmetry increased to 60% in the test group, compared to 8.6% in the control group. The authors consider this evidence of adverse effects on the CNS, including the thermoregulatory center.	Essentially a prospective design The exposure was confounded by the presence of ethanol (EtOH) and McOH vapors, and monochloroacetic acid Comparability of the controls is not discussed	Kamchatnov and Gayazova (1971) C-8
MeON ~ 3 2-6 5 (2 4-4 9) Toluene (0 6-1 0) CO (< 5 0) MeON and toluene were generated by even limited use of the copying machine	Workers in a busi- ness office	2	None	Workers complained of headaches, dry or sore throats, periods of illness seemed to correlate with operation of office copying machine	Confounded exposure Health effects poorly described No controls	Fannick (1980) C-5

  - C--. Summary of production, uses and toxicity of MeOH. Brief case histories of 15 persons affected by MeOH while working in stiffening departments of hat factories are presented as well as listing of  $\sim$  75 others injuried by the same type of exposure. Eye inflammation and loss of vision were reported in majority of cases.
- 7-005 Baumann, K., and J. Angerer. 1979. Occupational Chronic Exposure to Organic Solvents. VI. Formic Acid Concentration in Blood and Urine as an Indicator of Methanol Exposure. Int. Arch. Occup. Environ. Health 42(3-4):241-249.
  - B-9. Study of workers in printing shop exposed to MeOH at levels of  $\sim 10$  to 650 ppm (mean for 3 locations 85-134 ppm). Formic acid levels in blood and urine were measured in the morning and again in the afternoon to see if there was an increase during exposure to MeOH. Formic acid levels did significantly increase during exposure both compared to morning levels in the workers and in comparison to levels in control persons. Authors concluded urine and especially blood levels of formic acid can be checked for indication of exposure to MeOH but is not accurate enough to monitor occupational exposure because of individual variability.

Flury, Eds. Translated from German by E. King and H. F. Smith, Jr. The Williams and Wilkins Company, Baltimore, Maryland. pp. 198-325.

- C--. General discussion of MeOH use, human and animal toxicity, human poisoning and treatment.
- 7-016 Funes-Cravioto, F., C. Zapata-Gayon, B. Kolmodin-Hedman, B. Lambert, J. Lindsten, E. Norberg, M. Nordenskjoeld, R. Olin, and A. Swensson. 1977. Chromosome Aberrations and Sister-Chromatid Exchange in Workers in Chemical Laboratories and a Rotoprinting Factory and in Children of Women Laboratory Workers. Lancet 2(8033):322-325.
  - D-9. Workers were exposed to a variety of organic solvents, such that any possible abberations caused by MeOH are confounded by the other chemicals. Laboratory technicans were exposed to toluene and chloroform in addition to MeOH in each case as well as up to 4 other solvents. Possible exposure to MeOH occurred in 24 of the 73 workers studied. These MeOH exposed workers showed the same significant increase in chromosome aberrations and sister-chromatid exchange as the whole group of 73 workers studied. Authors conclude some environmental factor was causing the increased frequency of chromosome breaks but that the causative agent could not be determined.
- 7-051 Gadzhiev, G. P., V. G. Deinega, V. V. Sukhanov, I. M. Levshina, N. I. Yarym-Agaeva, and G. A. Petrenko. 1977. Hygienic Evaluation of a New Technology of Methane and Dust Control in Coal Mines. Gig. Sanit. No. 7:24-26 (Russ).
  - D-4. The physical condition of miners in mines treated with urea-HCHO resin did not differ after several months from that of miners in untreated mines. In treated mines, the air contained 0.02-0.13 mg  $\rm HCHO/m^3$  and 0.14-0.8 mg  $\rm MeOH/m^3$  during cleaning operations. Rats given an intratracheal dose of treated or untreated dust showed more severe bronchial changes if the dust was followed by a 6-mo exposure to 0.5-0.6 mg  $\rm HCHO/m^3$  and 5.0-6.0 mg  $\rm MeOH/m^3$ .

  - C--. Discussion of the dangers of exposure to MeOH. Report on the case of a man who worked dyeing hats for 2-3 h/d. He used a dye containing 4% MeOH which evidently was both inhaled and absorbed through his hands as they were reportedly often stained black. His vision began failing after ~ 3 mo and total blindness followed.
- 7-133 Roche, L., J. Champeix, L. Echegut, A. Nicolas, and A. Marin 1957. A Study of the Pathology of Collective Accidents Observed in an Industrial Establishment. Ann. Med. Leg. 37:43-51 (Fre.)

- D--. Case studies (6 in detail) of 52 workers making electrical apparatus with a range of medical complaints: narcosis, convulsions, nausea, vomiting, prickling in the extremities, violent headaches, dryness of mouth and pharynx, constriction of the thorax, coma, and syncope. The cause was believed to be vaporization of trichloroethylene and another unknown solvent, probably methanol. Experiments were done on guinea pigs exposed to each of these, alone and together (levels unknown), to confirm the belief. After removal of the solvent vats from the work area, only complaints of slight, benign symptoms were received, the authors attributing them to psychological causes.

  - D--. Lavsan fiber workers were exposed to several other compounds (dimethyl terephthalate, ethylene glycol, dinyl, and/or polyethylene terephthalate thermal decomposition products (terephthalic acid and acetaldehyde besides 1.6-25.5 mg MeOH/m<sup>3</sup>.
- Rodriguez, R., M. Lorenzana-Jimenez, A. Manjarrez, and H. Gomez-Ruiz. 1978. Behavioral Effects from the Acute and Chronic Inhalation of Thinner in Rats of Various Ages. In: Voluntary Inhalation Ind. Solvents. ADM-79-779, National Institute on Drug Abuse, Alcohol, and Mental Health Administration, U.S. Public Health Service, Department of Health, Education, and Welfare, Rockville, Maryland.
  - D-6. Rats were exposed to thinner containing 25% MeOH plus toluene, hetone, and other solvent constituents.  $LD_{50}$  decreased significantly with increased age, and young rats in general seemed more resistant than adults to effect of solvent, but chronic exposure did retard body development in young rats. Exposure was too confounded to relate any toxicity to MeOH.

  - A--. Compilation of odor threshold values reported by different researchers, for many compounds, including:

- 7-063 Varela Rodelo, F. 1978. Biochemistry of Methanol Intoxication. Rev. Inst. Nac. Med. Leg. Colomb. 3(1):79-91 (Spa).
  - D--. Review of the toxicity and metabolism of MeOH.
- 5-111 Vilisov, B. A., N. S. Irger, L. M. Kremko, Z. N. Pavlyutina, I. G. Tseluiko, Y. S. Danishevich, and S. S. Khudnitskii. 1980. Hygienic Evaluation of Some Synthetic Resins and Their Effect on the Health of Molding Department Workers. Zdravookhr. Beloruss. No. 1:31-34 (Russ).
  - D-7. Foundry core makers using phenol-formaldehyde copolymer, urea-formaldehyde, and furan resins suffered a higher rate of disorders of the skin, liver, kidney, and respiratory organs compared to workers involved in machine building. Metal casting workers using these resins were ill about half as often and half as long as the core makers. Amounts of substances released in g/ton during mixing and hardening of the resins (and during heating of the molds up to 800°C) were as follows: HCHO, 0.4-34.6 (not detected to 10.4); phenol, N. D. (not detected) to 1.7 (N.D.-8.5); MeOH, 1.6-124.9 (N.D.-4.2); furfurol, N.D.-2.9 (N.D.-1.6); furyl alcohol, N.D.-142.7 (N.D.); NH<sub>3</sub>, 0.3-16.7 (1.2-1875.5); CO, N.D.-61.5 (12.7-4014.7); and HCN, N.D.-0.6 (N.D.-376.3). Thus, the more frequently ill core makers were exposed to more HCHO, MeOH, and furyl alcohol than the casters; and the casters were exposed to more phenol, NH<sub>3</sub>, CO, and HCN than the core makers.

## 13 3011 LEMENTANT NOTE

## 16 ABSTRACT

Health effects literature primarily related to inhalation exposure to methanol was collected, evaluated, tabulated, and summarized. Approximately 160 documents were collected from computerized and manual literature searches covering the period 1901-1980. Pharmacologists and an M.D. epidemiologist rated the documents according to their applicability to the study and their methodology. The approximately 25 documents considered useful for deriving a range of concern for human exposure to methanol from automotive emissions were tabulated. The pages of tables detail the results of acute, repeated dose, and chronic testing of mice, rats, rabbits, dogs, monkeys and humans as well as human occupational studies. A brief summary of oral and skin absorption toxicity is included. Most of the documents evaluated are described in an annotated bibliography.
