The proposed rule states that emissions for an electric vehicle are zero. This position leaves no regulatory incentive to maximize efficiency or reduce weight within electrified vehicles and could result in larger amounts of critical elements consumed by larger batteries, as well as greater emissions from electric power sources needed to propel these vehicles than would otherwise be needed. This disregard for vehicle efficiency distinction across BEVs conflicts and does not align with the existing and historic approaches of the Corporate Average Fuel Economy (CAFE) program and is a potential disruption to harmonization. [EPA-HQ-OAR-2022-0829-0644, pp. 6-7]

Consistent with its current authority to regulate power plant emissions, EPA should specify a value for electric generation emissions for each year 2027-2032 and include this in BEV emissions calculations, based on vehicle energy use. [EPA-HQ-OAR-2022-0829-0644, pp. 6-7]

The assignment of an emission value per kWh of battery capacity in BEV would assure that public incentives for larger BEVS provide the environmental benefits promised and other advanced clean transportation alternatives also improve their propulsion system efficiencies. [EPA-HQ-OAR-2022-0829-0644, pp. 6-7]

This approach will also ensure more accurate assessments of BEV emissions. EPA could use the readily known and available national electricity generation data paired with miles per gallon equivalent (MPGe) to serve as a BEV emissions value for comparison. It is important this metric be aligned with NHTSA Corporate Average Fuel Economy (CAFE) standards. This metric is justified in the directions of 49 USC 39204 (a)(2)(B)(i), which require the Administrator of the EPA to consider net upstream emissions of electric vehicles when calculating fleet average fuel economy.4 [EPA-HQ-OAR-2022-0829-0644, pp. 6-7]

4 49 USC 39204 (a)(2)(B) "(B) If a manufacturer manufactures an electric vehicle, the Administrator shall include in the calculation of average fuel economy under paragraph (1) of this subsection equivalent petroleum based fuel economy values determined by the Secretary of Energy for various classes of electric vehicles. The Secretary shall review those values each year and determine and propose necessary revisions based on the following factors: (i) the approximate electrical energy efficiency of the vehicle, considering the kind of vehicle and the mission and weight of the vehicle."

A well-constructed rule will be technology-neutral and provide added regulatory certainty by fairly assessing carbon content of vehicle's technologies, their production and where vehicle charging electricity comes from. At this time, there is no review of carbon content of components or vehicles in the draft regulatory impact analysis. We understand the complexity of this endeavor, but EPA overlooks broad environmental impacts through a selectively narrow focus on tailpipe emissions. Electric vehicles have no tailpipe, and thus no tailpipe emissions. If EPA is determined to regulate zero-emissions vehicles, EPA should address lifecycle carbon content of vehicles in scope of this rule to better balance technology vs. tailpipe. [EPA-HQ-OAR-2022-0829-0644, pp. 6-7]

Organization: Minnesota Biofuels Association

Secondly, the proposed rule falsely assumes that electric vehicles have a zero grams per mile compliance value. Under a proper lifecycle evaluation, the upstream carbon emissions associated with using an electric vehicle would include electricity generated from coal or natural gas, high-energy and land use changes from critical mineral extraction, and vehicle construction and assembly. Ignoring the upstream emissions related to electricity generation and critical mineral extraction for electric vehicles creates an uneven playing field and risks undermining efforts to achieve our net-zero climate goals. [EPA-HQ-OAR-2022-0829-0672, pp. 1-2]

Before finalizing the rule, we urge EPA to consider the role of American-made biofuels in achieving enhanced vehicle efficiency and emissions reductions. A technology-neutral final rule can be achieved by equally incentivizing technologies like Flex Fuel Vehicles and Plug-in Hybrid Flex Fuel Vehicles and subjecting all vehicle and fuel options to similar carbon accounting treatment through a full lifecycle analysis that considers upstream emissions. [EPA-HQ-OAR-2022-0829-0672, pp. 1-2]

Thank you for considering our comments and we look forward to working with you on meaningful and achievable solutions to reduce greenhouse gas emissions from transportation. [EPA-HQ-OAR-2022-0829-0672, pp. 1-2]

Thank you for considering our comments and we look forward to working with you on meaningful and achievable solutions to reduce greenhouse gas emissions from transportation. [EPA-HQ-OAR-2022-0829-0672, pp. 1-2]

Organization: Minnesota Corn Growers Association (MCGA)

PERFOMANCE BASED/TECHNOLOGY NEUTRAL RULEMAKING NEEDED

The EPA is proposing that upstream emissions accounting for BEVs, which under the current regulations would begin in MY 2027, would be removed under the proposed program; thus, BEVs would continue to be counted as zero grams/mile in a manufacturer's compliance calculation. This is clearly not a performance-based or technology-neutral proposal, and it would have dire consequences for all other technologies which could potentially reduce emissions at lower cost, more quickly, with fewer geopolitical implications (such as critical minerals), and with greater consumer acceptance. [EPA-HQ-OAR-2022-0829-0612, pp. 4-5]

A recent study4 by Argonne National Lab, in cooperation with coauthors from the automotive and energy industries, shows a BEV with 400-mile range (BEV400) has lifecycle GHG emissions of about 250 g/mi. This is an improvement from a conventional internal combustion engine vehicle (ICEV) which is about 430 g/mi. However, the lifecycle GHG emissions of a BEV are far from zero. In fact, lifecycle GHG emissions of a BEV400 are comparable to other low-emission options such as E85 or PHEV. Regulations based only on tailpipe emissions are clearly inadequate for comparing BEVs to other pathways for reducing GHG emissions. [EPA-HQ-OAR-2022-0829-0612, pp. 4-5]

4 Kelly et al., "Cradle-to-Grave Lifecycle Analysis of U.S. Light-Duty Vehicle-Fuel Pathways: A Greenhouse Gas Emissions and Economic Assessment of Current (2020) and Future (2030-2035) Technologies", report ANL-22/27, June 2022.

The Argonne report demonstrates that other "vehicle-fuel pathways" can compete with BEVs. For example, a conventional gasoline hybrid (HEV) achieves about 310 g/mi and E85 in a non-HEV FFV achieves 260 g/mi. The future potential of HEVs combined with FFV technology, utilizing E85, is comparable to future BEVs with wind and solar power. [EPA-HQ-OAR-2022-0829-0612, pp. 4-5]

The proposed rulemaking does not allow other vehicle-fuel pathways to compete with BEVs. By regulating only tailpipe emissions, and ignoring the rich literature of lifecycle analysis, EPA would create artificial incentives for auto manufacturers to pursue only BEVs. This could have disastrous impacts on both the cost and the GHG emissions of future vehicles. The same Argonne report found the cost and GHG emissions of a BEV are strongly affected by the driving range. A BEV with 400-mile range is dramatically more expensive than one with 200-mile range, and its lifetime GHG emissions are substantially worse. In fact, a BEV with 400-mile range has only a slight GHG benefit compared to a HEV or an E85 FFV. But the proposed rule counts all BEVs as zero GHG emissions, regardless of battery size – and regardless of vehicle size and weight. [EPA-HQ-OAR-2022-0829-0612, pp. 4-5]

UPSTREAM EMISSIONS

EPA's proposal continues to treat EVs as carbon neutral, without regard to the source of electricity powering the vehicles. Depending on the sources of electricity – whether coal, natural gas, wind or nuclear and the mix of those sources - full lifecycle emissions of EVs vary widely, masking the true GHG emissions from these vehicles. Without accounting for upstream emissions from these vehicles, full lifecycle emissions are not considered. Furthermore, EPA notes in the proposal that increases in electricity demand will result in increased non-GHG emissions for some upstream pollutants. EPA does a disservice to emissions reduction goals by accounting for upstream emissions from some fuels and vehicle technologies but not others, providing an advantage to the sources for which "wells-to- wheels" upstream emissions are excluded and concealing emissions from coal power generation, mineral extraction, and other high-carbon sources. [EPA-HQ-OAR-2022-0829-0612, p. 6]

Organization: National Association of Convenience Stores (NACS) et al.

III. The Proposed Rule Fails to Account for the Lifecycle Emissions of Electric Vehicles.

Under the Proposal, electric vehicles effectively serve as the only means of compliance with the standards in part because the Agency focuses solely on tailpipe emissions rather than the full lifecycle emissions of light- and medium-duty EVs. This is a flawed approach. To ensure an accurate accounting of the lifecycle carbon intensity associated with each technology, EPA should incorporate lifecycle emissions into its analysis. This will facilitate continued investment in all decarbonization technologies alongside deployment of electric vehicles. [EPA-HQ-OAR-2022-0829-0648, pp. 10-12]

Though EVs do not directly have tailpipe emissions, other segments along the lifecycle of the EV do. The fuel source of an EV—a battery composed of carbon intensive minerals and the electricity generated to power the battery—produces meaningful emissions to which the Proposal turns a blind eye. Addressing the impact of climate change, however, requires mitigating emissions irrespective of whether they originate from a tailpipe, a mining operation, a power plant, or a battery plant. Consequently, emissions standards should account for the entire lifecycle emissions. [EPA-HQ-OAR-2022-0829-0648, pp. 10-12]

EPA's analysis examines only logistical challenges to EV manufacturing and does not account for carbon impacts of critical mineral mining, the use of natural resources for refining and processing, engine and battery manufacturing, and other confounding variables such as prolonged ICE turnover rates and vehicle end-of-life consequences. Importantly, a lifecycle analysis of EV emissions impacts will better equip EPA to understand the varying costs and emissions reductions associated with all technologies and best inform manufacturers and consumers of their options. [EPA-HQ-OAR-2022-0829-0648, pp. 10-12]

EPA also makes flawed assumptions regarding the total emissions impacts of the Proposal. Despite claiming that "upstream emissions impacts from fuel production at refineries and electricity generating units are considered in EPA's analysis of overall estimated emissions impacts and project benefits," 31 this analysis uses overgeneralizations and assumes cleaner and less expensive generation over time—incorrectly assuming as a certainty that the power sector will become cleaner through the increased use of wind and solar generation as well as electricity storage (e.g., batteries) despite opposition from the power sector.32 Although the Agency concedes these assumptions will still result in "some increases in ambient pollutant concentrations" and that "the specific locations of increased air pollution are uncertain," EPA fails to meaningfully engage with the consequences of even its own flawed analysis.33 [EPA-HQ-OAR-2022-0829-0648, pp. 10-12]

31 Proposed Rule at 29,252.

32 See, e.g., David Pomerantz, The New York Times, "Guess Who's Been Paying to Block Green Energy? You Have." (Jul. 5, 2023) available at https://www.nytimes.com/2023/07/05/opinion/utility-bills-clean-

energy.html; Susan Cosier, "Why Electric Utilities Are Resorting to Dark Money and Bribes to Resist Renewables," Audubon, March 16, 2021, available at https://www.audubon.org/news/why-electric-utilities-are-resorting-dark-money-and-bribes-resist- renewables ("Many utility companies cling to old business models and dirty fuels rather than go through the tough energy transition that climate change demands.") Comment from Southern Company on EPA Proposed Rule, Docket No. EPA-HQ-OAR-2022-0723, Comment ID EPA-HQ-OAR-2022-0723-0029 (Dec. 21, 2022) available at https://www.regulations.gov/comment/EPA-HQ-OAR-2022-0723-0029 (advocating for continued construction of new EGU infrastructure for fossil fuels and cautioning against unattainable limits for existing coal and natural gas EGUs); Valerie Volcovici and Nichola Groom, Reuters, "U.S. utilities want protection from Biden's tight timeline in clean energy mandate" (Apr. 14, 2021) available at https://www.reuters.com/business/sustainable-business/us- utilities-want-protection-bidens-tight-timeline-clean-energy-mandate-2021-04-14/.

33 Proposed Rule at 29,361.

The Proposed Rule fails to adequately evaluate local ambient air quality impacts from increased power generation. Though EPA modeled changes to power generation anticipated by the Proposed Rule as part of its upstream analysis, the Agency does not consider the potential degradation of air quality in areas in the direct vicinity of existing or new power plants.34 This is further complicated by the fact that emissions associated with electricity generation are not consistent across the U.S. In contrast to EPA's generalized emissions benefits, the emissions advantages of EVs are much lower in states with relatively high carbon profiles for electricity generation than those states with relatively low carbon profiles. Indeed, the Fuels Institute analyzed these differences and concluded that in states with high-carbon intensity electric generation, such as West Virginia, ICE vehicles produced decidedly less carbon emissions relative to EVs over the entire 200,000-mile life of the vehicles.35 Of course, the Report recognizes emissions advantages to EVs in those low-carbon states as well, but these differences further illustrate the importance of accurately accounting for full lifecycle emissions. Instead of comprehensively accounting for these emissions in compliance calculations, the Agency proposes to continue providing EVs with a discounted emissions rate by allowing these vehicles to be counted as producing 0 g/mile of CO2, and solidifying preferential treatment of one mode of technology: electric vehicles. [EPA-HQ-OAR-2022-0829-0648, pp. 10-12]

34 Proposed Rule at 29,361.

35 Ricardo Inc., FUELS INSTITUTE, "Lifecycle Analysis Comparison" (Jan. 2022) available https://transportationenergy.org/wp-content/uploads/2022/10/FI_Report_Lifecycle_FINAL.pdf.

While ICE-powered vehicles generally emit more carbon dioxide during operation, the emissions associated with the manufacturing of ICE-powered vehicles are significantly lower than those emitted from battery-electric vehicles.36 There is no climate rationale for EPA to pursue this rulemaking from a state of willful blindness over these distinctions. A recent examination conducted by Volvo provides a directly applicable case study. Volvo concluded that the "accumulated emissions from the [m]aterials production and refining, [Lithium-ion] battery modules and Volvo Cars manufacturing phases of C40 Recharge are nearly 70 percent higher than for XC40 ICE."37 Volvo explains, "[e]lectrification of cars causes a shift of focus from the use phase to the materials production and refining phase."38 [EPA-HQ-OAR-2022-0829-0648, pp. 10-12]

36 See IEA, "The Role of Critical Minerals in Clean Energy Transition" (May 2021) available at https://www.iea.org/reports/the-role-of-critical-minerals-in-clean-energy-transitions; see also David Biello, SCIENTIFIC AMERICAN, "Electric Cars Are Not Necessarily Clean,"(May 11, 2016) available at

https://www.scientificamerican.com/article/electric-cars-are-not-necessarily-clean/ ("Your battery-powered vehicle is only as green as your electricity supplier"); see also Nina Lakhani, THE GUARDIAN, "Revealed: How US Transition to Electric Cars Threatens Environmental Havoc," the Guardian, (January 24, 2023) available at https://www.theguardian.com/us-news/2023/jan/24/us-electric-vehicles-lithium-consequences-research. ("The US's transition to electric vehicles could require three times as much lithium as is currently produced for the entire global market, causing needless water shortages, Indigenous land grabs, and ecosystem destruction.").

38 Id. at pg. 5.

Further, the Proposed Rule overlooks the emissions impacts from the substantial expansion of the electrical grid. While EPA credits emissions reductions from assuming the power sector will become cleaner over time using renewable generation and electricity storage (e.g., batteries), it ignores the impacts of building out that associated infrastructure. New power generation, renewable power generation, and energy storage require the same critical minerals necessary for manufacturing EV batteries. Increased electricity demand will only further compound the stress on critical minerals. Indeed, copper and aluminum—both needed for EVs—are also the two main materials in wires and cables. Battery storage equipment for solar and other renewable energy sources rely on similar battery chemistries as EVs.39 Again, EVs may be the most environmentally compelling solution, but it does neither the climate nor American consumers any favors for the Agency to pretend the solution is more compelling or achievable than it actually is. [EPA-HQ-OAR-2022-0829-0648, pp. 10-12]

39 And, as described above, higher prices on these materials could have a major impact on future grid investments. INTERNATIONAL ENERGY AGENCY, The Role of Critical Minerals in Clean Energy Transitions (Mar. 2022), 77–80, available at https://iea.blob.core.windows.net/assets/ffd2a83b-8c30-4e9d-980a- 52b6d9a86fdc/TheRoleofCriticalMineralsinCleanEnergyTransitions.pdf.

The simultaneous spike in demand for materials such as copper and aluminum for both the grid and EV manufacturing will increase extraction and refining efforts globally, potentially exacerbating consequences on a regional level.40 By failing to consider geographic electricity generation differences and the potential benefits of a non-homogenized vehicle population, the Proposal misses the opportunity to most effectively respond to emissions concerns and, more importantly, could indirectly lead to increased emissions in certain regions. A full accounting of the relative advantages and disadvantages of the different vehicle technologies is necessary to ensure the Proposal harnesses the benefits of competition among different current and potential future vehicle technologies. [EPA-HQ-OAR-2022-0829-0648, pp. 10-12]

40 The U.S. is almost entirely dependent on other countries, especially China, for materials essential to manufacturing EVs, meaning the Proposal may potentially raise national security concerns.

Organization: National Corn Growers Association (NCGA)

The EPA is proposing that upstream emissions accounting for BEVs, which under the current regulations would begin in MY 2027, would be removed under the proposed program; thus, BEVs would continue to be counted as zero grams/mile in a manufacturer's compliance calculation. This is clearly not a performance-based or technology-neutral proposal, and it would have dire consequences for all other technologies which could potentially reduce emissions at lower cost, more quickly, with fewer geopolitical implications (such as critical minerals), and with greater consumer acceptance. [EPA-HQ-OAR-2022-0829-0643, p. 3]

A recent study 4 by Argonne National Lab, in cooperation with coauthors from the automotive and energy industries, shows a BEV with 400-mile range (BEV400) has lifecycle GHG emissions of about 250 g/mi. This is an improvement from a conventional internal combustion engine vehicle (ICEV) which is about 430 g/mi. However, the lifecycle GHG emissions of a BEV are far from zero. In fact, lifecycle GHG emissions of a BEV400 are comparable to other low-emission options such as E85 or PHEV. Regulations based only on tailpipe emissions are clearly inadequate for comparing BEVs to other pathways for reducing GHG emissions. [EPA-HQ-OAR-2022-0829-0643, p. 3]

4 Kelly et al., "Cradle-to-Grave Lifecycle Analysis of U.S. Light-Duty Vehicle-Fuel Pathways: A Greenhouse Gas Emissions and Economic Assessment of Current (2020) and Future (2030-2035) Technologies", report ANL-22/27, June 2022

The Argonne report demonstrates that other “vehicle-fuel pathways” can compete with BEVs. For example, a conventional gasoline hybrid (HEV) achieves about 310 g/mi and E85 in a non-HEV FFV achieves 260 g/mi. The future potential of HEVs combined with FFV technology, utilizing E85, is comparable to future BEVs with wind and solar power. [EPA-HQ-OAR-2022-0829-0643, pp. 3-4]

The proposed rulemaking does not allow other vehicle-fuel pathways to compete with BEVs. By regulating only tailpipe emissions, and ignoring the rich literature of lifecycle analysis, EPA would create artificial incentives for auto manufacturers to pursue only BEVs. This could have disastrous impacts on both the cost and the GHG emissions of future vehicles. The same Argonne report found the cost and GHG emissions of a BEV are strongly affected by the driving range. A BEV with 400-mile range is dramatically more expensive than one with 200-mile range, and its lifetime GHG emissions are substantially worse. In fact, a BEV with 400-mile range has only a slight GHG benefit compared to a HEV or an E85 FFV. But the proposed rule counts all BEVs as zero GHG emissions, regardless of battery size – and regardless of vehicle size and weight. [EPA-HQ-OAR-2022-0829-0643, pp. 3-4]

EPA’s proposal continues to treat EVs as carbon neutral, without regard to the source of electricity powering the vehicles. Depending on the sources of electricity – whether coal, natural gas, wind or nuclear and the mix of those sources - full lifecycle emissions of EVs vary widely, masking the true GHG emissions from these vehicles. Without accounting for upstream emissions from these vehicles, full lifecycle emissions are not considered. Furthermore, EPA notes in the proposal that increases in electricity demand will result in increased non-GHG emissions for some upstream pollutants. EPA does a disservice to emissions reduction goals by accounting for upstream emissions from some fuels and vehicle technologies but not others, providing an advantage to the sources for which “wells-to-wheels” upstream emissions are excluded and concealing emissions from coal power generation, mineral extraction, and other high-carbon sources. [EPA-HQ-OAR-2022-0829-0643, p. 4]

Organization: National Farmers Union (NFU)

IV. Regulatory Bias in Favor of Battery Electric Vehicles

EPA is proposing that upstream emissions accounting for battery electric vehicles (BEVs) as part of a manufacturer's compliance calculation, which under the current regulations would begin in MY 2027, be removed; "thus, BEVs would continue to be counted as zero grams/mile in a manufacturer's compliance calculation." 88 Fed. Reg. at 29,197. We do not believe such an approach is appropriate for a performance-based or technology-neutral proposal, as this approach would disadvantage and have negative consequences for all other technologies even if those technologies can reduce emissions at a lower cost, more quickly, with fewer geopolitical implications (such as those related to the need for critical minerals), and with less obstacles to gain increasing consumer acceptance that is critical to expand electric vehicle use. [EPA-HQ-OAR-2022-0829-0581, p. 6]

Numerous studies have used lifecycle analysis to quantify GHG benefits of BEVs compared to other options including hybrid electric vehicles (HEVs) and renewable fuels. As these studies show, BEVs are not zero emissions. Further, they are not the most cost-effective way to reduce GHG emissions. [EPA-HQ-OAR-2022-0829-0581, p. 6]

The proposed rulemaking would not allow other vehicle-fuel pathways to compete with BEVs. By regulating only tailpipe emissions, EPA would create artificial incentives for only BEVs. This could have disastrous effects on both the cost and the GHG emissions of future vehicles. As shown in Figure 37 from the same Argonne report (reproduced below),14 the cost and GHG emissions of a BEV are strongly affected by the driving range. A BEV with a 400-mile range is dramatically more expensive than one with a 200-mile range, and its lifetime GHG emissions are substantially worse. A 400-mile-range BEV has only a slight GHG benefit compared to a HEV or an E85 internal combustion engine vehicle (ICEV). But the proposed rule would count all BEVs as zero GHG emissions, regardless of battery size, vehicle size, or weight—all of which can have an impact on lifecycle GHG emissions and costs. [EPA-HQ-OAR-2022-0829-0581, p. 8]

14 Id. at 114.

[See original comment for graph of Lifetime Cost vs. GHGs, Current Tech] [EPA-HQ-OAR-2022-0829-0581, p. 8]

But the proposed emissions standards fail to address the large and growing problem of particulate emissions from tires, and instead focus on more stringent tailpipe particulate standards which will add cost without necessarily improving air quality. EPA should not artificially incentivize heavy BEVs by counting them as "zero emissions," when lighter weight solutions can provide similar GHG emissions benefits and better safety. EPA needs to look beyond the tailpipe and create holistic standards which incentivize real improvements. [EPA-HQ-OAR-2022-0829-0581, p. 12]

Organization: Natural Gas Vehicles for America

EPA Must Amend its Proposal to Account for Benefits of Biofuels

NGVAmerica is not alone in making the case that EPA must amend its proposal. Other organizations including the refinery industry, independent fuel retailers, and the ethanol industry have argued that EPA must make a course correction and following through on its prior commitment to do so. [EPA-HQ-OAR-2022-0829-0597, pp. 9-10]

In 2012, EPA10 committed to sunset the use of the 0 g/mi allowance for electric vehicles as explained below:

10 2012-21972.pdf (govinfo.gov)

EPA is finalizing the full net upstream GHG emissions approach for the compliance treatment for EV/PHEV/ FCVs beyond the per-company vehicle production threshold caps in MYs 2022–2025. EPA is not adopting any type of ‘‘phase-in’’, i.e., the compliance value will change from 0 g/mi to the full net upstream GHG emissions value once a manufacturer exceeds the cap. EPA believes that the levels of the per company vehicle production caps in MYs 2017–2025 are high enough to provide a sufficient incentive such that any production beyond those caps should use the full net upstream GHG emissions accounting. [EPA-HQ-OAR-2022-0829-0597, pp. 9-10]

The preamble to that rule included the following discussion aptly summarizing the opposition to the use of the 0 g/mi standard. [EPA-HQ-OAR-2022-0829-0597, pp. 9-10]

Two automakers opposed the use of 0 g/mi. Honda ‘‘believes that EPA should separate incentives and credits from the measurement of emissions. Honda believes that without accounting for the upstream emissions of all fuels, inaccurate comparisons between technologies will take place * * *. EPA’s regulations need to be comprehensive and transparent. By zeroing out the upstream emissions, EPA is conflating incentives and credits with proper emissions accounting.’’ EcoMotors International ‘‘encourages EPA to drop the 0 g/mile tailpipe compliance value.’’ Environmental advocacy groups also opposed the 0 g/ mi compliance treatment. The Natural Resources Defense Council claimed that 0 g/mi ‘‘undermines’’ the pollution and technology benefits of the program. Along with other environmental groups, the American Council for an Energy Efficient Economy also opposed 0 g/mi, but added that ‘‘[m]ost important, however, is that a zero-upstream treatment of plug-in vehicles not be continued indefinitely, and that full upstream accounting be applied to these vehicles by a date certain. EPA’s proposed treatment of EVs largely accomplishes this, so we strongly support that aspect of the proposal.’’ The American Petroleum Institute argued that ‘‘[i]gnoring the significant contribution of (and extensive compilation of published literature on) upstream CO_2 emissions from electricity generation, defies principles of transparency and sound science and distorts the market for developing transportation fuel alternatives. It incentivizes the electrification of the vehicle fleet with a pre- defined specific and costly set of technologies whose future potential is not measured with the same well-to-wheels methodology against that of advanced biofuels or other carbon mitigation strategies.’’ Organizations advocating fuels other than electricity also opposed the use of 0 g/mi. [EPA-HQ-OAR-2022-0829-0597, pp. 10-11]

Despite the expressed views, EPA nevertheless retained the 0 g/mi standard. In defense of continuing to retain the 0 g/mi treatment and providing multiplier credits, EPA stated that: [EPA-HQ-OAR-2022-0829-0597, pp. 10-11]

EPA believes that it is both reasonable and appropriate to accept some short- term loss of emissions benefits in the short run to increase the potential for far- greater game-changing benefits in the longer run. The agency believes that these multipliers may help bring some technologies to market more quickly than in the absence of incentives. [EPA-HQ-OAR-2022-0829-0597, pp. 10-11]

The European Biogas Association eloquently explained why the EU Commissions rules should account for well-to-wheel emissions and their explanation is worth including here: [EPA-HQ-OAR-2022-0829-0597, pp. 10-11]

The current “tank-to-wheel” approach does not compare the different technologies appropriately because it ignores emissions associated with the production of the fuel. It does not recognise the positive contribution of renewable fuels such as biomethane to climate protection, and thus biases one technology over others without a climate protection rationale. [EPA-HQ-OAR-2022-0829-0597, pp. 10-11]

The revised CO2 regulation should propose technology-neutral solutions to reduce emissions in an accelerated and cost-effective way. It should avoid one-size-fits-all options that could prove insufficient in the long-term and may lead to a slow, unfair and costly emissions reduction process. [EPA-HQ-OAR-2022-0829-0597, pp. 10-11]

The CO2 regulation should be amended to ensure an integrated transition that picks no single green technology over others and leaves no-one behind. All alternative fuels are necessary if transport decarbonisation is to be delivered at pace.11 [EPA-HQ-OAR-2022-0829-0597, pp. 10-11]

11 SMART CO2 STANDARDS FOR LEAN MOBILITY (europeanbiogas.eu)

Organization: Nebraska Corn Board (NCB) and Nebraska Corn Growers Association

This proposal gives EVs an unfair advantage when the EPA upstream emissions. [EPA-HQ-OAR-2022-0829-0583, p. 1]

Organization: Nissan North America, Inc.

In addition to an adjusted assumed EV phase-in schedule that accounts for market and societal challenges, the program should account for appropriate tailpipe emission benefits. [EPA-HQ-OAR-2022-0829-0594, pp. 5-6]

- Nissan supports EPA’s proposal to extend its policy of measuring GHG emissions for all vehicles, including EVs, based on tailpipe emissions, and not including upstream emissions associated with the electricity that powers these vehicles. Nissan supports the proposal to permanently apply a 0 g/mi CO2 measure for EV operation without any quantity cap. This is consistent with EPA’s long-term goal of increasing the EV market share and with the fact that automobile manufacturers only control tailpipe emissions and have no control over the fuel source for electric power. [EPA-HQ-OAR-2022-0829-0594, pp. 5-6]

VII. Endorsement of Comments from the Alliance for Automotive Innovation

As a member of the Alliance for Automotive Innovation (“the Alliance”), Nissan fully endorses the comments on the Proposed Multi-Pollutant Rule submitted separately by the Alliance. In particular, Nissan highlights several points from the Alliance’s comments, including: [EPA-HQ-OAR-2022-0829-0594, p. 9]

- Support continuation of tailpipe-based program and treatment of 0 g/mi for EVs [EPA-HQ-OAR-2022-0829-0594, p. 9]

Organization: North Dakota Farmers Union (NDFU)

Regulatory Bias in Proposed Rule

EPA is proposing that upstream emissions accounting for BEVs as part of a manufacturer's compliance calculation, which under the current regulations would begin in MY 2027, be removed; "thus, BEVs would continue to be counted as zero grams per mile in a manufacturer's compliance calculation." This is not an appropriate approach for a performance-based or technology-neutral proposal, because it would disadvantage all other technologies, regardless of whether those technologies can reduce emissions at a lower cost and more quickly. [EPA-HQ-OAR-2022-0829-0586, p. 5]

The proposed rulemaking would not allow other vehicle-fuel pathways to compete with BEVs. By regulating only tailpipe emissions, EPA would create artificial incentives for only BEVs. This could have disastrous effects on both the cost and the GHG emissions of future vehicles. [EPA-HQ-OAR-2022-0829-0586, p. 5]

Organization: Plains All American Pipeline, L.P.

In addition, the Proposal fails to fully consider all the implications and costs of effectively mandating EVs.8 It is contrary to a robust energy policy where all forms of energy are utilized to maintain and improve quality of life and promote economic growth. By effectively mandating a particular consumer product (i.e., EVs), the Proposal is favoring one technology, while dismissing the potential benefits of a more holistic approach to emission reduction, and additional conservation activities / mandates. It also omits from the discussion advances in technologies including lower carbon fuels, hybrid EVs and fuel cells, which are moving us towards a lower-emission future while also offering consumers multiple options to meet their needs. [EPA-HQ-OAR-2022-0829-0713, p. 2]

8 https://consumerenergyalliance.org/cms/wp-content/uploads/2023/06/CEA_EV_REPORT_2023.pdf

For all the above these reasons, Plains strongly urges the EPA to withdraw the Proposal, or in the alternative, modify the Proposal so that it employs a technology-neutral approach that accounts for the lifecycle emissions of all fuels and vehicles, not just tailpipe emissions. [EPA-HQ-OAR-2022-0829-0713, p. 2]

Organization: Plug In America

3. EPA requests comments on its proposed treatment of electrified vehicles in manufacturer compliance calculations. [EPA-HQ-OAR-2022-0829-0625, pp. 2-3]

Plug In America agrees with the EPA that manufacturers of either EVs or fossil-fuel vehicles should not account for upstream utility emissions in compliance calculations. EPA regulates fossil-fuel-fired power plants under separate authority and expects declining GHG emissions in the future. EPA should continue to focus on tailpipe emissions and count any vehicle with zero tailpipe emissions as 0g/mi as its compliance value. Consistent with other light-duty vehicles, compliance calculations should only include tailpipe emissions. [EPA-HQ-OAR-2022-0829-0625, pp. 2-3]

Organization: POET, LLC

OnLocation also finds that if BEV upstream emissions are considered, "real-world" emissions to the atmosphere from covered vehicles would be at levels significantly higher than the proposed compliance standards. More specifically, if upstream fuel production emissions are accounted for regarding BEVs, the Proposed Rule's 86 gram per mile target in 2032 cannot be met when using electric grid GHG emission intensities from EIA, the leading U.S. governmental source for independent energy statistics and analysis.116 Note that OnLocation's analysis does not seek to account for battery manufacturing lifecycle emissions, which is addressed in Trinity's report, as described above. As Trinity has shown, "actual BEV lifecycle emissions would be even higher if battery manufacturing impacts are considered."117 [EPA-HQ-OAR-2022-0829-0609, pp. 26-27]

116 Id. at 1, 10.

117 Id. at 10.

OnLocation further finds that "using only tailpipe emissions provides inconsistent incentives between BEV and ICE vehicles, while optimistic projections for the grid carbon intensity and BEV penetration could reduce the effectiveness of the Proposed Rule in reducing carbon."118 Regarding electric grid intensity, OnLocation finds that EPA's Draft Regulatory Impact Analysis (DRIA) using its model shows a 70% reduction of power sector-related CO2 emissions from current levels by 2055, while EIA's reference case "shows closer to a 50% reduction from current levels and substantially less CO2 reduction if renewable costs do not decline as quickly as in the Reference scenario."119 While ICE vehicles have incentives under the proposal to reduce their tailpipe GHG emissions, BEVs and the electric grid lack GHG reduction incentives since the Proposed Rule effectively assumes that all electricity used by BEVs is zero carbon.120 [EPA-HQ-OAR-2022-0829-0609, pp. 26-27]

Scenario 6: Adding Low Carbon Fuel and Upstream Emissions [EPA-HQ-OAR-2022-0829-0609, pp. 47-48]

[See original attachment for Figure 11 Compliance Path with Low Carbon Fuel and Upstream Emissions] [EPA-HQ-OAR-2022-0829-0609, pp. 47-48]

[See original attachment for Figure 12 Market Shares with Low Carbon Fuel and Upstream Emissions] [EPA-HQ-OAR-2022-0829-0609, pp. 47-48]

Scenario 6 presents a 75% reduction in fuel carbon intensity for gasoline, though including upstream emissions including those for BEVs. Figure 11 and Figure 12 show that using the model compliance with the Proposed Rule's targets still could be achievable, though outside of 2027 – 2032 timeframe when considering both upstream emissions and the impact if biofuels reduce ICE vehicle carbon intensity by 75%. In this scenario, the market share of BEVs only changes slightly from the Proposed Rule, however in the model greater total emission reductions (i.e., those that consider upstream emissions) are achieved by deploying low-carbon ICE vehicles. This scenario shows that with lower-carbon ICE fuels (such as low carbon bioethanol), and considering upstream emissions, compliance within the range of EPA's proposed target is possible. [EPA-HQ-OAR-2022-0829-0609, pp. 47-48]

Ignoring Upstream Emissions is Inconsistent with Incentivizing GHG Emission Reductions

The following section demonstrates that using only tailpipe emissions provides inconsistent incentives between BEV and ICE vehicles, while optimistic projections for the grid carbon intensity and BEV penetration could reduce the effectiveness of the Proposed Rule in reducing carbon. [EPA-HQ-OAR-2022-0829-0609, p. 48]

Upstream Emissions are Uncertain

While EPA's Draft Regulatory Impact Analysis (DRIA) using its model shows a 70% reduction of power sector- related CO2 emissions from current levels by 2055. As shown in Figure 13, EIA's reference scenario shows closer to a 50% reduction from current levels and substantially less CO2 reduction if renewable costs do not decline as quickly as in the Reference scenario. If included in the CO2 targets, differences between grid emissions and projections used in the Proposed Rule could have a significant impact on the ability of manufacturers to achieve compliance. [EPA-HQ-OAR-2022-0829-0609, p. 48]

[See original attachment Figure 13. Grid Intensity] [EPA-HQ-OAR-2022-0829-0609, p. 48]

Source: AEO 2023 Reference, High Technology Cost Tables 8, 18 [EPA-HQ-OAR-2022-0829-0609, p. 48]

Manufacturing emissions differ between EV and ICE [EPA-HQ-OAR-2022-0829-0609, pp. 49-50]

[See original attachment for Figure 14. Vehicle Manufacturing Emissions] [EPA-HQ-OAR-2022-0829-0609, pp. 49-50]

Emissions for BEV200, BEV300, and BEV400 compared with midsize gasoline ICEV. Source: Cradle-to-Grave Lifecycle Analysis of U.S. Light-Duty Vehicle-Fuel Pathways: A Greenhouse Gas Emissions and Economic Assessment of Current (2020) and Future (2030-2035) Technologies, Argonne National Lab, 2022 [EPA-HQ-OAR-2022-0829-0609, pp. 49-50]

As shown in Figure 14, compared with a midsize gasoline ICEV, a BEV has higher emissions from vehicle manufacturing under current technologies, ranging from approximately 10 gCO2e/mi in a BEV200, to 25 gCO2e/mi in a BEV300, and 35 gCO2e/mi in BEV400, according to the lifecycle analysis by the Argonne National Lab (battery emissions are embedded in Figure 14 within "vehicle" emissions, and are most significant in the data in Figure 14 labelled "Current Tech"). [EPA-HQ-OAR-2022-0829-0609, pp. 49-50]

Relative to the ~80 gCO2e/mi EPA proposed compliance value, where the alternatives are +-10 gCO2e/mi, these are substantial incremental emissions that are neglected when upstream emissions are ignored. [EPA-HQ-OAR-2022-0829-0609, pp. 49-50]

Ignoring upstream emissions has other negative effects on incentivizing reductions of GHG emissions from LDVs, including disregarding the substantially greater GHG manufacturing footprint of BEVs over conventional vehicles and decreasing incentives for clean electricity (since EPA assumes, under the Proposed Rule's compliance scheme, that all electricity used in EVs is effectively zero carbon). This analysis also shows that a rulemaking that also considers low-carbon ICE vehicles (such as enabled by low-carbon bioethanol) can facilitate compliance with EPA standards while decreasing the larger system emissions (including upstream emissions) in the atmosphere. [EPA-HQ-OAR-2022-0829-0609, p. 50]

The first of these concerns is that U.S. EPA has ignored upstream sources of GHG emissions other than electricity generation. This is of particular concern given that there are significant upstream emissions associated with the manufacturer of batteries for BEVs that do not occur with conventional vehicles. A paper published by ICCT4 notes that estimates of these GHG emissions range from 56 to 494 kilograms of CO2eq emissions per kWh of battery pack capacity which translates to between about 5 and 50 metric tons of GHG emissions per 100 kWh battery pack. Using U.S. EPA's assumption that the Proposed Rule will result in an additional 80,000,000 BEVs on the road in the U.S. by 2055 relative to the no- action case, and these estimates of GHG emissions from battery production, the cumulative increase in GHG emissions by would be between 400 and 4000 metric tons. This value can be compared to U.S. EPA's 710 metric ton estimate of the cumulative GHG emissions increase due to electricity generation for BEVs and the 8,000 ton reduction from conventional vehicles (see DRIA Table 9-21) to show the importance of accounting for battery production emissions. U.S. EPA might respond by noting that they have not accounted for upstream GHG emissions associated with the production of gasoline and diesel, but those are small compared to the GHG emissions from fuel combustion and accounting for them would assume a net global reduction in the use of those fuels which would likely, even with the Proposed Rule, still be used in other parts of the developing world. [EPA-HQ-OAR-2022-0829-0609, p. 62]

Organization: Porsche Cars North America (PCNA)

Porsche supports the zero upstream accounting of emissions for pure electric vehicles (and FCVs) and recognizes that stakeholders may view additional credit opportunities for these vehicles as resulting in vehicles with “negative CO2” values. Stakeholders may claim that the optics of having a vehicle with “negative CO2” appears nonsensical. However, Porsche contends that it is appropriate to step back and reconsider that the GHG fleet average regulations are not intended to be, and do not operate as, individual vehicle regulations. The program is not designed to reflect individual real-world performance of such vehicles. Rather, the CO2 regulation is a fleet level policy that operates in essence as an accounting program that utilizes a variety of calculations and credit mechanisms to drive down the overall annual CO2 emissions of a manufacturer's fleet. [EPA-HQ-OAR-2022-0829-0637, p. 20]

Organization: Renewable Fuels Association (RFA)

I. Executive Summary

EPA's proposed tailpipe emissions standards for 2027 and later years set extremely aggressive goals for reducing vehicular greenhouse gas (GHG) and criteria pollutant emissions. Achieving these goals would require dramatic changes not only in vehicle design, but also in the entire transportation energy supply chain. In addition, meeting the proposed emissions standards in the manner envisioned by EPA would require a massive and rapid shift in the vehicle purchasing and refueling behavior of American consumers. Indeed, if the rule is finalized as proposed, EPA projects that electric vehicles (EVs) “could account for 67% of new light-duty vehicle sales and 46% of new medium-duty vehicle sales in MY 2032.”1 By comparison, EVs accounted for just 5.8% of new light-duty vehicle sales in 2022 and accounted for just 1% of total registered light-duty vehicles.2 [EPA-HQ-OAR-2022-0829-0602, pp. 3-4]

1 U.S. Environmental Protection Agency. “Biden-Harris Administration Proposed Strongest-Ever Pollution Standards for Cars and Trucks to Accelerate Transition to a Clean-Transportation Future.” April 12, 2023. https://www.epa.gov/newsreleases/biden-harris-administration-proposes-strongest-ever-pollution-standards-cars-and.

2 Kelly Blue Book. “America Splits Into Thirds on Electric Cars.” (March 22, 2023). https://www.kbb.com/car- news/america-splits-into-thirds-on-electric-cars/.

While EVs are likely to play an important role in achieving emissions reductions goals, the growth in EVs projected by EPA would require enormous investment and rapid expansion in many global industrial sectors. Such a transition would require immediate and dramatic growth in the mining and processing of critical minerals, a massive increase in the generation and distribution of lower-carbon electricity, and the rapid buildout of a nationwide infrastructure network for recharging EVs. [EPA-HQ-OAR-2022-0829-0602, pp. 3-4]

It would be naïve and unrealistic to believe that such extraordinary changes in the marketplace can be achieved smoothly and quickly. There are numerous obstacles involved in a transition of this scale, including geopolitical and national security concerns; long lead times in permitting, material supply, design, and manufacturing; substantial capital investments; safety considerations; and unprecedented changes in consumer behavior and purchasing habits. [EPA-HQ-OAR-2022-0829-0602, pp. 3-4]

To achieve the Agency’s ambitious emissions reduction goals in the most robust, rapid, and affordable way, EPA should use this rulemaking to encourage multiple additional solutions that can decarbonize light- and medium duty transportation. EPA must also recognize that vehicles and fuels operate as integrated systems. Focusing only on emissions from the vehicle—while ignoring emissions related to the extraction and production of the fuel used to power the vehicle—will almost certainly result in falling far short of the administration’s overall climate goals. [EPA-HQ-OAR-2022-0829-0602, pp. 3-4]

Low-carbon liquid fuels like ethanol have a unique and vital role to play in the administration’s efforts to combat climate change and reduce overall emissions from the transportation sector—both immediately and in the long term. Fuels such as E15 (15% ethanol) are compatible with nearly all vehicles on the road today, and thus offer immediate emissions benefits on a much larger scale than changes to only new vehicles. In addition, E85 (51-83% ethanol) used in flexible fuel vehicles (FFVs) can substantially reduce GHG emissions from the light-duty vehicle sector. More than 25 million FFVs are already on the road today and FFV production can be ramped up quickly by automakers at no additional cost to the consumer. In the longer term, low-carbon or zero-carbon liquid fuels used in FFVs or plug-in hybrid electric FFVs can offer emissions solutions for market segments and customers that may not be well served by battery electric vehicles (BEVs). [EPA-HQ-OAR-2022-0829-0602, pp. 3-4]

To foster a vibrant and competitive landscape of multiple low-carbon solutions, it is critical for EPA to set performance-based and technology-neutral emissions standards. Unfortunately, the proposed rule falls short of this ideal by focusing narrowly on one technology and only one segment of the GHG emissions lifecycle (i.e., tailpipe emissions). It is essential that EPA look beyond tailpipe emissions; the Agency should use a full lifecycle3 analysis to fairly and accurately compare the climate impacts of all current and future transportation options. [EPA-HQ-OAR-2022-0829-0602, pp. 3-4]

3 Throughout these comments, the terms "full lifecycle analysis" refer to a complete "well-to-wheel" analysis as defined by Argonne National Laboratory.

II. The Proposed Rule Uses Inappropriate GHG Accounting Gimmicks to Create a De Facto Mandate for Battery Electric Vehicles

For light-duty vehicles, EPA is proposing an industry-wide average GHG emissions target of 82 grams CO2/mile (g/mile) in model year (MY) 2032. This represents a drastic 56% reduction from the MY 2026 target of 186 g/mile and a 63% reduction from the MY 2022 target of 224 g/mile. Notably, the estimated industrywide average GHG emissions rate has exceeded the annual standard each year since 2016, requiring automakers to use banked credits and other adjustments to comply.4 [EPA-HQ-OAR-2022-0829-0602, pp. 4-5]

4 Congressional Budget Office. "Emissions of Carbon Dioxide in the Transportation Sector." December 2022. https://www.cbo.gov/publication/58861.

For the purposes of calculating fleet-average GHG emissions, EPA is proposing to allow auto manufacturers to use a compliance value of 0 g/mile for BEVs, fuel cell electric vehicles (FCEVs), and the electric-only portion of operation for plug-in hybrid EVs (PHEVs). As EPA acknowledges, a compliance value of 0 g/mile for EVs ignores the upstream emissions associated with battery production and electricity generation (i.e., the "fuel" for EVs). [EPA-HQ-OAR-2022-0829-0602, pp. 4-5]

Given the stringency of the proposed standards (and the inability of most internal combustion engine (ICE) vehicles to meet them), EPA expects auto manufacturers will be strongly compelled to substantially increase EV production in order to benefit from the 0 g/mile assumption when calculating fleet-wide average emissions. According to EPA's own analysis, it is highly unlikely that automakers will be able to meet EPA's proposed emissions standards for 2027-2032 without dramatically increasing the production of EVs and reducing the production of ICE vehicles. The proposal's forced push toward EVs would be exacerbated by EPA's proposal to eliminate the "multiplier incentive" that allows automakers to count one BEV as more than one "zero emissions vehicle" in compliance calculations. In this way, EPA is essentially forcing auto manufacturers to increase production of EVs, and in turn forcing the entire transportation supply chain to undergo a massive shift toward electrification. [EPA-HQ-OAR-2022-0829-0602, pp. 4-5]

While significantly increasing the production of EVs may help automakers comply with the proposed future emissions standards, such a transition certainly does not guarantee that real-world GHG emissions associated with the full transportation supply chain will be meaningfully reduced. In fact, depending on the sources of electricity used to power EVs and the practices used for extraction and refining of critical battery minerals, EPA's proposal to force increased EV production could fall far short of accomplishing the administration's climate objectives. Thus, EPA's tailpipe emissions standards could perversely incentivize the production and sale of more expensive vehicles that, in reality, have little practical impact on reducing overall emissions. [EPA-HQ-OAR-2022-0829-0602, pp. 4-5]

a. BEVs are Not “Zero Emissions Vehicles.” Counting Only Tailpipe Emissions Results in a Flawed and Incomplete Assessment of the True Climate Impacts of BEVs

EPA’s proposal to assign a value of 0 g/mile to BEVs ignores the fact that significant CO2 emissions result from the extraction and processing of the critical minerals for EV batteries, as well as the production of electricity for BEVs. Some lifecycle analysis studies show that certain BEVs (using coal-generated electricity and battery minerals from intensive mining practices) may have a larger carbon footprint than conventional vehicles using liquid fuels in internal combustion engines.5,6 [EPA-HQ-OAR-2022-0829-0602, pp. 5-6]

5 See, for example, Paul Leinert. “Analysis: When do electric vehicles become cleaner than gasoline cars?” Reuters. July 7, 2021. https://www.reuters.com/business/autos-transportation/when-do-electric-vehicles-become-cleaner-than- gasoline-cars-2021-06-29/.

6 International Energy Agency. “The Role of Critical Minerals in Clean Energy Transitions.” May 2021. https://www.iea.org/reports/the-role-of-critical-minerals-in-clean-energy-transitions.

On average basis, a recent comprehensive analysis by Argonne National Laboratory (in cooperation with automotive and energy industry experts) found that the full lifecycle GHG emissions associated with a typical 400-mile range BEV are approximately 253 g/mile.7 This estimate takes into account the upstream emissions associated with the EV battery and production of the electricity used to power the vehicle. While the 253 g/mile figure represents a roughly 40% reduction in GHG emissions compared to a gasoline-powered ICE vehicle, it is far from “zero emissions.” At the same time, the Argonne study found that using today’s average E85 in an ICE FFV resulted in lifecycle GHG emissions of approximately 255 g/mile—generally the same as the 400-mile BEV. [EPA-HQ-OAR-2022-0829-0602, pp. 5-6]

7 Kelly et al., "Cradle-to-Grave Lifecycle Analysis of U.S. Light-Duty Vehicle-Fuel Pathways: A Greenhouse Gas Emissions and Economic Assessment of Current (2020) and Future (2030-2035) Technologies", report ANL-22/27, June 2022. https://www.osti.gov/biblio/1875764.

EPA’s proposed approach of assigning a 0 g/mile value to BEVs essentially assumes that the electricity and battery minerals powering the BEV are 100% renewable and free of any CO2 emissions impacts in every instance. Of course, we know this is not the case. Today, more than 60% of U.S. electricity generation comes from fossil fuels that contribute significant CO2 emissions (19.5% coal, 40% natural gas, 1% petroleum and other).8 Wind and solar provide only 13.6% of the nation’s electricity, with hydropower providing another 6.2%. Nuclear accounts for 18% of U.S. electric power generation. Overall, electric power generation is the second largest source of GHG emissions in the United States, accounting for 25% of total emissions (trailing only the transportation sector, which is responsible for 28% of U.S. emissions).9 [EPA-HQ-OAR-2022-0829-0602, pp. 5-6]

8 U.S. Energy Information Administration. “What is U.S. electricity generation by energy source?” March 2023. https://www.eia.gov/tools/faqs/faq.php?id=427&t=3.

9 U.S. Environmental Protection Agency. “Sources of Greenhouse Gas Emissions.” Accessed June 17, 2023. https://www.epa.gov/ghgemissions/sources-greenhouse-gas-emissions.

To ensure the final tailpipe standards have the desired effect of truly reducing GHG emissions from transportation, RFA strongly urges EPA to adopt a full lifecycle GHG accounting approach for all vehicles in the final rule. [EPA-HQ-OAR-2022-0829-0602, pp. 5-6]

III. EPA Admits its GHG Accounting Loophole for BEVs is Not Rooted in Science and is Instead Meant to Incentivize Production of BEVs

In the proposal, EPA readily acknowledges that operation of an EV is directly responsible for some amount of upstream GHG emissions related to electricity generation. Yet, the Agency proposes to ignore these emissions and continue the use of a scientifically dubious assumption that operation of an EV is entirely free of any GHG impacts. Indeed, EPA says it is proposing to continue the 0 g/mile compliance value for BEVs strictly as a means of "encouraging the continued development and introduction of electric vehicle technology."10 In other words, EPA proposes to use the 0 g/mile compliance value as a veiled subsidy to compel the production of a specific technology to the exclusion of other technologies that could deliver similar levels of emissions reduction. [EPA-HQ-OAR-2022-0829-0602, pp. 6-8]

10 88 Fed. Reg. 29252 (May 5, 2023).

The Agency's reasoning for maintaining the 0 g/mile compliance value for BEVs is highly questionable. EPA says it is continuing the 0 g/mile assumption because in 2020, "power sector emissions were declining and the trend was projected to continue."11 Yet, EPA also reports that "[i]n 2021, the electric power sector was the second largest source of U.S. greenhouse gas emissions, accounting for 25% of the U.S. total."12 EPA data show the electric power sector emitted nearly 1.6 billion metric tons of GHG emissions in 2021, yet the Agency's proposal effectively assumes those emissions don't exist and have no bearing on the climate impacts of EVs. [EPA-HQ-OAR-2022-0829-0602, pp. 6-8]

11 Id.

12 U.S. Environmental Protection Agency. "Sources of Greenhouse Gas Emissions." Accessed July 1, 2023. https://www.epa.gov/ghgemissions/sources-greenhouse-gas-emissions#electricity (emphasis added).

Additionally, according to the U.S. Energy Information Administration (EIA), "CO2 emissions created in the U.S. electric power sector rose by 7% in 2021 (102 MMmt) as a result of changes in both electricity usage and fuel mix."13 The 7% increase in electric power sector emissions was more than double the 3% increase in electric power generation, as the use of coal and petroleum both increased in 2021. EIA reports that these changes "led to a 4% increase in the carbon intensity of electricity" in 2021.14 [EPA-HQ-OAR-2022-0829-0602, pp. 6-8]

13 U.S. Energy Information Administration. "U.S. Energy Related Carbon Dioxide Emissions 2021." Accessed May 20, 2023.https://www.eia.gov/environment/emissions/carbon/#:~:text=Commercial%20sector%20emissions%20increased%20by,in%20the%20electricity%20fuel%20mix. (emphasis added).

14 Id.

[See original comment for graph of electricity generation] [EPA-HQ-OAR-2022-0829-0602, pp. 6-8]

While the use of coal for electricity declined in 2022 versus 2021, the use of both petroleum and natural gas for electricity in 2022 increased over 2021 levels, meaning total fossil fuel use for electricity continued to increase in 2022.15 Clearly, it is not safe to simply assume that electric power sector emissions will steadily decline over time, especially as electricity demand increases as a result of expanded EV sales and other factors. [EPA-HQ-OAR-2022-0829-0602, pp. 6-8]

15 U.S. Energy Information Administration. “Monthly Energy Review.” Table 7.2a Electricity Net Generation. Accessed July 1, 2023. https://www.eia.gov/totalenergy/data/monthly/pdf/sec7_5.pdf.

Notwithstanding the fact that RFA favors a full lifecycle GHG analysis and recommends against the use of the 0 g/mile compliance value for EVs, if EPA intends to use g/mile compliance values as policy incentives to stimulate the production of lower-carbon vehicles, it should be equitable in doing so. If the Agency believes it has the authority to compel greater production of lower-carbon vehicle technologies using GHG compliance values that always assume the best-case technology and energy mix, then it should do so fairly across the full portfolio of lower-carbon fuel and vehicle options. [EPA-HQ-OAR-2022-0829-0602, pp. 6-8]

IV. EPA Should Discontinue the Use of its Zero Gram per Mile Emissions Assumption for BEVs

EPA’s proposal solicits comment on the “proposed treatment of electrified vehicles in manufacturer compliance calculations” (i.e., the use of a 0 g/mile compliance value).16 For the reasons described throughout these comments, RFA strongly recommends that EPA discontinue the use of its 0 g/mile compliance value for BEVs. The 0 g/mile value unfairly compels automakers to produce one specific technology type, while also providing an inaccurate and incomplete picture of the true climate impacts of EVs. [EPA-HQ-OAR-2022-0829-0602, pp. 8-9]

16 88 Fed. Reg. 29252 (May 5, 2023).

Importantly, the 0 g/mile measure was also meant to be temporary. EPA previously finalized regulations that would phase down and ultimately eliminate the 0 g/mile compliance value for EVs. In response to public comments on EPA’s 2012 proposed rule for MY 2017 and later light-duty vehicle GHG standards, the Agency finalized an approach that would have required automakers to account for upstream electricity emissions for all MY 2022 and later EVs. However, in the 2020 vehicle GHG emissions standards rule, EPA reversed this approach and instead extended the use of the 0 g/mile compliance value through MY2026, with no phasedown. Now, defying the original temporary intent of the 0 g/mile value, EPA proposes to make the 0 g/mile assumption permanent for EVs. [EPA-HQ-OAR-2022-0829-0602, pp. 8-9]

RFA believes the 0 g/mile compliance value for EVs should be discontinued with MY2026 or sooner, as this “incentive” results in inaccurate accounting of emissions related to BEVs and it is no longer necessary to spur production of EVs. As EPA acknowledges, the 0 g/mile “functioned as intended” to stimulate increased production in EVs, which are “now coming into the mainstream.”17 As stated by EPA, automakers have already committed enormous investments toward EVs, and increased production of EVs is strongly incentivized under state policies and other federal programs like the Inflation Reduction Act. Thus, no additional incentive is needed under the tailpipe emissions regulation. [EPA-HQ-OAR-2022-0829-0602, pp. 8-9]

17 Id.

It is time for EPA to eliminate the use of the 0 g/mile compliance value for EVs and adopt a full lifecycle approach for determining GHG values. [EPA-HQ-OAR-2022-0829-0602, pp. 8-9]

VI. EPA Should Adopt a Full Lifecycle Analysis Approach for All Vehicle Options that Includes Upstream GHG Emissions Associated with Vehicle Fuel/Energy Use

Vehicles and fuels operate together as integrated systems. This is true whether the system is a battery electric vehicle operating on electricity, or an ICE vehicle operating on liquid fuel. To effectively regulate emissions associated with the operation of light- and medium-duty vehicles, EPA must adopt approaches that most accurately assess the overall climate impacts of various transportation options. Specifically, EPA should examine the full scope of lifecycle GHG emissions associated with each vehicle/fuel system and allow automakers to use g/mile compliance values that reflect the overall GHG impacts of various vehicle/fuel options. [EPA-HQ-OAR-2022-0829-0602, pp. 11-12]

In the proposal, EPA requests comments on its proposed treatment of electrified vehicles in manufacturer compliance calculations (i.e., the use of a 0 g/mile compliance value for EVs). As part of its rationale for proposing to maintain the 0 g/mile value for EVs, the Agency states that "[i]f EPA deviated from this tailpipe emissions approach [i.e., using 0 g/mile] by including upstream accounting, it would appear appropriate to do so for all vehicles, including gasoline-fueled vehicles."28 [EPA-HQ-OAR-2022-0829-0602, pp. 11-12]

28 88 Fed. Reg. 29252 (May 5, 2023).

RFA agrees with this statement by EPA and recommends that the Agency should indeed adopt an approach that accounts for full lifecycle emissions for all fuel and vehicle combinations. In fact, this is the only scientifically defensible approach for regulating emissions from light- and medium-duty vehicles. Implementing an approach that accounts for all lifecycle emissions would not only open the automotive market to greater competition and lower costs for consumers, but it would stimulate investment in lower- carbon technologies and practices across the entire fuel/vehicle supply chain. [EPA-HQ-OAR-2022-0829-0602, pp. 11-12]

RFA believes the final rule should take a market-based approach that sets clear and predictable annual full lifecycle GHG reduction requirements for automakers (in g/mile values), then allows the marketplace to determine the most cost-effective means for achieving the reductions. [EPA-HQ-OAR-2022-0829-0602, pp. 11-12]

Robust, peer-reviewed methodologies already exist for conducting full lifecycle emissions analysis for current and future vehicle and fuel options. Specifically, EPA should use the Department of Energy Argonne National Laboratory GREET model, which is accepted worldwide as the most robust and authoritative tool for lifecycle GHG accounting for a wide array of transportation fuels. The GREET model is also updated annually to incorporate the latest data. [EPA-HQ-OAR-2022-0829-0602, pp. 11-12]

VII. If EPA Maintains its Zero Gram per Mile Incentive for EV Production, the Agency Should Allow for a Similar Incentive for FFV Production

For the reasons described in detail above, RFA objects to the continued use of a 0 g/mile compliance value for EVs for the purposes of calculating fleet averages. However, if EPA ultimately finalizes a permanent incentive of 0 g/mile for EVs, then it must consider applying a similar incentive for other low-carbon vehicle technologies, including FFVs that can operate on E85 and other higher ethanol blends. [EPA-HQ-OAR-2022-0829-0602, pp. 12-13]

EPA's proposed approach for BEVs (i.e., using a value of 0 grams/mile) essentially assumes every BEV produced by automakers will only use zero-carbon renewable electricity over the entire lifespan of the vehicle. In other words, EPA's proposal credits all BEVs for their maximum potential CO_2 benefit, without requiring any evidence that such a benefit is actually achieved. [EPA-HQ-OAR-2022-0829-0602, pp. 12-13]

In order to create an equitable opportunity for biofuels to contribute to the effort to decarbonize light-duty transportation, EPA should institute a CO_2 emissions compliance value that similarly recognizes the potential carbon benefits of light-duty vehicles designed to operate on liquid fuels containing high levels of renewable ethanol. [EPA-HQ-OAR-2022-0829-0602, pp. 12-13]

EPA's final rule should adopt an assumption that FFVs operate on E85 all the time, just as the proposed 0 g/mile value effectively assumes BEVs operate on zero-carbon electricity all the time. Automakers who manufacture FFVs should be allowed to use a CO_2 emissions compliance value that reflects the lifecycle CO_2 savings from using E85. [EPA-HQ-OAR-2022-0829-0602, pp. 12-13]

According to the latest Argonne National Laboratory GREET model results, E85 made with average corn ethanol reduces full lifecycle CO_2-equivalent GHG emissions by 31% per mile compared to gasoline.29 This estimate includes hypothetical/potential emissions from direct and indirect land use changes. Accordingly, for the purposes of calculating fleet averages, EPA should allow automakers to use a CO_2 compliance value for an FFV that is 31% lower than the compliance value for a corresponding non-FFV model. As an example, if a non-FFV car is determined by the automaker to have a CO_2 value of 181 g/mile, the automaker should be allowed to use a compliance value of 125 g/mile for an FFV version of that same car. [EPA-HQ-OAR-2022-0829-0602, pp. 12-13]

29 The GREET2022 model shows that E0 gasoline results in fleet average full lifecycle GHG emissions of 421 g/mile, compared to fleet average emissions of 291 g/mile for the use of E85 in an FFV. Results verified via personal communication between RFA and Longwen Ou of Argonne National Laboratory.

This approach to incentivizing FFVs would be no different than the approach EPA has used historically, and is proposing to continue, for incentivizing EV production. This FFV mechanism would create a more level playing field for low-carbon liquid fuels and would provide a meaningful incentive for automakers to manufacture FFVs in addition to BEVs. Increased production of FFVs would unlock increased use of lower-carbon liquid fuel blends containing higher levels of ethanol, such as E85 and E30. [EPA-HQ-OAR-2022-0829-0602, pp. 12-13]

Alternatively, EPA could allow auto manufacturers to use the same 0 g/mile compliance value for ethanol's portion of FFV operation, given that the ethanol-related "tailpipe" CO_2 emissions from an FFV are biogenic in nature and fully offset by atmospheric CO_2 removal by the biomass feedstock at the beginning of the lifecycle. That is, if EPA remains committed to focusing only on tailpipe emissions (and ignoring upstream fuel production and supply chain emissions), then biofuels like ethanol should be treated as "zero emissions" fuels because CO_2 emissions from the vehicle are fully offset by CO_2 uptake by the feedstock. [EPA-HQ-OAR-2022-0829-0602, pp. 12-13]

Organization: Southern Environmental Law Center (SELC)

EPA must accurately account for tailpipe emissions and should not lose sight of upstream emissions. [EPA-HQ-OAR-2022-0829-0591, p. 9]

EPA is also proposing that BEVs and fuel cell electric vehicles (FCEVs)—i.e., vehicles with no internal combustion—retain a zero gram per mile (g/mi) compliance value and not be required to account for upstream emissions under the GHG standards.69 This aligns with the standards' treatment of other, fossil fuel-powered vehicles. Even though this regulatory regime deals specifically with tailpipe emissions, EPA should not lose sight of the upstream GHG or other emissions associated with light- and medium-duty vehicles—ZEVs or otherwise. We therefore support EPA's consideration of future gasoline fuel property standards that could provide additional meaningful reductions in PM emissions.70 However, even more could be done. Some states, for example, are leading the way by implementing low carbon fuel standards that consider lifecycle GHG emissions from energy used for fuel.71 [EPA-HQ-OAR-2022-0829-0591, p. 9]

Organization: Specialty Equipment Market Association (SEMA)

Tailpipe Emissions vs. Lifecycle Emissions

SEMA is disappointed that this proposal exclusively looks at tailpipe emissions and not the full carbon footprint surrounding the manufacture of BEVs, including their batteries and components. The EPA's calculations should include the environmental impacts associated with mining for battery minerals, manufacturing batteries, and the resources from the power grid to power a full fleet of BEVs. Of note, the U.S. Energy Information Administration reported that fossil fuels are the largest sources of energy for electricity generation in the United States with an estimated 61% of all the electricity generated in 2021 coming from a combination of coal, natural gas, and petroleum.4 While BEVs do not have tailpipe emissions, it is naï ve to assume that they are carbon neutral given the fossil fuels that the U.S. and other countries around the world rely upon to produce the power to operate these vehicles. An analysis from S&P Global Mobility found that for the sixth consecutive year in a row the average age of a vehicle on the road today is 12.5 years old. Conversely, the "average age of battery electric vehicles in the U.S. fell to 3.6 years down slightly from 3.7 years in 2022."5 According to a 2022 EPA report on greenhouse gas emissions, new vehicle fuel economy has increased 32% since model year 2004.6 SEMA believes that tailpipe emissions can continue to be reduced without shifting to a zero-based tailpipe emissions model. A diverse approach to addressing GHG emissions through a multifaceted approach of cleaner fuels, alternative fuels and electrification provides consumers with a choice in how they reduce their carbon footprint. [EPA-HQ-OAR-2022-0829-0596, p. 4]

- Maintain the existing zero emissions upstream approach for BEVs; [EPA-HQ-OAR-2022-0829-0792, p. 2]

A number of studies show that the light-duty sector must rapidly decarbonize beginning this decade to meet the U.S. commitments. Further, the need for the rapid deployment of light-duty BEVs is even more critical given the lengthening time it takes to turn over the light-duty fleet. Currently, the average age of light-duty vehicles on the road in the U.S. is now at an all-time high of 12.5 years compared to two decades ago when the average age was 9.7 years.58 To meet the goal of limiting global warming for below 1.5 degrees C the passenger fleet must primarily be composed of BEVs by 2050.59 Given the aging vehicle fleet, this requires vehicles sales consisting of 100% BEVs in the early 2030s.60 Other studies have similarly highlighted BEV sales need to reach 95% by 2035 to meet the 1.5 degree C target.61 Still others have found that in order to meet net-zero emission by 2050 60% of vehicle sales must be BEVs in 2030 with no new ICE vehicle sales occurring after 2035.62 [EPA-HQ-OAR-2022-0829-0792, p. 9]

EPA's Continuation of Its Zero Upstream Emissions Approach is Appropriate

Tesla agrees with the agency's decision to continue its approach of not requiring net upstream emissions accounting for BEVs in these standards.160 As described supra, BEVs represent the best emission reduction technology and have by far the lowest climate impact of any vehicle technology, and, in this regard, should not be treated differently than ICE vehicles. To date, EPA has not gone outside the tailpipe to account for upstream petroleum production or petroleum refinery emissions in setting ICE vehicles emission standards. Instead, the agency has historically sought to addresses these dangerous emissions through separate stationary source regulations.161 Similarly, in addressing electricity as a vehicle fuel, emissions from electric generating units are otherwise addressed through stationary source regulation.162 Accordingly, Tesla agrees that "If EPA deviated from this tailpipe emissions approach by including upstream accounting, it would appear appropriate to do so for all vehicles, including gasoline-fueled vehicles."163 [EPA-HQ-OAR-2022-0829-0792, pp. 25-26]

Organization: The Aluminum Association

The EPA's Proposal is Inconsistent With its Obligation to Account for Upstream Emissions and Does Not Take Into Account Important Factors that Support Assigning Carbon Emissions to BEVs

As referenced at 88 FR 29252, EPA requests comments on its proposed treatment of electrified vehicles in manufacturer compliance calculations. Its proposed treatment reflects that it plans to assign a permanent value of zero g/mile to BEV's and that this approach "has functioned as intended, encouraging the continued development and introduction of electric vehicle technology." While the Association agrees that this approach has incentivized the development and implementation of electric vehicle technology, it's permanent use is inconsistent with statutory requirements in addition to not fully considering incentives for vehicle efficiency improvements as has been the case in the past. The EPA's prior rulemakings showed that the agency recognizes a range of non-powertrain efficiency improvements, such as lowering aerodynamic coefficients, lower rolling resistance tires, more efficient air conditioning systems, and mass reduction as important components in helping automakers safely meet increasingly aggressive GHG reduction and fuel efficiency targets for their fleets2. The Association therefore encourages EPA to continue that focus in the current rulemaking. [EPA-HQ-OAR-2022-0829-0704, pp. 2-3]

2 86 FR 74485

Specifically, concerns regarding statutory requirements and incentives for vehicle efficiency improvements are further articulated below along with recommendations for addressing the concerns. [EPA-HQ-OAR-2022-0829-0704, pp. 3-4]

As expressed in prior rulemakings3, the alternative to the universal zero g/mile approach is to use net upstream GHG emissions accounting to consider the GHG emissions impact of BEV's and include them in sales fleet compliance calculations. This alternative is consistent with 49 USC 39204 (a)(2)(B)4 that requires the Administrator of the EPA to consider net upstream emissions of electric vehicles when calculating fleet average fuel economy: [EPA-HQ-OAR-2022-0829-0704, pp. 3-4]

3 77 FR 62651

4 49 USC 39204 - https://www.govinfo.gov/content/pkg/USCODE-2021-title49/pdf/USCODE-2021-title49-subtitleVI-partC-chap329-sec32904.pdf (Accessed June 23, 2023)

…..(B) If a manufacturer manufactures an electric vehicle, the Administrator shall include in the calculation of average fuel economy under paragraph (1) of this subsection equivalent petroleum based fuel economy values determined by the Secretary of Energy for various classes of electric vehicles. The Secretary shall review those values each year and determine and propose necessary revisions based on the following factors: (i) the approximate electrical energy efficiency of the vehicle, considering the kind of vehicle and the mission and weight of the vehicle, (ii) the national average electrical generation and transmission efficiencies… [EPA-HQ-OAR-2022-0829-0704, pp. 3-4]

The EPA is not free to disregard the statutory mandate to consider net upstream GHG emissions aligned with the Department of Energy's designation, albeit revising the process for its implementation. [EPA-HQ-OAR-2022-0829-0704, pp. 3-4]

EPA was set to properly implement this statutory requirement as of MY 2022, prior to subsequent factors that delayed its implementation. In the rulemaking for GHG emissions from light duty vehicles5 for the 2017-2025 Model Years, EPA determined that, while zero g/mile GHG emissions would initially be assigned to EV's in order to incentivize their production/sale, net upstream GHG emissions accounting would be applied to EV's once sales thresholds had been met, which ultimately was expected for MY 2022 as per 77 FR 62651): [EPA-HQ-OAR-2022-0829-0704, pp. 3-4]

5 2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions and Corporate Average Fuel Economy Standards; Final Rule (77 FR 63624)

For EVs, PHEVs and FCVs, EPA is also finalizing, as proposed, to set a value of 0 g/mile for the tailpipe CO2 emissions compliance value for EVs, PHEVs (electricity usage) and FCVs for MY 2017–2021, with no limit on the quantity of vehicles eligible for 0 g/mi tailpipe emissions accounting. For MY 2022–2025, EPA is finalizing, as proposed, that 0 g/mi only be allowed up to a per-company cumulative sales cap, tiered as follows: 1) 600,000 EV/ PHEV/FCVs for companies that sell 300,000 EV/PHEV/FCVs in MYs 2019– 2021; or 2) 200,000 EV/PHEV/FCVs for all other manufacturers. Starting with MY 2022, the compliance value for EVs, FCVs, and the electric portion of PHEVs in excess of individual automaker cumulative production caps must be based on net upstream accounting. [EPA-HQ-OAR-2022-0829-0704, pp. 4-5]

In rulemakings subsequent to the original 2017-2025 rulemaking, EPA has postponed implementing this provision and now suggests that it need not follow this path at all because the program has successfully achieved its goals of “encouraging the continued development and introduction of electric vehicle technology” without it. Yet EPA is losing sight of the fact that the long-term applicability of net upstream GHG emissions accounting to EV’s continues to be the most effective way to capture differences in EV efficiencies and therefore provide incentives for efficiency improvements chronologically across model years. [EPA-HQ-OAR-2022-0829-0704, pp. 4-5]

EPA also finds that zero grams/mile is appropriate because of expectations regarding power sector emissions, which may or may not be borne out by the future facts. EPA further relies on the notion that “if EPA deviated from this tailpipe emissions approach by including upstream accounting, it would appear appropriate to do so for all vehicles, including gasoline-fueled vehicles.” It is understood that current ICE based standards do not include emissions for gasoline production. However, nearly all the GHG emissions for an ICE vehicle come from burning gasoline while nearly all the GHG emissions for an EV come from electricity generation. Aligned with this reality, the Association believes that GHG emissions related to actual propulsion of the vehicle must be accounted for, regardless of the mechanism that provides that propulsion and that meaningful measures of efficiency must be provided for customers and manufacturers to act upon that would result in reduced GHG emissions overall. [EPA-HQ-OAR-2022-0829-0704, p. 5]

In order to comply with its statutory requirements and incentivize continued efficiency improvements in both the internal combustion and electrified vehicle fleets of the future in the most implementable way, EPA should utilize the existing metrics of miles per gallon (MPG) for internal combustion engine vehicles and miles per gallon equivalent (MPGe) for electrified vehicles as surrogates for GHG emissions. Using this metric, the GHG emissions related to actual propulsion of the vehicle are accounted for, regardless of the mechanism that provides that propulsion. [EPA-HQ-OAR-2022-0829-0704, p. 5]

Alternately, EPA can include a fixed electric generation emission value per kWh for MY 2027–2032 vehicles in the standard for calculation of vehicle emissions for BEV vehicles, based upon their efficiency. The emissions associated with generating 33.7 kWh of electricity (or 23.16 kWh/gal if the proposed revision to 10 CFR Part 474 (EERE-2021-VT- 0033) is enacted) can then be used along with the values obtained from vehicle dynamometer testing to get the g/mile CO2 emissions for any BEV. This would provide an incentive for improved vehicle efficiency and would also allow comparability between the EPA rules and the upcoming revised DOT/NHTSA CAFE standards. [EPA-HQ-OAR-2022-0829-0704, pp. 5-6]

In order to achieve the competitive offering that will attract wider consumer adoption, BEV’s will need to come down in cost and increase driving range. The major constraint that drives both overall vehicle cost and range is the size and weight of the battery pack required to achieve the desired performance. Based upon current production technology, lithium-ion battery specific energy density is between 150-200 wh/kg. Therefore, at an average consumption of ~0.30kwh/100 mi, for the average BEV to achieve a range of 300 miles, it will require a battery pack of 90-100 kwh, which can cost upwards of $15K dollars per car. Since the largest cost component of a BEV are the batteries, cost reductions are critical to reaching price parity with gas-powered vehicles.10 [EPA-HQ-OAR-2022-0829-0704, pp. 7-8]

10 According to Wright's Law, for every cumulative doubling of units produced, battery cell costs should fall by 28%.

A 100 kwh battery pack can add over 650 Kg of mass to the vehicle. Therefore, a BEV can save approximately $50 for every mile of range improvement by a reduction of the battery pack of 0.3 kwh or by a vehicle mass reduction of just 2kg. and, the lighter the vehicle, the smaller the battery pack needed, which further reduces mass and cost. As can be seen in Figure 1, BEV's with lower curb weight are significantly more efficient in their energy consumption. Therefore, mass reduction technology will remain a critical incentive beyond 2030 to ensure that the industry does not reverse the trend of improving vehicle efficiency in larger/heavier vehicles, thereby permitting the downsizing of IC engines to achieve significant improvements in emissions. In a similar fashion the EPA should not create the circumstance where there is no regulatory compliance difference between a large heavy BEV that requires an oversized battery to achieve the desired range performance and consumes significantly more energy per mile than a smaller lighter BEV. [EPA-HQ-OAR-2022-0829-0704, pp. 7-8]

[See original for graph titled "Figure 1: BEV Curb weight vs. Energy Consumption, Source: OEM Product Data Sheets"] [EPA-HQ-OAR-2022-0829-0704, pp. 7-8]

This disregard for vehicle efficiency distinction across BEV's in the proposed rule conflicts with the existing and historic approaches of the Corporate Average Fuel Economy (CAFE) program and is a potential disruption to harmonization. [EPA-HQ-OAR-2022-0829-0704, pp. 7-8]

Taken in totality, assigning GHG emissions to BEV's accounts for emissions differentials between vehicles which will incentivize the best technologies for all vehicles regardless of propulsion system. For EV's in particular, efficiency drives lower costs, which will assist with faster adoption. Efficiency also permits smaller batteries for the same range, which is essential for less critical mineral/material usage. Finally, efficiency promotes lighter weight vehicles in the larger vehicle classes, which enhances societal safety. [EPA-HQ-OAR-2022-0829-0704, pp. 8-10]

Organization: Toyota Motor North America, Inc.

Toyota supports EPA's proposal to permanently codify the zero g/mile treatment of tailpipe emissions for BEVs, FCEVs, and the all-electric driving portion of PHEVs. We have long opposed auto manufacturers being held responsible for upstream emissions beyond our control. That said, we do believe vehicle technology assessments supporting GHG rulemakings should account for life-cycle emissions under real-world operating conditions when evaluating the relative benefits of competing technologies. Limiting technology assessments to tailpipe emissions ignores factors such as geography, weather, and power sources which can mischaracterize the true relative performance and value of electrified powertrains, missing opportunities for further GHG emissions reductions. [EPA-HQ-OAR-2022-0829-0620, p. 32]

Organization: Valero Energy Corporation

B. EPA has inappropriately made the 0 g/mile upstream incentive permanent in the proposed rule.

EPA has proposed to "indefinitely exclude upstream emissions from BEV compliance calculations."332 EPA has long maintained that its decision to not count upstream emissions from BEVs was to provide a "temporary regulatory incentive."333 A temporary incentive was appropriate because while EVs do not have a tailpipe, the incentive did not "reflect the increase in upstream GHG emissions associated with electricity used by EVs."334 As EPA explained, in 2010 a midsize EV caused a net upstream GHG emissions increase of about 120 grams/mile compared to a midsize gasoline car.335 EPA's proposal to permanently extend this incentive is entirely unmerited. [EPA-HQ-OAR-2022-0829-0707, pp. 62-64]

EV charging necessarily affects the grid, one such effect is a contribution to greater electricity demand during peak demand hours.336 While today's grid has seen some emissions reductions in annual total output emission rates since 2010,337 based on EPA's own prior analysis, upstream greenhouse gas emissions would have needed to fall by two-thirds (or ~66%) from 2010 to the present day before the upstream emissions increase caused by EVs is equivalent to the ICE's upstream emissions.338 But greenhouse emissions, from a pure generation-basis perspective, have not fallen by nearly the required amount based on EPA's most recently available data.339 [EPA-HQ-OAR-2022-0829-0707, pp. 62-64]

338 See 2010 Rule, 75 Fed. Reg. 25435.

339 In 2010, the U.S. average GHG emissions rate for electricity was 1,238.52 lbs/MWh CO2e (eGRID 9th edition Version 1.0 year 2010 GHG Annual Output Emission Rates, supra). But in 2021, the U.S. average GHG emissions rate was 857.0 lbs/MWh CO2e (eGRID Summary Tables 2021, supra , at 2), that means U.S. average GHG emissions have only fallen by approximately one-third.

Even worse, the emissions associated with power plants called upon to supply the grid at peak hours generally have higher emissions per generated MWh.340 A fact borne out in EPA's data that shows that non-baseload power, which reflects the power dispatched to the grid during peak demand,341 has not seen any major declines in CO2 emissions since 2010, and is worse than the emissions associated with baseload power in 2010.342 This data suggests that the impact of EVs on CO2 emissions might be, at best, nearly identical to the upstream emissions increase in 2010. Regardless of which emissions source is used to calculate an EV's true footprint. Indeed, the table below illustrates just how arbitrary and inappropriate it is for EPA's proposal to ignore the upstream emissions increase caused by electric vehicle in light of this reality. [EPA-HQ-OAR-2022-0829-0707, pp. 62-64]

340 See DOE, Emission Reduction Calculation Roadmap (Jan. 2019), https://www.energy.gov/sites/default/files/2019/01/f58/Emission_Roadmap_FINAL.pdf

341 Susy S. Rothschild & Art Diem, Total, Non-baseload, EGRID Subregion, State? Guidance on the Use of eGRID Output Emission Rate, at 5 (last accessed May 2023), https://www3.epa.gov/ttn/chief/conference/ei18/session5/rothschild.pdf

342 In 2010, baseload power GHG emissions rate was 1,238.52 lbs/MWh CO2e (eGRID 9th edition Version 1.0 year 2010 GHG Annual Output Emission Rates, supra). In 2021, non-baseload GHG emissions rate was 1,417.3 lbs/MWh CO2e (eGRID Summary Tables 2021, supra , at 2). Despite the fact that "non-baseload values should not be used for assigning an emissions value for electricity," (Rothschild & Diem, supra) the non-baseload emissions rate reflects emissions for plants "that operate coincident with peak demand for electricity." (id.) Because EVs are expected to increase demand at peak hours (See Powell et al., supra) this may be the proper emissions rate to use when evaluating the upstream emissions associated with EVs.

	eGRID CO2e Emissions	EV Upstream CO2e Emissions343	ICEV Upstream CO2e Emissions344	Net Increase345
2010	1,238.52 lbs/MWh346	173.6 g/mile	60 g/mile	113.6 g/mile
2021	857.0 lbs/MWh347	120.1 g/mile	60 g/mile	60.1 g/mile
2021	1,417.3 lbs/MWh348	198.6 g/mile	60 g/mile	138.6 g/mile

[EPA-HQ-OAR-2022-0829-0707, pp. 62-64]

343 Calculated based on 2022 Tesla Model 3 Long Range AWD with an efficiency of 0.26 kWh/mi (see https://www.fueleconomy.gov/feg/Find.do?action=sbs&id=45011). Calculation uses an EV charging efficiency of 90% and a transmission efficiency of 93.5% (EPA LMDV OMEGA GHG Compliance Modeling Runs, "onroad_fuels_20220325.csv," supra).

344 See 2010 Rule, 75 Fed. Reg. 25435. Refers to a "typical midsize gasoline car."

345 Calculated as (EV upstream CO2e emissions) – (ICEV upstream CO2e emissions).

Organization: Volkswagen Group of America, Inc.

Upstream Emissions – Treatment of PEVs and FCEVs in the Fleet Average (Section III.B.7.)

Volkswagen supports EPA's proposal to make the current treatment of fully electrified vehicles (PEVs and FCEVs) through MY2026 permanent, accounting 0 g/mile toward emission compliance. Upstream emissions are emitted by power plants when producing electricity. Volkswagen supports the premise that upstream emissions linked to the production of electricity should not be accounted for in on-road vehicle regulations. Volkswagen has no control or influence on emissions from stationary source sectors and opposes tying emissions from stationary sources being tied to motor vehicle regulations. [EPA-HQ-OAR-2022-0829-0669, p. 4]

The transition to - 0 g/mile GHG for PEVs and FCEVs holds vehicle manufacturers accountable for our fleets in accordance with the standards. Energy suppliers have their own goals and regulations as we transition to increased "green" energy production. [EPA-HQ-OAR-2022-0829-0669, p. 4]

Organization: Western Energy Alliance

Congress did not give EPA authority to mandate the electrification of the vehicle fleet. The Energy Policy Act and Clean Air Act do not allow EPA to set standards that cannot be met with an internal combustion engine vehicles (ICEV). EPA does not have the authority to compel the transition to completely new vehicle types under the guise of setti ng tailpipe standards for ICEVs. Electric vehicles (EV) do not have a tailpipe, and although their emissions should be evaluated over the full lifecycle and not assumed to be zero as EPA does with this proposed rule, EPA only has authority to consider tailpipe emissions from ICEVs with this rule. EVs are technically not subject to the standards and thus ineligible for the fleet averaging scheme. [EPA-HQ-OAR-2022-0829-0679, p. 1]

Further, it is not at all clear that the proposed rule will reduce GHGs as planned. Pure plug-in battery- powered vehicles can create more emissions than hybrid EVs (HEV) and even more than some traditional ICEVs for a variety of reasons including the fuel mix of the electrical grid where the EV is being charged and the large GHG footprint for producing the battery. The manufacture of a battery can produce GHGs equivalent to driving 24,000 miles, in the case of a Nissan Leaf up to 60,000 miles in the case of a Tesla Model S.4 Those numbers are before a single mile is driven by the supposed ZEV with its associated GHGs from the electricity used. When CO2 emissions linked to the production of batteries and the energy mix are considered, a study in Germany found EVs emit 11% to 28% more than their diesel counterparts.5 Volvo reports that in comparing a gas-burning model with its fully electric equivalent, with both vehicles built in the same factory, on the same assembly line, and sharing a large number of components, it found the electric version results in 70% more emissions.6 [EPA-HQ-OAR-2022-0829-0679, p. 3]

4 "A Data-Driven Greenhouse Gas Emission Rate Analysis for Vehicle Comparisons," SAE International, Journal of Electrified Vehicles, V132-14EJ, April 13, 2022.

5 Kohlemotoren, Windmotoren und Dieselmotoren: Was zeigt die CO2-Bilanz?, Crhristoph Buchal et al., Ifo Institut, 2019.

6 "Building An EV Produces 70% More Emissions Than ICE, Says Volvo," InsideEVs, Andrei Nedelea, November 20, 2021.

EPA needs better analysis of the GHG reductions by EVs. The assumption that they are "zero emission" must be tested using a more comprehensive analysis of full lifecycle emissions sources from EVs. [EPA-HQ-OAR-2022-0829-0679, p. 3]

Organization: Zero Emission Transportation Association (ZETA)

ZETA supports the proposal to continue omitting upstream emissions from electricity generation for purposes of BEV CO2 g/mile calculations. As EPA notes, this is not currently done for ICE vehicles and there is a robust regulatory framework in place to reduce emissions from stationary sources. ZETA encourages EPA to finalize this policy of omitting upstream emissions from mobile source emissions control regulations. [EPA-HQ-OAR-2022-0829-0638, p. 29]

EPA Summary and Response

Summary:

In Section III.B.7 of the preamble in the NPRM, EPA proposed making the current treatment of PEVs and FCEVs through MY 2026 permanent; that is, EPA is including only emissions measured directly from the vehicle in the vehicle GHG program for MYs 2027 and later, consistent with the treatment of all other vehicles. Electric vehicle operation would continue to be counted as 0 g/mile, based on tailpipe emissions only; thus, vehicles with no IC engine (i.e., BEVs and FCEVs) would be counted as 0 g/mile in compliance calculations, while PHEVs would apply the 0 g/mile factor to electric-only vehicle operation (addressed in preamble Section III.C.7). EPA requested comments on its proposed treatment of electrified vehicles (i.e., ZEVs) in manufacturer compliance calculations.

We received comments from many stakeholders both supporting and opposing EPA's proposed compliance treatment of ZEVs. In Section III.B.7 of the preamble in the NPRM we discussed, at length, the justification for the decision to maintain a 0 g/mi tailpipe accounting for ZEVs. However, we reiterate some of those reasons in responses below.

The following summary addresses similar comments made by multiple commenters.

Auto manufacturers (and a few electric vehicle consortia) universally supported EPA's continued treatment of zero g/mi tailpipe emissions for BEVs, with some of them (GM, Honda) citing that it was inappropriate to hold the auto industry accountable for emissions that are beyond its control. EPA agrees with these comments. As we discuss in preamble Section III.C.7, this approach of only regulating vehicle emissions and letting stationary source GHG emissions be addressed by separate stationary source programs is consistent with how the compliance value for every other motor vehicle is calculated (and has been calculated). Emissions from stationary sources under CAA title I are regulated under an entirely different statutory scheme than mobile sources under CAA title II and the upstream adjustment EPA originally adopted (in the 2012 rule) would make the compliance test results of BEVs depend in part on factors entirely beyond the control of BEV manufacturers (i.e., the carbon emissions and transmission efficiency of the electricity grid, as compared to emissions of the refinery sector). We note that while upstream emissions are not included in vehicle compliance determinations, which are based on direct vehicle emissions, upstream emissions impacts from fuel production at refineries and electricity generating units are considered in EPA's analysis of overall estimated emissions impacts and projected benefits, as detailed in Sections VI and VII of the preamble.

Many commenters (including fuel suppliers and producers, renewable fuel producers, some environmental groups, automotive suppliers) voiced their opposition to the proposed treatment of ZEVs in compliance accounting and recommended that EPA include the upstream emissions from fuel production in the compliance calculations for ZEVs. (Alliance for Vehicle Efficiency, ACEEE, Arconic, BorgWarner, Clean Fuels Development, Commonwealth Agri-Energy, Delek US Holdings, Doug Peterson, East Kansas Agri-Energy, Environmental and Public Health Organizations, Exxon Mobil, John Graham, Kentucky AG, MECA, MEMA, Minnesota Corn Growers, National Corn Growers, National Farmers Union, Natural Gas Vehicles for America, Nebraska Corn Board, North Dakota Farmers Union, POET, Southern Environmental Law Center, The Aluminum Association, Valero).

Some commenters (AFP, Peterson) argued that the CAA gives EPA the authority to establish emissions of pollutants from “any class or classes of new motor vehicles or new motor vehicle engines… that endanger public health or welfare...” and that “this would obligate EPA to abandon its position that ZEVs are emission-less and would have to account for upstream and other lifecycle emissions.”

Similarly, several traditional and alternative fuel providers argued that EPA lacks the statutory authority to ignore upstream emissions for ZEVs (AVE, ACE, American Fuel and Petroleum Mfrs, Clean Fuels Development Coalition, HF Sinclair, Kentucky AG, Marathon, NGVA, POET, RFA, Valero).

Finally, some commenters claimed that our lack of upstream accounting for ZEVs renders the rule “arbitrary and capricious” (API, Clean Fuels Dev, Kentucky AG).

<u>Response:</u>

To these four groups of comments summarized above, EPA disagrees. In short, we already address those emissions under our stationary source provisions of Title I of the CAA; for further discussion, reference our discussion in the preamble and additional responses to comments in Sections 2 and 19 of the RTC.

In their comments, Arconic, the Aluminum Association, MECA and MEMA recommended a fixed electric generation emission value per kWh for BEVs. While this is a different approach than the prior upstream calculation in EPA’s regulations (that would have been applicable for future model years), it still adds an upstream component to the compliance calculation of vehicle emissions. EPA disagrees with this recommendation; as we discuss above and at length in Section III.C.7 of the preamble, we have provided a rationale for why we are only using tailpipe emissions in calculating GHG compliance from all vehicles.

Some commenters (fuel suppliers, fuel producers, automotive suppliers, non-governmental organizations, and a few environmental groups) advocated for EPA to adopt a full lifecycle analysis (LCA) approach in its treatment of BEVs, PHEVs and FCEVs, which would include the upstream emissions from fuel or electricity generation, including the mining and extraction of feedstocks, and production and disposal of the vehicles. EPA disagrees and is not adopting full lifecycle emissions in its regulation of motor vehicles. A majority of these commenters and similar comments are already represented in Section 19 of this RTC; likewise, responses for those comments also apply to the commenters in this section.

Some commenters (e.g., AVE, ACEEE) expressed the importance and the various benefits of more efficient BEVs and their belief that EPA has an obligation to regulate ZEV efficiency. While EPA recognizes the importance of more efficient ZEVs, we do not believe it is necessary or appropriate to adopt standards for efficiency. We believe there are strong market incentives for manufacturers to produce efficient electric vehicles, as doing so will improve driving range and reduce battery size and costs; in addition, the fuel economy and environment labels on new vehicles provide consumers with information on efficiency via the range and annual fuel cost metrics.

3.1.6 - PHEV utility factor

Comments by Organizations

Organization: Alliance for Automotive Innovation

2.PHEV Utility Factor

EPA is proposing a change to PHEV fleet utility factor (FUF), which will result in a calculated increase in GHG emissions of light- and medium-duty PHEVs. EPA claims "the real-world data available today clearly no longer supports the FUF established in SAE J2841 more than a decade ago."229 Auto Innovators disagrees and believes that the current published FUFs should remain in use for the purposes of GHG and CAFE compliance calculations. [EPA-HQ-OAR-2022-0829-0701, pp. 124-127]

229 88 Federal Register 29253.

EPA's analysis is limited to multiple publications from the International Council on Clean Transportation (ICCT). The ICCT publications focus on the limited electric driving share of PHEVs in Europe. In Europe, some corporations purchased only PHEVs for their fleet to take advantage of government incentives/subsidies. The users of these company cars could typically fuel the vehicle for free, and unfortunately had no incentive to plug-in their vehicle. The situation in Europe with tax incentives encouraging PHEVs coupled with limited charging infrastructure available in predominantly multifamily dwellings is simply not comparable to the United States. [EPA-HQ-OAR-2022-0829-0701, pp. 124-127]

We have also observed that the proposal excludes several relevant peer-reviewed publications, including papers by Toyota230 and UC Davis 231 that provide counter-balancing arguments to the claims that the SAE FUF is no longer appropriate. The lack of consideration of other studies, such as these, suggests that further consideration is required. [EPA-HQ-OAR-2022-0829-0701, pp. 124-127]

230 Hamza, K., Laberteaux, K. and Chu, K.C. "On inferred real-world fuel consumption of past decade plug-in hybrid electric vehicles in the US," Environ. Res. Let. 17 (2022) 104053. htps://doi.org/10.1088/1748-9326/ac94e8

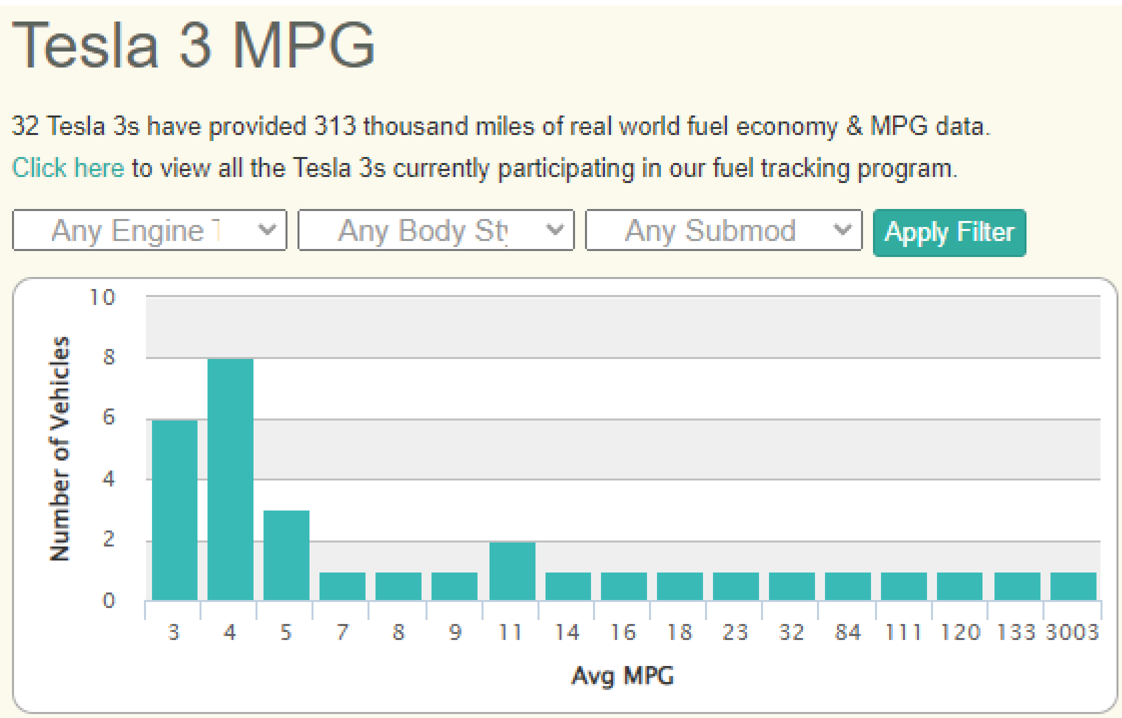
231 Raghavan, S. and Tal, G. "Plug-in hybrid electric vehicle observed utility factor: why the observed electrification performance differ from expectations." Int. J. Sustain. Transp. (2020) 16: 105-136

For its U.S. analysis ICCT, inspired by the European analysis, evaluated two data sources: user- reported data from Fuelly.com, and OBD data from the California Bureau of Automotive Repair (BAR). For the Proposed Rule, EPA has taken the ICCT datasets and performed their own analysis, which is essentially a copy of ICCT's work. The PHEV data analysis should include nationwide usage data and be peer-reviewed before it is used in rulemaking. [EPA-HQ-OAR-2022-0829-0701, pp. 124-127]

a)Fuelly Dataset

The data from fuelly.com is user-reported and subject to data entry errors. There is also a potential for data bias in the self-selected participants. (For example, users are likely more interested in fuel economy than the average driver, and may also be those less satisfied by their fuel economy given their own unique driving habits.) It should not be relied upon. Further, the fuelly.com data entry is built around gasoline fuel use with a miles per gallon perspective. An example of the unsuitability of this data for regulatory analysis is shown in Figure 35, below. [EPA-HQ-OAR-2022-0829-0701, pp. 124-127]

SEE ORIGINAL COMMENT FOR Figure 35: Fuelly.com data for Tesla Model 3.232 [EPA-HQ-OAR-2022-0829-0701, pp. 124-127]



232 Tesla 3 MPG - Actual MPG from 32 Tesla 3 owners (fuelly.com)

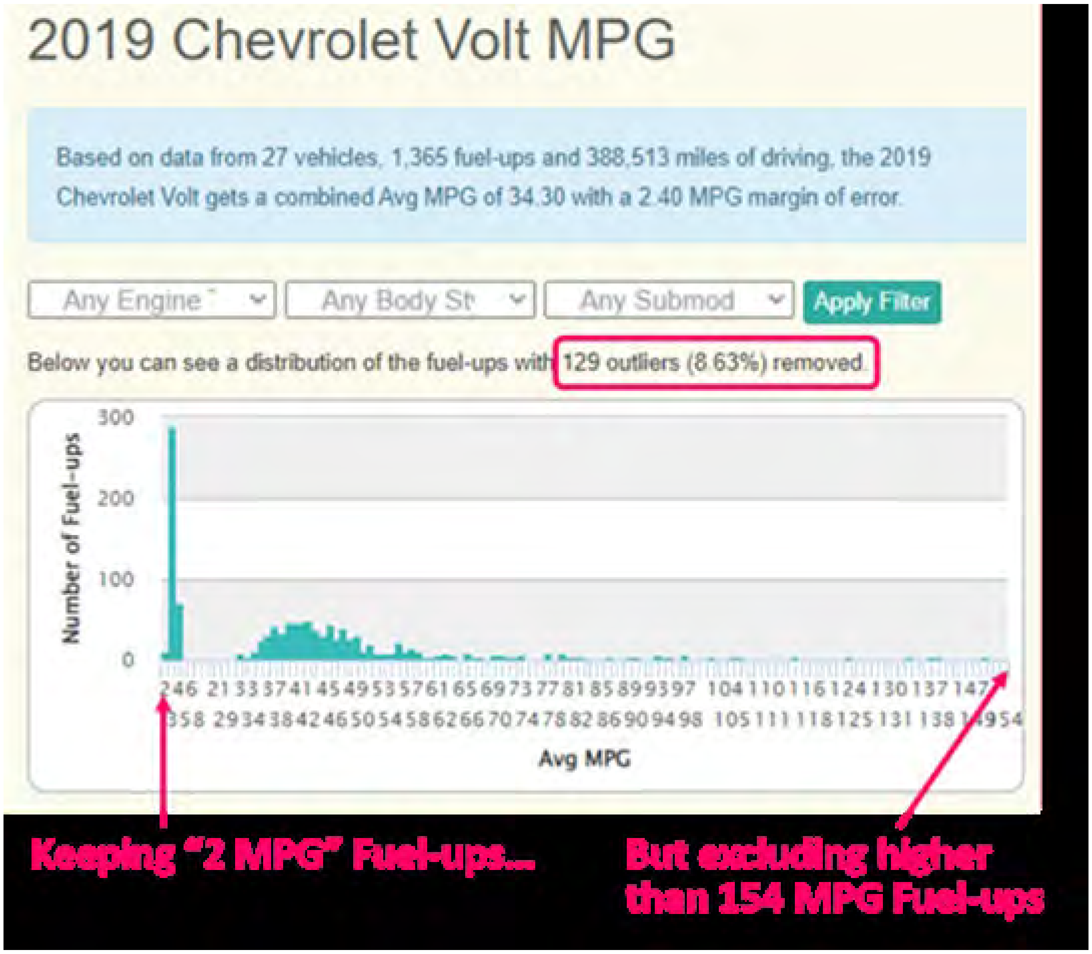
The Fuelly web app is primarily designed to track operating costs of gasoline vehicles and does not appear to be intended for electric or plug-in vehicles. The web-app has only one entry field for "fuel," which is intended to help users track their fuel costs. We have observed that most Tesla drivers appear to enter their electricity kWh values in the "fuel" data field of the Fuelly web app, where it is then treated as if it were gasoline. Although the graph shows "Avg MPG", the data suggests that it is actually "miles per kWh". [EPA-HQ-OAR-2022-0829-0701, pp. 124-127]

Most Tesla Model 3 users have entered between 3 to 4 miles/kW which converts to between 0.25 to 0.33 kWh/mile, the actual typical range of values for a Model 3. Vehicles entered as having very high "Fuel" numbers such 11 miles/kWh (converts to 0.09kWh/mile), let alone those entered as having 111 or 3,003 miles/kWh values (corresponds to between 0.009 kWh/mile to 0.0003 kWh/mile) are likely due to users forgetting to enter all of their charging events. It is possible these Model 3 users only counted charging at a Tesla supercharger but not the kWh from day-to-day charging at home. [EPA-HQ-OAR-2022-0829-0701, pp. 124-127]

As seen from the example above, electricity consumption values for a Model 3 and other BEVs are mistaken for gasoline consumption, resulting in a distinguishable pattern of impossibly low efficiency refueling events alongside normal refueling events. Data entry errors like this would cause the Fuelly web application to severely over-estimate the fuel consumption of PHEVs, therefore severely under-estimating the derived utility factor. [EPA-HQ-OAR-2022-0829-0701, pp. 124-127]

The refueling events for PHEVs having an accurately high charging frequency and utility factor have been excluded as outliers by the Fuelly application because their fuel economy is deemed too high. For example, a regularly charged Chevrolet Volt can attain 200+ MPG which can be filtered from the distribution of re-fuel events because the value lies beyond Fuelly's 3-sigma screening limit that is applied to fleet average MPG (see Figure 36 below). These omissions further mischaracterize PHEV real-world fleet performance. [EPA-HQ-OAR-2022-0829-0701, pp. 124-127]

SEE ORIGINAL COMMENT FOR Figure 36: Fuelly.com data for 2019 Chevrolet Volt.



These errors can be readily identified and corrected through a tedious manual process, which neither ICCT nor EPA appear to have attempted to date. [EPA-HQ-OAR-2022-0829-0701, pp. 124-127]

Given the web app is not designed for electric vehicles and the resulting plethora of uncorrected errors, Fuelly.com data should not be considered in rulemaking, even as a secondary source. [EPA-HQ-OAR-2022-0829-0701, pp. 124-127]

b)BAR Dataset

EPA also uses the California BAR OBD data downloaded from vehicles. The OBD data is reliable and is certainly a valid source of information. Still, Auto Innovators has concerns with which data is selected and how the data is processed and used. The proposal notes limitations with data availability. The BAR smog test program did not begin tracking PHEV operation until the 2019 model year. Participation in the program is required by vehicle age,233 or if a vehicle has been registered in California after moving from another state. Given the dataset cited for the proposal was collected during the 2022 calendar year, the age criteria do not apply. Therefore, the data is predominantly from registered MY 2019-2022 PHEVs arriving from another state collected during the 2020 through 2022 calendar years. Long-distance moves between states can involve significant miles accumulated primarily in charge sustaining mode which skews the recorded OBD data, making it unrepresentative of normal PHEV operation. Given that EPA accepted PHEVs with as low as 1,865 lifetime miles from the BAR dataset, even a few hundred miles without charging can bias the data toward a lower utility factor. [EPA-HQ-OAR-2022-0829-0701, pp. 124-127]

233 Any vehicle 8 years or older, or vehicles 4 model years or older that change ownership. See Frequently Asked Questions: Smog Check Program, CALIFORNIA BUREAU OF AUTOMOTIVE REPAIR, htps://www.bar.ca.gov/consumer/smog- check-program/faq.

In the DRIA, EPA notes, "As of October 2022, the BAR OBD dataset has around 8,400 PHEV vehicles, and over 233.2 million vehicle miles traveled. The filtered dataset has 30 PHEV models, and 2,060 individual vehicles that travelled 58.9 million miles."234 While some filtering of data to exclude outliers is expected, removing approximately 75% of the vehicles and vehicle mileage is not. As a result, many of the PHEV variants studied by EPA have a sample size of 30 vehicles, which is statistically insignificant to draw conclusions about real-world PHEV operation. Most PHEVs in the cited BAR dataset underwent the smog check during 2020 through 2022 calendar years, which includes the COVID pandemic, which significantly altered transportation trends. This period entailed unusual fluctuatioions in gasoline prices including a 10-year low in 2020 making for both unusual driving patterns and less motivation to charge. We expect that post- pandemic, real-world FUF trends will increase. [EPA-HQ-OAR-2022-0829-0701, pp. 124-127]

234 DRIA at 3-73.

Unfiltered BAR data and an explanation of filtering methodology was not provided as part of the NPRM or with the DRIA. Following a request, EPA did share the raw data and an explanation of the filtering used. While the information is now posted to the docket, the lack of inclusion with the regulatory documents means most stakeholders will not have awareness of the availability during the short 60-day comment period. Due to the large dataset, late delivery of information, and limited comment period, Auto Innovators is providing an initial analysis, but may submit more information to the docket once available, and likely after the comment period closes. [EPA-HQ-OAR-2022-0829-0701, pp. 124-127]

c)The Proposed Utility Factor

Utility factors have been fitted to an exponential equation, as shown below. The C coefficients are used to fit the curve and normalized distance establishes the distance where the utility factor is 100%. [EPA-HQ-OAR-2022-0829-0701, pp. 128-130]

UF = 1 – exp{ -[C1*(x/norm_dist) + C2*(x/norm_dist)2+ … + C10*(x/ norm_dist)10]}

ICCT did not properly fit the data, and that data was subsequently used to create EPA's proposal. As shown in Figure 37, instead of fitting the data properly, ICCT copied the 10 curve fitting coefficients from SAE J2841's multi-day independent utility factor (MDIUF) (developed from a different data set) and only changed the normalized distance to create their "curve fit". But normalized distance is the one variable in the equation that need not change. [EPA-HQ-OAR-2022-0829-0701, pp. 128-130]

SEE ORIGINAL COMMENT FOR Figure 37: Comparison of J2841 and ICCT Utility Factor Coefficients [EPA-HQ-OAR-2022-0829-0701, pp. 128-130]

Because of this error, we are not confident that ICCTs curve appropriately fits the underlying data. [EPA-HQ-OAR-2022-0829-0701, pp. 128-130]

EPA notes that they “created the proposed curve by averaging the SAE J2841 FUF curve and the ICCT–BAR curve.”235 While EPA used a least-squares regression method to create this average line, they changed only the normalized distance in this fit, otherwise copying the SAE J2841 FUF curve fitting coefficients that were also developed from a completely different dataset. Changing normalized distance doesn’t make sense unless overall driving distances have changed. In fact, EPA confirms that this isn’t the case, which is highlighted in their DRIA Footnote 35: “we used the latest NHTS data (2017) and executed the utility factor code that is in SAE J2841, Appendix C, and found that the latest NHTS data did not significantly change the utility factor curves.”236 This would indicate that the driving distances and overall distribution of driving has not changed. The normalized distance (Utility Factor=1) should remain unchanged. [EPA-HQ-OAR-2022-0829-0701, pp. 128-130]

235 DRIA at 3-78.

236 DRIA at 3-74.

In Figure 38, the first two rows are the curve fitting data for the two inputs EPA used to generate their proposed fleet utility factor, which is shown in the 3rd row. This shows the six curve fitting coefficients that were copied from earlier work contained in SAE J2841 fleet utility factor. [EPA-HQ-OAR-2022-0829-0701, pp. 128-130]

SEE ORIGINAL COMMENT FOR Figure 38: EPA Proposed Utility Factor Coefficients [EPA-HQ-OAR-2022-0829-0701, pp. 128-130]

Using this curve fitting technique, the result is that regardless of all-electric miles traveled on a certification test, only 68.5% of those miles count. This is equally true for PHEVs that travel 20 miles or 200 miles. This is not appropriate, and the proposed utility factor should not be included in the final regulation. [EPA-HQ-OAR-2022-0829-0701, pp. 128-130]

d)differences Between Real-World and Laboratory

The normal method to address differences between real-world and laboratory results, especially when due to driving behaviors, has been through post-compliance adjustments aimed at consumer awareness and occasionally by expanding test cycle requirements, and not by revising calculations used to determine compliance with the standards. While some data may suggest PHEVs are not being plugged in as frequently as the assumptions underlying the SAE UF curve, this should not be a problem atributed to automakers, nor should it be grounds to adjust a compliance measurement. Charging equipment is supplied with the vehicles sold by automakers. Changing regulatory outcomes based on variable consumer charging behavior would be akin to forcing derated CO2 compliance on ICE applications because some drivers behave aggressively performing “jack rabbit” starts frequently, thereby consuming more fuel. Fuel economy labels show adjusted values for the laboratory fuel economy and CO2 emissions results. [EPA-HQ-OAR-2022-0829-0701, pp. 128-130]

EPA recognizes that BEV technology is still maturing and needs support to build consumer acceptance. Appropriately, the proposal does not examine the advertised range, efficiency, and emissions performance of BEVs under real-world operation. PHEVs are in the same fragile stage of growth and should be treated no differently. [EPA-HQ-OAR-2022-0829-0701, pp. 128-130]

The proposal notes BEV technology improvements and charging infrastructure expansion, which applies to PHEVs as well. Given the investments in charging infrastructure being made as part of the IIJA, it is expected that over time more public and multi-unit family dwelling charging will become available. Also, as more vehicles electrify, plugging in a vehicle to charge will become ubiquitous, which should help reduce unwillingness to charge, and resolve knowledge gaps in how to charge. Lack of charging, to the extent it exists, should be best solved by consumer education, not by a change to the utility factor. [EPA-HQ-OAR-2022-0829-0701, pp. 128-130]

Efforts to address perceived concerns about real-world performance need to account for other solutions already in progress. The BAR dataset and more rigorous, peer-reviewed studies indicate some PHEVs have a lower ratio of EV driving versus ICE operation on-road versus certification, while other vehicles' performance is well-aligned to certification values.237 We believe this difference is due to the spread of performance capability of the electric machines in PHEVs. Lower capability electric machines demonstrate a greater difference in on-road versus on-cycle performance. EPA's proposed PHEV high power cold start requirement encourages more all-electric operation capability. Further, CARB requires a minimum 70-mile combined city/highway and minimum 40-mile US06 all-electric range starting with MY 2029. These requirements force all new PHEVs under development to be highly capable. EPA's linear curve fit is weighted toward vehicles with a range below 30 miles. Changing the utility factor based on such skewed data would discourage the introduction of new, higher-capability PHEVs. [EPA-HQ-OAR-2022-0829-0701, pp. 128-130]

237 Restate of FN 6 Hamza, K., Laberteaux, K. and Chu, K.C. "On inferred real-world fuel consumption of past decade plug-in hybrid electric vehicles in the US," Environ. Res. Let. 17 (2022) 104053. https://doi.org/10.1088/1748-9326/ac94e8.

Many current PHEVs already demonstrate good utility factor alignment between certification tests in the laboratory and real on-road driving. These vehicles would be unnecessarily punished by the proposed change in utility factor. Auto Innovators believes that growth in charging infrastructure coupled with higher capability PHEVs means that the current utility factor will be representative for future PHEVs and should remain unchanged. [EPA-HQ-OAR-2022-0829-0701, pp. 128-130]

e)Next Steps

Auto Innovators supports PHEVs attaining their advertised range for charge depleting/all-electric operation. We do not believe EPA's proposed regulatory action will achieve this outcome. The poor quality of supporting data in the proposal would make such an action arbitrary and capricious. We propose that industry, EPA, SAE, DOT, and the national laboratories collaborate on a project to acquire and process a large sample of nationwide PHEV data. This collaboration can be used to better understand the sources of variation and agree on logical data processing or filtering. If proven necessary, adjustments to SAE J2841 or advertised all- electric range, and other potential solutions can be explored following appropriate deliberation and peer review of the collaborative effort. [EPA-HQ-OAR-2022-0829-0701, pp. 128-130]

Organization: Alliance for Vehicle Efficiency (AVE)

PHEV Utility Factor

AVE urges EPA to review its approach to the utility factor proposed for plug-in hybrid electric vehicles (PHEV) and provide more certainty for this vehicle segment. It appears that EPA has established the proposed Utility Factor by averaging earlier estimates for PHEV range and consumer driving habits. Recent analysis, however, indicates significant improvement in PHEV's electric range.9 Additionally, to comply with California's Advanced Clean Cars II regulations, automakers are already announcing PHEVs that will greatly exceed California's requirements.10 [EPA-HQ-OAR-2022-0829-0631, p. 4]

9 https://www.iea.org/reports/global-ev-outlook-2022/trends-in-electric-light-duty-vehicles

10 https://www.greencarreports.com/news/1139305_toyota-plans-to-push-plug-in-hybrid-ev-range-beyond-120-miles

EPA should account for current and expected improved range for future PHEV models to determine the utility factor curve that should apply. [EPA-HQ-OAR-2022-0829-0631, p. 4]

Organization: Betsy Cooper

PHEVs fill an important gap, providing a transition vehicle that allow consumers to experience the benefits of all-electric driving without some of the risks: [EPA-HQ-OAR-2022-0829-0654, pp. 2-3]

- First, a gas backup can reduce range anxiety, especially in uncertain terrain or cold temperatures. While our family also owns a pure EV, we are not yet ready to commit to being a fully electric household. Not least, our PHEV is our vehicle of choice for any road trip in the snow or mountains, as we do not want to test our full range in a precarious, unpredictable location. [EPA-HQ-OAR-2022-0829-0654, pp. 2-3]

- Second, PHEVs are more family friendly than EVs; as parents (like us) of small children will tell you, charging on a road trip is one thing. Charging on the road with an unhappy toddler – or heaven forbid, one who only sleeps when the car is moving – is quite another. Having the option to keep driving on gas once the electric range runs out is a blessing. [EPA-HQ-OAR-2022-0829-0654, pp. 2-3]

- Third, and relatedly, this is particularly true because charging infrastructure has not yet caught up with EV demand. [EPA-HQ-OAR-2022-0829-0654, pp. 2-3]

- Rural and disadvantaged communities disproportionately lack access to public charging infrastructure [Link: https://www.marketplace.org/shows/marketplace-tech/rural-communities-are-slow-to-adopt-evs-but-a-national-charging-network-depends-on-them/]. So long as charging infrastructure is not as ubiquitous as gas stations are, gas backups remain an important option for long haul driving. [EPA-HQ-OAR-2022-0829-0654, pp. 2-3]

- Moreover, even in areas with well-developed charging infrastructure, such as in California where we live, it can be very difficult to find an available and working charger in a convenient location. Betsy's current commute has only two chargers within a mile, and both are broken. Aaron's work sponsors chargers, but even then demand is so high that employees require a complex interoffice notification system to ensure everyone gets a charge by the end of the day. [EPA-HQ-OAR-2022-0829-0654, pp. 2-3]

Short-Range PHEVs Do Not Achieve EPA's Greenhouse Gas Emissions Goals

While PHEVs fill an important market need, manufacturers' move to short range PHEVs (those with less than 40 miles of range) has reduced these benefits significantly. Small electric batteries do less to reduce range anxiety. Shorter ranges require more frequent charging, and make it more likely that drivers will need to charge in inconvenient locations away from home. And these annoyances may make it more likely that new PHEVs will rely on gas. [EPA-HQ-OAR-2022-0829-0654, p. 3]

EPA may rightfully wish to disincentivize the use of gas cars for any reason. But doing so by disincentivizing all PHEVs, as the current regulation proposes, is a mistake. The fundamental problem here is not with PHEVs; it is with the small electric range on offer in those vehicles. Longer range PHEVs with smaller gas tanks will reduce reliance on gas, helping to get the first-time electric vehicle consumer more comfortable relying on electric power for their daily needs. [EPA-HQ-OAR-2022-0829-0654, p. 3]

EPA Should Use Its Regulatory Authority To Incentivize Long-Range PHEVs

The EPA thus should use its regulatory process to encourage PHEV manufacturers to return long-train PHEVs to the market: by providing full off-cycle credits to those who give 50 or more miles of electric range. EPA's current plan will disincentivize all PHEVs, ignoring the real market benefits to keeping long-range versions of these cars in the market. Intentional or not, the effects of the EPA's current policy will be to push vehicle manufacturers further towards full EVs—before the charging infrastructure is ready to support them. In the meantime, consumers not ready to adopt full EVs – including for the same reasons we are not yet able to do so – will continue to buy gas cars instead. [EPA-HQ-OAR-2022-0829-0654, pp. 3-4]

With more long-range PHEVs on the market, more Americans will be able to drive their full commute on electricity and charge overnight at home (with reduced demand on the grid relatively to fast-charging of full EVs). Moreover, as longer range PHEV cars grow more popular, there will be greater incentives for individuals and communities to invest in improving charging infrastructure, thus reducing the friction facing current consumers. [EPA-HQ-OAR-2022-0829-0654, pp. 3-4]

By encouraging both EVs and long-range PHEVs, the EPA will encourage manufacturers to offer more long-range PHEV models, and to make more of them. As demand for the 42-mile RAV4 PHEV shows, consumers crave these long-range PHEV options. There just aren't currently any affordable and available ones to choose from. [EPA-HQ-OAR-2022-0829-0654, pp. 3-4]

We propose a 50+ mile PHEV range requirement for full off-cycle credit. There is already momentum in favor of this standard; California is planning to require 50+ mile range PHEVs by 2035 [Link: https://ww2.arb.ca.gov/news/california-moves-accelerate-100-new-zero-emission-vehicle-sales-2035]. Moreover, even with battery degradation, a PHEV rated for 50+ miles at the point of sale will still cover the average American commute many years later. [EPA-HQ-OAR-2022-0829-0654, p. 4]

The EPA may respond that its scaled utility factor already takes into account miles of range in its calculation. Even if true, by penalizing all PHEVs across the board, the EPA is incentivizing manufacturers to make fewer plug-in hybrid vehicles, period. Especially until charging infrastructure resembles the gas station infrastructure of today, long-range PHEV cars remain an important consumer option. By rewarding manufacturers for making PHEVs with a 50+ mile range, EPA will help bring an important class of climate-friendly vehicles back to market. [EPA-HQ-OAR-2022-0829-0654, p. 4]

Organization: BorgWarner Inc.

BorgWarner supports the goals of EPA's proposal.

BorgWarner supports EPA's approach to decarbonize the light- and medium-duty vehicle sectors. However, the proposed pace for battery electric vehicle (BEV) adoption requires continued significant support and incentives from state and federal regulators. [EPA-HQ-OAR-2022-0829-0640, pp. 3-4]

The demand for BEVs across all vehicles sectors is rising. Critical mineral supply will need to increase significantly to support the growth of the BEV market. Battery production, along with the necessary charging infrastructure, will ultimately depend on suppliers and manufacturers having access to increasingly domestically sourced and processed critical materials and minerals in sufficient quantities. Automotive suppliers operate in an integrated, complex worldwide supply chain and access to international markets is critical to our ability to meet production demands. [EPA-HQ-OAR-2022-0829-0640, pp. 3-4]

The Infrastructure Investment and Jobs Act (IIJA), the Inflation Reduction Act (IRA), and CHIPS & Science Act were each important initial steps to enable industry, consumers, and communities to make the EV transition across the U.S. These significant investments are critical in supporting the continued growth of U.S. manufacturing and ensuring the initial transition results in affordable EVs for consumers and profitability for manufacturers. EPA should recognize that a majority of the programs needed to help achieve the EV transformation are still awaiting regulations and guidelines. In addition, the supplier industry, along with automakers and communities, will need time to implement the necessary investments in supply chains, infrastructure, and workforce to make the shift to electrification successful. [EPA-HQ-OAR-2022-0829-0640, pp. 3-4]

To meet EPA's forecast for BEV penetration levels, there is little room for supply chain or production delays. Any setback could negatively impact the availability or purchase of new BEVs. EPA can reduce these risks to manufacturers by incentivizing vehicles with longer ranges and adjusting multipliers as better BEVs and plug-in hybrid electric vehicles (PHEVs) are introduced. [EPA-HQ-OAR-2022-0829-0640, pp. 3-4]

BorgWarner asks EPA to reconsider the agency's approach to the proposed PHEV utility curve. As proposed, EPA is addressing its concern for PHEVs operating on a vehicle's engine mode, based on dated assumptions of average consumer usage of prior generation PHEV models. To meet many of the requirements set by both EPA in this proposal and California in its Advanced Clean Car II rulemaking, PHEVs would have significantly increased electric range that make them more capable of all-electric operation, and together with a much-improved charging infrastructure, will change the pattern of consumer use. In fact, average new PHEV driving range increased 8.5% in 2021 and is expected to continue increasing.3 As such, EPA should model future consumer usage based on the expected models on sale from MY 2027, and further improvements to charging availability, and use the model to determine the utility factor curve that should apply. [EPA-HQ-OAR-2022-0829-0640, pp. 3-4]

3 https://www.iea.org/reports/global-ev-outlook-2022/trends-in-electric-light-duty-vehicles

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Plug-in Hybrid Electric Vehicles

California's ACC II program allows manufacturers to fulfill a portion of their ZEV sales requirements with PHEVs that meet certain standards, including certification to at least 70 miles of all-electric range (equivalent to approximately 50 miles of label range). While U.S. EPA's analysis of compliance pathways to meet the GHG standards does not rely on the use of PHEVs within the fleet to meet the proposed standards and most industry experts agree that PHEVs are a less cost-effective solution, CARB expects that PHEVs may have greater appeal to some consumers and comprise some share of the light-duty vehicle fleet in U.S. EPA's regulatory timeframe. [EPA-HQ-OAR-2022-0829-0780, p. 18]

The majority of emission benefits from a PHEV result from the vehicle's ability to travel on electric power, as opposed to combustion power. While PHEVs offer flexibility to consumers and can play an important role in broader ZEV adoption, emission benefits can vary widely. To determine how a PHEV's emission rate is counted toward meeting a manufacturer's GHG fleet average, U.S. EPA uses a fleet utility factor (FUF) to convert PHEV electric driving range into a weighting factor for 2-cycle GHG emission test results. Overvaluing PHEVs with an inflated FUF curve would be detrimental to the environment and overstate the emission reductions from the vehicles. [EPA-HQ-OAR-2022-0829-0780, p. 18]

The FUF curve U.S. EPA applies in its current regulation is the "SAE J2841 19 FUF" curve. Out of concerns that this curve overstates benefits, U.S. EPA is proposing to adopt a revised FUF curve that is less generous than the current curve in estimating GHG reductions from PHEVs. CARB has previously analyzed data that demonstrate that the SAE J2841 FUF curve may overestimate benefits, and CARB therefore supports U.S. EPA's proposal to revisit the FUF. However, based on a recent analysis of real-world PHEV data, CARB recommends that U.S. EPA adopt an even more conservative curve than it is currently proposing. U.S. EPA also presents—but does not propose to adopt—an additional curve, the "ICCT-BAR" curve, based on an analysis conducted by the International Council on Clean Transportation. The ICCT-BAR curve is even lower than the revised FUF curve U.S. EPA is proposing. CARB recommends that U.S. EPA adopt the ICCT-BAR curve, which is most representative of current data. [EPA-HQ-OAR-2022-0829-0780, p. 18]

19 SAE J2841 is an SAE Information Report that establishes a set of "Utility Factor" curves and the method for generating these curves.

Existing fleet utility factor

CARB agrees with U.S. EPA that the SAE J2841 FUF curve that U.S. EPA applies in its current regulation likely overstates emission benefits from PHEVs and points to two references to support this finding. [EPA-HQ-OAR-2022-0829-0780, pp. 19-20]

First, as part of its ACC I Midterm Review (MTR) completed in 2017, CARB analyzed millions of data points on thousands of ZEVs and PHEVs and found that the criteria pollutant and GHG emission benefits are highly driver dependent but generally increase with vehicle electric power capability and electric range. 20 CARB found that PHEVs were not driven the amount of electric vehicle miles traveled (eVMT) expected by the SAE J2841 FUF curve, particularly those with less range and more blended powertrains that turn on the internal combustion engine when a driver requires more vehicle power. [EPA-HQ-OAR-2022-0829-0780, pp. 19-20]

20 20 CARB. California Advanced Clean Cars Midterm Review. Appendix G: Plug-in Electric Vehicle In-Use and Charging Data Analysis. January 2017. https://ww2.arb.ca.gov/sites/default/files/2020-01/appendix_g_pev_in_use_and_charging_data_analysis_ac.pdf.

Second, as a separate data source, CARB contracted with the University of California, Davis (UC Davis) Institute of Transportation Studies to collect and analyze household-level travel and refueling behavior centered around BEVs, PHEVs, and FCEVs. 21 The study included installing data loggers on individual vehicles, including many different models of PHEVs. UC Davis found that all PHEVs, apart from the Chevrolet Volt, demonstrated lower utility factors than the SAE J2841-based FUF curve. The Chevrolet Volt had a much more capable electric powertrain that could keep its internal combustion engine from turning on before the battery depleted in almost all driving conditions, which made the Volt relatively unique amongst the other PHEVs in the logged data set. [EPA-HQ-OAR-2022-0829-0780, pp. 19-20]

21 Tal, Gil, Karanam, Vaishnavi Chaitanya, Favetti, Matthew P., et al. “Emerging Technology Zero Emission Vehicle Household Travel and Refueling Behavior.” April 2019. https://escholarship.org/uc/item/2v0853tp.

CARB analysis of updated real-world data

In its proposal, U.S. EPA proposes a revised FUF curve that is lower than the SAE J2841 FUF curve. Based on an analysis of additional real-world data, summarized below, CARB finds that the ICCT-BAR curve is even closer to what real-world data supports for eVMT. CARB therefore recommends that U.S. EPA adopt the ICCT-BAR curve. [EPA-HQ-OAR-2022-0829-0780, pp. 19-20]

In mid-May 2023, CARB staff acquired an updated dataset containing newer PHEV operational data from the California Bureau of Automotive Repair (BAR), which administers the State’s light-duty vehicle inspection and maintenance program known as SmogCheck. These data expand on the original dataset (acquired in October 2022) ICCT analyzed that U.S. EPA references in its proposal and contain various operational parameters related to PHEV operation. Among the relevant parameters in the dataset for this analysis were charge-depleting engine-off distance traveled and total distance traveled (i.e., odometer readings). Staff filtered the BAR dataset to remove low-mileage PHEVs (<## 3,000 miles), which may not provide sufficient data to be representative of the population. In addition, CARB staff ensured that all PHEV data were internally consistent by omitting those vehicles that had different readings for odometer distance and lifetime distance traveled as recorded by the vehicle’s on-board diagnostic system. Then, using the same calculations described in U.S. EPA’s proposal, CARB staff calculated utility factors for a wide range of 16 PHEV models from the 2019 through 2022 MYs. CARB included aggregated vehicle model data only for those vehicle models containing 30 or more individual vehicles. The final filtered dataset contained 3,454 vehicles. [EPA-HQ-OAR-2022-0829-0780, pp. 19-20]

There are certain inherent limitations to the BAR data, though. Vehicles are not required to participate in the SmogCheck program until they are eight years old unless they are undergoing a change of ownership or being newly imported into the State. As a result, the current sample of vehicles is only a fraction of the PHEVs in the State, and there may be some selection bias in those vehicles that are included. Therefore, until sufficient time has passed, and more PHEVs become subject to the SmogCheck program, this dataset will not have the necessary cross-section of PHEVs operating within California to be a truly representative sample. [EPA-HQ-OAR-2022-0829-0780, pp. 19-20]

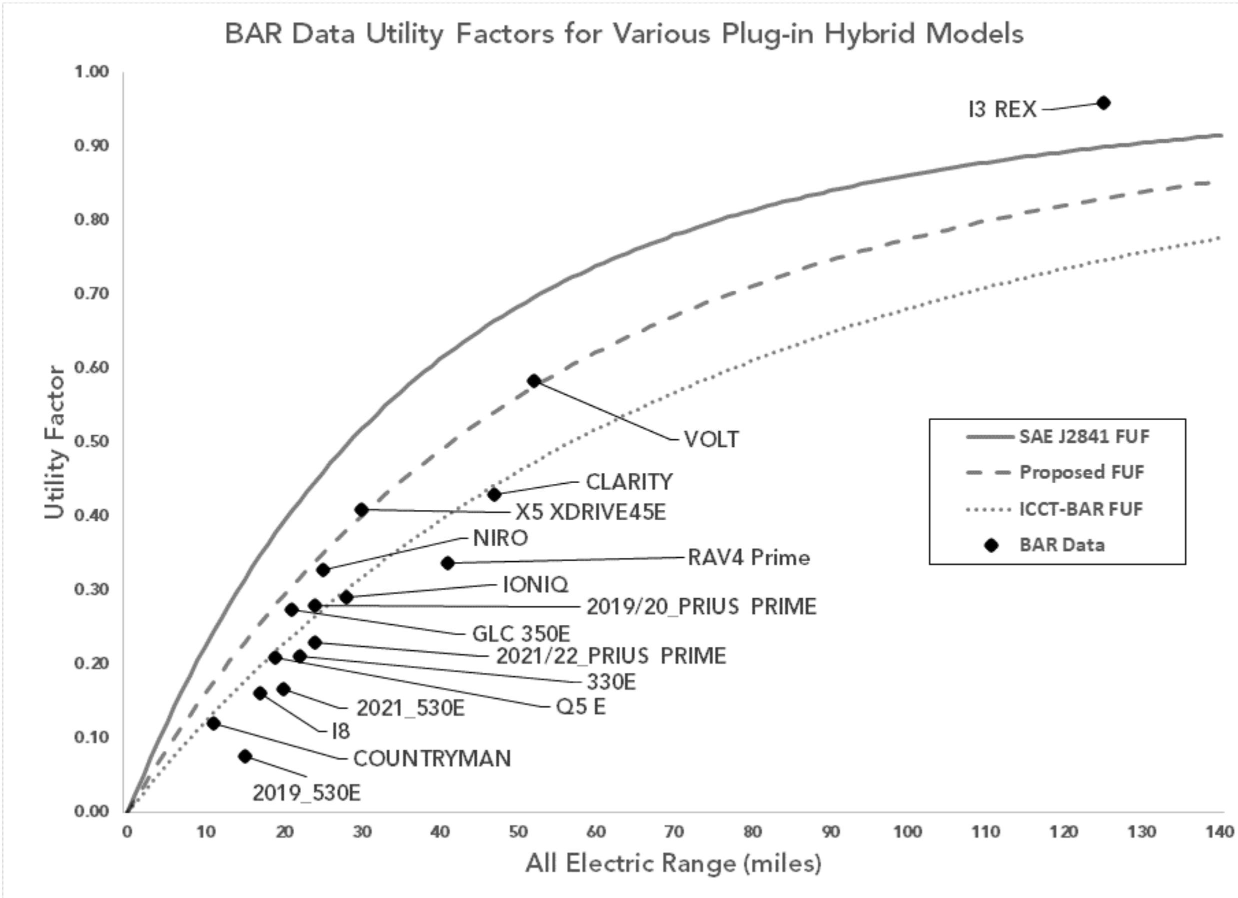
Analytical results

Figure 2 and Table 1 present CARB's results. As shown in Figure 2, most recent PHEV models fall below both the SAE J2841 22 curve and U.S. EPA's proposed FUF curve. Rather, the ICCT-BAR FUF curve that U.S. EPA's presents—but is not proposing to use—appears to be better correlated with actual real-world electric operation in these cases, and CARB's analysis reaffirms ICCT's original analysis. The notable exceptions are two vehicle models with unique architectures and higher all-electric ranges: the 2019 Chevrolet Volt (53-mile label range) and the 2019 BMW i3 REX (126-mile label range). 23 The 2019 Volt performed nearly identically to the U.S. EPA proposed FUF curve, and the i3 REX delivered more zero-emission miles than would be assigned under the SAE J2841 FUF. Notably, both of these models have been discontinued and used designs like a range-extender concept where the battery had to be depleted before the gasoline engine could be utilized. More recent models with similar all-electric capabilities like the Toyota RAV4 Prime and the Honda Clarity PHEV both averaged at or below even the lower ICCT-BAR FUF curve. [EPA-HQ-OAR-2022-0829-0780, pp. 20-22]

22 SAE J2841 is an SAE Information Report that establishes a set of "Utility Factor" curves and the method for generating these curves.

23 Data from prior MYs of these two vehicle models are not available as the necessary data parameters were not required until 2019 MY.

[See original for graph titled "Figure 2. Plug in Hybrid Electric Vehicle Utility Factors from Bureau of Automotive Repair Data."] [EPA-HQ-OAR-2022-0829-0780, pp. 20-22]



[See original attachment for "Table 1. Plug-in Hybrid Electric Vehicles Included in CARB's Analysis of Bureau of Automotive Repair (BAR) Data."] [EPA-HQ-OAR-2022-0829-0780, pp. 20-22]

Data collection and reporting

Given the variability in PHEV usage displayed to date, CARB recommends that U.S. EPA require auto manufacturers to collect and report in-use operational data at discrete intervals on PHEVs in future MYs. This would enable U.S. EPA to more accurately assess the GHG emissions associated with different PHEVs. Based on these data, EPA may then be better positioned to reassess the FUF curve for subsequent rulemakings. [EPA-HQ-OAR-2022-0829-0780, p. 22]

There are many factors that may alter the utility factor in the future that warrant ongoing data collection. For example, driver propensity to charge may change with time as the ZEV ecosystem evolves and drivers gain more access to home charging or other charging infrastructure, face varying differentials in cost for charging compared to gasoline refueling, or experience some battery degradation. Additionally, the types of PHEVs offered may also change in response to regulatory programs like ACC II or incentive funding. Finally, the everchanging dynamics of consumer awareness and market acceptance may influence the types of consumers who purchase PHEVs and how frequently they charge. [EPA-HQ-OAR-2022-0829-0780, p. 22]

Organization: Consumer Reports (CR)

6.4. Plug-in Hybrid Utility Factor Changes

CR generally supports EPA's proposed changes to the utility factor for plug-in hybrid electric vehicles (PHEVs). Real-world emissions from PHEVs are often significantly higher than the theoretical values estimated assuming optimum use conditions.46 CR agrees with EPA adjusting their approach to better match real-world use data. CR does not take a position on which of the proposed utility factor curves is the best option. However, CR does recommend that EPA periodically update their analysis of real world PHEV usage as more vehicles are sold, and more data becomes available. [EPA-HQ-OAR-2022-0829-0728, p. 23]

46 Real World Usage of Plug-In Hybrid Vehicles in the United States, The International Council on Clean Transportation, December 20, 2022, https://theicct.org/publication/real-world-phev-us-dec22/.

Organization: Electric Drive Transportation Association (EDTA)

We would also urge the agency to revisit modeling assumptions regarding the proposed plug-in hybrid (PHEV) utility curve to reflect next-generation PHEVs, whose electric range will be significantly larger than those modelled. New PHEVs' driving range increased 8.5% in 2021 and that trend is expected to continue. The increase in all-electric operation capability will change consumer use patterns over the regulated period and the rule for 2027-2032 should reflect that in an updated utility factor. [EPA-HQ-OAR-2022-0829-0589, p. 2]

Organization: Environmental. and Public Health Organizations

XII. EPA Should Improve Its Proposed Adjustment to the PHEV Fleet Utility Factor to More Accurately Capture the True Emissions from PHEVs. [EPA-HQ-OAR-2022-0829-0759, p. 93]

Below, we offer comment on EPA's proposed adjustment to the PHEV Fleet Utility Factor (FUF). EPA is correct to adjust the FUF to reflect real-world driving and recharging behavior, but the modification proposed is not sufficient to reflect the true emissions from PHEVs. Prior to the availability of PHEV models (and therefore in the absence of data on their actual usage), it was rational to use the Fleet Utility Factor as formulated in SAE 2841 in 2010 as the basis for estimating the percentage of operation without internal combustion engine use occurring in charge-depleting (CD) mode. However, there is now a significant body of real-world data that can be used to develop utility factors that more accurately reflect the actual tailpipe CO2 emissions from PHEV operation.227 Because EPA proposes to retain a zero gram per mile value for operation in CD mode, the choice of utility factor will play an important role in determining the compliance value for PHEVs. [EPA-HQ-OAR-2022-0829-0759, pp. 93-94]

227 Aaron Isenstadt et al., ICCT, Real World Usage of Plug-in Hybrid Vehicles in the United States (Dec. 2022), https://theicct.org/wp-content/uploads/2022/12/real-world-phev-us-dec22.pdf.

EPA has obtained California Bureau of Automotive Repair (BAR) data from onboard diagnostics devices (OBD) that show the real-world utilization of PHEVs in CD mode. The data show that all PHEV models in the dataset have actual utility factors lower than the current (SAE 2841) FUF. In some cases, the BAR data show real-world utility factors that are nearly 50% lower than the current FUF values. For example, the BAR data show the Honda Clarity PHEV as having a real-world utility factor of 0.359 while the SAE 2841 method gives the Clarity a FUF of 0.676.228 These results show that the SAE2841 method using travel survey data is a poor estimator of actual vehicle usage. The Agency proposes to reduce the FUF for compliance calculations by averaging the current FUF with a curve derived from the BAR real-world data. This averaging will lower the gap between actual emissions performance and the compliance value, but will still allow for compliance values for PHEVs that are higher than justified. Given that EPA now has clear real-world data showing that the current FUF is not reflective of actual emissions from PHEVs, it is inappropriate to use the original SAE J2841 FUF or to use it in an average with other data. EPA should instead use a FUF consistent with the actual in-use data from BAR and adopt the FUF labeled "ICCT-BAR" in the DRIA. [EPA-HQ-OAR-2022-0829-0759, p. 94]

228 The data is from EPA-HQ-OAR-2022-0829-0465_attachment_2.xlsx, and was processed using the method described in EPA-HQ-OAR-2022-0829-0465_attachment_1.pdf.

The decision to average real-world usage data with the SAE 2841 estimate is poorly justified. EPA states that "an overly low FUF curve could disincentivize manufacturers to apply this technology." 88 Fed. Reg. at 29254. However, both the current FUF curve and the proposed curve over-credit PHEVs. A curve that correctly credits PHEVs' reductions in emissions (such as the ICCT-BAR curve) will not disincentivize adoption of PHEVs, but instead will provide a lower incentive for the partial elimination of tailpipe emissions and a greater incentive for complete elimination via fully-electric powertrain options. Even with a lower FUF, the ability to reduce the compliance emissions values by use of zero grams per mile for the CD mode phase will provide a significant incentive for a manufacturer to choose a PHEV powertrain over a non-plug-in hybrid. Choice of a lower FUF curve will at the same time ensure that there is a sufficient incentive to encourage the continued development and deployment of zero-emission technologies. [EPA-HQ-OAR-2022-0829-0759, p. 94]

EPA also cites future models with longer electric range and greater all-electric performance as leading to future real-world performance that meets the proposed FUF curve. This is not supported by the available data. The longest electric range PHEV currently available is the Toyota RAV4 Prime. The RAV4 Prime data from the BAR dataset show a real-world utility factor of 0.35, significantly lower than the proposed FUF for a 42-mile all-electric range (AER) vehicle (0.52) and even lower than the ICCT-BAR curve (0.41). EPA states that "increased consumer technology familiarity" will also make future PHEV usage approach the proposed FUF curve. 88 Fed. Reg. at 29254. Increased consumer knowledge may make purchasers able to shift more driving to electric-only mode. However, it is also possible that purchasers (especially in the secondary market) may buy a PHEV without the ability to plug in or may choose a PHEV because of incentives that make the purchase more attractive relative to a non-plug-in vehicle. Existing research on the use of PHEVs shows that the largest factor leading to lower real-world observed utility factors is lack of charging, with 20-30% of some PHEV models starting their travel day on a nearly empty battery.229 [EPA-HQ-OAR-2022-0829-0759, pp. 94-95]

229 Seshadri Srinivasa Raghavan & Gil Tal, Plug-in hybrid electric vehicle observed utility factor: Why the observed electrification performance differ from expectations, 15 Int'l J. of Sustainable Transp. 105, 122 (2022), https://www.sciencedirect.com/org/science/article/pii/S1556831822004269.

The proposed FUF could lead to PHEVs with a large difference between real-world emissions and the compliance values for CO_2 emissions. The use of PHEV powertrains in larger vehicles such as SUVs and pickups will cause this gap to grow, due to the gap between the zero grams per mile CD operation and the high gram per mile operation when the internal combustion engine is running. Over-crediting PHEVs' purported electric driving would create a new and unjustified loophole that would likely slow down the path to greater deployment of zero-emission technologies within the fleet. For example, for a PHEV that has compliance CO_2 charge sustaining (CS) mode emissions of 250 g/mile and an electric range of greater than 28 miles, the proposed FUF would artificially reduce the combined mode PHEV emissions by over 25 g/mile when compared to the ICCT-BAR FUF. (Figure XII.1). The gap between the proposed FUF and the real-world data (ICCT-BAR) is highest for vehicles with a CD range between 42 and 62 miles. California's ZEV regulations for model year 2029 and subsequent vehicles require a minimum certification electric range of 70 miles to be eligible for credit values, which is approximately a 50-mile label range. Therefore, PHEVs designed to meet the minimum range for ZEV credit value eligibility are likely to have the largest deviations between real-world emissions and the compliance emissions calculated using the proposed FUF. [EPA-HQ-OAR-2022-0829-0759, p. 95]

Figure XII.1. Difference in Compliance CO_2 Between Proposed FUF and ICCT-BAR FUF for 250 g/mi CS Mode Vehicle [EPA-HQ-OAR-2022-0829-0759, p. 96]

[See original attachment for graph Figure XII.1.]. [EPA-HQ-OAR-2022-0829-0759, p. 96]

Organization: Environmental Defense Fund (EDF) (1of 2)

Using EPA's proposed formula for calculating a vehicle model's utility factor (UF)—the split of a PHEV's driving between gasoline and electricity—the UF for a PHEV50 is about 0.67. This means that 67% of a PHEV50's mileage is performed using electricity and 33% of its mileage uses gasoline. In terms of CO_2 emissions, a PHEV50 can be considered equivalent to two-thirds of a BEV and one-third of a strong hybrid ICEV. EDF further assumed that the GHG performance of a PHEV50 while operating on gasoline would be 205 g/mi, the same level as described in the ICEV control-focused run above.32 [EPA-HQ-OAR-2022-0829-0786, pp. 13-15]

32 Since PHEVs are required to meet the same criteria pollutant emission standards as ICEVs when operating on gasoline, substituting PHEVs for BEVs at equivalent fleetwide GHG levels has no impact on criteria pollutant emissions.

PHEVs cost more than BEVs due to requiring both electric and gasoline powertrains. Because the OMEGA 2 output did not project costs for complete PHEVs, we used the incremental cost difference between Roush's BEV and PHEV50 costs and applied that difference to EPA's BEV costs to derive projected PHEV costs.33 On a sales-weighted basis, considering the difference in electrification costs across vehicle segments and the types of vehicles that OMEGA2 is projecting to become electrified, we found that the average incremental PHEV50 cost, absent IRA vehicle tax credits, was $6,700 in MY 2032 relative to a BEV.34 Following EPA's methodology for applying the IRA vehicle tax credits, we included the credit for the additional number of BEV plus PHEV sales in each pathway, as EPA had already accounted for the tax credits available for BEVs projected in their analysis. [EPA-HQ-OAR-2022-0829-0786, pp. 13-15]

33 Roush's BEV costs are lower than EPA's, so we took this approach in lieu of substituting Roush's costs for both BEVs and PHEV50s.

34 Based on interpolation between costs in MY 2027 and MY 2035.

C. The PHEV utility factor should be conservative, with manufacturers given a voluntary alternative to use a utility factor based on real world data.

We likewise support EPA's proposal to amend its current approach to PHEV utility factors based on improved data about real world PHEV usage.178 However, we encourage EPA to rely fully on this more accurate data, rather than continuing to consider the UFs developed in SAE J2841, which are based on dated and inaccurate assumptions.179 The data compiled by ICCT from real- world sources represents the best estimate of actual PHEV utilization and should be the primary source for EPA's UF curves. [EPA-HQ-OAR-2022-0829-0786, p. 64]

178 88 Fed. Reg. 29254.

179 88 Fed. Reg. 29253.

EPA's current approach to assigning fuel economy to PHEVs was first adopted in a 2011 rulemaking supporting the 2010 GHG standards.180 Under that rulemaking, PHEVs are given a fuel economy that combines a 0 g/mi emissions value with their measured GHG emissions from operation on liquid fuel.181 The utility factor for weighting the two values is based on a PHEV's charge-depleting range for city and highway driving.182 These utility factor numbers were developed in SAE J2841"using data from the 2001 Department of Transportation 'National Household Travel Survey.'"183 Because PHEVs were just beginning to be introduced at that time,184 the utility factors were not based on real-world PHEV use. Instead, they assume that "[t]he first mode of operation is always electric assist or all electric drive, vehicles will be charged once per day, and future PHEV drivers will follow drive patterns exhibited by the drivers in the surveys used [in calculating the utility factors]."185 EPA acknowledged in promulgating these utility factors that "current understanding of the above assumptions and the data upon which UFs were developed may change" and that "therefore, EPA may change the application of UFs in light of new data."186 However, these utility factors have not been amended since the 2011 rule. [EPA-HQ-OAR-2022-0829-0786, p. 64]

Meanwhile, California's treatment of PHEVs under the ACC II program is far more conservative, resulting in lower utility factors than EPA. ACC II allows PHEVs to "fulfill a portion of their total Annual ZEV Requirement" if they meet several qualifications.187 A PHEV must have a "minimum certification range value of greater than or equal to 70 miles," based on California's 2026 ZEV and PHEV test procedures,188 and have a minimum US06 all-electric range value greater than or equal to 40 miles to be considered a ZEV under the rules.189 PHEVs that don't meet these requirements can still be counted for partial credit if they have a minimum certification range value between 43 and 70 miles190 or have a US06 all-electric range of at least 10 miles.191 Additionally, PHEVs can only be used to meet 20 percent of a manufacturer's total ZEV requirement.192 [EPA-HQ-OAR-2022-0829-0786, pp. 64-65]

187 California Zero-Emission Vehicle Requirements for 2026 and Subsequent Model Year Passenger Cars and Light- Duty Trucks, 13 C.C.R. § 1962.4(c)(e)(1).

188 California Test Procedures for 2026 and Subsequent Model Year Zero-Emission Vehicles and Plug-In Hybrid Electric Vehicles, in the Passenger Car, Light-Duty Truck and Medium-Duty Vehicle Classes, incorporated by reference in 13 C.C.R. § 1962.4, available at https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/ACC II/ACC IIfro_zev_tp_2026%2B.pdf. Certification range value is defined as a "PHEV's calculated combined urban and highway all-electric range values," equal to ".55 x Urban-All Electric (or Driving for FCEV) Range Value + .45 x Highway All-Electric (or Driving for FCEV) Range Value." 13 C.C.R. §1962.4(l).

191 How much credit these PHEVS get is calculated based on an equation where the partial vehicle value is equal to Certification Range Value/100 + .20. Id. at § 1962.4(c)(e)(1)(B)(1).

192 Id. at § 1962.4(c)(e)(1)(B)(2)

It is imperative that EPA assign a utility factor for PHEVs that reflects real-world electric drive share. A recent ICCT study examined the current state of PHEV usage in the United States and found strong evidence that real-world electric drive share is far below EPA's current utility factor label rating.193 According to ICCT, "previous research and data from early adopters of PHEVs in the United States demonstrated that PHEVs achieved real-world electric drive share close to that expected by the U.S. Environmental Protection Agency (EPA) and National Highway Traffic Safety Administration (NHTSA)." ICCT notes that EPA assumes that PHEVs achieve real-world electric drive share close to EPA's utility factor label rating in its treatment of PHEVs in the 2023-2026 light-duty GHG rule. [EPA-HQ-OAR-2022-0829-0786, pp. 64-65]

193 Isenstadt, A., Zifei, Y., Searle, S., German, J. 2022. Real World Usage of Plug-In Hybrid Vehicles in the United States, ICCT. https://theicct.org/publication/real-world-phev-us-dec22/ (Attachment Y).

ICCT's analysis uses more recent data from two previously unexplored sources: self-reported fuel consumption from Fuelly.com and engine-off distance traveled collected by the California Bureau of Automotive Repair (BAR), which cover a broader variety of PHEV models and newer model years than prior datasets. ICCT concludes that real-world electric drive share may be 26-

56% lower than assumed and real-world fuel consumption may be 42-67% higher than assumed within EPA's labeling program for light-duty vehicles. [EPA-HQ-OAR-2022-0829-0786, pp. 65-66]

ICCT also looked at studies in Europe that echoed their findings. "Recent studies with user data from over 20,000 European PHEVs have shown that, in real-world usage conditions, the [electric drive share] of PHEVs falls far short of the [utility factor] curve assumed in the [Worldwide Harmonized Light Vehicles Test Procedure (WLTP)]. For PHEVs owned by private individuals, the real-world fuel consumption is on average three times higher than the official WLTP values, while for company car PHEVs the fuel consumption is on average five times higher. Moreover, despite an increasing electric range and more public charging infrastructure, the deviation between real-world and official fuel consumption of PHEVs in Europe is observed to be growing."194 [EPA-HQ-OAR-2022-0829-0786, pp. 65-66]

194 Id.

EPA acknowledges in the proposal that its current approach "significantly underestimates PHEV CO2 emissions"195 and that the real-world data collected by ICCT from BAR is, in contrast, "a reasonable source for evaluating the real-world utility factors for recent PHEV usage."196 However, instead of relying fully on this new data for developing its UF curve, EPA proposes to average the two datasets, giving each an equal weight.197 Because, as discussed above, the ICCT- BAR UFs are a significantly better representation of real-world PHEV usage than EPA's current approach, EDF suggests that the agency rely solely on this data in setting its new UF curve. In addition to aligning EPA's default UF with the best available real-world data, we encourage the agency to provide manufacturers with an option to submit rigorous, real-world data to demonstrate their UFs are higher than these default values. An approach along these lines could allow for retrospective adjustment based on annual driving information submitted along with a manufacturer's compliance demonstration. An approach along these lines—a rigorous default UF combined with the option to certify better performance—would help to better reflect the actual emissions performance of PHEVs and provide incentives for manufacturers to develop and deploy PHEVs that operate more regularly on electricity. [EPA-HQ-OAR-2022-0829-0786, pp. 65-66]

Organization: Ford Motor Company

Plug-In Hybrid Vehicle Utility Factor

Ford does not support the proposed update to the Plug-In Hybrid (PHEV) utility factor (UF). We do not believe it is appropriate to recalibrate the PHEV compliance benefit at the same time the EPA is proposing other sweeping changes and historically stringent standards. Product planning lead time and uncertainty in EV market growth requires that all electrification options be available with stable and predictable compliance benefits. Ford would support an EPA program designed to gather additional data for use in a future rulemaking which would yield a robust basis for a UF update and prevent disruption to EV product compliance plans. [EPA-HQ-OAR-2022-0829-0605, p. 8]

Organization: International Council on Clean Transportation (ICCT)

On PHEVs, ICCT applauds EPA for and its proposal to adjust the PHEV utility factor (UF) curve to better fit real-world PHEV usage data. [EPA-HQ-OAR-2022-0829-0569, p. 5]

PLUG-IN HYBRID ELECTRIC VEHICLES

Utility factor

ICCT applauds EPA for adjusting the PHEV utility factor (UF) curve to better fit real-world PHEV usage data. As the PHEV models available for purchase today differ in operation and all-electric utility from when the original UF curve was developed, this update is direly need (ICCT 2022 PHEV).149 Due to the growing repository of public, real-world PHEV data, ICCT recommends EPA adjust the proposed fleet utility factor (FUF) curve to reflect the best-available data, while allowing for potential updates to the curve based on more real-world data as it accumulates. [EPA-HQ-OAR-2022-0829-0569, pp. 58-60]

149 Isenstadt, A., Yang, Z., Searle, S., German, J. (2022). Real world usage of plug-in hybrid vehicles in the United States. International Council on Clean Transportation. https://theicct.org/publication/real-world-phev-us-dec22/ (ICCT 2022 PHEV)

In DRIA figure 3-29, EPA's analysis of the California Bureau of Automotive Repair (BAR) PHEV data clearly shows that a reduced UF curve is a better fit of the real-world data. This fit matches ICCT's non-linear regression fit of the BAR data. Utilizing the same methodology described in ICCT 2022 PHEV but with EPA's proposed FUF coefficients (Preamble 29442), ICCT finds the appropriate normalized distance to be 802 miles (vs proposed 583 miles). This curve more accurately reflects the current state of PHEV usage. Thus, ICCT recommends that EPA adopt a normalized distance of 802 miles, instead of 583 miles as proposed. [EPA-HQ-OAR-2022-0829-0569, pp. 58-60]

Within the timeframe of the proposed rule EPA expects PHEVs with longer all-electric range to become available (in part due to California's ACCII PHEV performance requirements), and EPA seeks to avoid disincentivizing PHEVs with a too low FUF curve (Preamble 29254). For these reasons, EPA proposed a FUF curve higher than what the BAR data supports. This argument puts the expectation of future PHEV performance ahead of the data. However, because there is no guarantee that future PHEV models will achieve the assumed higher electric driving shares, the best practice is to let the data dictate the shape of the UF curve. EPA can establish a provision by which it can adjust the UF curve to better account for PHEVs with varying all-electric range, as additional data is collected. To simultaneously ensure PHEVs are not given too-high UF without disincentivizing longer all-electric range PHEVs, EPA can allow manufacturers to provide publicly available, real-world data with accurate UF measurements that support higher FUF for specific PHEV models. Alternatively, EPA could automatically apply the higher FUF curve (e.g., the current proposed curve, as opposed to the ICCT-BAR curve) for vehicles that meet minimum all-electric performance requirements, such as 70 miles all-electric 2-cycle range and 40 miles all-electric US06 range. This latter option would incentivize greater all-electric capability among PHEVs. [EPA-HQ-OAR-2022-0829-0569, pp. 58-60]

Organization: Jaguar Land Rover NA, LLC (JLR)

JLR would like to highlight our concerns over EPA's plans to incorporate PHEVs into their analysis for the final rule. If EPA proceeds with the planned changes to the certified PHEV CO2 value, namely through the adjustment of the utility factor, they must acknowledge the impact this will have on fleet compliance, greatly reducing their contribution to the fleet. As such, the baseline GHG target and projected ZEV share should also be adjusted by an equal amount, to avoid an increase in target stringency by stealth. [EPA-HQ-OAR-2022-0829-0744, pp. 4-5]

We would like to comment on the statement made by EPA that "this is a projection and represents one out of many possible compliance pathways for the industry. The proposed standards are performance-based and do not mandate any specific technology for any manufacturer or any vehicle type." Due to the multitude of changes including those to PHEVs and reduction in credit flexibilities, there is very little choice with regards to technologies that will meet the incredibly challenging standards set. [REDACTED]CBI [EPA-HQ-OAR-2022-0829-0744, pp. 4-5]

In addition, the goals set out in the E.O. 14037 and Blueprint refer to vehicles sales in 2030 Calendar Year (CY), whereas the ambitious target set by EPA refers to the 2030MY fleet, which will contain a combination of vehicles sold in 2029 and 2030CY, effectively bringing the target forward by six months. [EPA-HQ-OAR-2022-0829-0744, pp. 4-5]

Organization: Kia Corporation

- Kia supports EPA assuming PHEVs will see higher levels of electric operation and continue to see high penetration rates. Kia opposes EPA's assumptions for PHEVs including revising the Fleet Utility Factor (FUF) curve to reflect a PHEVs lower electric operation. [EPA-HQ-OAR-2022-0829-0555, p. 3]

Plug-in Hybrid Electric Vehicles Play Critical Role in the Transition

Kia does not support the assumptions on PHEVs outlined in the NPRM. EPA explains that its current PHEV compliance methodology significantly underestimates PHEV CO2 emissions. Consequently, EPA proposes to revise the light vehicle PHEV Fleet Utility Factor (FUF) curve downward to reflect as assumed PHEVs lower electric operation beginning in MY2027.13 EPA's proposal essentially lowers the benefits of PHEVs for compliance which will reduce consumer choice and make feasibility of the standards much more challenging. [EPA-HQ-OAR-2022-0829-0555, pp. 7-8]

13 88 Fed. Reg. 29,252.

EPA's analysis is limited to multiple publications from the International Council on Clean Transportation (ICCT). The EPA's use of the ICCT-BAR curve is inappropriate given the expansion of Level 2 charging occurring as EVs increase across the country. The ICCT publications focus on the limited electric driving share of PHEVs in Europe. ICCT's assumptions are skewed as they assume the same situation in Europe where there were unique PHEV tax incentives, coupled with limited charging infrastructure available in multifamily dwellings. All of which are not good comparisons to the United States. If EPA feels strongly that the real-world fleet utility factor is too low, Kia recommends that EPA work with industry to help incentivize reminders for consumers to plug in more often. [EPA-HQ-OAR-2022-0829-0555, pp. 7-8]

PHEVs play an integral role in facilitating the transition to higher vehicle electrification. Kia strongly supports EPA assuming PHEVs will continue to see high penetration rates and higher levels of electric drive. PHEVs will lower emissions, promote consumer acceptance of electrified powertrains, and reduce tension in the supply chain, workforce, and needed U.S. charging infrastructure. PHEVs are expected to represent at least 20 percent of ZEV sales for the next five years.14 Consequently, Kia continues to strongly support multiple ZEV technological pathways to meet the targets. [EPA-HQ-OAR-2022-0829-0555, pp. 7-8]

14 CARB ACC II Workshop, slide 38 (May 6, 2021).

Organization: MECA Clean Mobility

EPA should conduct a prospective analysis of appropriate PHEV utility factors based on more recent PHEV models with longer all electric range likely to result in a shift to greater electric operation. [EPA-HQ-OAR-2022-0829-0564, p. 29]

PHEVs will continue to be an important compliance strategy which can integrate and optimize the best of combustion and electric technologies to increase vehicle efficiency and facilitate the transition to fully zero tailpipe emissions vehicles. This will be particularly important as the charging infrastructure and supply chains develop that are necessary for battery electric vehicle adoption at the rates projected in the proposal. PHEVs also serve as a bridge technology that can provide consumers confidence in electric vehicle technology while alleviating range anxiety for those who drive long distances. [EPA-HQ-OAR-2022-0829-0564, p. 29]

Similar to previous EPA technology analyses prepared to support future rulemakings, MECA requests that EPA conduct a prospective analysis of utility factors of PHEVs based on the direction of the technologies being released into the market place today as well as announcements of future releases. Of particular note, EPA relied upon past data of older technology PHEVs with limited all electric ranges to justify the proposed reduction in the PHEV utility factors from today's acceptable values that are based on SAE J2841.38 [EPA-HQ-OAR-2022-0829-0564, p. 29]

38 https://www.sae.org/standards/content/j2841_201009/

While EPA is not proposing to adopt the minimum range requirements for PHEVs that are included in CARB ACC II, MECA believes that these requirements along with the market will drive PHEVs with longer all electric ranges. In fact, VW recently announced a PHEV Tiguan SUV available for MY 2025 with an all-electric range of 62 miles.39 This in combination with build out of charging infrastructure, especially from Inflation Reduction Act and Infrastructure Investment and Jobs Act funding sources, will provide consumers with easier access to charge PHEVs and enable them to drive more miles on electricity rather than petroleum. The result will be that future fleet utility factors will increase rather than decrease. MECA suggests that EPA consider these developments, including studying the correlation between fleet utility factor and workplace charger availability, and not base utility factors on older PHEV technology. Finally, MECA suggests that EPA allow PHEVs certifying with all electric range greater than 50 miles to claim higher fleet utility factors, and consider scaling utility factor with a vehicle's all electric range. [EPA-HQ-OAR-2022-0829-0564, p. 29]

Organization: MEMA, The Vehicle Suppliers Associated

Plug-in Hybrid Electric Vehicle (PHEV) Utility Factor

The data relied upon to establish the proposed reduction in utility factor for PHEV is flawed for a number of reasons and we urge EPA to conduct its own, current and future, real-world U.S. measurement of PHEV usage prior to implementing a revised utility factor. Such an analysis will find greater utility in PHEV usage than is suggested by the data used in the current proposal. [EPA-HQ-OAR-2022-0829-0644, pp. 7-9]

The current data is inappropriate because it is primarily non-domestic, selective and ignores the significant changes already underway in infrastructure and vehicle design that enable greater PHEV utility. [EPA-HQ-OAR-2022-0829-0644, pp. 7-9]

Much of the current data leverages European Union (EU) use patterns in PHEV owners, which has several flaws. First, as the ICCT notes,5 there was a significant deviation between the utility factor for personally owned vs. company owned vehicles. Logic would suggest this makes sense - if drivers do not own their vehicles themselves, they are likely to be less-inclined to maximize their electric utility. That argument is compounded by the fact that many companies in Europe also provide gas cards to employees to support their transportation needs but provide no similar subsidization of charging needs. From this one may infer that EU employees used their "free" gas rather than pay for electricity, which would cause distortive bias in the data. [EPA-HQ-OAR-2022-0829-0644, pp. 7-9]

5 https://theicct.org/publication/real-world-phev-use-jun22/

The ICCT study additionally relied on prominently for EPA's U.S. utility factor analysis used data collected in California, where incentives for PHEV purchasing are more generous than in the rest of the country and may even make the purchase of a PHEV less costly than a traditional ICE vehicle. While California is an admirable leader in ZEV deployment, its incentive structure for PHEV purchases differs from the rest of the country; a large percentage of population resides in multi-unit dwellings (often without consistent overnight charging access), and it ranked (as of last year) behind at least 15 other U.S. states in terms of charging ports per EV, signifying a potential problem of constrained charging access that needs further examination.6 The ICCT itself stated that, "More data collection could provide greater precision and clarity regarding the deviation of real-world electric drive share and what is assumed in EPA labeling." There is no indication that this additional data collection has since occurred. [EPA-HQ-OAR-2022-0829-0644, pp. 7-9]

6 https://www.govtech.com/biz/data/which-states-have-the-most-chargers-per-electric-vehicle

Another distinction worth noting is that the PHEVs and charging infrastructure of the past five years (primarily in Europe, in the case of the data relied upon) have little resemblance to the vehicles and charging capacity projected by EPA in its forecast for the U.S. For example, CARB's ACC Il regulation compels PHEVS to have an electric range of at least 50 miles to meet its ZEV criteria for real-world conditions and 70 miles for minimum certification range.7 This will enable many drivers to complete all daily driving tasks on a single charge,8 and will likely promote greater utility in PHEVs. Furthermore, the need for a more comprehensive nationwide EV charging infrastructure has been recognized by Congress and the Administration several times in recent years, whether through billions of dollars in new EV charging infrastructure direct investment and billions more for incentives to support private and public charging. Those investments will enable greater accessibility for PHEV drivers to charging stations, but it has yet to be realized at this point in time or reflected in the studies on which EPA relies to propose this amended utility factor. [EPA-HQ-OAR-2022-0829-0644, pp. 7-9]

7 https://ww2.arb.ca.gov/news/california-moves-accelerate-100-new-zero-emission-vehicle-sales-2035 and Clause § 1962.4(e)(1)(a) in Title 13 CCR https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/accii/2acciifro1962.4.pdf

8 US Average miles traveled per year. 13,476; per day: 36.92 - https://www.caranddriver.com/auto-loans/a32880477/average-mileage-per-year/

If further study indicates that a change in PHEV utility factor is warranted, it must be substantiated by real-world and forward-looking data collected by EPA under reliable and repeatable test conditions. Absent that needed analysis, we strongly urge EPA to reconsider its amendment to utility factor calculations. [EPA-HQ-OAR-2022-0829-0644, pp. 7-9]

MEMA urges:

• EPA to maintain previous PHEV utility factor or conduct U.S.-based study and forecast to replace current PHEV utilization data and recalculate PHEV utility factor. [EPA-HQ-OAR-2022-0829-0644, pp. 7-9]

Organization: Mitsubishi Motors North America, Inc. (MMNA)

Mitsubishi participated in the development of - and supports - the comments submitted by Auto Innovators. [EPA-HQ-OAR-2022-0829-0682, p. 2]

In addition, based on its considerable experience discussed previously with BEV and PHEV leadership, Mitsubishi provides the following recommendations to supplement the comments of Auto Innovators: [EPA-HQ-OAR-2022-0829-0682, p. 2]

1. Closely align the multi-pollutant emissions standards with President Biden’s 2030 goal by assuming no more than 40-50% PHEVs and FCEVs by 2030, even though our experience leads us to caution that this itself is very ambitious, and is predicated on the assumption that the necessary supportive policies will be effectively implemented. [EPA-HQ-OAR-2022-0829-0682, p. 2]

2. Consider the many benefits of PHEVs to consumers and the environment during the expected period of constrained battery critical minerals production capacity, and how PHEVs are the perfect stepping- stone to full BEV acceptance. [EPA-HQ-OAR-2022-0829-0682, p. 2]

3. Maintain the current PHEV Utility Factor (UF) and work with industry to identify opportunities to increase PHEV electric operation. This is the ideal stepping-stone technology to encourage long-term BEV acceptance and utilization. [EPA-HQ-OAR-2022-0829-0682, p. 2]

4. Keep the proposed approach to determine the passenger car curves, and consider adjusting the cutpoint and stringency levels of the light-duty trucks during the early years of the program. [EPA-HQ-OAR-2022-0829-0682, p. 2]

5. Maintain the existing GHG program flexibilities, such as Air Conditioning and Off-Cycle technologies credits (including the alternative method to apply off-cycle credits), and

allow previously approved technologies to continue receiving credits. [EPA-HQ-OAR-2022-0829-0682, p. 2]

6. Align the Tier-4 (criteria pollutants) with CARB's LEV-IV criteria test procedures and standards. [EPA-HQ-OAR-2022-0829-0682, p. 2]

7. Consider the impact that very aggressive GHG standards will have on vehicle affordability, and especially the detrimental impact to low-to-moderate income families. Regardless of the vehicles that regulation may require us to produce, it is critical that regulators always keep the accessibility of consumers in mind.

The rationale for each one of these recommendations is further explained below. [EPA-HQ-OAR-2022-0829-0682, p. 2]

Equally as importantly, we also ask EPA to consider our recommendations regarding the PHEV NMOG+NOx Contribution Factor and the PHEV Utility Factor (UF) as discussed in other sections of our comments. [EPA-HQ-OAR-2022-0829-0682, pp. 3-4]

3. PHEV Utility Factor

Mitsubishi shares the views expressed by Auto Innovators regarding application of the PHEV Utility Factor (UF). In addition to Auto Innovators' comments, we also provide the following observations in support of retaining the existing UF. [EPA-HQ-OAR-2022-0829-0682, pp. 4-5]

A. PHEV Data Sources

In developing the proposed utility factor (UF), EPA relies primarily on the work conducted by the International Council on Clear Transportation (ICCT) and comparisons to its own analysis with PHEV data from the California Bureau of Automotive Repair (BAR). The BAR data is based on vehicle information retrieved from the vehicle On-board Diagnostic (OBD) system and includes total distance traveled and distance traveled during charge-depleting mode. Upon comparison of its results with ICCT's, EPA averaged the current SAE J2841 UF curve with the curve generated by ICCT based on the BAR data to generate the proposed UF equation. [EPA-HQ-OAR-2022-0829-0682, pp. 4-5]

The BAR data is a collection of PHEV data from MY19 through MY22 vehicles. The data was then filtered to remove any vehicles that show inconsistent data regarding distance traveled and grid energy utilization. While filtering of incomplete or inconsistent data is a typical operation in data analysis, the results of the analysis can be substantially altered based on the filters applied. We believe the filtering methods used by EPA filtered out too many vehicles. For example, the grid energy in/out filter completely removes one of the highest utility factor vehicle models4 from the entire data set. Whether such filtering was necessary for that vehicle is questionable. At the same time, it may be necessary to apply alternative filters. Due to the time constraints of this comment period, Mitsubishi was unable to fully evaluate the filtering methods EPA used in its analysis, but we may still provide feedback to EPA after the comment period. We ask EPA to provide additional information about the filters applied, and the effect those filters have on the overall utility factor analysis. [EPA-HQ-OAR-2022-0829-0682, pp. 4-5]

4 The BMW i3

B. Current PHEV Performance and Future PHEV Requirements

Mitsubishi appreciates the work conducted by EPA and ICCT to analyze recent PHEV performance to reevaluate the electric operation of plug-in electric hybrid vehicles. The data can be a powerful tool in understanding the habits of consumers and the levers needed for both current and future consumers to fully utilize the electric capability of PHEVs. However, with regard to applying the data to utility factor estimates, the BAR data does not represent PHEVs within the timeframe of the proposed rule as EV utility is likely to increase compared to today's PHEVs due to improved EV performance and increased availability of EV charging infrastructure. [EPA-HQ-OAR-2022-0829-0682, pp. 4-5]

PHEVs come in many forms due to the flexibility they offer in terms of internal combustion engine (ICE) and EV operation. The amount of EV range, charge time, and ICE operation during charge-depleting mode are just a few of the specifications that can vary between PHEV models. It is important to ensure the utility factor applied to MY27 and later vehicles is reflective of the specifications and performance for vehicles of that time period. In addition, the utilization of PHEV electric mode is dependent on the charging and driving behaviors of the vehicle owner. As with the vehicle, owner behavior today may be different than PHEV owners in the MY27 and later time frame. [EPA-HQ-OAR-2022-0829-0682, pp. 4-5]

California's MY26 and later Advanced Clean Car II (ACC II) regulation developed PHEV technical requirements "that functionally emphasize the ZEV capabilities of these vehicles." CARB estimates the minimum all-electric range required under ACC II will meet the daily needs of 74 to 84 percent of new car and truck buyers in California5. It is likely that most, if not all, MY27 and later PHEVs will be more ZEV- capable than the vehicles provided in the BAR data. Among requirements CARB included in the ACC II regulation are: [EPA-HQ-OAR-2022-0829-0682, pp. 4-5]

- Starting with MY26: Phase in of PHEVs capable of operating in all-electric mode at further distances, and under most driving conditions [EPA-HQ-OAR-2022-0829-0682, pp. 4-5]

- MY29 and later: All PHEVs must meet extended range (70-mile 2-cycle and 40-mile US06 EV range) and charging requirements to be eligible ZEVs under the ACC II regulation [EPA-HQ-OAR-2022-0829-0682, pp. 4-5]

- Enhanced battery durability requirements to ensure PHEV capabilities for the first owner as well as subsequent owners. [EPA-HQ-OAR-2022-0829-0682, pp. 4-5]

In addition to CARB's intention to increase ZEV capability through PHEV technical requirements, the approach vehicle owners take to PHEV operation may change. Consumer education and increased available of charging infrastructure will make it easier for PHEV owners to charge vehicles when convenient, and thus more likely that they will do so on a more regular basis. [EPA-HQ-OAR-2022-0829-0682, pp. 4-5]

C. Potential Effect of UF and PEF on CAFE Standard

The development of the proposed utility factor by EPA considers the impact of changes within the context of the light-duty GHG standard. However, the utility factor is also used in developing fuel economy compliance values for the NHTSA CAFE standard. There is little mention of the utility factor's influence on CAFE compliance, despite the direct effect it has on PHEV CAFE compliance values. Unlike the GHG standard, which correctly treats electric operation as zero emissions, the CAFE regulation assigns PHEVs and BEVs a petroleum-equivalent fuel economy. The disconnect between the GHG and CAFE programs results in different weighting of compliance benefits for PHEVs and BEVs relative to conventional ICE vehicles. [EPA-HQ-OAR-2022-0829-0682, pp. 5-6]

Expanding on this issue, the Department of Energy (DOE) is proposing changes to the Petroleum Equivalency Factor (PEF) starting with MY27. The PEF is used to estimate the mile per gallon equivalent (MPGe) of BEV and PHEV electric mode operation. The DOE is proposing a 72% reduction of the PEF resulting in a significant reduction of the BEV and PHEV CAFE compliance value. [EPA-HQ-OAR-2022-0829-0682, pp. 5-6]

The combined effect of the changes to the UF and PEF on the CAFE standard are difficult to assess considering the proposed CAFE standard for MY27 through MY32 has not been published. For now, we can only assume that the structure of the current CAFE standard will remain unchanged. Based on this assumption, the combined effect of the UF and PEF will result in certain PHEVs having less compliance benefit than comparable Strong Hybrid-Electric Vehicles (SHEVs). Figure 1 is an example of the effects the proposed UF and PEF would have on the CAFE compliance of small SUV PHEVs relative to comparable SHEVs. In Figure 1 (left), the current Utility Factor and PEF means most PHEVs correctly have fuel economy greater than all comparable SHEVs. For Figure 1 (center), the proposed PEF with current UF results in a CAFE compliance value reduction of all PHEVs, in addition, several PHEVs would have a CAFE compliance value less than many SHEVs. For Figure 1 (right), the proposed changes to the UF are added resulting in further reductions in PHEVs compliance values and additional reductions in performance relative to SHEVs. Despite the real-world petroleum reduction advantage of PHEVs, the reduced UF and PEF will result lower CAFE compliance values for several PHEVs relative to comparable SHEVs. [EPA-HQ-OAR-2022-0829-0682, pp. 5-6]

[See original for graph titled “Figure 1. Comparison of PHEV and SHEV CAFE Compliance Value with Current and Proposed PEF and UF”] [EPA-HQ-OAR-2022-0829-0682, pp. 5-6]

D. PHEV Utility Factor Recommendations

For the reasons described above, Mitsubishi believes the PHEV data EPA used to derive its proposed UF is outdated and not representative of the ACC II compliant PHEVs that will be in the market for the timeframe covered by this rulemaking. Therefore, Mitsubishi recommends EPA maintain the utility factor as it is currently, and continue to collect PHEV data to develop programs that encourage customers to maximize the EV operation of PHEVs. In addition, Mitsubishi recommends EPA coordinate with DOE and NHTSA to ensure the combined effects of the proposed UF, PEF and structure of the NHTSA CAFE standard ensure CAFE compliance reflects the real-world petroleum reduction benefit of PHEVs. [EPA-HQ-OAR-2022-0829-0682, pp. 5-6]

Organization: National Association of Clean Air Agencies (NACAA)

With respect to other issues, NACAA believes plug-in hybrid electric vehicles (PHEVs) have an important role to play in the LMDV GHG program provided their contribution toward the fleet average GHG requirements is limited strictly to the distance over which they operate fully on electricity. We concur with EPA’s conclusion that the current LDV PHEV compliance methodology overstates the operation of PHEVs on electricity thereby significantly underestimating PHEV CO2 gm/mi compliance results. Therefore, NACAA commends EPA for proposing to reduce the PHEV Fleet Utility Factor (FUF) curve used in the CO2 compliance calculation for PHEVs beginning in MY 2027 but recommends that the FUF curve be even lower than proposed. We also recommend that EPA require data collection and reporting or accessibility to better inform the methodology in the future. [EPA-HQ-OAR-2022-0829-0559, p. 8]

Organization: Porsche Cars North America (PCNA)

4. Porsche does not support the proposed reduction in the PHEV utility factor.

EPA's proposed reduction in the utility factor for PHEVs will reduce the weighting for electric operation which will negatively impact the GHG compliance value for PHEVs. This is an unfortunate proposal to undercut an incentive to deploy electrified vehicles especially in the context of the MPR that is premised on a fleet that in less than 10 years must have 2 out of every 3 new cars sold be electrified. Porsche recognizes that PHEVs may play a minority role in the overall composition of future electrified vehicles sales, but nevertheless continues to see an important market role for PHEVs. PHEVs expand the range of electrification choice for consumers, choice that provides access to the benefits of electrification in cases where a consumer may be unable or unwilling to adopt fully electrified vehicles. For a regulation as aggressive as this proposal, a regulation that seeks to transform the US light-duty market towards electrification, adopting this change would simply be counter to that effort. Worse yet, it's a change whose entire premise is based on looking backward on PHEV recharging, and not leveraging the anticipated future charging environment included within the assumptions of the MPR. A future that EPA projects will greatly expand the availability, reliability, and usage of electric vehicle charging. [EPA-HQ-OAR-2022-0829-0637, pp. 21-23]

EPA's proposal devalues future PHEV performance based on historic charging behavior of existing on-road PHEV drivers. Porsche has not reviewed the details of the California BAR or fuelly.com data but can understand if in some cases consumer use of electric drive has been lower than expected. This is not surprising given the well-documented challenges and complaints related to the general lack of public charging infrastructure in the past few years. Besides challenges within finding reliable public charging, many consumers have faced difficulties in installing home charging, especially for multifamily and rental dwellers, and have complained about the general lack of workplace charging. However, the entire foundation of this MPR and the dramatic shift towards electrification rests upon assumptions regarding improvements in electric vehicles and more specifically in the availability and reliability of public and private electric vehicle charging. Issues that past owners of PHEVs may have experienced that likely led to the examples of lower-than-expected usage of electric drive would be addressed according to EPA's assumptions on improved charging. As such, the decision to alter the utility factor for future PHEVs should not focus on decreasing the utility factor due to challenges customers experienced in the past, but rather should maintain the existing utility factor based on improved usage of charging in 2027 and later given EPA's projections for rapidly expanding charging infrastructure. [EPA-HQ-OAR-2022-0829-0637, pp. 21-23]

It is nonsensical that future PHEV drivers would continue to pass up on charging opportunities once charging is more ubiquitous in the public, at home and at work. In fact, this would be counter to EPA's assumed consumer valuation of fuel savings that has been consistently referred to in GHG rulemakings. If consumers value fuel savings, and if charging availability is no longer a barrier to usage, EPA would have to assume that PHEV drivers would naturally seek to maximize their usage of electric drive if the cost per mile to drive electric is less than that of gasoline. If for some reason drivers continued to avoid using electric operation, then EPA would have to reevaluate the entire premise of consumer demanded fuel savings. As charging resources increase, utility factor should increase along with it, not go down. [EPA-HQ-OAR-2022-0829-0637, pp. 21-23]

EPA acknowledges uncertainty regarding future charging usage by stating that the agency could revisit the utility factor once again in a future rulemaking if it appears that PHEVs are using more electric operation due to improved vehicle technology and greater charging infrastructure. However, undercutting PHEVs in this rulemaking, only to increase the value of PHEVs in a future rulemaking creates too much uncertainty. If EPA expects the charging environment to improve, why reduce the assumed driving usage now only to increase it again later? This back-and-forth uncertainty on utility factor would not be helpful since the current proposal would so undercut the incentive for PHEVs that manufacturers would have likely reconsidered continued support for the technology. If the agency is concerned about the actual real-world usage of PHEV electric operation, it seems that the approach would be to work with stakeholders to improve the charging experience today while the charging infrastructure is expanding over the next few years. “Fixing” the issue by undercutting the technology in regulation neither improves the technology, nor helps address charging challenges customers are facing. [EPA-HQ-OAR-2022-0829-0637, pp. 21-23]

Porsche anticipates that with improved electric ranges and greatly increased charging opportunities, PHEVs electric operation should increase in the future. The White House reported on June 27 that the goal to achieve 500,000 public chargers remains on track and the 2030 DOE report on nationwide charging supports the point that current public and private investment into charging also appears on track to support projected EV penetrations. Why would EPA undercut a class of electrified vehicles based on yesterday’s charging challenges, when other government entities are increasingly declaring charging challenges to be on track to being solved? [EPA-HQ-OAR-2022-0829-0637, pp. 21-23]

Porsche continues to offer PHEVs in the US market and has recently launched an upgraded version of a PHEV utility that features significantly increased electric range. Porsche recognizes that PHEVs can play a valuable role in helping our customers achieve the benefits that even partial electrification can provide in terms of improved efficiency, reduced petroleum consumption and dynamic performance. [EPA-HQ-OAR-2022-0829-0637, pp. 21-23]

Porsche notes that EPA’s proposed update to the PHEV utility factor will also influence CAFE compliance calculations due to the allowance within statute and regulation for manufacturers to optionally select weighted operation. EPA did not provide analysis as to how this change would affect CAFE compliance especially considering Department of Energy (DOE) recent NPRM to reduce the Petroleum Equivalence Factor (PEF) by 72% for electric vehicles. This dramatic proposal from DOE to undercut the incentive for electric vehicles within CAFE is premature given that proposed CAFE standards for model years 2027 and later have not yet been released by NHTSA. Porsche recommended in comments to DOE for their NPRM that DOE include the assessment of EPA’s proposed change in the utility factor to better understand the combined effect of lower PEF and lower utility factor. DOE did not acknowledge, or was unaware of, the proposed reduction in utility factor from EPA. The PEF statutory basis requires DOE, as it has done for over 40 years, to incentivize electrified vehicles in CAFE. This statute also requires DOE, NHTSA and EPA to consult on changes related to PEF and CAFE. Neither the EPA MPR NPRM nor the DOE PEF NPRM appear to discuss the mutual impacts that each other's proposed updates could have on future CAFE compliance. As NHTSA has yet to release their CAFE proposal, it is unclear if NHTSA will address both the EPA and DOE proposals and how both could impact CAFE compliance. To Porsche, it is unclear as to why these NPRMs appear disjointed and so far, have failed to discuss the impacts of each other's proposals on the other regulations. Porsche recommends EPA provide analysis of the impact of the reduced utility factor on the PEF and CAFE compliance in coordination with DOE and NHTSA. Ideally, all the proposals would have been released together to provide manufacturers with the ability to understand how each of the agency's actions would interact with each other and continue to support and incentivize technologies such as PHEV. This is especially relevant considering the overarching goal to achieve a dramatic increase in light-duty electrification. [EPA-HQ-OAR-2022-0829-0637, pp. 21-23]

Organization: Rivian Automotive, LLC

Additional Technical Comments

Modifications to the PHEV Fleet Utility Factor ("FUF")

Rivian applauds EPA's decision to revise the FUF for PHEVs. We agree with the agency that the current compliance methodology "significantly underestimates PHEV CO2 emissions."35 As the agency details in its analysis, and as Rivian has commented in the past, PHEVs exhibit significant variability in their environmental performance. Research from Europe shows that PHEVs deliver poorer environmental benefits in real-world usage than certified under test procedures, with troubling implications for the projected benefits of regulatory programs that encourage the development and sale of these vehicles.36 In the United States, PHEVs drive fewer electric miles than assumed for labeling purposes, with fuel consumption as much as two-thirds higher than nominally anticipated.37 Simply put, PHEV drivers often do not plug in their vehicles as much as was previously assumed. [EPA-HQ-OAR-2022-0829-0653, pp. 12-13]

The FUF remains important for calculating PHEV emissions for regulatory compliance, but the weight of the evidence clearly compels EPA to revise the curve. The initial proposal marks a significant improvement over the status quo, but onboard diagnostic data from California support an even lower FUF.38 EPA rightly acknowledges this in the Draft Regulatory Impact Analysis ("DRIA").39 Nonetheless, EPA proposes a higher curve. The agency's justification rests on speculation that future PHEVs could deliver greater all-electric performance as well as stated concerns that an accurate FUF would "disincentivize" PHEV development.40 If PHEVs fall short of their environmental promise, the technology does not merit an artificially inflated regulatory incentive regardless of its potential. Far from an unfair disincentive, an accurate FUF would ensure that the regulation works as intended—achieving reliable, real-world emissions reductions. To safeguard the regulation's environmental integrity, Rivian encourages EPA to finalize a FUF that accurately reflects the best available data from real-world driving behavior. Organization: Southern Environmental Law Center (SELC)

Under the GHG standards portion of the tailpipe emissions standards, a Fleet Utility Factor (FUF) is used to determine the portion of the electric operation of a plug-in hybrid electric vehicle (PHEV) that contributes to the fleet average. Studies have shown, however, that the current FUF overestimates the operation of PHEVs on electricity.67 As a result, "the current light- duty vehicle PHEV compliance methodology significantly underestimates PHEV CO2 emissions."68 We therefore support EPA's proposal to revise the FUF curve used in CO2 compliance calculations for PHEVs beginning in model year 2027 and urge EPA to consider a FUF curve that is even lower than the current proposal. It is essential that the GHG emissions from vehicles are properly accounted for in fleet averages to ensure the standards are resulting in the greatest emission reductions possible. [EPA-HQ-OAR-2022-0829-0591, p. 9]

Organization: Stellantis

Separately, EPA is discounting the benefit of a consumer facing technology that in the near-term addresses many of the concerns around pure BEV technology (e.g., range, infrastructure, etc.). Specifically, EPA is decreasing the GHG benefits of PHEV technology by proposing a change to PHEV Fleet Utility Factor (FUF) that will increase GHG emissions of light- and medium-duty PHEVs. EPA claims the published FUF used on test cycles to account for on-road electric operation is no longer appropriate. We have analyzed EPA's work and find shortcomings in the data sets (both the fuelly.com and CA-BAR), the filtering and analysis of the data, and the curve fitting techniques used. To address these problems, we propose that industry, EPA, SAE, DOT, and the national labs collaborate on an update to SAE J2841 that can be published following peer reviews. [EPA-HQ-OAR-2022-0829-0678, pp. 12-13]

The two issues that can lead to shortfalls in PHEV electric operation usage are (1) lack of charging and (2) differences in performance between regulated cycles and on-road operation. We believe charging rates will improve as more public infrastructure emerges and charging becomes ubiquitous. As for capability concerns, CARB is requiring a 70-mile combined cycle minimum range and a high-power cold start requirement (that EPA also proposes to adopt in this rule). These two requirements will force future PHEVs to have more range and power in all-electric operation, thus eliminating or minimizing any performance differences on-road versus regulated cycles. [EPA-HQ-OAR-2022-0829-0678, pp. 12-13]

EPA should be encouraging PHEV technology, not discouraging it. EPA clearly recognizes PHEVs could be an appropriate form of electrification for:

- Pickup trucks where BEVs struggle to deliver the needed range while towing

- Consumers who are not ready for BEVs, but could use a PHEV as a bridge [EPA-HQ-OAR-2022-0829-0678, pp. 12-13]

Improved capability PHEVs are coming and offer a battery mineral preserving bridge to full electrification (i.e., PHEVs can address consumer needs with smaller batteries than pure BEVs). EPA’s own analysis in the prior 2023-2026MY GHG emissions standards rulemaking5 found that PHEVs can play a significant role in meeting GHG emissions standards. [EPA-HQ-OAR-2022-0829-0678, pp. 12-13]

5 Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards, 86 Fed. Reg. 74434, 74493-94 (Dec. 30, 2021).

Stellantis agrees with the Auto Innovators’ recommendation that EPA should explicitly model PHEVs in the light-duty and MDV pickup applications in the final rule. However, the proposed Utility Factor will discourage PHEVs. Stellantis disagrees with the proposed Utility Factor changes and recommends that the current published Utility Factor remain in use. [EPA-HQ-OAR-2022-0829-0678, pp. 12-13]

The combined impact of the proposed changes described above compound the stringency of an already aggressive target makes the overall “net effect” of what EPA is proposing infeasible – especially in the initial year of the program. [redacted text.] [EPA-HQ-OAR-2022-0829-0678, pp. 12-13]

Third, EPA should retain credit for off-cycle GHG technologies that will continue to reduce real-world GHG emissions on ICE and EV product without artificially ramping down credit prematurely. Similarly, EPA should retain today’s PHEV Utility Factor to motivate sales of even more capable PHEVs. These technologies remain important in reducing the GHG emissions of a combined ICE/EV fleet, and the overall influence of the credit mechanisms in place to incentivize technology proliferation will scale down naturally as BEV technology proliferates. [EPA-HQ-OAR-2022-0829-0678, pp. 14-15]

In addition to these three pieces, and as a separate matter to setting feasible standards, EPA should consider implementing transparent and objective mechanisms that monitor key market enablers (infrastructure, battery costs, and raw material availability) and create adjustments if these essential enablers fall short of projections. These mechanisms are not a substitute for appropriately set targets, but rather a compliment to address uncertainties that are beyond the control of both industry and EPA. [EPA-HQ-OAR-2022-0829-0678, pp. 14-15]

Stellantis recommends that EPA should:

GHG Standards

- Revise standards that align to achievable EV adoption rates that do not force an overly optimistic technology transition for the market and industry: [EPA-HQ-OAR-2022-0829-0678, p. 24]

-Revise stringency adopting an 'Alternative 3' profile removing front-loading of EV adoption, modified to ensure 2030MY standards can be met with a 40-50% BEV+PHEV+FCEV combined technology penetration [EPA-HQ-OAR-2022-0829-0678, p. 24]

-Include PHEV technology as a critical transition technology to a fully electrified future – without incorrect discounting – particularly in highly capable vehicle segments [EPA-HQ-OAR-2022-0829-0678, p. 24]

-Retain GHG saving technology flexibilities recognizing the GHG benefit that continues to be present on electric vehicles and that will naturally decrease as EV penetration increases [EPA-HQ-OAR-2022-0829-0678, p. 24]

-Treat trucks and SUVs fairly by including PHEV technology as an important bridge to a BEV future, and ensure year-over-year required improvements are the same as cars [EPA-HQ-OAR-2022-0829-0678, p. 24]

-Fix incorrect MDV adjustments that mistakenly force medium-duty vehicles into light-duty standards and double stringency of high capability products arbitrarily [EPA-HQ-OAR-2022-0829-0678, p. 24]

- Include a provision that compliance with EPA's GHG standards would constitute compliance with CAFE standards [EPA-HQ-OAR-2022-0829-0678, p. 24]

Organization: Strong Plug-in Hybrid Electric Vehicle (PHEV)

Regarding the Fleet Utility Factor (FUF or UF) and the issue of PHEVs plugging in we have many recommendations. We recognize this is an important issue and a complicated one. We share EPA's desire to have PHEVs plug-in frequently in order to achieve needed emission reductions and make the averaging, banking and trading system work. We believe that a combination of regulatory requirements, incentives and disincentives discussed below will address the issues EPA raised and improve the FUF. [EPA-HQ-OAR-2022-0829-0646, p. 6]

a) We strongly recommend against using the California Bureau of Automotive Repair (BAR) data and Fuelly.com data as the basis for a new FUF for PHEVs. The Technical Committee of the Strong PHEV Coalition includes researchers who have been engaged with development and evaluation of UF calculations for more than 20 years. We are very familiar with the set of datasets that are available in the public and private domain for UF evaluation and have researched the datasets and authored many of the studies referenced in the Draft Regulatory Impact Analysis (DRIA). Our assessment and recommendations in response to the request for input on UF data in the DRIA is that the proposed changes to UF are based on a very poor dataset, poor analysis, and statistically indefensible methods. These datasets and methods are inadequate to inform policy of the importance and impact of EPA's emissions standards. See Appendix A for our critique of the BAR and Fuelly.com data sets. [EPA-HQ-OAR-2022-0829-0646, p. 6]

We strongly recommend keeping the SAE J2841 FUF curve for PHEVs in the final rule because the SAE standard FUF is an accepted, standardized, and well-understood model. The analyses that are presented by EPA and ICCT as evidence of the unrepresentativeness of J2841 are based on very poor data sources and analysis that is not statistically relevant or predictive. We agree that FUF and PHEV credits should be derived from operational data, but the proposed data sources and analyses are inadequate and reflect poorly on EPA's knowhow. EPA should engage with experts to derive a data-driven FUF using more representative datasets and methods including those of the CARB-funded UC Davis data logger study, or the EV Project analysis . See Appendix A for more explanation. Another factor that we request EPA informally consider is that PHEV batteries typically use five times or less lithium per all-electric mile than battery EVs, and as a result save substantial amounts of GHG from battery manufacturing. Strong PHEVs have the same GHG footprint as a 300-mile range BEV and Strong PHEVs have much higher all-electric range than PHEVs with a low all-electric range. (See Appendix B below.) We support EPA not considering battery manufacturing GHG emissions in this rulemaking, but request that EPA informally include this factor when developing the final FUF. While SAE J2841 is not perfect given the factors above it is more than adequate when combined with our package of recommendations below. [EPA-HQ-OAR-2022-0829-0646, pp. 6-7]

c) Further, we support EPA's desire to update the FUF in a future rulemaking when new data becomes available, and we commit to helping EPA acquire this data as we are a very data driven coalition that includes five universities (or similar research centers). Over time data derivable from CA BAR and other state's smog check programs will improve as more on-board diagnostic data becomes available which should be used in a future rulemaking with appropriate data quality testing, and improved methods. [EPA-HQ-OAR-2022-0829-0646, pp. 6-7]

EPA should extend the FUF to 130 miles in order to encourage automakers. For example, Toyota has announced that it is planning a PHEV with over 124-mile all- electric range.4 While we don't know which test cycle this range is based on, EPA should encourage this long all electric range.5 Another example is the BMW i3 REX which was designed to primarily drive all-electric miles but is now only sold as a used PHEV. [EPA-HQ-OAR-2022-0829-0646, p. 7]

EPA, in the final rule or future rule, should include a true-up system for automaker's FUF where debits or credits are provided based on actual data from on-board diagnostics and reporting by automakers of a fairly large sample. In other words, under this proposal, an automaker would lose or gain credits after-the-fact based on actual data on how consumers drive both new and older PHEVs. If EPA opts not to do this, we request that EPA should, at minimum, require manufacturers in this rulemaking to share anonymized actual data from PHEVs so that in future years, the EPA can make informed decisions about the FUF based upon real world data.

g) EPA should adopt a provision to discourage low-range PHEVs by requiring them to count as an HEV with no zero emission miles. We suggest a cut-off of 50 km (31 miles). Further we are not suggesting a ban on low-range PHEVs but rather a disincentive to produce them. Low-range PHEVs according to the UC Davis data logger project and the EV Project have greater likelihood of not plugging in and this could increase as PHEVs get older. PHEVs with a long all-electric range offer much greater benefits to consumers and show much higher levels of plugging in.

4 Toyota Planning Plug-In Hybrid Vehicles With Over 124 Miles Of Electric Range (motor1.com)

5 If this 124-mile range is based on the WLTP test (instead of EPA two cycle test) it is a very good all electric range for a PHEV.

Our assessment and recommendations in response to the request for input on UF data in the DRIA is that the proposed changes to UF are based on a very poor dataset, poor analysis, and statistically indefensible methods. These datasets and methods are inadequate to inform policy of the importance and impact of EPA's emissions standards. See our recommendations section above for what should be done instead. [EPA-HQ-OAR-2022-0829-0646, p. 12]

Critiques of the datasets that are input into the EPA UF calculations The BAR and Fuelly.com datasets that are referenced in the DRIA are both very poor datasets, methodologically and practically ill-suited to sample the population of PHEV owners. [EPA-HQ-OAR-2022-0829-0646, p. 12]

The Fuelly.com dataset is wholly inadequate to perform this function. It is a self-selected, self-reported online gasoline consumption log; Fuelly.com is not a survey, makes no claim to statistical representativeness, and does not have inputs or data to electric operation in any way. Methodologically, the means by which ICCT and EPA calculate UF from Fuelly.com data is to compare real-world fuel consumption to EPA rated CS fuel consumption, which is completely incoherent if one realizes that EPA rated fuel consumption and on-road fuel consumption are not the same thing. EPA researchers know better than any the many sources of variance between real-world fuel consumption and EPA -rated fuel consumption. In the ICCT calculation, the variance between these two fuel consumptions (which is strongly correlated with weather conditions, driving conditions, tire inflation, etc.) has entirely and indefensibly been allocated to a lower UF. In both the data and analysis of Fuelly.com fuel logs, EPA and ICCT are using unrepresentative data and deeply inadequate analysis to make policy. [EPA-HQ-OAR-2022-0829-0646, p. 12]

The BAR dataset is a relatively improved dataset, and we believe that in the future, a nationally representative dataset derived from many states who will be gathering this data will have value for measuring the real-world operation of PHEVs and will enable a data driven UF calculation in a future EPA rulemaking. At present, the BAR dataset has comprehensive data quality problems, and the naïve data filtering algorithms that ICCT and EPA used to wrangle and preprocess the data are inadequate to realize a coherent and representative analysis. [EPA-HQ-OAR-2022-0829-0646, p. 12]

Because our coalition has been systematically studying the operation of PHEVs, we have also seen that the FUFs of vehicle models in the BAR dataset are changing as a function of time. We asked for and received from ICCT and CA BAR both the datasets that ICCT used for their analyses (from ICCT), and an updated dataset of the same fields of data up to the present date (May 2023).These datasets show comprehensively different results in calculating PHEV operation. For example, BMW X5 XDRIVE45E vehicles (MY 2019-2022) that meet the ICCT/EPA filtering criteria tested before 17 May 2022 have an average individual UF of 30%. X5 XDRIVE45E vehicles (MY 2021-2023) that meet the ICCT/EPA filtering criteria tested after 17 May 2022 have an average individual UF of 68%. These types of problems with the BAR dataset seem to be unrecognized and not validated by the research community, and further strengthen the case for not using the BAR dataset for research or policy making. [EPA-HQ-OAR-2022-0829-0646, pp. 12-13]

There is evidence of systematic importing of used PHEVs into California, a type of data pollution that is not affecting most of the conventional vehicles. For example, a set of vehicles included in the ICCT dataset are six 2019-2020 Toyota Prius Primes. These six Prius Primes are all tested on a single day, they each have >#### 3000 mi, and five of six of them are present in the ICCT analysis (one has a technician-recorded odometer inconsistency). Whatever the history of these vehicles, the fact that 6 of them are being tested back-to-back on the same day is evidence that these vehicles are not under the operation and ownership of the general public, and that their operational history is not representative of the general public. These clusters of similar vehicles undergoing back-to-back testing are common and easily identifiable in the BAR data used for ICCT and EPA analysis. [EPA-HQ-OAR-2022-0829-0646, p. 13]

Prius Prime 1 tested on 02NOV2020:09:00:00.442000

Prius Prime 2 tested on 02NOV2020:10:34:51.141000

Prius Prime 3 tested on 02NOV2020:11:28:26.939000

Prius Prime 4 tested on 02NOV2020:12:14:16.189000

Prius Prime 5 tested on 02NOV2020:12:25:32.846000

Prius Prime 6 tested on 02NOV2020:13:36:16.952000

[EPA-HQ-OAR-2022-0829-0646, p. 13]

There is strong evidence that automakers (OEMs) are not implementing the data collection algorithms consistently. For example, all 2019 Chrysler Pacifica hybrid vehicles, transmitted the data required for these calculations from the HPCM-HybridPtCtrl control module, instead of from the ECM*-EngineControl control module which was used by all other OEMs. In reviewing and operating the ICCT's Data Import Algorithm (BAR Data Import.R, shared by A. Isenstadt 5/13/23), these vehicles are excluded from ICCT's analysis. Given that 2019 is the first year that on- board diagnostic technology allows data collection, and we anticipate better data reporting and processing in future years, but the handling of these types of inconsistencies is not in evidence in the ICCT/EPA data wrangling processes. [EPA-HQ-OAR-2022-0829-0646, pp. 13-14]

4. There is strong evidence of many significant inconsistencies between the technician and OEM-derived data that are present in the BAR data. For example, of the BMW 530e PHEVs in the ICCT dataset (ICCT_OBD_DATASET_MY2019, requested from BAR in April 2023), 585 (of a total 988) of them failed the odometer reading test (that the technician-entered odometer [in mi] is well-outside the OBD-reported odometer reading [converted to mi]). There is no reason why technicians are so comprehensively misreporting this very simple datum for a vehicle that is one of the most reported vehicles in this dataset (which has ~4000 PHEVs in total). [EPA-HQ-OAR-2022-0829-0646, pp. 13-14]

There are many more examples of these types of problems, none of which are identified or discussed in any of the ICCT/EPA literature or analyses. In summary, at this time, the BAR dataset is not a representative dataset to be able to assess the operation of PHEV in real world operation. In the future, as vehicles in CA (and in other states)10 age into annual emissions testing, the BAR datasets will have a more comprehensive sample of privately owned and operated vehicles and may be evaluated at that time for its suitability for research and policy making. [EPA-HQ-OAR-2022-0829-0646, pp. 13-14]

> 10 For example, in the state of Colorado, Colorado's Department of Public Health and the Environment will record and make available similar data when 2019 MY vehicles enter emissions inspections after they are 8 years old. This data will be available for researchers and policy makers.

We assert that the methods used to derive the proposed fleet utility factors (FUFs) from transportation datasets are not statistically defensible, and that the process of "averaging" FUF curves is inappropriate and does not improve predictive ability. [EPA-HQ-OAR-2022-0829-0646, pp. 14-18]

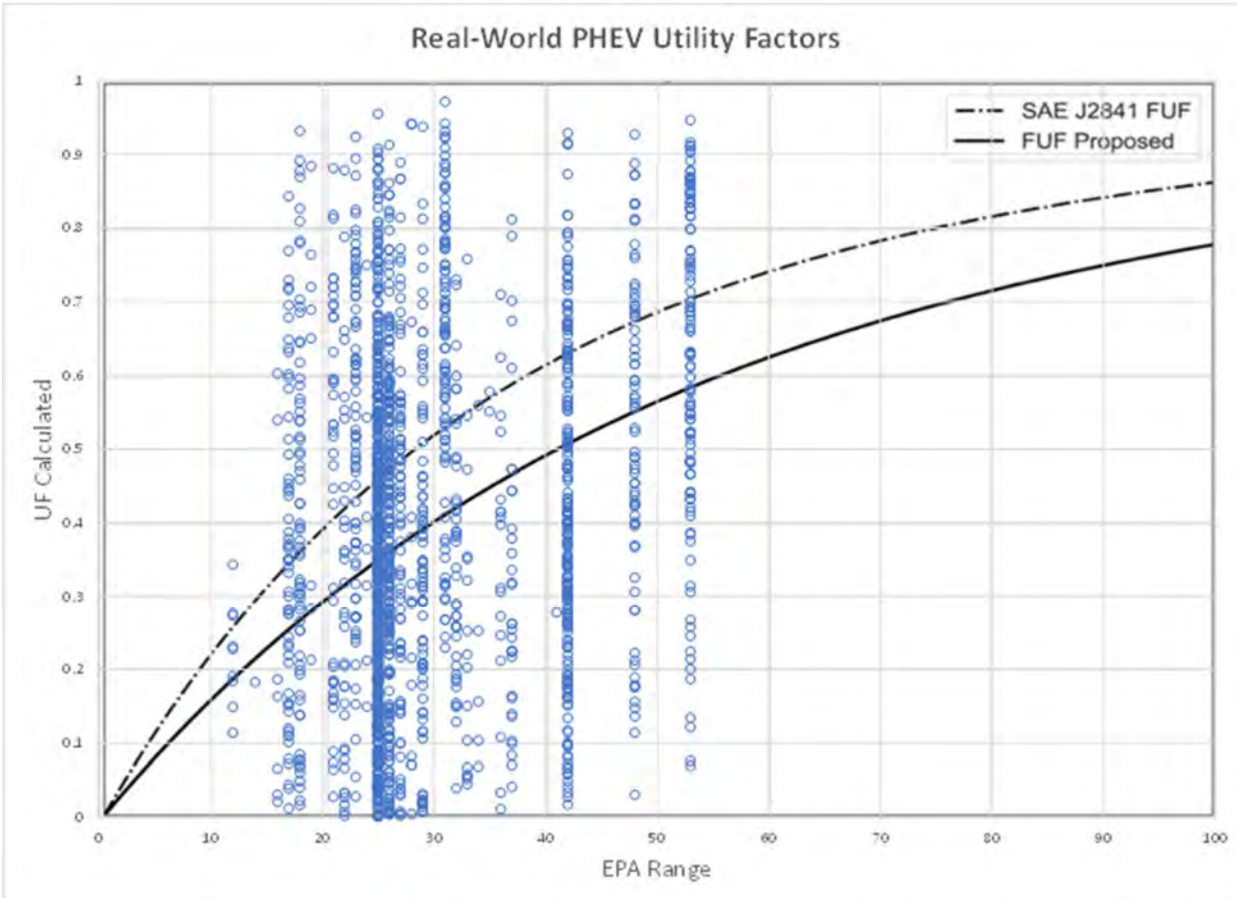
Apart from the inconsistencies described in the section above, policy makers and researchers must take caution in deriving findings from transportation data. [EPA-HQ-OAR-2022-0829-0646, pp. 14-18]

Figure 1 illustrates the set of individual vehicle-level UFs that are derived from an updated data pull from BAR. Of course, the data are extremely scattered and do not illustrate the validity of the UF curves for either the SAE J2841 FUF or the proposed FUF. When EPA or ICCT perform least-squares regression to derive a particular UF curve, they must calculate the confidence interval around the parameter estimates. When we perform that regression with vehicle models' pooled averages, we find that this dataset provides no evidence that the EPA FUF model is more representative than the SAEJ2841 model. [EPA-HQ-OAR-2022-0829-0646, pp. 14-18]

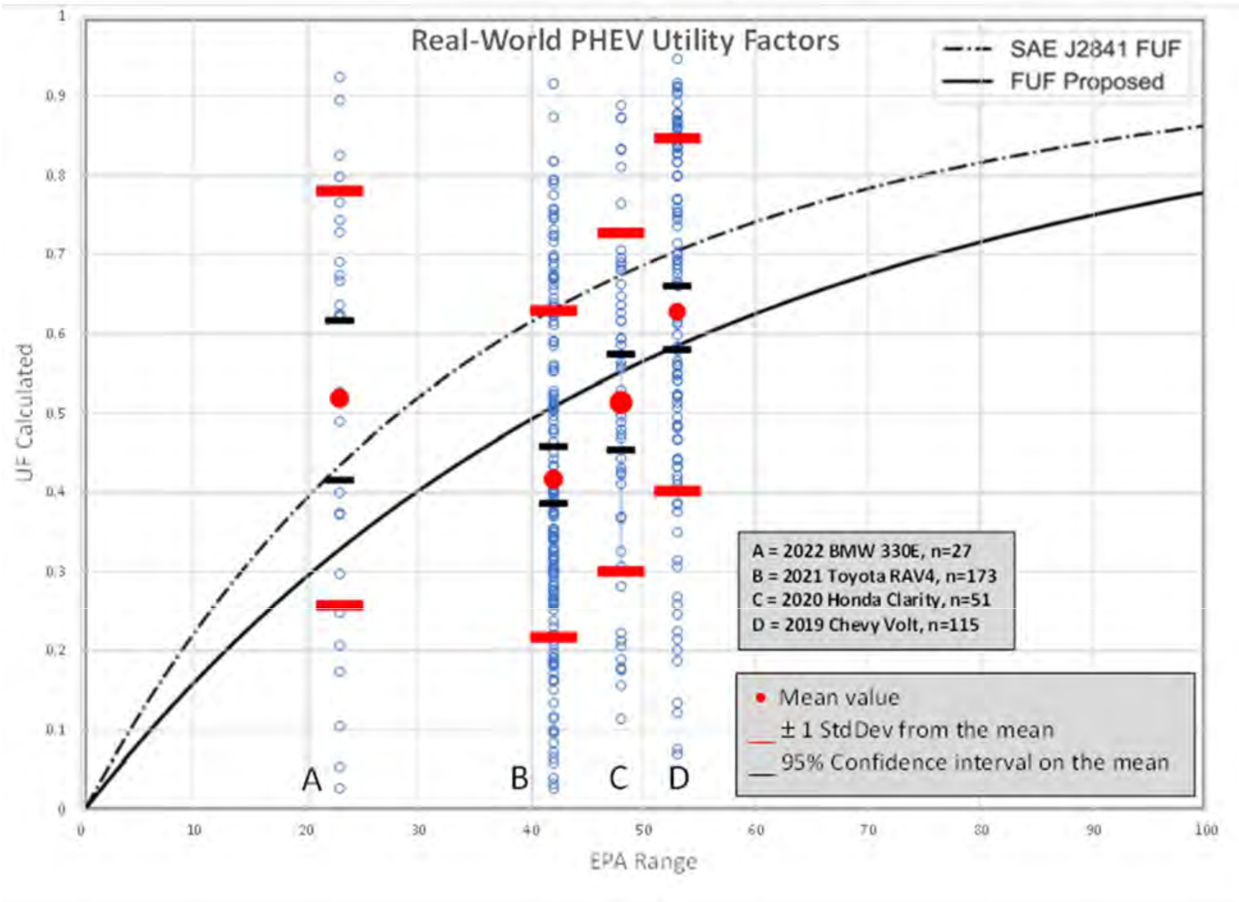
To illustrate this point more visually, Figure 2 provides additional statistical detail for some selected vehicle models. Figure 2 illustrates the wide dispersion of measured individual UFs and shows that the 95% confidence intervals on the mean value may or may not encompass any particular pre- derived response curve. [EPA-HQ-OAR-2022-0829-0646, pp. 14-18]

Finally, EPA's method of "averaging" of Fuelly/BAR/J2841 UF curves does not have any statistical/theoretical/practical power in achieving UF prediction and is inappropriate given the varied and disperse nature of these data. [EPA-HQ-OAR-2022-0829-0646, pp. 14-18]

A more data-driven approach that incorporates a number of driver and vehicle operating factors is needed to better characterize the real-world utility factors that are likely to arise over time. As the BAR database expands and becomes cleaner and more regularized, it can form the basis of a statistically relevant and more acceptable data-driven model. [EPA-HQ-OAR-2022-0829-0646, pp. 14-18]



[See original for graph titled "Figure 1. Calculated real-world PHEV utility factors for all vehicle models in the data set compared to the SAE J2841 FUF and the proposed FUF. Values are displayed as a function of EPA range irrespective of vehicle model and model year (e.g., EPA CD range of 31 encompasses two versions of the 2022 Hyundai Santa Fe and three model years of the BMW X5 XDrive45E). Note the wide variation in calculated utility factors compared to the two FUF curves for all EPA ranges."] [EPA-HQ-OAR-2022-0829-0646, pp. 14-18]



[See original for graph titled "Figure 2. Statistics of calculated real-world utility factors for four selected PHEV models compared to SAE J2841 FUF and proposed FUF. Model variations (e.g., Volt and Volt Premier) do not exhibit significantly different utility factors, on average, and are combined in this figure. Model year is constant for each model to minimize potential year-to-year differences."] [EPA-HQ-OAR-2022-0829-0646, pp. 14-18]

There are better data sets that support EPA using SAE J2741 for now. Regarding PHEVs not plugging in, there are many factors that impact plugging in and it is a complicated subject that needs more research.11 This August 2020 paper from UC Davis is one of the best analyses and uses data loggers from actual drivers and shows that PHEVs with longer AERs do not have a substantial issue with not plugging in (e.g., about 3-5%).12 See Table 1 below. Also, there are many factors that could see this decrease in the future. We make the case above that better data in the future will allow a new rulemaking on the FUF issue. [EPA-HQ-OAR-2022-0829-0646, pp. 14-18]

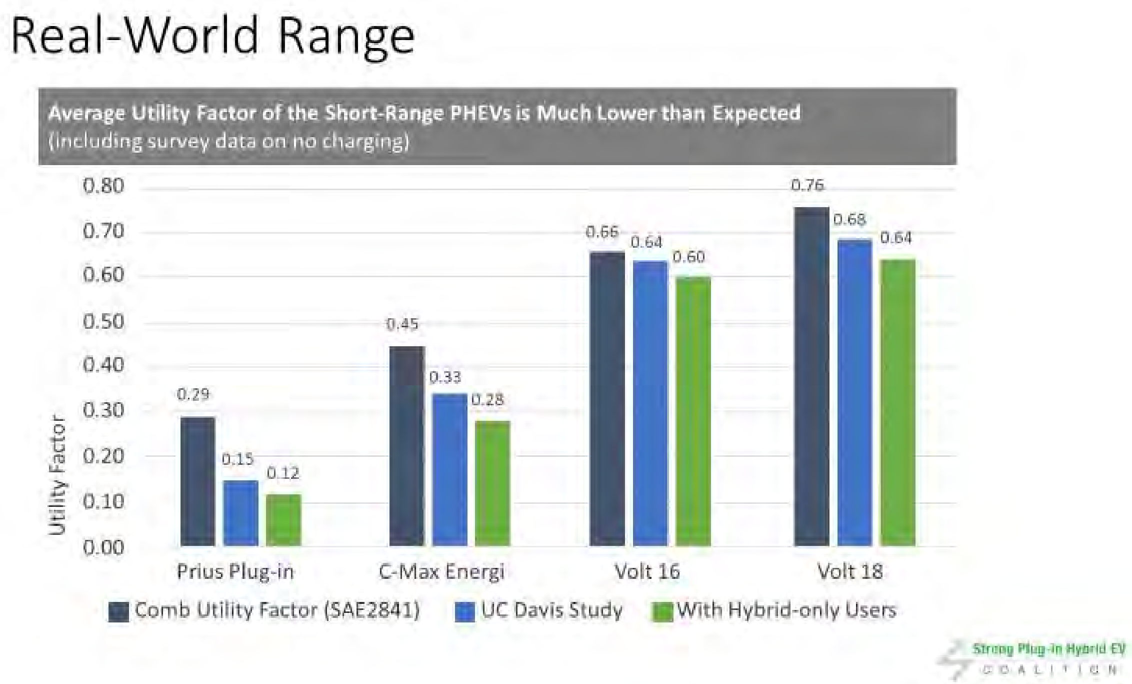
Table 1.

For short range PHEVs	AER EPA label	Percent not plugging in
Toyota Prius Gen 1	11 miles	17.6%
Ford Cmax and Ford Fusion	20 miles	12%
Audi e-tron	17 miles	9%
Toyota Prius Prime Gen 2	25 miles	9%
For longer-range PHEVs	AER EPA label	Percent not plugging in
Chrysler Pacifica	33 miles	4%
Chevy Volt Gen 2-	53 miles	5%
Chevy Volt Gen 1-	38 miles	3%
Honda Clarity	48 miles	4%
For very long-range PHEVs	AER EPA label	Percent not plugging in
BMW i3 rex	128 miles	no data
Karma Revero	60 miles	no data

[See original for graph on the Average Utility Factor of the Short-Range PHEVs] [EPA-HQ-OAR-2022-0829-0646, pp. 14-18]



[See original for graphic on PHEV Mils Driven in Charge-Sustaining Mode (Using Gasoline) or Charge-Depleting Mode (Using Battery)] [EPA-HQ-OAR-2022-0829-0646, pp. 14-18]

While we understand the desire by EPA to simplify the regulation and reduce the use of bonus multiplier credits, we believe a small bonus credit in the final regulation for a few years is justified and needed to unlock this technology because of the large emission reduction benefits and other benefits enabled by bidirectional charging. [EPA-HQ-OAR-2022-0829-0646, p. 9]

EPA should provide small bonus credits (multipliers) in 2027 to 2030 for several advanced technologies including PHEVs with a long all-electric range that are not being produced today. While we understand the need to simplify the regulation and dramatically reduce the use of multipliers, we do support very limited continuation of multiplier to advance technologies that do not exist today or are in very limited numbers such as bidirectional charging vehicles (recommendation 4) and PHEVs with an all-electric range of 60 or more miles. These technologies need extra lead time to develop. Having multiple technologies helps in reaching many hard-to-reach customer segments, and PHEVs with over 60 mile all-electric range by legacy automakers are not offered today and have rarely been produced and sold. Also see our recommendation 8 below. [EPA-HQ-OAR-2022-0829-0646, p. 10]

Organization: Tesla, Inc.

Tesla supports the proposed Alternative 1 with added stringency so that the final performance standards achieves a fleet BEV penetration rate greater than 69% in MY 2032.2 Alternative 1 is estimated to provide greater CO2 emissions reduction of -51% from no action by 2050 compared to -46% under EPA’s proposal, and the additional stringency will result in even greater emission reductions.3 Accordingly, Tesla asserts the EPA should amend its proposal with a more stringent version of Alternative 1 and take, inter alia, the following additional steps to increase the performance and overall stringency of the proposed standards: [EPA-HQ-OAR-2022-0829-0792, p. 2]

2 See, 88 Fed. Reg. 29332-33, Table 96.

3 Id., at 29348 (comparing Tables 135 and 136).

- Eliminate off-cycle crediting for all types of vehicles; [EPA-HQ-OAR-2022-0829-0792, p. 2]

- Revisit the plug-in hybrid electric vehicle (PHEV) utility factor to accurately reflect real world emissions; [EPA-HQ-OAR-2022-0829-0792, p. 2]

- Amend the proposal to create parity in promoting motor vehicle air conditioning (MVAC) efficiency adoption; [EPA-HQ-OAR-2022-0829-0792, p. 2]

- Maintain the existing zero emissions upstream approach for BEVs; [EPA-HQ-OAR-2022-0829-0792, p. 2]

- Eliminate credit multipliers for all vehicles; and [EPA-HQ-OAR-2022-0829-0792, p. 2]

- Ensure BEVs continue to be accounted for, and participate in, the NMOG + NOx reduction standard. [EPA-HQ-OAR-2022-0829-0792, p. 2]

While the agency proposes limiting the remaining off-cycle credit generation based on PHEVs fleet utility factor, as discussed above, this still would inequitably favor a legacy technology at the expense of full vehicle electrification.150 Nevertheless, EPA is appropriately revisiting the PHEV Fleet Utility Factor because PHEV compliance to date has significantly underestimated CO_2 emissions by overestimating their use of electricity.151 Reducing the PHEV utility factor is appropriate and overdue. [EPA-HQ-OAR-2022-0829-0792, pp. 24-25]

150 88 Fed. Reg. at 29251.

151 Id., at 29252.

PHEVs have consistently been overrewarded compared to their actual emissions reduction performance.152 In a 2020 study, the International Council on Clean Transportation (ICCT) found that real-world PHEV fuel consumption and emissions were about 2-4 times higher than certified levels.153 According to ICCT, one of the main reasons for this is that, “For private cars, the average utility factor (UF)—an expression for the portion of kilometers driven on electric motor versus kilometers driven on combustion engine—is 69% for New European Drive Cycle (NEDC) type approval but only around 37% for real-world driving. For company cars, an average UF of 63% for NEDC and approximately 20% for real-world driving was found.”154 Essentially, PHEV drivers utilize ICE engines for travel far more than electric drive when operated in real world conditions. Similarly, Transport and Environment found that emissions from three of the most popular PHEVs in the EU were 28-89% higher than certified levels even under ideal test conditions (e.g., fully charged battery).155 Other studies suggest hybrids offer little benefit compared to ICE vehicles.156 The California Air Resources Board (CARB) has also recognized these concerns by calling out excessive PHEV cold start emissions.157 In sum, Tesla supports the agency revisiting the PHEV Fleet Utility Factor. [EPA-HQ-OAR-2022-0829-0792, pp. 24-25]

Organization: Toyota Motor North America, Inc.

4. The proposed rule discriminates against plug-in hybrid electric vehicles (PHEVs) based on flawed data and analysis from an environmental NGO to arbitrarily lower the “Utility Factor” (UF). EPA’s proposed UF slashes the compliance benefit of PHEVs by between 25% and 45% and discourages OEMs from pursuing this technology. EPA should retain the current Society of Automotive Engineers (SAE) method for assessing the UF. PHEVs should be encouraged by this regulation, not discouraged – they are an extremely efficient use of limited and expensive minerals, provide significant GHG reduction benefits, are more affordable than similar BEVs, and require less reliance on charging infrastructure. [EPA-HQ-OAR-2022-0829-0620, p. 2]

EPA requests any relevant performance or utility data that may help inform their analyses for the Final Rule. We appreciate the opportunity to share data which will help elevate the role PHEVs in the Final Rule to be an important part of a sustainable transition to electrification. We plan to share such PHEV data outside of the comment period, possibly, including confidential information. For now, we request EPA consider the data we have provided that suggests PHEVs should be considered be an important contributor in whatever assumed PEV sales mix. [EPA-HQ-OAR-2022-0829-0620, p. 32]

6.4. PHEV Utility Factor

The proposed revisions to the SAE vehicle Fleet Utility Factor (FUF) curve would significantly diminish PHEV compliance benefits and challenge the technology’s market viability at a time when consumers and the proposed standards need more plug-in electric vehicle (PEV) options available. Toyota believes the FUF should remain unchanged as the proposal offers insufficient evidence to support such a consequential test procedure change for which there has been minimal industry engagement. [EPA-HQ-OAR-2022-0829-0620, p. 33]

6.4.1. Supporting Studies Lack Peer Review

EPA contends available real-world data suggests the current PHEV compliance methodology which incorporates the SAE J2841 FUF curve significantly underestimates PHEV CO2 emissions. The proposal references the authors of several studies that have questioned the efficacy of the SAE UF for PHEVs in Europe. These studies are not relevant to PHEV operation in the U.S. It is well documented that the real-world data in Europe is skewed by less capable PHEVs that were provided by companies to employees with free gasoline as a perk, but not free electricity. Further, tax policy in Europe incentivizes PHEV purchases but charging opportunities are often limited for multifamily dwellings which are common. Not surprisingly, PHEVs in the Europe-focused studies were primarily driven as conventional hybrids on gasoline. Finally, the potential for discrepancies in label versus real-world all-electric PHEV range is greater in Europe where the values resulting from the labeling procedure are significantly more optimistic than those in the U.S. [EPA-HQ-OAR-2022-0829-0620, pp. 33-34]

As seen in Table 4, several studies or articles are referenced in support of the proposed revision to the SAE FUF, only one of which has been peer reviewed by a neutral third-party, i.e. not chosen by the authoring organization. The proposal excludes several relevant peer-reviewed publications, including papers by Toyota22 and UC Davis23 that provide counter-balancing arguments to the claims that the SAE UF is no longer appropriate. Toyota's paper was peer-reviewed using a double- blind process managed by the editors of the journal Environmental Research Letters. This paper directly rebuts the Fraunhofer/International Council on Clean Transportation (ICCT) paper and was published in the same journal as that Fraunhofer/ICCT paper, and after the Fraunhofer/ICCT appeared. [EPA-HQ-OAR-2022-0829-0620, pp. 33-34]

Instead, the proposed FUF change relies on the analyses of two error-filled datasets to depict real- world PHEV operation in the U.S. ICCT first presented the Fuelly and California BAR datasets in a December 2022 whitepaper.24 Both the data and the analyses lack the scientific rigor required to support revising the SAE FUF curve. [EPA-HQ-OAR-2022-0829-0620, pp. 33-34]

24 “Real world usage of plug-in hybrid vehicles in the United States.” Aaron Isenstadt, Zifei Yang, Stephanie Searle, John German, ICCT Report, December 2022.

6.4.2. Fuelly Web Application Dataset

The Fuelly website application is designed for gasoline vehicle users to input miles driven, refuel amount, and fuel price to calculate fuel economy and the operating costs incurred.25 The input parameters do not allow charge-depleting (CD) and charge-sustaining (CS) driving miles to be calculated. The web application lacks separate inputs for electricity and gasoline consumption. Instead, there is a single input field labeled “Fuel” used to calculate the cost of fuel consumption which is the primary purpose of the web application. [EPA-HQ-OAR-2022-0829-0620, pp. 34-37]

25 Fuelly is also available as a mobile phone application.

Inspecting the data in the Fuelly application has confirmed the lack of a dedicated interface for electricity consumption leads to data input errors. For example, samples of certain Tesla battery electric vehicles have values labeled as “miles per gallon” (MPG) entered in the “Fuel” input field instead of the appropriate “miles per kilowatt-hour” (kWh) units. This results in extremely low mile-per-gallon numbers being reported, significantly lower than expected for comparable- class gasoline vehicles. We believe that when owners attempt to track their electricity cost with the Fuelly interface, the application’s back-end code treated the entered kilowatt-hour values as gasoline miles per gallon values, as suggested by Figure 11. This error significantly increases the inferred fleet-wide fuel usage and decreases the utility factor for PHEVs. [EPA-HQ-OAR-2022-0829-0620, pp. 34-37]

[See original for Graphic, Figure 11 Selected Fuelly Data Entries for Tesla Model S] [EPA-HQ-OAR-2022-0829-0620, pp. 34-37]

At the opposite end of the error spectrum, refueling events for PHEVs with an accurately high charging frequency and utility factor have been excluded as outliers by the Fuelly application solely because of their superior fuel economy. For example, it is not uncommon for a regularly charged Chevrolet Volt to attain 200+ MPG which can be filtered by from the distribution of re-fuel events because the value lies beyond Fuelly’s 3-sigma screening limit that is applied to fleet average MPG (see Figure 12 below). These omissions further mischaracterize PHEV real-world fleet performance. [EPA-HQ-OAR-2022-0829-0620, pp. 34-37]

[See original for graphic, Figure 12 Fuelly Results for 2019 Chevrolet Volt] [EPA-HQ-OAR-2022-0829-0620, pp. 34-37]

The left side of Figure 13 compares for selected PHEVs the UFs that ICCT inferred from the Fuelly data to both the SAE and EPA proposed UF curves. Though tedious, it is possible to correct or “clean” the Fuelly data for every refuel event of the selected PHEVs. The right side of Figure 13 shows that Toyota’s cleaning of those selected data points results in the corrected Fuelly data curve being much closer to the SAE curve.26 It is also important to note that, using the methodology ICCT used, and Toyota repeated (after appropriately cleaning the data), if the charge sustaining (CS) fuel-economy (in MPG) is lower than the EPA label CS fuel-economy (in

MPG), then the calculated values, shown below, only represent lower bounds of UF on the on-road.27 [EPA-HQ-OAR-2022-0829-0620, pp. 34-37]

26 No footnote text provided.

27 See Appendix B for a description of the data cleaning process.

[See original for graphs, Figure 13 Impact of Correcting Erroneous Data on Fleet Utility Factor (FUF)] [EPA-HQ-OAR-2022-0829-0620, pp. 34-37]

Prior to the proposal being issued, Toyota met with EPA to raise concerns about the efficacy of ICCT attempt to infer a real-world PHEV UF from the Fuelly web application. We reviewed a slide deck that deconstructed ICCT's methodology and identified examples of uncorrected data entry errors that directly impact the conclusions reached in ICCT's whitepaper.28 Our efforts to replicate the Fuelly-based calculations described by ICCT in the 2022 Whitepaper and this proposal strongly suggest such cleaning of the data errors still has not happened. [EPA-HQ-OAR-2022-0829-0620, pp. 34-37]

28 The slide deck from the March 13, 2023 meeting is included as Appendix C.

6.4.3 BAR OBD Dataset

The OBD data obtained from the California Bureau of Automotive Repair (BAR) program does provide the vehicle parameters necessary to calculate an in-situ Utility Factor such as charge- depleting distance, charge-sustaining distance, and total distance traveled. However, as the proposal notes, there are limitations with the available data which Toyota believes make it unfit for depicting normal PHEV usage patterns. The BAR Smog Check program, which periodically collects the abovementioned parameters, is required in California for vehicles:

- 8-years or older,

- 4 model-years or older that change ownership, or

- Registered in California after moving from another state. [EPA-HQ-OAR-2022-0829-0620, pp. 37-40]

The PHEV data tracking requirement in the BAR program started with 2019 model year but did not fully phase in until 2021 model year. The most recent vehicles in the cited BAR dataset used to support the proposal are from the 2022 model year, so none of the PHEVs in the sample were obligated to participate due to the age criteria referenced above. Considering a California Smog Test requires some effort and money from the vehicle owner, it is reasonable to conclude that few vehicle owners are going to pursue a test if it is not required. Therefore, the BAR OBD data evaluated for this proposal is dominated by recently registered 2019-2022 model year PHEVs that underwent the mandatory smog check, because they were recently registered in CA from another state. It is reasonable to assume that many of those moves to California involved a long-distance trip, and possibly relocation arrangements that at least temporarily limited access to charging. The recorded OBD data for vehicles that move between states is likely to include hundreds or thousands of recent miles accumulated primarily in CS mode, even if the owner regularly charges before and after the relocation. These unique circumstances suggest that cited BAR data will significantly underestimate typical, real-world FUF for PHEVs. [EPA-HQ-OAR-2022-0829-0620, pp. 37-40]

EPA's attempts to manage the rampant errors in the BAR dataset renders it statistically insignificant for an analysis of normal PHEV usage. The proposal explains that despite relaxing the data quality criteria to accept up to 20 percent mileage error29 and vehicles with as low as 1,865 lifetime miles, only 2,060 out of more than 8,000 vehicles were retained from the BAR dataset. As a result, many of the PHEV variants studied by EPA have a sample size of 30 vehicles or less as seen in the legend on the right in Figure 14 below. The cleaned BAR dataset Excel file shared by EPA in the docket also confirms the inadequate sample size.30 Because EPA accepted very low-mileage PHEVs for their supporting analysis, even a few hundred miles without charging can bias the results to a lower Utility Factor. [EPA-HQ-OAR-2022-0829-0620, pp. 37-40]

29 The mileage error is in the discrepancy between odometer reading and vehicle lifetime miles reported from the OBD system.

30 Docket Number EPA-HQ-OAR-2022-0829-0408.

As mentioned previously, most PHEVs in the cited BAR dataset underwent the smog check in 2020 through 2022 calendar years. The data collection through the 2020 calendar year includes the period when transportation was significantly impacted by the COVID-19 pandemic. Impacts included unusual fluctuations in gasoline prices including a 10-year low in 2020 making for both unusual driving patterns and less motivation to charge. We expect real-world FUF trends will increase post-pandemic. [EPA-HQ-OAR-2022-0829-0620, pp. 37-40]

During the March 2023 meeting with EPA, Toyota raised general concerns that the collection limitations and the necessary error filtering of the BAR dataset make it statistically insignificant and unrepresentative of typical PHEV usage patterns. We were unable to conduct a quantitative analysis of the data until it was placed in the docket after the proposal was issued. After evaluating the BAR dataset, our concerns are now bolstered by findings that long distance moving trips and the anomaly of COVID impacts bias the observed driving patterns and charging behaviors making the BAR data unfit for assessing the appropriateness of the SAE J2841 FUF curves. According to the proposal, EPA analyzed a filtered subset of the BAR OBD data results to address the data quality challenges and developed the "EPA BAR Linear Regression" curve listed in Figure 14 which also contains the two ICCT UF curves labeled as "ICCT-BAR" and "ICCT-FUELLY/EPA Proposal". EPA points out their linear regression fit of the BAR data subset lies on top of the "ICCT-BAR" curve fit from the full OBD dataset, implying good agreement between the two separate analyses of the BAR data. [EPA-HQ-OAR-2022-0829-0620, pp. 37-40]

Figure 14 PHEV Utility Factor Curves Considered in the Proposal.31 [EPA-HQ-OAR-2022-0829-0620, pp. 37-40]

31 Multi-Pollutant Emission Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, EPA- 420-D-23-003, DRIA, April 2023, Fig. 3-29, pg. 3-79.

[See original for graph, Figure 14 PHEV Utility Factor Curves Considered in the Proposal] [EPA-HQ-OAR-2022-0829-0620, pp. 37-40]

Just how EPA developed the linear regression fit from the BAR OBD data is unclear. Given the scatter in the data, an exponential regression seems more appropriate if the aim is to infer a Utility Factor curve. The linear regression happens to match the ICCT analysis but provides no scientifically significant information unless EPA intends to propose linear UF curves. [EPA-HQ-OAR-2022-0829-0620, pp. 37-40]

6.4.4 Proposed UF Based on EPA's Analysis

The proposed FUF curve that results from EPA's analysis is calculated as the average of the SAE J2841 FUF curve and the ICCT-BAR curve which happens to match the curve fit of the problematic Fuelly data. The proposed curve shares the same weighting coefficients as the SAE curve under scrutiny. As seen in Table 5, the only difference between the SAE curve and the proposed curve is the Normalized Distance (ND) increasing from 399.9 miles to 583 miles. All other terms in the proposed revised equation to the right of Table are the same. [EPA-HQ-OAR-2022-0829-0620, pp. 40-42]

[See original for table and equation, Table 5 Comparison of Proposed and Existing SAE FUF Terms] [EPA-HQ-OAR-2022-0829-0620, pp. 40-42]

The proposed ND adjustment amounts to discounting the advertised electric range of every PHEV by about 32 percent for compliance calculations because increasing the normalized distance has the same effect as lowering the CD range (see Figure 15). [EPA-HQ-OAR-2022-0829-0620, pp. 40-42]

Figure 15 Revised Normalized Distance Derates All-Electric Range for Compliance
[See original for graph, Figure 15 Revised Normalized Distance Derates All-Electric Range for Compliance] [EPA-HQ-OAR-2022-0829-0620, pp. 40-42]

The Draft Regulatory Impact Analysis explains that EPA "used the latest NHTS data (2017) and executed the utility factor code that is in SAE J2841, Appendix C, and found that the latest NHTS data did not significantly change the utility factor curves."32 We are therefore confused over the basis for revising the normalized distance if overall driving distances have not changed. EPA's analysis suggests the normalized distance should remain unchanged. Toyota opposes the normalized distance being changed based on the existing data. [EPA-HQ-OAR-2022-0829-0620, pp. 40-42]

32 Multi-Pollutant Emission Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, EPA- 420-D-23-003, DRIA, April 2023, Footnote 35, pg. 3-74.

6.4.5 EPA's Analysis and Conclusions Misaligned with Available Data

The previously mentioned Toyota and UC Davis work conclude that the real-world performance of previous-decade PHEVs in the US approximate the SAE UF curves reasonably well as seen in Figure 16. This is especially the case with more capable, longer-range PHEVs, a trend the problematic Fuelly and BAR datasets also support. However, EPA's linear curve fit that anchors the proposed UF curve revision is weighted toward vehicles with a range below 30 miles (see legend to right of Figure 14) whereas modern PHEVs with higher range and motor power outperform the vehicles used for EPA's analysis. [EPA-HQ-OAR-2022-0829-0620, p. 42]

[See original for graphs, Figure 16 Estimated Real World Utility Factor for U.S. Datasets Versus SAE J28] [EPA-HQ-OAR-2022-0829-0620, p. 42]

6.4.6 Treat Potential Discrepancies Between Real-World and Laboratory Evenly [EPA-HQ-OAR-2022-0829-0620, pp. 42-44]

Concerns over differences between real-world and laboratory performance, particularly those due to driving behaviors, have traditionally been resolved through post-compliance data adjustments aimed at consumer awareness and occasionally by expanding test cycle requirements. Not by revising the calculations used to determine compliance with the standards. The compliance benefit of internal combustion powertrains has never been penalized when studies have found on-road driving is more aggressive or fuel consuming than the test cycles indicate. Instead, lab results for CO2 emissions and fuel economy are adjusted on the fuel economy label to better reflect real- world performance, and consumers are educated on how their mileage may vary based on their driving conditions. [EPA-HQ-OAR-2022-0829-0620, pp. 42-44]

PHEVs should be treated no differently than BEVs. Both technologies are still evolving, maturing and need support towards mainstream market adoption. The proposal appropriately does not scrutinize the advertised range, efficiency, and emissions performance of BEVs under real-world conditions. A BEV not attaining its advertised range can result in more ICE miles driven. One recent vehicle usage study concluded the average BEV is driven 29% less than the average non- BEV.33 Figure 17 comes from another academic study that found that battery electric vehicles (BEVs) are driven on average 2,700 fewer miles annually compared to their conventional counterparts.34 [EPA-HQ-OAR-2022-0829-0620, pp. 42-44]

Figure 17 Mileage Accumulation by Powertrain Type

[See original for graphs, Figure 17 Mileage Accumulation by Powertrain Type] [EPA-HQ-OAR-2022-0829-0620, pp. 42-44]

The proposal heavily relies on the BEV technology improvements and charging infrastructure expansion to justify the standards. Those same improvements will also benefit PHEVs, since home charging, consumers awareness, and technology advancements will drive PHEV utilization closer to that of pure BEVs as consumers place greater emphasis on achieving advertised range and have greater desire and means to achieve it. [EPA-HQ-OAR-2022-0829-0620, pp. 42-44]

Existing regulation will also help spread the deployment of more capable PHEV designs that perform closer to their advertised all-electric range. The California ACC2 provisions will drive more capable architectures by requiring PHEVs to have a minimum all-electric range of 40 miles over the aggressive US06 test cycle that eventually increases to 50 miles, and a minimum of 70 mile range over the combined city/highway test cycle. Further, EPA’s proposed PHEV high-power cold-start requirement will necessitate more all-electric capability. [EPA-HQ-OAR-2022-0829-0620, pp. 42-44]

6.4.7 Suggested Approach Moving Forward

Toyota is interested in ensuring PHEVs achieve their assumed emissions benefits. However, a proper science-based data collection and assessment of PHEV performance needs to inform real-world PHEV usage patterns and the resulting emissions. An analysis of a small sample of two error-filled datasets is not an appropriate basis from which to draw conclusions about PHEV all-electric range during real-world operation. An unprecedented revision of the Utility Factor curve based on the data in the proposal would be arbitrary and capricious. [EPA-HQ-OAR-2022-0829-0620, pp. 44-45]

We recommend EPA request SAE establish a consortium of auto companies, DOE, DOT, and other stakeholders to evaluate PHEV usage trends by architecture and performance capability. A first order of business should be determining a consensus method for measuring real-world EV range. The output of this effort should be a report that EPA would use to consider adjustments to the UF curve, alternative metrics such as PHEV design criteria, and/or improved information for consumer purchase decisions. [EPA-HQ-OAR-2022-0829-0620, pp. 44-45]

If proven necessary, PHEV electric range on the consumer-facing label could be adjusted. In such a scenario, increased knowledge about all-electric range could stoke competition in a growing market and motivate continued investment to refine and improve PHEV performance. Penalizing PHEV compliance with the proposed revision to the Utility Factor curve would only stifle investment and hamper deployment of new PHEVs leaving consumers less choice to reduce CO2 emissions at a suitable price. [EPA-HQ-OAR-2022-0829-0620, pp. 44-45]

Appendix B – Procedure for (Partial) Cleaning of Fuelly Data for PHEVs

1 Overview of Errors in Using Fuelly Data

When examining Fuelly web site for some make-model (example in Figure 1 shows Chevrolet Volt), it shows multiple data cards, one for each model-year. Each data card shows some notable pieces of information including number of vehicles, total miles tracked and average MPG. [EPA-HQ-OAR-2022-0829-0620, pp. 67-99]

Figure 1 Screenshot From: https://www.fuelly.com/car/chevrolet/volt

[See original for graphic on Fuelly website for Chevrolet Volt] [EPA-HQ-OAR-2022-0829-0620, pp. 67-99]

One might be tempted to compare the average MPG to the EPA label for combined cycle MPG in charge sustaining (CS) mode to infer fleet utility factor (FUF). This is how it was done in the 2022 ICCT Whitepaper (which the EPA NPRM relied heavily on), and this is an incorrect approach that includes several errors stemming from limitations of Fuelly data, summarized as follows: [EPA-HQ-OAR-2022-0829-0620, pp. 67-99]

1.The average MPG for make/model/model-year reported on data cards (such as in Figure 1) excludes what Fuelly web site's back-end code considers to be "Outlier refueling" events. Spot-checking Fuelly data suggests that the criteria for being considered an outlier is the "standard" statistical criterion of being outside of 3-sigma (three standard deviations) bounds from the average value. Unfortunately, in case of PHEVs, the variation in "MPG numbers" can be very large, with some PHEVs that are charged regularly capable of attaining more than 200 MPG (as a single vehicle average). Thus, with a fleet that has an average of 100 MPG and standard deviation of 50 MPG is often, a refueling event at near- zero-MPG is still "within 3-sigma", while a refueling event at 300 MPG is "outside of 3- sigma" thus, large amounts of electric-miles can be missing from the make/model/model- year data card shown in Figure 1. [EPA-HQ-OAR-2022-0829-0620, pp. 67-99]

2. Since Fuelly data is self-report by users and the website (or phone App) has only one data field for the amount of “Fuel”, one observed recurring error is when a user mistakenly enters an amount of electricity as “fuel]”, which, for a typical electric driving at ~0.33 kWh per mile = 3 miles per kWh, can completely distort the average MPG if/when seen by the back end code of Fuelly as a “3 MPG” refueling event [EPA-HQ-OAR-2022-0829-0620, pp. 67-99]

3. Assumption that a PHEV is “exactly attaining” its EPA label for combined cycle CS mode fuel economy, when in fact, most vehicles (PHEVs being no exception) can be somewhat less efficient (within certain limits, 10% to 15% worse MPG than EPA label often considered “normal”) leads to under-estimation of the faction of miles driven on grid electricity. [EPA-HQ-OAR-2022-0829-0620, pp. 67-99]

In section 2 of this appendix, we show a procedure to correct error #1 and error #2, but Fuelly data, which does not show the split between charge sustaining and charge depletion, is insufficient for making corrections to error #3. As such, after conducting the data cleaning, the estimated utility factors are still only lower bounds for the true real-world utility factors. [EPA-HQ-OAR-2022-0829-0620, pp. 67-99]

2 Correction of Error #1 and Error #2

Clicking on an individual data card for make/model/model-year (such as the ones shown in Figure 1) opens a set of data card summaries for each individual vehicle sample, as shown in Figure 2. [EPA-HQ-OAR-2022-0829-0620, pp. 67-99]

[See original for graphic on Fuelly] [EPA-HQ-OAR-2022-0829-0620, pp. 67-99]

Next, one needs to click on the data card of each individual vehicle sample in order to open a detailed page for the individual vehicle sample, as shown in Figure 3 and Figure 4. Details included in these pages show the total miles tracked, as well as the average MPG of the vehicle (throughout its total miles tracked). These numbers should be noted separately for each vehicle (thereby bypassing Error #1). The detailed page also includes the log book of miles travelled and refueling events, which one needs to carefully inspect for entries that may have incorrectly reported electricity usage as gasoline (example in Figure 4), and if discovered, the affected vehicle sample is excluded. [EPA-HQ-OAR-2022-0829-0620, pp. 67-99]

Ones then needs to repeat the procedure for every individual vehicle sample. Next, would be to infer (lower bound of) each vehicle’s fraction of electric miles, and then lastly, one can estimate (lower bound of) overall fleet utility factor. [EPA-HQ-OAR-2022-0829-0620, pp. 67-99]

[See original for Appendix C – Materials from EPA-Toyota Meeting on SAE Utility Factor for PHEVs] [EPA-HQ-OAR-2022-0829-0620, pp. 67-99]

Organization: Volkswagen Group of America, Inc.

PHEV Utility Factor – Proposed Approach for the PHEV Fleet Utility Factor (Section III.B.8.)

Based on the driving statistics from a 2001 national household travel survey and supplementary datasets as input for the utility factor in SAE J2841, EPA believes that the current fleet utility factory (FUF) underestimates the PHEV CO2 emissions in real world. Beginning MY2027, EPA has proposed a revised light-duty vehicle PHEV Fleet Utility Factor curve to be used in the PHEV CO2 compliance calculation. [EPA-HQ-OAR-2022-0829-0669, pp. 4-5]

In addition to AFAI's detailed comments regarding the lack of statistically based changes to EPA's proposed FUF, Volkswagen also requests no modifications to the current FUF at this time. Data quality to derive a FUF is highly dependent on assumptions that can be easily influenced by multiple variables. In additional to the conditions discussed by AFAI (e.g., charging infrastructure, driving behavior, customer use education, etc.), Volkswagen believes that PHEV ownership is influenced by current Federal and State purchasing incentives and the environmental benefits may be a secondary or tertiary reason for the purchase of a PHEV over the ICE vehicle alternative. The DoE Alternative Fuels Data Center shows 398 incentives for personal vehicle owner for PHEVs. In addition, the FUF should take into account future driving behavior where PHEVs attain a higher range for ZEV-qualifying PHEVs. [EPA-HQ-OAR-2022-0829-0669, pp. 4-5]

Volkswagen acknowledges there are ongoing discussions in the U.S. and Europe to modify the FUF. Both regions are comparing the current FUF with newly collected real world data. Europe is updating its FUF on 01/01/2028, where the methodology defined in the legislation and the factor will be dependent on data collected over next several years. Volkswagen suggests that this timing is appropriate and recommends that the current FUF remain in place until the new data is available. [EPA-HQ-OAR-2022-0829-0669, pp. 4-5]

Organization: Zero Emission Transportation Association (ZETA)

- ZETA supports the proposed changes to the PHEV fleet utility factor (FUF) to more accurately apportion the benefit of PHEVs' electric operation. Ensuring accurate compliance calculations is critical to preserving programmatic integrity and reducing emissions. As EPA notes, SAE J2841 was developed more than ten years ago during the early introduction of light-duty PHEVs and at the time was a reasonable approach. However, with the benefit of more real world data and information about actual vehicle operating characteristics, we support EPA revisiting the FUF curve at this time. [EPA-HQ-OAR-2022-0829-0638, p. 29]

EPA Summary and Response

Use of European publications and fuelly.com dataset

Summary:

Alliance for Automotive Innovation (AAI), Kia, MEMA (The Vehicle Suppliers Associated), Strong PHEV Coalition, and Toyota made the following comments:

AAI: In Europe, some corporations purchased only PHEVs for their fleet to take advantage of government incentives/subsidies. The users of these company cars could typically fuel the vehicle for free, and unfortunately had no incentive to plug-in their vehicle. The situation in Europe with tax incentives encouraging PHEVs coupled with limited charging infrastructure available in predominantly multifamily dwellings is simply not comparable to the United States.

For its U.S. analysis ICCT, inspired by the European analysis, evaluated two data sources: user- reported data from Fuelly.com, and OBD data from the California Bureau of Automotive Repair (BAR). For the Proposed Rule, EPA has taken the ICCT datasets and performed their own analysis, which is essentially a copy of ICCT's work. The PHEV data analysis should include nationwide usage data and be peer-reviewed before it is used in rulemaking.

The data from fuelly.com is user-reported and subject to data entry errors. There is also a potential for data bias in the self-selected participants.

Kia: EPA's analysis is limited to multiple publications from the International Council on Clean Transportation (ICCT). The EPA's use of the ICCT-BAR curve is inappropriate given the expansion of Level 2 charging occurring as EVs increase across the country. The ICCT publications focus on the limited electric driving share of PHEVs in Europe. ICCT's assumptions are skewed as they assume the same situation in Europe where there were unique PHEV tax incentives, coupled with limited charging infrastructure available in multifamily dwellings. All of which are not good comparisons to the United States.

MEMA: The current data is inappropriate because it is primarily non-domestic, selective and ignores the significant changes already underway in infrastructure and vehicle design that enable greater PHEV utility.

Strong PHEV Coalition: The Fuelly.com dataset is wholly inadequate to perform this function. It is a self-selected, self-reported online gasoline consumption log; Fuelly.com is not a survey, makes no claim to statistical representativeness, and does not have inputs or data to electric operation in any way. Methodologically, the means by which ICCT and EPA calculate UF from Fuelly.com data is to compare real-world fuel consumption to EPA rated CS fuel consumption, which is completely incoherent if one realizes that EPA rated fuel consumption and on-road fuel consumption are not the same thing. EPA researchers know better than any the many sources of variance between real-world fuel consumption and EPA -rated fuel consumption. In the ICCT calculation, the variance between these two fuel consumptions (which is strongly correlated with weather conditions, driving conditions, tire inflation, etc.) has entirely and indefensibly been allocated to a lower UF. In both the data and analysis of Fuelly.com fuel logs, EPA and ICCT are using unrepresentative data and deeply inadequate analysis to make policy.

Toyota: The data cited for lower Ufs lack peer review. The studies of PHEVs in Europe are not applicable to the US. Of the UF studies referenced, only Fraunhoffer/ICCT was peer reviewed by a neutral third-party. The proposed FUF relies on two error-filled datasets: Fuelly and CA BAR.

Response:

EPA did not use any European dataset or the fuelly.com dataset to calculate fleet utility factors. Therefore, the literature using European datasets, fuelly.com dataset or fuel consumption data are not applicable to EPA's revised FUF curve and data analysis. EPA provided references to some of the European studies as support that the Agency should review the current PHEV UF values as some researchers may have documented regional behavior which is not captured in their respective compliance procedures. In no way was EPA suggesting that US domestic PHEV operation and activity was identical to Europe or any other countries.

EPA did not use or depend on ICCT's analysis of the FUF curve. FUF data analysis at EPA was performed independently using the November 2023 CARB OBD PHEV dataset versus 2-cycle combined GHG emission-certified CD ranges while ICCT analyzed the 2022 version of CARB OBD dataset versus label CD ranges. Therefore, the two analyses use different data sets and have different data filtering criteria. As is common in any scientific assessment it is often useful and important to compare and contrast other related technical work. In this case, EPA was merely comparing other studies to its only conclusions.

The CARB BAR dataset used by EPA in its analysis is the best large public data set available at this time. Despite multiple stakeholders providing negative comments on the BAR data set, none of the commentors provided alternative datasets to be considered. Independent analyses by EPA, CARB and ICCT found very similar results of UF fitting curve using the real-world CARB OBD PHEV big dataset.

We carefully reviewed the peer-reviewed publications and the recent ICCT paper using U.S. PHEV dataset. All of the UF values in the literature are calculated using the labeled CD ranges which were multiplied by the "0.7" 5-cycle adjustment factors from 2-cycle combined GHG emission-certified CD ranges. There are significant discrepancies when translating the same UF values on 2-cycle combined GHG emission certified CD ranges, which were about 43 percent higher than the labeled CD ranges. When including OEM's voluntary labeled CD range reductions, the FUF values on 2-cycle combined GHG emission-certified CD ranges are not directly related to the MDIUF (Multi-Day Individual Utility Factor) on the labeled CD ranges. Therefore, the UF values on the labeled CD ranges in the literature cannot be directly compared to the FUF values on 2-cycle combined GHG emission-certified CD ranges.

Comments on other datasets

<u>Summary:</u>

Alliance for Automotive Innovation (AAI), California Air Resources Board (CARB), and Toyota made the following comments:

AAI: The proposal excludes several relevant peer-reviewed publications, including papers by Toyota and UC Davis that provide counter-balancing arguments to the claims that the SAE FUF (Fleet Utility Factor) is no longer appropriate. The lack of consideration of other studies, such as these, suggests that further consideration is required.

CARB: CARB contracted with the University of California, Davis (UC Davis) Institute of Transportation Studies to collect and analyze household-level travel and refueling behavior centered around BEVs, PHEVs, and FCEVs. The study included installing data loggers on individual vehicles, including many different models of PHEVs. UC Davis found that all PHEVs, apart from the Chevrolet Volt, demonstrated lower utility factors than the SAE J2841-based FUF curve. The Chevrolet Volt had a much more capable electric powertrain that could keep its internal combustion engine from turning on before the battery depleted in almost all driving conditions, which made the Volt relatively unique amongst the other PHEVs in the logged data set.

Toyota: The data cited for lower Ufs lack peer review. The Toyota/UC Davis paper was excluded.

EPA requests any relevant performance or utility data that may help inform their analyses for the Final Rule. We appreciate the opportunity to share data which will help elevate the role PHEVs in the Final Rule to be an important part of a sustainable transition to electrification. We plan to share such PHEV data outside of the comment period, possibly, including confidential information. For now, we request EPA consider the data we have provided that suggests PHEVs should be considered be an important contributor in whatever assumed PEV sales mix.

Response:

The BAR data is the best available public data set at this time. Despite multiple stakeholders providing negative comments on the BAR data set, none of the commentors provided any other new datasets for consideration and referred only to third party analyses. The BAR dataset comes directly from production vehicles being operated on public roads by private owners. The data is recorded in production vehicles using algorithms and storage techniques derived by the individual vehicle manufacturers. While the data did not come directly from vehicle manufacturers, the data is recorded in accordance with regulations established by the California Air Resources Board and the vehicle manufacturers are under a legal obligation to ensure the quality of the recorded data.

The filtered CARB OBD PHEV dataset has 42 PHEV models and 89 model variants, and approximately 8,600 individual vehicles that travelled approximately 163.2 million miles. This filtered dataset contains approximately 98 percent of the 43 PHEV models and about 8,800 PHEV vehicles from the unfiltered data in the November 2023 version of CARB OBD PHEV public dataset.

In contrast to the CARB OBD PHEV dataset, the UC Davis paper referenced by commenters used a small selection of volunteer vehicle owners to create the dataset used to develop UF values. The data consists of 3 PHEV models and four model variants of 153 PHEV owners (out of 19,000 recruited owners) in the USA. Likewise, the Toyota paper referenced by commenters combined datasets obtained with multiple methodologies. Some of these datasets included only one model; others were based on fuel consumption, from which all-electric mileage was inferred. As the UF is based on travel distance rather than energy usage, the additional steps required to extract a UF from fuel consumption data make the datasets less robust for this purpose.

As noted by CARB, UC Davis also found that all PHEVs, apart from the discontinued Chevrolet Volt, demonstrated lower utility factors than the SAE J2841-based UF curve.

After carefully considering alternative datasets, EPA believes that the CARB OBD PHEV dataset is the most robust dataset for UF analysis available at this time for use in setting the FUF curve. EPA, having reviewed the data in two consecutive years, also believes that the data is a valid representation of how PHEV's are being operated and an appropriate basis for a revised UF curve. In the event that vehicle manufacturers or other stakeholders come forward in the future with additional PHEV data that could be used to inform future evaluations of the FUF, EPA is committed to working with stakeholders in conducting a future evaluation. If such evaluation were to support a proposed revision to the FUF, EPA could initiate a rulemaking to revise the FUF.

EPA acknowledges receiving a presentation from Toyota evaluating the ICCT methodology for determining UF; however, EPA has not received new data pertaining to the FUF curve for consideration. EPA considered the points raised by Toyota in their evaluation of the ICCT methodology, and provides more detailed responses to individual points in other portions of this Chapter.

BAR dataset issues: out-of-state vehicles, low gasoline prices, back-to-back testing, data collection algorithms and technician-entered odometer readings

Summary:

Alliance for Automotive Innovation (AAI), Toyota, and Strong PHEV Coalition made the following comments:

AAI: The data is predominantly from registered MY 2019-2022 PHEVs arriving from another state collected during the 2020 through 2022 calendar years. Long-distance moves between states can involve significant miles accumulated primarily in charge sustaining mode which skews the recorded OBD data, making it unrepresentative of normal PHEV operation.

Most PHEVs in the cited BAR dataset underwent the smog check during 2020 through 2022 calendar years, which includes the COVID pandemic, which significantly altered transportation trends. This period entailed unusual fluctuations in gasoline prices including a 10-year low in 2020 making for both unusual driving patterns and less motivation to charge. We expect that post-pandemic, real-world FUF trends will increase.

Toyota: The BAR data is made up mostly of vehicles that came into CA from out of state, possibly traveling a long-distance with limited access to charging. Also, after reducing the data set to 2,060 from 8,000 many of the PHEV variants studied by EPA have a sample size of 30 or less. Finally, the time period sampled includes the pandemic, when there were low gas prices. Toyota expects UF trends will increase post-pandemic.

Strong PHEV Coalition: There is evidence of systematic importing of used PHEVs into California, a type of data pollution that is not affecting most of the conventional vehicles. For example, a set of vehicles included in the ICCT dataset are six 2019-2020 Toyota Prius Primes. These six Prius Primes are all tested on a single day, they each have 3000 miles, and five of six of them are present in the ICCT analysis (one has a technician-recorded odometer inconsistency). Whatever the history of these vehicles, the fact that 6 of them are being tested back-to-back on the same day is evidence that these vehicles are not under the operation and ownership of the general public, and that their operational history is not representative of the general public. These clusters of similar vehicles undergoing back-to-back testing are common and easily identifiable in the BAR data used for ICCT and EPA analysis. [EPA-HQ-OAR-2022-0829-0646, p. 13]

Prius Prime 1 tested on 02NOV2020:09:00:00.442000

Prius Prime 2 tested on 02NOV2020:10:34:51.141000

Prius Prime 3 tested on 02NOV2020:11:28:26.939000

Prius Prime 4 tested on 02NOV2020:12:14:16.189000

Prius Prime 5 tested on 02NOV2020:12:25:32.846000

Prius Prime 6 tested on 02NOV2020:13:36:16.952000

There is strong evidence that automakers (OEMs) are not implementing the data collection algorithms consistently. For example, all 2019 Chrysler Pacifica hybrid vehicles, transmitted the data required for these calculations from the HPCM-HybridPtCtrl control module, instead of from the ECM*-EngineControl control module which was used by all other OEMs. In reviewing and operating the ICCT's Data Import Algorithm (BAR Data Import.R, shared by A. Isenstadt 5/13/23), these vehicles are excluded from ICCT's analysis. Given that 2019 is the first year that on- board diagnostic technology allows data collection, and we anticipate better data reporting and processing in future years, but the handling of these types of inconsistencies is not in evidence in the ICCT/EPA data wrangling processes.

There is strong evidence of many significant inconsistencies between the technician and OEM-derived data that are present in the BAR data. For example, of the BMW 530e PHEVs in the ICCT dataset (ICCT_OBD_DATASET_MY2019, requested from BAR in April 2023), 585 (of a total 988) of them failed the odometer reading test (that the technician-entered odometer [in mi] is well-outside the OBD-reported odometer reading [converted to mi]). There is no reason why technicians are so comprehensively misreporting this very simple datum for a vehicle that is one of the most reported vehicles in this dataset (which has ~4000 PHEVs in total).

Response:

In response to comments on out-of-state registration, EPA notes that in the BAR dataset, about 79 percent of PHEV vehicles that traveled approximately 140.4 million miles are from in-state ownership transfers, and around 21 percent of PHEV vehicles that traveled around 23.1 million miles are from out-of-state vehicle registrations. The "BAR Regression Fit" in RIA Chapter 3.4.3.2.1 is more influenced by about a factor of six by in-state ownership transfer PHEV vehicles since the FUF values are calculated by a distance-weighted basis. Additionally, there is no reason to expect one-time long-distance moving miles to make up more than a small portion of the 23.1 million miles from out-of-state vehicle registration vehicles.

The averaged FUF values calculated by the regression fit curves of the in-state ownership transfers and out-of-state registrations are within 2.3 percent and -4.8 percent of the averaged FUF values represented by the "BAR Regression Fit" curve when using a minimum sample size of 2. When using larger sample sizes greater than or equal to 10, the averaged FUF values of in-state ownership transfers and out-of-state PHEV vehicle registrations in the filtered model data are within 1.5 percent. As shown in Figure 3-38 in RIA Chapter 3.4.3.2.1, the difference between averaged FUF values calculated using in-state ownership transfers and averaged FUF values calculated using out-of-state registrations are insignificant. In contrast, the averaged FUF values calculated by the "SAE J2841 FUF" fit curve are about 51.4 percent higher than those represented by the best-case regression fit curve of in-state ownership transfers.

In response to comments about low gasoline prices, EPA notes that about 4.7 percent of PHEV vehicles in the BAR dataset, which had traveled approximately 5.6 million miles, are from the period of low gasoline prices (the pandemic period from March 1, 2020, to March 30, 2021). Around 95.3 percent of PHEV vehicles that traveled around 157.6 million miles are from the normal gasoline price period (mostly pre- and post-pandemic). The distance weighted "BAR Regression Fit" curve in RIA Chapter 3.4.3.2.2 is more significantly affected by about a factor of

28 by the higher total distance travelled when gasoline prices (U.S. EIA 2023) were normal. Furthermore, the averaged FUF values calculated by the regression fit curves of the normal gasoline price period and the low gasoline price period are within 0.1 percent and -8.1 percent of the averaged FUF values represented by the "BAR Regression Fit" curve when using a minimum sample size of 2. When using larger sample sizes greater than or equal to 10, the averaged FUF values of the normal gasoline prices and the low gasoline prices in the filtered model data are within 1.6 percent. The averaged FUF values predicted by the "SAE J2841 FUF" curve are still approximately 54.7-percent higher than those represented by the best-case regression fit curve at normal gasoline prices.

In response to comments about back-to-back testing, EPA notes that the UF represents an average of all PHEV operation. There is no indication that the small number of vehicles referenced by the commenter are operated in a way that is being over-represented in the dataset. The six vehicles mentioned by the Coalition have an average FUF of 0.40, which is in fact somewhat higher than the approximately 0.25 average FUF of the Prius Prime PHEVs in the November 2023 version of CARB OBD PHEV dataset. The "Prius Prime 4" and "Prius Prime 6" mentioned by the Coalition were filtered out by 3000-km minimum ICCT filter. EPA believes that the CARB BAR dataset used by EPA in its analysis is the best large public data set available at this time.

In response to comments about data collection, EPA notes that CARB OBD requirements mandate that the vehicle, as a whole, supports and reports the required data. CARB does not dictate that a particular ECU has to have the data or that it all has to come from one ECU.

CARB filtered the updated the November 2023 version of CARB OBD dataset to include only PHEV vehicles, and to exclude vehicles with less than 3,000 miles of total lifetime distance traveled. Also, vehicles that CARB identified as having incorrectly logged data in the lifetime distance OBD data fields used for this analysis were excluded. Excluded vehicles included the Chrysler Pacifica referenced by the Strong PHEV Coalition. However, EPA calculated the FUF values of Pacifica using PHEV data from separated ECU in the October 2022 version of CARB OBD dataset.

In response to comments on odometer readings, EPA notes that the odometer reading data field was not used for filtering the updated November 2023 version of CARB OBD dataset. EPA concluded that a mismatch between the technician-recorded odometer reading and the OBD data was not indicative of any issue with our use of the OBD lifetime distance traveled data fields for calculating FUF.

BAR dataset: data filtering

<u>Summary:</u>

Alliance for Automotive Innovation (AAI), Mitsubishi Motors North America, Inc. (MMNA), and Toyota made the following comments:

AAI: Given that EPA accepted PHEVs with as low as 1,865 lifetime miles from the BAR dataset, even a few hundred miles without charging can bias the data toward a lower utility factor.

In the DRIA, EPA notes, "As of October 2022, the BAR OBD dataset has around 8,400 PHEV vehicles, and over 233.2 million vehicle miles traveled. The filtered dataset has 30 PHEV models, and 2,060 individual vehicles that travelled 58.9 million miles." While some filtering of data to exclude outliers is expected, removing approximately 75% of the vehicles and vehicle mileage is not.

MMNA: The BAR data is a collection of PHEV data from MY19 through MY22 vehicles. The data was then filtered to remove any vehicles that show inconsistent data regarding distance traveled and grid energy utilization. While filtering of incomplete or inconsistent data is a typical operation in data analysis, the results of the analysis can be substantially altered based on the filters applied. We believe the filtering methods used by EPA filtered out too many vehicles. For example, the grid energy in/out filter completely removes one of the highest utility factor vehicle models4 from the entire data set. Whether such filtering was necessary for that vehicle is questionable. At the same time, it may be necessary to apply alternative filters. Due to the time constraints of this comment period, Mitsubishi was unable to fully evaluate the filtering methods EPA used in its analysis, but we may still provide feedback to EPA after the comment period. We ask EPA to provide additional information about the filters applied, and the effect those filters have on the overall utility factor analysis.

Toyota: The proposal explains that despite relaxing the data quality criteria to accept up to 20 percent mileage error and vehicles with as low as 1,865 lifetime miles, only 2,060 out of more than 8,000 vehicles were retained from the BAR dataset. As a result, many of the PHEV variants studied by EPA have a sample size of 30 vehicles or less.

<u>Response:</u>

CARB filtered the November 2023 CARB BAR OBD dataset to include only PHEV vehicles, and to exclude vehicles with less than 3,000 miles of total lifetime distance traveled. Also, vehicles that CARB identified as having incorrectly logged data in the lifetime distance OBD data fields used for this analysis were excluded. Only a few data points like the "missing" and the "Z" rows in the "INSPECTIONREASON" data field were filtered out in EPA. The detailed "Descriptions of Data Source and Filtering Method" and the "Influence of Data Filtering" are presented in RIA Chapters 3.4.2 and 3.4.3.

The November 2023 "CARB BAR OBD PHEV" dataset used for the finalized FUF curve contains approximately 8,800 PHEV vehicles from 43 PHEV models with 90 PHEV model variants, and over 169.4 million vehicle miles traveled. The filtered dataset used in the RIA Chapter 3.4.2.1 removes only about 2 percent of the vehicles. This final filtered dataset contains approximately 8,600 individual vehicles from 42 PHEV models and 89 model variants, and approximately 163.2 million miles travelled.

Similar findings and conclusions are observed by independent studies from EPA, CARB and ICCT.

BAR dataset: statistical validity

<u>Summary:</u>

Alliance for Automotive Innovation (AAI), Strong PHEV Coalition, and Toyota made the following comments:

AAI: Many of the PHEV variants studied by EPA have a sample size of 30 vehicles, which is statistically insignificant to draw conclusions about real-world PHEV operation.

Strong PHEV Coalition: We strongly recommend against using the California Bureau of Automotive Repair (BAR) data and Fuelly.com data as the basis for a new FUF for PHEVs. The Technical Committee of the Strong PHEV Coalition includes researchers who have been engaged with development and evaluation of UF calculations for more than 20 years. We are very familiar with the set of datasets that are available in the public and private domain for UF evaluation and have researched the datasets and authored many of the studies referenced in the Draft Regulatory Impact Analysis (DRIA). Our assessment and recommendations in response to the request for input on UF data in the DRIA is that the proposed changes to UF are based on a very poor dataset, poor analysis, and statistically indefensible methods. These datasets and methods are inadequate to inform policy of the importance and impact of EPA's emissions standards. See Appendix A for our critique of the BAR and Fuelly.com data sets.

Our assessment and recommendations in response to the request for input on UF data in the DRIA is that the proposed changes to UF are based on a very poor dataset, poor analysis, and statistically indefensible methods. These datasets and methods are inadequate to inform policy of the importance and impact of EPA's emissions standards.

Individual vehicle-level UFs that are derived from an updated data pull from BAR are extremely scattered and do not illustrate the validity of the UF curves for either the SAE J2841 FUF or the proposed FUF. When EPA or ICCT perform least-squares regression to derive a particular UF curve, they must calculate the confidence interval around the parameter estimates. When we perform that regression with vehicle models' pooled averages, we find that this dataset provides no evidence that the EPA FUF model is more representative than the SAEJ2841 model.

An examination of four models illustrates the wide dispersion of measured individual UFs and shows that the 95% confidence intervals on the mean value may or may not encompass any particular pre- derived response curve.

Toyota: EPA's attempts to manage the rampant errors in the BAR dataset renders it statistically insignificant for an analysis of normal PHEV usage. The proposal explains that despite relaxing the data quality criteria to accept up to 20 percent mileage error29 and vehicles with as low as 1,865 lifetime miles, only 2,060 out of more than 8,000 vehicles were retained from the BAR dataset. As a result, many of the PHEV variants studied by EPA have a sample size of 30 vehicles or less as seen in the legend on the right in Figure 14 below. The cleaned BAR dataset Excel file shared by EPA in the docket also confirms the inadequate sample size.30 Because EPA accepted very low-mileage PHEVs for their supporting analysis, even a few hundred miles without charging can bias the results to a lower Utility Factor.

Response:

The November 2023 CARB BAR OBD PHEV dataset used for the finalized FUF curve contains approximately 8,800 PHEV vehicles from 43 PHEV models with 90 PHEV model variants, and over 169.4 million vehicle miles traveled. The filtered dataset used in the RIA Chapter 3.4.2.1 removes only about 2 percent of the vehicles. This final filtered dataset contains approximately 8,600 individual vehicles from 42 PHEV models and 89 model variants, and approximately 163.2 million miles travelled.

EPA disagrees with the commenters' assessment of the statistical validity of our FUF analysis. In particular, the FUF curve represents the average usage of the fleet as a whole rather than individual vehicles. A scattering of individual vehicle-level UFs is to be expected. EPA also disagrees with the comment that the "UF are based on a very poor dataset". The BAR dataset comes directly from production vehicles being operated on public roads by private owners. The data is recorded in production vehicles using algorithms and storage techniques derived by the individual vehicle manufacturers. While the data did not come directly from vehicle manufacturers, the data is recorded in accordance with regulations established by the California Air Resources Board and the vehicle manufacturers are under a legal obligation to ensure the quality of the recorded data.

EPA has expanded the statistical analysis of all of the available data to address some of the technical concerns raised in comments. EPA has done a statistical check on the November 2023 version of CARB OBD PHEV dataset EPA used and found it to be statically significant as shown in RIA Chapter 3.4.3.3. In their statistical analysis, the Strong PHEV Coalition appears to be using does vehicle-weighted individual UF (MDIUF) values, rather than the distance-weighted FUF values used for GHG emission certifications. The vehicle-weighted individual UF (MDIUF) values used by the Strong PHEV Coalition are used for CAFE (Corporate Average Fuel Economy) standards compliance and labeling the all-electric ranges and CD ranges of PHEV vehicle stickers and not for GHG emission certifications.

Curve Fitting Comments

<u>Summary:</u>

Alliance for Automotive Innovation (AAI) and Toyota made the following comments:

AAI: Utility factors have been fitted to an exponential equation. The C coefficients are used to fit the curve and normalized distance establishes the distance where the utility factor is 100%. But Normalized Distance (ND) is the one variable in the equation that need not change. Changing normalized distance doesn't make sense unless overall driving distances have changed.

Using this curve fitting technique, the result is that regardless of all-electric miles traveled on a certification test, only 68.5% of those miles count. This is equally true for PHEVs that travel 20 miles or 200 miles. This is not appropriate, and the proposed utility factor should not be included in the final regulation.

EPA's linear curve fit is weighted toward vehicles with a range below 30 miles. Changing the utility factor based on such skewed data would discourage the introduction of new, higher-capability PHEVs.

Toyota: EPA's linear curve fit is weighted towards vehicles with a range below 30miles.

The proposed FUF curve that results from EPA's analysis is calculated as the average of the SAE J2841 FUF curve and the ICCT-BAR curve. The only difference between the SAE curve and the proposed curve is the Normalized Distance (ND) increasing from 399.9 miles to 583 miles. All other terms in the proposed revised equation to the right of Table are the same.

The proposed ND adjustment amounts to discounting the advertised electric range of every PHEV by about 32 percent for compliance calculations because increasing the normalized distance has the same effect as lowering the CD range.

Response:

The "BAR Regression Fit" shown in Figure 3-46 of RIA Chapter 3.4.3.2.5, contains about 8,600 valid PHEV data points from the November 2023 BAR OBD dataset fitted using nonlinear 6-fitting coefficients. The dataset contains multiple vehicles with ranges above 30 miles to 180-miles. EPA believes the "BAR Regression Fit" line shown in the figure accurately represents performance of vehicles both above and below 30 miles range.

Five hundred eighty-three (583)-mile normalized distances in the "FUF Finalized (FRM)" of Table 3-23 in RIA Chapter 3.4.3.2.5 were calculated by the minimization of the sum of the squared residual norm in Equation 3-2 when using SAE J2841 FUF fitting coefficients. The "FUF Illustrative Final" curve, which is created using 6-new curve fitting coefficients and 399.9-mile normalized distances in the "FUF Illustrative Final, using SAE Normalized Distance" of Table 3-23, lies on top of the "FUF Finalized" curve in Figure 3-46 of RIA Chapter 3.4.3.2.5. Therefore, the same FUF fitting curve can be developed using either a new ND and current SAE J2841 FUF fitting coefficients or 399.9-mile SAE Normalized Distance and new 6-fitting coefficients.

With respect to the suggestion that the changes will discourage the introduction of new, higher-capability PHEVs, our goal with the finalized FUF curve is to appropriately characterize the actual charge depleting share of driving distance for PHEVs in the rulemaking timeframe, rather than incentivizing PHEVs with certain ranges. However, our finalized FUF curve already provides an incentive for more capable PHEVs, based on operational data, with continuously higher FUF values for vehicles with greater charge depleting range.

Comments on the Effect of Future Charging Availability, PHEV Capability, and Incentives on FUF

Summary:

Alliance for Automotive Innovation (AAI), BorgWarner, Stellantis, MECA Clean Mobility (MECA), MEMA, Mitsubishi Motors North America, Inc. (MMNA), Strong PHEV Coalition, Toyota, Porsche, VW, and Kia made the following comments:

AAI: The BAR dataset and more rigorous, peer-reviewed studies indicate some PHEVs have a lower ratio of EV driving versus ICE operation on-road versus certification, while other vehicles' performance is well-aligned to certification values. We believe this difference is due to the spread of performance capability of the electric machines in PHEVs. Lower capability electric machines demonstrate a greater difference in on-road versus on-cycle performance.

EPA's proposed PHEV high power cold start requirement encourages more all-electric operation capability. Further, CARB requires a minimum 70-mile combined city/highway and minimum 40-mile US06 all-electric range starting with MY 2029.

Lack of charging, to the extent it exists, should be best solved by consumer education, not by a change to the utility factor.

While some data may suggest PHEVs are not being plugged in as frequently as the assumptions underlying the SAE UF curve, this should not be a problem attributed to automakers, nor should it be grounds to adjust a compliance measurement. Charging equipment is supplied with the vehicles sold by automakers.

BorgWarner: To meet many of the requirements set by both EPA in this proposal and California in its Advanced Clean Car II rulemaking, PHEVs would have significantly increased electric range that make them more capable of all-electric operation, and together with a much-improved charging infrastructure, will change the pattern of consumer use. In fact, average new PHEV driving range increased 8.5% in 2021 and is expected to continue increasing. As such, EPA should model future consumer usage based on the expected models on sale from MY 2027, and further improvements to charging availability, and use the model to determine the utility factor curve that should apply.

Stellantis: The two issues that can lead to shortfalls in PHEV electric operation usage are (1) lack of charging and (2) differences in performance between regulated cycles and on-road operation. We believe charging rates will improve as more public infrastructure emerges and charging becomes ubiquitous. As for capability concerns, CARB is requiring a 70-mile combined cycle minimum range and a high-power cold start requirement (that EPA also proposes to adopt in this rule). These two requirements will force future PHEVs to have more range and power in all-electric operation, thus eliminating or minimizing any performance differences on-road versus regulated cycles.

MECA: This in combination with build out of charging infrastructure, especially from Inflation Reduction Act and Infrastructure Investment and Jobs Act funding sources, will provide consumers with easier access to charge PHEVs and enable them to drive more miles on electricity rather than petroleum. The result will be that future fleet utility factors will increase rather than decrease. MECA suggests that EPA consider these developments, including studying the correlation between fleet utility factor and workplace charger availability, and not base utility factors on older PHEV technology.

MEMA: While California is an admirable leader in ZEV deployment, its incentive structure for PHEV purchases differs from the rest of the country; a large percentage of population resides in multi-unit dwellings (often without consistent overnight charging access), and it ranked (as of last year) behind at least 15 other U.S. states in terms of charging ports per EV, signifying a potential problem of constrained charging access that needs further examination.

MMNA: In addition to CARB's intention to increase ZEV capability through PHEV technical requirements, the approach vehicle owners take to PHEV operation may change. Consumer education and increased available of charging infrastructure will make it easier for PHEV owners to charge vehicles when convenient, and thus more likely that they will do so on a more regular basis.

Strong PHEV Coalition: We have also seen that the FUFs of vehicle models in the BAR dataset are changing as a function of time. For example, BMW X5 XDRIVE45E vehicles (MY 2019-2022) that meet the ICCT/EPA filtering criteria tested before 17 May 2022 have an average individual UF of 30%. X5 XDRIVE45E vehicles (MY 2021-2023) that meet the ICCT/EPA filtering criteria tested after 17 May 2022 have an average individual UF of 68%. These types of problems with the BAR dataset seem to be unrecognized and not validated by the research community, and further strengthen the case for not using the BAR dataset for research or policy making.

Toyota: The proposal heavily relies on the BEV technology improvements and charging infrastructure expansion to justify the standards. Those same improvements will also benefit PHEVs, since home charging, consumers awareness, and technology advancements will drive PHEV utilization closer to that of pure BEVs as consumers place greater emphasis on achieving advertised range and have greater desire and means to achieve it.

Existing regulation will also help spread the deployment of more capable PHEV designs that perform closer to their advertised all-electric range. ACC2 and EPA's proposed high-power cold start requirement will result in more all-electric capability. Recommend that EPA request SAE establish a consortium to evaluate PHEV usage trends.

Porsche: Porsche does not support the proposed reduction in the PHEV utility factor. EPA's proposal devalues future PHEV performance based on historic charging behavior of existing on-road PHEV drivers. Porsche has not reviewed the details of the California BAR or fuelly.com data but can understand if in some cases consumer use of electric drive has been lower than expected. This is not surprising given the well-documented challenges and complaints related to the general lack of public charging infrastructure in the past few years. Besides challenges within finding reliable public charging, many consumers have faced difficulties in installing home charging, especially for multifamily and rental dwellers, and have complained about the general lack of workplace charging. However, the entire foundation of this MPR and the dramatic shift towards electrification rests upon assumptions regarding improvements in electric vehicles and more specifically in the availability and reliability of public and private electric vehicle charging. Issues that past owners of PHEVs may have experienced that likely led to the examples of lower-than-expected usage of electric drive would be addressed according to EPA's assumptions on improved charging. As such, the decision to alter the utility factor for future PHEVs should not focus on decreasing the utility factor due to challenges customers experienced in the past, but rather should maintain the existing utility factor based on improved usage of charging in 2027 and later given EPA's projections for rapidly expanding charging infrastructure.

It is nonsensical that future PHEV drivers would continue to pass up on charging opportunities once charging is more ubiquitous in the public, at home and at work. In fact, this would be counter to EPA's assumed consumer valuation of fuel savings that has been consistently referred to in GHG rulemakings. If consumers value fuel savings, and if charging availability is no longer a barrier to usage, EPA would have to assume that PHEV drivers would naturally seek to maximize their usage of electric drive if the cost per mile to drive electric is less than that of gasoline. If for some reason drivers continued to avoid using electric operation, then EPA would have to reevaluate the entire premise of consumer demanded fuel savings. As charging resources increase, utility factor should increase along with it, not go down.

VW: In addition to the conditions discussed by AFAI (e.g., charging infrastructure, driving behavior, customer use education, etc.), Volkswagen believes that PHEV ownership is influenced by current Federal and State purchasing incentives and the environmental benefits may be a secondary or tertiary reason for the purchase of a PHEV over the ICE vehicle alternative. The DoE Alternative Fuels Data Center shows 398 incentives for personal vehicle owner for PHEVs. In addition, the FUF should take into account future driving behavior where PHEVs attain a higher range for ZEV-qualifying PHEVs.

Kia: If EPA feels strongly that the real-world fleet utility factor is too low, Kia recommends that EPA work with industry to help incentivize reminders for consumers to plug in more often.

Response:

EPA's task in this rulemaking is to evaluate the expected use of the secondary fuel used on these dual fuel vehicles and properly give credit much like EPA does when assigning the F-factor for E85 Vehicles. After careful consideration of the available data, EPA finds that the SAE-based FUF is assigning lower CO_2 emissions for PHEV compliance calculations than are being realized in in-use data.

However, EPA recognizes that PHEV owners' propensity to recharge the battery may change in the future for multiple reasons, including those described by commenters. As discussed in the preamble Section III.C.8, we are delaying the application of the revised FUF until MY 2031 to provide additional lead time for manufacturers, including consideration of the availability of future charging infrastructure and vehicle manufacturers influence on improving PHEV owners' propensity to charge. We consider the final FUF to be a reasonable FUF for model years beginning 2031. As noted in the preamble and in RIA Chapter 3.4.1, if vehicle manufacturers or other stakeholders come forward in the future with additional PHEV data that could be used to inform future evaluations of the FUF, EPA is committed to working with stakeholders in conducting a future evaluation.

In response to comments on the FUFs of the BMW X5 XDRIVE45E vehicles, EPA calculated the FUFs for vehicles tested before and after 17 May 2022 as indicated by the Strong PHEV Coalition, using the November 2023 CARB OBD dataset. The calculated FUF values are 0.32 for vehicles tested before 17 May 2022 and 0.39 for vehicles tested after 17 May 2022. These are both substantially lower than 0.65 FUFs calculated by SAE J2841 standard certified at 2-cycle combined CD ranges.

EPA further notes that PHEV GHG emissions are certified using fleet utility factors (FUF) over 2-cycle combined CD ranges. Strong PHEV Coalition appears to be using the individual UFs (MDIUF) over the label CD range. These are used for CAFE (Corporate Average Fuel Economy) standards compliance and labeling the all-electric ranges and CD ranges of PHEV vehicle stickers, but not for GHG compliance purposes.

Comments recommending a lower FUF curve

Summary:

California Air Resources Board (CARB), Environmental Defense Fund (EDF), Environmental. And Public Health Organizations, International Council on Clean Transportation (ICCT), National Association of Clean Air Agencies (NACAA), Southern Environmental Law Center (SELC), Zero Emission Transportation Association (ZETA), Tesla, Inc and Rivian Automotive, LLC made the following comments.

CARB: In its proposal, U.S. EPA proposes a revised FUF curve that is lower than the SAE J2841 FUF curve. Based on an analysis of additional real-world data, summarized below, CARB finds that the ICCT-BAR curve is even closer to what real-world data supports for eVMT. CARB therefore recommends that U.S. EPA adopt the ICCT-BAR curve.

Environmental Defense Fund (EDF): The data compiled by ICCT from real- world sources represent the best estimate of actual PHEV utilization and should be the primary source for EPA's UF curves. Meanwhile, California's treatment of PHEVs under the ACC II program is far more conservative, resulting in lower utility factors than EPA. ACC II allows PHEVs to "fulfill a portion of their total Annual ZEV Requirement" if they meet several qualifications. A PHEV must have a "minimum certification range value of greater than or equal to 70 miles," based on California's 2026 ZEV and PHEV test procedures and have a minimum US06 all-electric range value greater than or equal to 40 miles to be considered a ZEV under the rules. PHEVs that don't meet these requirements can still be counted for partial credit if they have a minimum certification range value between 43 and 70 miles or have a US06 all-electric range of at least 10 miles. Additionally, PHEVs can only be used to meet 20 percent of a manufacturer's total ZEV requirement.

A recent ICCT study examined the current state of PHEV usage in the United States and found strong evidence that real-world electric drive share is far below EPA's current utility factor label rating. According to ICCT, "previous research and data from early adopters of PHEVs in the United States demonstrated that PHEVs achieved real-world electric drive share close to that expected by the U.S. Environmental Protection Agency (EPA) and National Highway Traffic Safety Administration (NHTSA)." ICCT notes that EPA assumes that PHEVs achieve real-world electric drive share close to EPA's utility factor label rating in its treatment of PHEVs in the 2023-2026 light-duty GHG rule.

Environmental. And Public Health Organizations: The BAR data show the Honda Clarity PHEV as having a real-world utility factor of 0.359 while the SAE 2841 method gives the Clarity a FUF of 0.676. These results show that the SAE2841 method using travel survey data is a poor estimator of actual vehicle usage. The Agency proposes to reduce the FUF for compliance calculations by averaging the current FUF with a curve derived from the BAR real-world data. This averaging will lower the gap between actual emissions performance and the compliance value, but will still allow for compliance values for PHEVs that are higher than justified. Given that EPA now has clear real-world data showing that the current FUF is not reflective of actual emissions from PHEVs, it is inappropriate to use the original SAE J2841 FUF or to use it in an average with other data. EPA should instead use a FUF consistent with the actual in-use data from BAR and adopt the FUF labeled "ICCT-BAR" in the DRIA.

The decision to average real-world usage data with the SAE 2841 estimate is poorly justified. EPA states that "an overly low FUF curve could disincentivize manufacturers to apply this technology. However, both the current FUF curve and the proposed curve over-credit PHEVs. A curve that correctly credits PHEVs' reductions in emissions (such as the ICCT-BAR curve) will not disincentivize adoption of PHEVs, but instead will provide a lower incentive for the partial elimination of tailpipe emissions and a greater incentive for complete elimination via fully-electric powertrain options. Even with a lower FUF, the ability to reduce the compliance emissions values by use of zero grams per mile for the CD mode phase will provide a significant incentive for a manufacturer to choose a PHEV powertrain over a non-plug-in hybrid. Choice of a lower FUF curve will at the same time ensure that there is a sufficient incentive to encourage the continued development and deployment of zero-emission technologies.

EPA also cites future models with longer electric range and greater all-electric performance as leading to future real-world performance that meets the proposed FUF curve. This is not supported by the available data. The longest electric range PHEV currently available is the Toyota RAV4 Prime. The RAV4 Prime data from the BAR dataset show a real-world utility factor of 0.35, significantly lower than the proposed FUF for a 42-mile all-electric range (AER) vehicle (0.52) and even lower than the ICCT-BAR curve (0.41). EPA states that "increased consumer technology familiarity" will also make future PHEV usage approach the proposed FUF curve. 88 Fed. Reg. at 29254. Increased consumer knowledge may make purchasers able to shift more driving to electric-only mode. However, it is also possible that purchasers (especially in the secondary market) may buy a PHEV without the ability to plug in or may choose a PHEV because of incentives that make the purchase more attractive relative to a non-plug-in vehicle. Existing research on the use of PHEVs shows that the largest factor leading to lower real-world observed utility factors is lack of charging, with 20-30% of some PHEV models starting their travel day on a nearly empty battery.

The proposed FUF could lead to PHEVs with a large difference between real-world emissions and the compliance values for CO2 emissions. The use of PHEV powertrains in larger vehicles such as SUVs and pickups will cause this gap to grow, due to the gap between the zero grams per mile CD operation and the high gram per mile operation when the internal combustion engine is running. Over-crediting PHEVs' purported electric driving would create a new and unjustified loophole that would likely slow down the path to greater deployment of zero-emission technologies within the fleet. For example, for a PHEV that has compliance CO2 charge sustaining (CS) mode emissions of 250 g/mile and an electric range of greater than 28 miles, the proposed FUF would artificially reduce the combined mode PHEV emissions by over 25 g/mile when compared to the ICCT-BAR FUF. (Figure XII.1). The gap between the proposed FUF and the real-world data (ICCT-BAR) is highest for vehicles with a CD range between 42 and 62 miles. California's ZEV regulations for model year 2029 and subsequent vehicles require a minimum certification electric range of 70 miles to be eligible for credit values, which is approximately a 50-mile label range. Therefore, PHEVs designed to meet the minimum range for ZEV credit value eligibility are likely to have the largest deviations between real-world emissions and the compliance emissions calculated using the proposed FUF.

ICCT: ICCT applauds EPA for adjusting the PHEV utility factor (UF) curve to better fit real-world PHEV usage data. As the PHEV models available for purchase today differ in operation and all-electric utility from when the original UF curve was developed, this update is direly need (ICCT 2022 PHEV). Due to the growing repository of public, real-world PHEV data, ICCT recommends EPA adjust the proposed fleet utility factor (FUF) curve to reflect the best-available data, while allowing for potential updates to the curve based on more real-world data as it accumulates.

In DRIA figure 3-29, EPA's analysis of the California Bureau of Automotive Repair (BAR) PHEV data clearly shows that a reduced UF curve is a better fit of the real-world data. This fit matches ICCT's non-linear regression fit of the BAR data. Utilizing the same methodology described in ICCT 2022 PHEV but with EPA's proposed FUF coefficients (Preamble 29442), ICCT finds the appropriate normalized distance to be 802 miles (vs proposed 583 miles). This curve more accurately reflects the current state of PHEV usage. Thus, ICCT recommends that EPA adopt a normalized distance of 802 miles, instead of 583 miles as proposed.

Within the timeframe of the proposed rule EPA expects PHEVs with longer all-electric range to become available (in part due to California's ACCII PHEV performance requirements), and

EPA seeks to avoid disincentivizing PHEVs with a too low FUF curve (Preamble 29254). For these reasons, EPA proposed a FUF curve higher than what the BAR data supports. This argument puts the expectation of future PHEV performance ahead of the data.

NACAA: We concur with EPA's conclusion that the current LDV PHEV compliance methodology overstates the operation of PHEVs on electricity thereby significantly underestimating PHEV CO2 gm/mi compliance results. Therefore, NACAA commends EPA for proposing to reduce the PHEV Fleet Utility Factor (FUF) curve used in the CO2 compliance calculation for PHEVs beginning in MY 2027 but recommends that the FUF curve be even lower than proposed.

ZETA: supports the proposed changes to the PHEV fleet utility factor (FUF) to more accurately apportion the benefit of PHEVs' electric operation. Ensuring accurate compliance calculations is critical to preserving programmatic integrity and reducing emissions. As EPA notes, SAE J2841 was developed more than ten years ago during the early introduction of light-duty PHEVs and at the time was a reasonable approach. However, with the benefit of more real world data and information about actual vehicle operating characteristics, we support EPA revisiting the FUF curve at this time.

SELC: Studies have shown, however, that the current FUF overestimates the operation of PHEVs on electricity. As a result, "the current light- duty vehicle PHEV compliance methodology significantly underestimates PHEV CO2 emissions." We therefore support EPA's proposal to revise the FUF curve used in CO2 compliance calculations for PHEVs beginning in model year 2027 and urge EPA to consider a FUF curve that is even lower than the current proposal.

Tesla: Tesla asserts the EPA should revisit the plug-in hybrid electric vehicle (PHEV) utility factor to accurately reflect real world emissions.

Nevertheless, EPA is appropriately revisiting the PHEV Fleet Utility Factor because PHEV compliance to date has significantly underestimated CO2 emissions by overestimating their use of electricity. Reducing the PHEV utility factor is appropriate and overdue.

Rivian: Rivian applauds EPA's decision to revise the FUF for PHEVs. We agree with the agency that the current compliance methodology "significantly underestimates PHEV CO2 emissions." As the agency details in its analysis, and as Rivian has commented in the past, PHEVs exhibit significant variability in their environmental performance. In the United States, PHEVs drive fewer electric miles than assumed for labeling purposes, with fuel consumption as much as two-thirds higher than nominally anticipated. Simply put, PHEV drivers often do not plug in their vehicles as much as was previously assumed.

The FUF remains important for calculating PHEV emissions for regulatory compliance, but the weight of the evidence clearly compels EPA to revise the curve. The initial proposal marks a significant improvement over the status quo, but onboard diagnostic data from California support an even lower FUF. EPA rightly acknowledges this in the Draft Regulatory Impact Analysis ("DRIA"). Nonetheless, EPA proposes a higher curve. The agency's justification rests on speculation that future PHEVs could deliver greater all-electric performance as well as stated concerns that an accurate FUF would "disincentivize" PHEV development. If PHEVs fall short of their environmental promise, the technology does not merit an artificially inflated regulatory incentive regardless of its potential. Far from an unfair disincentive, an accurate FUF would ensure that the regulation works as intended—achieving reliable, real-world emissions reductions. To safeguard the regulation's environmental integrity, Rivian encourages EPA to finalize a FUF that accurately reflects the best available data from real-world driving behavior.

Response:

As discussed in preamble III.C.8, although we believe the data on current PHEV activity supports further revisions to the utility factor, EPA is setting a FUF for future model years based on our expectations about charging and PHEV performance that will occur in those future years. We are also taking into consideration the likelihood that the improvements automakers anticipate in product design (such as range), consumer education and awareness, and charging convenience with expanded infrastructure will result in PHEV activity that is similar to the finalized FUF. In light of manufacturer plans to improve PHEV technology and the potential for improved customer knowledge and infrastructure, EPA is finalizing the PHEV utility factor as proposed.

At the same time, EPA is committed to an ongoing evaluation of future PHEV FUF data to assess whether the revised FUF is in fact adequately representative of future PHEV operation, as a result of future PHEV designs and consumer charging behavior, or if there is merit in further adjusting the FUF. EPA encourages researchers and other stakeholders, including manufacturers, to supplement the publicly available data by providing data directly to EPA for inclusion in an updated analysis. EPA will engage with stakeholders to share results of our assessments, and to hear from stakeholders who may have their own data and analysis to share, for example, through public forums. If EPA determines that changes to the FUF are warranted, we will engage with stakeholders on technical details such as the shape of the FUF curve and the appropriate timing for its implementation. If such evaluation were to support a proposed revision to the FUF, EPA could initiate a future rulemaking to revise the FUF for MY 2031.

Comments recommending a higher FUF curve; timing and compliance effects

Summary:

Ford, Jaguar Land Rover NA, LLC (JLR), Kia Corporation, MECA Clean Mobility, MEMA, The Vehicle Suppliers Associated, Mitsubishi Motors North America, Inc. (MMNA), Stellantis, Toyota, Porsche Cars North America (PCNA), and Volkswagen Group of America, Inc (VW) made the following comments.

Ford: does not support the proposed update to the Plug-In Hybrid (PHEV) utility factor (UF). We do not believe it is appropriate to recalibrate the PHEV compliance benefit at the same time the EPA is proposing other sweeping changes and historically stringent standards. Product planning lead time and uncertainty in EV market growth requires that all electrification options be available with stable and predictable compliance benefits. Ford would support an EPA program designed to gather additional data for use in a future rulemaking which would yield a robust basis for a UF update and prevent disruption to EV product compliance plans.

JLR: JLR would like to highlight our concerns over EPA's plans to incorporate PHEVs into their analysis for the final rule. If EPA proceeds with the planned changes to the certified PHEV CO_2 value, namely through the adjustment of the utility factor, they must acknowledge the impact this will have on fleet compliance, greatly reducing their contribution to the fleet. As such, the baseline GHG target and projected ZEV share should also be adjusted by an equal amount, to avoid an increase in target stringency by stealth.

Kia: Kia does not support the assumptions on PHEVs outlined in the NPRM. EPA explains that its current PHEV compliance methodology significantly underestimates PHEV CO2 emissions. Consequently, EPA proposes to revise the light vehicle PHEV Fleet Utility Factor (FUF) curve downward to reflect as assumed PHEVs lower electric operation beginning in MY2027. EPA’s proposal essentially lowers the benefits of PHEVs for compliance which will reduce consumer choice and make feasibility of the standards much more challenging.

MECA: Similar to previous EPA technology analyses prepared to support future rulemakings, MECA requests that EPA conduct a prospective analysis of utility factors of PHEVs based on the direction of the technologies being released into the marketplace today as well as announcements of future releases. Of particular note, EPA relied upon past data of older technology PHEVs with limited all electric ranges to justify the proposed reduction in the PHEV utility factors from today’s acceptable values that are based on SAE J2841.

MEMA: EPA to maintain previous PHEV utility factor or conduct U.S.-based study and forecast to replace current PHEV utilization data and recalculate PHEV utility factor.

MMNA: Maintain the current PHEV Utility Factor (UF) and work with industry to identify opportunities to increase PHEV electric operation. This is the ideal stepping-stone technology to encourage long-term BEV acceptance and utilization.

Stellantis recommends keeping the current UF for the final rule. The combined impact of the proposed changes described above compound the stringency of an already aggressive target makes the overall “net effect” of what EPA is proposing infeasible – especially in the initial year of the program.

Toyota: EPA’s proposed UF discriminates against PHEVs based on flawed data and analysis from and environmental NGO. PHEVs should be encouraged, rather than discouraged by these regulations. Toyota plans to provide PHEV data outside of comment period. The data cited for lower Ufs lack peer review.

Porsche: EPA acknowledges uncertainty regarding future charging usage by stating that the agency could revisit the utility factor once again in a future rulemaking if it appears that PHEVs are using more electric operation due to improved vehicle technology and greater charging infrastructure. However, undercutting PHEVs in this rulemaking, only to increase the value of PHEVs in a future rulemaking creates too much uncertainty. If EPA expects the charging environment to improve, why reduce the assumed driving usage now only to increase it again later? This back-and-forth uncertainty on utility factor would not be helpful since the current proposal would so undercut the incentive for PHEVs that manufacturers would have likely reconsidered continued support for the technology. If the agency is concerned about the actual real-world usage of PHEV electric operation, it seems that the approach would be to work with stakeholders to improve the charging experience today while the charging infrastructure is expanding over the next few years. “Fixing” the issue by undercutting the technology in regulation neither improves the technology, nor helps address charging challenges customers are facing.

VW: Volkswagen acknowledges there are ongoing discussions in the U.S. and Europe to modify the FUF. Both regions are comparing the current FUF with newly collected real world data. Europe is updating its FUF on 01/01/2028, where the methodology defined in the legislation and the factor will be dependent on data collected over next several years. Volkswagen suggests that this timing is appropriate and recommends that the current FUF remain in place until the new data is available.

Response:

EPA carefully considered all of the comments we received in response to the proposed revised FUF. EPA agrees with commenters on the importance of PHEVs as a technology that might be best suited to meet the needs of some consumers, particularly over the timeframe of this rulemaking. PHEVs have the potential to reduce vehicle GHG emissions, but the degree to which that potential is realized depends on whether they are charged and operating on electricity. Based on our updated assessment of the latest and best available data in the public record, EPA finds that the SAE-based FUF is assigning lower CO_2 emissions for PHEV compliance calculations than are being realized in in-use data. In other words, PHEVs are currently over-credited for the amount of electric range and zero-emissions operation. Although the data could support an even lower FUF than that proposed, EPA has decided to finalize a moderate change to the FUF.

As discussed in preamble III.C.8, although we believe the data on current PHEV activity could support further revisions to the utility factor, EPA is setting a FUF for future model years based on our expectations about charging and PHEV performance that will occur in those future years. EPA disagrees that there is any compelling evidence that typical PHEVs in the future will reach the SAE J2841 level of charge depleting operation.

As shown in RIA Chapter 3.4.3, the "BAR Regression Fit" curve between 0 and 180-mile 2-cycle combined GHG emission-certified CD ranges using November 2023 CARB dataset are substantially lower than those by the SAE J2841 FUF curve. In addition, EPA conducted a statistical evaluation of the FUF based on real-world data (RIA Chapter 3.4.3.3). The confidence intervals for the vast majority of models do not span the SAE J2841UF trend, suggesting that the measured FUFs are lower than the trend.

The finalized FUF curve represents a modest change of about 11 percent from SAE J2841 FUF curve while the averages of the SAE J2841 FUF curve are approximately 55 percent higher than those calculated using the “BAR Regression Fit” curve between 0 and 180-mile 2-cycle combined GHG emission-certified CD ranges using November 2023 CARB dataset.

However, we do see evidence in the BAR data, such as the Chevy Volt, where PHEVs with higher charge depleting driving capability and power tend to have higher FUF than typical PHEVs in use today. The agency has built on comments received from the Strong PHEV Coalition, specifically their statistical analysis of several PHEVs and the range of charge depleting operation associated with these vehicles. EPA expanded on that analysis and applied a similar technique to the California BAR data. In performing this analysis, EPA noted that several vehicles are demonstrating utility at or near the proposed utility factor. In other words, EPA noted that there are “top runner” vehicles and behavior that supports the final utility factor.

At the time of this final rule, MY 2025 vehicle production has already commenced. This means that manufacturers have approximately two years of lead time to address the revised standards and provisions finalized in this final rule. While lead time is addressed in many ways throughout this rulemaking, such as the year over year change in emission standard stringency and extensions of the phase-down of off-cycle and air conditioning leakage credits, we recognize that a fundamental change to the compliance methodology for any single technology in as little as two years could be significantly disruptive to some vehicle manufacturers' current compliance plans. Several auto manufacturers commented that the proposed revised PHEV utility factor would impact product planning and the overall emission reductions projected for their fleets to meet the standards. We also understand that several vehicle manufacturers have already made significant investments in PHEV technology and are relying on PHEVs as an important portion of their GHG compliance strategy. Without adequate time to adjust their product plans to the revised compliance values for PHEVs under the revised utility factor, and to plan for additional GHG-reducing technologies to ensure adequate additional emissions reductions to meet the standards, the revised FUF may disproportionately impact those manufacturers planning large volumes of PHEVs as compared to manufacturers who are not relying as heavily on PHEV technology. To mitigate such a potential impact and to address concerns about adequacy of lead time for the early years of the program, we are delaying the application of the revised FUF until MY 2031. EPA believes that the revising the FUF in MY 2031 will provide vehicle manufacturers adequate lead time for product development and product plan adjustments, given that the average vehicle redesign cycle is approximately five years.

CAFE compliance calculations

Summary:

Porsche and Mitsubishi Motors North America, Inc. (MMNA) made the following comments:

Porsche notes that EPA's proposed update to the PHEV utility factor will also influence CAFE compliance calculations due to the allowance within statute and regulation for manufacturers to optionally select weighted operation. EPA did not provide analysis as to how this change would affect CAFE compliance especially considering Department of Energy (DOE) recent NPRM to reduce the Petroleum Equivalence Factor (PEF) by 72% for electric vehicles. This dramatic proposal from DOE to undercut the incentive for electric vehicles within CAFE is premature given that proposed CAFE standards for model years 2027 and later have not yet been released by NHTSA. Porsche recommended in comments to DOE for their NPRM that DOE include the assessment of EPA's proposed change in the utility factor to better understand the combined effect of lower PEF and lower utility factor. DOE did not acknowledge, or was unaware of, the proposed reduction in utility factor from EPA. The PEF statutory basis requires DOE, as it has done for over 40 years, to incentivize electrified vehicles in CAFE. This statute also requires DOE, NHTSA and EPA to consult on changes related to PEF and CAFE. Neither the EPA MPR NPRM nor the DOE PEF NPRM appear to discuss the mutual impacts that each other's proposed updates could have on future CAFE compliance. As NHTSA has yet to release their CAFE proposal, it is unclear if NHTSA will address both the EPA and DOE proposals and how both could impact CAFE compliance. To Porsche, it is unclear as to why these NPRMs appear disjointed and so far, have failed to discuss the impacts of each other's proposals on the other regulations. Porsche recommends EPA provide analysis of the impact of the reduced utility factor on the PEF and CAFE compliance in coordination with DOE and NHTSA. Ideally, all the proposals would have been released together to provide manufacturers with the ability to understand how each of the agency's actions would interact with each other and continue to support and incentivize technologies such as PHEV. This is especially relevant considering the overarching goal to achieve a dramatic increase in light-duty electrification. proposal is changing test fuel, which is broadly supported by industry).

MMNA: The development of the proposed utility factor by EPA considers the impact of changes within the context of the light-duty GHG standard. However, the utility factor is also used in developing fuel economy compliance values for the NHTSA CAFE standard. There is little mention of the utility factor's influence on CAFE compliance, despite the direct effect it has on PHEV CAFE compliance values.

Response:

CAFE compliance calculations will not be affected, as EPA is not revising the SAE J2841 MDIUF curve, which is used for CAFE standards compliance and labeling all electric range (AER), CD range, and electric energy consumption of PHEV vehicle stickers.

Real-world vs. laboratory performance

Summary:

Alliance for Automotive Innovation (AAI) and Toyota made the following comments:

AAI: The normal method to address differences between real-world and laboratory results, especially when due to driving behaviors, has been through post-compliance adjustments aimed at consumer awareness and occasionally by expanding test cycle requirements, and not by revising calculations used to determine compliance with the standards. While some data may suggest PHEVs are not being plugged in as frequently as the assumptions underlying the SAE UF curve, this should not be a problem attributed to automakers, nor should it be grounds to adjust a compliance measurement.

EPA recognizes that BEV technology is still maturing and needs support to build consumer acceptance. Appropriately, the proposal does not examine the advertised range, efficiency, and emissions performance of BEVs under real-world operation. PHEVs are in the same fragile stage of growth and should be treated no differently.

Toyota: Concerns over differences between real-world and laboratory performance, particularly those due to driving behaviors, have traditionally been resolved through post-compliance data adjustments aimed at consumer awareness and occasionally by expanding test cycle requirements. Not by revising the calculations used to determine compliance with the standards. The compliance benefit of internal combustion powertrains has never been penalized when studies have found on-road driving is more aggressive or fuel consuming than the test cycles indicate. Instead, lab results for CO2 emissions and fuel economy are adjusted on the fuel economy label to better reflect real- world performance, and consumers are educated on how their mileage may vary based on their driving conditions.

PHEVs should be treated no differently than BEVs. Both technologies are still evolving, maturing and need support towards mainstream market adoption. The proposal appropriately does not scrutinize the advertised range, efficiency, and emissions performance of BEVs under real-world conditions. A BEV not attaining its advertised range can result in more ICE miles driven. One recent vehicle usage study concluded the average BEV is driven 29% less than the average non- BEV. Another academic study found that battery electric vehicles (BEVs) are driven on average 2,700 fewer miles annually compared to their conventional counterparts.

Response:

The UF for a PHEV represents the proportion of electric miles driven by the vehicle, and is entirely dependent on how often the consumer is willing to recharge the vehicle. This charging frequency is not determined by a laboratory test, and thus a change in the FUF is not due to any differences between real-world and laboratory performance. Instead, it is due to differences between observed real-world behavior and assumed real-world behavior during in the development of the original SAE J2841 curve.

EPA disagrees that the issue is a discrepancy between laboratory results and the real world. For example, SAE J2841, which is based on real-world driving behavior, states explicitly that the UF represented in SAE standard assumes that a PHEV is fully charged at least once per day. However, there are about 3 percent of PHEVs which were charged less than 1-kwh and about 28 percent of PHEVs which were charged less than 200-kWh lifetime total grid energy into the battery packs, respectively, when filtering out vehicles with less than 3,000-mile total lifetime traveled distance. FUF values are significantly affected by charging frequencies.

EPA disagrees that this rule treats BEVs and PHEVs differently. In this rule, EPA is treating PHEVs, BEVs, and conventional vehicles in the same manner. Both BEVs and PHEVs are allocated zero g/mile CO2 in all-electric driving. Average annual VMT variations, while different for individual vehicle models, is not considered in compliance calculations for BEVs, PHEVs, or conventional vehicles.

Incentivizing PHEV range with a modified FUF

Summary:

ICCT, Strong PHEV Coalition, MECA Clean Mobility (MECA), Electric Drive Transportation Association (EDTA), Alliance for Vehicle Efficiency (AVE), and Betsy Cooper made the following comments:

ICCT: EPA could automatically apply the higher FUF curve (e.g., the current proposed curve, as opposed to the ICCT-BAR curve) for vehicles that meet minimum all-electric performance requirements, such as 70 miles all-electric 2-cycle range and 40 miles all-electric US06 range. This latter option would incentivize greater all-electric capability among PHEVs.

Strong PHEV Coalition: EPA should extend the FUF to 130 miles in order to encourage automakers. For example, Toyota has announced that it is planning a PHEV with over 124-mile all electric range.4 While we don’t know which test cycle this range is based on, EPA should encourage this long all electric range. Another example is the BMW i3 REX which was designed to primarily drive all-electric miles but is now only sold as a used PHEV.

EPA should adopt a provision to discourage low-range PHEVs by requiring them to count as an HEV with no zero emission miles. We suggest a cut-off of 50 km (31miles). Further we are not suggesting a ban on low-range PHEVs but rather a disincentive to produce them. Low-range PHEVs according to the UC Davis data logger project and the EV Project have greater likelihood of not plugging in and this could increase as PHEVs get older. PHEVs with a long all-electric range offer much greater benefits to consumers and show much higher levels of plugging in.

EPA should provide small bonus credits (multipliers) in 2027 to 2030 for several advanced technologies including PHEVs with a long all-electric range that are not being produced today.

While we understand the need to simplify the regulation and dramatically reduce the use of multipliers, we do support very limited continuation of multiplier to advance technologies that do not exist today or are in very limited numbers such as bidirectional charging vehicles (recommendation 4) and PHEVs with an all-electric range of 60 or more miles. These technologies need extra lead time to develop. Having multiple technologies helps in reaching many hard-to-reach customer segments, and PHEVs with over 60-mile all-electric range by legacy automakers are not offered today and have rarely been produced and sold. Also see our recommendation 8 below.

In a future rule, EPA should require automakers to only produce in the early 2030s PHEVs with 50 miles or greater all-electric range, along with BEVs and fuel cell EVs. Due to the climate catastrophe, even more electrification will be required. However, for all the reasons provided in this letter, we do not believe the approach taken by the European Union to ban PHEVs is appropriate. Further, this current rulemaking by adopting our recommendations above will help lead to a transition in the 2030s to requirements for Strong PHEVs, BEVs and FCEVs.

MECA: MECA Clean Mobility: Finally, MECA suggests that EPA allow PHEVs certifying with all electric range greater than 50 miles to claim higher fleet utility factors, and consider scaling utility factor with a vehicle’s all electric range.

EDTA: New PHEVs’ driving range increased 8.5% in 2021 and that trend is expected to continue. The increase in all-electric operation capability will change consumer use patterns over the regulated period and the rule for 2027-2032 should reflect that in an updated utility factor.

AVE: Additionally, to comply with California’s Advanced Clean Cars II regulations, automakers are already announcing PHEVs that will greatly exceed California’s requirements. EPA should account for current and expected improved range for future PHEV models to determine the utility factor curve that should apply.

Betsy Cooper: Shorter ranges require more frequent charging, and make it more likely that drivers will need to charge in inconvenient locations away from home. And these annoyances may make it more likely that new PHEVs will rely on gas.

EPA Should Use Its Regulatory Authority to Incentivize Long-Range PHEVs. The EPA thus should use its regulatory process to encourage PHEV manufacturers to return long-train PHEVs to the market: by providing full off-cycle credits to those who give 50 or more miles of electric range. We propose a 50+ mile PHEV range requirement for full off-cycle credit. There is already momentum in favor of this standard; California is planning to require 50+ mile range PHEVs by 2035 [Link: https://ww2.arb.ca.gov/news/california-moves-accelerate-100-new-zero-emission-vehicle-sales-2035]. Moreover, even with battery degradation, a PHEV rated for 50+ miles at the point of sale will still cover the average American commute many years later.

The EPA may respond that its scaled utility factor already takes into account miles of range in its calculation. Even if true, by penalizing all PHEVs across the board, the EPA is incentivizing manufacturers to make fewer plug-in hybrid vehicles, period.

<u>Response:</u>

Our goal with the finalized FUF curve is to appropriately characterize the actual charge depleting share of driving distance for PHEVs in the rulemaking timeframe, rather than incentivizing PHEVs with certain ranges. However, our finalized FUF curve already provides an incentive for more capable PHEVs, based on operational data, with continuously higher FUF values for vehicles with greater charge depleting range. We do not believe that appropriately accounting for CO2 emissions of PHEVs incentivizes of or penalizes PHEVs; instead, it treats these vehicles equally compared to other technologies.

We don't currently have any evidence or data that vehicles above and below a particular range value (e.g. 70 miles 2-cycle charge depleting range and 40 miles all-electric US06 range, or 50-mile all-electric labeled range) are used in dramatically different ways that would support a discontinuous FUF curve. However, in the event that vehicle manufacturers or other stakeholders come forward in the future with additional PHEV data that could be used to inform future evaluations of the FUF, EPA is committed to working with stakeholders in conducting a future evaluation. If such evaluation were to support a proposed revision to the FUF, EPA could initiate a rulemaking to revise the FUF.

Requiring or incentivizing in-use data collection and reporting:

Summary:

California Air Resources Board (CARB) and Environmental Defense Fund (EDF), NACAA, and Strong PHEV Coalition made the following comments:

CARB: Given the variability in PHEV usage displayed to date, CARB recommends that U.S. EPA require auto manufacturers to collect and report in-use operational data at discrete intervals on PHEVs in future MYs. This would enable U.S. EPA to more accurately assess the GHG emissions associated with different PHEVs. Based on these data, EPA may then be better positioned to reassess the FUF curve for subsequent rulemakings.

Environmental Defense Fund (EDF): However, instead of relying fully on this new data for developing its UF curve, EPA proposes to average the two datasets, giving each an equal weight. Because, as discussed above, the ICCT- BAR UFs are a significantly better representation of real-world PHEV usage than EPA's current approach, EDF suggests that the agency rely solely on this data in setting its new UF curve. In addition to aligning EPA's default UF with the best available real-world data, we encourage the agency to provide manufacturers with an option to submit rigorous, real-world data to demonstrate their UFs are higher than these default values. An approach along these lines could allow for retrospective adjustment based on annual driving information submitted along with a manufacturer's compliance demonstration. An approach along these lines—a rigorous default UF combined with the option to certify better performance—would help to better reflect the actual emissions performance of PHEVs and provide incentives for manufacturers to develop and deploy PHEVs that operate more regularly on electricity.

NACAA: We also recommend that EPA require data collection and reporting or accessibility to better inform the methodology in the future.

Strong PHEV Coalition: EPA, in the final rule or future rule, should include a true-up system for automaker's FUF where debits or credits are provided based on actual data from on-board diagnostics and reporting by automakers of a fairly large sample. If EPA opts not to do this, we request that EPA should, at minimum, require manufacturers in this rulemaking to share anonymized actual data from PHEVs so that in future years, the EPA can make informed decisions about the FUF based upon real world data.

Response:

Thank you for your suggestion to collect and report in-use PHEV operational data. After careful consideration, EPA is not requiring manufacturers to collect or report data in this final rulemaking. EPA may consider mandatory data submission in the future and/or allow vehicle manufacturers to submit data to inform their own UF calculation.

However, in the event that vehicle manufacturers or other stakeholders voluntarily come forward in the future with additional PHEV data that could be used to inform future evaluations of the FUF, EPA is committed to working with stakeholders in conducting a future evaluation. If such evaluation were to support a proposed revision to the FUF, EPA could initiate a rulemaking to revise the FUF. EPA will continue to monitor real-world data as new BAR OBD datasets become available, or an OEM dataset becomes available.

Data collection and analysis post-rulemaking:

Summary:

Alliance for Automotive Innovation (AAI), Strong PHEV Coalition, Toyota, Consumer Reports (CR), and ICCT made the following comments:

AAI: We propose that industry, EPA, SAE, DOT, and the national laboratories collaborate on a project to acquire and process a large sample of nationwide PHEV data. This collaboration can be used to better understand the sources of variation and agree on logical data processing or filtering. If proven necessary, adjustments to SAE J2841 or advertised all-electric range, and other potential solutions can be explored following appropriate deliberation and peer review of the collaborative effort.

Strong PHEV Coalition: Further, we support EPA's desire to update the FUF in a future rulemaking when new data becomes available, and we commit to helping EPA acquire this data as we are a very data driven coalition that includes five universities (or similar research centers). Over time data derivable from CA BAR and other state's smog check programs will improve as more on-board diagnostic data becomes available which should be used in a future rulemaking with appropriate data quality testing, and improved methods.

In the longer term, EPA, the DOE, or the national labs should conduct an analysis on the value of PHEVs as a platform for low-carbon alternative fuels including whether to allow PHEVs with 85% or more low carbon liquid biofuels blended with gasoline to be treated as zero emission vehicles (ZEVs) in future EPA regulations. The main issue to be studied is feedstock availability in the long run for both diesel and gasoline substitutes that could be used in PHEVs to make them have lower life cycle emissions. Related environmental issues could be studied.

EPA should engage with experts to derive a data-driven FUF using more representative datasets and methods including those of the CARB-funded UC Davis data logger study, or the EV Project analysis. Another factor that we request EPA informally consider is that PHEV batteries typically use five times or less lithium per all-electric mile than battery EVs, and as a result save substantial amounts of GHG from battery manufacturing. Strong PHEVs have the same GHG footprint as a 300-mile range BEV and Strong PHEVs have much higher all-electric range than PHEVs with a low all-electric range. We support EPA not considering battery manufacturing GHG emissions in this rulemaking, but request that EPA informally include this factor when developing the final FUF.

Toyota: EPA requests any relevant performance or utility data that may help inform their analyses for the Final Rule. We appreciate the opportunity to share data which will help elevate the role PHEVs in the Final Rule to be an important part of a sustainable transition to electrification. We plan to share such PHEV data outside of the comment period, possibly, including confidential information. For now, we request EPA consider the data we have provided that suggests PHEVs should be considered be an important contributor in whatever assumed PEV sales mix.

We recommend EPA request SAE establish a consortium of auto companies, DOE, DOT, and other stakeholders to evaluate PHEV usage trends by architecture and performance capability. A first order of business should be determining a consensus method for measuring real-world EV range. The output of this effort should be a report that EPA would use to consider adjustments to the UF curve.

Consumer Reports (CR) CR agrees with EPA adjusting their approach to better match real-world use data. CR does not take a position on which of the proposed utility factor curves is the best option. However, CR does recommend that EPA periodically update their analysis of real-world PHEV usage as more vehicles are sold, and more data becomes available.

ICCT: However, because there is no guarantee that future PHEV models will achieve the assumed higher electric driving shares, the best practice is to let the data dictate the shape of the UF curve. EPA can establish a provision by which it can adjust the UF curve to better account for PHEVs with varying all-electric range, as additional data is collected. To simultaneously ensure PHEVs are not given too-high UF without disincentivizing longer all-electric range PHEVs, EPA can allow manufacturers to provide publicly available, real-world data with accurate UF measurements that support higher FUF for specific PHEV models.

Response:

EPA appreciates commenters acknowledgement of the importance of data collection. As discussed in the preamble, EPA is committed to an ongoing evaluation of future PHEV UF data to assess whether the revised UF is in fact adequately representative of future PHEV operation, as a result of future PHEV designs and consumer charging behavior, or if there is merit in further adjusting the UF. EPA will continue to gather and monitor publicly available data such as that made available by California BAR. EPA will also collect, and monitor data extracted from available in-use PHEV testing and may further supplement the data set through other data gathering mechanisms, such as work done by the Department of Energy or independent contractors and researchers. Although vehicle manufacturers chose not to submit data as part of their public comments, EPA believes that with additional time it is reasonable to project that vehicle manufacturers can gather the same type of data, and in greater quantities, on their own PHEV models than available to EPA through the California BAR; we encourage auto manufacturers to share such data with EPA to inform this future assessment. Thus, second, EPA encourages researchers and other stakeholders, including manufacturers, to supplement the publicly available data by providing data directly to EPA for inclusion in an updated analysis. Stakeholders will also be encouraged to independently assess the publicly available data and provide individual conclusions.

EPA's task in this rulemaking is to evaluate the expected use of the secondary fuel used on these dual fuel vehicles and properly give credit much like EPA does when assigning the F-factor for E85 Vehicles. EPA may reevaluate the utility factor in the coming years as more data becomes available.

EPA appreciates the comments on including battery manufacturing GHG emissions in a future FUF rulemaking; however, this is beyond the scope of this current rulemaking.

3.1.7 - LDV small volume manufacturer standards

Comments by Organizations

Organization: Ad Hoc Small OEM Group

B. Overview

-The US sales of Small OEMs have a minuscule impact on US air pollution. [EPA-HQ-OAR-2022-0829-0563, pp. 1-2]

-The US sales of Small OEMs represent a tiny fraction of the US automobile market [EPA-HQ-OAR-2022-0829-0563, pp. 1-2]

-Together the companies in the Ad Hoc Group accounted for about 4000 car sales in the US in CY 2022 [EPA-HQ-OAR-2022-0829-0563, pp. 1-2]

-If we just look at the Small Businesses in the Ad Hoc Group, they collectively sold about 100 cars in the US in 2022. [EPA-HQ-OAR-2022-0829-0563, pp. 1-2]

-In addition, Small OEM vehicles drive far fewer miles than the average car. Typical Small OEM vehicle lifetime mileage is around 60,000 miles. [EPA-HQ-OAR-2022-0829-0563, pp. 1-2]

-Lower lifetime Vehicle Miles Travelled (VMT) is typical for Small OEM vehicles because they are niche vehicles bought by enthusiasts and collectors, who typically own numerous cars used only for short, occasional rides. [EPA-HQ-OAR-2022-0829-0563, pp. 1-2]

The combination of low sales volumes plus low VMT means that the actual real world pollution impact of Small OEM vehicles is de minimis. This key fact supports granting Small OEMs extra lead-time and flexibility [EPA-HQ-OAR-2022-0829-0563, pp. 1-2]

-Small OEMs are distinct from large volume manufacturers [EPA-HQ-OAR-2022-0829-0563, pp. 1-2]

Small OEMs are different from large volume manufacturers because Small OEMs have: [EPA-HQ-OAR-2022-0829-0563, pp. 1-2]

-Limited product portfolios [EPA-HQ-OAR-2022-0829-0563, pp. 1-2]

-Limited number of drivetrains [EPA-HQ-OAR-2022-0829-0563, pp. 1-2]

-Limited financial and human resources, and [EPA-HQ-OAR-2022-0829-0563, pp. 1-2]

-Longer product development times and vehicle life cycles [EPA-HQ-OAR-2022-0829-0563, pp. 1-2]

The above facts: [EPA-HQ-OAR-2022-0829-0563, pp. 1-2]

-Restrict Small OEMs' ability to meet frequent and significant increases in the stringency of standards [EPA-HQ-OAR-2022-0829-0563, pp. 1-2]

-Make it unreasonable to expect Small OEMs to meet fleet average standards aimed at large OEMs [EPA-HQ-OAR-2022-0829-0563, pp. 1-2]

II. EPA'S NPRM FAILS TO PROVIDE SMALL OEMS WITH SUFFICIENT AND REASONABLE LEAD-TIME AND FLEXIBILITY

A. In General

EPA has recognized in prior criteria pollutant and GHG rulemakings that special flexibility rules for Small OEMs are appropriate. Historically, EPA has therefore had a policy for many years to allow SVMs to skip phase-ins and comply100% at the end of the phase-in period. [EPA-HQ-OAR-2022-0829-0563, pp. 2-3]

The GHG rules and the Tier 3 rules provided even further SVM and Small Business flexibility. [EPA-HQ-OAR-2022-0829-0563, pp. 2-3]

Tier 3 included a separate SVM-only compliance pathway for a period of 10 years with specific SVM-only fleet average requirements. This flexibility in 40 CFR 86.1811-17(h) -- specifically for SVMs -- was the result of extensive SVM discussions with EPA during the Tier 3 rulemaking. [EPA-HQ-OAR-2022-0829-0563, pp. 2-3]

Similarly, the GHG rules to date have both afforded Small Businesses an exemption from GHG requirements as well as provided an SVM procedure for company-specific GHG standards. These flexibilities were also the result of extensive Small OEM input to EPA. [EPA-HQ-OAR-2022-0829-0563, pp. 2-3]

In both the Tier 3 and GHG rulemakings, EPA promulgated these flexibilities after acknowledging that SVMs and Small Businesses are distinct from large volume manufacturers and special provisions for Small OEMs were necessary and proper. [EPA-HQ-OAR-2022-0829-0563, pp. 2-3]

Significantly, California has very recently reaffirmed the appropriateness of special SVM provisions in promulgating the CARB 2022 Advanced Clean Cars II (ACCII) rulemaking. EPA should follow this approach. [EPA-HQ-OAR-2022-0829-0563, pp. 2-3]

-The NPRM, does not sufficiently consider the proposal's effect on SVMs and Small Businesses [EPA-HQ-OAR-2022-0829-0563, pp. 2-3]

Unlike in past rulemakings, EPA's multi-pollutant NPRM, fails to adequately address SVM and Small Business issues -- and EPA does not explain why it did not do so.1 The proposal has no provision for Small OEM lead-time / flexibility with respect to criteria emissions. This omission is a significant, unreasonable and unexplained change of policy. The NPRM also proposes to revamp SVM alternative GHG standards by sweeping SVMs into the large volume rules. The manner in which EPA proposes to do this will result in significant hardship for SVMs without achieving meaningful air quality benefits. [EPA-HQ-OAR-2022-0829-0563, pp. 2-3]

1 On the positive side, we do acknowledge that the NPRM

-SVMs may delay complying with the proposed new Tier 4 OBD requirements until model year 2030; [EPA-HQ-OAR-2022-0829-0563, pp. 2-3]

-OEMs can count BEVs in their Tier 4 fleet average calculations; [EPA-HQ-OAR-2022-0829-0563, pp. 2-3]

-Small entities have certain exemptions from the 86.1815 Battery-related requirements for electric vehicles and plug-in hybrid (but no special provisions for SVMs); [EPA-HQ-OAR-2022-0829-0563, pp. 2-3]

-Continues the current GHG exemption for small entity manufacturers. [EPA-HQ-OAR-2022-0829-0563, pp. 2-3]

Under the Clean Air Act, EPA must recognize and fully consider the impacts of its proposed standards on Small OEMs and must promulgate standards that are feasible for Small OEMs. [EPA-HQ-OAR-2022-0829-0563, pp. 3-4]

In the NPRM Preamble, EPA states as follows:

The Administrator finds that the standards proposed herein are consistent with EPA's responsibilities under the CAA and appropriate under CAA section 202(a). EPA has carefully considered the statutory factors, including technological feasibility and cost of the proposed standards and the available lead time for manufacturers to comply with them. Based on our analysis, it is our assessment that the proposed standards are appropriate and justified under section 202(a) of the CAA. Our analysis for this proposal supports the preliminary conclusion that the proposed standards are technologically feasible and that the costs of compliance for manufacturers would be reasonable. [EPA-HQ-OAR-2022-0829-0563, pp. 3-4]

As regards Small OEMs, we do not agree with the above EPA conclusions. First, Small OEMs are not mentioned in the above conclusion. Furthermore, the NPRM provides no support for the applying the above conclusions to Small OEMs. In this regard, the Preamble has an entire section (“V”) on “EPA's Basis That the Proposed Standards Are Feasible and Appropriate Under the Clean Air Act”, but nowhere in that section are the terms “Small Volume Manufacturer” or “Small Business” mentioned. [EPA-HQ-OAR-2022-0829-0563, pp. 3-4]

We further believe that the NPRM’s proposed Small OEM standards and trajectories do not meet the requirements of CAA § 202(a) that standards “take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such a period.” [EPA-HQ-OAR-2022-0829-0563, pp. 3-4]

EPA should reconsider its proposed provisions from a Small OEM impact viewpoint, determine what is feasible for Small OEMs, and finalize Small OEM rules that are consistent with what Small OEMs can achieve. Small OEM rules must have emissions levels and an incremental phase-in with periods of stability, all of which reflect both the limited resources of Small OEMs and the specialized nature and limited sales of their products. [EPA-HQ-OAR-2022-0829-0563, pp. 3-4]

-EPA’s apparent misunderstanding of what Small OEMs are selling in the US [EPA-HQ-OAR-2022-0829-0563, pp. 4-5]

And EPA’s apparent misunderstanding of who is selling what in the US may also extend beyond the Small Business segment of the industry to the larger SVM segment as well. All SVMs in the AD Hoc Group sell ICE vehicles. Nowhere in the Draft RIA does the term “small volume manufacturer” even appear, and the Draft RIA thus also fails to address the SVM segment of the industry. We question to what extent EPA has considered the NPRM’s impact on SVMs. [EPA-HQ-OAR-2022-0829-0563, pp. 4-5]

Small OEMs cannot effectively fleet average

Perhaps the absence of Small OEM extra lead-time and flexibility may also be the result of EPA’s incorrect assumptions. One assumption supporting the NPRM which is not applicable to Small OEMs is that all OEMs have the ability to average the emissions of their various test groups in order to meet a fleet standard. Small OEMs have long maintained – and do so again here -- that with only one or two high-performance test groups, they cannot use “fleet averaging” as a compliance strategy and therefore have needed, and still need, the long-standing EPA policy affording extra lead-time and flexibility to Small OEMs. In the absence of such flexibility, a fleet average standard becomes in effect a REQUIRED (BIN) STANDARD for these Small OEMs. [EPA-HQ-OAR-2022-0829-0563, p. 5]

Significantly, because Small OEMs cannot effectively utilize fleet averaging, without extra flexibility and lead-time, they are placed at a distinct competitive disadvantage in the marketplace. Why? Because Small OEMs must compete with niche products of large OEMs who CAN fleet average. [EPA-HQ-OAR-2022-0829-0563, p. 5]

-It is improper for EPA to justify the stringency of a standard on the theoretical availability of credits for sale – especially when EPA knows that a Small OEM would have to rely predominantly/entirely on credits from another manufacturer to maintain compliance [EPA-HQ-OAR-2022-0829-0563, p. 5]

EPA projects that SVM fleets on average, and individually, will exceed the proposed standards, thereby requiring purchased credits in order to continue selling vehicles in the US. EPA therefore justifies the standards it has proposed for Small OEMs on the assumption that credit purchasing will be the means for Small OEMs to achieve compliance. We strongly believe that this regulatory approach in fundamentally unfair. [EPA-HQ-OAR-2022-0829-0563, pp. 5-6]

Relying on credits from another manufacturer is an illusory compliance option without some impartial mechanism supporting the availability of credits. The decision to sell credits, who to sell them to, what price to sell them at, and when to sell them (or to keep them for later use or future value) is a business decision 9f the selling manufacturer. There is nothing that requires a manufacturer to sell its credits, or to sell them to a particular party. Realistically speaking, how can a reasonable Small OEM business plan be based on buying credits? [EPA-HQ-OAR-2022-0829-0563, pp. 5-6]

[Non-footnote statement at the bottom of page: Interestingly, the SBREFA processes for EPA’s Tier 2 and Tier 3 rulemakings DID include foreign Small Businesses. See Final Report of the Small Business Advocacy Review Panel on EPA's Planned Proposed Rule Control of Air Pollution from New Motor Vehicles: Tier 3 Emission and Fuel Standards (October 14, 2011) [EPA-HQ-OAR-2022-0829-0563, pp. 5-6]

Final Report of the SBREFA Small Business Advocacy Review Panel on EPA's Planned Proposed Rule for Tier 2 Light- Duty Vehicle and Light-Duty Truck Emission Standards, Heavy-Duty Gasoline Engine Standards, and Gasoline Sulfur Standards (October 26, 1998)] [EPA-HQ-OAR-2022-0829-0563, pp. 5-6]

It is interesting –and we have pointed this out in the past -- that on the one hand EPA justifies its standard setting on the basis that credits can be bought, but on the other hand, EPA steadfastly maintains that it will not get involved in credit trading and leaves it to the free market. As a result, the availability and cost of credits is inherently risky, including the risk that credit-generating manufacturers may strategically withhold credits to limit Small OEM market access. [EPA-HQ-OAR-2022-0829-0563, pp. 5-6]

And finally, compliance with EPA's proposed standards is largely premised on very high levels of electrification. If EPA's projections are incorrect, and sales of electric vehicles are not as high as expected, many manufacturers will likely need to hold onto credits to maintain their own compliance. [EPA-HQ-OAR-2022-0829-0563, p. 6]

-It is critical that EPA

-Acknowledge that for Small OEMs to achieve fleet electrification, they face challenges that can be particularly acute given their limited resources and the high-performance nature of Small OEM product lines, which necessitates lighter- weight, high-density batteries. Overcoming these challenges requires time. [EPA-HQ-OAR-2022-0829-0563, p. 6]

-Understand that given these technical challenges facing Small OEMs seeking to electrify their lightweight sports cars, it is not possible for them to reduce emissions to the level set for Large Volume Manufacturers on the timetable set for Large Volume Manufacturers. [EPA-HQ-OAR-2022-0829-0563, p. 6]

-Recognize that requiring Small OEMs to do so would be contrary to the Clean Air Act's mandate that EPA provide sufficient lead-time "to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within [the lead-time] period." [EPA-HQ-OAR-2022-0829-0563, p. 6]

-Adhere to past EPA precedent and established policy providing Small OEM flexibility and extra lead-time [EPA-HQ-OAR-2022-0829-0563, p. 6]

-Set the Small OEM standards and trajectory with step-downs whose frequency and degree reflect the realities facing Small OEMs as regards limited product lines, longer product development and life cycles [EPA-HQ-OAR-2022-0829-0563, p. 6]

-Seriously consider harmonizing as much as possible with the CARB 2022 [EPA-HQ-OAR-2022-0829-0563, p. 6]

Advanced Clean Cars II (ACCII) rulemaking with regard to special Small OEM provisions [EPA-HQ-OAR-2022-0829-0563, p. 6]

1. CRITERIA EMISSIONS

-EPA cannot "move the NMOG+NOx goalpost" for MY 27 and 28 [EPA-HQ-OAR-2022-0829-0563, pp. 6-8]

EPA proposes to abandon the MY 27 and 28 SVM NMOG+NOx standards set forth in Tier 3 (and on which SVMs have been rightfully relying), and to require SVMs to adhere to the Tier 4 large volume (and short) phase-in. [EPA-HQ-OAR-2022-0829-0563, pp. 6-8]

This inequitably conflicts with the already-established and in effect SVM phase-in set forth in 40 CFR 86.1811-17 (h)(1), as follows:

SVM Fleet Average NMOG+NOx Standard (mg/mile)

Model year: 2027 In effect Tier 3: 51 Proposed Tier 4: 22

Model year: 2028 In effect Tier 3: 30 Proposed Tier 4: 20

[EPA-HQ-OAR-2022-0829-0563, pp. 6-8]

The NPRM's proposed change means that in MY 27, SVMs would have to meet a fleet average NMOG+NOx standard that is 57% more stringent than what they have been planning in reliance on 40 CFR 86.1811-17(h)(1). And then, for MY 28, they would have to meet a fleet average NMOG+NOx standard that is 33% lower than what they have been planning in reliance on 40 CFR 86.1811-17(h)(1). This would be an unjust and impermissible "moving the goalpost". [EPA-HQ-OAR-2022-0829-0563, pp. 6-8]

-The proposed NMOG+NOx requirements are excessively stringent for Small OEMs – too stringent, too soon [EPA-HQ-OAR-2022-0829-0563, pp. 6-8]

This is especially so considering the starting point of existing Tier 3 levels and how the CARB ACCII rulemaking appropriately maintained an SVM NMOG+NOx fleet standard of 51 mg/mi through MY 34, as shown shown in the graph below. [EPA-HQ-OAR-2022-0829-0563, pp. 6-8]

[See original attachment for graph titled "SVM FTP NMOG+NOx LIMIT 9g/mi] [EPA-HQ-OAR-2022-0829-0563, pp. 6-8]

EPA assumes that OEMs will move to electrification in order to meet the Tier 4 standards. As Small OEMs have explained, however, the batteries necessary to provide performance and range required by Small OEM sports cars is not yet available, and thus Small OEMs cannot move forward with EVs on the same timeline as Large Volume Manufacturers producing mass market vehicles. [EPA-HQ-OAR-2022-0829-0563, pp. 6-8]

The Proposed Tier 4 NMOG+NOx fleet average is unrealistic for companies that cannot make use of fleet averaging; Small OEMs should not have to rely on credit purchasing [EPA-HQ-OAR-2022-0829-0563, pp. 6-8]

There is no recognition in the NPRM that an SVM may have only one or two ICE test groups, neither of which meets the Tier 4 fleet NMOG+NOx average. The fleet average concept in such a situation offers no flexibility; having nothing to "average", such an SVM would simply fall into a deficit situation. It was precisely to address this type of scenario that the Tier 3 SVM flexibility provisions in 40 CFR 86.1811-17(h) were promulgated. The current rulemaking should follow suit and adopt comparable SVM flexibility. [EPA-HQ-OAR-2022-0829-0563, pp. 6-8]

As regards credit purchasing, we reiterate how it is unfair to force Small OEMs to rely on risky credit purchasing (at an unknown cost) in order to meet criteria emissions requirements. [EPA-HQ-OAR-2022-0829-0563, pp. 6-8]

-Bin 125 should remain available to Small OEMs [EPA-HQ-OAR-2022-0829-0563, pp. 6-8]

Moreover, the NPRM also proposes to eliminate Bin 125, a Bin currently relied upon by SVMs. Eliminating Bin 125 would bring about the severe result of preventing some hypercar manufacturers from certifying with EPA and from selling in the Federal US market. [EPA-HQ-OAR-2022-0829-0563, pp. 8-9]

For other SVMs, the elimination of Bin 125 would be unfair and unreasonable because it would put them in the untenable position of having to, with limited resources, simultaneously implement EVs while also investing in an attempt to reengineer Bin 125 vehicles to a much more stringent standard. [EPA-HQ-OAR-2022-0829-0563, pp. 8-9]

Bin 125 should be kept in place for the exclusive use of SVMs, as California has permitted. CARB ‘s ACCII rules allow SVMs to continue to use Bin 125 until 2035. EPA should follow suit. Retaining Bin 125 for SVMs is simply not contrary to the goal of cleaner air. [EPA-HQ-OAR-2022-0829-0563, pp. 8-9]

-The Proposed Interim Tier 4 provision does not provide flexibility to SVMs

We note that one general flexibility concession in the NPRM -- the category of “Interim Tier 4 vehicles” -- does not provide relief to SVMs. As proposed, the Interim Tier 4 provision leaves SVMs empty-handed because the benefits of Interim Tier 4 are restricted to OEMs who can otherwise meet the 40% and 80% phase-in percentages with their full Tier 4 test groups (and thus use the Interim Tier 4 category for the remaining 60% and 20% of their fleets during the phase in). Given that SVMs – particularly those with only one or two test groups -- cannot meet the phase-in percentages with full Tier 4 cars, EPA’s proposal unfairly denies SVMs the ability to make use of the benefits of the Interim Tier 4 category. [EPA-HQ-OAR-2022-0829-0563, pp. 8-9]

-In sum, as regards criteria emissions, EPA: [EPA-HQ-OAR-2022-0829-0563, pp. 8-9]

-Should follow CARB’s ACCII rules and continue the availability of Bin 125 to SVMs through MY 2034. [EPA-HQ-OAR-2022-0829-0563, pp. 8-9]

-Must justify imposing on SVMs the proposed new cold NMOG+NOx standard; until EPA can establish that the environmental benefits outweigh the burdens on SVMs, SVMs should be exempted. [EPA-HQ-OAR-2022-0829-0563, pp. 8-9]

-With regard to NMOG+NOx FTP and US06 standards [EPA-HQ-OAR-2022-0829-0563, pp. 8-9]

-In order to properly account for the problems facing SVMs with regard to “fleet averaging” and the risks of credit purchasing, as explained above, set [EPA-HQ-OAR-2022-0829-0563, pp. 8-9]

-The degree and frequency of SVM step-downs to reflect SVM realities -- limited product lines, longer product development and life cycles [EPA-HQ-OAR-2022-0829-0563, pp. 8-9]

-MY 2027 -- Maintain for all SVMs the already-in effect (86-1811-17(h) MY 27 Tier 3 SVM NMOG+NOx standard (51m g/mi) [EPA-HQ-OAR-2022-0829-0563, pp. 8-9]

-MY 2028 -- Maintain for all SVMs the already-in effect MY 28 Tier 3 SVM NMOG+NOx standard (30 g/mi) [EPA-HQ-OAR-2022-0829-0563, pp. 8-9]

-MY 2029-32 – continue the 30 mg/mi standard for SVMs given that the doubtful environmental benefits of a more stringent SVM standard are vastly outweighed by the burden on SVMs. [EPA-HQ-OAR-2022-0829-0563, pp. 8-9]

-Make the Interim Tier 4 category more flexible and available to Small OEMs [EPA-HQ-OAR-2022-0829-0563, pp. 8-9]

-Add a new paragraph (e) to proposed 40 CFR 86.1811-27 to read as follows:

(e) If meeting the standards set forth in this section 40 CFR 86.1811-27 would cause severe economic hardship, small-volume manufacturers may ask us to approve an extended compliance deadline under the provisions of 40 CFR 1068.250, except that the solvency criterion does not apply and there is no maximum duration of the hardship relief. [EPA-HQ-OAR-2022-0829-0563, pp. 8-9]

This provision would mirror the SVM relief made available under Tier 3 in 40 CFR 86.1811-17. [EPA-HQ-OAR-2022-0829-0563, pp. 8-9]

The above steps are necessary to comply with the Clean Air Act's section 202(a) mandate that EPA provide sufficient lead-time "to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such [lead-time]." [EPA-HQ-OAR-2022-0829-0563, pp. 8-9]

2. GHG

-EPA's Small OEM GHG policy must be fair and equitable. [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

As explained by the Alliance for Automotive Innovation, the NPRM's GHG standards are a bridge too far for large automakers. https://www.autosinnovate.org/posts/blog/epas-rules-are-out-of-whack-five-ways-to-fix-them . They are especially onerous for Small OEMs. [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

As explained above, Small OEMs need extra time and flexibility for GHG compliance. The Ad Hoc Group's GHG position is therefore founded on two main points:

-Small Businesses should, as EPA has proposed, continue to be exempted from GHG requirements [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

-The current system of setting company-by-company SVM alternative standards should be eliminated as unwieldly -- too time-consuming and burdensome for all parties – and replaced with reasonable and achievable separate GHG standards for all SVMs [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

The set of SVM GHG standards would be separate from the large volume standards and would reflect the challenges faced by SVMs, discussed above, while still requiring SVMs to make significant GHG improvement. [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

Simply requiring Small OEMs to switch to the large volume standards over a short period of time would impose a dramatic increase in stringency of the GHG standard applicable to SVMs (from MY 24 to 25). In fact, the standard's level would drop precipitously, akin to falling off a cliff, and this is both unfair and unachievable. [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

-Small OEMs cannot rely on fleet averaging or GHG credits as a compliance strategy

As discussed above, SVMs cannot use averaging as a successful compliance strategy. In addition, forcing SVMs to use credits as a primary if not exclusive compliance strategy is both unfair and improper, and this is especially so as regards GHG since SVMs expect the open market availability of GHG credits to decline starting in 2026MY when the phase-in of changes to MPGe begins to affect the ability of manufacturers of PHEVs and BEVs to generate GHG credits.4 [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

4 The Small OEM GHG situation is also exacerbated by the following:
-EPA proposes to eliminate AC leakage credits (we do not fully understand why the goal of fighting climate change demands this) [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]
-The NPRM would maintain AC Efficiency Credits (which we support) but the NPRM test procedure unfairly penalizes SVMs who cannot provide suitable test samples to perform the test as proposed. [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

-In sum, as regards GHG, EPA should proceed as follows:

-For Small Businesses -- continue the existing GHG exemption for Small Businesses5

-For SVMs

-For MY 22, 23, 24 and 25 -- for SVMs that have been granted alternative bespoke standards in the 2020 notice Federal Register :: Determinations of Light-Duty Vehicle Alternative Greenhouse Gas Emissions Standards for Small Volume Manufacturers, continue for MY 22, 23, 24 and 25 the alternative standards for MY 21 set in the FR notice [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

-For MY 2026 and later, eliminate company-by-company alternative SVM GHG standards [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

-Instead, in order to properly account for the problems facing SVMs with regard to "fleet averaging" and the risks of credit purchasing (as discussed above), create a new regulatory provision applicable to all SVMs (using the definition of SVM in 40 CFR 86.1838-01) setting forth SVM standards and an SVM trajectory [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

-The SVMs in the Ad Hoc Group who are not Small Businesses believe that [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

-It is untenable that EPA's NPRM would require SVMs to have more than 50% BEVs in their fleet in MY2026 – a level far higher than that expected from Large Volume [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

Manufacturers under the Primary Standard phase-in starting in MY 2027. [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

-Reasonably achievable SVM CO2 levels and a feasible SVM trajectory are necessary to account for challenges and limitations specific to SVMs. [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

-An SVM-specific phase-in must understandably require a substantial GHG reduction by MY 2032, but it must also start with a period of stability in order to account for SVMs' limited product lines and limited availability/access to necessary technologies. [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

-EPA should therefore, in order to comply with the Clean Air Act's section 202(a) lead-time mandate:

-Set an SVM phase-in that requires in MY 2032 a 50% GHG reduction compared to MY 25 (e.g., compared to the average of the MY 25 alternative bespoke standards). [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

-Establish a trajectory from MY 2026 to MY 2032 that has either a reasonable linear reduction or one or more reasonable stepped reductions. [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

[See original attachment for graph titled "2022 + GHG Proposed Targets"] [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

-Defer consideration of incorporating SVMs into the Primary Standard until a subsequent separate rulemaking. [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

-Add a new paragraph to 40 CFR 86.1818-12 to read as follows:

(e) If meeting the standards set forth in this section 40 CFR 86.1818-12 would cause severe economic hardship, small- volume manufacturers may ask us to approve an extended-compliance deadline under the provisions of 40 CFR 1068.250, except that the solvency criterion does not apply and there is no maximum duration of the hardship relief. [EPA-HQ-OAR-2022-0829-0563, pp. 9-11]

5 EPA is requesting comment on the idea of imposing on Small Business manufacturers an annual production cap (e.g., 200-500 vehicles per year) on vehicles eligible for the Small Business GHG exemption. The Small Business members of the AD Hoc Group oppose any such cap on the grounds that setting a cap at a given level would be totally arbitrary, and the environmental benefits of any such cap are virtually nonexistent and are vastly outweighed by the potential burden.

Organization: Ad Hoc Tier 4 Light-Duty Small Manufacturer Group

II. EPA'S NPRM FAILS TO PROVIDE SMALL OEMS WITH SUFFICIENT AND REASONABLE LEADTIME AND FLEXIBILITY

A. IN GENERAL

EPA has recognized in prior criteria pollutant and GHG rulemakings that special flexibility rules for Small OEMs are appropriate. Historically, EPA has therefore had a policy for many years to allow SVMs to skip phase-ins and comply 100% at the end of the phase-in period. [EPA-HQ-OAR-2022-0829-0509, pp. 2-3]

The GHG rules and the Tier 3 rules provided even further SVM and Small Business flexibility. [EPA-HQ-OAR-2022-0829-0509, pp. 2-3]

Tier 3 included a separate SVM-only stepped increase in fleet average stringency over a designated period of time (apart from the large volume phase-in). This flexibility in 40 CFR 86.1811-17(h) -- specifically for SVMs -- was the result of extensive SVM discussions with EPA during the Tier 3 rulemaking. [EPA-HQ-OAR-2022-0829-0509, pp. 2-3]

Similarly, the GHG rules to date have both afforded Small Businesses an exemption from GHG requirements as well as provided an SVM procedure for company-specific GHG standards. [EPA-HQ-OAR-2022-0829-0509, pp. 2-3]

These flexibilities were also the result of extensive Small OEM input to EPA. [EPA-HQ-OAR-2022-0829-0509, pp. 2-3]

In both the Tier 3 and GHG rulemakings, EPA promulgated these flexibilities after acknowledging that SVMs and Small Businesses are distinct from large volume manufactures and special provisions for them were necessary and proper. [EPA-HQ-OAR-2022-0829-0509, pp. 2-3]

Significantly, California has very recently reaffirmed the appropriateness of special SVM provisions in promulgating its 2022 Advanced Clean Cars II (ACCII) rulemaking. EPA should follow this approach. [EPA-HQ-OAR-2022-0829-0509, pp. 2-3]

- The NPRM, does not consider the proposal’s effect on SVM and Small Business [EPA-HQ-OAR-2022-0829-0509, pp. 2-3]

The problem here is that in EPA’s multi-pollutant NPRM, SVM and Small Business considerations have largely disappeared without explanation.[1] The proposal has no provision for Small OEM leadtime / flexibility with respect to criteria emissions. This omission is a significant and unreasonable change of policy. The NPRM also proposes to revamp SVM alternative GHG standards by sweeping SVMs into the large volume rules. The manner in which EPA proposes to do this will result in significant hardship for SVMs. [EPA-HQ-OAR-2022-0829-0509, pp. 2-3]

1 On the positive side, we do acknowledge that the NPRM

- SVMs may delay complying with the proposed new Tier 4 OBD requirements until model year 2030; [EPA-HQ-OAR-2022-0829-0509, pp. 2-3]

- OEMs can count BEVs in their Tier 4 fleet average calculations; [EPA-HQ-OAR-2022-0829-0509, pp. 2-3]

- Small entities have certain exemptions from the 86.1815 Battery-related requirements for electric vehicles and plug-in hybrid (but no special provisions for SVMs); [EPA-HQ-OAR-2022-0829-0509, pp. 2-3]

- Continues the current GHG exemption for small entity manufacturers. [EPA-HQ-OAR-2022-0829-0509, pp. 2-3]

Limited product portfolios and longer product development and life cycles restrict Small OEM ability to meet frequent and significant increases in stringency. [EPA-HQ-OAR-2022-0829-0509, pp. 2-3]

Simply put, EPA must recognize and fully consider the impacts of its proposed standards on Small OEMs, and must promulgate standards that are feasible as required by the Clean Air Act. We believe that the proposed Small OEM standards do not meet the requirements of CAA § 202(a) that standards "take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such a period." [EPA-HQ-OAR-2022-0829-0509, p. 3]

And EPA's apparent misunderstanding of who is selling what in the US may also extend beyond the Small Business segment to the larger SVM segment as well. All SVMs in the AD Hoc Group sell ICE vehicles. Nowhere in the Draft RIA does the term "small volume manufacturer" even appear, and the Draft RIA thus fails to address the SVM segment of the industry. Should we take this to mean that the NPRM's impact on SVMs was not thoroughly considered? [EPA-HQ-OAR-2022-0829-0509, pp. 3-4]

- Small OEMs cannot effectively fleet average [EPA-HQ-OAR-2022-0829-0509, pp. 3-4]

Perhaps the absence of Small OEM extra leadtime and flexibility may be the result of EPA's incorrect assumptions. One assumption supporting the NPRM which is not applicable to Small OEMs is that all OEMs have the ability to average the emissions of their various test groups in order to meet a fleet standard. Small OEMs have long maintained – and do so again here -- that with only one or two high-performance test groups, they cannot use "averaging" as a compliance strategy and have therefore needed, and still need, the long-standing EPA policy affording extra leadtime and flexibility to Small OEMs. [EPA-HQ-OAR-2022-0829-0509, pp. 3-4]

It is improper to set a standard so stringent that it requires a Small OEM to rely entirely on credits from another manufacturer to maintain compliance [EPA-HQ-OAR-2022-0829-0509, p. 4]

EPA projects that SVM fleets on average, and individually, will exceed the proposed standards, requiring purchased credits in order to continue selling vehicles in the US. EPA therefore relies on credit trading flexibility as a key means by which Small OEMs will maintain compliance with standards. We disagree with this approach. [EPA-HQ-OAR-2022-0829-0509, p. 4]

It is inappropriate to set a standard so stringent that it requires a manufacturer to rely entirely on credits from another manufacturer to maintain compliance. The decision to sell credits, who to sell them to, what price to sell them at, and when to sell them (or to keep them for later use or future value) is a business decision. There is nothing that requires a manufacturer to sell its credits, or to sell them to a particular party. [EPA-HQ-OAR-2022-0829-0509, p. 4]

It is interesting –and we have pointed this out in the past -- that on the one hand EPA justifies its standard setting on the basis that credits can be bought, but on the other hand, EPA steadfastly maintains that it will not get involved in credit trading and leaves it to the free market. As a result, the availability and cost of credits is inherently risky, including the risk that credit-generating manufacturers may strategically withhold credits to limit Small OEM market access. [EPA-HQ-OAR-2022-0829-0509, p. 4]

And finally, compliance with EPA's proposed standards is largely premised on very high levels of electrification. If EPA's projections are incorrect, and sales of electric vehicles are not as high as expected, many manufacturers will likely need to hold onto credits to maintain their own compliance. [EPA-HQ-OAR-2022-0829-0509, p. 4]

B. THERE ARE FOUR SPECIFIC TOPICS IN THE NPRM THAT ARE OF DEEP CONCERN TO SMALL OEMS

1. CRITERIA EMISSIONS

- You can't "move the goalpost" for MY 27 and 28 [EPA-HQ-OAR-2022-0829-0509, pp. 4-6]

EPA proposes to abandon the MY 27 and 28 SVM NMOG+NOx standards set forth in Tier 3 (AND ON WHICH SVMs HAVE BEEN RIGHTFULLY RELYING), and to require SVMs to adhere to the Tier 4 large volume (and short]) phase-in. [EPA-HQ-OAR-2022-0829-0509, pp. 4-6]

This inequitably conflicts with the already-established and in effect SVM phase-in set forth in 40 CFR 86.1811-17 (h)(1), as follows: [EPA-HQ-OAR-2022-0829-0509, pp. 4-6]

SVM Fleet Average NMOG+NOx Standard (mg/mile)

Model year: 2027; In effect Tier 3: 51; Proposed Tier 4: 22

Model year: 2028; In effect Tier 3: 30; Proposed Tier 4: 20 [EPA-HQ-OAR-2022-0829-0509, pp. 4-6]

The NPRM's proposed change means that in MY 27, SVMs would have to meet a fleet average NMOG+NOx standard that is 57% more stringent than what they have been planning in reliance on 40 CFR 86.1811-17(h)(1). And then, for MY 28, they would have to meet a fleet average NMOG+NOx standard that is 33% lower than what they have been planning in reliance on 40 CFR 86.1811-17(h)(1). This would be an unjust "moving the goalpost". [EPA-HQ-OAR-2022-0829-0509, pp. 4-6]

- The proposed NMOG+NOx requirements are excessively stringent – too stringent, too soon [EPA-HQ-OAR-2022-0829-0509, pp. 4-6]

This is especially so considering Tier 3 levels and that the CARB ACCII rulemaking appropriately maintained an SVM NMOG+NOx fleet standard of 51 mg/mi through MY 34, as shown shown in the graph below. [EPA-HQ-OAR-2022-0829-0509, pp. 4-6]

[See original attachment for "SVM FTP NMOG+NOx LIMIT [g/mi]"] [EPA-HQ-OAR-2022-0829-0509, pp. 4-6]

-The Proposed Tier 4 NMOG+NOx fleet average is unrealistic for companies that cannot make use of fleet averaging; Small OEMs should not have to rely on credit purchasing [EPA-HQ-OAR-2022-0829-0509, pp. 4-6]

There is no recognition in the NPRM that an SVM may have only one or two ICE test groups, neither of which meets the Tier 4 fleet NMOG+NOx average. The fleet average concept in such a situation offers no flexibility; having nothing to "average", such an SVM would simply fall into a deficit situation. It was precisely to address this type of scenario that the Tier 3 SVM flexibility provisions in 40 CFR 86.1811-17(h) were promulgated. The current rulemaking should follow suit and adopt comparable SVM flexibility. [EPA-HQ-OAR-2022-0829-0509, pp. 4-6]

As regards credit purchasing, we reiterate how it is unfair to force Small OEMs to rely on risky credit purchasing (at an unknown cost) in order to meet criteria emissions requirements. [EPA-HQ-OAR-2022-0829-0509, pp. 4-6]

- Bin 125 should remain available to Small OEMs [EPA-HQ-OAR-2022-0829-0509, pp. 4-6]

Moreover, the NPRM also proposes to eliminate Bin 125, a Bin currently relied upon by SVMs. EPA has not provided a reason why Bin 125 cannot be kept in place for the exclusive use of Small OEMs as California has permitted. CARB 's ACCII rules allow SVMs to continue to use Bin 125 until 2035. [EPA-HQ-OAR-2022-0829-0509, pp. 4-6]

The elimination of Bin125 is unfair and unreasonable as regards SVMs because it puts SVMs in the untenable position of having to, with limited resources, simultaneously implement EVs and also reengineer Bin125 vehicles to a much more stringent standard. [EPA-HQ-OAR-2022-0829-0509, pp. 4-6]

- The Proposed Interim Tier 4 provision does not provide flexibility to SVMs [EPA-HQ-OAR-2022-0829-0509, p. 6]

We note that one general flexibility concession in the NPRM -- the category of “Interim Tier 4 vehicles” -- does not provide relief to SVMs. As proposed, the Interim Tier 4 provision leaves SVMs empty-handed because – [EPA-HQ-OAR-2022-0829-0509, p. 6]

-The benefits of Interim Tier 4 are restricted to OEMs who can otherwise meet the 40% and 80% phase-in percentages with their full Tier 4 test groups (and thus use the Interim Tier 4 category for the remaining 60% and 20% of their fleets during the phase in). Given that SVMs – particularly those with only one or two test groups -- cannot meet the phase-in percentages with full Tier 4 cars, EPA’s proposal unfairly denies SVMs the ability to make use of the benefits of the Interim Tier 4 category. [EPA-HQ-OAR-2022-0829-0509, p. 6]

In sum, as regards criteria emissions, EPA should:

-Follow CARB’s ACCII rules and continue the availability of Bin 125 to SVMs through MY 2034 and not require NMOG+NOx limits for cold testing.[3] [EPA-HQ-OAR-2022-0829-0509, p. 6]

-With regard to NMOG+NOx FTP and US06 standards [EPA-HQ-OAR-2022-0829-0509, p. 6]

-In order to properly account for the problems facing SVMs with regard to “fleet averaging” and the risks of credit purchasing, as explained above, set the degree and frequency of SVM step-downs to reflect SVM realities -- [EPA-HQ-OAR-2022-0829-0509, p. 6]

limited product lines, longer product development and life cycles and limited access to technologies (particularly batteries). [EPA-HQ-OAR-2022-0829-0509, p. 6]

-MY 2027 -- Maintain for all SVMs the already-in effect (86-1811-17(h) MY 27 Tier 3 SVM NMOG+NOx standard (51m g/mi) [EPA-HQ-OAR-2022-0829-0509, p. 6]

-MY 2028 -- Maintain for all SVMs the already-in effect MY 28 Tier 3 SVM NMOG+NOx standard (30 g/mi) [EPA-HQ-OAR-2022-0829-0509, p. 6]

-MY 2029-32 – continue the 30 mg/mi standard for SVMs given that the environmental benefits of a more stringent standard have not been established and are vastly outweighed by the potential burden on SVMs. [EPA-HQ-OAR-2022-0829-0509, p. 6]

-Make the Interim Tier 4 category more flexible and available [EPA-HQ-OAR-2022-0829-0509, p. 6]

-Add a new paragraph (e) to proposed 40 CFR 86.1811-27 to read as follows:

(e) If meeting the standards set forth in this section 40 CFR 86.1811-27 would cause severe economic hardship, small-volume manufacturers may ask us to approve an extended compliance deadline under the provisions of 40 CFR 1068.250, except that the solvency criterion does not apply and there is no maximum duration of the hardship relief. [EPA-HQ-OAR-2022-0829-0509, p. 6]

This provision would mirror the SVM relief made available under Tier 3 in 40 CFR 86.1811-17. [EPA-HQ-OAR-2022-0829-0509, p. 6]

3 EPA must justify imposing on SVMs the proposed new cold NMOG+NOx standard. Until EPA can establish that the environmental benefits outweigh the burdens on SVMs, SVMs should be exempted.

2. GHG

- EPA's Small OEM GHG policy needs to be fair and equitable. [EPA-HQ-OAR-2022-0829-0509, p. 7]

As explained above, extra time and flexibility are very much needed by Small OEMs. Our GHG position is founded on two main points: [EPA-HQ-OAR-2022-0829-0509, p. 7]

-Small Businesses should, as EPA has proposed, continue to be exempted from GHG requirements [EPA-HQ-OAR-2022-0829-0509, p. 7]

-The current system of setting company-by-company SVM alternative standards should be eliminated as unwieldly -- too time-consuming and burdensome for all parties – and replaced [EPA-HQ-OAR-2022-0829-0509, p. 7]

We therefore propose that there be a separate GHG standard for all SVMs – separate from the large volume standard -- which requires significant GHG improvement, yet reflects the challenges faced by SVMs discussed above. [EPA-HQ-OAR-2022-0829-0509, p. 7]

Requiring a Small OEM to switch to large volume standards over a short period of time would impose a dramatic decrease in the GHG standard (from MY 24 to 25). Simply put, the standard would drop precipitously, akin to falling off a cliff. This is both unfair and unachievable. [EPA-HQ-OAR-2022-0829-0509, p. 7]

- Small OEMs cannot rely on fleet averaging or GHG credits as a compliance strategy [EPA-HQ-OAR-2022-0829-0509, p. 7]

As discussed above, SVMs cannot use averaging as a successful compliance strategy. In addition, forcing SVMs to use credits as a primary if not exclusive compliance strategy is both unfair and improper, and this is especially so as regards GHG since SVMs expect the open market availability of GHG credits to decline starting in 2026MY when the phase-in of changes to MPGe begins to affect the ability of manufacturers of PHEVs and BEVs to generate GHG credits. [EPA-HQ-OAR-2022-0829-0509, p. 7]

In sum, as regards GHG, EPA should

-Continue the existing GHG exemption for Small Businesses [EPA-HQ-OAR-2022-0829-0509, pp. 7-8]

-For MY 22, 23 and 24 -- for all SVMs that have been granted alternative bespoke standards in the 2020 notice Federal Register :: Determinations of Light-Duty Vehicle [EPA-HQ-OAR-2022-0829-0509, pp. 7-8]

Alternative Greenhouse Gas Emissions Standards for Small Volume Manufacturers, continue for MY 22, 23 and 24 the alternative standard for MY 21 set in the FR notice [EPA-HQ-OAR-2022-0829-0509, pp. 7-8]

- For MY 2025 and later, eliminate company-by-company alternative SVM GHG standards. [EPA-HQ-OAR-2022-0829-0509, pp. 7-8]

- Instead, in order to properly account for the problems facing SVMs with regard to “fleet averaging” and the risks of credit purchasing (as discussed above), create a new regulatory provision applicable to all SVMs (using the definition of SVM in 40 CFR 86.1838-01) setting forth [EPA-HQ-OAR-2022-0829-0509, pp. 7-8]

- SVM GHG targets (expressed as a multiple of the large volume GHG targets) and [EPA-HQ-OAR-2022-0829-0509, pp. 7-8]

- an SVM GHG trajectory. [EPA-HQ-OAR-2022-0829-0509, pp. 7-8]

-Recognize that given technical challenges in electrifying lightweight super cars it is not possible for SVMs to reduce GHG to level of set for large volume manufacturers by MY 2032. [EPA-HQ-OAR-2022-0829-0509, pp. 7-8]

-Set an SVM trajectory that has step-downs whose frequency and degree reflect the realities facing SVMs as regards limited product lines, longer product development and life cycles, and limited access to technologies (particularly batteries); [EPA-HQ-OAR-2022-0829-0509, pp. 7-8]

-Add a new paragraph to 40 CFR 86.1818-12 to read as follows: (e) e. If meeting the standards set forth in this section 40 CFR 86.1818-12 would cause severe economic hardship, small-volume manufacturers may ask us to approve an extended compliance deadline under the provisions of 40 CFR 1068.250, except that the solvency criterion does not apply and there is no maximum duration of the hardship relief]. [EPA-HQ-OAR-2022-0829-0509, pp. 7-8]

Organization: Alliance for Automotive Innovation

3.Allow Carry-Over Throughout the Duration of the Rule

The NPRM allows a three-year phase in from MY 2027 through MY 2029, but that phase-in is too quick of a transition. Auto Innovators recommends the use of carry-over throughout the duration of the rule. Requiring new data, for a vehicle that is carryover, for MY2030 and beyond adds unnecessary testing burden. [EPA-HQ-OAR-2022-0829-0701, p. 132]

VI. Small-Volume Manufacturer Provisions

Auto Innovators includes Ferrari and McLaren among its members. Both have U.S. sales of less than 5,000 units per model year and are considered small-volume manufacturers (SVM). Their low U.S. and global volumes result in lower access to suppliers and delayed access to supplier- provided technologies. They have limited, narrowly focused product lines that do not have significant redesigns every year, and that receive little flexibility from fleet emission averaging programs. [EPA-HQ-OAR-2022-0829-0701, p. 207]

The products of these small volume manufacturers are high-performance supercars and track cars that are nonetheless certified for on-road use. The purchasers of such vehicles expect high performance, including racetrack capability, even if most will not be used for racing and are constrained in on-road use by U.S. traffic laws and highway designs and conditions. [EPA-HQ-OAR-2022-0829-0701, p. 207]

Emissions from vehicles sold by small volume manufacturers are negligible. Despite generally having higher emission rates (grams per mile), their average lifetime mileage accumulation is extremely low – approximately 2,543 miles.313 EPA should consider the de minimis use of these vehicles when considering final standards under this rulemaking. [EPA-HQ-OAR-2022-0829-0701, p. 207]

313 U.S. Department of Transportation, National Highway Traffic Safety Administration, Exemptions From Average Fuel Economy Standards; Passenger Automobile Average Fuel Economy Standards (Proposed rule; proposed decision to grant exemption), 87 Fed. Reg. 39439, 39449 (Jul. 1, 2022).

Historically, EPA has recognized the unique design considerations and compliance challenges faced by SVMs. They have been provided with additional flexibilities such as alternative, less stringent standards and alternative phasedowns with periods of stability to address those challenges. [EPA-HQ-OAR-2022-0829-0701, p. 207]

These challenges and the need for additional flexibility remain pertinent for MY 2027 and later regulations. The customers of these companies will still demand high performance from any vehicle sold by these manufacturers. The challenges of limited, highly focused product lines will not be eased by vehicle electrification. Limited product portfolio and product development cycles mean the ability to make regular improvements is a challenge. Battery technology has not developed enough for application within high-performance supercars. Technology is developing and SVMs have plans to electrify further; however, time is needed. Supply chain access and lead-time challenges will continue and potentially grow given rapidly rising global demand for lithium-ion batteries and trends toward vertical integration by larger companies to secure critical mineral supplies. Furthermore, given low production volumes there is also limited ability to amortize expensive product development across a volume of products – R&D and investment payback is longer. This leads to SVMs having different investment cycles which will mean they will require additional time to comply with GHG and criteria pollutant regulations. [EPA-HQ-OAR-2022-0829-0701, pp. 207-208]

With this backdrop, we are concerned that EPA appears to now dismiss these challenges in general, proposing much reduced flexibility in MY 2027 and later. [EPA-HQ-OAR-2022-0829-0701, pp. 207-208]

A. SVM Greenhouse Gas Emissions Standards

EPA has proposed alternative greenhouse gas emission standards for SVMs. We appreciate that EPA has at least considered alternative standards. [EPA-HQ-OAR-2022-0829-0701, pp. 208-210]

1. Concerns with the Proposed SVM GHG Standards

a) Massive Increase in Stringency Without Lead-Time

Auto Innovators is concerned that EPA's proposal envisions a massive increase in stringency in MY 2025 SVM standards (a 53% average stringency increase314) with no lead-time. [EPA-HQ-OAR-2022-0829-0701, pp. 208-210]

314 Calculation by Auto Innovators based on the proposed targets for Ferrari and McLaren, assuming constant footprint and production.

EPA states, "SVM alternative standards established for MY 2021 would apply through MY 2024 to provide stability for SVMs so that SVMs have an opportunity to reduce their GHG emissions in future years." However, there is no lead-time provided. MY 2023 production has already begun, the start of MY 2024 production is imminent, and will certainly be underway by the time this proposal is finalized in early 2024, and MY 2025 could begin as early as January 2, 2024.315 Therefore, the lead-time provided by EPA's proposed MY 2025 alternative standards is at most approximately four months, and potentially less.316 [EPA-HQ-OAR-2022-0829-0701, pp. 208-210]

315 See 40 C.F.R. § 85.1502(a)(8).

316 Assuming a March 2024 final rule and a July 2024 start of MY 2024 production. EPA's proposal affects SVM GHG standards long before MY 2027. EPA has failed to provide any explanation of how circumstances for SVMs have changed so significantly that the revised requirements can be met in general and particularly without lead-time. The lack of lead-time may also raise reliance interest concerns.

b) Equitability of SVM GHG Standards

It is important for GHG policy to be fair and equitable. However, EPA's proposal would increase the stringency of SVM standards more rapidly than the primary standards with the goal of moving SVMs to the primary standard by 2032, another concern (Figure 76). [EPA-HQ-OAR-2022-0829-0701, pp. 208-210]

[See original comment for Figure 76: Cumulative GHG standard stringency increase relative to MY 2021, comparing the proposed SVM standards to the current and proposed primary standards.]317 [EPA-HQ-OAR-2022-0829-0701, pp. 208-210]

317 Calculation by Auto Innovators based on the current and proposed targets and assuming constant footprint and production mix.

c) Projected Technology Requirements of SVM GHG Standards

The technology requirements of EPA's proposal are also concerning. EPA estimates SVMs will be required to achieve a higher EV market share than the industry on average (Figure 77) [See original comment for Figure 77: EPA-Projected BEV Market Share for SVMs compared to other manufacturers.]318, while also rapidly improve remaining ICE vehicles (Figure 78). [See original comment for Figure 78: EPA-Projected ICE Improvement Rates for SVMS.]319 [EPA-HQ-OAR-2022-0829-0701, pp. 208-210]

318 Auto Innovators calculation based on data in EPA's proposal central analysis OMEGA […]vehicles.csv output file.

319 Auto Innovators calculation based on data in EPA's proposal central analysis OMEGA […]vehicles.csv output file.

d) EPA's Reliance on Credit Trading for SVMs to Meet the Proposed GHG Standards

Despite EPA's projections for rapid EV update and ICE improvement, EPA's modeling also suggests that SVMs will be required to heavily rely on credit trading flexibility to maintain compliance with GHG standards.320 We believe this is inappropriate for several reasons and demonstrates that the proposed alternative standards do not meet the requirements of CAA § 202(a) that standards "take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such a period." First, it is inappropriate to set a standard so stringent as to effectively require a manufacturer to entirely rely on another manufacturer to maintain compliance. Additionally, there is an inherent risk that even if a credit-generating manufacturer is willing to sell credits, the credits may be purchased by other parties before SVMs can access them. [EPA-HQ-OAR-2022-0829-0701, p. 211]

320 Credit purchase claim based on examination of EPA's proposal central analysis OMEGA output files for credit transactions, noting degree of credit balances listed as "PAST DUE". Such deficits would require credit purchases.

These proposed standards for SVMs do not meet the Clean Air Act's requirement to provide adequate time for the development and application of the necessary technologies (BEVs in the case of such rapid increases in stringency and overall stringency levels). They are also not equitable to those of other manufacturers given the significantly higher BEV market share required to meet them and the more rapid increases in stringency. [EPA-HQ-OAR-2022-0829-0701, p. 211]

2. Recommendations for SVM GHG Standards

Auto Innovators proposes the following approach to address these concerns:

We support EPA's proposal to sunset the individual application process for alternative standards. However, for the above reasons, we recommend that EPA maintain the approved MY 2021 individual standards through MY 2026. Such an approach would provide time to start implementing electrification-compatible technologies, help address lead-time concerns in general, and make the timing of later changes consistent with the model years EPA is focused on in this rulemaking. [EPA-HQ-OAR-2022-0829-0701, p. 211]

As described above, and related to overall industry concerns highlighted in Section I of these comments (EV Feasibility), SVMs are concerned with both the overall level of electrification likely required by EPA's proposed standards and the relatively greater improvements that EPA is proposing for SVMs relative to industry as a whole. For MY 2032 SVM alternative standards, we recommend that EPA address these concerns by requiring SVMs to improve their emissions levels by the same percentage as the primary standards require between MY 2026 (which would be based on MY 2021 for SVMs) and MY 2032. (E.g., 50% under the current proposal.) [EPA-HQ-OAR-2022-0829-0701, p. 211]

We suggest that the improvements be done as annual linear decreases. Figure 79 provides a generic demonstration of the above concepts. [See original attachment for Figure 79: Conceptual Illustration of Recommended SVM Alternative Standard Approach] [EPA-HQ-OAR-2022-0829-0701, p. 212]

EPA seeks to bring SVM targets into alignment with the primary 2032 targets. Given the unique challenges SVMs face as compared to full-line manufacturers, we believe it is too soon to propose a convergence of the alternative and primary standards. We respectfully suggest that EPA defer consideration of placing SVMs on the primary standards to a subsequent rulemaking. [EPA-HQ-OAR-2022-0829-0701, p. 212]

B. SVM Criteria Pollutant Standards

q) SVM Concerns with the Proposed Criteria Pollutant Standards

As described above, small-volume manufacturers face unique challenges in meeting very stringent emission regulations, particularly those premised largely on electrification. Such is also the case for criteria pollutant standards, particularly given that EPA has not proposed any additional flexibility for SVMs. [EPA-HQ-OAR-2022-0829-0701, pp. 212-213]

Under EPA's proposal, SVMs would need to meet the same criteria, air toxic, and particulate mater emission standards on the same schedule as large manufacturers with diverse product lines. EPA is also proposing to truncate a previously granted flexibility.321 [EPA-HQ-OAR-2022-0829-0701, pp. 212-213]

321 Under EPA's Tier 3 standards, small volume manufacturers were allowed to meet a 0.051 g/mile NMOG+NOx standard through MY 2027.

Historically, EPA has provided special provisions for meeting criteria pollutant emission standards, recognizing these manufacturers' challenges. Likewise, similar provisions are provided in CARB's ACC II LEV IV regulation. For this reason, Auto Innovators recommends that EPA align with the current California's emissions standards and related phase-in flexibilities for small volume manufacturers. This would be particularly helpful given the limited number of vehicle models in SVMs' portfolio and the additional time required to implement new technologies. [EPA-HQ-OAR-2022-0829-0701, pp. 212-213]

b) Recommendations for SVM Criteria Pollutant Standards

In particular we recommend that EPA include the following additional flexibilities for SVMs. These are largely based on the California ACC II approach. [EPA-HQ-OAR-2022-0829-0701, pp. 212-213]

- NMOG+NOx fleet average requirement of 0.051 g/mile (including BEVs). [EPA-HQ-OAR-2022-0829-0701, pp. 212-213]

- Availability of Bin 125 through MY 2034. [EPA-HQ-OAR-2022-0829-0701, pp. 212-213]

- SVM-specific phase-in provisions, allowing SVMs to defer compliance with new regulatory requirements until the end of the phase-in period granted under the primary regulations. (E.g., if the primary phase-in is 40/80/100, the SVM phase-in would be 0/0/100.) [EPA-HQ-OAR-2022-0829-0701, pp. 212-213]

Organization: Aston Martin Lagonda (AML)

Selling fewer than 5000 units per year in the US, AML qualifies as a small volume manufacturer (SVM) and has many specific dynamics and characteristics when it comes to design, manufacturing, sales, CO2 footprint and lifecycle of its vehicles compared to larger original equipment manufacturers (OEMs). The specific challenges of SVMs have long been recognised in US regulations, with the consistent provision of appropriate derogations. These flexibilities are especially important for an operationally independent SVM like AML because we are not part of a larger automotive group and therefore cannot access benefits from being part of a large manufacturer. [EPA-HQ-OAR-2022-0829-0566, pp. 1-2]

Furthermore, SVMs represent a tiny fraction of the US automobile market and have a minuscule impact on US air pollution. AML sold 977 cars in the US in 2022, which represents 0.03% of the total market. As SVMs contribute an extremely small fraction of CO2 emissions, EPA can offer levels of temporary but necessary flexibility, without compromising its overall policy ambition. [EPA-HQ-OAR-2022-0829-0566, pp. 1-2]

In addition, Aston Martin cars are typically not vehicles which are driven daily, but rather tend to be bought by enthusiasts and collectors, and are driven occasionally, mainly for shorter distances. As a result, the average annual mileage driven by these vehicles is likely to be drastically lower. Considering information from the EPA and the UK's Royal Automobile Club Foundation, we estimate due to this lower average usage, the CO2 emissions from an Aston Martin in the US per year amount to less than half that of the average US car. The combination of low sales volumes plus low vehicle miles travelled (VMT) means that the actual pollution impact of SVMs is de minimis. [EPA-HQ-OAR-2022-0829-0566, p. 2]

Limited product portfolios, fewer number of drivetrains, limited financial and human resources, and longer product development times and vehicle life cycles restrict SVMs' ability to meet frequent and significant increases in the stringency of standards and to meet fleet average standards aimed at large OEMs. [EPA-HQ-OAR-2022-0829-0566, p. 2]

The approach to provide flexibilities, as was done in the past, would enable AML to focus valuable resources on investment in the development and production of zero emission cars rather than diverting them to pay financial penalties imposed by any new regulation in the next few years. [EPA-HQ-OAR-2022-0829-0566, p. 2]

AML is committed to doing its fair share to introduce advanced technology at the earliest technically and commercially feasible opportunity. However special accommodation must be made for companies that took strategic decisions and made technological and financial commitments more than 5 years ago and are unable to make rapid adjustments to meet new regulations. [EPA-HQ-OAR-2022-0829-0566, p. 2]

We understand EPA's ambition and we share the goal of decarbonisation however we have some concerns regarding the proposed legislation. We outline our position and recommendations in the pages that follow. [EPA-HQ-OAR-2022-0829-0566, p. 2]

A. IN GENERAL: EPA'S NPRM FAILS TO PROVIDE SVMs WITH SUFFICIENT AND REASONABLE LEADTIME AND FLEXIBILITY

• EPA has recognized in prior criteria pollutant and GHG rulemakings that special flexibility rules for SVMs are essential. Historically, EPA has therefore had a policy for many years to allow SVMs to skip phase-ins and comply 100% at the end of the phase-in period. [EPA-HQ-OAR-2022-0829-0566, p. 3]

The GHG rules and the Tier 3 rules provided even further SVM flexibility. [EPA-HQ-OAR-2022-0829-0566, p. 3]

Tier 3 included a separate SVM-only compliance pathway for a period of 10 years with specific SVM only fleet average requirements. This flexibility is clearly articulated in 40 CFR 86.1811-17(h). [EPA-HQ-OAR-2022-0829-0566, p. 3]

Similarly, the GHG rules to date have both afforded Small Businesses an exemption from GHG requirements as well as providing a SVM procedure for company-specific GHG standards. [EPA-HQ-OAR-2022-0829-0566, p. 3]

In both the Tier 3 and GHG rulemakings, EPA promulgated these flexibilities after acknowledging that SVMs are distinct from large volume manufactures and special provisions for them were necessary and proper. [EPA-HQ-OAR-2022-0829-0566, p. 3]

California has very recently reaffirmed the appropriateness of special SVM provisions in promulgating the CARB 2022 Advanced Clean Cars II (ACCII) rulemaking. EPA should follow this approach. [EPA-HQ-OAR-2022-0829-0566, p. 3]

• The NPRM, does not sufficiently consider the proposal's effect on SVMs. [EPA-HQ-OAR-2022-0829-0566, p. 3]

Unlike in past rulemakings, EPA's multi-pollutant NPRM, fails to adequately address SVM issues - and EPA does not explain why it did not do so.1 The proposal has no provision for SVM lead-time/ flexibility with respect to criteria emissions. This omission is a significant, unreasonable and unexplained change of policy. The NPRM also proposes to revamp SVM alternative GHG standards by sweeping SVMs into the large volume rules. The manner in which EPA proposes to do this will result in significant hardship for SVMs without achieving meaningful air quality benefits. [EPA-HQ-OAR-2022-0829-0566, p. 3]

1 On the positive side, we do acknowledge that the NPRM

• SVMs may delay complying with the proposed new Tier 4 OBD requirements until model year 2030; [EPA-HQ-OAR-2022-0829-0566, p. 3]

• OEMs can count BEVs in their Tier 4 fleet average calculations; [EPA-HQ-OAR-2022-0829-0566, p. 3]

• Small business entities have certain exemptions from the 86.1815 Battery-related requirements for electric vehicles and plug-in hybrid (but no special provisions for SVMs); [EPA-HQ-OAR-2022-0829-0566, p. 3]

• Continues the current GHG exemption for small business entity manufacturers [EPA-HQ-OAR-2022-0829-0566, p. 3]

Due to their low volume, specialisms, and diversity, it is critical that the impact of regulations and standards for SVMs is fully understood when under development. Regulatory impact assessments catering to the different vehicle segments are required to ensure the impact is felt proportionately. Suitable lead times are required ahead of the introduction of new regulations. SVMs' products have much longer life cycles than mass market products, which is necessary to recover investment costs due to lower annual volumes of sales. Therefore limited product portfolios and longer product development and life cycles restrict SVMs' ability to meet frequent and significant increases in stringency. [EPA-HQ-OAR-2022-0829-0566, p. 3]

Under the Clean Air Act, EPA must recognize and fully consider the impacts of its proposed standards on SVMs and must promulgate standards that are feasible for SVMs. [EPA-HQ-OAR-2022-0829-0566, pp. 3-4]

In the NPRM Preamble, EPA states as follows:

The Administrator finds that the standards proposed herein are consistent with EPA's responsibilities under the CAA and appropriate under CAA section 202(a). EPA has carefully considered the statutory factors, including technological feasibility and cost of the proposed standards and the available lead time for manufacturers to comply with them. Based on our analysis, it is our assessment that the proposed standards are appropriate and justified under section 202(a) of the CAA. Our analysis for this proposal supports the preliminary conclusion that the proposed standards are technologically feasible and that the costs of compliance for manufacturers would be reasonable. [EPA-HQ-OAR-2022-0829-0566, pp. 3-4]

SVMs are not mentioned in the above conclusion and the NPRM provides no support for applying the above conclusions to SVMs. In this regard, the Preamble has an entire section ("V") on "EPA's Basis That the Proposed Standards Are Feasible and Appropriate Under the Clean Air Act", but nowhere in that section are the terms "Small Volume Manufacturer" or "Small Business" mentioned. [EPA-HQ-OAR-2022-0829-0566, pp. 3-4]

We believe that the NPRM's proposed SVM standards and trajectories do not meet the requirements of CAA§ 202(a) that standards "take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such a period." The reality is that SVMs do not have access to technology developed by larger OEMs or tier one suppliers and this difficulty has been recognised in prior EPA regulations. It is only fair that such derogations are provided for SVMs under these new rules. The ability of SVMs to make changes at the same rate as large companies has not changed, therefore appropriate legislative consideration is needed for SVMs. [EPA-HQ-OAR-2022-0829-0566, pp. 3-4]

EPA should reconsider its proposed provisions and finalize SVM rules that are consistent with the principles of an incremental phase-in with periods of stability, that are reflective of both the function and limited emissions contribution of SVM products, and without forcing SVMs to be overly-reliant on purchasing credits from other manufacturers. Note that compelling SVMs through a regulatory regime which forces credits to be purchased will limit the ability of SVMs to invest in EVs and other lower carbon technologies with R&D funds being allocated to pay for credits. This is not an effective way to enable technological progress by imposing a charge on a company which has no ability to make a rapid course correction. [EPA-HQ-OAR-2022-0829-0566, pp. 3-4]

- Understanding what SVMs are selling in the US

Neither with regard to criteria emissions nor GHG does EPA explain in the NPRM the paucity (verging on absence) of Small OEM flexibility or additional lead-time. A misstatement in the preamble may shed light on this: in the preamble (88 FR 29405) (May 5, 2023), EPA incorrectly states (as does the Draft Regulatory Impact Analysis) that the "proposed NMOG+NOx standards should have no impact on the existing Small Business manufacturers, which currently produce only electric vehicles." This is simply not so. There most certainly are SVMs that produce internal combustion engine (ICE) vehicles for the US market, AML being one of them. Nowhere in the draft RIA does the term "small volume manufacturer" even appear, and the draft RIA thus fails to address the SVM segment of the industry. Given that the EPA has consistently recognised the SVM category, it is unusual that it would bring forward punitive regulations at those companies less able to deal with heavy sanctions. [EPA-HQ-OAR-2022-0829-0566, p. 4]

- SVMs cannot effectively fleet average

One assumption supporting the NPRM which is not applicable to SVMs is that all OEMs have the ability to average the emissions of their various test groups in order to meet a fleet standard. SVMs have long maintained that with only one or two high-performance test groups, they cannot use "averaging" as a compliance strategy and have therefore needed, and still need, the long-standing EPA policy affording extra leadtime and flexibility to SVMs. In the absence of such flexibility, a fleet average standard becomes in effect a required (BIN) standard for these SVMs. [EPA-HQ-OAR-2022-0829-0566, pp. 4-5]

This point further underlines the simple reality that large car makers can achieve lower averages, whereas an SVM with a narrow or niche offering of products simple does not have this ability to comply with the regulation. [EPA-HQ-OAR-2022-0829-0566, pp. 4-5]

- It is improper to set a standard so stringent that it requires an SVM to rely entirely on credits from another manufacturer to maintain compliance

EPA projects that SVM fleets on average, and individually, will exceed the proposed standards, requiring purchased credits to continue selling vehicles in the US. EPA therefore relies on credit trading flexibility as a key means by which SVMs will maintain compliance with standards. We disagree with this approach. [EPA-HQ-OAR-2022-0829-0566, pp. 4-5]

It is counterproductive to set a standard so stringent that it requires a manufacturer to rely entirely on credits from another manufacturer to maintain compliance. The decision to sell credits, who to sell them to, at what price to sell them, and when to sell them (or to keep them for later use or future value} is a business decision. There is nothing that requires a manufacturer to sell its credits, or to sell them to a particular party. [EPA-HQ-OAR-2022-0829-0566, pp. 4-5]

This approach would prevent SVMs from focusing valuable resources on investment in the development and production of zero emission cars and instead divert resources to buy credits or pay financial penalties. [EPA-HQ-OAR-2022-0829-0566, pp. 4-5]

On the one hand, EPA justifies its standard setting on the basis that credits can be bought, but on the other hand, EPA steadfastly maintains that it will not get involved in credit trading and leaves it to the free market. As a result, the availability and cost of credits is inherently risky, including the risk that credit-generating manufacturers may strategically withhold credits to limit SVMs' market access. [EPA-HQ-OAR-2022-0829-0566, pp. 4-5]

And finally, compliance with EPA's proposed standards is largely premised on very high levels of electrification. If EPA's projections are incorrect, and sales of electric vehicles are not as high as expected, many manufacturers will likely need to hold onto credits to maintain their own compliance. [EPA-HQ-OAR-2022-0829-0566, pp. 4-5]

- It is critical that EPA:

- acknowledge that for SVMs to achieve fleet electrification, they face challenges that can be particularly acute given their limited resources and the high-performance nature of SVMs product lines, which necessitates lighterweight, high-density batteries. Overcoming these challenges requires time. [EPA-HQ-OAR-2022-0829-0566, pp. 5-6]

- understand that given these technical challenges facing SVMs seeking to electrify their lightweight sports cars, it is not possible for them to reduce emissions to the level set for Large Volume Manufacturers on the timetable set for Large Volume Manufacturers. [EPA-HQ-OAR-2022-0829-0566, pp. 5-6]

- recognize that requiring SVMs to do so would be contrary to the Clean Air Act's mandate that EPA provide sufficient lead-time "to permit the development and application of the requisite technologies, giving appropriate consideration to the cost of compliance within [the lead-time] period." [EPA-HQ-OAR-2022-0829-0566, pp. 5-6]

- adhere to past EPA precedent and established policy providing SVM flexibility and extra lead time set the SVM standards and trajectory with step-downs whose frequency and degree reflect the realities facing SVMs as regards limited product lines, longer product development and life cycles [EPA-HQ-OAR-2022-0829-0566, pp. 5-6]

- consider harmonizing as much as possible with the CARB 2022 Advanced Clean Cars II (ACCII) rulemaking with regard to special SVM provisions [EPA-HQ-OAR-2022-0829-0566, pp. 5-6]

B. THERE ARE FOUR SPECIFIC TOPICS IN THE NPRM THAT ARE OF DEEP CONCERN TO SVMs

1. CRITERIA EMISSIONS

- "Moving the goalpost" for MY 27 and 28 makes the trajectory exceptionally challenging for SVMs therefore appropriate derogations are essential. Special accommodation must be made for SVMs that took strategic decisions and made technological and financial commitments more than 5 years ago and are unable to make rapid adjustments to adapt to new regulation at pace. [EPA-HQ-OAR-2022-0829-0566, pp. 6-7]

EPA proposes to abandon the MY 27 and 28 SVM NMOG+NOx standards set forth in Tier 3 (and on which SVMs have been rightfully relying), and to require SVMs to adhere to the Tier 4 large volume (and short) phase-in. [EPA-HQ-OAR-2022-0829-0566, pp. 6-7]

This inequitably conflicts with the already established and in effect SVM phase-in set forth in 40 CFR 86.1811-17 (h)(l), as follows:

SVM Fleet Average NMOG+NOx Standard (mg/mile)

Model year: 2027: In effect Tier 3: 51; In effect Tier 4: 22

Model year: 2028: In effect Tier 3: 30; In effect Tier 4: 20 [EPA-HQ-OAR-2022-0829-0566, pp. 6-7]

The NPRM's proposed change means that in MY 27, SVMs would have to meet a fleet average NMOG+NOx standard that is 57% more stringent than what they have been planning in reliance on 40 CFR 86.1811-17(hl(l). And then, for MY 28, they would have to meet a fleet average NMOG+NOx standard that is 33% lower than what they have been planning in reliance on 40 CFR 86.1811-17(h)(l). This would be an unjust "moving the goalpost".[EPA-HQ-OAR-2022-0829-0566, pp. 6-7]

- The proposed NMOG+NOx requirements are excessively stringent - too stringent, too soon This is especially so considering Tier 3 levels and that the CARB ACCII rulemaking appropriately maintained an SVM NMOG+NOx fleet standard of 51 mg/mi through MY 34, as shown in the graph below. [EPA-HQ-OAR-2022-0829-0566, pp. 6-7]

[See original comment for bar graph of SVM FTP NMOG+NOx LIMIT [g/mi]]

- The Proposed Tier 4 NMOG+NOx fleet average is unrealistic for companies that cannot make use of fleet averaging; SVMs should not have to rely on credit purchasing. [EPA-HQ-OAR-2022-0829-0566, pp. 6-7]

There is no recognition in the NPRM that an SVM may have only one or two ICE test groups, neither of which meets the Tier 4 fleet NMOG+NOx average. The fleet average concept in such a situation offers no flexibility; having nothing to "average", such an SVM would simply have no ability to comply and would fall into a deficit situation. It was precisely to address this type of scenario that the Tier 3 SVM flexibility provisions in 40 CFR 86.1811-17(h) were promulgated. The current rulemaking should follow suit and adopt comparable SVM flexibility. [EPA-HQ-OAR-2022-0829-0566, p. 7]

As regards credit purchasing, we reiterate how it is unfair to force SVMs to rely on risky credit purchasing (with unknown availability and at an unknown cost) to meet criteria emissions requirements. [EPA-HQ-OAR-2022-0829-0566, p. 7]

- Bin 125 should remain available to SVMs

Moreover, the NPRM also proposes to eliminate Bin 125, a Bin currently relied upon by SVMs. EPA has not provided a reason why Bin 125 cannot be kept in place for the exclusive use of SVMs as California has permitted. CARB 's ACCII rules allow SVMs to continue to use Bin 125 until 2035. [EPA-HQ-OAR-2022-0829-0566, p. 7]

The elimination of Bin 125 is unfair and unreasonable as regards SVMs because it puts SVMs in the untenable position of having to, with limited resources, simultaneously implement EVs and also reengineer Bin 125 vehicles to a much more stringent standard. [EPA-HQ-OAR-2022-0829-0566, p. 7]

Bin 125 should be kept in place for the exclusive use of SVMs, as California has permitted. CARB's ACCII rules allow SVMs to continue to use Bin 125 until 2035. EPA should follow suit. Retaining Bin 125 for SVMs is simply not contrary to the goal of cleaner air. [EPA-HQ-OAR-2022-0829-0566, p. 7]

- The Proposed Interim Tier 4 provision does not provide flexibility to SVMs [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

We note that one general flexibility concession in the NPRM -- the category of "Interim Tier 4 vehicles" -- does not provide relief to SVMs. As proposed, the Interim Tier 4 provision leaves SVMs empty-handed because the benefits of Interim Tier 4 are restricted to OEMs who can otherwise meet the 40% and 80% phase-in percentages with their full Tier 4 test groups (and thus use the Interim Tier 4 category for the remaining 60% and 20% of their fleets during the phase in}. Given that SVMs - particularly those with only one or two test groups -- cannot meet the phase-in percentages with full Tier 4 cars, EPA's proposal unfairly denies SVMs the ability to make use of the benefits of the Interim Tier 4 category. [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

- In sum, as regards criteria emissions, EPA should:

- follow CARB's ACCII rules and continue the availability of Bin 125 to SVMs through MY 2034 and not require NMOG+NOx limits for cold testing.2 [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

2 EPA must justify imposing on SVMs the proposed new cold NMOG+NOx standard. Until EPA can establish that the environmental benefits outweigh the burdens on SVMs, SVMs should be exempted.

- with regard to NMOG+NOx FTP and US06 standards [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

- In order to properly account for the problems facing SVMs with regard to "fleet averaging,, and the risks of credit purchasing, as explained above, set the degree and frequency of SVM step-downs to reflect SVM realities -- limited product lines, longer product development and life cycles [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

- MY 2027 -- Maintain for all SVMs the already-in effect {86-1811-17{h} MY 27 Tier 3 SVM NMOG+NOx standard {51m g/mi} [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

- MY 2028 -- Maintain for all SVMs the already-in effect MY 28 Tier 3 SVM NMOG+NOx standard (30 g/mi) [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

- MY 2029-32 - continue the 30 mg/mi standard for SVMs given that the environmental benefits of a more stringent standard have not been established and are vastly outweighed by the potential burden on SVMs. [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

- Make the Interim Tier 4 category more flexible and available [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

- Add a new paragraph (e} to proposed 40 CFR 86.1811-27 to read as follows:

(e) If meeting the standards set forth in this section 40 CFR 86.1811-27 would cause severe economic hardship, small-volume manufacturers may ask us to approve an extended compliance deadline under the provisions of 40 CFR 1068.250, except that the solvency criterion does not apply and there is no maximum duration of the hardship relief [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

This provision would mirror the SVM relief made available under Tier 3 in 40 CFR 86.1811-17. [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

The above steps are necessary to comply with the Clean Air Act's section 202{a} mandate that EPA provide sufficient lead-time "to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such [lead-time].” [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

2. GHG

- EPA's SVM GHG policy needs to be fair and equitable.

The current system of setting company-by-company SVM alternative standards should be eliminated as unwieldly -- too time-consuming and burdensome for all parties - and be replaced. [EPA-HQ-OAR-2022-0829-0566, pp. 8-9]

We therefore propose that there be a separate GHG standard for all SVMs - separate from the large volume standard -- which still requires significant GHG improvement, yet reflects the challenges faced by SVMs discussed above. Requiring SVMs to switch to large volume standards over a short period of time would impose a dramatic decrease in the GHG standard (from MY 24 to 25). Simply put, the standard would drop precipitously, akin to falling off a cliff. This is both unfair and unachievable. [EPA-HQ-OAR-2022-0829-0566, pp. 8-9]

- SVMs cannot rely on fleet averaging or GHG credits as a compliance strategy

As discussed above, SVMs cannot use averaging as a successful compliance strategy. In addition, forcing SVMs to use credits as a primary if not exclusive compliance strategy is both unfair and improper, and this is especially so as regards GHG since SVMs expect the open market availability of GHG credits to decline starting in 2026MY when the phase-in of changes to MPGe begins to affect the ability of manufacturers of PHEVs and BEVs to generate GHG credits. [EPA-HQ-OAR-2022-0829-0566, pp. 8-9]

In sum, as regards GHG, EPA should:

For MY 22, 23, 24 and 25 -- for SVMs that have been granted alternative bespoke standards in the 2020 notice Federal Register :: Determinations of Light-Duty Vehicle Alternative Greenhouse Gas Emissions Standards for Small Volume Manufacturers, continue for MY 22, 23, 24 and 25 the alternative standard for MY 21 set in the FR notice [EPA-HQ-OAR-2022-0829-0566, pp. 8-9]

For MY 2026 and later, eliminate company-by-company alternative SVM GHG standards,

Instead, in order to properly account for the problems facing SVMs with regard to "fleet averaging" and the risks of credit purchasing (as discussed above), create a new regulatory provision applicable to all SVMs (using the definition of SVM in 40 CFR 86.1838-01) setting forth SVM standards and an SVM trajectory. [EPA-HQ-OAR-2022-0829-0566, pp. 9-10]

Reasonably achievable SVM CO2 levels and a feasible trajectory are needed to account for challenges and limitations specific to SVMs. EPA's NPRM proposal would require SVMs to have more than a 50% BEVs in their fleet in MY2026 - a level far higher than that expected from Large Volume Manufacturers under the Primary Standard phase-in starting in MY 2027. [EPA-HQ-OAR-2022-0829-0566, pp. 9-10]

There is a need for an SVM-specific phase-in requiring a substantial GHG reduction by MY 2032, but starting with a period of stability in order to account for SVMs' limited product lines and limited availability/access to necessary technologies. Therefore, EPA should: [EPA-HQ-OAR-2022-0829-0566, pp. 9-10]

Bring SVMs towards the Primary Standard via an SVM phased-in target reduction requiring a 50% GHG reduction in MY 2032 compared to MY 2025. [EPA-HQ-OAR-2022-0829-0566, pp. 9-10]

- Establish a trajectory from MY 2026 to MY 2032 that has either a linear reduction or one or more reasonable step changes. [EPA-HQ-OAR-2022-0829-0566, pp. 9-10]

- Defer consideration of incorporating SVMs into the Primary Standard until a subsequent separate rulemaking. [EPA-HQ-OAR-2022-0829-0566, pp. 9-10]

[See original attachment for 2022+ GHG Proposed Targets] [EPA-HQ-OAR-2022-0829-0566, pp. 9-10]

- Add a new paragraph to 40 CFR 86.1818-12 to read as follows: [EPA-HQ-OAR-2022-0829-0566, p. 10]

(e) If meeting the standards set forth in this section 40 CFR 86.1818-12 would cause severe economic hardship, small-volume manufacturers may ask us to approve an extended compliance deadline under the provisions of 40 CFR 1068.250, except that the solvency criterion does not apply and there is no maximum duration of the hardship relief. [EPA-HQ-OAR-2022-0829-0566, p. 10]

4. PARTICULATE MATTER

- EPA's proposed PM reduction to O.Smg/mi across the FTP and US06 and Cold Testing goes far beyond what SVMs are able to achieve in a short period of time [EPA-HQ-OAR-2022-0829-0566, pp. 11-12]

EPA's proposed PM reduction to 0.Smg/mi across the FTP and US06 and Cold Testing is an enormous increase in stringency over a short period of time. This is a regulatory combination that SVMs simply cannot meet. We recognize that the regulation of PM is headed towards necessitating the use of Gasoline Particulate Filters (GPF), but further research and development is needed with respect to GPF aging and monitoring for purposes of California OBD. This issue is not yet fully understood and requires more lead-time under the CAA section 202(a). [EPA-HQ-OAR-2022-0829-0566, pp. 11-12]

In addition, there are also technical issues and costs associated with measuring PM emissions below 1 mg/mile, and specialized, expensive test facilities may be needed to reliably measure PM at such a low level. [EPA-HQ-OAR-2022-0829-0566, pp. 11-12]

It is thus unreasonable to impose the proposed PM standards and timetable on SVMs, especially considering the minimal environmental benefit obtained together with how drastic the proposed change is compared to existing Tier 3 levels and the CARB ACCII PM standards, as shown in the graph below. [EPA-HQ-OAR-2022-0829-0566, pp. 11-12]

[See original attachment for bar graph of Tailpipe PM Limit [mg/mi]] [EPA-HQ-OAR-2022-0829-0566, pp. 11-12]

In sum, as regards SVMs and PM, EPA should harmonize with the CARB ACC/1 SVM PM approach as follows:

- FTP

-- For MY 2027-2028 -- 3 mg/mile.

-- For MY 2029 and later - 1 mg/mi. [EPA-HQ-OAR-2022-0829-0566, pp. 11-12]

- SFTP

-- For MY 2027 - 2029 - 6 mg /mi

-- For MY 2030 and later - 3 mg/mi [EPA-HQ-OAR-2022-0829-0566, pp. 11-12]

- No Cold Testing for SVMs given that it is not yet fully understood what is needed to meet the 0.5mg standard at 20F with high-performance engines. [EPA-HQ-OAR-2022-0829-0566, pp. 11-12]

We further note the above levels and timetable are consistent with the EU regulation of PM. GPFs will be necessary on all European engines in 2030 with the implementation of EU7's mandating PM measurement for both Port Fuel Injection Engines and Gasoline Direct Injection Engines. [EPA-HQ-OAR-2022-0829-0566, pp. 11-12]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Inclusion of Small Volume Manufacturers

U.S. EPA is proposing to include small volume manufacturers in its GHG program by MY 2032. CARB supports this proposal and finds that the lead time is appropriate. Under ACC II, CARB requires that small volume manufacturers comply with the annual ZEV sales requirement beginning with the 2035 MY and submit a compliance plan to CARB’s Executive Officer by 2032. The investments these small volume manufacturers make to comply with California’s policies will facilitate their compliance with U.S. EPA’s proposed standards. [EPA-HQ-OAR-2022-0829-0780, p. 26]

Organization: Environmental. and Public Health Organizations

XIV. EPA Should Finalize Its Proposed Changes for Small Volume Manufacturers.

We support EPA's proposal to transition small volume manufacturers ("SVMs") into the primary program standards by MY 2032.236 As illustrated in Table 37, the emissions standards presently applicable to SVMs are significantly less protective than those that apply to other manufacturers.237 For MY 2021, SVM standards ranged from 308-376 g/mile.238 By comparison, the revised footprint curve in SAFE 2 for passenger cars for MY 2021 was 161.8 to 220.9 g/mile.239 [EPA-HQ-OAR-2022-0829-0759, p. 98]

236 88 Fed. Reg. at 29197, 29255.

237 Id. at 29256.

238 Id.

239 84 Fed. Reg. 24174, 25268 (Apr. 30, 2020).

As EPA explains, there has been a significant shift in the vehicle market since EPA established the SVM alternative standards.240 For example, "[v]ehicle electrification technologies are currently being implemented across many vehicle types including both luxury and high-performance vehicles by larger manufacturers and EPA expects this trend to continue."241 In addition, as EPA notes, the credit trading market has become more robust since the SVM alternative standards were initially developed, expanding compliance options for SVMs. EPA concluded that "meeting the CO2 standards is becoming less a feasibility issue and more a lead time issue for SVMs."242 [EPA-HQ-OAR-2022-0829-0759, pp. 98-99]

240 88 Fed. Reg. at 29256.

241 Id.

242 Id.

EPA's conclusions that a transition of SVMs to the primary program coheres with the recent announcements and developments in the business model of the SVMs who have previously pursued less stringent standards. There are only four SVMs currently subject to less stringent standards: Ferrari, Aston Martin, Lotus, and McLaren. All are moving toward greater hybridization and electrification, which will facilitate compliance with the primary LDV GHG standards. [EPA-HQ-OAR-2022-0829-0759, p. 99]

Ferrari in 2022 announced plans to rapidly electrify its vehicle offerings, achieving 40% BEV sales by 2030 and 80% electrified (PHEV + BEV) vehicles.243 Ferrari already sells two PHEVs, the SF90 Stradale244 and the 296 GTB.245 Likewise, Aston Martin has committed to electrification. It will offer its first BEV in 2025 and has committed to having every model available with an electrified powertrain by 2026.246 It will begin delivering its first PHEV, the Valhalla, in 2024.247 Lotus is offering the all-electric Evija248 and Eletre SUV.249 The Eletre will be available in the United States beginning in 2024.250 And McLaren has recently developed its first hybrid vehicle, the Artura, and indicated that all its vehicles will eventually be gas-electric hybrids or electric-only.251 [EPA-HQ-OAR-2022-0829-0759, p. 99]

Based on the SVMs' active transition into hybrid and battery electric vehicles—with its attendant improvements in GHG emissions—the existence of a robust credit trading market, and the significant lead time proposed by EPA for transitioning the SVMs into the broader program, We support EPA's proposal. [EPA-HQ-OAR-2022-0829-0759, p. 99]

Organization: Ferrari N.V. and Ferrari North America, Inc.

Innovation runs within Ferrari, so the challenge of building a Ferrari for a low-emissions future is one that we are already embracing despite our negligible contribution to the total air pollutant emissions due to the low volumes and typical low average annual mileage. [EPA-HQ-OAR-2022-0829-0572, pp. 2-3]

FERRARI CONTRIBUTION

Ferrari fully supports and welcomes the climate protection initiatives of the United States (US) Government, provided that all stakeholders contribute their share, and that the achievements obtained so far are taken into account. [EPA-HQ-OAR-2022-0829-0572, pp. 2-3]

Saying that all stakeholders should contribute their part means that the negligible contribution to air pollutant emissions of vehicles registered in US and produced by SVMs should be taken into account in the Impact Analysis evaluations. [EPA-HQ-OAR-2022-0829-0572, pp. 2-3]

The even more negligible contribution to the total emissions of high performance vehicles registered in US and produced by low volume manufacturers due to the typical low mileage of 2,543 miles per year2 should also be considered. [EPA-HQ-OAR-2022-0829-0572, pp. 2-3]

2 Proposed Decision on "Exemption from Average Fuel Economy Standards", National Highway Traffic Safety Administration

The integration of hybrid and electric technologies more broadly into our car portfolio over time may present challenges and costs. We expect to increase R&D spending in the medium term particularly on hybrid and electric technologies related projects. In addition, this transformation of our car technology creates risks and uncertainties such as the impact on driver experience, and the impact on the cars' residual value over time, both of which may be met with an unfavorable market reaction. [EPA-HQ-OAR-2022-0829-0572, p. 3]

In the long term, although we believe that combustion engines will continue to be fundamental to the Ferrari driver experience, hybrid and pure electric cars may become a much more essential technology for performance sports cars thereby displacing combustion engine models. Having said that, we trust that the effort required by EPA must be commensurate with the share of emissions for which each stakeholder is responsible. [EPA-HQ-OAR-2022-0829-0572, p. 3]

SVM's PECULIARITIES

The strong reduction in greenhouse gas and air pollutant emissions over the past decade – driven mainly by engine and after treatment efficiency improvements – was achieved despite our peculiarities. [EPA-HQ-OAR-2022-0829-0572, pp. 3-4]

Customer acceptance [EPA-HQ-OAR-2022-0829-0572, pp. 3-4]

Our brand symbolizes exclusivity, innovation, state-of-the-art sporting performance and Italian design, craftsmanship and engineering heritage. [EPA-HQ-OAR-2022-0829-0572, pp. 3-4]

The heart of a Ferrari is its engine. Proof of this, for the fourth year running, Ferrari's turbocharged V8 engine has been named Engine of the Year 2019 at the prestigious International Engine of the Year Awards, a feat never achieved by any other engine in the history of the awards. [EPA-HQ-OAR-2022-0829-0572, pp. 3-4]

Ferrari cars should make a customer's dream become true. [EPA-HQ-OAR-2022-0829-0572, pp. 3-4]

Ferrari cars are developed for the joy of driving to deliver an exhilarating experience behind the wheel, they are not simple passenger cars. [EPA-HQ-OAR-2022-0829-0572, pp. 3-4]

Therefore, considering that SVM have to face more severe technology requirements in order to maintain their unique selling points like sounds and performance, Ferrari trusts this to be taken into proper consideration by providing more time to such manufacturers. [EPA-HQ-OAR-2022-0829-0572, pp. 3-4]

Unique solutions [EPA-HQ-OAR-2022-0829-0572, p. 4]

Several emission control technologies may not be simply implemented on a high performance vehicle without losing the performance level and the real nature of the product. More time is needed to develop and adapt emission control technologies to the sports cars, finding the way to guarantee peculiarities. Moreover, for an OEM, the development of an ad-hoc technological solution is linked to the technological capacity of a company and therefore to its global size: considering Small Volume Manufacturer's production capacity and their Companies size, more time should be guaranteed due to the resulting limited technological potential. [EPA-HQ-OAR-2022-0829-0572, p. 4]

No benefit related to mass production standard technologies [EPA-HQ-OAR-2022-0829-0572, p. 4]

SVM suppliers have to adapt their products to unique applications without the mass production standard technologies benefits, since the SVM production volume request is very low. Therefore, extra time is needed also for the supply chain adjustment. [EPA-HQ-OAR-2022-0829-0572, p. 4]

Keep achieving outstanding results on technological innovation with limited human and financial resources [EPA-HQ-OAR-2022-0829-0572, p. 4]

As a luxury performance car manufacturer and low volume producer, despite the high margins of our cars, we compete with larger automobile manufacturers many of which have greater financial resources. Nevertheless, we have been able to achieve outstanding results on technological innovation with limited human and financial resources. [EPA-HQ-OAR-2022-0829-0572, p. 4]

SVM Criteria Pollutant Standards [EPA-HQ-OAR-2022-0829-0572, p. 5]

As described above, EPA has historically recognized the peculiarities and challenges that manufacturers responsible of high-performance vehicles face. This is also the case for criteria pollutant standards, especially considering that EPA, differently from the current Tier 3 approach, has not proposed any special provisions for SVMs. In this regard, we suggest including a specific impact assessment on the elimination of Tier 4 derogations for SVMs. [EPA-HQ-OAR-2022-0829-0572, p. 5]

Ferrari also suggests EPA to reconsider the possibility of maintaining provisions like those already granted in current US Regulation. Similarly, the CARB ACC II LEV IV Regulation, recognizing the challenges and negligible impact of SVMs4, allows them to benefit from special provisions. [EPA-HQ-OAR-2022-0829-0572, p. 5]

4 CARB ACC II Regulations Initial Statement of Reasons (April 12, 2022), chapter III, section C, paragraph 7

a) NMOG+NOx Standards

EPA is proposing to remove any NMOG+NOx fleet-average flexibility for SVMs, requiring an alignment to Large Volume Manufacturers (LVMs) targets starting with MY 2027, unreasonably changing the current Tier 3 regulation that allows SVMs to comply with 51 mg/mi standard until MY 2027, and therefore cutting their target by more than half (i.e. 22 mg/mi compared to 51 mg/mi). For later years, EPA is requiring SVMs to comply with an overall 76% standard reduction in just 5 model years. [EPA-HQ-OAR-2022-0829-0572, pp. 5-6]

Ferrari strongly believes this approach is unfair, especially in light of the unexpected change of the Tier 3 regulation and the huge implied percentage of BEVs that manufacturers responsible of high performance vehicles shall include in their fleet. While most LVMs can benefit from a wide range of models to compensate for the few vehicles that pollute the most, independent SVMs like Ferrari have to deal with a huge and unfeasible BEV penetration in their car portfolios since the beginning of the legislation. [EPA-HQ-OAR-2022-0829-0572, pp. 5-6]

Ferrari acknowledges EPA’s intention of aligning SVM targets to those of LVMs. However, this sharp reduction in NMOG+NOx standards is not feasible in such a short amount of time. In support of this, California recognized the impracticability of these manufacturers4, allowing them to comply with a fleet-average standard of 51 mg/mi for the entire regulatory period. [EPA-HQ-OAR-2022-0829-0572, pp. 5-6]

4 CARB ACC II Regulations Initial Statement of Reasons (April 12, 2022), chapter III, section C, paragraph 7

Ferrari's commitment to reducing NMOG+NOx emissions is reflected on several of our models (Ferrari Portofino M, Ferrari Roma, 296 GTB, Ferrari Purosangue) which are currently certified as BIN 50. An even more remarkable result has been achieved with our Ferrari Purosangue, the first and only V12 model certified as BIN 50 in the United States. [EPA-HQ-OAR-2022-0829-0572, pp. 5-6]

However, the current state of art does not allow high-performance vehicles with modern passive heating systems to achieve a certification level below BIN 50, and therefore large investments and time-consuming activities on active heating devices (e.g. burner, electric heating catalyst) are required. In addition, the very limited demand of those devices due to mass market focus on electrification will inevitably lead to ad hoc development with related huge costs and times. [EPA-HQ-OAR-2022-0829-0572, pp. 5-6]

SVM Greenhouse Gas Emissions Standards [EPA-HQ-OAR-2022-0829-0572, pp. 7-8]

Historically, EPA has recognized the unique design considerations and compliance challenges faced by SVMs, allowing them to benefit from alternative GHG standards. EPA is now proposing to keep providing SVMs special provisions, resulting in an extension of the already approved MY 2021 alternative CO2 target through MY 2024 included. And then, starting with MY 2025, EPA is requesting SVMs to align with Large Volume Manufacturer (LVM) CO2 targets with a very limited phase-in. [EPA-HQ-OAR-2022-0829-0572, pp. 7-8]

Ferrari welcomes EPA's proposal of keep providing flexibilities for SVMs. However, we strongly believe that these provisions are minor as they require SVMs to comply with a very sharp GHG standard reduction well before the commencement of the regulation (i.e. MY 2025 rather than MY 2027). Moreover, by establishing an alignment with LVM standards, EPA is currently requesting SVMs an improvement that is far greater than that required to LVMs (see Figure 1). [EPA-HQ-OAR-2022-0829-0572, pp. 7-8]

EPA also recognized that it is impossible for SVMs to comply with the proposed CO2 standards and expects them to seek credit purchases as a compliance strategy. This demonstrates that the proposed alternative targets do not meet the requirements of CAA §202 (a) which states that standards "take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such a period". [EPA-HQ-OAR-2022-0829-0572, pp. 7-8]

Ferrari completely agree with EPA's statement on the unfeasibility of the proposed CO2 standards for small volume manufacturers. Moreover, we believe it is unfair to set a standard so stringent as to effectively require SVMs to entire rely on another manufacturer to guarantee compliance. For these reasons, Ferrari strongly believes that the same GHG improvements requested to LVMs should also be applied to SVMs (see Figure 2). [EPA-HQ-OAR-2022-0829-0572, pp. 7-8]

Therefore, the alternative standards approved for model year 2021 should continue to apply through model year 2026 included. Starting with new regulation in model year 2027, small volume manufacturers should comply with GHG standards according to a reduction percentage of no more than 50% in MY 2032 compared to MY 2026, consistent with the improvement requested to LVMs. [EPA-HQ-OAR-2022-0829-0572, pp. 7-8]

Ferrari's commitment to reducing GHG emissions is reflected in several business decisions, such as large investments in advanced assets and industrial buildings with the aim of extending our concept of global GHG emission reduction. To deliver our commitment to electrification, in 2022, we started the construction of the 40 thousand square meter e-building, where we will handcraft the unique Ferrari electric engines, inverters, battery modules, magnets and assembly lines that you will only find in a Ferrari. [EPA-HQ-OAR-2022-0829-0572, pp. 7-8]

This plant development will assure us a technical capacity in excess of our needs for the years to come, while maintaining the uniqueness of our model and remaining true to the Ferrari DNA which has characterized our history. [EPA-HQ-OAR-2022-0829-0572, pp. 7-8]

Organization: Mclaren Automotive, McLaren Group

Background

Given that we are significantly below the 5,000 USA sales per year, we fall within the Small-volume manufacturer (SVM) definition. As a SVM we have limited product portfolios, limited number of drivetrains, limited financial and human resources, and longer product development times and vehicle life cycles. Unlike other parts of the market, given our limited product portfolio we do not have the ability to make significant redesigns each year and as such we are unable to take advantage of fleet emission averaging programs. [EPA-HQ-OAR-2022-0829-0748, pp. 1-2]

We produce lightweight high-performance supercars, which drive far fewer miles than the average car. As such, emissions from our vehicles are negligible. Despite generally having higher emission rates (grams per mile), SVM average total mileage accumulation is extremely low – approximately 2,543 miles1. We believe that EPA should consider the de minimis use of our vehicles and those of SVMs when considering final standards under this rulemaking. [EPA-HQ-OAR-2022-0829-0748, pp. 1-2]

1 U.S. Department of Transportation, National Highway Traffic Safety Administration, Exemptions From Average Fuel Economy Standards; Passenger Automobile Average Fuel Economy Standards (Proposed rule; proposed decision to grant exemption), 87 Fed. Reg. 39439, 39449 (Jul. 1, 2022).

EPA'S NPRM need to provide SVMs with sufficient and reasonable lead time together with adequate flexibilities [EPA-HQ-OAR-2022-0829-0748, pp. 1-2]

Historically, EPA has recognized the unique design considerations and compliance challenges faced by SVMs. We have been provided with additional flexibilities such as alternative, less stringent standards, and alternative phasedowns with periods of stability to address the challenges we face. Unlike in past rulemakings, we do not believe that the EPA's multi-pollutant NPRM adequately addresses SVM concerns and challenges. [EPA-HQ-OAR-2022-0829-0748, p. 2]

The need for additional flexibilities and lead-times remains exceptionally high for SVMs and McLaren for the following reasons: [EPA-HQ-OAR-2022-0829-0748, p. 2]

- Electrification remains extremely challenging given limited resources available and the lack of technological developments in battery technology to produce the lightweight high-density batteries required to electrify a high-performance supercar. [EPA-HQ-OAR-2022-0829-0748, p. 2]

- Battery technology has not developed enough for application within high-performance lightweight supercars. Technology is developing and we have plans to electrify further, however time is needed. [EPA-HQ-OAR-2022-0829-0748, p. 2]

- Limited product portfolio and longer product life cycles mean that making regular improvements to products is exceptionally challenge for SVMs like McLaren. When electrification is available, there is limited ability to rapidly roll out technology across the whole product portfolio - time will be needed. [EPA-HQ-OAR-2022-0829-0748, p. 2]

While technology is developing and there are plans for electrification in the future, it still remains that time is needed for technology to catch up to the needs of a lightweight high-performance super car. Furthermore, with low production volumes our ability to amortize expensive product development costs is also limited, our R&D paybacks are far longer. At McLaren, our journey to electrification will be challenging given the pressures we see in the market, the demand for battery components and key materials, furthermore, we are without a larger OEM partner to share the development burden or to take external technology. [EPA-HQ-OAR-2022-0829-0748, p. 2]

These challenges and the need for additional flexibilities remain important for MY 2027 and later. Demand for our products remains high, as does the performance. Electrifying lightweight high performance supers is exceptionally challenging. While there has been greater electrification of mass market vehicles, as outlined above, it is important to note that battery technology has not developed enough for application within high-performance supercars. Technology is developing and we have plans to electrify further; however, time is needed. McLaren are targeting launching a full BEV towards the end of the decade, we see some developments in battery technology and other core components which may make a BEV lightweight supercar possible. [EPA-HQ-OAR-2022-0829-0748, pp. 2-3]

This is further evident when looking at the market for BEV supercars and the current and potential market offerings which are around the $1m plus price bracket. Lightweight BEV supercars must compete with ICE/PHEVs for all performance attributes. Below the $1m+ low volume segment, there are currently no lightweight high-performance BEV Supercars in the 'series production' category, which for brands such as McLaren, are products that contribute the majority of our annual production volume. [EPA-HQ-OAR-2022-0829-0748, pp. 2-3]

Given the challenges we have highlighted in moving towards greater electrification for SVMs like McLaren, EPA is effectively relying on credit trading flexibility as the means by which

SVMs will maintain compliance with GHG standards. We believe this is inappropriate for several reasons and demonstrates that the proposed alternative standards do not meet the requirements of CAA§ 202(a) that standards "take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such a period". First, we believe it is inappropriate to set a standard so stringent as to effectively require a manufacturer to entirely rely on another manufacturer to maintain compliance. Additionally, there is an inherent risk that even if a credit-generating manufacturer is willing to sell credits, the credits may be purchased by other parties before SVMs can access them. Having to purchase credits to comply with the proposed GHG standard would also divert resources away from electrification challenges. [EPA-HQ-OAR-2022-0829-0748, p. 3]

As stated, allowing for certainty and time to adjust to changes remains important for SVM like McLaren. An SVM standard also must take into account that engines and vehicles already developed will have to company with a standard in MY2024 which is currently unknown. Allowing for early years less stringent targets is essential given that design decisions which have already been made. It is also important for GHG policy to be fair and equitable. The EPA SVM proposal would require over 50% BEV mix in MY2026, based on McLaren analysis, far higher than Primary Standards requirements and effectively impossible given the lack of technology available to electrify high performance supercars. [EPA-HQ-OAR-2022-0829-0748, p. 3]

Key areas of concern for McLaren

In order to address the concerns that we have highlighted in this submission we propose the following recommendations to the EPA. [EPA-HQ-OAR-2022-0829-0748, pp. 3-4]

SVM Greenhouse Gas Emissions Standards

We support the EPA's proposal to sunset the individual application process for alternative SVM standards. However, given the challenges we have outlined above around technology developments and the need for extra lead time, we propose that the EPA maintain the approved MY2021 individual standards through to the end of MY2025. The EPA proposes to change requirements for SVMs before MY 2027 with little or no explanation of how circumstances have changed significantly since those regulations were agreed or how SVMs will meet the revised requirements with virtually no lead-time. Furthermore, the EPA's proposal envisions a massive increase in stringency in MY 2025 (53% average stringency increase) again, with no lead-time. [EPA-HQ-OAR-2022-0829-0748, pp. 3-4]

Allowing certainty to the continued individual standards through to MY2025, will allow for greater time for developing and implementing electrification compatible technologies and help address lead time concerns. [EPA-HQ-OAR-2022-0829-0748, pp. 3-4]

We propose the following:

- For MY 22, 23, 24 and 25: For SVMs that have been granted alternative bespoke standards in the 2020 notice Federal Register: Determinations of Light-Duty Vehicle Alternative Greenhouse Gas Emissions Standards for Small Volume Manufacturers, continue for MY 22, 23, 24 and 25 the alternative standard for MY 21 [EPA-HQ-OAR-2022-0829-0748, pp. 3-4]

- For MY 2026 and later, eliminate company-by-company alternative SVM GHG standards and create a new regulatory provision applicable to all SVMs. [EPA-HQ-OAR-2022-0829-0748, pp. 3-4]

- Bring SVMs towards the Primary Standard via an SVM phased-in target reduction requiring a 50% GHG reduction in MY 2032 compared to SVM MY 2025 emissions. [EPA-HQ-OAR-2022-0829-0748, pp. 3-4]

- Establish a trajectory from MY 2026 to MY 2032 that has either a linear reduction or one or more reasonable step changes. [EPA-HQ-OAR-2022-0829-0748, pp. 3-4]

- Defer consideration of incorporating SVMs into the Primary Standard until a subsequent separate rulemaking. [EPA-HQ-OAR-2022-0829-0748, pp. 3-4]

This proposal will provide the additional time SVMs like McLaren [EPA-HQ-OAR-2022-0829-0748, pp. 3-4]

SVM Criteria Pollutant Standards

As outlined above, as a SVM we face unique challenges in meeting very stringent GHG standards, particularly those that rely on electrification. This is also the case for criteria pollutant standards which we are impacted by further, given the reduction in flexibilities proposed by the EPA. The EPA proposes to abandon the MY 27 and 28 SVM NMOG+NOx standards set out in Tier 3 (and on which we have been planning towards), and propose instead to increase stringency and require SVMs to adhere to the primary Tier 4 NMOG+NOx standard. Under the EPA's proposal, we would need to meet the same criteria pollutant and particulate matter emission standards on the same schedule as large manufacturers, despite our much less frequent new model platform introductions and lower fleet diversity, resulting in our corresponding limited ability to utilise average provisions. [EPA-HQ-OAR-2022-0829-0748, p. 4]

Historically, EPA have provided additional flexibilities and provision to SVMs, recognising the challenges we face. Furthermore, these flexibilities have been recognised and provided for in CARB's ACC II LEV IV regulation. With limited engine families, SVMs like McLaren are unable to utilise flexibilities with averaging, unlike mass market OEMs with many product lines. In order to properly account for the unique challenges faced by SVMs with regard to fleet averaging - based standards, it is important to set the degree and frequency of SVM step-downs to reflect SVM realities -- limited product lines, with longer product development and life cycles. We would propose the following alternative to the EPA's proposal: [EPA-HQ-OAR-2022-0829-0748, p. 4]

- MY 2027 -- Maintain for all SVMs the already-in effect MY 27 Tier 3 SVM NMOG+NOx standard (51m g/mi) [EPA-HQ-OAR-2022-0829-0748, p. 4]

- MY 2028 -- Maintain for all SVMs the already-in effect MY 28 Tier 3 SVM NMOG+NOx standard (30 g/mi) [EPA-HQ-OAR-2022-0829-0748, p. 4]

- MY 2029-32 - continue the 30 mg/mi standard for SVMs [EPA-HQ-OAR-2022-0829-0748, p. 4]

Organization: Specialty Equipment Market Association (SEMA)

Effects on Low-Volume Manufacturers and Major Manufacturers

The current proposal, if finalized, would end the exemption for low-volume manufacturers. The EPA's prior criteria pollutant and GHG rulemakings recognized that special flexibility rules for small automakers were necessary and appropriate. These smaller OEMs typically manufacture and sell about 4,000 cars each year, which represents 0.02% of the total 14 million US passenger car sales in 2022.15 Most of these specialty vehicles are not "daily drivers" but are for "occasional use." As a result, the average annual miles driven by these vehicles is drastically less than that of a typical passenger vehicle. SEMA believes that small-volume manufactured vehicles have minimal impact on the environment, and their existing exemption should remain in place. [EPA-HQ-OAR-2022-0829-0596, p. 6]

15 The Detroit News: Cox Automotive increases its 2023 new-vehicle sales forecast (Link: https://www.detroitnews.com/story/business/autos/2023/06/27/cox-automotive-boosts-new-vehicle-sales-forecast-2023/70359959007/).

EPA Summary and Response

Summary

General comments:

SVMs commented that most of their vehicles are for "occasional use," with average annual miles driven far less than that of a typical passenger vehicle, and typical lifetime mileage of about 60,000 miles. The SVMs also commented that their low U.S. and global volumes result in lower access to suppliers and delayed access to supplier-provided technologies. They further assert that they have limited, narrowly focused product lines that do not have significant redesigns every year, and that receive little flexibility from fleet emission averaging programs.

SVMs also commented that EPA should establish provisions for hardship relief, which would allow the Agency to approve requests for extended compliance deadlines based on a situation of severe economic hardship, but with no requirement to demonstrate all of the elements of severe economic hardship and no maximum duration of the hardship relief.

Air conditioning (AC) GHG comments:

SVMs commented that the elimination of AC leakage credits along with what they believe are changes in the AC efficiency test procedures make the compliance situation worse for them. They specifically are concerned with the number of suitable test samples needed to perform the AC efficiency tests.

GHG comments:

SVM commenters assert that EPA projects that SVM fleets on average, and individually, will exceed the proposed standards, requiring purchased credits in order to continue selling vehicles in the US. SVM commenters disagree that they should be required to rely on credit trading flexibility as a key means to maintain compliance with standards. SVM commenters assert that the proposed standards would have a large increase in stringency without proper lead time. In order to comply with the proposed standards, they believe credits would have to be purchased, and there is uncertainty in an SVM's ability to obtain credits. SVMs believe that a standard that cannot be achieved without the purchase of credits is unfair. SVMs noted that EPA's modeling shows that the proposed standards cannot be met without purchasing credits which they feel demonstrates that the proposed alternative targets do not meet the requirements of CAA §202 (a). SVMs support EPA's proposal to sunset the individual application process for alternative standards and recommend that EPA maintain the approved MY 2021 individual standards through MY 2026. SVMs also noted that EPA proposed to start their program before most of the regulation comes into effect (MY 2025 rather than MY 2027), and to bring SVM targets into alignment with the primary MY 2032 targets. SVMs believe that this proposal would require SVMs to comply with a very sharp GHG emissions reduction. They believe that given the unique challenges they face as compared to full-line manufacturers it is too soon to propose a convergence of the alternative and primary standards. They suggested that EPA defer consideration of placing SVMs on the primary standards to a subsequent rulemaking.

Mclaren Automotive commented that battery technology has not developed enough for application within high-performance supercars, and that BEV supercars must compete with ICE/PHEVs for all performance attributes.

Environmental and Public Health Organizations supports our approach for phasing in the SVMs into the primary program. They also stated that EPA's conclusions that a transition of SVMs to the primary program coheres with the recent announcements and developments in the business model of the SVMs who have previously pursued less stringent standards. They noted that there are only four SVMs currently subject to less stringent standards (Ferrari, Aston Martin, Lotus, and McLaren) and all are moving toward greater hybridization and electrification, which will facilitate compliance with the primary LDV GHG standards.

Criteria pollutant comments:

SVMs commented that EPA has a history of giving SVMs additional lead time to comply with criteria pollutant standards. In the proposal they felt EPA has not given additional lead time to SVMs and did not explain a basis, which they felt was a mistake. They comment that the phase-in proposed for larger OEMs does not work for SVM since they have few models. They also noted that the new NMOG+NOx standards supersede the previously established Tier 3 phase in for SVM which extended compliance through MY 2027 and MY 2028. They also stated the proposed NMOG+NOx requirements are excessively stringent – too stringent, too soon.

Some SVMs commented that the elimination of Bin 125 would be unfair and unreasonable because it would put them in the untenable position of having to, with limited resources, simultaneously implement EVs while also investing in an attempt to reengineer Bin 125 vehicles to a much more stringent standard.

SVMs commented that it is thus unreasonable to impose the proposed PM standards and timetable on SVMs, especially considering the minimal environmental benefit obtained together with how drastic the proposed change is compared to existing Tier 3 levels and the CARB ACCII PM standards. SVMs further recommended that they be exempt from cold testing requirements given that they believe it is not yet fully understood what is needed to meet the 0.5 mg/mile standard at 20F with high-performance engines.

Specialty Equipment Manufacturers stated that SVMs have an existing exemption from criteria pollutants.

Response:

General comments response:

In response to the SVM claims that they should be exempt from standards on the basis that their high performance vehicles are driven less than typical vehicles, EPA disagrees that standards should be established based on a projection of annual miles driven or lifetime mileage accumulation. Any such data is too speculative, and anecdotal at best, to serve as a basis for determining appropriate emissions standards, and would be unenforceable as there would be no workable means to track vehicles subject to the SVM standards as they are driven over their useful lives to monitor mileage.

Regarding the comment that SVMs have limited access to technology and need additional lead time, as discussed further below, for both the GHG and criteria pollutant programs, EPA is providing additional lead time compared to the proposal. We believe that this additional lead time will provide the time needed to access the technologies needed to meet the standards.

SVMs requested hardship relief. EPA notes that there are existing hardship provisions for small businesses in 40 CFR part 1068 allowing for temporary exemption from certain standards in the case of severe economic hardship. These existing provisions attempt to balance concerns about the need for every manufacturer to take steps to produce vehicles that meet the standards with concerns that EPA does not wish to force small businesses into insolvency if it can be avoided. Accordingly, under 40 CFR 1068.250 where a small business can demonstrate it has "taken all possible business, technical, and economic steps to comply" and "[n]ot having the exemption will jeopardize the solvency of your company" and "[n]o other allowances are available under the regulations in this chapter to avoid the impending violation," EPA has discretion to grant up to three one-year delays in the compliance deadline.

EPA believes it would be inappropriate to extend the existing hardship provision to SVMs for multiple reasons. First, the SVMs are not small businesses, but established automotive companies. Second, EPA judges that the credit market is sufficiently robust and mature that it is highly unlikely an SVM could make a showing that "no other allowances are available" for compliance. Third, the purpose of this provision is to provide a temporary relief valve to avoid insolvency, but the commenters propose eliminating the requirement to show a risk of insolvency and to make the process indefinite. This would be fundamentally inconsistent with the purpose and function of the hardship exemption. While we disagree that hardship relief is appropriate for SVMs, we are providing several years of additional lead time to meet the final standards, as described further below in this section.

AC GHG comments response:

SVMs commented that it would not be fair to eliminate AC leakage credits. For the final rule, EPA is not eliminating AC leakage credits as proposed, but instead is phasing them down over multiple years as discussed in Section 3.1.3 of this RTC and preamble section III.C.5. SVMs commented that the AC efficiency test procedure was problematic. EPA has not reopened the AC efficiency test procedures in this rulemaking. Manufacturers have successfully complied with the existing AC efficiency test procedures, and those procedures continue to apply.

GHG comments response:

Commenters asserted that EPA's modeling shows that SVMs will not comply as a group or individually without credit trading. EPA disagrees. We have modeled reasonable compliance paths for the SVMs and have also modeled a "no credit trading" scenario which identifies a reasonable compliance path for the SVMs even if no automaker is willing to sell credits, a situation which we consider very unlikely to occur (especially in light of the surplus credits generated by EV-only manufacturers).

In other words, EPA demonstrates that SVMs can comply with the final standards if either appropriate GHG-reducing technologies are applied or, like other OEMs, SVMs avail themselves of the credit trading flexibilities.

SVMs commented that their respective MY2021 alternative standards should be kept in place through MY 2026, instead of EPA's proposal that SVMs phase into the primary program standards starting in MY 2025. EPA acknowledges that MY 2025 has already begun, and that MY 2026 begins as early as January 2, 2025, approximately 9 months from the date of this final rule. In response to these comments, EPA believes it is appropriate to extend the SVM alternative standards established in MY2021 through MY 2026, instead of through MY 2024 as proposed. Specifically, EPA is finalizing that SVM alternative standards established for MY 2021 will apply through MY 2026 to provide the requested stability for SVMs so that SVMs have an opportunity to reduce their GHG emissions in future years. This schedule provides a total of an additional five years of stability for the SVMs to transition from their existing MY 2021 standards into delayed primary program standards after MY 2026. Starting in MY 2027, SVMs will meet primary program standards albeit with additional lead-time. EPA is finalizing that SVMs will meet the primary program standards for MY 2025 in MY 2027, providing an additional two years of lead time, and then under a continued phase-in SVMs will be subject to the primary program standards for MYs 2032 and later. EPA believes this phase-in structure provides adequate lead time for the SVMs to transition into the primary program.

Commentors stated they had concerns about the availability of the credit market, but our compliance data indicates that SVMs in fact all have purchased GHG credits in the past several years, evidence that the credit market is available to them if needed. EPA notes that the cost of credits is likely to be small relative to the MSRP of the supercars that these manufacturers produce.

SVMs commented that we should establish provisions similar to the California ACC II program. As EPA has discussed in responding to other comments, the ACC II program has a somewhat different structure, focused primarily on a phased-in ZEV mandate, than EPA's performance-based standards. Accordingly, EPA does not believe it is always appropriate to compare the individual standards in each program to each other without considering the broader context. More broadly, EPA recognizes that CARB has offered some special accommodations to SVMs, but notes that EPA has likewise offered significant accommodations to SVMs. EPA notes that CARB commented that they expect that ACC II will set the SVMs on the correct path to be in compliance with EPA's standards by 2032, which is exactly as we have phased SVMs into the EPA final standards. We did not propose tracking the ACC II provisions for SVMs because we found it is more appropriate, for purposes of EPA's program, to bring SVMs into compliance with the generally applicable standards, albeit with significant additional lead time, and because we found that there is a feasible compliance path for SVMs to meet the GHG standards as finalized. After reviewing comments (including both those of SVMs as well as those of CARB and other commenters) we find our proposed conclusions, that the standards are feasible and appropriate for SVMs, are still warranted and we decline to adopt ACC II standards for SVMs. .

In response to McLaren Automotives comment on supercars and BEV technology, EPA notes that the final rule provides the SVMs a delayed phase-in that should allow the time needed for SVMs to develop appropriate pollution control technologies suited for their products, or if they choose to rely on credits trading, to purchase such credits.

Criteria pollutant comments response:

In response to SVM concerns about the need for additional lead time in meeting the criteria pollutant emissions standards, in the final rule EPA has provided additional lead time. Upon consideration of the comments, EPA recognizes that the proposed phase-in would be challenging for the SVMs. Thus, EPA is delaying the phase-in period for SVMs to comply with the Tier 4 criteria pollutant program until the last year of the overall program's phase-in period, MY 2032. This extended phase-in should alleviate the concerns that the standards stringency increases too quickly. EPA is also re-establishing the phase-in that existed under the Tier 3 program for MYs 2027 and 2028. In response to commenters concerns about the availability of the credit market, our compliance records show that at least one SVM has participated in the criteria pollutant credit market, and all SVMs have participated in the GHG credit market (see response above in this section).

Regarding the SVM concerns that Bin 125 should be available indefinitely, as discussed in Section III.D.10 of the preamble, EPA believes it is not appropriate to keep Bin 125 indefinitely, given this emissions level is considerably higher than the final fleet average standard of 15 mg/mi, and that producing vehicles far below 125 g/mi is feasible in the timeframe of this rule. However, EPA is providing SVMs with additional time to phase-down to lower emissions bin certification levels in that we are allowing SVMs the option to certify at Bin 125 through the end of the phase-in period, MY 2032.

Specialty Equipment Market Association states that SVMs have been exempted previously from criteria pollutant and GHG standards, which is an incorrect statement. EPA's rules have not in the past exempted SVMs; for GHGs, in past rules we have provided a process for SVMs to seek alternative emissions standards, and in this final rule we are providing an extended time period for SVMs to continue being subject to higher (less stringent) emissions standards than in the primary program for larger volume manufacturers, with a final phase-in to the primary program by MY 2032. For criteria pollutants, EPA is providing an extended phase-in for SVMs, similar to past programs.

SVM's commented that EPA must justify imposing on SVMs the proposed new cold NMOG+NOx standard. EPA disagrees that it must specifically evaluate with respect to SVMs the costs of compliance relative to the air quality benefits, or that it must conduct a benefit-cost analysis specific to SVMs. The standards that EPA is adopting in this rule are fully justified under the Clean Air Act as explained in preamble Sections III-V. The text and structure of Act sets forth EPA's authority to set forth emissions standards for classes of motor vehicles and generally require all "manufacturers" to comply, see, e.g., CAA section 202(a)(1)-(3), 206(a), with specific exceptions not applicable here, see, e.g., CAA section 202(b)(1), 206(a)(5). Consistent with the statute, EPA generally requires all manufacturers to meet the standards that EPA has found to be feasible and appropriate under the CAA. This approach achieves the pollution control and public health goals of the CAA and the particular standards at issue, and it ensures a level playing field for all manufacturers. Nothing in applicable standard-setting provisions imposes special analytical requirements on EPA with regard to SVMs or indicates that EPA is legally required to exempt SVMs from generally applicable emissions regulations.[362]

In some cases, EPA has derogated from the general policy of uniform standards when other policy concerns provide a sufficient reason to do so. For example, small businesses have been granted certain exemptions, consistent with the Small Business Regulatory Enforcement Fairness Act. Similarly, EPA has provided certain accommodations to small volume manufacturers in the past in recognition that the small volume manufacturers do have some features that distinguish them from larger OEMs. However, EPA has never indicated that prior accommodations would persist permanently; rather we evaluate the additional flexibility granted to SVMs based on the record before us. In our judgment, the market for pollution control technologies and the market for tradeable credits have both developed significantly since EPA originally provided some additional leeway to SVMs. Although the Act does not require EPA to conduct analysis specific to SVMs, EPA has done so. We assessed the feasibility of SVMs to comply with these standards and have found that the SVMs can attain standards could be attained at a reasonable cost in the lead time allowed. Even in the absence of modeling, EPA would be justified in expecting that large, sophisticated automotive manufacturing firms such as these, selling luxury cars and other vehicles at the high end of the automotive market, could identify a path to compliance, whether by installing additional pollution control technologies or the purchase of credits. EPA has judged that the standards being adopted today are justified under the CAA and that over the course of these model years SVMs will no longer warrant special treatment under those standards, and those conclusions together justify the application of these standards to SVMs.

3.1.8 - MDV incentive multipliers

Comments by Organizations

Organization: Alliance for Automotive Innovation (Alliance)

V. Medium-Duty Vehicle (MDV) Requirements

A. MDV Incentive Multipliers

EPA requests comment on two suggested changes to MDV Incentive Multipliers for BEVs, PHEVs and FCEVs as part of this proposal296; neither of these two changes are appropriate and neither should be adopted. First, EPA proposes to eliminate the multiplier one year earlier than currently allotted in the regulations. Second, EPA proposes potentially also phasing out the multiplier incentive over multiple model years by revising the multipliers to reduce their magnitude for model years prior to MY2027, for example for MYs 2025-2026. EPA points to "rapid increase in vehicle electrification in the MDV market" as a justification for its proposal. [EPA-HQ-OAR-2022-0829-0701, pp. 190-191]

296 NPRM at 29244.

---

[362] *See also* International Harvester Co., 478 F.2d at 640 ("The driving preferences of hot rodders are not to outweigh the goal of a clean environment.").

The current advanced technology multipliers in existing Heavy-Duty GHG Phase 2 for MYs 2021 through 2027 [297] are reproduced below:

297 Greenhouse Gas Emissions and Fuel efficiency Standards for Medium- and Heavy-Duty engines and Vehicles –Phase 2, 81 Fed. Reg. 73478 (October 25, 2016) (Phase 2 rule).

Figure 68: Advanced Technology Multipliers in Existing Heavy-Duty GHG Phase 2

Technology: Multiplier

Plug-in hybrid electric vehicles: 3.5

All-electric vehicles: 4.5

Fuel cell-electric vehicles: 5.5 [EPA-HQ-OAR-2022-0829-0701, pp. 190-191]

Due to multiple unknowns in the market uptake for battery electric MDVs, it would be inappropriate to reduce the magnitude of the multipliers prior to MY2027 or end the use of these multipliers one year early. Sales volumes of electric powertrains are much lower for MDV and heavy-duty vehicles (HDVs), especially for specialized vehicles applications. These vehicles are primarily work vehicles, which makes predictable reliability of existing technologies and versatility important. HDVs are generally more expensive than light-duty vehicles, which makes it a greater monetary risk for purchasers to invest in new technologies. [EPA-HQ-OAR-2022-0829-0701, pp. 190-191]

EPA also points to the Inflation Reduction Act as an enabling factor to reduce the multipliers prior to MY2027; however, there remain significant uncertainties to the extent customers will be able to take advantage of IRA tax incentive provisions of for MDVs. If MDV battery packs do not meet the battery component and critical mineral requirements, or the MDVs are not assembled in North America, those vehicles will be ineligible for 30D tax incentives. Moreover, while businesses and fleets can use IRA Section 45W, it is not clear to what extent MDV buyers will utilize these provisions, because the commercial entity, particularly if purchasing the vehicles, must have sufficient tax headroom to offset any claimed the credits. [EPA-HQ-OAR-2022-0829-0701, pp. 190-191]

EV multipliers are crucial to provide sufficient time for the market to develop, especially to support a substantial transformation in the MDV segment. EPA recognized important reasons for these EV multipliers in the Phase 2 rule, including medium- and heavy-duty vehicles are more expensive, they are primarily work vehicles, sales volumes are lower, and adoption rates for advanced technologies are minimal. EPA proposes to continue to provide EV incentives for at least FCEVs in the concurrent EPA HD GHG rulemaking. [EPA-HQ-OAR-2022-0829-0701, p. 191]

While EPA suggests the IRA and other measures might cushion the blow, these other factors are uncertain and do not warrant eliminating the EV multipliers. Importantly, the IRA tax incentives are not coupled with charging infrastructure funding. These MDVs will likely require, in many cases, dedicated high-power charging stations to ensure work and fleet vehicles are charged in a timely and efficient manner for their work cycle. Larger batteries will require more time and power to charge, an aspect of EPA's EV feasibility analysis that was not addressed and ignores the additional challenges of electrification for this sector. [EPA-HQ-OAR-2022-0829-0701, p. 191]

Further, any change in the multipliers would disrupt the planning and development cycles already underway. Any such change would also reduce stability and certainty associated with MDV GHG standards, potentially resulting in compliance challenges or additional, unnecessary industry cost. [EPA-HQ-OAR-2022-0829-0701, p. 191]

For all the reasons provided above, these EV multipliers for BEVs, PHEVs, and FCEVs should be left in place and unaltered through MY2027 to encourage manufacturers to continue to invest in advanced technologies in the Medium-Duty space and provide manufacturers necessary lead-time to make appropriate investment decisions. [EPA-HQ-OAR-2022-0829-0701, p. 191]

Organization: California Air Resources Board (CARB)

U.S. EPA requested comment on its proposal to eliminate advanced technology multipliers for medium-duty BEVs, PHEVs, and FCEVs after the 2026 MY. CARB supports this proposal. As U.S. EPA rightly notes, multipliers provide important incentives for spurring technology advancement but must be balanced with potential emission increases from conventional vehicles. With rapid ZEV technology development in the medium-duty vehicle segment, the timing is appropriate to sunset multiplier credits for medium-duty vehicles as U.S. EPA has already done for light-duty vehicles. [EPA-HQ-OAR-2022-0829-0780, pp. 17-18]

As noted above, the ACT and ACF rules will dramatically increase the penetration of ZEVs in the medium- and heavy-duty vehicle segments in California. These policies will accelerate ZEV technology development and adoption in the medium-duty sector, further reducing the need for multiplier credits. [EPA-HQ-OAR-2022-0829-0780, pp. 17-18]

Organization: International Council on Clean Transportation (ICCT)

Regarding some finer details of the proposed MD standards, ICCT supports EPA's proposal to phaseout ZEV multipliers in MY2026 instead of MY2027. The expected growth in MD BEV van share by MY2027 could result in overcompliance credits being available in MY2027, which can be used to offset undercompliance by vans and pickups which are still ICE-powered. Generally, ending multipliers earlier would improve the real-world climate benefits of the proposed rule. Additionally, recent ICCT research on the costs of BEV and PHEV MD vans and pickups suggests that within the timeframe of the proposed rule, plug-in MDVs will be cost-competitive with their gasoline or diesel counterparts either upfront or both upfront and during ownership.160 Consequently, such advanced technology vehicles will not need multipliers as a production incentive. Lastly, ICCT also supports the proposed 22,000 lbs limit to the GCWR input in the work factor equation, for the reasons EPA provided in its proposal (Preamble 29242). [EPA-HQ-OAR-2022-0829-0569, pp. 60-62]

160 Mulholland, E. (2022). Cost of electric commercial vans and pickup trucks in the United States through 2040. International Council on Clean Transportation. https://theicct.org/publication/cost-ev-vans-pickups-us-2040-jan22/

Organization: Natural Gas Vehicles for America (NGVA)

EPA Must Take Steps to Address the Damage Caused by Its Uneven Treatment of Low Carbon Technologies

EPA's prior notice as part of the Clean Truck Initiative was extremely frank about the reasons that the agency had provided significant regulatory credits for electric vehicles.12 Pertinent parts of that discussion are included here: [EPA-HQ-OAR-2022-0829-0597, pp. 12-13]

12 2022-04934.pdf (govinfo.gov)

As stated in the HD GHG Phase 2 rulemaking, our intention with these multipliers was to create a meaningful incentive to those considering adopting these qualifying advanced technologies into their vehicles. The multipliers are consistent with values recommended by California Air Resources Board (CARB) in their supplemental HD GHG Phase 2 comments. (footnote omitted). CARB's values were based on a cost analysis that compared the costs of these technologies to costs of other conventional GHG- reducing technologies. Their cost analysis showed that multipliers in the range we ultimately promulgated would make these technologies more competitive with the conventional technologies and could allow manufacturers to more easily generate a viable business case to develop these technologies for heavy-duty vehicles and bring them to market at a competitive price. [EPA-HQ-OAR-2022-0829-0597, pp. 12-13]

****

As we stated in the 2016 HD GHG Phase 2 final rule preamble, we determined that it was appropriate to provide such large multipliers for these advanced technologies at least in the short term, because they have the potential to provide very large reductions in GHG emissions and fuel consumption and advance technology development substantially in the long term. However, because the credit multipliers are so large, we also stated that we should not necessarily allow them to continue indefinitely. Therefore, they were included in the HD GHG Phase 2 final rule as an interim program continuing only through MY 2027. [EPA-HQ-OAR-2022-0829-0597, pp. 12-13]

The above passages appear on pages 17594 and 17595 of the March 28, 2022, Federal Register notice. [EPA-HQ-OAR-2022-0829-0597, pp. 12-13]

It is noteworthy that EPA acknowledges the credits are not based on emission benefits. The credits are based on cost with the intent on making electric vehicles "more competitive" with conventional technologies. It is noteworthy that the notice in this rulemaking contains virtually the exact word for word explanation regarding the incentives for electric vehicles.13 [EPA-HQ-OAR-2022-0829-0597, pp. 12-13]

Organization: Rivian Automotive, LLC

Evaluate Stricter MDV Emissions Standards and Begin Phasing Out Advanced Technology Vehicle ("ATV") Multipliers in MY25 [EPA-HQ-OAR-2022-0829-0653, pp. 10-12]

Second, EPA should phase out ATV multipliers starting in MY25. EPA originally devised ATV multipliers to encourage the use of advanced technologies such as electric drivetrains. According to the agency, when first implemented in the GHG Phase 2 program, ATV multipliers represented a "tradeoff" between incentivizing nascent technologies and providing credits unattached to real-world environmental benefits, "which could allow higher emissions from credit-using engines and vehicles."32 At least one study of policy design issues in fuel economy and GHG emissions standards calls the efficacy of multipliers into question for precisely this reason. By artificially enhancing the compliance value of BEVs, PHEVs, and FCEVs, the multiplier can enable manufacturers to sell additional conventional vehicles if those units deliver a greater financial return at the expense of greater emissions.33 [EPA-HQ-OAR-2022-0829-0653, pp. 10-12]

32 Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, 88 Fed. Reg. 87 (May 5, 2023) (revising 40 C.F.R. Parts 85, 86, 600, 1036, 1037, and 1066), 29,244.

33 Kenneth Gillingham, NBER Working Paper No. 29067, Designing Fuel-Economy Standards in Light of Electric Vehicles (2021), available at https://www.nber.org/system/files/working_papers/w29067/w29067.pdf.

As EPA acknowledges, the costs and benefits of this approach might balance out differently when the incentivized technologies barely exist on a commercial scale, but that is simply no longer the case among MDVs. Accordingly, Rivian welcomes the agency's proposal to remove ATV multipliers but recommends beginning a phaseout in MY25 as suggested below, with the value of the BEV/FCEV multiplier stepping down to 2.5 and then 1.5 before sunsetting entirely. PHEV multipliers should step down in value to 1.75 and 1.25 in MY25 and MY26, respectively. [EPA-HQ-OAR-2022-0829-0653, pp. 10-12]

Technology: PHEV; MY24: 3.5; MY25: 1.75; MY26: 1.25; MY27: -

Technology: BEV; MY24: 4.5; MY25: 2.5; MY26: 1.5; MY27: -

Technology: FCEV; MY24: 5.5; MY25: 2.5; MY26: 1.5; MY27: -

[EPA-HQ-OAR-2022-0829-0653, pp. 10-12]

Table 3. Rivian recommends phasing out ATV multipliers on a declining schedule beginning in MY25. [EPA-HQ-OAR-2022-0829-0653, pp. 10-12]

With sales of BEV vans already growing quickly, a glut of multiplied credits could come into the market before the proposed sunset year of MY27. New regulatory obligations under ACT will come into force in six states by MY25 and only compound this reality, leading to the sale of thousands of MD BEVs nationwide— each worth potentially 4.5 times their true benefit for federal GHG compliance purposes. This could have consequences for BEV sales across the MD segment for several years. [EPA-HQ-OAR-2022-0829-0653, pp. 10-12]

For the most impactful rules possible, we recommend EPA reconsider more stringent emissions standards and begin phasing out ATV multipliers in MY25. [EPA-HQ-OAR-2022-0829-0653, pp. 10-12]

Organization: Stellantis

EPA should maintain previously defined EV Multipliers

EPA is proposing to end advanced technology (BEV, FCEV, and PHEV) multipliers for medium-duty vehicles in 2027MY, one year earlier than scheduled. The agency also seeks comment on reducing the magnitude of the multipliers for 2025-26MY. Aligned with Auto

Innovators, Stellantis does not believe the advanced technology credit multipliers should be adjusted or reduced in the 2025-27MY timeframe. The Phase 2 rule was finalized in 2016, and [redacted text.] We believe the proposal to change or end advanced technology multipliers in the 2025-27MY does not provide sufficient lead time as required by the Clean Air Act. [EPA-HQ-OAR-2022-0829-0678, p. 22]

EV Multipliers – Ends Advanced Technology (EV) multipliers in 2027MY (one year early) and is considering limiting/reducing 2025-26MY multiplier credits. [EPA-HQ-OAR-2022-0829-0678, pp. 17-18]

Stellantis recommends that EPA should:

-Retain GHG saving technology flexibilities recognizing the GHG benefit that continues to be present on electric vehicles and that will naturally decrease as EV penetration increases [EPA-HQ-OAR-2022-0829-0678, p. 24]

Organization: Tesla, Inc.

Accordingly, Tesla asserts the EPA should amend its proposal with a more stringent version of Alternative 1 and take, inter alia, the following additional steps to increase the performance and overall stringency of the proposed standards: [EPA-HQ-OAR-2022-0829-0792, p. 2]

2 See, 88 Fed. Reg. 29332-33, Table 96.

3 Id., at 29348 (comparing Tables 135 and 136).

- Eliminate credit multipliers for all vehicles; and [EPA-HQ-OAR-2022-0829-0792, p. 2]

Credit Multipliers Decrease BEV Deployment and Should Not Be Extended or Renewed

Tesla supports the continuing elimination of advanced technology multipliers to ensure overall program integrity. Firmly establishing a one-for-one credit ratio is a more rational and transparent compliance mechanism and creates actual BEV vehicle deployment, thereby enabling deeper emission reduction targets.164 [EPA-HQ-OAR-2022-0829-0792, p. 26]

164 Id., at 29197.

Tesla asserts that providing credit multipliers can unnecessarily dampen actual deployment of BEVs and lead to backsliding on emission reductions. This is true regardless of the technology to which a multiplier may be attached and is not applicable just to BEVs. Accordingly, Tesla also supports the agency's proposed elimination of the medium-duty credit multipliers for all ZEVs after MY 2026.165 Indeed, considering the high level of the current medium-duty multiplier, rather than serve as an incentive, the multiplier is likely to further delay manufacturers from deploying large amounts of medium-duty BEVs in the U.S. until 2027. [EPA-HQ-OAR-2022-0829-0792, p. 26]

165 Id., at 29244-45.

EPA Summary and Response

Summary:

EPA received comments both in support of and in opposition to its proposal to eliminate MDV multiplier incentives for MY 2027 vehicles. The Alliance and Stellantis opposed the elimination of the multipliers for MY 2027, which were established in 2016 under the Phase 2 GHG standards, as they believed the multipliers are important given market uncertainties, the lower sales volumes of MDVs compared to LDVs, and that any changes in the multipliers would be disruptive to manufacturers' planning and development cycles already underway. Stellantis asserted that removing the MY 2027 multipliers would be counter to the Clean Air Act lead time provisions. In response to EPA's request for comment on whether we should phase-down the existing MDV multipliers for MYs 2025 and 2026, the Alliance and Stellantis also opposed any changes in the multipliers for these model years, on the same basis as their comments regarding the MY 2027 multipliers.

In contrast, several commenters (CARB, ICCT, Rivian and Tesla) supported EPA's proposal to remove multipliers for MY 2027. These commenters believed that multipliers are no longer necessary given the rapid advancement of BEVs in the MDV market and given their concern that multipliers erode the emissions benefits of the program and could result in emissions backsliding. With respect to EPA's request for comment on whether to phase-down the multipliers for MYs 2025 and 2026, Rivian supported phasing out the multipliers starting in MY 2025 and suggested specific values for stepping down the MY 2025-2026 multipliers. Rivian pointed to BEV van sales growing rapidly, especially with the adoption of the Advanced Clean Trucks program by several states, and the concern that the existing multipliers could result in a glut of credits.

NGVA asserts that the multiplier credits were originally established with the "intent on making electric vehicles more competitive" with conventional technologies.

Response:

EPA agrees with the commenters who supported elimination of the MDV multipliers for MY 2027, and we are finalizing that provision as proposed. As discussed further in section III.C.3.iii of the preamble, while we did anticipate some growth in electrification would occur due to the credit incentives in the Phase 2 final rule back in 2016, we did not expect the level of innovation since observed, or the IRA or BIL incentives. Given these developments, we believe the existing advanced technology multiplier credit levels for MY 2027 MDVs are no longer appropriate for maintaining the balance between encouraging manufacturers to continue to invest in new advanced technologies over the long term and potential emissions increases in the short term. We further agree with commenters that, if left as is, the MY 2027 MDV multiplier credits may allow for backsliding of emission reductions expected from ICE vehicles for some manufacturers in the near term (i.e., the generation of excess credits which could delay the introduction of technology in the near or mid-term) as sales of advanced technology MDVs that can generate the incentive credit continue to increase. In light of the rapid increase in vehicle electrification in the MDV market, as proposed, EPA is removing the BEV, PHEV, and FCEV multipliers for MY 2027.

Though EPA requested comment on phasing down the MDV multipliers for MYs 2025 and 2026, we have decided not to make any changes to the multiplier levels for those model years. In response to the comment from Stellantis that ending the MDV multipliers in 2025-2027 does not provide sufficient lead time under the Clean Air Act (CAA), EPA notes that for GHG standards the statute does not establish minimum lead time requirements. However, EPA does consider lead time as a factor in determining the appropriate standards under CAA section 202(a), and we have in fact considered the issue of lead time in the context of the MDV multipliers and the overall stringency of MDV standards. Given that MY 2025 has already begun and that MY 2026 begins as early as nine months from this final rule, EPA believes it would not be appropriate to change the MY 2025 or 2026 multipliers. Therefore, the MDV MY 2025-2026 multipliers will remain in effect as established under the Phase 2 rule.

In response to NGVA, as EPA discussed in the Phase 2 rule initially establishing the MDV multipliers and recapped in the light/medium-duty proposal, we acknowledge that multipliers represent a tradeoff between incentivizing new advanced technologies that could have significant benefits well beyond what is required under the standards and providing credits that do not reflect real world reductions in emissions, which could allow higher emissions from credit-using engines and vehicles. At relatively low adoption levels, we believe the balance between the benefits of encouraging development of advanced technologies as compared to any negative emissions impacts of multipliers would be appropriate and justify maintaining the current advanced technology multipliers through MY 2026.

3.1.9 - Timeframe of the standards

Comments by Organizations

Organization: American Honda Motor Co., Inc.

Regulation End Date

The agency requests stakeholder feedback on whether standards under this program should be set beyond MY2032: [EPA-HQ-OAR-2022-0829-0652, pp. 30-31]

EPA is requesting comments on whether the standards should increase in stringency beyond MY 2032. EPA seeks comment on whether the trajectory (i.e., the levels of year-over-year stringency rates) of the proposed standards for MYs 2027 through 2032 should be extended through 2033, 2034 or 2035, or whether EPA should consider additional approaches to the trajectory of any standards that were to continue increasing in stringency beyond 2032.51 [EPA-HQ-OAR-2022-0829-0652, pp. 30-31]

51 88 Fed. Reg. 29239 (May 5, 2023)

Although Honda would prefer that EPA set standards through MY2031 in order to align its regulatory timeline with that of the upcoming CAFE rule by NHTSA (an agency that is statutorily restricted to setting rules no longer than five years in length), we acknowledge that approach is not under consideration by EPA.52 [EPA-HQ-OAR-2022-0829-0652, pp. 30-31]

52 Honda also plans to provide feedback to NHTSA on its forthcoming CAFE NPRM, a similarly important rule that has significant overlap – as well as distinct differences – with the vehicle GHG regulation.

As noted earlier in these comments, the agency's proposed stringency is heavily predicated upon an assumed swift and seamless EV market transformation. In reality, that transformation has many uncertainties and risks associated with it, including multiple influential factors that are entirely outside the control of automakers. Given the high degree of uncertainty associated with this market transformation, we believe this rulemaking should not include standards beyond the agency's proposed MY2032 window. [EPA-HQ-OAR-2022-0829-0652, p. 31]

Recommendation: Honda suggests the agency set standards no later than MY2032. [EPA-HQ-OAR-2022-0829-0652, p. 31]

Organization: American Lung Association (ALA) et al.

EPA should set a course to emission controls out through the 2035 model year to address the ongoing need for cleaner combustion and increased certainty for zero-emission technologies. By capturing vehicle model years out to 2035 as an increasing number of states' ACCII standards have, EPA can ensure that the policies stay ahead of, rather than trail, zero-emission vehicle markets and automakers' announced combustion engine phaseouts to provide ongoing certainty in emission reductions. [EPA-HQ-OAR-2022-0829-0745, p. 3]

Organization: Arconic Corporation (ARCO)

7. The EPA is requesting comments on whether the standards should increase in stringency beyond MY 2032. EPA seeks comment on whether the trajectory (i.e., the levels of year-over-year stringency rates) of the proposed standards for MYs 2027 through 2032 should be extended through 2033, 2034 or 2035, or whether EPA should consider additional approaches to the trajectory of any standards beyond 2032.

Arconic recommends including the upstream power generation emissions for BEV vehicles. With that change, Arconic supports more stringent EPA standards in coordination with DOT CAFE standards beyond the 2027-2032 range covered in this proposed rule. [EPA-HQ-OAR-2022-0829-0741, p. 4]

Organization: CALSTART

2. Automaker Market Signal

In addition to pairing impactful incentives with ambitious regulations in the legislative ecosystem, automakers benefit from clear market signals. The automotive industry has committed to expanding ZEV offerings and many automakers are already on a roadmap to transitioning to 100% ZEVs by 2035. Providing market certainty through strong regulation unlocks greater deployment of capital, as evidenced by the $200+ billion worth of announced sector investments within the past two years.2 [EPA-HQ-OAR-2022-0829-0618, pp. 3-4]

2 https://www.atlasevhub.com/data_story/210-billion-of-announced-investments-in-electric-vehicle-manufacturing-headed-for-the-u-s/.

By enacting strong vehicle emissions standards that require vehicle manufacturers to produce increasingly efficient and clean vehicles, as well as drive the electrification of the transportation sector, the EPA will help ensure wide-scale availability of the vehicles that support healthy communities. Commensurately, as battery and vehicle production achieve greater economies of scale, ZEV cost declines are expected. Projections show ZEVs reaching purchase cost parity with internal combustion engine (ICE) vehicles by the mid to late 2020's, after which they are projected to further decline in cost, saving money for all consumers, with particular benefit for low-income consumers. [EPA-HQ-OAR-2022-0829-0618, pp. 3-4]

CALSTART believes there are important takeaways from these comments that can help inform and structure a stronger Light-Duty and Medium-Duty Vehicles standard:

3. Extend the proposed rule to 2035, resulting in the equivalent of 100% ZEV sales by 2035, consistent with ACC II.

Organization: Elders Climate Action

We ask EPA to revise the rule to set a zero emission standard for all new L/MDVs by 2035, and establish a phase-in schedule for the standard that includes ZEV sales targets for MYs 2027-29 that are the same as the CARB ACT rule. [EPA-HQ-OAR-2022-0829-0737, pp. 10-11]

Organization: Kia Corporation

- Kia supports EPA’s six model year time period proposed for the standards from MYs 2027–2032. There is considerable uncertainty associated with the uptake of these technologies in ways that are difficult to predict even within the six model years.3 Consequently, extending the rule beyond MY2032 is inappropriate at this time. [EPA-HQ-OAR-2022-0829-0555, p. 3]

3 88 Fed. Reg. 29,311.

Six Model Year Timeline for Program is Appropriate

EPA requests feedback on whether the standards should extend beyond MY2032.5 Kia urges EPA not to extend the rulemaking beyond MY2032. As drafted, the proposal – any or all of the alternatives proposed – will require the automotive industry to take on transformative efforts, including historic investments, and rely on sufficient investments from industries beyond the automotive industry. Further, the industry will take on significant risks regarding consumer EV acceptance. As EPA has pointed out in the proposal, there is considerable uncertainty associated with the uptake of these technologies in ways that are difficult to predict even within the six model years.6 Consequently, extending the rule beyond MY2032 is inappropriate at this time. [EPA-HQ-OAR-2020829-0555, p. 4]

12 5 88 Fed. Reg. 29,239.

6 88 Fed. Reg. 29,311.

Organization: Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC)

EPA should consider extending and increasing both the LDV and MDV standards through MY 2035, which will send a strong signal to industry and the public and align with MYs covered by the ACC II and ACT regulations. [EPA-HQ-OAR-2022-0829-0584, p. 9]

Organization: POET, LLC

VII. EPA Should Not Yet Extend Continually More Aggressive Standards Beyond Model Year 2032.

Vehicle technologies and market dynamics may considerably change by 2023, including BEV-induced strains on the electric transmission and local distribution grids, critical mineral supply chains, and energy security risks created by EPA over-indexing on a preferred technology. Accordingly, POET strongly recommends against having standards set now that continue to increase in stringency beyond 2032. [EPA-HQ-OAR-2022-0829-0609, p. 29]

Organization: South Coast Air Quality Management District

12. There are five key issues we request U.S. EPA address before finalizing the rule. Extend the phase-in period and adopt more stringent standards to align with California's ACC II regulation. The proposed standards will be phased in over a six-year period from model year (MY) 2027 through 2032 with increasing stringency each year. We recommend that the phase-in period be extended to 2035 and later model years to better align with the ACC II implementation schedule which extends out to MY 2035 and subsequent years. [EPA-HQ-OAR-2022-0829-0659, p. 2]

Organization: Toyota Motor North America, Inc.

EPA requests comment on whether the standards should extend beyond the 2032 model year. Toyota is concerned that the proposal has not adequately addressed the market uncertainty surrounding the proposed standards through 2032 model year. Therefore, we believe it would be inappropriate to extend the standards beyond 2032. [EPA-HQ-OAR-2022-0829-0620, pp. 26-27]

Organization: Wisconsin Department of Natural Resources

In this action, EPA is proposing new, more stringent emissions standards for criteria pollutants and greenhouse gases (GHG) for light-duty vehicles and medium-duty vehicles that would phase-in over model years 2027 through 2032. [EPA-HQ-OAR-2022-0829-0507, p. 1]

The WDNR offers the following specific comments on the proposal:

2. Extending standards to model year 2035. EPA is requesting comment on if these new standards should be extended to MY 2035. If EPA elects to extend the standards an additional three years, EPA should consider undertaking a "mid-course review" to ensure the standards are still appropriate and whether a change in stringency (to reflect the current state of technologies and the market) is warranted. [EPA-HQ-OAR-2022-0829-0507, p. 2]

EPA Summary and Response

Summary:

In its NPRM, EPA requested comment on whether the trajectory (i.e., the levels of year-over-year stringency rates) of the proposed standards for MYs 2027 through 2032 should be extended through 2033, 2034 or 2035, or whether EPA should consider additional approaches to the trajectory of any standards beyond 2032.

In their comments, some NGOs and state organizations supported extending the standards through 2035, citing the need to send a strong market signal, and/or to be consistent with ACC II. In contrast, automakers that responded expressed concerns of market uncertainty, were EPA to extend the rulemaking past MY 2032. In its comments, while acknowledging that EPA did not seek comment on a shorter timeframe, Honda requested that EPA only set standards through MY 2031 which they believe is important to align with the proposed CAFE standards.

Response:

EPA responds to many of these comments in Section III.C.2.iv.c of the preamble. In sum, EPA understands commenters' concerns about uncertainty out to the MY 2035 time frame, and believes it is appropriate to consider standards for MY 2033 and beyond in a future rulemaking. EPA disagrees with Honda's request to set standards only through MY 2031 as the rulemaking lays out a strong basis that standards through MY 2032 are feasible and appropriate under the Clean Air Act.. After considering all of these comments, EPA is finalizing standards for MYs 2027 through MY 2032 for both light-duty and medium-duty vehicles.

3.1.10 - Alternative compliance pathway

Comments by Organizations

Organization: Environmental Defense Fund (EDF) (1of 2)

ii. EPA should finalize a Leadership Pathway to incentivize compliance with ACC II nationwide.

In response to EPA's request for comments on GHG regulatory alternatives, EDF recommends EPA finalize an alternative, "Leadership Pathway." Under the Leadership Pathway, manufacturers could choose to comply with California's ACC II ZEV sales requirements nationwide to demonstrate compliance with EPA's greenhouse gas requirements. Manufacturers would continue to comply with EPA's proposed Tier 4 air pollution standards. [EPA-HQ-OAR-2022-0829-0786, pp. 41-45]

The leadership pathway would be a voluntary, alternative compliance framework that manufacturers could choose, but once chosen, it would be enforceable. EPA has included similar, alternative pathways in past regulations where doing so would deliver equivalent or greater environmental benefits. Adopting a leadership pathway along these lines in these standards would allow manufacturers that anticipate exceeding the level of ZEVs reflected in EPA's proposal to comply with the same set of requirements in California and 177 states and nationwide in a consistent and streamlined fashion. As we demonstrate below, it would also deliver significant additional pollution reductions as compared to any of EPA's proposed alternatives. [EPA-HQ-OAR-2022-0829-0786, pp. 41-45]

Under ACC II, ZEVs must constitute a set percentage of a manufacturer's light-duty sales in MYs 2026 through 2035. The percentage of ZEV sales in MY 2032 is 82% growing to 100% by 2035. PHEVs with an EPA rated range of 50 miles count as a ZEV up to 20% of the ZEV percentage requirement (i.e., 16.4% of total sales in 2032). There are no explicit GHG standards for ICEVs starting in 2026. EPA projects that manufacturers could meet its proposed 2032 GHG standards by selling 67% BEVs by 2032, 15% less than under ACC II. While ICEV emissions are included in fleet-average GHG emissions counting towards the proposed standards, EPA's modeling indicates that little new ICEV controls are applied beyond 2026. Thus, on the surface, the ACC II ZEV standards appear to be more stringent than EPA's proposed GHG standards. In order to confirm this, EDF has conducted modeling using OMEGA 2 to compare fleet-average

GHG emissions under ACC II ZEV standards and under EPA's proposed GHG standards. We analyzed a scenario in which ACC II ZEV requirements would be met through 2035, with ZEV sales constant thereafter (ACC II 2035). [EPA-HQ-OAR-2022-0829-0786, pp. 41-45]

EDF used OMEGA 2 to model the ZEV sales requirements by setting the minimum fraction of BEV sales within a vehicle segment (i.e., sedans, CUV/SUVs, and pickups) in the "required sales share" file to match those of ACC II. This is analogous to the approach taken by EPA when it modeled the impact of ACC II in California and ACC II adopting States. However, our analysis applied minimum ZEV sales requirements to all vehicle sales and did not create a second vehicle fleet for those sold in the ACC II states.111 [EPA-HQ-OAR-2022-0829-0786, pp. 41-45]

111 EDF also increased the cap on total battery capacity usage on line 67 of the OMEGA 2 batch file. This arbitrary increase is not material to this case, as EDF is not claiming that there will be sufficient battery availability for all manufacturers to comply with ACC II nationwide. We only want to determine the relative benefits of individual manufacturers who might desire this option. They would only do so if they believed that they would have adequate access to ZEV battery capacity.

As discussed above, ACC II allows PHEVs with a 50-mile on-road range to count as a full ZEV. EPA's proposal would set the utility factor for a PHEV50 at roughly 67%. The current OMEGA 2 model does not include the modeling of PHEVs. However, if a manufacturer chose to meet the ACC II ZEV sales requirements with the maximum 20% level of PHEV50 sales, effectively 6.7% of total ZEV operation would be powered by gasoline. For example, assuming maximum PHEV share in 2032, the 82% ZEV standard could be equivalent to 76.5% BEVs and 23.5% ICEVs. [EPA-HQ-OAR-2022-0829-0786, pp. 41-45]

We left the selection of which vehicles to electrify entirely up to OMEGA 2. We also left the GHG standards constant at the levels of the current MY 2025 GHG standards, as ACC II imposes no direct restrictions on ICEV emissions after 2025. As a practical matter, the control of ICEV emissions has little or no impact on fleetwide GHG emissions or vehicle electrification after 2025. [EPA-HQ-OAR-2022-0829-0786, pp. 41-45]

Table 9 shows BEV sales under the ACC II scenario, as well as under EPA's proposed GHG standards and EPA's Alternative 1 standards.

[See original attachment for Table 9: ZEV Sales as a Function of Total Vehicle Sales] [EPA-HQ-OAR-2022-0829-0786, pp. 41-45]

As the Table shows. Projected ZEV sales under the EPA proposal and Alternative 1 are significantly less than those projected for the ACC II scenario. At the same time, while still higher than EPA's two scenarios, the projected BEV sales under the ACC II scenario using OMEGA 2 are lower than required by ACC II. The shortfall between the ACC II ZEV sales requirement and the level of ZEV sales in the OMEGA 2 simulation in 2032 is 8%. In 2035, the shortfall grows to 17%for ACC II 2035.112 [EPA-HQ-OAR-2022-0829-0786, pp. 41-45]

112 EDF was unable to direct OMEGA 2 to increase BEV sales to meet the ACC II targets. As a result, the projected impacts for the ACC II scenarios are under-estimated.

We noticed that OMEGA 2 decreases its projections of ZEV sales in 2033 for some GHG/ZEV scenarios presumably due to the end of the IRA tax credits. This occurs to a greater degree for less stringent scenarios, like the Proposal, but to a much smaller degree for

Alternative 1 and ACC II 2035. BEV sales then recover to 2032 levels by 2035 under the Proposal. Regardless of these modeling differences, actual real-world compliance with ACC II requirements would result in greater levels of ZEVs and greater environmental benefits than we have shown here. [EPA-HQ-OAR-2022-0829-0786, pp. 41-45]

Fleetwide GHG levels under the various scenarios are shown in Table 10.

[See original attachment for Table 10: Fleetwide GHG Certification Levels from OMEGA 2 Output (g/mi)] [EPA-HQ-OAR-2022-0829-0786, pp. 41-45]

The above table shows fleetwide certification (tailpipe) GHG emission levels are significantly lower under the ACC II scenario than under either EPA scenario. [EPA-HQ-OAR-2022-0829-0786, pp. 41-45]

We then used EPA's Effects Model to project total GHG and criteria air pollutant emission reductions from passenger cars and light-trucks through 2055. EDF used the same emission input files as EPA used in modeling its Proposal and Alternative, which assumed that new vehicles were equipped with gasoline particulate filters (i.e., emission_rates_vehicles-with_gpf.csv). [EPA-HQ-OAR-2022-0829-0786, pp. 41-45]

The results are shown in Table 11. Reductions of both upstream and downstream emissions relative to EPA's No Action scenario are included, using EPA's upstream emissions input files.113 [EPA-HQ-OAR-2022-0829-0786, pp. 41-45]

113 We believe that EPA's estimates of upstream gasoline emissions are substantially under-estimated, as they fail to consider emissions from petroleum production, petroleum transportation and gasoline distribution. This issue is discussed in more detail in our heavy-duty comments.

[See original attachment for Table 11: Cumulative GHG and Criteria Pollutant Emission Reductions from Passenger Car and Light Trucks Through 2055 (GHG: million metric tons; criteria pollutant: U.S. tons)] [EPA-HQ-OAR-2022-0829-0786, pp. 41-45]

ACC II 2035 is projected to achieve 53% more cumulative GHG emission reductions through 2055 than EPA's Proposal and 36% more than EPA's Alternative 1. The ACC II scenario would also achieve substantially greater criteria pollutant emission reductions than either EPA scenario. [EPA-HQ-OAR-2022-0829-0786, pp. 41-45]

Table 12 shows the monetized benefits projected for the three scenarios.

[See original attachment for Table 12: Cumulative Net Monetized GHG and Criteria Pollutant Benefits from Passenger Car and Light Trucks Through 2055: Net Present Value in 2027 (billion 2021 dollars, discounted at 3% per year)] [EPA-HQ-OAR-2022-0829-0786, pp. 41-45]

The ACC II scenario would provide more GHG and criteria pollution benefits than either of the two EPA scenarios. [EPA-HQ-OAR-2022-0829-0786, pp. 41-45]

Accordingly, EDF recommends that EPA adopt an alternative Leadership Pathway with ZEV sales consistent with ACC II through 2035 as an option for compliance with its Final Rule.114 While the above analysis focuses on ACC II through 2035, EDF also evaluated ACC II through 2032 and likewise found it would deliver greenhouse gas and air pollutant benefits as compared to the proposal (although lesser in magnitude than ACC II through 2035). This reinforces our conclusion that a voluntary compliance alternative along these lines would deliver important additional environmental benefits and provide a pathway to align requirements with those that California and many other states either have, or likely will, adopt. [EPA-HQ-OAR-2022-0829-0786, pp. 41-45]

> 114 EDF also modeled a leadership pathway with ACC II ZEV consistent sales through only 2032. While EDF recommends having the leadership pathway extend through 2035, if EPA limited it to only 2032, it would still provide benefits in excess of any of EPA's current proposals. See Appendix B for more details.

Organization: General Motors, LLC (GM)

GM is an industry leader with plans to become carbon neutral in its global product portfolio and its operations by 2040 and has set science-based targets in line with the Paris Agreement and the U.S. Nationally Determined Contribution in support of that goal. GM understands the importance of greenhouse gas (GHG) regulations that are aligned with complementary policies. Ultimately, these policies, which include support for permitting reform, domestic supply chain development,consumerncentives, and charging infrastructure, are critical to the overall success o f the regulations. GM, and the U.S. auto industry overall, have made great strides with GHG reduction technologies since the first GHG standards were adopted for the 2012 model year. We look forward to accelerating that progress with our EV transition. [EPA-HQ-OAR-2022-0829-0700, pp. 2-3]

Today, GM reiterates our commitment to support a regulation that reaches the Administration' s original goals (i.e., 50% EV share 2030, 60% GHG reduction from model year 2021 to 2030) and is aligned with other applicable vehicle regulations. These goals represent the appropriate path toward all EVs by 2035 and re-affirm our commitment to long-term science-based climate targets. These goals also recognize the profound uncertainties of supply chain, manufacturing, infrastructure, and consumer market dynamics through the interim years, as well as related to the implementation of the Inflation Reduction Act (IRA) through the regulation timeframe. [EPA-HQ-OAR-2022-0829-0700, p. 3]

GM supports the creation of a "Leadership Pathway," an optional compliance path for fast-moving companies that will further accelerate EV deployment. We encourage EPA to develop an innovative opt- in compliance pathway that rewards companies that deliver greater-than-projected EV volumes for greater multipollutant reductions. A voluntary program for companies with higher EV deployment has the potential to result in greater overall national EV volumes than the Executive Order 2030 goal (i.e., 50% EVs), the NPRM 2032 goal (67% EVs), and California's Advanced Clean Cars II. [EPA-HQ-OAR-2022-0829-0700, p. 5]

This Leadership Pathway is consistent with General Motors's ground-breaking call in 2018 for a National Zero Emission Vehicle (NZEV) program that enables scale by promoting ZEV investment that meets customer demand throughout the entire nation to address climate change. Given the continued acceleration of EV sales, a Leadership Pathway would provide a logical extension of that NZEV concept. Given companies have committed to the transition in the U.S., we believe that U.S. transportation climate, local air pollution, and petroleum use goals can and should be achieved through high-volume EV sales. If properly conceived, a Leadership Pathway would exceed the Administration's criteria pollutant, GHG emission, and fuel consumption goals, and reward automakers that are acceleratin g that transition to zero-emission vehicles with less complexity and with fewer certification requirements. [EPA-HQ-OAR-2022-0829-0700, p. 5]

Organization: Porsche Cars North America (PCNA)

Porsche supports the development of an alternative compliance pathways, providing additional flexibility within the overall suite of light-duty regulation.

Porsche appreciates EPA including within the MPR preamble reference to alternative compliance pathways that may be considered and included within the Final Rule. Porsche agrees with the agency that an alternative pathway could be developed to help encourage earlier adoption of zero- and near-zero emission technologies that would match or even accelerate GHG and criteria emission reductions beyond the levels proposed within the various scenarios in the proposal. Alternative compliance pathways have been, and can continue to be, a pragmatic regulatory tool that helps agencies achieve their desired policy outcomes while providing manufacturers with greater choice and potentially improved alignment with their individual product strategies. [EPA-HQ-OAR-2022-0829-0637, pp. 4-5]

Porsche would support the development of an alternative pathway for this final rule. An alternative pathway could be an option available to any Original Equipment Manufacturer that would establish requirements that could be met in lieu of primary vehicle certification and fleet average performance-based standards. Each manufacturer would have an equal opportunity to review and participate in this pathway. Porsche believes that an alternative pathway could be developed that would be equitable in terms of manufacturers contributing to the policy goals of the NPRM. Furthermore, Porsche believes that an alternative pathway could be structured such that regardless of how many manufacturers chose to participate, there would be no incremental burden on non-participating manufacturers. Porsche respects that manufacturers serve very different market segments and that an alternative pathway may not be appropriate for all manufacturers. [EPA-HQ-OAR-2022-0829-0637, pp. 4-5]

An alternative pathway that focuses on the deployment of zero- and near-zero emission vehicles will directly contribute to the carbon and pollution reduction policy goals of this MPR, in addition to the petroleum reduction goals of DOT's CAFE regulation and with the air quality goals within California's recently adopted Advanced Clean Cars 2 regulations. In addition, this pathway will help manufacturers concentrate their human and financial resources into the development and manufacturing capacity of zero- and near-zero emission vehicles, potentially leading to accelerated deployment of such vehicles and with the greater potential for cost reductions. This type of pragmatic focused pathway can deliver regulatory certainty, compliance streamlining, and increased environmental and energy benefits. [EPA-HQ-OAR-2022-0829-0637, p. 5]

.In general, like the primary suite of regulations, Porsche believes an alternative pathway would center upon an annual compliance requirement that would contain a mix of targets, boundary conditions, and flexibilities. Manufacturers would commit to utilizing this pathway the details of which could be defined within a new Subpart. Compliance with the terms within this new Subpart would be in lieu of compliance with the primary performance-based fleet average and vehicle certification requirements. [EPA-HQ-OAR-2022-0829-0637, pp. 5-6]

With regards to form and structure, Porsche generally views an alternative pathway that would likely be centered on an accelerated ramp rate of zero- and near-zero emission vehicles and technologies. The alternative pathway could include annual targets for the nationwide deployment of zero- and near-zero emission vehicles. The targets could reflect an incremental level above the industrywide projected rates of zero- and near-zero emission vehicles needed to comply with finalized performance-based standards. In addition, Porsche believes that the pathway could provide recognition for actions from manufacturers that support electrification through complementary measures such as deployment of charging infrastructure or customer education programs that would both be helpful to increasing consumer adoption. [EPA-HQ-OAR-2022-0829-0637, pp. 5-6]

Porsche recognizes that this type of pathway may be characterized as a Nationwide "EV mandate" which could negatively impact consumer choice and remove other technologies from the market. Porsche believes that the alternative pathway could be structured with flexibility to include technologies that are able to demonstrate significant and meaningful emissions benefits. Porsche recognizes that certain vehicle segments may better achieve emissions goals and customer acceptance through technologies other than full electrification. As such, a flexibility for being inclusive, even if for a limited portion of the overall requirement, may be a pragmatic and helpful approach. [EPA-HQ-OAR-2022-0829-0637, pp. 5-6]

Porsche is aware of discussions associated with these types of zero-emission vehicle policies regarding the performance requirements for the remaining combustion models that would continue to be sold. The dialogue being that combustion models would be free to "backslide" in their emission performance or fuel efficiency should they no longer be subjected to stringent certification and fleet average requirements. Stakeholders have contended that this potential "backsliding" could erode or otherwise offset the benefits being achieved even with increased zero-emission vehicle sales. Porsche believes that a reasonable set of boundary conditions could be developed as part of the alternative pathway that would help ensure policy outcomes by preventing backsliding of the remaining combustion fleet. There are likely a series of measures that could be implemented to protect against such erosion of emissions or fuel economy performance that would allow manufactures to focus on their zero-emission fleet, but not at the expense of reduced combustion vehicle performance. These types of "anti-backslide" measures have been used in the past within vehicle regulations. Manufacturers could outline their roadmap of remaining combustion models and demonstrate to the Administrator how the manufacturer would preserve the level of performance for each remaining vehicle over the duration of the regulation. Porsche believes there could also be some requirements for limited, targeted improvements in these combustion concepts that may help achieve incremental emissions benefits without major redesign or certification resources. Overall, this approach could effectively "snap a chalk line" for each manufacturer to preserve combustion vehicle performance as the vehicles phase-down in a manufacturers fleet. [EPA-HQ-OAR-2022-0829-0637, pp. 5-6]

As mentioned above, Porsche believes it is likely that the terms of an alternative pathway would need to be consistent for each participating manufacturer regardless of overall size within the US market. Because smaller volume-based manufacturers already are provided limited flexibilities for annual compliance, it is unlikely that additional flexibilities would be needed within an alternative pathway. As such, EPA could consider whether it remains appropriate to maintain provisions for related entities as such provisions may no longer serve a purpose. Manufacturers could be provided the option to participate in the alternative pathway on an individual basis or to continue with the current coordinated compliance. [EPA-HQ-OAR-2022-0829-0637, pp. 5-6]

Porsche also believes that the potential benefits of an alternative pathway could extend beyond the boundaries of this specific NPRM. Porsche recognizes that an alternative pathway developed within this rulemaking would necessarily be limited to acting in lieu of regulatory requirements directly under EPA's management. However, Porsche recognizes that an alternative pathway could provide similar benefits within the regulatory structure of other related State and Federal regulations. As noted earlier, an accelerated ramp rate of zero- and near-zero emission technologies could equally serve these programs. As such, Porsche recommends that an alternative pathway be structured and coordinated across agencies to provide manufacturers with a holistic, comprehensive compliance strategy that would significantly improve regulatory certainty and streamlined implementation. Porsche believes it could be possible for California and NHTSA to coordinate with EPA to develop equivalent alternative pathways that would work separately under each agencies own statutory authority, but aligned to ensure that a manufacturer who brings an accelerated rate of zero- and near-zero emission vehicles to market can achieve compliance with the full range of requirements. [EPA-HQ-OAR-2022-0829-0637, pp. 6-7]

Porsche acknowledges that this would be an extensive investment in agency resources to define the specifics of an alternative path in time for a Final Rule as projected in CY2024. Nevertheless, Porsche hopes that these comments are sufficiently responsive to the request for comment by EPA which could create the opportunity for details to be developed by EPA. Porsche would seek to be an active, constructive resource for the agency in helping to inform the details on such an alternative pathway. [EPA-HQ-OAR-2022-0829-0637, pp. 6-7]

Organization: Volkswagen Group of America, Inc.

Alternative Pathway

With respect to alternatives to the current Averaging, Banking and Trading (ABT) program to allow manufacturers flexibility to comply, EPA seeks public comment on the potential merits of such an alternative pathway concept, whether it would be advantageous for both the GHG as well as the criteria pollutant standards program, and how it might be structured. Volkswagen supports the EPA's consideration of alternative pathways to help encourage earlier adoption of zero emission vehicles with the aim to accelerate GHG and criteria emission reductions beyond the levels adopted. [EPA-HQ-OAR-2022-0829-0669, pp. 3-4]

Electrification is the core of future mobility. Volkswagen believes an inter-agency coordinated alternative compliance pathway could simplify overall GHG, CAFE and criteria compliance to all standards by recognizing an optional National ZEV program alternative. [EPA-HQ-OAR-2022-0829-0669, pp. 3-4]

Alternative optional compliance pathways can be a regulatory tool for agencies to achieve their desired policy outcomes while providing manufacturers with greater choice and improved alignment with their product strategies. Volkswagen recognizes that manufacturers follow different strategies, while serving very different market segments and customer needs. Each manufacturer would have an opportunity to participate. The pathway would require structuring such that non-participating manufacturers would not be disadvantaged. [EPA-HQ-OAR-2022-0829-0669, pp. 3-4]

Volkswagen proposes that OEMs who meet the optional National ZEV alternative pathway, above the EV final rule threshold, be found in compliance with all performance-based standards, including GHG, CAFE and Tier 4/LEV IV emissions regulation. Local ZEV III standards would stay in place. This would become a meaningful alternative to achieve EPA's objective of transitioning the U.S. automotive fleet towards EVs and would set a clear focus on transformation and investment in ZEV technologies. A comparable approach is currently in development in the United Kingdom, which plans to establish a ZEV mandate as the new lead regulation, instead of strengthening the existing CO2 fleet standards. [EPA-HQ-OAR-2022-0829-0669, pp. 3-4]

Volkswagen believes that an alternative pathway that focuses on the acceleration of zero emission vehicles will help manufacturers concentrate their resources into development and manufacturing of these vehicles. Investing in a diminishing ICE fleet would direct resources away from EV ramp-up, which would be counterproductive to the goal. By having a complete focus on an EV fleet, the regulatory complexity and burden for manufacturers would be drastically reduced. In turn, this could improve vehicle speed to market and deliver more choices at lower costs for customers. [EPA-HQ-OAR-2022-0829-0669, pp. 3-4]

Volkswagen acknowledges that the alternative pathway could potentially result in an emission "backslide" in ICE vehicles. Volkswagen therefore suggests establishing a reasonable set of boundary conditions as part of the alternative pathway to ensure anti-backsliding for the remaining ICE fleet. [EPA-HQ-OAR-2022-0829-0669, pp. 3-4]

The optional alternative pathway will ultimately serve the objectives of the Clean Air Act, State air quality and federal fuel economy standards. Volkswagen believes that legislative and regulatory action would be needed to complete the transition of vehicles on the road from ICE to ZEV. A clear, focused pathway will help provide regulatory certainty, compliance streamlining and increased environmental benefits. [EPA-HQ-OAR-2022-0829-0669, pp. 3-4]

Volkswagen recognizes that this would be a potentially significant agency and legislative resource investment to include in time for the Final Rule, and that these comments do not provide exact suggestions for structure and requirements of such an alternative path. Volkswagen does not have specific parameters outlined for this pathway as they could extend past the scope of this NPRM. However, EPA should consider using this rulemaking as an opportunity to offer an optional alternative ZEV compliance pathway for greenhouse gas and criteria emissions that could be implemented in concert with similar alternative ZEV compliance pathways for the CAFE and CARB regulatory programs. Volkswagen will be an active and constructive resource for the agencies and manufacturers to discuss and define the details on such an alternative pathway. [EPA-HQ-OAR-2022-0829-0669, pp. 3-4

EPA Summary and Response

Summary:

In the NPRM, EPA solicited public comments on whether there would be merit to considering alternative pathways that might encourage manufacturers to achieve lower CO_2 emissions than the final standards earlier in the program. Three stakeholders (EDF, GM, Porsche and Volkswagen) each provided comment in support of a conceptual voluntary pathway that would be more stringent than the standards finalized in this rulemaking.

Response:

EPA appreciates commenters feedback and willingness to discuss and develop such an alternative, or “leadership” pathway concept. As we more fully describe in Section III.C.2.iv.c of the preamble, EPA is not finalizing such a pathway in its final rulemaking, due to the need for additional exploration and assessment of such a pathway. However, EPA is open to continued dialogue with stakeholders in the spirit of trying to better define such a pathway for a potential future action.

3.2 - GHG standard curves

3.2.1 - LDV footprint curves

Comments by Organizations

Organization: Alliance for Automotive Innovation

A. Major Concerns with the Proposed GHG Standards

2. Footprint Attribute

Auto Innovators supports the continued use of footprint-based standards. Historically, the footprint attribute has served relatively well as a surrogate for vehicle tractive energy requirements, providing a means to set standards appropriate to different sizes of vehicles. [EPA-HQ-OAR-2022-0829-0701, p. 110]

9.Development of Footprint Curves

a)Footprint Trends

Auto Innovators disagrees with EPA’s assessment that the footprint-based standards have resulted in a general increase in vehicle footprint as a means to reduce compliance burden. When vehicles are redesigned, their footprint may change for any number of reasons. Furthermore, we believe a closer look at vehicle trends would reveal that vehicle type and segment size shifts play as large a role in changing average footprints as increases in footprint for any given model of vehicle. Finally, while a slightly larger footprint may yield a nominal compliance benefit, such benefits are relatively small (a couple of g/mile at most) and are limited by other model design parameters. [EPA-HQ-OAR-2022-0829-0701, pp. 120-121]

The relatively short comment period prevents us from exploring this topic more thoroughly, and we may take time outside of the rulemaking comment period to discuss this issue further if it remains a concern to EPA. [EPA-HQ-OAR-2022-0829-0701, pp. 120-121]

b).Footprint Curves

Regardless of the shape of the footprint curves, we are concerned that their level in general will require rapid EV uptake through both the early and late majority market phases in less than a decade, from the early adopter stage the market is in today. [EPA-HQ-OAR-2022-0829-0701, pp. 120-121]

EPA’s proposed approach to seeing footprint-based target curves is a dramatic change from prior rulemakings.

In the 2010 rule, target curves were developed with the concept of fitting known vehicle data, and then applying gram per mile improvement requirements across the range of vehicle sizes. In 2012, some adjustments were made to the truck curve shape and cut-points to better reffect the light-duty truck fleet. EPA then generally applied percentage reductions to the targets year- over-year with the understanding that greenhouse gas reduction technologies would achieve similar percentage improvements across the entire size range of vehicles. That same general process was followed in the 2020 and 2021 GHG rulemakings. Mathematically and technologically, this process has resulted in gradually flattening slopes and a truck target curve that has generally moved closer to passenger car target curve in each year, other than when corrections were made to the curve fitting in the 2012 rulemaking. Over the history of these developments, one can still trace back to the premise of curves that reflect the energy demands of various sizes and types of vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 120-121]

Now, EPA proposes to move away from the prior process of applying a percentage reduction to both passenger car and light-duty truck curves. For light trucks, EPA proposes to set a target curve based on the passenger car curve with an off-set for four-wheel/all-wheel-drive and a linear function to represent increasing towing capacity with increasing vehicle size. The base passenger car target curve (upon which the truck curve is based) has had its slope fattened to the point where footprint plays little role in the target. [EPA-HQ-OAR-2022-0829-0701, pp. 120-121]

These changes, particularly setting a truck curve based on the car curve, are technical in nature, and difficult to fully evaluate and comment adequately on in the short period of time provided for comment. The proposed changes are based on the sort of analysis that would have been better discussed with the public in advance of a proposed rule. Auto Innovators may continue analysis post-comment period and would appreciate further discussion with EPA if needed. In the meantime, we offer the following observations. [EPA-HQ-OAR-2022-0829-0701, pp. 120-121]

i)Target Curve Slope

Flater GHG performance across vehicle size is an expected outcome of applying ZEV technology (with zero tailpipe emissions instead of a percentage improvement to a prior technology) across the entire range of vehicle sizes. However, making the assumption of rapid EV market share gains across all vehicle sizes effectively forecloses opportunities for plug-in hybrid electric vehicles that have some zero emission operation, but also include ICE operation that would be better suited to a target curve with some slope. [EPA-HQ-OAR-2022-0829-0701, pp. 121-123]

Concerns with a flat passenger car curve grow when that passenger car curve is then used to derive a light truck curve. Although the proposed truck curves have more slope than the passenger car curves they are derived from, that slope is intended (at least to our understanding of EPA's analysis) to account for towing capacity. However, the underlying assumption of massive EV uptake is there because the towing adjustment is applied to the underlying passenger car curve. Such an approach fails to consider potential differences in overall EV uptake and type of EV uptake in the light-duty truck fleet. EPA may model that BEV uptake in the light-duty fleet will rapidly catch and equal that in the passenger car fleet across all vehicle types, but that is an artifact of the model itself. The model simply reacts to whatever targets it is given, and outputs the technology path, associated emission levels, etc. that would be required to meet that target. It does not consider the market as automakers do, where different technologies might be better suited to different vehicles to meet market needs. [EPA-HQ-OAR-2022-0829-0701, pp. 121-123]

ii)Light-Duty Truck Curves Based on Passenger Car Curves

There was insufficient time for us to analyze EPA's derivation of the four-wheel/all-wheel-drive offset and towing utility functions for light-duty trucks. However, we are concerned that even if applying such adjustments to passenger car targets is technically accurate (we withhold judgement here) and the derivations are correct (again withholding judgement), EPA proposes to make the switch from a system based on historic performance to a new one based on the passenger car curves starting in MY 2027. This results in a large increase in truck stringency in the first year of the proposed program. As can be observed in the EPA Trends Report, light-duty trucks have already gradually fallen behind regulatory requirements on average.223 Now, EPA asks them to make a large leap forward in emissions performance from an already disadvantaged position with virtually no lead-time. (Some manufacturers have already begun offering MY 2024 vehicles; MY 2027 can begin in less than three years.) [EPA-HQ-OAR-2022-0829-0701, pp. 121-123]

223 To some extent, this is likely because manufacturers have generally added electric vehicles to passenger car fleets, using passenger car compliance to offset truck fleet emissions. Light-duty truck electrification has generally trailed that of passenger cars.

iii)"Footprint Neutral" Slope

We similarly have not had enough opportunity to evaluate EPA's derivation of a "footprint-neutral" slope. However, we can say that regardless of any math that EPA might apply, manufacturers simply don't think about vehicle footprint in those terms. They consider wheelbase and trackwidth in terms of driving dynamics, vehicle customer functionality, safety, and other attributes that customers care about. [EPA-HQ-OAR-2022-0829-0701, pp. 121-123]

iv)Low and High Footprint Cut Point Changes

EPA also proposes changes to the cut points where the target curves become flat instead of following a function of footprint. [EPA-HQ-OAR-2022-0829-0701, pp. 121-123]

We do not oppose moving the low footprint cut points for passenger cars and light-duty trucks higher. While the market implications of such action are unclear, we can certainly agree that the extremely low GHG emission targets for the smallest vehicles have been a challenge to meet. [EPA-HQ-OAR-2022-0829-0701, pp. 121-123]

EPA is also proposing to lower the high footprint cut point for trucks. In 2012, the high cut point was increased in recognition that there were already a number of larger vehicles with footprints higher than the cut point, resulting in standards that did not reflect their size. There remain a number of vehicles up to approximately 78 ft2 footprint in the light truck fleet. Lowering the high footprint cut point would only serve to punish those vehicles. We recommend that EPA keep the light-duty truck high footprint cut-point at 74 ft2. [EPA-HQ-OAR-2022-0829-0701, pp. 121-123]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

The proposed standards need to limit upsizing as the light-duty fleet electrifies [EPA-HQ-OAR-2022-0829-0642, pp. 6-8]

In the past decade the U.S. automotive market has seen a shift towards larger vehicles. The average footprint for all vehicle types has increased and more and more light trucks are being sold compared to cars. This has been a major factor for the recent stagnation in real- world fuel efficiency of the fleet.17 We applaud EPA for attempting to counter these trends with the proposed standards and for correcting conditions from past GHG rulemakings that have exacerbated the issue. Lowering the cutpoints on the light truck curve will reduce emissions by setting a more stringent standard for the largest trucks, as will the flattening of both the car and light truck curves and reducing the GHG grams per mile (gpm) gap between them. [EPA-HQ-OAR-2022-0829-0642, pp. 6-8]

17 https://www.epa.gov/automotive-trends

EPA must correct the slope of its car curve to accurately reflect BEV penetration [EPA-HQ-OAR-2022-0829-0642, pp. 6-8]

ACEEE agrees that the slopes of the car and light truck curves that demonstrate the relationship between vehicle footprint and the relevant emissions targets should reflect rising BEV penetration over the period of the standards, and that the appropriate slope for ZEVs should be zero. Tailpipe-only accounting combined with steep curves means that the production of large ZEVs can generate a considerable number of credits for a given manufacturer, which will incentivize vehicle companies to upsize their ZEV offerings and ignore improvements to ICEV options. For an ICEV car curve, EPA has determined that the appropriate slope to avoid incentivizing vehicle upsizing or downsizing is 0.8 gpm/ft2 and contends that the curve should be adjusted over time based on the ZEV share of sales. However, the car curve slopes for both the proposed standards and Alternative 1 are inconsistent with this finding, as explained below. [EPA-HQ-OAR-2022-0829-0642, pp. 6-8]

Table 1. Car curve slope unadjusted and adjusted for BEV penetration

Model Year	Proposed Standard Car Curve Slope (gpm/sq-ft)	Expected Car BEV Penetration	Adjusted Slope (gpm/sq- ft)	Alternative 1 Car Curve Slope	Expected Car BEV Penetration	Adjusted Slope (gpm/sq-ft)
2027	0.64	43%	1.12	0.59	44%	1.05
2028	0.56	51%	1.14	0.51	50%	1.02
2029	0.47	59%	1.15	0.42	58%	1.00
2030	0.43	65%	1.23	0.38	67%	1.15
2031	0.39	69%	1.26	0.34	72%	1.21
2032	0.35	73%	1.30	0.30	74%	1.15

[EPA-HQ-OAR-2022-0829-0642, pp. 6-8]

ACEEE calculated the adjusted slopes in Table 1 based on EPA's description of their methodology in the Draft Regulatory Impact Analysis (DRIA) where a slope of 0.8 is scaled to 0.4 to reflect 50% ZEV penetration (p.1-7). The adjusted slopes shown in Table 1 are far higher than 0.8 and rise over time with increases in BEV penetration. If 0.8 is the slope that minimizes the incentive to upsize or downsize vehicles, then anything higher than that would encourage the manufacture of larger vehicles and lead to higher emissions. Given that the light truck curve is based on EPA's car curve but has added offsets, the light truck curve would be similarly affected. EPA projects that average footprints will rise as a result of the proposed standard, further evidence that the curves as proposed are too steep (DRIA p.1- 14). We strongly recommend that EPA flatten both curves to accurately reflect expected BEV penetration in accordance with its own analysis. [EPA-HQ-OAR-2022-0829-0642, pp. 6-8]

Offsets for the light truck curve should be decreased to reflect real-world conditions [EPA-HQ-OAR-2022-0829-0642, pp. 6-8]

EPA constructs the light truck curve for the proposed standards by adding offsets (in the form of higher levels of emissions for a given footprint) to the car curve then similarly adjusting it for light truck BEV penetration. The first offset is for all-wheel drive (AWD) capability. EPA assumes that crossover vehicles need additional emissions allowances to allow for AWD capability, which would effectively classify them as truck crossovers (DRIA p.1-8). This offset is set at 10 grams per mile (gpm) and is applied uniformly across the entire ICEV-only light truck curve. However, not all light trucks have AWD and EPA's adjustment to the emissions allowance is based on an analysis of what is needed to add AWD to a model (DRIA p.1-8 – 1-9). Therefore, applying this offset to all light trucks, regardless of whether they have AWD, unnecessarily increases the allowable emissions level. In 2021, 78% of pickups and 87% of truck SUVs had AWD while almost 20% of car SUVs and sedans had AWD capabilities.18 The 10 gpm offset should be reduced to account for this and not further incentivize the shift of cars to trucks. [EPA-HQ-OAR-2022-0829-0642, pp. 6-8]

18 https://www.epa.gov/automotive-trends

The second adjustment that EPA makes to the car curve to create the light truck curve is for towing and hauling capability. To accommodate towing and hauling, EPA increases towing allowance linearly from 0-63 gpm for light trucks with footprints between 45 and 70 square feet on an all-ICEV curve. However, EPA assumes that all light trucks need to be able to haul and tow and therefore applies the allowance across the board . Not every vehicle classified as a light truck needs to tow or haul significant amounts of cargo. The vehicles that do need to tow or haul may only do so occasionally, and some may never need to.19 The 63 gpm offset for the all-ICEV light truck curve should be lowered to reflect the data on usage of towing and hauling capabilities by light truck owners. [EPA-HQ-OAR-2022-0829-0642, pp. 6-8]

Organization: American Petroleum Institute (API)

vii. The proposed emissions standards are unfounded because EPA fails to explain its rationale for selecting the proposed emissions control levels.

EPA provides an expansive explanation of the Proposed Rule in the 263-page Federal Register notice. But noticeably missing is any explanation of how EPA derived the numeric emissions standards that the Proposed Rule would establish. The "footprint-based standard curve coeffcients" for cars and light trucks are clearly presented in the proposal. 88 Fed. Reg. at 29236. While EPA describes these curves as "targets, rather than standards," the curves effectively represent the emissions standards because the enforceable obligation for each manufacturer is derived by summing the actual sales-weighted values derived through application of the curves. Id. at 29236 n. 405. Because of the ABT compliance provisions, a manufacturer can demonstrate compliance for its fleet even if each of its vehicles does not meet the emissions limit applicable to that vehicle according to the curves. But each manufacturer must meet an enforceable in-use emissions standard for each vehicle type based on the level of emissions to which the vehicle is certified. [EPA-HQ-OAR-2022-0829-0641, pp. 32-33]

In presenting the curves, EPA discusses a wide variety of relevant factors -- including the upper and lower cutpoints, the slope of the curve, incentives/disincentives for consumer choice of larger vehicles (and the resulting impact on overall GHG emissions reductions), the impact of BEVs, and the relationship between the car and truck curves (the later Including consideration of load and towing capacity). In addition, the preamble includes extensive discussion of the predicted costs of the Proposed Rule and technical feasibility. But nowhere does EPA explain how the numeric values of the curves (i.e., the actual GHG emissions rate that would be applied to each vehicle upon application of the curve) were derived and how those particular values are justified. [EPA-HQ-OAR-2022-0829-0641, pp. 32-33]

It is bedrock administrative law that an "agency must examine the relevant data and articulate a satisfactory explanation for its action including a rational connection between the facts found and the choice made." Motor Vehicle Mfrs. Assn. of the United States, Inc. v. State Farm Mut. Automobile Ins. Co., 463 U.S. 29, 43 (1983). EPA's failure to do so here renders the Proposed Rule fatally arbitrary and capricious. [EPA-HQ-OAR-2022-0829-0641, pp. 32-33]

Additionally, the lack of explanation violates EPA's procedural obligation to develop a statement of basis and purpose that, among other things, explains "the factual data on which the proposed rule is based" and "the methodology used in … analyzing the data." CAA § 307(d)(3). Unless that failure is corrected, API and other interested parties do not have adequate notice of and opportunity to comment on one of the most fundamental aspects of the Proposed Rule. [EPA-HQ-OAR-2022-0829-0641, pp. 32-33]

Organization: Arconic Corporation (ARCO)

4. Arconic agrees with proposed cut points on the proposed emission target curves. These cut point changes will limit the future vehicle footprint increases. [EPA-HQ-OAR-2022-0829-0741, p. 3]

Organization: CALSTART

12. 1. Close the footprint loophole which incentivizes automakers to classify vehicles as light trucks resulting in larger, less efficient vehicles that decrease overall safety for all road users. [EPA-HQ-OAR-2022-0829-0618, p. 2]

Footprint Loophole

As the EPA is well aware, SUV and light truck sales have surged over recent decades because these vehicle types have faced less stringent emissions regulations, leading OEMs to focus on their sales. While stricter emissions regulations have reduced the missions impact of cars, the loophole has also decreased new car sales from around 50% to 20% as OEMs prioritized SUVs and light trucks. These larger vehicles consume around 20% more fuel than conventional cars, making it especially important to address this loophole.1 [EPA-HQ-OAR-2022-0829-0618, pp. 2-3]

1 https://www.wired.com/story/the-us-wants-to-close-the-suv-loophole-that-supersized-cars/.

One possible solution to address the loophole is the changes to footprint-based standards, which would reduce the “offset” between the car and truck slopes. Extending standards through 2035 would also minimize uncertainty and provide the market ample clarity that it must transition all light cars, trucks, and SUVs to be zero-emission by 2035. [EPA-HQ-OAR-2022-0829-0618, pp. 2-3]

Organization: Center for American Progress (CAP)

d. Eliminate Incentives to Make Larger Vehicles–In its final rule, EPA should work to eliminate all incentives to make vehicles larger, including avoiding incentivizing larger ZEVs. To accomplish this, EPA should remove ZEVs from the footprint curve system entirely. At a minimum, EPA should credit ZEVs at the midpoint of their respective curves, removing the incentive to build larger ZEVs. Eliminating incentives to build larger vehicles both increases pedestrian safety and contributes to the overall success of the rule in decreasing emissions.26 Larger vehicles are on average more expensive and their larger size and corresponding losses in aerodynamic efficiency are realized by the consumer as reduced range or increased upfront cost in order to compensate for this inefficiency. EPA should also remove incentives to upsize ICE vehicles in its final rule. To do so, EPA should further reduce the difference between the car and truck curves and scale the car curve such that it does not create an incentive to upsize ICE vehicles. Larger ICE vehicles present the same safety concerns as large ZEVs and also emit more during operation. [EPA-HQ-OAR-2022-0829-0658, p. 6]

26 Insurance Institute for Highway Safety and the Highway Loss Data Institute, “SUVs, other large vehicles often hit pedestrians while turning, March 17, 2022, available online: https://www.iihs.org/news/detail/suvs-other-large-vehicles-often-hit-pedestrians-while-turning

Organization: Consumer Reports (CR)

6.3. Changes to the Footprint Curves

Overall CR supports the efforts by EPA to eliminate the regulatory incentive for automakers to shift their fleet mix from smaller cars to larger light trucks. This shift towards larger and less efficient vehicles has eroded a significant portion of the emissions improvements that could have been delivered by EPA’s past light-duty vehicle GHG standards. A recent analysis by CR found that while the average fuel economy from new vehicles has improved by 30% from 2003 to 2021, it would have improved by 43% had the fleet mix stayed the same as it was in 2003.44 [EPA-HQ-OAR-2022-0829-0728, p. 22]

44 Vehicle Price Trends: Fuel Economy and Safety Improvements Come Standard, Consumer Reports, February 21, 2023, https://advocacy.consumerreports.org/wp-content/uploads/2023/02/CR-Vehicle-Price-Trends-Feb-21-202 3.pdf.

While consumers can and should be able to select the vehicle that best suits their needs, the EPA GHG program should not provide an implicit incentive for automakers to build and promote larger and more polluting vehicles. The efforts by EPA to narrow the gap between the car and light truck curves, and to reduce the slopes of both footprint curves in this current rulemaking will go a long way towards reducing the incentive for automakers to use mix shifting as a compliance strategy, but it is unclear if it will completely eliminate the incentive. [EPA-HQ-OAR-2022-0829-0728, p. 22]

CR agrees with the data-driven approach EPA used to identify the appropriate offset for vehicles with 2-wheel drive versus vehicles with 4-wheel drive. However, there are questions about the use of towing as a means to define the slope of the truck curve. [EPA-HQ-OAR-2022-0829-0728, p. 22]

Most Americans never use their vehicle's towing capabilities.45 Granting vehicles significant additional emissions allowance for an attribute that is rarely actually utilized by consumers has the potential to continue to perpetuate the shift towards larger vehicles, without appreciable improvement in functional utility for consumers. At a minimum, EPA should factor in the actual consumer demand and usage of towing capabilities into their analysis for the footprint curves, or consider alternative potential definitions of utility. One alternative would be to consider combined passenger and cargo volume, which is more likely to be valued and utilized by consumers. [EPA-HQ-OAR-2022-0829-0728, p. 22]

45 You Don't Need A Full-Size Pickup Truck, You Need a Cowboy Costume, The Drive, March 15, 2019, https://www.thedrive.com/news/26907I-dont-need-a-full-size-pickup-truck-you-need-a-cowboy-costume.

Organization: District of Columbia Department of Energy and Environment (DOEE)

Footprint Curves

DOEE is generally supportive of the concept of revising the vehicle footprint curves. Research has shown that vehicle footprint's use in determining compliance can distort production decisions toward larger vehicles17, which results in vehicles that are less safe to pedestrians and bicyclists and also can lead to an emission rebound effect. However, there are still issues with EPA's proposal. Perpetuating a disconnection between cars and trucks will likely continue the movement toward larger vehicles, therefore, EPA should apply only one curve to all passenger vehicles. This curve should either be flat or near flat since vehicle downsizing is a preferred policy effect that reduces vehicle footprints, and the reduced vehicle footprint in turn reduces emission rebound effects and dangers to pedestrians and bicyclists that engage in the truest zero-emission transportation options. [EPA-HQ-OAR-2022-0829-0550, pp. 5-6]

VII. Revisions to Elements of the Light-Duty Regulatory Program Are Warranted.

In addition to promulgating strong emission standards for light-duty vehicles, EPA should finalize important revisions to the light-duty regulatory program. As detailed below, we recommend that EPA revise the light-duty footprint curves and ensure that the final standards do not incentivize larger BEVs. We also urge EPA not to permanently foreclose the possibility of including upstream emissions in compliance accounting. [EPA-HQ-OAR-2022-0829-0759, p. 57]

A. EPA is correct to address the misaligned incentives present in the current footprint attribute curves.

As EPA identified in its analysis of the market, sales of utility vehicles have greatly outpaced the sales of cars (sedans, coupes, etc.) over the past decade.153 Unfortunately, the design of the footprint attribute curves underpinning the Agency's GHG standards has played a role in incentivizing manufacturers to shift market share towards utility vehicles, which generally have emissions targets much higher than passenger car equivalents.154 EPA is appropriately proposing to revise the design of these curves by considering not just what is technically achievable but also how manufacturers would respond to a given attribute curve,155 rather than starting from a broader view of makeup of the current fleet, as was used to originally define the attribute curves.156 [EPA-HQ-OAR-2022-0829-0759, p. 57]

153 DRIA, Section 1.1.1 & 1-4, Figs. 1.1 & 1.2.

154 A review of this evidence is available at Union of Concerned Scientists, The SUV Loophole: How a changing sales mix is affecting the efficacy of light-duty vehicle efficiency regulations (2016), https://downloads.regulations.gov/EPA-HQ-OAR-2015-0827-4016/attachment_2.pdf.

155 "In determining an appropriate slope for the car curve, EPA modeled a range of car slopes to evaluate the footprint response – that is, to assess the tendency of the fleet to upsize or downsize as a compliance strategy." DRIA at 1-6.

156 A full discussion is available in Section 3.2 of the RIA to EPA's MY 2012-2016 LDV GHG standards. U.S. EPA, Final Rulemaking to Establish Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards: Regulatory Impact Analysis. EPA-420-R-10-009 (Apr. 2010), available at https://nepis.epa.gov/Exe/ZyPDF.cgi/P1006V2V.PDF?Dockey=P1006V2V.PDF. See also U.S. EPA & NHTSA, Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards; Final Rule, 75 Fed. Reg. 35324, 25359-68 (May 7).

1. EPA has appropriately characterized its footprint attribute curve for passenger cars.

In developing the car curve, EPA has appropriately balanced technology-driven emissions reductions for vehicles of different sizes and manufacturers' likely non-technology responses to its attribute curves. EPA should finalize these updates to the car curve. [EPA-HQ-OAR-2022-0829-0759, p. 57]

2. EPA has overestimated performance-related emissions when calculating the footprint attribute curves for light trucks. [EPA-HQ-OAR-2022-0829-0759, p. 58]

In determining the shape of the light truck attribute curve, EPA has appropriately started from the passenger car curve, compensating for different features that distinguish a passenger car and light truck. However, EPA has overestimated the impacts of those factors. [EPA-HQ-OAR-2022-0829-0759, p. 58]

The first characteristic it uses to distinguish a light truck is the addition of 4- or all-wheel-drive (4/AWD) to a crossover utility vehicle, which shifts a vehicle from the passenger car to light truck classification.157 EPA estimated this value in a similar manner to previous work and arrived at a comparable but slightly reduced value for the difference in CO2 values,158 likely resulting from improvements in all-wheel-drive packages that have diminished the powertrain losses associated with the driveshaft and differential. This is a reasonable estimate to use as an offset, if the offset is applied solely to the share of light trucks with 4/AWD, as EPA has done.159 [EPA-HQ-OAR-2022-0829-0759, p. 58]

157 This is true provided the vehicle also meets the requirements of 49 C.F.R. § 523.5(b)(2).

158 Compare 12.5 g/mi (EPA, DRIA at 1-9) to 14.2 g/mi from UCS, The SUV Loophole, at 3.

159 “Based on this anal’sis, EPA's proposed footprint curves reflect an offset between the car and truck curves of 10 g/mi for ICE vehicles equipped with AWD.” DRIA at 1-9.

SEE ORIGINAL COMMENT FOR Figure VII.A-1. Maximum tow rating, by footprint (model year 2019) [EPA-HQ-OAR-2022-0829-0759, p. 58]

The other additional criterion EPA uses to distinguish the light truck curve from the passenger car curve is the application of towing. Considering the maximum towing capacity, we were largely able to reproduce the slope of the curve for maximum towing capacity vs. footprint independently (Figure VII.A-1). However, maximum towing capacity does not actually reflect the real towing capabilities of the fleet because the maximum towing capability for a large share of models is dependent upon additional equipment installation. As a result, EPA is unintentionally incorporating into its regulatory curves excess performance capability—while there may be variance for a vehicle’s maximum tow capability based on powertrain and drivetrain, without a tow package (which may include a trailer hitch, changes to wiring to support connection to a trailer, and an upgraded rear axle), a vehicle’s ability to tow may be significantly more limited (as illustrated in Table VII.A-1). With one ton or more difference between a vehicle’s capability with and without the tow package, ascribing the maximum capability to all vehicles could unreasonably allow more than 20 g/mi additional GHG emissions based on the Agency’s estimate of 9 g/mi per 1,000 pounds payload.160 EPA should apply any adjustment only according to the capability of vehicles as sold in the final rule. [EPA-HQ-OAR-2022-0829-0759, pp. 58-59]

160 DRIA at 1-11.

Table VII.A-1. Maximum towing capacity for 10 most popular light trucks with and without tow package161[EPA-HQ-OAR-2022-0829-0759, p. 59]

161 These towing capacities reflect the trim variant with the highest towing packages, both with and without the vehicle’s tow package. Many of these vehicles have engine options that offer lower towing capability.

Vehicle Make and Model: Ford F-150

Maximum Towing Capacity (lbs.)

With Tow Package: 14,000

Without Tow Package: 11,300

Vehicle Make and Model: Chevy Silverado/GMC Sierra

Maximum Towing Capacity (lbs.)

With Tow Package: 13,300

Without Tow Package: 9,900

Vehicle Make and Model: Ram 1500

Maximum Towing Capacity (lbs.)

With Tow Package: 12,750

Without Tow Package: 10,100

Vehicle Make and Model: Toyota RAV-4

Maximum Towing Capacity (lbs.)

With Tow Package: 3,500

Without Tow Package: 1,500

Vehicle Make and Model: Honda CR-V

Maximum Towing Capacity (lbs.)

With Tow Package: 1,500

Without Tow Package: n/a

Vehicle Make and Model: Toyota Tacoma

Maximum Towing Capacity (lbs.)

With Tow Package: 6,800

Without Tow Package: 3,500

Vehicle Make and Model: Jeep Grand Cherokee

Maximum Towing Capacity (lbs.)

With Tow Package: 7,200

Without Tow Package: 3,500

Vehicle Make and Model: Toyota Highlander

Maximum Towing Capacity (lbs.)

With Tow Package: 5,000

Without Tow Package: n/a

Vehicle Make and Model: Chevy Equinox

Maximum Towing Capacity (lbs.)

With Tow Package: 1,500

Without Tow Package: n/a

Vehicle Make and Model: Ford Explorer

Maximum Towing Capacity (lbs.)

With Tow Package: 5,600

Without Tow Package: 3,000

In contrast to its application of the 4/AWD emissions factor, EPA did not apply its adjustment for towing-related emissions in a sales-weighted fashion. By instead applying the assumed maximum tow capability regardless of application of the towing package needed to support this, EPA is basing the curve on outsized performance characteristics. Just as EPA did not factor in whether there might be sports cars or high-output luxury models in determining the passenger car attribute curve, EPA should limit its assessment of light truck characteristics to only those features which are actually deployed. While there may be a subset of the market that requires towing performance, which thus differentiates the light trucks from cars, that additional emissions offset should be applied on a sales-weighted basis solely to the respective segment of the fleet that is utilizing the maximum tow package. For the remainder of the fleet, only the base tow capability should be considered. This will necessarily reduce the slope of the attribute curve as currently defined. [EPA-HQ-OAR-2022-0829-0759, pp. 59-60]

3. EPA should further reduce the footprint of the cut point for light trucks based on pickup certification. [EPA-HQ-OAR-2022-0829-0759, p. 60]

EPA has proposed phasing down the footprint of the cut point ("elbow") of the light truck attribute curve down to 70 sq. ft. The Agency should reduce it further, faster. [EPA-HQ-OAR-2022-0829-0759, p. 60]

EPA has identified the need for the reduction in the cut point but has mistakenly focused on the average footprint of full-size pickups as the rationale.162 While it is true that the average footprint has increased, and EPA is right to be concerned about incentives to upsize the pickup fleet, a large part of the reason for this increasing footprint is related to the growing share of four-door pickups. For example, the Ford F-150 has shifted from a mix of standard/extended/crew cab split of 17/50/33 in 2012 to 5/30/65 in 2022,163 which increases the average wheelbase significantly for a standard bed and, thus, the vehicle's footprint. However, it is not the average footprint that is the relevant factor in setting the location of the cut point, but the relationship between the certified emissions from a full-size pickup truck and its footprint. [EPA-HQ-OAR-2022-0829-0759, p. 60]

162 DRIA–at 1-14 - 1-15.

163 Data from Wards Intelligence, "U.S. Light Vehicles by Bod' Style, '22 Model Ye'r" and "'12 Model U.S. Domestic Car and Light Truck Output by Body Style."

SEE ORIGINAL COMMENT FOR Figure VII.A-2. 2020 light-duty pickup market share and emissions, by footprint164

164 MY 2020 data taken from EPA's CCEMS modeling supporting the 2023-2026 final rulemaking. https://www3.epa.gov/otaq/ld/EPA-CCEMS-PostProcessingTool-Project-FRM.zip.

(left) While one-quarter of pickup sales are so-called “mid-size” pickups, the full-size pickup market in 2020 was highly concentrated around a footprint of 66 to 70 square feet, with 68% of all pickup sales falling in that narrow range. (right) While some larger pickups exist, those vehicles have virtually the same emissions because they have similar capability as the smaller vehicle, even if they have a larger bed and/or cab. This is indicated by horizontal “lines” of dots (proportional to sales) for a given sub-model trim (e.g., the Stellantis pickups with 410 g/mi). [EPA-HQ-OAR-2022-0829-0759, p. 60]

The effect of increasing the footprint at which the cut point occurs is to relax the standard for full-size pickup trucks, particularly those with longer beds and larger cabs, which have larger footprints. This cut point does not reflect the level of technical feasibility or actual certification of those larger pickups, however. As can be seen in Figure VII.A-2, pickups of a given powertrain and towing package configuration are certified to virtually identical fuel economy and emissions standards, as indicated by the flat rows of dots in Figure VII.A-2 spanning a range of footprints. This suggests that these larger pickup trucks should have standards consistent with the smallest full-size footprint vehicles, as was identified when the curves were first designed. [EPA-HQ-OAR-2022-0829-0759, p. 61]

EPA should move swiftly to set the cut point of its standards at the average footprint of full-size pickups with a standard cab and bed because any vehicles with a larger footprint will be certified at virtually identical emissions levels, and it is precisely this flattening that the position of the cut point of the curve is meant to reflect. That footprint would correspond to 68.1 sq. ft. for MY 2022. [EPA-HQ-OAR-2022-0829-07591]

12. B. EPA should ensure that the final standards do not incentivize larger BEVs.

While we support EPA’s incorporation of projected BEV penetration into the slopes of the footprint curves for the model years covered by the Proposal, we remain concerned that the Proposal retains the incentive for automakers to manufacture larger BEVs, a trend that has the potential to erode the environmental benefits of EPA’s vehicle standards and that EPA anticipates will occur under the Proposed Standards. The final standards should incorporate a regulatory treatment of BEVs that discourages upsizing or selective manufacturing of larger BEVs. [EPA-HQ-OAR-2022-0829-0759, p. 61]

As discussed previously, we support EPA’s proposal to reflect projected BEV penetration in developing the slopes of the footprint curves. As EPA explains, the curves’ flatter slope is “by design and reflects our projection of the likelihood that a future fleet will be characterized by a greatly increased penetration of BEVs, even in a no-action scenario.” 88 Fed. Reg. at 29235. Inclusion of BEVs in establishing the curves has the effect of flattening their slope because BEVs have no tailpipe emissions and therefore factor into the curves at 0 g/mile. [EPA-HQ-OAR-2022-0829-0759, p. 61]

While it is appropriate to reflect projected rates of BEV penetration in setting the slope of the footprint curves, it does not follow that it is appropriate to distinguish BEVs based on their vehicle footprint for purposes of regulatory compliance, effectively “rewarding” larger footprint BEVs. “From a physics perspective, a positive footprint slope for [combustion] vehicles makes sense because as a vehicle’s size increases, its mass, road loads, and required power (and corresponding tailpipe CO_2 emissions) will increase accordingly.” 88 Fed. Reg. at 29235. The corollary, however, is that regulatory distinctions based on vehicle footprint lack a compelling basis for BEVs. As EPA notes, “a fleet of all BEVs would emit 0 g/mi, regardless of their respective footprints.” Id. “[F]ootprint does not have any relationship with tailpipe emissions from BEVs.” DRIA at 1-6. [EPA-HQ-OAR-2022-0829-0759, pp. 61-62]

Currently, manufacturers receive a considerable regulatory compliance benefit from producing larger-footprint BEVs: these BEVs increase the average footprint of the fleet and thus loosen the GHG emissions standard that the overall fleet will be required to meet. Because the GHG benefit of BEVs does not depend on their footprint and there is no practical need for crediting larger-footprint BEVs more robustly than smaller-footprint BEVs, the laxer standards applicable to fleets with larger-footprint BEVs come without any attendant climate benefit. At the same time, larger-footprint BEVs are likely to be heavier and less efficient, requiring more electricity to travel a given distance and typically requiring larger batteries and more of the materials that comprise those batteries, and carrying increased purchase costs. BEV footprint upsizing has adverse consumer, grid-related, and environmental consequences. [EPA-HQ-OAR-2022-0829-0759, p. 62]

Concerns about incentivizing a shift to larger BEVs are well-founded. According to EPA’s modeling, BEVs in MY 2032 are projected to increase in size relative to MY 2020. DRIA at 1-13–1-14, Fig. 1-12. The increase is 1.6 sq. feet for sedans, 1.9 square feet for CUVs/SUVs, and 3.3 square feet for pickups. DRIA at 1-13, Tbl. 1-2. Selective manufacturing of larger-footprint BEVs—which similarly raises the average footprint of the fleet—is already occurring. Automaker GM recently ceased production of its lone small-footprint BEV: the Chevy Bolt.165 GM’s remaining near-term BEV offerings are all larger vehicles: SUVs and pickup trucks.166 A number of other automakers are also selectively manufacturing exclusively larger-footprint BEVs, including Ford, which currently produces only an SUV (the Mustang Mach-E) and a pickup truck (the F-150 Lightning); Rivian, which produces only an SUV (the R1S) and pickup truck (the R1T); and Volvo, which produces only a cross-over (the C40) and three SUVs (the XC40, EX30, and EX90).167[EPA-HQ-OAR-2022-0829-0759, p. 62]

165 Khristopher J. Brooks, GM to stop making Chevrolet Bolt, its best-selling electric vehicle, CBS News (Apr. 26, 2023), https://www.cbsnews.com/news/chevy-bolt-end-production-gm-vehicle/.

EPA’s final regulations should include a regulatory mechanism that discourages the manufacture of larger BEVs. [EPA-HQ-OAR-2022-0829-0759, p. 62]

Organization: Ford Motor Company

Car vs. Truck Stringency

Ford appreciates EPA’s efforts to develop a data-driven, analytical basis for determining the appropriate relative stringency between the car and truck footprint curves. It is essential to full-line OEMs that the utility provided by trucks—particularly large pickup trucks—continue to be appropriately credited in the footprint-based standards. Any changes should made cautiously and gradually, with awareness of the broader context of the other sweeping changes that automakers are managing during the timeframe of this rule. [EPA-HQ-OAR-2022-0829-0605, pp. 5-6]

Ford believes the following modifications to the EPA's truck utility methodology are appropriate:

- Increase the 9 g CO2/mile per 1000 lbs of incremental towing to 11 g CO2/mile to account for increased road loads on highly capable towing vehicles (e.g., losses from larger brakes, axles, and engine parasitics). [EPA-HQ-OAR-2022-0829-0605, pp. 5-6]

- Increase the sales weighted towing delta from 7000 lbs to 8500 lbs to better capture the full range of towing capabilities for full size pickup trucks. [EPA-HQ-OAR-2022-0829-0605, pp. 5-6]

- Decrease the expected EV penetration rate from 50% to 35% for the harder-to-electrify full-size pickup truck market. [EPA-HQ-OAR-2022-0829-0605, pp. 5-6]

These refinements would result in an approximately 40 g CO2/mile difference between the Car and Truck curves by 2032MY utilizing the maximum footprint of 70 ft2, as shown in the graph below. Ford would like to continue to work with EPA to fully explain our rational and recommendations. [EPA-HQ-OAR-2022-0829-0605, pp. 5-6]

[See original comment for Graph 1: Vehicle Utility vs Truck Footprint Curves] [EPA-HQ-OAR-2022-0829-0605, pp. 5-6]

Organization: International Council on Clean Transportation (ICCT)

On footprint curves, ICCT commends EPA for its proposed standards becoming increasingly flat, and we see clear evidence that the car and truck footprint curves could be flattened even further, as discussed below. [EPA-HQ-OAR-2022-0829-0569, p. 5]

OBSERVATIONS ABOUT PROPOSED FOOTPRINT CURVES

ICCT supports EPA's proposed standards' stringency, as well as the shape of the footprint curves. Nevertheless, data suggests that the footprint curves can be adjusted both to increase stringency (within the limits of the proposal) as well as to slow or reverse the trend of upsizing and the shift from cars to trucks. [EPA-HQ-OAR-2022-0829-0569, pp. 56-58]

ICCT commends EPA for its proposed standards becoming increasingly flat. The proposal to flatten the curves over time and move the truck cutpoints inwards are a welcome shift that can help prevent upsizing to some extent. [EPA-HQ-OAR-2022-0829-0569, pp. 56-58]

ICCT also commends EPA for reducing the gap between the truck and the car curves, and for its transparency and request for comments on the development of the truck curve (Preamble III.B.2.ii; DRIA 1.1.3.2). By EPA's own acknowledgement, and supported by recent data, there is clear evidence that EPA could flatten both the car and the truck curves even further. This is discussed below. [EPA-HQ-OAR-2022-0829-0569, pp. 56-58]

EPA assumed in the OMEGA model inputs that the willingness-to-pay (WTP) of vehicle footprint is $200/sq ft, which is "on the low end of the range suggested in the literature (e. a. Greene 2018)" and recognizes "a higher WTP would create a stronger upsizing tendency, which would suggest an even flatter "size-neutral" slope". The Greene, (2018) paper cited by EPA refers to the summary in Whitefoot and Skerlos, (2012) that the average marginal WTP ranges from $340 to $2,000 for an additional square foot of vehicle size (i.e., the overall length of a vehicle multiplied by the width). Considering the potentially wide difference in the average consumer valuation of vehicle attributes in the literature, EPA could assume the mid-point, rather than the low end, of the average values of WTP from literature as the basis to determine the slope of the footprint-based standard curve. As a result, the slope of the passenger cars curve, which is also used as the baseline to develop the truck curve, would be flatter than the proposed standard curves. [EPA-HQ-OAR-2022-0829-0569, pp. 56-58]

EPA recognizes that the majority of light-duty vehicles serve to "move passengers and their nominal cargo" which implies light-duty vehicles "could be represented by a single curve" (Preamble 29234). ICCT supports the application of a single curve for all light-duty vehicles, due to the similar purpose and utility across all light vehicles. However, in the absence of a single curve for all light-duty vehicles, the proposed approach of deriving the truck curve from the car curve is generally sound. As discussed further below, ICCT recommends flattening the truck curve further by reducing the offset allocated to trucks. [EPA-HQ-OAR-2022-0829-0569, pp. 56-58]

To justify the truck curve offset, EPA states that it "identified a subset of light trucks…which are more appropriately controlled with a modified set of standards" (Preamble 29234). EPA identifies these vehicles as those "larger trucks which are designed for more towing and hauling capability [and] require design changes to allow for handling of these larger loads and this is reflected in increased engine capability, body-on-frame design, and greater structural mass" [emphasis added] (DRIA 1.1.3.2, page 1-8). EPA's analysis of fleet tailpipe CO2 emissions data from these vehicles establishes the "utility offset" which is built into the truck curve. (EPA also analyzed an AWD offset, but this offset is a significantly lower g/mi adjustment than the utility offset.) Importantly, EPA states: "many crossover vehicles and SUVs exhibit similar towing capability between their 2WD and AWD versions" (Preamble 29235). [EPA-HQ-OAR-2022-0829-0569, pp. 56-58]

Since many crossovers and SUVs classified as trucks differ from their car variants only due to the presence of AWD, these truck crossovers and SUVs benefit from the utility offset of the truck curve, without demonstrating any purported need for such a utility. This leads to targets that are comparatively easy to meet for these vehicles. EPA further states, "The purpose of maintaining a unique truck curve is centered around accounting for the utility of [full size pickups] in particular" (Preamble 29235). [EPA-HQ-OAR-2022-0829-0569, pp. 56-58]

In summary, the utility offset is calculated by and added to the truck curve to specifically account for the higher emissions of full-size pickups, or body-on-frame vehicles, as these vehicles are distinguished by "[use] for more work-like activity" (Preamble 29235). Because the utility offset is based on the vehicles most likely to be used for their higher utility, the offset ideally would be calculated based on the number of vehicles that meet those criteria. Bearing these criteria in mind, there is evidence that the utility offset could be adjusted lower. [EPA-HQ-OAR-2022-0829-0569, pp. 56-58]

Although the utility offset is based on pickups, since this offset is added to the truck curve, it applies to all vehicles classified as trucks. EPA projects that pickups will represent 24% of all trucks in MY2027-2032.146 Thus, only 24% of trucks meet the criteria EPA used to determine the utility offset. Furthermore, by MY2030, EPA projects the MY2030 pickup share to be 45% (EPA chooses MY2030 as a reference point, DRIA 1-12). The initial estimated utility offset of 63 g/mi (DRIA 1-11) could be reduced accordingly to account for the projected share of vehicles that actually have higher utility and non-zero tailpipe emissions: [EPA-HQ-OAR-2022-0829-0569, pp. 56-58]

Initial utility offset: 63 g/mi MY2030 pickup share: 24% MY2030 ICE pickup share: 55% ICE pickup share-adjusted utility offset: 8.3 g/mi [EPA-HQ-OAR-2022-0829-0569, pp. 56-58]

146 central analysis output file, 2023_03_14_22_42_30_central_3alts_20230314_Proposal_vehicles.csv

Alternatively, the utility offset could be recalculated according to the projected MY2030 sales share of body-on-frame vehicles, which is roughly one third. Of these, roughly half are ICE, leading to a body-on-frame-based utility offset of about 11 g/mi. [EPA-HQ-OAR-2022-0829-0569, pp. 56-58]

In addition to the characteristic of having greater structural mass (mainly due to body-on-frame construction), EPA stipulates that increased engine capability also supports the addition of the utility offset. However, as discussed previously (see Atkinson cycle and MHEV subsections), most pickups and large SUVs spend most driving time under low load. Contrary to EPA's assertion that these vehicles are used for more work-like activity (Preamble 29235), data suggests truck drivers rarely use the extra utility for which their light-duty trucks are built. One 2019 study found 75% of truck owners tow once or never each year, 35% haul once or never each year, and 70% go off-road once or less per year.147 In a 2023 report, 63% of F150 owners were found to tow rarely or never, 32% rarely or never hauled, over half frequently commuted in their trucks, and 87% frequently used their trucks for shopping/errands.148 That is, despite having more capable engines, data supports the conclusion that pickups rarely use this extra capability. Consequently, when outfitted with advanced engines, such vehicles are likely to spend more time than cars in highly efficient combustion modes, which are better suited for lower load driving. Pickups and SUVs also stand to benefit the most from advances in MHEV technologies. As current MY2023-2026 and proposed MY2027-2032 standards engender efficient pickups, the real-world utility impact will diminish, due to both greater efficiency and high share of low load driving. This conclusion further supports reducing the truck utility offset. [EPA-HQ-OAR-2022-0829-0569, pp. 56-58]

1. How Much Do Regulations for Fuel Economy and Emissions Incentivize the Production of Larger Vehicles?

In Section III.B.2.ii of the proposed standards, EPA "solicits comments on the proposed changes to the shape of the footprint curves, including the flattening of the car curve and our approach for deriving the truck curve from the car curve." Using estimated compliance costs estimated from a recent working paper, I quantify how much the existing footprint curves incentivize vehicle manufacturers to reclassify cars as light trucks and to increase vehicle footprint. The implication is that flattening the curves would reduce these incentives. [EPA-HQ-OAR-2022-0829-0635, pp. 4-6]

Since 2012, vehicle manufacturers have faced greenhouse gas (GHG) emissions requirements that depend on the mix of vehicles sold; a manufacturer that sells larger vehicles and light trucks rather than cars faces less stringent requirements for GHG emissions. This regulatory structure incentivizes manufacturers to shift their product offerings to avoid strict GHG requirements, which potentially increases emissions. Just how strong are those incentives? [EPA-HQ-OAR-2022-0829-0635, pp. 4-6]

1.1. Regulatory Background and Recent Vehicle Size and Class Trends

Safety and technology rationales have driven GHG emissions standards to depend on vehicle size and class (e.g., car or light truck). Prior to 2012, a single fuel economy standard of 27 miles per gallon applied to all cars, and about 20–25 miles per gallon applied to all trucks. Reducing a car's weight and size can both increase its fuel economy and reduce its GHG emissions—making a vehicle smaller and lighter could help a manufacturer meet both standards. [EPA-HQ-OAR-2022-0829-0635, pp. 4-6]

However, the US Department of Transportation's (DOT) concerns about the safety of smaller vehicles have led it to discourage manufacturers from reducing vehicle size by setting higher Corporate Average Fuel Economy (CAFE) requirements for smaller vehicles relative to larger ones. In turn, EPA harmonized its GHG standards with CAFE standards by setting weaker GHG emissions standards for larger vehicles like trucks, given that GHG emissions are inversely related to fuel economy. DOT and EPA have made the car/truck distinction for statutory and technological reasons, since vehicle attributes that are common to light trucks, such as all-wheel drive, increase a vehicle's emissions rate and reduce its fuel economy. [EPA-HQ-OAR-2022-0829-0635, pp. 4-6]

Since the adoption of size-based standards in 2012, new vehicles have been getting larger, and sales have shifted from cars to light trucks. Between 2011 and 2022, the average vehicle footprint (roughly, the area defined by the four wheels) increased by about 4 percent, and the share of cars in total passenger vehicle sales dropped from about 65 percent to 40 percent. In the GHG standards that EPA proposed in April this year, the agency notes that the increasing size and shift from cars to trucks has increased average emissions rates by about 10 percent. [Link: https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf] [EPA-HQ-OAR-2022-0829-0635, pp. 4-6]

1.2. Incentives to Increase Vehicle Size or Convert Cars to Light Trucks

What could have caused the size increase of vehicles and the shift to light trucks? The GHG regulations themselves could be a factor, since increasing a vehicle's size or converting a car to a light truck hypothetically would yield extra compliance credits, all else equal (a car can be reclassified as a light truck if it has all-wheel drive and satisfies a few other conditions). Consumer demand also could play a role, if consumers want big cars and light trucks and manufacturers respond to consumer preferences. Production costs also may affect vehicle size. For instance, lower production costs for larger vehicles may motivate manufacturers to make more large vehicles. [EPA-HQ-OAR-2022-0829-0635, pp. 4-6]

Disentangling these explanations is not easy since we'd have to predict what sizes and car/truck mix manufacturers would have offered if consumer demand were different or if emissions and fuel economy standards did not depend on vehicle footprint. But we can get a sense of the relative incentive of the existing standards by comparing them with incentives that instead are created by consumer demand. [EPA-HQ-OAR-2022-0829-0635, pp. 4-6]

From a regulatory standpoint, the value of making a vehicle larger or converting a car to a light truck depends on how many compliance credits are generated and the value of those credits. In recent research [Link: https://www.resources.org/common-resources/can-state-level-regulations-help-reduce-national-emissions-from-passenger-vehicles/], I estimated those credit values (other research [Link: https://www.journals.uchicago.edu/doi/abs/10.1093/reep/rex010] has used the few publicly observed trades to estimate those credit values). Table 1 shows how much a manufacturer would have profited by increasing a vehicle's size or converting a car to a light truck, based on the credit values and crediting rules from 2022. Note that these calculations hold all else equal, so the numbers don't account for the decrease in fuel economy that typically results from making a vehicle larger (and heavier) or converting a car to a light truck. [EPA-HQ-OAR-2022-0829-0635, pp. 4-6]

Table 1. Incentives to Increase Vehicle Size or Convert Cars to Light Trucks

	Increase vehicle size	Reclassify car as a light truck
Value of additional greenhouse gas credits	$2,679	$3,124
How much consumers would pay	$12,264	$8.942

Note: Figures are presented as 2022 dollars.

[EPA-HQ-OAR-2022-0829-0635, pp. 4-6]

Table 1 shows that increasing a vehicle's footprint from 45 to 55 square feet generates about $2,700 in additional credits per vehicle. For reference in terms of smaller vehicles, a Toyota Prius v has a footprint of 45 square feet, and the Mercedes S-Class (a large luxury car) has a footprint of 55 square feet. For light trucks, the Honda CRV (a small crossover) has a footprint of 45 square feet, and the Range Rover has a footprint of roughly 55 square feet. These examples are meant to contextualize the footprint numbers—remember that the $2,700 refers to hypothetically taking the Prius v or CRV and increasing its footprint from 45 to 55 square feet without changing the vehicle's fuel economy or performance. The table also shows that converting a car to a light truck, again without changing fuel economy or performance, yields about $3,100 per vehicle. [EPA-HQ-OAR-2022-0829-0635, pp. 4-6]

Consumers also incentivize manufacturers to offer larger vehicles and convert cars to light trucks. Consumers tend to prefer larger vehicles because of the additional cabin and cargo space. They also may prefer light trucks to cars (all else equal) because of some of the attributes that trucks tend to offer, such as all-wheel drive or extra towing capacity, or because of differences in style or perception. I've estimated consumer preferences for vehicle size and all-wheel drive, which can provide a sense of how much consumers have incentivized manufacturers to offer larger vehicles or convert cars to light trucks. Table 1 shows that consumers value a car or light truck that has 55 rather than 45 square feet to the tune of about $12,000, which is more than four times the value of the additional credits derived from selling a larger vehicle. Likewise, consumers are willing to pay about $8,900 extra for all-wheel drive, which captures some of the value of a light truck over a car, which is about three times larger than the value of the additional credits for reclassifying the vehicle. [EPA-HQ-OAR-2022-0829-0635, pp. 4-6]

Do these numbers represent a big or small incentive for a manufacturer to increase a vehicle's footprint or convert a car to a light truck? The calculations in Table 1 show that the standards for GHG emissions and fuel economy have provided a substantial incentive to increase vehicle size or convert cars to light trucks. The incentives from the regulations are smaller than the incentives of consumer demand, but several thousand dollars per vehicle could be sufficient to change how manufacturers approach vehicle size or classification. [EPA-HQ-OAR-2022-0829-0635, pp. 4-6]

1.3. Conclusions

When EPA finalizes the post-2026 standards, the agency could reduce the importance of vehicle footprint or the difference in credit value between cars and light trucks. Such changes would make it less likely that reclassifying cars or increasing vehicle size would undermine expected emissions gains of the post-2026 standards. The changes would reduce the incentives for increasing vehicle size or reclassifying vehicles, not just for gasoline-powered vehicles but also for plug-in electric models. Any changes in the final standards also could affect the demand for batteries and critical minerals indirectly, given that larger plug-in vehicles require larger batteries, which in turn increases vehicle weight and the need for critical minerals. [EPA-HQ-OAR-2022-0829-0635, pp. 4-6]

Organization: Lucid Group, Inc.

Industry commitments and investment in EVs along with both government and industry investments in the associated infrastructure demonstrate the momentum and capacity to accelerate the electrification transition. Lucid agrees with the agency and expects that the U.S. vehicle fleet in the future will be largely electric. Vehicle footprints on U.S. roadways are steadily getting larger.9 Whether attributable to consumer demand or in conjunction with other factors, EPA has noted that previously finalized footprint curves may have played a role in fostering this trend and states that a slope too flat would incentivize overall fleet downsizing, while a slope too steep would encourage upsizing as a compliance strategy. Lucid believes the reversal of this trend is highly dependent on the outcome of this rulemaking process and will require stringent tailpipe emission standards in addition to the mitigation of potential compliance avoidance strategies. [EPA-HQ-OAR-2022-0829-0664, pp. 3-5]

9 The 2022 EPA Automotive Trends Report, available at https://www.epa.gov/system/files/documents/2022-12/420r22029.pdf.

Organization: Kate Whitefoot

1. The proposed flatter footprint curves are advantageous to decreasing incentives to further increase vehicle size. Since MY2008, the light-duty GHG regulations have set different targets for vehicles depending on the vehicle's footprint (a measure of size computed as wheelbase track width). A peer-reviewed study by Whitefoot and Skerlos (Whitefoot and Skerlos, 2012) shows that these standards en- courage automakers to design larger vehicles as a path to compliance. Specifically, they encourage a combination of adjusting prices to shift demand to larger vehicles and making adjustments to vehicle footprint during redesign. As EPA's 2022 Automotive Trends Report shows, sales-weighted average size and weight of light-duty vehicles has indeed

increased since the footprint-based standards first went into effect. This increase in vehicle size has been seen across all body-styles from MY2008-MY2022, with the largest size increases in pickup trucks. Moreover, the share of larger vehicles in the market has grown dramatically, with a decrease in sedans, and increase in pickup trucks, and a large increase in truck SUVs. In the proposed regulation, EPA proposes flattening both the passenger car and light truck footprint curves to decrease this incentive to further increase the size of vehicles in response to the policy. [EPA-HQ-OAR-2022-0829-0703, pp. 2-3]

Recommendation: EPA move forward with flattening the footprint curves for both passenger cars and light trucks in the final rule to decrease the incentive to increase vehicle size. [EPA-HQ-OAR-2022-0829-0703, pp. 2-3]

2. Differences between the car and light truck footprint curves may still create incentives to further “upsize” the fleet. Differences in the passenger car and light truck footprint curves - both in terms of the offset between the curves and differences in slope - can create an incentive to produce more light trucks or reclassify what would have been a passenger car as a light truck as a compliance pathway, as pointed out in Whitefoot and Skerlos (2012) and National Academies of Sciences, Engineering, and Medicine (2021). In the proposed rule, EPA has decreased the difference between the car and truck curves and flattened the curves to reduce the numerical difference be- tween passenger car and light trucks. This is advantageous to reducing these incentives to shift the fleet further toward light trucks and reclassify cars as light trucks in response to the policy. However, since light trucks have less stringent GHG targets than passenger cars, even if they are of identical size, the proposed regulations may still create an incentive to reclassify cars as light trucks and/or further increase production of light trucks relative to cars due to the structure of the policy. [EPA-HQ-OAR-2022-0829-0703, pp. 2-3]

Recommendation: EPA should consider further flattening the footprint curve for light trucks or other changes to the structure of the regulation that would disincentivize reclassifying cars as light trucks and/or further increasing the production of light trucks relative to cars in response to the regulations. [EPA-HQ-OAR-2022-0829-0703, pp. 2-3]

3. Drawbacks of using footprint as a proxy for towing and hauling capability. EPA describes that the reasoning for the offset and steeper slope of the light truck footprint curve from that of the car curve is (in addition to AWD) because of the towing requirements of light trucks, which may make it more difficult for these vehicles to meet lower GHG rate targets. However, there is significant variation of towing and hauling ratings of different light trucks of the same size. And, consumers have a range of preferences for the towing and hauling rating of the light trucks they consider purchasing. By using vehicle footprint as a proxy for towing and hauling capabilities, the proposed regulation may create distorted incentives. [EPA-HQ-OAR-2022-0829-0703, pp. 2-3]

Recommendation: EPA should consider whether using towing and hauling capability directly as attributes in this or future rules rather than using footprint as a proxy for towing and hauling capabilities would eliminate incentives to further “up- size” the fleet or otherwise create unintended shifts in vehicle designs in response to the GHG regulations. [EPA-HQ-OAR-2022-0829-0703, pp. 2-3]

Organization: Mazda North American Operations

In addition, the standards immediately increase dramatically in stringency beginning in 27MY, with a resulting 36% BEV requirement. These standards are particularly accelerated for vehicles classified as light trucks, since the gap between passenger cars and light trucks is reduced. Mazda believes it is very important that the ramp-up and the light truck gap reduction should be slower in the early years of the program, as the industry, consumers, and suppliers adapt to this new reality. Mitsubishi participated in the develo–ment of - and –upports - the comments submitted by Auto Innovators. [EPA-HQ-OAR-2022-0829-0682, p. 2]

In addition, based on its considerable experience discussed previously with BEV and PHEV leadership, Mitsubishi provides the following recommendations to supplement the comments of Auto Innovators:

1. Closely align the multi-pollutant emissions standards with President Biden's 2030 goal by assuming no more than 40-50% PHEVs and FCEVs by 2030, even though our experience leads us to caution that this itself is very ambitious, and is predicated on the assumption that the necessary supportive policies will be effectively implemented. [EPA-HQ-OAR-2022-0829-0682, p. 2]

2. Consider the many benefits of PHEVs to consumers and the environment during the expected period of constrained battery critical minerals production capacity, and how PHEVs are the perfect stepping- stone to full BEV acceptance. [EPA-HQ-OAR-2022-0829-0682, p. 2]

3. Maintain the current PHEV Utility Factor (UF) and work with industry to identify opportunities to increase PHEV electric operation. This is the ideal stepping-stone technology to encourage long-term BEV acceptance and utilization. [EPA-HQ-OAR-2022-0829-0682, p. 2]

4. Keep the proposed approach to determine the passenger car curves, and consider adjusting the cutpoint and stringency levels of the light-duty trucks during the early years of the program. [EPA-HQ-OAR-2022-0829-0682, p. 2]

5. Maintain the existing GHG program flexibilities, such as Air Conditioning and Off-Cycle technologies credits (including the alternative method to apply off-cycle credits), and

allow previously approved technologies to continue receiving credits. [EPA-HQ-OAR-2022-0829-0682, p. 2]

6. Align the Tier-4 (criteria pollutants) with CARB's LEV-IV criteria test procedures and standards. [EPA-HQ-OAR-2022-0829-0682, p. 2]

7. Consider the impact that very aggressive GHG standards will have on vehicle affordability, and especially the detrimental impact to low-to-moderate income families. Regardless of the vehicles that regulation may require us to produce, it is critical that regulators always keep the accessibility of consumers in mind. [EPA-HQ-OAR-2022-0829-0682, p. 2]

The rationale for each one of these recommendations is further explained below. [EPA-HQ-OAR-2022-0829-0682, p. 2]

4. GHG Footprint Curves

Mitsubishi holds a unique position in the industry as the manufacturer with the smallest fleet-average vehicle footprint. As such, Mitsubishi also has the strictest GHG and CAFE standard among vehicle manufacturers. Despite having the lowest fleet GHG emissions of any mass-market vehicle manufacturer6, Mitsubishi has accrued GHG deficits for MY20 and MY21, while other manufacturers with higher GHG fleet emissions have accrued credits7. While we understand the math that delivers this result, we question whether this outcome is what the program set out to achieve. Mitsubishi supports EPA's reevaluation of the footprint curves, and the attempt to ensure fleetwide GHG reduction in a neutral manner. [EPA-HQ-OAR-2022-0829-0682, pp. 6-8]

6 Excludes BEV-only manufacturers

7 2022 EPA Automotive Trends Report

The following section includes suggestions for improving upon the proposed curves. [EPA-HQ-OAR-2022-0829-0682, 6-8]

12. A. Footprint Curve Slope

The footprint curves were developed to ensure all vehicles large and small are encouraged to improve efficiency. But the curves must also prevent unintended consequences resulting in total fleet GHG reductions not meeting the original intended goal. To that end, the footprint curves should not place larger vehicles at an advantage over smaller vehicles, thereby biassing the market toward larger, heavier vehicl–s which - even if fully ele–trified - are worse for the environment that smaller electric vehicles, primarily because of the amount of battery minerals they use, and the amount of energy needed to propel them. [EPA-HQ-OAR-2022-0829-0682, pp. 6-8]

In developing the proposed footprint passenger car curves, EPA utilized a "willingness-to-pay" methodology, which compares the willingness of a consumer to purchase a larger vehicle, against the additional cost and emissions of a larger vehicle. In addition to willingness-to-pay, EPA adjusts the curves based on projected BEV sales, which are set at a compliance-value of zero g/mi. The result is a relatively flat curve compared to previous light-duty GHG regulations. [EPA-HQ-OAR-2022-0829-0682, pp. 6-8]

Mitsubishi supports an approach for creating a "neutral" slope that balances vehicle size and emissions improvements, to ensure all vehicles are incentivized equally. Due to the limited comment period, Mitsubishi is not able to comment on whether EPA has achieved a neutral slope, but Mitsubishi believes EPA is taking the right approach to achieve this goal, and that the adjustments made in the proposed passenger car curves are directionally correct. Mitsubishi may provide EPA additional feedback after the defined comment period. [EPA-HQ-OAR-2022-0829-0682, pp. 6-8]

In developing the light truck footprint curves, EPA uses the passenger car curve as a baseline. EPA then adds two offsets in developing the light truck curves, 2WD vs AWD performance and towing/hauling capability. Finally, these offsets are reduced by the BEV share expected by passenger cars and light trucks for the given model year. [EPA-HQ-OAR-2022-0829-0682, pp. 6-8]

The light truck fleet will be affected the most by this approach by requiring a 21% reduction in GHG emissions between MY26 and MY27. To date, the light truck fleet between MY12 and MY21 has, at best, achieved a year-over-year GHG reduction of 4% (MY18)8. As it is proposed, the standard puts an unreasonable burden on the light truck fleet to achieve historic GHG reductions in a very limited timeframe. Based on considerable historical performance, a 21% improvement in one model year is simply not reasonable or achievable, and EPA should reconsider the stringency increase of light trucks for MY27. [EPA-HQ-OAR-2022-0829-0682, pp. 6-8]

8 Ibid

With the current proposed light duty footprint curve, a typical BEV light-duty pickup truck could receive a credit of 46 Mg while a typical small CUV would receive a credit of 32 Mg9. The proposed footprint curves would still result in a considerable incentive to electrify the largest of vehicles, which typically use more battery resources than a smaller electrified vehicle (see Figure 2). One possible approach to mitigate this discrepancy could be to adjust the lower cutpoint on the footprint curve. EPA has proposed increasing the cutpoint to 45 sq.ft. to provide an additional incentive for smaller Icles which are both economical and fuel efficient. However, EPA also decided to phase in the cutpoint by increasing the cutpoint by 1 sq.ft. each year, until achieving a cutpoint of 45 sq.ft. by MY30. To provide additional incentive for these smaller vehicles, EPA should increase the cut point to 45 sq.ft for all vehicles in MY27, rather than phasing it from MY27 to MY30. [EPA-HQ-OAR-2022-0829-0682, pp. 6-8]

9 For MY27: a 69 sq.ft. light truck would earn a credit of 202.2 g/mi/vehicle (~46 Mg/vehicle) and a 45 sq.ft. light truck would earn 140.8 g/mi/vehicle (~32 Mg/vehicle)

[See original for graph titled " Figure 2. BEV Battery System Weight versus Vehicle Footprint"]10 [EPA-HQ-OAR-2022-0829-0682, pp. 6-8]

10 Survey of BEV Battery System Weight in A2MAC1 Database

Mitsubishi asks EPA to reconsider the approach used in developing the light truck footprint curve and take into further consideration the over-incentive to upsizing light truck BEVs. In addition, EPA should consider incentivizing smaller light truck BEVs, as we believe this would provide a zero emissions benef [EPA-HQ-OAR-2022-0829-0682, pp. 6-8]

Organization: National Automobile Dealers Association (NADA)

The proposal would maintain the footprint structure of the existing light-duty standards, but update the footprint standard curves "to flatten the slope of each curve and to narrow the numerical stringency difference between the car and truck curves" based on the vehicle technologies EPA projects automakers will use to comply.9 [EPA-HQ-OAR-2022-0829-0656, p. 3]

9 88 Fed. Reg. at 29196, 29234.

D. EPA Should Retain the Existing Compliance Flexibilities, Multipliers, Credits, and Footprint- Based Structure of its Standards.

NADA strongly supports EPA's stated intention to retain the footprint-based structure of its light-duty standards.70 The vehicle footprint attribute-based framework has worked well to encourage continuous improvements across all vehicle types, regardless of product mix, to reduce incentives to downsize or down-weight vehicles (thereby helping to maximize occupant safety), to spread compliance costs broadly across all regulated OEMs, and to enable fleet mixes that allow OEMs to capitalize on the critical consumer choice factors that drive successful fuel economy and emissions improvements. [EPA-HQ-OAR-2022-0829-0656, p. 16]

70 88 Fed. Reg. at 29196, 29234.

NADA strongly opposes any flattening of footprint curves to correspond with projected increases in new EV market penetration.71 Fleet-wide standards should be technology neutral and set at levels that are achievable without EVs so as not to penalize those OEMs (and their dealers) that choose not to aggressively develop, produce, and push EVs to market.72 [EPA-HQ-OAR-2022-0829-0656, p. 16]

71 88 Fed. Reg. at 29234-38.

72 NADA shares the concerns raised by AAI in it comments regarding proposed footprint curve changes.

Organization: Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC)

NESCAUM and the OTC also generally support EPA's proposal to revise the footprint standards for LDVs and work factor standards for MDVs. EPA should adopt footprint curves that incentivize downsizing of all LDV and MDV types and classes to protect pedestrians and cyclists. [EPA-HQ-OAR-2022-0829-0584, p. 9]

Organization: POET, LLC

On Location also finds other technical issues that EPA should further evaluate to support a robust vehicle GHG regulatory program. For instance, OnLocation finds that if BEV "penetration is different than EPA projections, then EPA's proposed compliance curves are likely to be inconsistent with the analysis used in their development and penalize larger footprint vehicles."124 OnLocation also finds that additional review by EPA of its battery learning curve (i.e., the extent to which EPA projects battery costs will decline) is warranted, for reasons including that EPA could be substantially understating the total cost of the rule.125 [EPA-HQ-OAR-2022-0829-0609, p. 27]

124 Id.

125 Id at 8.

Shape of footprint curve depends on BEV penetration rate

As noted in the Proposed Rule, “The slope that corresponded with a neutral response for ICE vehicles only (overall, no change in the average footprint of ICE vehicles) was 0.8 g/mi/square foot. This slope was then scaled down accordingly-for example, based on a nominal BEV sales penetration of around 50%, this 0.8 slope would be scaled down to 0.4 (based on the remaining 50% of ICE vehicles).”6 [EPA-HQ-OAR-2022-0829-0609, pp. 49-50]

6 Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles Draft Regulatory Impact Analysis, 1-7.

The targets defined in the Proposed Rule are a function of vehicle footprint. That is, the compliance target depends upon the footprint of the vehicle. Figure 15 shows the EPA’s proposed footprint for cars. If the penetration of BEV is much below the proposal, the footprint target function is too flat relative to the actual market share of non-BEV vehicles, penalizing ICE vehicles. [EPA-HQ-OAR-2022-0829-0609, pp. 49-50]

Organization: Stellantis

Proposed Standards Tougher on the Most Popular Vehicles

As discussed above, EPA’s rule sets aggressive targets for vehicle GHG emissions reductions. EPA’s proposed rule targets fleet performance improvement exceeding a 50% reduction in CO2 emissions. [EPA-HQ-OAR-2022-0829-0678, pp. 9-11]

Analysis shown in EPA’s NPRM showcases industry fleet targets and impacts representing an aggregate of vehicle types. In reality, an industry or OEM fleet target is actually comprised of volume weighted targets of different vehicles divided into two separate car and truck fleets. [EPA-HQ-OAR-2022-0829-0678, pp. 9-11]

EPA proposes significantly more stringent standards for trucks and SUVs – the segments most demanded by customers – than it does for sedans/small cars. As seen in Figure 8 below, pickup stringency exceeds sedan stringency by 14% in 2027MY, and SUV stringency exceeds sedan stringency by 10%. In fact, sedan stringency is relaxed in the first year of the rule (by 1%).[EPA-HQ-OAR-2022-0829-0678, pp. 9-11]

[EPA-HQ-OAR-2022-0829-0678, pp. 9-11]

The disproportionate impact of EPA's proposal on different vehicle types can been seen in the footprint curves in the proposed rule. As seen in Figure 9 below, EPA is applying much more stringent targets to trucks and large sedans with much less stringent standards for small cars. [EPA-HQ-OAR-2022-0829-0678, pp. 9-11]

SEE ORIGINAL COMMENT FOR CHART Car Fleet Stringency Curves vs Light Duty Truck Feet Stringency Curves Figure 9 - Large cars and all trucks face more difficult standards [EPA-HQ-OAR-2022-0829-0678, pp. 9-11]

As shown in Figure 10 below, taken from the 2022 EPA Trends Report, pickups and truck SUVs are by far the most popular vehicles demanded by customers, making up over 60% of industry vehicle sales. EPA's proposed rule disproportionately punishes these vehicles while giving small sedans relief in initial years of the rule. This results in certain vehicles taking on more of the GHG reduction burden than others. [EPA-HQ-OAR-2022-0829-0678, pp. 9-11]

Also shown in Figure 10, OEM mix of vehicle types can vary widely, and these differences drive significant stringency differences when calculating an OEM's overall fleet average target. As discussed above, the NPRM proposes drastically different stringencies for cars vs trucks. This stringency imbalance will compound through an OEM's higher or lower mix of certain vehicle types producing disproportionately easier standards for "car centric" OEMs and harder standards for truck and SUV biased OEMs. These disproportionate stringencies may result in an electrification pace that is infeasible for some vehicle types and less challenging for others. [EPA-HQ-OAR-2022-0829-0678, pp. 9-11]

SEE ORIGINAL COMMENT FOR Table 3.4 Model Year 2021 Estimated Real-World Fuel Economy and CO2 by Manufacturer and Vehicle Type and Figure 10 – EPA is proposing more stringent standards on the trucks and SUVs – the most popular vehicles in the market today [EPA-HQ-OAR-2022-0829-0678, pp. 9-11]

EPA should apply stringency evenly across vehicle types driving the entire industry at the same rate of improvement regardless of vehicle types or product mix towards the ultimate goal of further GHG reductions by 2032MY. [EPA-HQ-OAR-2022-0829-0678, pp. 9-11]

Organization: Tesla, Inc.

Tesla welcomes the EPA's proposal to reduce GHG emission standards across the light- and medium- fleet and to adjust the footprint-based standards curves to reduce incentives to upsize vehicles.115 [EPA-HQ-OAR-2022-0829-0792, p. 16]

115 88 Fed. Reg. at 29196.

Organization: Zero Emission Transportation Association (ZETA)

ZETA supports the proposed revisions to the car and light truck footprint curves, including the flattening of each slope over the timeframe covered by the standards, and we encourage EPA to finalize the changes as proposed. As EVs continue to grow in market share, EPA emission standards should reflect the decreasing disparity in emissions from different sized vehicles within each vehicle segment. In other words, there are no tailpipe emissions from EVs and as they become the predominant vehicle technology in automakers' fleets, EPA standards should be designed to continue incentivizing zero-emission technologies rather than to encourage production of larger, higher-emitting ICEVs. To that same end, we support the proposed revisions to the footprint cutpoints as well and encourage EPA to finalize them as proposed. [EPA-HQ-OAR-2022-0829-0638, p. 27]

EPA Summary and Response

In the NPRM, EPA requested comment on its methodology for establishing the slopes for the car and truck curves. EPA received comments from several stakeholders. We summarize and address a majority of them in our discussion of the derivation of car and truck slopes in Section III.C.2.ii of the preamble.

Other unique aspects of stakeholder comments are provided here:

In its comments, API argues that EPA did not have any basis or explain how the numeric values of the curves were derived. API stated "nowhere does EPA explain how the numeric values of the curves (i.e., the actual GHG emissions rate that would be applied to each vehicle upon application of the curve) were derived and how those particular values are justified." EPA disagrees. As the commenter correctly notes, compliance with the GHG program is based on fleet average emissions values and includes flexibilities for banking and trading credits. As such, there is no requirement or expectation that any single vehicle will meet its own GHG target. This is a well-established approach based on previous light- and medium-duty GHG standards (which EPA did not reopen) and is an important feature of the GHG program, since it gives manufacturers the flexibility to apply technologies in a way that best meets individual vehicle product characteristics with their respective business strategies. In selecting the numerical level of the GHG targets, EPA considered ranges of values both higher and lower than the final standards and the costs, lead time and emission reductions associated with various levels of stringency, as well as other factors. These ranges were presented as Alternatives in the NPRM, and the higher and lower values were excluded considering the balance of factors such as feasibility and lead time, cost, and safety as described in preamble Section V of the NPRM preamble. Upon consideration of public comments and our updated analysis based on the best available information in the public record, EPA refined the range of considered values further for this final rule with curves and numerical targets that are higher and lower than the final standards. Furthermore, in addition to the level of the final standards, EPA has described the technical bases upon which the numerical values for curve slopes and cut points were determined (as described in Sections III.C.2.ii and iii of the final rule preamble). Throughout the process of evaluating various levels of stringency and the associated emissions reductions EPA also assessed each stringency level in consideration of manufacturing costs and lead time. EPA's selection of the final standards was neither arbitrary nor capricious but firmly guided by EPA's CAA authority to reduce vehicle emissions, and is fully described in Sections III, IV and V of the preamble to this final rule and the accompanying RIA.

The Alliance commented that EPA had deviated in its traditional methodology for establishing footprint curves. The Alliance noted that EPA had historically assessed the performance of the existing fleet and used the current fleet as a basis for year over year improvements. EPA disagrees with the Alliance's comments. Although on the surface the methodology for establishing the curves may look different as compared to previous rulemakings the fundamental objectives and metrics remain the same. The agency considered various levels of stringency and the associated emissions reductions with respect to cost of compliance, energy, lead-time and safety as well as manufacturing constraints for emerging technology and materials. The relative increases in stringency of past rulemakings were largely tempered by incremental improvements in advanced gasoline technology and low to moderate penetrations of electrification. However, given significant amounts of electrification which support a manufacturers compliance at 0 g/mile, a methodology which focuses on incremental improvements in ICE technology is no longer appropriate.

In its comments, the Alliance "disagrees with EPA's assessment that the footprint-based standards have resulted in a general increase in vehicle footprint as a means to reduce compliance burden." In contrast, EPA received comments from other stakeholders which supported EPA's approach to establishing the footprint curves. In its comments, RFF estimated that increasing a vehicle's footprint from 45 to 55 square feet generates about $2,700 in additional credits per vehicle. Dr. Whitefoot referenced a peer-reviewed study showing that the footprint standards have encouraged automakers to design larger vehicles as a path to compliance.[363] EPA disagrees with the Alliance's position. While EPA acknowledges that there are multiple other factors (target market/consumer preference, profit potential, etc) that might incentivize a manufacturer to redesign a vehicle with a larger footprint than its predecessor, there is clear evidence that the average vehicle footprint – for each of the five vehicle classes presented in the EPA Trends report – has increased since the outset of the footprint-based standards.[364]

Later, the Alliance commented that EPA's "assumption of rapid EV market share gains across all vehicle sizes effectively forecloses opportunities for plug-in hybrid electric vehicles that have some zero-emission operation, but also include ICE operation that would be better suited to a target curve with some slope." EPA disagrees: there are certainly opportunities for PHEVs to contribute towards compliance, as they will achieve an appropriate percentage of zero-tailpipe GHG according to their respective utility factor. In fact, EPA demonstrates through a sensitivity case that the standards could be met largely through the use of PHEVs, under a scenario where we held the level of BEVs to those available in the current market; see preamble Section III.F.4.

The Alliance and Stellantis noted that under the proposed standards there was an effective large increase in truck stringency for the first year of the program due to the change in the slopes and relative offset between the car and truck curves. As we discuss in Section I.C of the preamble and more fully in RTC Section 3.3, we have addressed this concern raised by the Alliance and other stakeholders in our selection of the final standards, which provide adequate lead time and a slower pace of the standards in the early years of the program.

The following comments address EPA's approach to using towing in the utility offset in the development of the truck curve:

In its comments, Consumer Reports was supportive of the reduction in both the car/truck offset and the overall slope; it expressed "questions about the use of towing as a means to define the slope of the truck curve," while pointing to a survey that shows most Americans never tow. Instead, CR suggested using combined passenger and cargo volume as an alternative attribute to towing for purposes of establishing the truck slope. While EPA recognizes there might be other

[363] Whitefoot and Skerlos (2012). Design incentives to increase vehicle size created from the us footprint-based fuel economy standards. Energy Policy, 41:402–411
[364] Environmental Protection Agency, "The 2023 EPA Automotive Trends Report: Greenhouse Gas Emissions, Fuel Economy, and Technology since 1975," EPA-420-R-23-033, December 2023.

attributes that could indicate an appropriate slope of the truck curve, we believe that towing is the most appropriate; further unlike other attributes where consistent data across vehicles is lacking, towing data is available for each vehicle model, and were able to successfully correlate towing with increased tailpipe CO2 (via GCWR rating and required engine torque) as we describe in RIA Chapter 1.1.3.2.

Dr. Whitefoot outlined the drawbacks of using footprint as a proxy for towing and hauling capability and highlighted the variation of towing and hauling of different trucks of the same size. She recommended that EPA might consider whether using towing and hauling capability directly as attributes in this or future rules, rather than using footprint as a proxy for towing and hauling capabilities, would eliminate incentives to further "up-size" the fleet or otherwise create unintended shifts in vehicle designs in response to the GHG regulations. EPA thanks the commenter for this suggestion. However, as towing and hauling ratings may vary by model and trim level, these ratings are not as easily verified and may present an opportunity for towing capability to be added to a vehicle as means of complying with less stringent standards if they are directly used as attributes that determine a vehicle's CO2 target. This may have an unintended consequence of added weight and reduced aerodynamics and increased vehicle emissions.

The following comments address the level of the utility offset in the development of the truck curve:

In its critique of the utility offset for the truck curve, the Alliance claims that EPA "fails to consider potential differences in overall EV uptake and type of EV uptake in the light-duty truck fleet." We are interpreting this commenter's remark as asserting that EVs are more suitable for some market segments and may be preferred in some market segments more than others. While the OMEGA model does not restrict EVs from any particular vehicle segment within the light-duty fleet because EPA has concluded that the technology is feasible across the entire light duty fleet, EPA does recognize that there may be varying consumer preferences for EVs, for example, between a sedan buyer and a pickup truck buyer. These consumer differences are characterized in the consumer module of OMEGA, described in RIA Chapters 8.1 through 8.3, and also discussed further in RTC Section 13.2. EPA anticipates that vehicle manufacturers will continue to balance their customer product preferences and compliance plans, just as they have historically done.

In its comments, Ford – while supportive of the general methodology used to derive the truck curve – suggested modifications to EPA's assumptions used to calculate the truck slope, including increasing the towing-based CO2 offset (from 9 g/mile per 1000 lbs towing to 11 g/mile to account for increased road loads on highly capable towing vehicles), an increase in the towing delta from least to most capable truck offset, and a reduction in assumed PEV penetrations (from 50% down to 35%) of full-size pickups. Taken together, all of these changes to inputs would result in an increase of 40 g/mi to the maximum utility offset. While EPA appreciates the specific technical recommendations, we have investigated each one and believe there is insufficient data on which to base changes in these factors of our analysis (and note that Ford did not provide data upon which to support their technical recommendations), especially upon consideration of comments from other stakeholders as discussed below.

In contrast, several other commenters (e.g., ACEEE, CR) argued that EPA overestimated the utility offset, because we did not scale down the offset according to real-world usage data indicating minimal levels of towing and hauling. While aware of this usage disparity, EPA disagrees with this suggestion. Regardless of the amount of time a truck is used to tow or haul in the real world, the 2-cycle emissions of a vehicle designed for greater towing and hauling will consistently reflect an increase in tailpipe emissions commensurate with a more capable powertrain, a heavier frame, and higher road loads (even though it is tested unloaded per the regulations). In essence, the design changes necessary to enable the more capable vehicle will continuously impact vehicle emissions independent of the real-time towing/hauling activity, and thus EPA believes it is appropriate to reflect such utility in the relative CO2 targets for light trucks.

ICCT argued that EPA should not base the full offset on only 24% of the light truck fleet that is projected to be pickups in MY 2027-2032. Instead, ICCT believes the offset should be scaled down accordingly. EPA disagrees, as the applied amount of g/mi offset increases linearly with footprint, and the majority of pickup trucks reside at the maximum footprint near 70 square feet. Because of the linearly increasing nature of the offset from smallest to largest footprint, the smaller footprint trucks naturally scale down as they are also reflective of lower utility. The sales-weighted average footprint of all light trucks was approximately 53 square feet in MY 2022 – so in terms of its overall stringency effect for light trucks under this approach, the sales-weighted utility-based offset would only average about 1/3 of the maximum offset, or about 10.5 g/mile over the fleet. This is almost the same as the magnitude of the offset that ICCT suggested (11 g/mile) in their alternative scaling using percentage of body-on-frame trucks as a basis for the offset.

On the other hand, Environmental and Public Health Organizations also commented that EPA based its utility offset calculation assuming the maximum towing capacity for each model, which does not apply to each individual vehicle within towing models. It argued that the maximum towing capacity is only relevant to those models equipped with additional options (towing packages, etc). EPA agrees with this comment, although we do not have sales data to identify exact tow ratings (or a distribution of tow ratings) for all vehicles sold. We recognize that our assessment of average utility offset might be conservative for this reason.

In its comments, CAP stated “EPA should further reduce the difference between the car and truck curves and scale the car curve such that it does not create an incentive to upsize ICE vehicles. ” EPA thanks CAP for its comment recommending that the offset be further decreased; however, CAP did not provide any supporting basis or data for EPA to review in this context. Regarding the car curve: in RIA Chapter 1.1.3.1, EPA explains the methodology used to determine a “neutral-slope” car curve. Supported by our modeling analysis, it is EPA’s assessment that the derivation of the neutral slope strikes a balance in neither incentivizing increase or decreases in vehicle footprint. Overall, the fleet average footprint is projected to remain relatively unchanged under the final footprint curves.

As we discussed in Section III.C.2.ii of the preamble, upon consideration of all the above comments in support of both larger and smaller offsets, we believe that the proposed level of offsets applied to the truck curve are appropriate and are finalizing the offsets between the car and truck footprint curves as proposed.

Environmental and Public Health Organizations and CAP expressed a desire for EPA to avoid incentivizing large ZEVs. Furthermore, CAP recommended that EPA should remove ZEVs from the footprint curve and credit ZEVs at the midpoint of the car and truck curves. As we describe in Section III.C.7 of the preamble, EPA is treating all light duty vehicles similarly. Thus, we are setting the emissions targets for BEVs based on their footprints and including only emissions measured directly from the vehicle in the vehicle GHG program for MYs 2027 and later, consistent with the treatment of all other vehicles. We have taken into consideration the goal raised by these commenters to avoid incentivizing larger BEVs, and we believe our adjustments to the footprint curves are a more appropriate means of addressing this concern, For further discussion on comments related to the treatment of BEV emissions in this rulemaking refer to Section 3.1.5 of this RTC.

NESCAUM / OTC recommended curves that incentivize downsizing of all types to protect pedestrians/cyclists. EPA's aim in establishing the footprint curves is to neither incentivize upsizing or downsizing of the fleet. We further consider issues of vehicle safety in RTC section 22.

DOEE and ICCT recommended that EPA adopt a single curve applicable to all vehicles, both cars and trucks. EPA stated in the proposal that we did not reopen the issue of separate standards (footprint curves) for cars and trucks. While we are maintaining the two curve standards, as we discuss in Section III.C.2. of the preamble and Chapter 1.1.3 of the RIA, we are establishing car and truck curves more appropriate for their respective fleets while accounting for differences in utility within the footprint-based standards. With these changes, EPA believes the program mitigates any incentives manufacturers might have had in the prior program to shift regulatory classes or upsize vehicles as a means of compliance.

ICCT commented that EPA used too low of a willingness to pay (WTP) valuation in its OMEGA inputs, and suggested that EPA use a higher value, for example, the midpoint of the range they cited which would be $1170. EPA thanks commenter for the suggestion, but we consider our WTP to be appropriate at this time.

In its comments, NADA "strongly opposes any flattening of footprint curves to correspond with projected increases in new EV market penetration." Similarly, in its comments, POET stated "If the penetration of BEV is much below the proposal, the footprint target function is too flat relative to the actual market share of non-BEV vehicles, penalizing ICE vehicles." EPA disagrees with both commenters claims. As in past GHG rulemakings, these standards are performance based, fleet-averaging, and technology-neutral. When the curves were first established, almost every vehicle was a conventional ICE vehicle and steeper slopes were more appropriate for that type of powertrain as those vehicles emitted more GHG on a g/mile basis and emissions rates were more sensitive to increases in footprint. However, with cleaner vehicle technologies, regardless of the powertrain (with BEVs as the extreme case of 0 g/mi tailpipe), vehicle emissions are less sensitive to increases in footprint, and the slope will appropriately become flatter as a byproduct of a more stringent fleet average. In short, the stringency defines the slope rather than an example BEV penetration which might be achieved to comply with that stringency. There should be no difference in the curve slope amongst complying fleets of different BEV penetrations and technology mixes which achieve the same fleet stringency.

3.2.2 - MDV work factor curves; work factor definition

Comments by Organizations

Organization: Alliance for Automotive Innovation (Alliance)

B. Major Concerns with the Proposed Medium-Duty GHG

Standards [EPA-HQ-OAR-2022-0829-0701, pp. 192-193]

1. Too Stringent of a GHG Standard

EPA has set too difficult of a GHG target for medium-duty vehicles. The proposal, shown in Figure 69 below, requires a 37% GHG reduction from 2028MY to 2032MY, with an additional 6.1% burden on 2027MY gas engines with a retroactive change to the previously published GHG standards to achieve fuel neutral standards. The agency relies on flawed modeling that results in overly aggressive EV penetration estimates to develop the work factor standards. The overall stringency is harder still with the proposed early removal of EV multipliers, capping GCWR contribution to work factor, and adjustments to the Medium-Duty Passenger Vehicle Definition. [EPA-HQ-OAR-2022-0829-0701, pp. 192-193]

[See original attachment for Figure 69: EPA Proposed Medium-Duty GHG Standards (2027-32MY)] [EPA-HQ-OAR-2022-0829-0701, pp. 192-193]

2. Assumes overly aggressive EV penetration (98% EV cargo vans)

EPA, through modeling, has forecast an unreasonably high EV penetration. This is particularly true for Medium-Duty cargo vans. For example, Figure 70 below shows the results of EPA's Omega modeling for Industry compared to CARB's HD ZEV rule. While we agree that last mile delivery is a great opportunity for electrification, it is preposterous to believe that nationwide electrification of cargo vans will outstrip CARB requirements by 20% in 2027, almost 50% in 2030 and over 60% in 2032. Similarly, it is unrealistic and infeasible for new cargo vans sales to reach 98% EV in 2032 (starting from essentially 0% today in EPA's model). [EPA-HQ-OAR-2022-0829-0701, pp. 192-193]

[See original attachment for Figure 70: Comparison of electrification -EPA OMEGA Forecast vs CARB HD ZEV rule] [EPA-HQ-OAR-2022-0829-0701, pp. 192-193]

Light-duty electrification is already well under way and has been progressing for about 20 years. Plus, the Administration set a stretch goal of 40-50% electrification by 2030. It does not make sense to estimate 92% electrification of this MDV segment in 2030MY when it is only just starting to introduce EVs in the formative years of the rule. There is no empirical support for a forecast of such rapid market adoption. Further, public charging infrastructure will not generally be practical to delivery companies. This means a massive installation of charging infrastructure on private property will be required within a few years. It has not, however, begun in a meaningful way. [EPA-HQ-OAR-2022-0829-0701, pp. 192-193]

For EPA's forecast to be true, it would have to apply to not just the well-known last mile delivery companies, but also to many small businesses such as HVAC, plumbing, and flower delivery. It is very unlikely that such small businesses will be near EPA's assumed EV penetration rate for cargo vans. Based on the above, at most, EPA should model industry as just meeting CARB's requirements each year, with no more than one half of the estimated electrification in states that do not adopt CARB's rule. [EPA-HQ-OAR-2022-0829-0701, pp. 192-193]

EPA attempts to justify reopening of the published HD Phase 2 final rule due to its anticipated levels of electrification of medium duty vehicles in 2027MY, as shown in Figure 71, below. [EPA-HQ-OAR-2022-0829-0701, pp. 192-193]

[See original attachment for Figure 71: EPA Table 13-132, Projected BEV Penetrations, Proposed Standards – MDVs]298 [EPA-HQ-OAR-2022-0829-0701, pp. 192-193]

298 Draft Regulatory Impact Analysis, p. 13-53.

3. Weight Impacts of Proposal

Manufacturers recommend that EPA not limit GCWR beginning in MY 2030 in the Work Factor equation. The EPA proposed action interacts with MDPV definition, and creates more stringent standards for high GVWR, high GCWR vehicles when compared to lower GVWR, high GCWR counterparts. If EPA would like to limit GHG targets for high work factor vehicles, manufacturers recommend that EPA do that directly, like how EPA limits GHG targets for high footprint vehicles in light-duty. [EPA-HQ-OAR-2022-0829-0701, p. 194]

Manufacturers recommend that EPA consider the extent to which pickups may "weight out" to Class 4, if equipped with battery electric vehicle technology, while retaining the capability of Class 3 internal combustion engine vehicles common in the market today. In other words, to maintain these vehicles' work functionality, a larger (heavier) battery will be needed, resulting in possibly increasing vehicle weight to exceed the Class 3 category. To the extent that adopting ZEV technology would shift vehicles to different regulatory (weight) classes, EPA should take this into account when setting standards by either offering manufacturers flexibilities on regulatory groupings or by setting stringency that reflects the vehicles remaining in the regulatory set, after manufacturers incorporate ZEV technology. This concern is also discussed below under the MDPV definition section. [EPA-HQ-OAR-2022-0829-0701, p. 194]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Medium-duty pickups need to electrify faster

The proposed standards for medium-duty vehicles (MDVs) are premised on 46% BEV adoption by MY 2032 (FR 29331), well below the 67% BEV penetration anticipated for LDVs. EPA expects MDV electrification to be driven by vans, 98% of which would be electric by MY 2032. Pickups, which account for almost two-thirds of MDV sales (DRIA Table 3-1), would reach only 19% electrification. EPA should adjust penetration estimates for these large pickups. [EPA-HQ-OAR-2022-0829-0642, pp. 8-9]

It is not clear from the proposal or DRIA how EPA arrived at such low medium-duty pickup electrification projections. These projections stand in sharp contrast with those for light-duty pickup electrification, which would reach 68% in 2032 (FR 29329 Table 80). Not long ago, full-size light-duty pickups were viewed as unlikely candidates for electrification. That concern was not borne out, as evidenced by several recent popular releases. EPA projects an average footprint of 69.1 square feet for BEV pickups in MY 2032 (DRIA 1-14), placing the average BEV pickup well into the full-size pickup range. [EPA-HQ-OAR-2022-0829-0642, pp. 8-9]

Medium-duty BEV pickups are not yet on the market, and skepticism regarding their imminent arrival is common, based largely on high towing requirements common for these trucks. Yet at this juncture, it is reasonable to anticipate that their electrification potential would approach that of full-size light-duty pickups. EVs excel at providing the torque needed for towing, so the challenge for electric medium-duty pickups is not capability to tow but rather towing range, i.e., battery capacity. Even vehicles requiring high towing capacity may not need to tow their loads for extended distances; many medium-duty pickups are engaged in mining, construction, and utility work, where towing needs may be for work on site, rather than for accessing the site. EPA should segment medium-duty pickups by application and by towing and range requirements and assess their electrification potential accordingly. [EPA-HQ-OAR-2022-0829-0642, pp. 8-9]

California's Advanced Clean Trucks program requires 40% of Class 2b-3 pickups to be ZEVs in 2032. After considering the various applications of these trucks in California, over 70% of which were for personal use, and following developments in the electric truck market, CARB decided to accelerate requirements for Class 2b-3 pickups to start in MY 2024 instead of waiting until 2027 as initially proposed.20 California's Advanced Clean Fleet program also will require about 40% of pickups to be ZEVs by 2032 under the EV milestone option.21 [EPA-HQ-OAR-2022-0829-0642, pp. 8-9]

20 https://ww3.arb.ca.gov/regact/2019/act2019/fsor.pdf

21 https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/acf22/fsor.pdf Table IV-8

Moreover, EPA's heavy-duty Phase 3 proposal finds electrification potential rates for all categories of heavy-duty trucks, ranging from Class 4 versions of medium-duty pickups to tow trucks to long haul tractors, higher than the 19% projected for medium-duty pickups in MY 2032. This is further evidence that EPA should consider in more detail the actual requirements for medium-duty pickups and the extent to which BEVs might meet those needs. [EPA-HQ-OAR-2022-0829-0642, pp. 8-9]

Finally, for those medium-duty pickups that must tow heavy loads long distances, both plug-in hybrid electric vehicles (PHEVs) and fuel cell vehicles (FCEVs) should be considered. As EPA notes, PHEVs may be well suited to Class 2b pickups (DRIA 3-11). We urge EPA to incorporate in the final rule findings from contract work now underway to investigate the potential for PHEVs in pickup applications (FR 29298), including by adding PHEVs as a compliance option and increasing the stringency of MDV standards to the extent appropriate. Similarly, EPA should include an analysis of fuel cells for high-mileage, high-towing pickups. EPA's heavy-duty Phase 3 proposal projected that 25% of long haul tractors could be FCEVs by MY 2032, indicating confidence that any infrastructure and cost challenges associated with FCEVs can be addressed by then. [EPA-HQ-OAR-2022-0829-0642, pp. 8-9]

Organization: Environmental. and Public Health Organizations

VIII. Stronger GHG and Criteria Pollutant Standards for Medium-Duty Vehicles Are Feasible.

We now turn to EPA's proposed emission standards for medium-duty vehicles. Below, we examine the combustion vehicle and zero-emission technologies that can further reduce GHG emissions from the medium-duty fleet, comment on EPA's modeling, address economic considerations, and make suggestions on certain aspects of EPA's regulatory program. We also offer recommendations for the Tier 4 NMOG+NOx standards and PM requirements. As detailed below, strong GHG and criteria pollutant emission standards for MDVs are feasible and cost-reasonable. [EPA-HQ-OAR-2022-0829-0759, p. 64]

A. EPA must strengthen its GHG standards for MDVs.

EPA's proposed GHG standards for MDVs significantly underestimate the potential for feasible emissions reductions from the Class 2b-3 fleet, particularly pickup trucks. EPA has primarily focused on the electrification of MDVs in setting its standards.169 However, not only has it underestimated the share of MDVs that could be electrified, it has underestimated the technologies available to reduce GHG emissions from gasoline- and diesel-fueled vehicles. EPA should adopt more stringent final standards for MDVs that reflect greater application of both the zero-emission powertrain and conventional emission control technologies that are feasible and widely available. [EPA-HQ-OAR-2022-0829-0759, p. 64]

169 DRIA at 1-21: "The feasibility of the 2027-2032 GHG standards is based primarily upon an assessment of the potential for a steady increase in MDV electrification, primarily within the van segment."

1. The combustion vehicle technology pathways show the feasibility of stronger standards.

EPA proposes as its 2027 standard the current (Phase 2) standards for diesel pickups and vans, and then adjusts those standards in the future based on assumptions about the level of electrification within the fleet. In fact, in EPA's modeling, combustion MDVs actually increase average direct tailpipe emissions by 1.5% between 2022 and 2032, with the increase being even larger for the Phase 2 baseline. The modeling thus indicates that no technological improvements to combustion MDVs are needed to comply with even the existing Phase 2 standards through 2027.170 [EPA-HQ-OAR-2022-0829-0759, p. 64]

170 This remains true for the "No IRA" sensitivity, though there is virtually no difference in the assumed production of electric MDVs between the default modeling run and this sensitivity case, indicating the degree to which electrification is expected to take off in the commercial van space due to improved TCO.

Subsequent to finalization of the Phase 2 standards in 2016, a number of technologies have been developed that EPA did not originally consider in establishing those standards; nor were the Phase 2 standards predicated on the full adoption of even those technologies that were identified at the time. As EPA noted in its Phase 3 heavy-duty vehicle proposal: "In developing the Phase 2 CO2 emission standards, we developed technology packages that were premised on technology adoption rates of less than 100%. There may be an opportunity for further improvements and increased adoption through MY 2032 for many of these technologies included in the heavy-duty (HD) GHG Phase 2 technology package used to set the existing MY 2027 standards."171 [EPA-HQ-OAR-2022-0829-0759, p. 65]

171 88 Fed. Reg. at 25960.

By ignoring technologies for Class 2b-3 combustion vehicles that could achieve emissions reductions beyond the Phase 2 standards, EPA is setting its MDV standards below a level of readily achievable technology adoption (and, indeed, many of these technologies are already being deployed). Below, we walk through a number of the technologies that EPA should assume will be deployed by MDV manufacturers in the timeframe of the MDV Proposal. [EPA-HQ-OAR-2022-0829-0759, p. 65]

a. EPA should consider additional compression-ignition (diesel) engine technologies.

Manufacturers of diesel engines for Class 2b-3 pickups and vans will deploy new engines in order to meet the 2027 NOX standards that EPA finalized last year.172 However, the Agency's modeling assumes that diesel vehicles will reduce GHG emissions by less than 1% from 2022 to 2032. This leaves a tremendous amount of technology on the table, not just from what the Agency identified in the Phase 2 rulemaking and assumed would be needed to meet the standards already on the books, but also from additional improvements that have been developed since then. [EPA-HQ-OAR-2022-0829-0759, p. 65]

172 See 88 Fed. Reg. 4296.

Diesel engine efficiency continues to increase, with HHD (Class 8) diesel engines demonstrating up to 55% brake-thermal efficiency (BTE) in response to the second phase of the SuperTruck program. The Navistar and Cummins/Peterbilt teams demonstrated 55% BTE, compared to the 50% target for the first phase, while Daimler, Volvo, and PACCAR all demonstrated over 50% BTE, with a clear pathway towards the 55% target. The PACCAR team's progress is particularly illuminating, as they undertook an additional challenge to meet "ultra low NOX" targets consistent with EPA's recent regulation as part of their overall efficiency effort, indicating that these levels of thermal efficiency are not incompatible with achieving the 2027 NOX standards.173 [EPA-HQ-OAR-2022-0829-0759, pp. 65-66]

173 See Zukouski, Russ, Navistar SuperTruck II: Development and demonstration of a fuel-efficient class 8 tractor & trailer, DOE Annual Merit Review, (Jun. 21-23, 2022) https://www1.eere.energy.gov/vehiclesandfuels/downloads/2022_AMR/ace103_%20Zukouski_2022_o_4-29_1232p m_ML.pdf; Mielke, David, 2022 Annual Merit Review: Cummins/Peterbilt SuperTruck II, DOE Annual Merit Review, (Jun. 21-23, 2022) https://www1.eere.energy.gov/vehiclesandfuels/downloads/2022_AMR/ace102_dickson_2022_o_rev2%20-%20Trai lLife-GCCC%20IN0110%20REVISED.pdf; Bashir, Murad, et al., Daimler: Improving transportation efficiency through integrated vehicle, engine, and powertrain research - SuperTruck 2, DOE Annual Merit Review, (Jun. 21-23, 2022) https://www1.eere.energy.gov/vehiclesandfuels/downloads/2022_AMR/ace100_Villeneuve_2022_o_4-30_1116am_ ML.pdf; Bond, Eric, et al, Volvo SuperTruck 2: Pathway to cost-effective commercialized freight efficiency, DOE Annual Merit Review, (Jun. 23, 2022) https://www1.eere.energy.gov/vehiclesandfuels/downloads/2022_AMR/ace101_bond_2022_o_5-1_129pm_ML.pdf; Meijer, Maarten, Development and demonstration of advanced engine and vehicle technologies for class 8 heavy-duty vehicle ([PACCAR] SuperTruck II), DOE Annual Merit Review (Jun. 21-23, 2022), https://www1.eere.energy.gov/vehiclesandfuels/downloads/2022_AMR/ace124_Meijer_2022_o_4-29_1056pm_KF. pdf.

Significant improvements in efficiency are not limited to the largest engines and can also be feasibly deployed on Class 2b-3 vehicles. Ford's latest iteration of its 6.7L Power Stroke diesel engine cut GHG emissions by 3.5% over the previous generation when it was introduced in 2020, and 2023 saw an additional 3% improvement due to a revised injection system.174 General Motors released its new 6.6L Duramax diesel engine in 2023 with improved cylinder heads, fuel injection, and other features in a design that is meant to increase both power and efficiency, particularly at higher output.175 These engine improvements are already being deployed today but are not captured in the Agency's OMEGA2 modeling. [EPA-HQ-OAR-2022-0829-0759, p. 66]

174 To assess these improvements, we refer to the combined transient cycle certification results for the MHD Power Stroke family of diesel engines available in the chassis cab/F-650 and F-750 configurations. The engines available in the heavy-duty pickups are not required to certify to isolated engine tests, but are likely to see similar levels of improvement, even with the higher power output, since they also have the same underlying technology.

175 GMC Pressroom, The Ultimate Heavy Duty: GMC Introduces its Most Luxurious, Advanced and Capable Sierra HD Ever (Oct. 6, 2022), https://media.gmc.com/media/us/en/gmc/home.detail.html/content/Pages/news/us/en/2022/oct/1006-sierra.html. It is difficult to compare apples-to-apples between the new and old Duramax engines due to limited certification data and because some of that efficiency improvement was used to reduce tailpipe NOx, since the new diesel-equipped Silverado/Sierra HD 2500 have a reduced NMOG+NOx bin of 200 vs. 250 mg/mile. Additionally, because the standards are set by "work factor," the increase in power used to raise towing capacity by 4000 pounds increases the allowable emissions for the engine, which means that despite an apparent increase in certified CO2 emissions of 2.4%, there could be a net improvement in compliance of up to nearly 5% as the result of up to a 7% increase in the model year 2023 emissions target.

Mild electrification also offers increased emissions reduction capabilities. Eaton demonstrated that it is possible to outperform simultaneously the 2027 NOx standards and the Phase 2 CO2 standards through a number of different aftertreatment and powertrain combinations,176 including those applicable to Class 2b-3 vehicles. A recent research paper by Eaton demonstrates various combinations of control technologies manufacturers can target CO2 and NOx emissions levels over different regulatory cycles to develop a technology package that is suitable for compliance, including packages that can achieve CO2 reductions beyond Phase 2 while meeting EPA's future 2027 NOx standards.177 [EPA-HQ-OAR-2022-0829-0759, pp. 66-67]

176 See generally Dorobantu, Mihai, Eaton considerations on MD/HD GHG Phase 3, OIRA-Eaton meeting, (Mar. 23, 2023), https://www.reginfo.gov/public/do/eoDownloadDocument?pubId=&eodoc=true&documentID=215442

177 McCarthy, J., et al. 2023. "Technology levers for meeting 2027 NOX and CO2 regulations." SAE Technical Paper 2023-01-0354. https://doi.org/10.4271/2023-01-0354.

One of the strategies deployed by Eaton is a 48V electric heater, which could be deployed easily with a 48V mild hybrid powertrain, again illustrating the complementary technology packages available to manufacturers to simultaneously meet GHG and NOx standards. The 48V mild hybrid powertrain can power accessories, including those related to emissions control, and can also help reduce engine-out NOx. This was also demonstrated through testing by FEV as a strategy particularly relevant to medium-heavy-duty vehicles that share chassis and power requirements with the Class 2b-3 pickups and vans covered by this proposal.178 Such developments should be incorporated into the Agency's analysis of the level of emissions reductions achievable from diesel-powered Class 2b-3 vehicles. [EPA-HQ-OAR-2022-0829-0759, p. 67]

178 Fnu, D., et al. 2023. "Application of 48V mild-hybrid technology for meeting GHG and low NOX regulation for MHD vehicles." SAE Technical Paper 2023-01-0484. https://doi.org/10.4271/2023-01-0484.

In the Phase 2 rulemaking, EPA excluded cylinder deactivation from medium-duty diesel engines,179 but its own analysis now shows that manufacturers are likely to deploy that technology to meet the heavy-duty NOx standards.180 Similarly, a recent report by Roush identified cylinder deactivation as a likely engine configuration for many Class 2b-3 vehicles.181 The Agency should consider this technology in its OMEGA2 modeling, further increasing the available emissions reductions technologies for diesel-powered vehicles. [EPA-HQ-OAR-2022-0829-0759, p. 67]

179 81 Fed. Reg. at 73754, Table VI-4. Note, however, that the agencies did consider a "right-sizing" of diesel engines, based on a 4-cylinder vs. 6-cylinder engine, and cylinder deactivation could be seen as a control-based attempt to yield the equivalent improvement without altering the maximum output. See NHTSA, Commercial medium- and heavy-duty truck fuel efficiency technology study – Report #2, U.S. Dep. of Transportation, 52–53 (Feb. 2016), https://www.nhtsa.gov/sites/nhtsa.gov/files/812194_commercialmdhdtruckfuelefficiency.pdf.

181 Himanshu Saxena et al., Electrification Cost Evaluation of Class 2b and Class 3 Vehicles in 2027–2030, Roush, at 24-25, 28-30 (May 2023), https://cdn.mediavalet.com/usva/roush/r0YBSBBv00edOiBP759yoA/3Hcv7F_W-0G9ek0ODPgNMg/Original/Elect rification%20Cost%20Evaluation%20of%20Class%202b-3%20Vehicles%20in%202027-2030_ROUSH.pdf. [hereinafter Saxena et al., Electrification Cost Evaluation].

b. EPA should consider additional spark-ignition (gasoline) engine technologies.

Another significant opportunity for increased improvement to combustion vehicles lies in spark-ignition (SI) engines, for which Phase 2 required no engine improvements beyond the 2016 SI engine standard. While this is somewhat rectified in EPA's move to a fuel-neutral standard for Class 2b-3 pickups and vans—which effectively results in a 5-6% increase in stringency for MDVs—this still does not fully recognize the potential improvement available from gasoline engines. And in fact, in the Agency's modeling, gasoline vehicles see, on average, 5% higher emissions in 2032, compared to 2022.182 [EPA-HQ-OAR-2022-0829-0759, pp. 67-68]

182 Because the model preferentially selects vans for electrification, some of this decrease is related to a shift in the vehicles included in the remaining gasoline fleet. However, even when limited to gasoline pickups there is an apparent backsliding in emissions, with an increase of 3%. This is similar to the backsliding that appears in the modeling of light-duty vehicles (see Section VI.A.2).

The weakness in EPA's Phase 2 targets for SI engines and vehicles is apparent in looking at manufacturers' growing bank of compliance credits to-date, particularly for Ford Motor Company, the largest SI engine supplier. Ford has run a credit surplus in every year of the vocational engine program, but this surplus exploded in MY 2020 with the release of its latest 7.3L V8 engine, codenamed "Godzilla."183 Even though the engine platform is relatively low-tech (naturally aspirated, pushrod V8), by utilizing variable cam timing and a variable-displacement oil pump, Ford's engine achieved a significant improvement in efficiency. The engine was also designed with fuel economy at load in mind for applications like towing. A smaller engine built on the same platform replaced the older base engine in 2023, no doubt increasing Ford's overcompliance and increasing the efficiency of even more of the MDV fleet. [EPA-HQ-OAR-2022-0829-0759, p. 68]

183 EPA, Final Phase 1 EPA Heavy-Duty Vehicle and Engine Greenhouse Gas Emissions Compliance Report (Model Years 2014-2020), Appendix B, at 40-42 (Nov. 2022) https://nepis.epa.gov/Exe/ZyPDF.cgi/P1016962.PDF?Dockey=P1016962.pdf.

General Motors is not standing still, either—its fifth-generation small-block V8 platform is getting a next generation update to a 5% improvement over the current generation,184 and the current generation is already a credit generator for GM's heavy-duty vehicles under the Phase 2 program.185 No further details are available about the heir to the current iron-block direct-injection L8T variant found in GM's heavy-duty offerings. [EPA-HQ-OAR-2022-0829-0759, p. 68]

184 Wren, Wesley, This is why GM is launching a new small block V8, Autoweek, (Feb. 3, 2023) https://www.autoweek.com/news/industry-news/a42746723/why-gm-is-launching-a-new-small-block-v8/.

185 EPA, Final Phase 1 EPA Heavy-Duty Vehicle and Engine Greenhouse Gas Emissions Compliance Report (Model Years 2014-2020), Appendix B, at 43.

Note that neither of these new improvements reflect technology adoption that was further anticipated for gasoline engines when the Phase 2 regulations were finalized. EPA assumed that cylinder deactivation (discrete or continuous), downsizing, and mild and strong hybridization would be used to meet those standards,186 yet none have yet been deployed in Class 2b-3 pickups and vans. This further underscores the significant amount of emissions reductions that are still readily achievable for Class 2b-3 vehicles. [EPA-HQ-OAR-2022-0829-0759, p. 68]

186 81 Fed Reg. at 73776, Table VI-13.

Organization: Ford Motor Company (Ford)

Medium-Duty Vehicle GHG Stringency

Ford does not support EPA's proposal to limit the gross combined weight rating (GCWR) input into the work factor equation to 22,000lb. EPA's stated goal with this proposed modification is "to prevent increases in the GHG emissions target standards that are not fully captured within the loads and operation reflected during chassis dynamometer GHG emissions testing." However, work factor is not only used in determining MDV GHG emissions targets—it is also part of determining whether a vehicle in the 8,501-14,000lb gross vehicle weight rating (GVWR) range is an MDV or an MDPV in EPA's proposed revisions to the MDPV definition. Limiting work factor by capping GCWR input may reclassify MDVs as MDPVs in ways contrary to EPA's stated goals of capturing vehicles that "do not have significant work capabilities (e.g., towing and hauling), as measured by the work factor, relative to other vehicles in the MDV category." This would be an inappropriate and inaccurate comparison to make if work factor, the basis of the comparison, is not calculated in the same way over time. [EPA-HQ-OAR-2022-0829-0605, pp. 9-10]

To meet EPA's stated goal and ensure that manufacturers do not "generate windfall compliance credits for higher GCWR ratings," it would be more straightforward to modify the structure of MDV GHG standards directly. As one possibility, rather than a linear equation with the CO_2 g/mi standard constantly increasing as a function of work factor, the CO_2 standard could increase linearly only up to a certain work factor value, after which it would remain constant even if work factors continued to increase. In this way, EPA could address increases in GHG emission standards due to increasing GCWRs without distorting the use of work factors in other areas. [EPA-HQ-OAR-2022-0829-0605, pp. 9-10]

Organization: International Council on Clean Transportation (ICCT)

MEDIUM-DUTY VEHICLES

ICCT supports EPA's proposed standards for MDVs but believes the available evidence could justify greater stringency than proposed. ICCT also recommends the MDV standards be fuel neutral and require public availability of MDV-related data (sales, emissions, fuel consumption, vehicle attributes/technologies).152 These recommendations form the basis for ICCT's comments on the proposed MDV standards, discussed further below. [EPA-HQ-OAR-2022-0829-0569, pp. 60-62]

152 Lutsey. N. (2015). Regulatory considerations for advancing commercial pickup and van efficiency technology in the United States. International Council on Clean Transportation. https://theicct.org/sites/default/files/publications/ICCT_pickup-van-efficiency_20150417.pdf

Stringency

ICCT supports the proposed MDV standards but believes they could be strengthened. The proposed standards would not require as high GHG reductions for MDVs as for light-duty trucks. The proposed MDV standards, if finalized, would require a net 36.5% improvement in tailpipe CO2 emissions, for a given work factor over MY2027-2032. This total improvement is much higher than that required by the current Phase 2 standards. However, the proposed LD truck standards require a total 46% improvement for a given footprint over MY2027-2032. This level of improvement comes after years of increased efficiency required by MY2017-2026 regulations. Figure 16 compares the 2-cycle CO2-e emissions of ICE LD pickups, MD vans, and MD pickups versus footprint. Each datapoint represents a single ICE model as calculated by OMEGA in MY2022 (baseline MY2021 emissions values are not available for all models, and OMEGA projects virtually 0% BEV share of these segments in MY2022). Since MD vehicles are tested at higher weight than LD vehicles, to compare MD and LD data, the emissions data of MDV were adjusted downwards assuming a test weight equal to curb weight plus 300 lbs (equivalent to the LD test weight). It was assumed that for every 10% reduction in test weight, CO2 emissions decreased by 4%.153 Solid-filled points represent a single model, and pattern-filled points represent the sales-weighted average emissions in MY2022, and the projected emissions in MY2032 to comply with the standard.154 Projected emissions were calculated based on the proposed standard curves for MY2032 assuming constant footprint (for LD pickups) or constant work factor with average test weight adjustment (for MD vehicles). As the figure shows, LD pickups are more efficient than similarly sized MDV, and the required improvement over the course of MY2022-MY2032 is much higher for LD than for MD. The different utility of LD vs MD notwithstanding, due to years of lagging behind the stringency levels of LDV, there are opportunities for increasing the stringency of the MD standards. [EPA-HQ-OAR-2022-0829-0569, pp. 60-62]

154 Preamble Tables 27 & 31

SEE ORIGINAL COMMENT FOR Figure 16. Comparison of on-cycle CO2 emissions of light-and medium-duty trucks, by model (solid fill) and sales-weighted average (pattern fill) calculated in OMEGA in MY2022. Average MY2022 and projected required MY2032 emissions are shown connected by arrows, indicating the percent reduction in emissions over MY2022-2032. [EPA-HQ-OAR-2022-0829-0569, pp. 60-62]

As acknowledged by EPA (DRIA 1-19), many gasoline and diesel efficiency-improving technologies have yet to be broadly implemented among medium-duty vehicles. In particular, many LD-related technologies like those discussed in previous sections in these comments can be applied to MD vans and some pickups. For instance, strong and mild hybrid systems that are well-suited for full-size LD SUVs and pickups could be scaled up for MD implementation. Light heavy-duty diesel powertrains can also benefit from hybridization and heavy-duty versions of LD efficiency technologies.155,156,157 Hybrid versions of LD vans and pickups today suggest that mild, strong, or plugin hybridization may be viable options for certain MD applications.158 [EPA-HQ-OAR-2022-0829-0569, pp. 60-62]

157 Posada, F., Isenstadt, A., Badshah, H. (2020). Estimated cost of diesel emission-control technology to meet the future California low NOx standards in 2024 and 2027. International Council on Clean Transportation. https://theicct.org/publication/estimated-cost-of-diesel-emissions-control-technology-to-meet-the-future-california-low-nox-standards-in-2024-and-2027/

158 According to the MY2023 Fuel Economy Guide (https://fueleconomy.gov/feg/download.shtml), the Ford F150 hybrid is 17%-20% more efficient in combined, unadjusted (2-cycle) fuel consumption than its non-hybrid counterpart with the same 3.5L engine; the Pacifica PHEV in charge sustaining mode is 31% more efficient than its equivalent non-hybrid counterpart (3.6L engine); Tundra HEV is 5.3%-10.3% more efficient than non-HEV equipped with Atkinson cycle engine; Ram 1500 mild hybrid is 13.3%-16% more efficient than its non-hybrid version

If EPA incorporated into its analysis additional cost curve classes (incorporating MD versions of advanced gasoline engines and hybrid powertrains), as well as additional options for lightweighting (high strength steel body and frame and/or percentage-based mass reduction), and PHEVs (see PHEV discussion earlier), then its MD analysis would be much more robust. [EPA-HQ-OAR-2022-0829-0569, pp. 60-62]

Just as many LD ICE technology improvements extend to MD ICE vehicles, all of the innovations and developments in BEV technologies and battery packs discussed earlier also apply to both LD and MD classes. As with LDV BEV modeling, incorporating lower battery costs, rightsized motors, and improved EV efficiency within OMEGA for MDV would reduce the cost of MD BEVs. In a 2022 study on relative costs of EV MDV, ICCT projected that MD pickups and vans of 300-mile range or less would reach price parity with their diesel counterparts within the timeframe of this proposal.159 Over the first five years of ownership, MD BEVs of 300-mile range or less reach total cost parity with both their diesel and gasoline counterparts before 2030. In other words, well within the timeframe of the proposal battery-electric MDVs are cheaper to purchase and own than non-plugin MDVs. [EPA-HQ-OAR-2022-0829-0569, pp. 60-62]

159 Mulholland, E. (2022). Cost of electric commercial vans and pickup trucks in the United States through 2040. ICCT. International Council on Clean Transportation. https://theicct.org/publication/cost-ev-vans-pickups-us-2040-jan22/

Discussed further below, it is difficult to assess specific areas to improve the analysis of the MD proposed standards due to minimal explanation of the technical inputs into the MD analysis, and how they differ from or are similar to the LD analysis. [EPA-HQ-OAR-2022-0829-0569, pp. 60-62]

Regarding some finer details of the proposed MD standards, ICCT supports EPA's proposal to phaseout ZEV multipliers in MY2026 instead of MY2027. The expected growth in MD BEV van share by MY2027 could result in overcompliance credits being available in MY2027, which can be used to offset undercompliance by vans and pickups which are still ICE-powered. Generally, ending multipliers earlier would improve the real-world climate benefits of the proposed rule. Additionally, recent ICCT research on the costs of BEV and PHEV MD vans and pickups suggests that within the timeframe of the proposed rule, plug-in MDVs will be cost-competitive with their gasoline or diesel counterparts either upfront or both upfront and during ownership.160 Consequently, such advanced technology vehicles will not need multipliers as a production incentive. Lastly, ICCT also supports the proposed 22,000 lbs limit to the GCWR input in the work factor equation, for the reasons EPA provided in its proposal (Preamble 29242). [EPA-HQ-OAR-2022-0829-0569, pp. 60-62]

160 Mulholland, E. (2022). Cost of electric commercial vans and pickup trucks in the United States through 2040. International Council on Clean Transportation. https://theicct.org/publication/cost-ev-vans-pickups-us-2040-jan22/

Fuel neutrality

ICCT strongly supports EPA's switch to a single set of standards curves for all MDVs, regardless of fuel type. [EPA-HQ-OAR-2022-0829-0569, pp. 62-64]

Organization: Rivian Automotive, LLC

EPA proposes meaningful improvements to the MDV standards that, as modeled, would result in BEV sales of 46 percent in the MDV segment by MY32—higher even than the requirements of the Advanced Clean Trucks ("ACT") rule. Rivian applauds this level of foresight. As our own products demonstrate, BEVs can readily meet the needs of Class 2b-3 fleets. Regulations can and should push the pace of emissions reduction via electrification in this category. [EPA-HQ-OAR-2022-0829-0653, pp. 10-12]

However, closer examination of the proposal reveals uneven outcomes. While EPA rightly expects rapid and widespread electrification of vans—achieving 98 percent BEV penetration in MY32—pickups languish. In fact, EPA's modeling shows electrification backsliding in the pickup segment in the early years of the regulation. [EPA-HQ-OAR-2022-0829-0653, pp. 10-12]

Projected BEV Penetrations29

MY: 2027; Vans: 35%; Pickups: 7%; Combined: 17%

MY: 2028; Vans: 55%; Pickups: 1%; Combined: 20%

MY: 2029; Vans: 73%; Pickups: 3%; Combined: 28%

MY: 2030; Vans: 92%; Pickups: 4%; Combined: 34%

MY: 2031; Vans: 97%; Pickups: 15%; Combined: 43%

MY: 2032; Vans: 98%; Pickups: 19%; Combined: 46%

[EPA-HQ-OAR-2022-0829-0653, pp. 10-12]

Table 2. The penetration rate for BEVs declines in the pickup segment in the early years of the regulation. [EPA-HQ-OAR-2022-0829-0653, pp. 10-12]

29 U.S. Environmental Protection Agency, Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light- Duty and Medium-Duty Vehicles: Draft Regulatory Impact Analysis (April 2023), 13-53.

EPA should take care not to inadvertently establish a regulatory framework that allows for “slow-walking” MD pickup electrification. The technology can meet the needs of many duty cycles, including those involving towing. But the rapid uptake of BEVs in the van fleet coupled with ATV multipliers in the early years of the program could inflate credit banks. As a consequence, van electrification could slow to some extent, and/or manufacturers could prolong the life of conventional MD pickups in their planning portfolios for longer than would otherwise be necessary. [EPA-HQ-OAR-2022-0829-0653, pp. 10-12]

We recommend a two-track approach to ensuring the strongest possible standards for MDVs. First, EPA should evaluate the feasibility of even more stringent emissions requirements. As in the LD segment, EPA’s modeling appears to omit Rivian.30 Yet, Rivian’s order book includes 100,000 all-electric Class 2b-3 vans, several thousand of which already operate on U.S. roads. Similarly, the agency‘s analysis does not appear to account for the effects of California‘s Advanced Clean Fleets (“ACF”) regulation. Approximately 142,000 Class 2b-3 vehicles will be subject to the requirements of ACF in California alone and will be required to electrify over the coming years. CARB expects ACF to add significantly to the state‘s medium- and heavy-duty ZEV population above and beyond the impact of the companion ACT rule.31 The agency should assess to what extent ACF implementation and the addition of Rivian’s committed BEV van production to the national fleet could support a lower fleet average emissions target. [EPA-HQ-OAR-2022-0829-0653, pp. 10-12]

30 The agency reports projected GHG emission rates for five MDV manufacturers—Ford, General Motors, Mercedes- Benz, Nissan, and Stellantis, per U.S. Environmental Protection Agency, Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles: Draft Regulatory Impact Analysis (April 2023), 13-49.

31 California Air Resources Board, “Advanced Clean Fleets Regulation Summary,” May 17, 2023, available at www.arb.ca.gov/resources/fact-sheets/advanced-clean-fleets-regulation-summary.

Organization: RV Industry Association (RVIA)

RVIA strongly opposes EPA’s overreaching proposed rule for the reasons discussed below and requests the agency exclude motor homes from having to comply with the proposed medium- duty vehicle standards. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

In contradiction to this NPRM, the EPA has already proposed, in the Phase 3 GHG rule (see 88 FR 25996), to establish standards for motor homes that correctly acknowledge the reality that motor homes are not well-suited for electrification. Under the proposed Phase 3 GHG rules, the EPA would establish a CO2 standard of 226 g/mi for MY2027 and later motor homes. As discussed in the Phase 3 GHG NPRM, the agency has proposed this standard given the negative implications of electrifying the motor home chassis. To power a motor home, the batteries would take up space that is otherwise necessary for housing the various elements of a motor home. It would also add significant amounts of weight to the motor home making it no longer capable of being equipped with the components typically found in a motor home. It makes no difference whether a motor home falls under the MD/HD Phase 3 GHG rules or the LD/MD rules, the issues are the same. Standards which can only be met by battery-powered vehicles are not practicable for motor homes. EPA staff who authored the Phase 3 GHG rule have acknowledged this. In establishing standards for medium-duty vehicles within this rule, staff need to be consistent and exclude motor homes from standards that would force them to be electrified. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

Motor homes are often operated in locations where there is no electricity. This is known as "boondocking." Frequently, motor homes will be operated for weeks at a time at such locations. When motor homes are operated in a boondocking scenario, there is no possibility of EV charging. Electrification simply does not work for this operating use case. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

Unlike medium-duty vehicles that might be conveniently recharged overnight, motor homes are routinely driven 500 miles or more a day making it necessary to fully recharge mid-trip. A multi- hour charging event is simply not something the typical motor home driver would find acceptable. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

Motor homes are typically a discretionary purchase by families who tend to be very cost sensitive. Large increases in price for a vehicle that is operated on average only 20 days per year and that travels on average only 4,000 miles will not be viewed favorably by potential buyers. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

The ability to recoup higher vehicle costs through refueling savings is minimal given motor homes are driven sparingly by their owners. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

If finalized, EPA's rule will severely limit the use and affordability of motor homes. As a result, it will severely hurt motor home manufacturers, dealers, their employees and their families. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

Regarding the certification of medium-duty motor homes powered by internal combustion engines, as well as vehicles used to tow RVs, RVIA supports the concerns raised by the Alliance for Automotive Innovation in its comment letter. Such concerns include: [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

• EPA's proposed rule is neither reasonable nor achievable in the timeframe provided. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

• EPA's proposed rule is a de facto battery electric vehicle mandate. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

• EPA outstrips Biden administration's own 50 percent light-duty electrification executive order from 2021. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

• EPA underestimates battery costs and makes unrealistic battery electric vehicle (BEV) sales assumptions. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

• EPA makes no concurrent requirements to support the infrastructure and battery critical minerals for the required EVs or the drivers that must buy them. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

Organization: Stellantis

Implicit / Explicit MDV GHG Standards are Infeasible

The EPA is proposing a very challenging set of regulatory changes for the medium-duty vehicles that are infeasible. This includes direct core stringency changes along with four other actions that further increase stringency: [EPA-HQ-OAR-2022-0829-0678, pp. 17-18]

- Core Stringency Changes – Proposes an overall 37% reduction in work factor based GHG standards for 2028-32MY [EPA-HQ-OAR-2022-0829-0678, pp. 17-18]

- Work Factor Cap – Introduces a 22,000 lbs. GCWR Cap on Work Factor that further increases the GHG stringency [redacted text.] [EPA-HQ-OAR-2022-0829-0678, pp. 17-18]

- Fuel Neutrality Changes – Saddles gas product with an additional 6.1% reduction by modifying current 27MY standards (i.e., pushing fuel neutrality) [EPA-HQ-OAR-2022-0829-0678, pp. 17-18]

Core Stringency - EPA overestimated MDV GHG Reduction [EPA-HQ-OAR-2022-0829-0678, pp. 17-18]

EPA has proposed a 37% GHG reduction from 2028MY to 2032MY. The overall stringency is largely driven by a very high assumed rate (98% in 2032MY) of electrification for cargo vans. Stellantis supports AAI's comments questioning this level of electrification for cargo vans, and requests that EPA model industry electrification for the cargo van segment as just meeting CARB's requirements each year in California and states that adopted the HD ZEV rule, and no more than half that rate in other states. GHG standards should be established from this more realistic electrification rate. [EPA-HQ-OAR-2022-0829-0678, pp. 17-18]

Work Factor Cap – Further increases MDV GHG Stringency (and Forces Criteria Engine Certification) [EPA-HQ-OAR-2022-0829-0678, pp. 17-18]

In the multi-pollutant draft rule, the agency proposes to limit the GCWR contribution to work factor calculations at 22,000 lb. starting in 2030MY. This is proposed due to an agency concern that higher GCWR values are not reflected in the inertia weight of the vehicle when tested for GHG. In the HD GHG Phase 1 rule7, work factor was developed as a standard due its very high correlation to CO2. The agency has not provided data to demonstrate this is no longer accurate. [EPA-HQ-OAR-2022-0829-0678, pp. 17-18]

7 Greenhouse Gas Emissions Standards and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles, 76 Fed. Reg. 57106 (Sept. 15, 2011).

[redacted text.] [EPA-HQ-OAR-2022-0829-0678, pp. 17-18]

Fuel Neutrality – EPA Punishes Gasoline ICE MDVs

EPA proposes new, fuel neutral GHG standards for medium-duty vehicles beginning in 2027MY for spark-ignition (gas) engines by reopening the Phase 2 GHG rule, resulting in a 6.1% jump in stringency. EPA explains that reopening of the current published rule is needed due to their anticipated levels of electrification of MDVs in 2027MY. [EPA-HQ-OAR-2022-0829-0678, p. 20]

Stellantis disagrees with this approach. [redacted text.] Respecting lead time needs, fuel neutrality should be phased in over several years (30/60/100), and not fully implemented until 2032MY. [EPA-HQ-OAR-2022-0829-0678, p. 20]

Stellantis recommends that EPA should:

GHG Standards

- Revise standards that align to achievable EV adoption rates that do not force an overly optimistic technology transition for the market and industry: [EPA-HQ-OAR-2022-0829-0678, p. 24]

-Revise stringency adopting an ‘Alternative 3’ profile removing front-loading of EV adoption, modified to ensure 2030MY standards can be met with a 40-50% BEV+PHEV+FCEV combined technology penetration [EPA-HQ-OAR-2022-0829-0678, p. 24]

-Include PHEV technology as a critical transition technology to a fully electrified future – without incorrect discounting – particularly in highly capable vehicle segments [EPA-HQ-OAR-2022-0829-0678, p. 24]

-Treat trucks and SUVs fairly by including PHEV technology as an important bridge to a BEV future, and ensure year-over-year required improvements are the same as cars [EPA-HQ-OAR-2022-0829-0678, p. 24]

-Fix incorrect MDV adjustments that mistakenly force medium-duty vehicles into light-duty standards and double stringency of high capability products arbitrarily [EPA-HQ-OAR-2022-0829-0678, p. 24]

- Include a provision that compliance with EPA’s GHG standards would constitute compliance with CAFE standards [EPA-HQ-OAR-2022-0829-0678, p. 24]

Organization: Winnebago Industries (Winnebago Industries)

While Winnebago Industries is very excited about the potential to introduce ZEVs such as the eRV2, there are significant practical technological and economic challenges to ZEV motorhomes in the motorhome Class B product category, which often align with EPA medium duty vehicles between 8,501 and 14,000 lbs. gross vehicle weight rating. The Proposed Rules do not adequately address this category of motorhomes, and if promulgated in its current state, these rules will create a serious risk of substantial negative impacts to this important Winnebago Industries group of products. [EPA-HQ-OAR-2022-0829-0636, p. 2]

For reference, the Proposed Rule will impact eighty-nine percent of the Winnebago brand motorhomes currently being produced. For the larger RV industry, based on calendar year 2022, the Proposed Rule would affect approximately fifty percent of the nearly 50,000 motorized RVs produced. This is very significant and impactful for the RV industry but, in comparison, is an extremely small portion of the millions of light- and medium-duty vehicles produced annually for the U.S. market. [EPA-HQ-OAR-2022-0829-0636, p. 2]

As EPA is aware, RVing throughout the United States often involves driving several hundred miles to reach a stationary location, frequently through very remote areas of the country including to "off-the grid" locations. In particular, Winnebago Industries' medium duty Class B camper vans have a highly unique use compared to other products in the same regulatory category, a reality which is not currently reflected in the Proposed Rule. This very unique vehicle usage presents great practical challenges to the RV/motorhome industry to transition to ZEV technologies with current and foreseeable future developments in battery and overall vehicle design as well as the obviously critical charging and energy supply infrastructures that are needed for long-distance and remote-area RV usage. [EPA-HQ-OAR-2022-0829-0636, pp. 2-3]

It is therefore of critical importance to Winnebago Industries (and the entire motorhome industry) that EPA provide sufficient flexibility in engine and vehicle certifications to allow Americans to continue to take part in one of our country's favorite recreational activities and avoid catastrophic impacts to our business and the RV industry. [EPA-HQ-OAR-2022-0829-0636, pp. 2-3]

Based on this impact, Winnebago Industries respectfully requests the Proposed Rule exclude motor homes from having to comply with the proposed medium-duty vehicle standards. Given the low volumes in question, there would be a negligible impact on overall vehicle emissions, allowing the RV industry to continue to serve the important roles in American business and way of life. [EPA-HQ-OAR-2022-0829-0636, pp. 2-3]

In the alternative, we have two further suggestions to address the impacts the Proposed Rule would have on Winnebago Industries. First, that EPA adopt a low volume exemption for the medium-duty vehicle category, specific to motor homes, that would allow Winnebago Industries and its certifying chassis suppliers to continue to produce internal combustion engine (ICE) vehicles while ZEV technologies for medium duty vehicles continues to evolve. The potential ramifications cannot be overstated: if Winnebago Industries' chassis suppliers determine that production of a low volume of chassis for motorhomes is no longer commercially beneficial or technically viable, Winnebago Industries and the entire RV industry could suffer tremendously. [EPA-HQ-OAR-2022-0829-0636, p. 3]

Secondly, we encourage EPA to adopt a form of optional custom chassis motorhome vehicle certification standard, similar to the provisions in the heavy-duty greenhouse gas (GHG) 2 and proposed GHG 3 rules. An optional certification standard for manufacturers of medium duty motorhome chassis – again, manufacturing at a very low volume compared to other vehicle types in the Proposed Rule – would permit Winnebago Industries' chassis suppliers to meet our limited needs. [EPA-HQ-OAR-2022-0829-0636, p. 3]

EPA Summary and Response:

Summary

EPA appreciates the comments received regarding the MDV Work Factor (WF) Curves. EPA received a range of comments and recommendations that are summarized below.

ACEEE and ICCT both commented that the Agency's analysis incorporated too few BEV pickups and that increased levels of electrification of MDV. ACEEE, ICCT, and EPHO all supported more stringent MDV GHG standards than proposed. ACEEE and ICCT provided comparisons of MDV pickup truck electrification to light-duty pickup truck electrification as justification for increased electrification of MDV pickups, including MDV applications requiring high towing capacity. ACEE commented that the Heavy-duty Phase 3 NPRM had higher percentages of BEV in heavy-duty categories of Class 4 and above than included within the analysis of MDV for the Light- and Medium-duty Multipollutant NPRM. ACEEE also commented that both PHEVs and FCEVs should be incorporated into EPA's MDV analysis. ICCT commented that PEV MDVs would be cost competitive with ICE MDVs within the timeframe of this rulemaking. ICCT further supported phasing out ZEV multipliers in 2026 instead of 2027. EPHO commented that additional compression ignition technologies could be applied within the Agency's analysis and provided examples of specific Class 8 long-haul trucks within the DOE SuperTruck Program achieving 55% brake thermal efficiency. EPHO also provided examples of recent, more efficient versions of the Ford 6.7L and GM 6.6L MDV compression ignition engines. Similarly, EPHO commented that additional spark ignition engine technologies could be applied within the Agency's analysis, citing recently developed Ford 7.3L and GM MDV spark ignition engines. EPHO also commented that 48V MHEV would also be applicable to MDV applications.

Within its comments on MDV GHG, Ford neither specifically supported nor opposed the stringency of the GHG standards. Ford's MDV GHG comments focused specifically on opposition to the proposed changes to the work factor (WF) calculation that capped GCWR within the WF calculation to no greater than 22,000 pounds. Ford suggested that the GHG standards could increase linearly up to a certain WF value and then standards could flatten above such a WF value and that such an approach would adequately address the Agency's concerns as stated in the proposal.

Winnebago's comments asserted that the proposed regulations, if unchanged would pose a serious risk to Winnebago's motorhome products. Winnebago was specifically concerned regarding its Class B motorhome products and in general described that there would be practical challenges for motorhomes to transition to ZEV technologies "…with current and foreseeable future developments in battery and overall vehicle design as well as the obviously critical charging and energy supply infrastructures that are needed for long-distance and remote-area RV usage." Winnebago asked the Agency consider two alternatives to the proposed GHG standards specifically for MDV motorhome applications:

1. Adoption of a low volume exemption from GHG standards specifically for MDV motorhomes
2. Adoption of an optional custom chassis motorhome vehicle certification standard, similar to the provisions in the Heavy-Duty Greenhouse Gas Phase 2 Final Rule and the Heavy-Duty Greenhouse Gas Phase 3 GHG Proposed Rule

RVIA voiced strong opposition to the proposed GHG standards. They asserted that there were specific exceptions for motorhomes both within the Heavy-Duty Phase 3 GHG Proposed Rule and within the previous Heavy-Duty Phase 2 GHG standards. They also asserted that the proposed MDV standards could only be met by battery electric vehicles and thus represented a BEV mandate for MDV. RVIA stated that battery electric drivetrains are not practical for motor homes. RVIA further asserted that the standards would not be achievable within the rulemaking timeframe. They also stated that there would be no EV charging capability during RV boondocking (off-grid camping). RVIA asked for motorhomes to be excluded from GHG emissions standards.

Both the Alliance and Stellantis opposed the GHG standards for MDV, stating that were too stringent and with Stellantis further characterizing the standards as "infeasible". The Alliance and Stellantis specifically cited a 37% reduction in GHG from MY 2028 through MY 2032 as too stringent, and that the assumption of 98% electrification of van applications in the proposal was too high. The Alliance referred to an Administration electrification "stretch goal" for MDV of 40 to 50% vs. what the Alliance estimated to be 92% electrification of MDV. Both the Alliance and Stellantis opposed proposed changes to the WF calculation that capped GCWR within the WF calculation to no greater than 22,000 pounds.

The Alliance requested that the Agency "…consider the extent to which pickups may "weight out" to Class 4, if equipped with battery electric vehicle technology…" and to take into consideration vehicles shifting to different regulatory weight classes when setting GHG standards and/or offering GHG compliance flexibilities.

Stellantis requested that van electrification not exceed that required for CARB HD ZEV compliance for vans. Stellantis also requested that the GHG standards be revised to "achievable EV adoption rates that do not force an overly optimistic technology transition for the market and industry". Stellantis stated that the move to fuel neutral standards for MDV GHG in 2027 "punishes ICE gasoline" and that such neutrality should be phased in at a rate of 30%, 60%, and 100%, with the 100% not occuring until 2032. Stellantis asked the Agency to include PHEV technology within its analysis. Stellantis requested that EPA include provisions such that compliance with Federal GHG standards for MDV would constitute simultaneous compliance with Federal Corporate Average Fuel Economy standards for MDV.

Response:

The Agency does not agree with ACEEE and ICCT that GHG standards and levels of electrification, and other technologies applicable light-duty pickup trucks are necessarily appropriate for MDV pickup trucks. Such an approach does not take into full consideration the different use cases for MDV trucks compared to light-duty pickups, in particular substantially higher tow capability which, in the case of some diesel MDV pickups, includes GCWR as high as 45,000 pounds, approximately twice that of the highest light-duty truck GCWR. The adjustments applied by ICCT to MDV pickup trucks to allow comparison with light-duty pickup trucks do not fully account for differences between testing at loaded vehicle weight for light-duty trucks versus adjusted loaded vehicle weight for MDV. The adjustment applied by ICCT also does not account at all for other significant impacts on vehicle road loads for MDV, such as increased aerodynamic drag from the increased frontal area due to both powertrain cooling requirements and higher load suspension requirements; increased road load from tire friction and tire aerodynamic drag, especially for dual-rear-wheel applications; increased frictional and rotational losses from heavier-duty axle and differential components; etc. Vehicle dynamometer testing, PEMS testing, or use of full vehicle energy simulations using models such as the EPA ALPHA model or using commercial simulation packages such as Gamma Technologies GT-SUITE™ would allow a valid estimate comparing similar technologies applied to both light-duty and MDV applications and their resulting impacts on either footprint-based or WF-based GHG standards; however none of these approaches appear to have been used within ICCT's analysis.

With respect to ACEEE's comparison of MDV electrification to the analysis supporting the Heavy-duty Phase 3 proposal, similar to light-duty to MDV comparisons, the use cases for heavy-duty applications are also different from MDV. The higher percentages for BEVs in the heavy-duty proposal were for a combination of vocational and long-haul applications, and there are also considerable differences between electrification of vocational heavy-duty compared to that of long-haul heavy-duty applications. Vocational applications in MDV are largely represented by incomplete MDV, which make up less than 5% of MDV sales. Towing capability and adaptability to a variety of uses are key considerations within the design of MDV pickup trucks, and the required utility for MDV differs from that of both lighter and heavier weight categories, and also differs within MDV between van and pickup truck applications. Our compliance modeling for the final rule shows a PEV total of 41% of total MDV sales in 2032, of which more than three-fourths of the PEVs are BEVs (See RIA Chapter 12.2.3).

With regards to EPHO's comments that more advanced technology should be considered within EPA's analysis, many updates to the MDV technologies available within OMEGA are consistent with EPHO's recommendations. For example, the Ford 7.3L MDV spark ignition referred to by EPHO is used within EPA's updated ALPHA and OMEGA analyses for the final rule (see RIA Chapter 3.5.1). A more recent and higher efficiency engine design than the two MDV compression ignition engines cited by EPHO was used to represent future MDV compression ignition engines. The agency also included more advanced engine technologies in its analysis for the final rule, going beyond EPHO's recommendations. For example, we included advanced spark ignition Miller-cycle dedicated hybrid engines and downsized compression ignition dedicated hybrid engines within the OMEGA analysis of MDV PHEVs for the final rule.

With respect to comments from ACEEE and Stellantis regarding the Agency including PHEVs within its analysis of MDV GHG emissions, EPA completed a detailed modeling study that included modeling of an MDV PHEV with considerable all-electric range capability and very high towing capability, referred to as a range extended electric truck or REET (Bhattacharjya et al. 2024). The study demonstrated the potential for an approximately 80% reduction in CO_2 emissions over the regulatory drive cycles for a MDV REET pickup with a maximum GCWR of approximately 30,000 pounds and without compromising towing range relative to ICE MD while in charge-sustaining operation. Results from the study were incorporated into OMEGA compliance modeling of MDV for the final rule. Our OMEGA compliance modeling for the final rule shows that PHEVs may play a larger role than BEVs with respect to MDV pickup truck GHG compliance. For example, OMEGA results for MY 2032 estimated MDV pickup truck sales at 11% PHEV and 10% BEV (See RIA Chapter 12.2.3).

Bhattacharjya, S. et al. (2024). Heavy-light-duty and Medium-duty Range-extended Electric Truck Study – Final Report. Docket EPA-HQ-OAR-2022-0829.

The Agency has not finalized a ZEV multiplier phase out in 2026 as recommended by ICCT. Within the final rule, the BEV, PHEV, and FCEV multipliers are removed for MY 2027. The rate of MDV electrification, particularly with respect to anticipated growth of electric van sales used for last mile delivery applications, is consistent with a MY 2027 elimination of multiplier.

The Agency agrees with Ford that eliminating the cap on GCWR within the WF calculation and instead applying a flattening of standards above a WF threshold would still address the Agency's concerns. This approach would also eliminate the impacts on MDPV work factors and the MDPV definition as described in the comments from Stellantis and the Alliance. We estimated that the GCWR of 22,000 pounds from the proposed WF calculation change would be approximately equivalent to an MDV WF of 5,500 pounds and implemented a change in the MDV GHG compliance curve coefficients such that flat standards apply above a WF of 5,500 pounds beginning in MY 2030. The Agency also finalized a more gradual change to the impact of WF on the standards than that reflected by the WF calculation change in the proposal. The flattening of the standards applies at WF ≥ 8,000 pounds in 2028 and WF ≥ 6,800 pounds in 2029. This approach is analogous that the Agency has taken with respect to the gradual phase-in of flattening within the light-duty foot-print-based curves. For more information regarding the final WF-based MDV GHG compliance curves and coefficients, please see preamble Section III.C.3.

Regarding the two specific recommendations from Stellantis to "Fix incorrect MDV adjustments that mistakenly force medium-duty vehicles into light-duty standards and double stringency of high capability products arbitrarily and "include a provision that compliance with EPA's GHG standards would constitute compliance with CAFE standards," EPA responds to the former in Section 3.1.1 of this document. Regarding the latter recommendation about CAFE standards, EPA does not have the statutory authority to implement this type of declaration.

RVIA's and Winnebago's comments regarding the proposed 2027 and later MDV GHG standards, potential impacts on MDV Class B and Class C[365] motorhomes, the manner in which Heavy-Duty Phase 2 has been implemented for motorhomes, and the provisions regarding motorhomes in the Heavy-duty Phase 3 proposal incorrectly conflate previous and current flexibilities available for engine-certified applications which are not, and have not been, applicable to chassis-certified applications. For example, 2022 through 2024 model MDV Class B and Class C motorhomes have certificates of conformity as either complete MDV vans (in the case of Class B motorhomes) and thus are subject to GHG standards under 40 CFR § 86.1819 or are incomplete vehicles (in the case of Class C motorhomes) that are certified as "cab-complete" vehicles using the cab-complete and sister-vehicle provisions of 40 CFR § 86.1819-14 (j) (2). There are currently motorhome-specific GHG standards for motorhomes subject to engine certification. These provisions were discussed by RVIA and Winnebago within the context of Class 2b and Class 3 vehicles under the Heavy-duty Phase 2 GHG and within the context of MDV subject to 2027 and later GHG standards. The Phase 2 GHG standards applicable to motorhomes are summarized in Table 5 of 40 CFR § 1037.105. Those specific standards are only applicable to heavy-duty vehicles at or below 14,000 pounds GVWR that are excluded from the standards in 40 CFR 86.1819. Since MDV (or previously, Class 2b and Class 3) motorhomes are currently certified as either complete vehicles or as cab-complete vehicles, they must comply with GHG standards under 40 CFR § 86.1819 and are specifically excluded from GHG

[365] Note that Class B and Class C are industry designations for motorhomes and are not regulatory terms.

compliance under 40 CFR § 1037 and thus the motorhome-specific standards under 40 CFR § 1037.105 have not been applicable to MDV motorhomes under the Heavy-Duty Phase 2 program (see 40 CFR § 86.1819, 40 CFR § 1037.5 and 40 CFR § 1037.105). Also, the specific applicability under 40 CFR § 86.1819 and 40 CFR § 1037.5 was not changed within either the 2027 and later Light- and Medium-duty Multipollutant NPRM, the Heavy-duty Phase 3 GHG NPRM, nor the Light- and Medium-duty Multipollutant Final Rule. Since we did not propose changes to applicability for the MDV and/or Class 2b and Class 3 GHG standards, and since we did not ask for comment on any such changes to applicability, we consider such changes to applicability to be out of scope for this final rule.

Both RVIA and Winnebago provide details regarding the challenges of applying BEV technology to MDV motorhomes. The GHG standards are performance-based standards that do not require specific technologies for compliance. Our OMEGA compliance modeling for the final rule estimates that approximately 32% of MDVs sold in MY 2032 are projected to be BEV and 9% are projected to be PHEV, with remaining 59% being conventional ICE vehicles. If we look solely at vans, OMEGA projects 75% of vans to be BEV, 5% to be PHEV, and the remaining 20% to be conventional ICE. For the final rule, we also analyzed a "No Additional BEVs" sensitivity in OMEGA that relied primarily on PHEVs for GHG compliance and assumed no MDV BEVs at all. For that sensitivity, OMEGA projects 50% of total MDV sales as PHEV. See preamble section IV.G.2. Of those, 63% of MDV pickup sales and 25% van sales were projected to be PHEV, and the remaining vehicles were conventional ICE.

According to RVIA published data (RVIA, 2020), Class B motorhome sales for MY2020 totaled 7,222 vehicles, which represents 0.82% of total MDV sales in 2020 or 2% of MDV van sales in 2020. Similarly, Class C motorhome sales for MY2020 totaled 21,685, which represents 2.5% of total MDV sales in 2020 or 7% of total MDV van sales in 2020. These percentages are very small when compared either to total MDV sales or MDV van sales, and thus there are many different compliance scenarios under which manufacturers of MDVs can provide either complete vans or cab-complete vehicles to the RV industry for completion into motorhomes that are entirely based upon either:

- conventional ICE technologies
- a combination of ICE and PHEV technologies -or -
- a combination of ICE, PHEV and BEV

RVIA (2020). 2020 RV Shipments Surpass 2019 By 6% With December Shipments Best on Record – Market Report, December 2020. https://www.rvia.org/news-insights/2020-rv-shipments-surpass-2019-6-december-shipments-best-record

With respect to Winnebago's request that the Agency consider two MDV GHG alternatives for the final rule, namely, a low volume exemption specifically for MDV motorhomes or adopting an optional custom chassis motorhome vehicle certification standard, either alternative would be a significant departure from either the proposed rule or from the manner in which chassis-certified MDV have been treated in previous GHG regulations. Motorhome manufacturers do not certify these products to MDV GHG standards - they purchase complete and cab-complete vans from manufacturers who hold certificates of conformity. The van designs upon which MDV motorhomes are based on not small volume, despite the relatively small volume of the motorhomes that the MDV vans are converted to. Manufacturers will continue to produce products suitable for RV use, including complete and cab-complete PHEV and conventional ICE vans in sufficient quantity to meet demand for RV use while still complying with the MDV GHG standards that we have finalized. Neither Winnebago nor RVIA provided any information to substantiate that MDV manufacturers intend to cease sales of future ICE and potential future PHEV vans or cab-complete vans to RV manufacturers as MDV manufacturers comply with future GHG standards. Given the changes EPA has made in the stringency of the final MDV standards in the early years of the program, which provide additional lead time for manufacturers to develop and apply technologies compared to the proposal, and given the importance of the air pollutant emissions reductions for public health and welfare, we believe it is not appropriate to provide additional exemptions and flexibilities.–

3.3 - Feasibility

EPA appreciates the comments received on the topic of the feasibility of the final GHG standards. Many of the more detailed comments that are focused on specific aspects of feasibility are addressed in other sections of the preamble and RTC. The discussion and responses here are related to feasibility of the GHG standards in the broad sense and the appropriateness of the level of standards that EPA is setting (RTC Section 3.3.1). Also addressed are the specific topic of lead time needed to reach the final level of stringency in MY 2032 (RTC Section 3.3.2) and the feasibility of vehicle technologies for reducing GHG emissions (RTC Section 3.3.3). Comments related to the feasibility of the PEV supply chain and critical materials are addressed in RTC Chapter 15. Comments related to the feasibility of electricity generation and charging infrastructure needed to support greater numbers of PEVs are addressed in RTC Chapters 17 and 18. Comments related to the consumer markets for light- and medium-duty vehicles are addressed in RTC Chapters 13 and 14.

3.3.1 - Levels/stringency of the standards

Comments by Organizations

Organization: Alliance for Automotive Innovation

GHG Standards

Leap-frogs Biden administration’s own 50% executive order

The stringency of the NPRM proposed standards increases faster than at any time in history. In fact, by assuming BEVs alone will make up 60% of the new vehicles sold in 2030 and 67% of new vehicles just two years later, the proposed requirements leap-frog even President Biden’s ambitious 2030 target of 50%, which included BEVs, fuel cell electric vehicles (FCEVs), and plug- in hybrid electric vehicles (PHEVs) by 2030. The 60% BEV-only proposal also goes beyond the same goal of 50% electric vehicles by 2030 (which again included BEVs, PHEVs, and FCEVs) described in The U.S. National Blueprint for Transportation Decarbonization, authored by four cabinet level agencies including EPA and issued in January 2023 – just a few months before this proposal was published. [EPA-HQ-OAR-2022-0829-0701, pp. 3-4]

Recommendation

GHG – Better align to President Biden's 2030 electrification goal

To address the concerns identified above, Auto Innovators and our members recommend EPA reevaluate the GHG standards and more closely align with President Biden's 2030 goal. Thus, we recommend adopting requirements for 40 to 50% BEV, PHEV, and FCEVs in 2030 with continued increases through 2032. These standards should be coupled with and connected to regularly measured infrastructure deployment and battery critical mineral supply levels available during this rule. [EPA-HQ-OAR-2022-0829-0701, pp. 7-8]

A. Major Concerns with the Proposed GHG Standards

1. Overall Stringency / BEV Market Share Required

EPA has proposed greenhouse gas standards that it estimates will require approximately 60% BEV sales by MY 2030 and 67% BEV sales by 2032.150 As explained in Section I (EV Feasibility), the conditions which would enable such a high level of BEV market share are not present today and are highly uncertain in the timeframe considered by this rulemaking. Some manufacturers have already started to build MY 2024 vehicles,151 and establishing the necessary infrastructure, supply chains, manufacturing capacity, and customer acceptance in less than six years (in the case of MY 2030) or eight years (in the case of MY 2032) is far from certain. [EPA-HQ-OAR-2022-0829-0701, p. 89]

150 NPRM at 29329.

151 See FuelEconomy.gov.

B. Discussion on Alternatives Considered by EPA

1. Alternative 1 (More Stringent)

We support EPA's conclusion that "Alternative 1 would not be appropriate because of uncertainties concerning the cost and feasibility of such standards."170 Alternative 1 would lower GHG standards by approximately 10 g/mile relative to the proposed standards, bringing forward proposed requirements by approximately one to two years. This alternative would further exacerbate the concerns, and further stress the need for market feasibility, that Auto Innovators already has with the proposed standards. [EPA-HQ-OAR-2022-0829-0701, pp. 93-94]

170 NPRM at 29347.

2. Alternative 2 (Less Stringent)

Although Alternative 2 is relatively easier than the proposed standards, it still does not address Auto Innovators' concerns. In particular, Alternative 2 is estimated to require greater than 50% BEV market share by 2030, albeit with somewhat less of a requirement in 2032. [EPA-HQ-OAR-2022-0829-0701, pp. 93-94]

3. Alternative 3 (More Consistent Stringency Increases MYs 2027-2029)

Of the alternatives presented by EPA, Alternative 3 best addresses our concerns with the front- loading of the proposed standards while still achieving 97% of the estimated CO_2 emission reductions.171 However, MY 2030 (which can begin as early as calendar year 2029) BEV penetration rates estimated by EPA under Alternative 3 remain in excess of 50%, which is a cause for concern, without any inclusion of the role of PHEVs. Post-2030 BEV penetration is also a potential concern, but at least provides a couple of more years of lead-time to develop the necessary supply chains, manufacturing capacity, market, and supporting fueling infrastructure. [EPA-HQ-OAR-2022-0829-0701, pp. 93-94]

171 7,300 MMT total CO_2 emissions reduction through 2055 under the proposed standards (NPRM at 29348, Table135) vs. 7,100 MMT total CO_2 emissions reduction through 2055 under Alternative 3 (NPRM at 29350, Table 138).

C. Auto Innovators Recommendation

As a logical outgrowth from EPA's Alternative 2 and 3 and The U.S. National Blueprint for Transportation Decarbonization, Auto Innovators recommends the following approach. [EPA-HQ-OAR-2022-0829-0701, p 71]

1.Adjust the linear approach in Alternative 3 from MY 2026 to MY 2030 to arrive at Auto Innovators' goal of achieving 40-50% EV market share (inclusive of BEVs, PHEVs, and FCEVs) in 2030 and The U.S. National Blueprint for Transportation Decarbonization.172 [EPA-HQ-OAR-2022-0829-0701, p. 71]

172 Note, MY 2031 can start as early as January 2, 2030.

2. From MY 2030 to MY 2032 use a separate linear reduction to arrive at final performance-based standards that are supported by reasonably certain projections of EV supply chain, manufacturing, market, and infrastructure in that timeframe. (Please see our additional comments on EV feasibility in Section I, comments on EPA's other alternatives in Section III.B, and comments on a conceptual adjustment mechanism in Section II.) [EPA-HQ-OAR-2022-0829-0701, p. 71]

3. Performance-based standards should assume de minimis improvements in the overall efficiency of the average internal combustion engine vehicle, allowing manufacturers to focus investments on the design and production of EVs, and improving ICE vehicles only where it makes sense to do so. (Please see our additional comments on improvements to internal combustion engine vehicles, below.) [EPA-HQ-OAR-2022-0829-0701, p. 71]

Auto Innovators' proposed alternative outlined above represents a logical outgrowth of the Proposed Rule. "Agencies, are free — indeed, they are encouraged — to modify proposed rules as a result of the comments they receive," as long as "interested parties 'should have anticipated' that the change was possible, and thus reasonably should have filed their comments on the subject during the notice-and-comment period."173 Indeed, stakeholder comments proposing an idea may themselves indicate that an outcome was the logical outgrowth of the agency's initial proposal.174 [EPA-HQ-OAR-2022-0829-0701, pp. 71-72]

173 Ne. Md. Waste Disposal Auth. V. E.P.A., 358 F.3d 936, 951-52 (D.C. Cir. 2004) (internal quotation omitted).

174 See, e.g., id. At 952 (noting that "[n]numerous commenters" raised an issue); Nat. Res. Defense Council, Inc. v. Thomas, 838 F.2d 1224, 1243 (D.C. Cir. 1988) (noting that "public comments raised the possibility" of a particular approach).

In this case, our proposal naturally flows from the objectives, approach, and broad range of alternatives identified in the Proposed Rule and could have reasonably been anticipated by interested parties. To the extent EPA has concerns as to whether adopting this proposal would be a logical outgrowth of the Proposed Rule, we encourage it to take steps that would explicitly identify the proposal as a possibility for comment by interested parties.175 [EPA-HQ-OAR-2022-0829-0701, p. 72]

> 175 See, e.g., Thomas, 838 F.2d at 1243 (endorsing a procedure in which EPA issued a public notice advising of the possibility of a new approach suggested by a comment on the proposed rule, affording interested parties the opportunity to respond prior to promulgation of the final rule).

Organization: American Honda Motor Co., Inc.

In our view, neither the proposed standards nor any of the three alternatives adequately address the inherent market uncertainties and potential for noncompliance that exists within the agency's ambitious timeline. Rather, the proposal sets the stage for what may be a profoundly disruptive and costly set of noncompliance obligations across the industry. We respectfully urge the agency to finalize a more reasonable emissions reduction trajectory, along with a broader array of compliance flexibilities. We believe that standards in line with Honda's publicly stated electrification targets are representative of a challenging but workable requirement. [EPA-HQ-OAR-2022-0829-0652, pp. 32-33]

Organization: American Lung Association (ALA) et al.

Fortunately, the Inflation Reduction Act (IRA) and the Infrastructure Investment and Jobs Act (IIJA) provide for hundreds of billions in investment in cleaner vehicles, energy and infrastructure to accelerate the transition away from combustion to protect health across the nation. Further, seven states have so far adopted the Advanced Clean Cars II program (ACCII) that sets a 100 percent sales requirement by 2035. EPA's stronger standards through Model Year 2026 were strengthened to deliver a critical ramp to greater zero-emission technology pathways. Given these developments and the rapid growth in the zero-emission vehicle market, we view the proposed standards and stronger Alternative 1 as strong starting points for approving stringent standards in 2023. [EPA-HQ-OAR-2022-0829-0745, p. 2]

Therefore, we recommend that EPA set multi-pollutant passenger vehicle standards for 2027 and later years that:

Build upon the more stringent Alternative 1 Greenhouse Gas Proposal
EPA's proposal includes a more stringent Alternative 1 that should be strengthened and adopted as the final rule. Alternative 1 provides for a more stringent standard of approximately 10 mg/mile of greater GHG emission reductions. This is a good start that should be strengthened further to achieve greater reductions in the later years of the program beyond 2030. The final rule should be based upon increasingly tighter standards beyond the 2030 timeframe to exceed the benefits of the proposed rule, but to also accelerate emission reductions in the later years of the rule. As noted above, a growing number of states have adopted the Advanced Clean Cars II program to establish a 100 percent zero-emission vehicle sales standard for model year 2035. EPA's proposal estimates that one technology pathway for compliance could see battery electric vehicles representing nearly 70 percent of new vehicle sales by 2032. Setting the Alternative 1 GHG standard in line with the states' pathway to 100 percent sales in 2035 would increase the benefits of the standard. [EPA-HQ-OAR-2022-0829-0745, p. 2]

Health Benefits of Zero-Emission Technologies

EPA's proposals note the significant clean air benefits of the proposed rule and illustrate the increased benefits of the stronger Alternative 1. The American Lung Association's recent "Driving to Clean Air" report highlighted that approaching a 100 percent zero-emission sales scenario by 2035, along with a non-combustion electricity generation grid, could result in major health benefits. The report found that the cumulative health benefits could reach $978 billion by 2050, including nearly 90,000 premature deaths avoided, over 2 million asthma attacks avoided and more than 10 million lost workdays avoided due to cleaner air.4 EPA's analysis shows that a potential compliance pathway for the proposal could result in nearly 70 percent of new vehicle sales being battery electric vehicles by 2032. We call on EPA to continue the trajectory of a stronger Alternative 1 to include more stringent GHG standards through 2035. [EPA-HQ-OAR-2022-0829-0745, p. 3]

4 American Lung Association. "Driving to Clean Air." June 2023. https://www.lung.org/clean-air/electric-vehicle-report/driving-to-clean-air.

Organization: Arconic Corporation (ARCO)

6. EPA is soliciting comment on the proposed standards as well as Alternatives 1, 2, and 3. EPA anticipates that the appropriate choice of final standards lies within this range. We understand the suggested three alternatives to the proposed standards to be:

- Alternative 1 is more stringent than the proposal across the MY 2027-2032 time period-on average 10 g/mile lower than the proposed targets. [EPA-HQ-OAR-2022-0829-0741, pp. 3-4]

- Alternative 2 is less stringent than the proposal across the MY 2027-2032 time period-on average 10 g/mile higher than the proposed targets. [EPA-HQ-OAR-2022-0829-0741, pp. 3-4]

- Alternative 3 achieves the same stringency as the proposed standards in MY 2032 but provides for a more consistent rate of stringency increase for MY 2027-2031. This has the effect of less stringent year-over-year increases in the early years of the program. [EPA-HQ-OAR-2022-0829-0741, pp. 3-4]

Arconic suggests revising the definition of emissions for BEVs to include the upstream power generation emissions. Revising this definition would likely require some modification to the yearly emissions targets. With targets modified in this manner, Arconic does not have a position on the trajectory (i.e., the levels of year-over-year stringency rates) in this rule making. [EPA-HQ-OAR-2022-0829-0741, pp. 3-4]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

CARB finds that a more stringent set of standards, and thus certainly the proposed standards as well, are technically feasible and cost-effective and recommends that U.S. EPA incorporate CARB's recommendations and adopt the most stringent standards feasible. [EPA-HQ-OAR-2022-0829-0780, p. 67]

Organization: California Attorney General's Office, et al.

Our States and Cities1 hereby submit these comments in response to the United States Environmental Protection Agency's ("EPA") notice of proposed rulemaking titled "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles." 88 Fed. Reg. 29,184 (May 5, 2023) ("Proposal"). We strongly support increasing the stringency of EPA's greenhouse gas ("GHG") and criteria pollutant emissions standards, and we urge EPA to adopt standards more stringent than the proposed standards. [EPA-HQ-OAR-2022-0829-0746, p. 1]

> 1 The States of California, Colorado, Connecticut, Delaware, Hawaii, Illinois, Maine, Maryland, Minnesota, New Jersey, New Mexico, New York, North Carolina, Oregon, Rhode Island, Vermont, Washington, and Wisconsin; the Commonwealths of Massachusetts and Pennsylvania; the District of Columbia; the City and County of Denver; and the Cities of Chicago, Los Angeles, New York, and Oakland.

EPA has long recognized that GHG and criteria pollutant emissions from new motor vehicles and new motor vehicle engines endanger public health and welfare, and, under Section 202(a) of the Clean Air Act, this recognition triggers a mandatory duty to reduce such emissions. The technologies necessary to reduce GHGs and criteria pollutants from new motor vehicles already exist and are widely in use in the market today. The costs of these technologies are reasonable and declining, and the application of these technologies generally results in consumers saving money over the life of a new vehicle. Moreover, the societal benefits of more stringent standards significantly exceed the costs of those standards. EPA thus has every reason to adopt stronger emissions standards to satisfy its statutory mandate to reduce emissions of harmful air pollution. [EPA-HQ-OAR-2022-0829-0746, p. 1]

In the Proposal, EPA set forth four alternative sets of GHG standards: the proposed standards, a more stringent alternative (Alternative 1), a less stringent alternative (Alternative 2), and an alternative similar in stringency to the proposed standards on a different timeline (Alternative 3). [EPA-HQ-OAR-2022-0829-0746, pp. 1-2]

We believe that the record before the agency supports the adoption of standards more stringent than the proposed standards and accordingly set forth potential improvements to EPA's models and compliance program below. As EPA recognizes in the Proposal, the necessary emission control technologies have already been developed and brought to market, and automakers have been planning for substantially more stringent standards in large portions of the global market. In addition, the crediting flexibilities already built into the program (which EPA has not reopened)—including the ability to trade, carry-forward, and carry-back credits—place automakers in even better positions to craft strategies to comply with more stringent standards. [EPA-HQ-OAR-2022-0829-0746, pp. 1-2]

As discussed below, the need for more stringent standards is critical, and the industry's ability to meet stronger standards and to cost-effectively reduce dangerous pollution is clear. We urge EPA to adopt standards more stringent than the proposed standards. [EPA-HQ-OAR-2022-0829-0746, pp. 1-2]DISCUSSION

EPA's proposed standards carry out the purpose and requirements of Section 202(a) of the Clean Air Act. See 42 U.S.C. § 7521(a). The proposed standards would reduce current and impending threats to public health and welfare and provide manufacturers sufficient lead time to apply the requisite emission control technologies, all at reasonable costs of compliance. However, given that emissions reductions beyond the proposed standards are feasible and cost-effective, our States and Cities urge EPA to adopt standards more stringent than the proposed standards. [EPA-HQ-OAR-2022-0829-0746, p. 27]

Standards more stringent than EPA's proposed standards would comport with its statutory mandate in Section 202(a) and further the statutory objective by reducing the threats from vehicle pollution to public health and welfare. EPA projects that the proposed standards will reduce GHG emissions by more than 7.3 billion metric tons of carbon dioxide (CO2), 120,000 metric tons of methane (CH4), and 130,000 metric tons of nitrous oxide (N2O) through 2055, in addition to criteria pollutant reductions of 44,000 tons per year of nitrogen oxides (NOx), 9,800 tons per year of fine particulate matter (PM2.5), 200,000 tons per year of non-methane organic gases (NMOG), 2,800 tons per year of sulfur oxides (Sox), and 1.8 million tons per year of carbon monoxide (CO) by 2055. 88 Fed. Reg. at 29,348 (Table 135); id. At 29,351 (Table 139). More emission reductions are feasible. See CARB Comment at 17-22. Given EPA's description of these emissions reductions as an "essential factor" in its determination of the appropriate level of the proposed standards, id. At 29,344, and the primacy Congress placed on addressing pollution's danger to public health and welfare in Section 202(a), 42 U.S.C. § 7521(a)(1), our States and Cities urge EPA to increase the stringency of its standards beyond those proposed. [EPA-HQ-OAR-2022-0829-0746, p. 28]

Our States and Cities agree with EPA's recent conclusion that, in light of the "increased urgency of the climate crisis," the United States needs "to achieve far deeper GHG reductions from the light-duty sector in future years beyond the compliance timeframe for the [2023-26] standards." 86 Fed. Reg. 74,434, 74,498 (Dec. 30, 2021). EPA's proposed standards are an important step toward those deeper reductions, but it can go further. Standards that effectively require the production and deployment of lower-emitting and zero-emission vehicles will promote longer- term, deeper emissions reductions critical to avoiding catastrophic impacts of climate change. [EPA-HQ-OAR-2022-0829-0746, p. 29]

C. The Benefits of the Proposed Standards Significantly Outweigh their Costs

Our States and Cities agree with EPA's practice to "set standards to achieve improved air quality consistent with [S]ection 202, and not to rely on cost-benefit calculations, with their uncertainties and limitations, as identifying the appropriate standards." 88 Fed. Reg. at 29,198. Likewise, we agree that EPA's cost-benefit analysis "reinforces [EPA's] view that the proposed standards are appropriate," id., and we believe it also supports adoption of standards more stringent than the proposed standards. To promote transparency and clarity around the proposed standards, we add a few comments pertinent to EPA's cost-benefit analysis below. [EPA-HQ-OAR-2022-0829-0746, p. 36]

Organization: CALSTART

2. Adopt the strongest possible option, providing stringency which is at least as strong as Alternative 1. [EPA-HQ-OAR-2022-0829-0618, p. 2]

At a high level, strong standards maintain the recent positive momentum in the light duty sector and provide a regulatory framework that complements the historic incentives of the Bipartisan Infrastructure Law (BIL) and Inflation Reduction Act (IRA) and is consistent with the current market. We applaud EPA staff for its ambitious and highly necessary Phase 2 stringency and encourage EPA to adopt a Phase 3 at least as stringent as Alternative 1. Below, we describe our justification for Recommendation 1 (closing the footprint loophole) and then discuss the drivers, barriers, and possible solutions to Recommendations 2-4 (adopting standards at least as stringent as Alternative 1, and extending the standards through 2035, and sending clear market signals). [EPA-HQ-OAR-2022-0829-0618, p. 2]

1. Ecosystem-Supportive Activities

This regulation represents a historic step in transitioning the automotive industry toward 100% sales of ZEVs. The proposed rule works in concert with IIJA, IRA, ACC II, LCFS, and other critical clean transportation programs that will reduce tailpipe emissions and increase the number and quality of light-duty ZEVs and plug-in hybrid electric vehicles (PHEVs) on the road. With game changing federal incentives now in place and stringent California regulations leading the way, the EPA now has the opportunity to match these incentives and guide the nation towards accelerated light-duty vehicle decarbonization with a Phase 3 standard at least as stringent as Alternative 1. Transitioning light-duty vehicles to electric power will dramatically improve air quality as well as substantially reduce greenhouse gas emissions due to the progressively cleaner energy generation portfolio of the nation's electrical grid. [EPA-HQ-OAR-2022-0829-0618, p. 3]

3. Fleet Electrification

A strong Light-Duty and Medium-Duty Vehicles standard will enable businesses small and large to electrify their light duty fleets and operations, which will result in cost savings through lower fuel and maintenance costs, a significant reduction in the risks that volatile fuel prices and supply pose to the economy and will help those businesses meet their climate goals. Coupled with incentives and programs associated with the IRA, the EPA's Alternative 1 proposed standards will accelerate electric vehicle adoption and allow manufacturers to meet the demand of businesses and consumers across the country. [EPA-HQ-OAR-2022-0829-0618, p. 5]

For example, CALSTART recently hosted a Ride and Drive event in Fresno, California on behalf of CARB's Advanced Clean Fleets (ACF) Rule. In support of this rule, CALSTART launched its Cal Fleet Advisor program that educates and offers fleets assistance as they work to electrify and meet ACF requirements. [EPA-HQ-OAR-2022-0829-0618, p. 5]

After meeting with dozens of fleets in Fresno, one takeaway became clear: most of these fleets were not planning to electrify until they were regulated to do so, but now that a clear time horizon has been set, they are beginning the necessary conversations with utilities, OEMs, and other relevant stakeholders. [EPA-HQ-OAR-2022-0829-0618, p. 5]

The lack of a clear and ambitious requirement like ACF was bottlenecking progress rather than technical and market limitations. Similarly, a clear and expedited timeline like Alternative 1 and beyond will drive fleets to make electrification a priority. Ultimately, this will benefit fleets with lifetime cost savings, reduced local air pollution, and climate mitigation. [EPA-HQ-OAR-2022-0829-0618, p. 5]

Organization: Center for American Progress (CAP)

CAP Recommendations:

1. Based upon the above considerations, CAP urges EPA to adopt a final rule that reflects its Alternative 1 proposal with the following modifications:

a. Increase Later Year Stringency–Alternative 1 features robust emissions reductions from 2027 through 2029, with emissions targets decreasing by at least 17 g/mi between those years.22 This continued pace of increasing stringency is essential to ensuring the uptake of available technologies that reduce greenhouse gas (GHG) emissions. However, the potential benefits of this robust ramp up may be lost due to a lack of continued stringency in the latter years of the rule from 2029 through 2032, during which time emissions targets only decrease by a maximum of 9 g/mi per year.23 EPA should improve upon its Alternative 1 stringency levels between 2029 and 2032 to achieve more significant emissions reductions in its final rule. Failing to do so could undermine the standard because automakers could count on credits generated by overcompliance during the rule's later years to delay investments in emissions reducing technologies. [EPA-HQ-OAR-2022-0829-0658, p. 5]

22 U.S. Environmental Protection Agency, "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles Draft Regulatory Impact Analysis," April 2023, available online: https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf

23 Ibid.

b. Maintain Early Year Ramp-up–Likewise, it is also critical that EPA maintain Alternative 1's ramp up between 2027 and 2029 to encourage investments in proven technologies to reduce emissions and avoid automakers delaying investments in compliance technologies that are available now. As noted previously, automakers are making historical investments in EV manufacturing and technology24. A weakening of the early year ramp up could potentially allow for overcompliance during those years, with credits being relied upon for compliance in later years. Such delay would needlessly increase the volume of higher emission vehicles to the American vehicle fleet for decades to come. [EPA-HQ-OAR-2022-0829-0658, p. 5]

24 Environmental Defense Fund, "U.S. Electric Vehicle Manufacturing Investments and Jobs," March 2023, available online: https://www.edf.org/media/report-finds-investments-us-electric-vehicle-manufacturing-reach-120-billion- create-143000

Organization: Ceres BICEP (Business for Innovative Climate and Energy Policy) Network

The BICEP Network commends the U.S. Environmental Protection Agency (EPA) for proposing multipollutant emission standards for light- and medium-duty vehicles (LMDV) through Model Year (MY) 2032 and urges EPA to finalize standards aligned with U.S. climate commitments. As businesses with footprints across the country, BICEP network companies seek greater availability of clean vehicles in every state to reduce consumer and business transportation costs as well as greenhouse gas (GHG) emissions, protect public health, and enhance the global competitiveness of U.S. industry. [EPA-HQ-OAR-2022-0829-0600, p. 1]

Specifically, the BICEP Network urges EPA to adopt light-duty vehicle (LDV) GHG emissions standards at least as strong as Alternative 1 through 2030, and stronger thereafter. The BICEP Network also urges EPA to adopt LDV criteria pollutant standards and medium-duty vehicle (MDV) multi-pollutant emissions standards at least as stringent as currently proposed. To ensure alignment with U.S climate goals, support businesses in reducing transportation costs, meeting corporate commitments, and address public health concerns, these regulations must drive a significant shift to electrification as well as ensure the efficiency of and reduce criteria pollutants from internal combustion engine (ICE) vehicles. [EPA-HQ-OAR-2022-0829-0600, p. 1]

Existing policies, market trends, and available funding, including the Advanced Clean Cars II (ACC II) rule adopted by California and six other states; manufacturer and corporate zero-emission vehicle (ZEV) commitments; and the significant incentives provided by the Infrastructure Investment and Jobs Act (IIJA) and the Inflation Reduction Act (IRA) for vehicle and battery manufacturers, purchasers, and charging infrastructure, all justify standards supporting greater ZEV sales shares. [EPA-HQ-OAR-2022-0829-0600, p. 1]

BICEP Network companies see climate change as a significant business risk, reducing GHG emissions as a major economic opportunity, and recognize the urgency of ensuring near-term reductions. In its most recent March 2023 report,1 the International Panel on Climate Change (IPCC) emphasized the necessity to "massively fast-track climate efforts by every country and every sector and on every timeframe,"2 underscoring the urgency of drastically reducing GHG emissions by 2030. Given that the transportation sector is the largest source of U.S. GHG emissions,3 strong vehicle emission standards are critical to meeting U.S. climate goals. Recent analysis from the International Council of Clean Transportation (ICCT) concludes that aligning the light-duty vehicle sector with climate goals would require a 77% zero- emission vehicle (ZEV) sales share in 2030.4 A key finding of BloombergNEF's 2023 Electric Vehicle Outlook was that "(d)irect electrification via batteries is the most efficient, cost-effective and commercially available route to fully decarbonizing road transport."5 Although ICCT predicts that IRA incentives could stimulate up to 56-67% electric vehicle sales by 2032,6 even Alternative 1 falls short of this level of electric vehicle sales share, let alone what is needed to meet climate goals. Further, given that ICE vehicles will make up the majority of the fleet for many years, it is also necessary to ensure greater GHG reductions from these vehicles. [EPA-HQ-OAR-2022-0829-0600, pp. 1-2]

5 https://about.bnef.com/electric-vehicle-outlook/.

6 https://theicct.org/publication/ira-impact-evs-us-jan23/ (p. ii).

BICEP members' abilities to meet their own climate commitments are contingent on strong standards that will ensure the availability of clean vehicles across the U.S. and drive the necessary shift to electrification. Unfortunately, the U.S. currently lags behind the European Union and China in EV sales,7and a recent study projects a shortage of EVs needed to meet American consumer demand.8 Strong U.S. vehicle emission standards are necessary to ensure the availability of clean vehicles for our members and the global competitiveness of the U.S. auto industry. [EPA-HQ-OAR-2022-0829-0600, pp. 1-2]

8 https://advocacy.consumerreports.org/wp-content/uploads/2023/03/Excess-Demand-The-Looming-EV-Shortage.pdf.

Thus, on behalf of the companies in the BICEP network, I urge EPA to adopt light-duty vehicle (LDV) GHG emissions standards at least as strong as Alternative 1 through 2030, and stronger thereafter. I also urge EPA to adopt LDV criteria pollutant standards and medium-duty vehicle (MDV) multi-pollutant emissions standards at least as strong as those currently proposed to mitigate climate risk, strengthen U.S. economy, and address public health and equity concerns. [EPA-HQ-OAR-2022-0829-0600, p. 3]

Organization: Ceres Corporate Electric Vehicle Alliance (CEVA)

The Alliance applauds the Environmental Protection Agency (EPA) for its commitment to adopting multi-pollutant emissions standards for Model Years (MY) 2027 and later light- and medium- duty vehicles and greenhouse gas (GHG) emissions standards for heavy-duty vehicles, and urges EPA to align these standards with U.S. climate and public health goals.1 Specifically, the Alliance supports: [EPA-HQ-OAR-2022-0829-0511, p. 1]

1 https://www.energy.gov/sites/default/files/2023-01/the-us-national-blueprint-for-transportation-decarbonization.pdf

-Light-duty vehicle GHG emissions standards aligned with Alternative 1, the strongest standard proposed in this rulemaking, which will result in a 59% reduction in average fleetwide carbon dioxide emissions by MY2032 from a MY2026 baseline. The Alliance also encourages EPA to move forward with its proposed criteria pollutant emissions standards for light-duty vehicles, reducing fleetwide average MY2032 criteria pollutant emissions 60% from MY2025 levels.2 [EPA-HQ-OAR-2022-0829-0511, p. 1]

2 https://www.epa.gov/system/files/documents/2023-04/lmdv-multi-pollutant-emissions-my-2027-nprm-2023-04.pdf (p.42)

-Medium-duty vehicle (Class 2b and 3) multi-pollutant emissions standards aligned with its current proposal, which will ensure a 44% reduction in average fleetwide GHG emissions by MY2032 from a MY2026 baseline, and a 66 76% reduction in criteria pollutant emissions by MY2032 from a MY2025 baseline.3 [EPA-HQ-OAR-2022-0829-0511, p. 1]

3 Ibid. (p.42)

https://ww2.arb.ca.gov/sites/default/files/2023-06/ACT-1963.pdf (p.5)

Light- and Medium-Duty Vehicle Standards:

Coupled with the significant financial incentives of the Inflation Reduction Act, EPA's Alternative 1 proposed standards for light-duty vehicles will galvanize manufacturers to improve battery technology, increase ZEV range, and boost production volume, thus providing more affordable and operationally diverse zero-emission light-duty vehicles as the ZEV market matures. Alternative 1 will go farthest in supporting Alliance members' fleet electrification goals, many of which aim to reach full fleet electrification by 2030 or soon thereafter. [EPA-HQ-OAR-2022-0829-0511, p. 2]

Organization: Colorado Energy Office, Colorado Department of Transportation, and Colorado Department of Public Health and Environment

In response to EPA's request for comments on specific aspects of the rule, we offer the following suggestions to ensure the rule is as successful as possible:

- EPA requested comment on what levels of carbon dioxide (CO_2) emissions stringency to pursue between 2026 and 2032, and suggested one recommended stringency schedule and three alternative schedules. We believe that the federal government needs to streamline widespread adoption of EVs to avoid the inefficiency that comes with significantly varied markets across the country. At times, it has been hard to get the products consumers want in Colorado, because the initial stock of popular models gets sent to larger states like California even though our state is an ideal market with strong EV incentives. For example, the State of Colorado put In an order for over 100 Ford F-150 Lightnings, but only four have been delivered thus far. Similarly, it has been challenging for consumers to access popular models with great potential for mountain driving, such as the Toyota RAV-4 Prime. Thankfully, delivery times are starting to improve, but as the supply chain normalizes, it is critical that states like Colorado have equal access to the full range of vehicle choices, and that will be enhanced by the federal government taking the lead on regulations that normalize production and delivery across the country. Alternative 1 would provide the most consistency with what Colorado is already pursuing. We urge the federal government to place even greater focus on consistency and streamlining of regulations in order to help us accelerate EV adoption with the urgency that we need. [EPA-HQ-OAR-2022-0829-0694, pp. 2-3]

Organization: Darius

I write in opposition to the U.S. Environmental Protection Agency's proposed multipollutant standards for light-and medium-duty vehicles (Docket ID No. EPA-HQ-OAR-2022-0829). I have serious concerns with all three of the options included in the draft rulemaking, as the EPA seeks to lower carbon emissions under timelines that effectively make electric vehicles the only option for automakers to meet the pollution limits from 2027 through 2032. [EPA-HQ-OAR-2022-0829-0519, p. 1]

The future of automotive technology matters to consumers, millions of automotive enthusiasts, and all the men and women who work in the industry. Accordingly, I ask that the EPA does not follow through on any of the three options outlined in this proposed rulemaking and instead pursues a rulemaking for light and medium-duty vehicles that embrace a technology-neutral approach that factors in the infrastructure that exists, the innovation we are all capable of, consumer preferences, and the lifecycle emissions of the technology that powers our vehicles. [EPA-HQ-OAR-2022-0829-0519, p. 1]

Organization: District of Columbia Department of Energy and Environment (DOEE)

DOEE supports EPA's action to address light-duty and medium-duty vehicle emissions. DOEE believes the Proposal and Alternatives 2 and 3 are not sufficiently stringent to ensure the health, prosperity, and safety of citizens, particularly those who are already overburdened and vulnerable to air pollution from vehicles. DOEE supports the multipollutant emissions standards in Alternative 1 as it is projected to result in industry-wide reductions of 61 percent (61%) in fleet average GHG emissions target levels from existing MY 2026 standards. Alternative 1 also boasts CO2 levels that are 10 g/mi lower on average than the proposed targets and reduces greenhouse gasses (GHG) at more significant rates than either the Proposal, Alternative 2, or Alternative 3. [EPA-HQ-OAR-2022-0829-0550, p. 1]

EPA Proposal and Alternatives 1, 2, and 3

DOEE recognizes that EPA's proposed light-duty and medium-duty Multi-Pollutant Emissions Standards requiring lower vehicle emissions are feasible and appropriate under the Clean Air Act (CAA). The proposed rulemaking, while it falls short, is a necessary important step toward meeting climate goals and cleaner, healthier air. As EPA illustrates, there is a critical need for further criteria pollutant and GHG reductions to address the adverse impacts of air pollution from light and medium duty vehicles on public health and welfare. With continued advances in internal combustion emissions controls and vehicle electrification technologies coming into the mainstream as primary vehicle emissions controls, EPA believes substantial further emissions reductions are feasible and appropriate under the Clean Air Act. 88 FR 29341. [EPA-HQ-OAR-2022-0829-0550, pp. 1-2]

Vehicle emission reduction technology advancements validate substantial reductions in vehicle emissions to impactfully address climate change and people's health. Eliminating polluting emissions from vehicles is crucial to protect public health and mitigate the negative effects of climate change. EPA has demonstrated in its proposal that light- and medium-duty emissions reductions are both technologically feasible and will result in varying degrees of health benefits. Despite each proposal's feasibility and health benefits, DOEE finds that EPA's Proposal, Alternative 2, and Alternative 3 are insufficient in comparison to the feasible Alternative 1. Alternative 1 provides a stronger foundation for improving quality of life and mitigating detrimental climate change impacts. Therefore, DOEE recommends that EPA adopts Alternative 1. [EPA-HQ-OAR-2022-0829-0550, pp. 1-2]

As EPA mentions in Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles Section II, without substantial changes to the way people drive, how people travel, or what people use to travel, the District, and the United States as a whole, will not avoid the worst consequences of climate change. EPA recognizes that vehicles, including passenger vehicles, are major sources of air pollution and poor health, yet the proposed rulemaking from EPA fails to be analogous to the severity of the ensuing climate change impacts. In fact, [EPA-HQ-OAR-2022-0829-0550, p. 2]

EPA proposes to find that standards substantially more stringent than Alternative 1 would not be appropriate because of uncertainties concerning the cost and feasibility of such standards. EPA proposes to find that standards substantially less stringent than Alternative 2 or 3 would not be appropriate because they would forgo feasible emissions reductions that would improve the protection of public health and welfare. 88 FR 29201. [EPA-HQ-OAR-2022-0829-0550, p. 2]

DOEE recognizes that the costs involved in implementing and meeting stringent emissions requirements would be high. However, DOEE disagrees that standards substantially more stringent than Alternative 1 would be inappropriate due to cost and feasibility. The cost of inaction or insufficient action toward eliminating vehicle emissions in conjunction with climate change will be far greater to both public and environmental health and welfare. [EPA-HQ-OAR-2022-0829-0550, p. 2]

Summary

It is crucial that EPA promulgate the new criteria pollutant and greenhouse gas emission standards for light-duty and medium-duty vehicles in a timely fashion. DOEE urges the EPA to alleviate air pollution burdens by adopting vehicle emission standards as strict as those stated in Alternative 1. The criteria pollutant and greenhouse gas emission standards in Alternative 1 will result in tangible and sufficient emission reductions that substantially reduce adverse health burdens while mitigating further disastrous health, climate, and environmental consequences. The cost of inaction on the health of people and the environment far outweighs the cost of a rulemaking requiring zero or near-zero emission vehicles. [EPA-HQ-OAR-2022-0829-0550, p. 6]

Organization: Elders Climate Action

The latest climate modeling report (AR6) from the Intergovernmental Panel on Climate Change (IPCC) now makes clear that exceeding 1.5o C before 2050 is "more likely than not" even with implementation of the most aggressive GHG reduction scenario, but that the excursion above 1.5o C can be limited to a few decades if we reduce GHG emissions by half before 2030, and achieve net zero emissions by 2050. But if we fail to meet either of those targets, it is "more likely than not" that global temperatures will reach 2.0 o C with dire consequences for humanity. [EPA-HQ-OAR-2022-0829-0737, pp. 10-11]

To achieve net-zero emissions economy wide by 2050, zero emission technologies currently available must be deployed as soon as possible to put GHG emissions from our largest source of emissions – transportation – on the path toward zero. EPA's proposed rule merely reduces carbon fuel combustion by less than 1%. A zero emission economy cannot be achieved if vehicles continue to burn carbon fuels. Internal combustion engines (ICEs) must be replaced as quickly as possible by zero emission vehicles (ZEVs). [EPA-HQ-OAR-2022-0829-0737, pp. 10-11]

EPA's proposed L/MDV rule does not chart a course toward implementing either the national policy declared by President Biden or reflect the urgent need to cut GHG emissions in half by 2030 to avoid much worse future climate catastrophes. The rule preamble acknowledges that the proposed rule changes will reduce L/MDV CO_2 emissions by only .2 MMT during MY 2027 from 29 MMT to 28.8 MMT. Over the 20 year useful life of vehicles sold in MYs 2027-29 the rule will allow millions of diesel and gasoline vehicles to be added to the Nation's highways which will emit an estimated 1.7 billion MT of CO_2. These emissions will wipe out more than half of the 3.1 billion MT of CO_2 reduction achieved by EPA's SAFE 2 rule for light duty vehicles. These L/MDV emissions are the equivalent of operating 21 new coal-fired power plants. A large fraction of these emissions could be avoided if EPA adopted the CARB zero emission standard for L/MDVs in the ACT rule. The rule does not achieve, or describe how it will contribute to achieving, zero emissions by 2050. [EPA-HQ-OAR-2022-0829-0737, pp. 10-11]

We ask EPA to revise the rule to set a zero emission standard for all new L/MDVs by 2035, and establish a phase-in schedule for the standard that includes ZEV sales targets for MYs 2027-29 that are the same as the CARB ACT rule. [EPA-HQ-OAR-2022-0829-0737, pp. 10-11]

ZEV sales targets are needed now – [EPA-HQ-OAR-2022-0829-0737, pp. 10-11]

- to establish benchmarks for all engine manufacturers to create a level playing field that promotes competitive market conditions for zero emission vehicles based on performance, reliability and cost;

- to ensure a market for ZEVs that will justify early investment by third parties in the development of supply chains needed for production of batteries and fuel cells;

- to ensure the capacity of the industry to ramp up to 100% of sales to ensure that ZEVs will be available in time to replace on-road ICE vehicles by 2050;

- for MY 2027 to give the industry enough lead time to develop supply chains, plan the conversion of production facilities and develop marketing campaigns designed to assure public acceptance of their products. [EPA-HQ-OAR-2022-0829-0737, pp. 10-11]

Organization: Electrification Coalition (EC)

To mitigate the impacts of climate change and to reduce national and economic security threats, the U.S. needs a solution that will decarbonize our economy, reduce dependence on oil and position the U.S. to maintain our status as a global leader in a new economy that is based on minerals. The shift to electricity as a fuel source, also called transportation electrification, is the solution to this triad of concerns. [EPA-HQ-OAR-2022-0829-0588, pp. 2-3]

For these reasons, the adoption of the strongest possible proposal would significantly limit the greenhouse gas emissions from internal combustion engine vehicles and require them to be cleaner, bringing the market for these internal combustion engine vehicles to the tipping point and thereby accelerating the adoption of EVs. The EPA forecasts that the proposed rule would lead to 67% of new sales of LD/MD vehicles being zero-emission (electric) in 2032, depending on the vehicle type. [EPA-HQ-OAR-2022-0829-0588, pp. 2-3]

Therefore, the EC supports the adoption of the strongest possible proposal, as it will accelerate the adoption of EVs in the LD/MD sector. [EPA-HQ-OAR-2022-0829-0588, pp. 2-3]

Organization: Energy Innovation

Energy Innovation appreciates the opportunity to submit these comments to the U.S. Environmental Protection Agency (EPA) regarding its Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles (proposed rule). Energy Innovation is a nonpartisan energy and climate policy firm. We provide independent analysis and science-based research to policymakers and other decision-makers seeking to understand which policies are most effective to ensure a climate-safe future for all. Our team has expertise in modeling climate policy, including policies that support a cleaner power grid and electrify transportation, buildings, and industry. Our recommendations are data-driven and informed, in part, by our peer-reviewed Energy Policy Simulator (EPS) model. [EPA-HQ-OAR-2022-0829-0561, p. 1]

We appreciate the EPA's extensive work to develop these proposed emissions standards for criteria pollutants and greenhouse gases for light-duty and medium-duty vehicles (LDVs and MDVs, respectively) for model years 2027 (MY 2027) and later. We commend the EPA's diligent analysis in its development of the proposed rule, which reflects the impact of new federal and state policies and advances in clean vehicle technologies. The EPA has set forth a proposed rule that aligns with its statutory directive in Section 202(a)(1) of the CAA to enhance the stringency of LDV and MDV vehicle tailpipe standards needed to reduce emissions that endanger public health and welfare: "'the Administrator shall by regulation prescribe (and from time to time revise)…standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles … which in his judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare.'"1 We concur with the EPA's analysis that the proposed rule and Alternative 1 are aligned with its statutory directive—the proposed more stringent standards offer technologically feasible and cost-effective options to reduce harmful GHG and other air polluting emissions over the timeframe the standards would be in place. [EPA-HQ-OAR-2022-0829-0561, p. 1]

1 U.S. EPA, "Proposed Rules: Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles (EPA–HQ–OAR–2022–0829; FRL 8953–03– OAR)," Federal Register 88, no. 87 (May 5, 2023), https://www.govinfo.gov/content/pkg/FR-2023-05-05/pdf/2023-07974.pdf, 29231-2.

II. Modeling shows that new federal policies combined with state policies will advance the battery electric vehicle (BEV) market faster, which supports the EPA's adoption of the more stringent Alternative 1 in the proposed rule. [EPA-HQ-OAR-2022-0829-0561, p. 2]

In the EPA's proposed rule, the GHG tailpipe standards for LDVs are "projected to result in an industry-wide average target for the light-duty fleet of 82 grams/mile (g/mile) of carbon dioxide (CO_2) in MY 2032, representing a 56 percent reduction in projected fleet average GHG emissions target levels from the existing MY 2026 standards."12 The proposed GHG standards for MDVs are "projected to result in an average target of 275 grams/mile of CO_2 by MY 2032, which would represent a reduction of 44 percent compared to the current MY 2026 standards."13 The proposed rule will also reduce cumulative GHG emissions between 2027 and 2055: CO_2 by 26 percent, methane (CH_4) by 17 percent, and nitrous oxide (N_2O) by 25 percent, compared to no-action scenario.14 See table 135 below from the proposed rule. [EPA-HQ-OAR-2022-0829-0561, pp. 5-7]

12 U.S. EPA, "Proposed Rules," May 5, 2023, 29196.

13 U.S. EPA, 29196.

14 U.S. EPA, 29348.

[See original attachment for "Table 135 – Estimated GHG Impacts of the Proposed Standards Relative to the No Action Scenario, Light-Duty and Medium-Duty"]

While the proposed rule is an improvement over the status quo, greater emissions reductions via higher rates of electrification in the LDV and MDV sectors are needed to reduce harmful air pollutants and mitigate climate change. We believe EPA's alternative to the proposed rule (Alternative 1) is the preferred option (as discussed further below) because it will achieve greater emissions reductions more quickly, while still being technologically feasible and cost-effective. [EPA-HQ-OAR-2022-0829-0561, pp. 5-7]

Fortunately, the Inflation Reduction Act (IRA) and the Bipartisan Infrastructure Law (BIL) helped tip the scale in favor of climate-oriented investments and the adoption of zero-emission technologies,[ii] particularly battery electric vehicles (BEVs), and also hydrogen fuel cell electric vehicles (FCEVs).[iii] [EPA-HQ-OAR-2022-0829-0561, pp. 4-5] ii This includes technologies that eliminate tailpipe GHG emissions and other pollutants, namely battery electric vehicles (BEVs) for LDVs and MDVs.

iii Based on our analysis and current market trends, we do not anticipate FCEVs will play a sizable role in the LDV and MDV market for the foreseeable future. However, we recognize the value of technology-neutral standards.

Energy Innovation's modeling reveals that the IRA's transportation electrification incentives (combined with infrastructure investments in the BIL) can jump-start transportation decarbonization this decade. However, these federal policies are insufficient to cut the sector's GHG emissions at the pace needed to achieve the U.S. nationally determined contribution (NDC) and to align with the Paris Agreement to limit global warming and achieve net zero by 2050. Mitigating the transportation sector's (especially LDVs and MDVs) impact on the climate and public health will require additional policy and regulatory action in the next decade, including stronger federal tailpipe emissions standards. Our modeling shows that widespread deployment of clean vehicles, powered by a clean grid, can help reduce GHG emissions to meet the U.S. NDC.8 See Figures 1 and 2. [EPA-HQ-OAR-2022-0829-0561, pp. 4-5]

Closing the Emissions Gap Between the IRA and 2030 U.S. NDC. [EPA-HQ-OAR-2022-0829-0561, pp. 4-5]

As we discuss in the next section, BIL and IRA have put the U.S. on the cusp of a cleaner transportation future. Incentives and investments made possible by these laws will help tip the scale in favor of BEVs and zero- emission technologies. However, they are not enough to fully transform the transportation sector. The standards set forth in the final rule must be sufficiently stringent to expedite the shift away from polluting ICE vehicles for the sake of climate stability, human health, society, and future generations. [EPA-HQ-OAR-2022-0829-0561, p. 8]

II. MODELING SHOWS THAT NEW FEDERAL POLICIES COMBINED WITH STATE POLICIES WILL ADVANCE THE BEV MARKET FASTER, WHICH SUPPORTS THE EPA'S ADOPTION OF THE MORE STRINGENT ALTERNATIVE 1 IN THE PROPOSED RULE. [EPA-HQ-OAR-2022-0829-0561, p. 8]

We agree with the EPA that the passage of the BIL and IRA represent significant "support for investment in expanding the manufacture, sale, and use of zero-emission vehicles by addressing elements critical to the advancement of clean transportation and clean electricity generation in ways that will facilitate and accelerate the development, production and adoption of zero-emission technology during the time frame of the rule."20 Our modeling supports these findings. [EPA-HQ-OAR-2022-0829-0561, p. 8]

20 U.S. EPA, 29195.

A primary takeaway from the ICCT-EI Study analysis is that the IRA's financial incentives for vehicles and manufacturers enable and support the adoption of more stringent federal vehicle standards at a lower cost and higher benefit to consumers.25 However, EV sales shares from our analysis are not guaranteed. Federal tailpipe standards are a critical tool that give auto manufacturers clear direction to retool their production lines to produce ZEVs at scale. [EPA-HQ-OAR-2022-0829-0561, pp. 9-11]

25 Peter Slowik et al., "Analyzing the Impact of the Inflation Reduction Act on Electric Vehicle Uptake in the United States" (International Council on Clean Transportation and Energy Innovation, January 2023), https://energyinnovation.org/wpcontent/uploads/2023/01/Analyzing-the-Impact-of-the-Inflation-Reduction-Act-on-EV-Uptake-in-the-U.S..pdf.

The IRA incentives provide one lever to move the market, and the EPA's standards provide an additional lever. The ICCT-EI Study and other studies mentioned in the EPA's proposed rule point to "greatly increased penetration of electrification across the U.S. light-duty fleet in the coming years, without specifically considering the effect of increased emission standards under this proposed rule."26 Given that fact, it is reasonable to infer that the EPA's proposed rule represents more of a floor, not a ceiling. [EPA-HQ-OAR-2022-0829-0561, pp. 9-11]

26 U.S. EPA, "Proposed Rules," May 5, 2023, 29189.

Given the urgent need to reduce harmful GHG emissions and other tailpipe pollutants, any additional amount of emissions reductions that final standards can achieve is preferable to other alternatives. And modeling demonstrates that more emissions reductions are feasible in the time frame, given the availability of incentives in the BIL and IRA. [EPA-HQ-OAR-2022-0829-0561, p. 12]

In conclusion, we invite the EPA to rely on the ICCT-EI Study and other analyses to support adoption of the most stringent set of emission standards (Alternative 1) to accelerate the adoption of pollution-free BEVs. [EPA-HQ-OAR-2022-0829-0561, p. 12]

In the next section, we discuss several relevant factors that may further accelerate EV adoption and impact learning curves for BEV economics, which provide additional rationale for the adoption of the most stringent standards. [EPA-HQ-OAR-2022-0829-0561, p. 12]

Organization: Environmental. and Public Health Organizations

While the market is clearly heading in the right direction, EPA's standards should facilitate even greater deployment of zero-emission and combustion vehicle technologies to help protect the public from the destructive effects of climate change and air pollution generally. To this end, we urge EPA to finalize the strongest possible emission standards. While we do not believe it is necessary for EPA to set standards beyond 2032 at this point, it is critical that the final standards are sufficiently stringent through model year 2032 to ensure that the U.S. is on track to reach 100% new ZEV sales in 2035. The standards in Alternative 1, but with greater stringency after 2030, are feasible and would better serve EPA's statutory mandate to address the environmental and health impacts of air pollution from light- and medium-duty vehicles. Finalizing such standards will provide feasible, critical air pollution emission reductions, as directed by Congress in the Clean Air Act. [EPA-HQ-OAR-2022-0829-0759, pp. 8-9]

IV. EPA's Own Analysis Shows that Additional Stringency Is Feasible and Would Produce Greater Societal Benefits.

While we support the Proposed Standards, EPA must go further—specifically, by adopting Alternative 1 with a steeper increase in stringency after 2030 to ensure the country is on track to reach 100% new ZEV sales by 2035. As detailed throughout this comment letter, such standards are feasible and offer significantly more air pollution reductions, consumer savings, and societal benefits. And as EPA itself acknowledges, adopting less stringent standards where more stringent ones are achievable "would forgo feasible emissions reductions that would improve the protection of public health and welfare." 88 Fed. Reg. at 29201. In this section, we explain how EPA's own data show that final standards more stringent than the Proposed Standards are warranted. In the sections that follow, we detail the feasibility and superiority of Alternative 1 with a steeper increase in stringency after 2030. [EPA-HQ-OAR-2022-0829-0759, p. 24]

Alternative 1 also provides greater pollution reductions and societal benefits than the Proposed Standards. Under EPA's modeling, Alternative 1 would avoid 8,100 million metric tons (MMT) of CO2 emissions through 2055 relative to the No Action scenario, id. at 29203, tbl. 14, in contrast to the 7,300 MMT avoided under the Proposed Standards, id. at 29198, tbl. 3. Alternative 1 also provides greater reductions in criteria pollutants and air toxics. Compare id. at 29198-99, tbls. 4 and 5, to id. at 29203-05, tbls. 13-16. In addition, Alternative 1 has greater societal net benefits: ranging from $1,500-2,500 billion through 2055, id. at 29205-06, tbl. 17 (3% discount rate), depending on the values used for the GHG emission reductions, versus a range of $1,400-2,300 billion under the Proposed Standards. Id. at 29200, tbl. 6. [EPA-HQ-OAR-2022-0829-0759, p. 25]

EPA's analysis shows that Alternative 1 is also feasible. It relies on the same existing technology—vehicle electrification—at the core of the Proposed Standards, and the share of battery-electric vehicles (BEVs) in the new vehicle fleet projected by EPA under Alternative 1 is very similar to those under the Proposed Standards, with the share under Alternative 1 never exceeding those under the Proposed Standards by more than 3 percentage points through 2032. Id. at 29333, tbl. 99 (BEV penetration of 60% under the Proposed Standards in 2030, versus 63% under Alternative 1). While we are recommending that EPA finalize a modified version of Alternative 1 (which would yield higher levels of BEV penetration, as detailed in Section V below), EPA's analysis at least shows that BEV levels associated with Alternative 1 are eminently feasible. [EPA-HQ-OAR-2022-0829-0759, p. 25]

According to the Alliance for Automotive Innovation, in the first quarter of 2023, there were 55 BEV models and 40 Plug-in Hybrid (PHEV) models available in the United States, representing a variety of vehicle types, including sedans, crossovers, SUVs, and light-duty trucks.102 The technology is only improving, and the number of models of plug-in electric vehicles (PEVs, which include both BEVs and PHEVs) available in the U.S. is projected to reach 197 by the end of 2025.103 Higher levels of PEV adoption are already driven by strong consumer demand and greater model choice. And as is discussed throughout these comments, the charging infrastructure, electric grid, and vehicle supply chain will be able to accommodate the projected levels of BEVs—indeed, sending a strong regulatory signal will facilitate that process. Moreover, given the flexibility in EPA's program, as well as the fact that EPA's modeling did not include any PHEVs or improvements to combustion vehicle greenhouse gas emissions (and in fact projects increasing GHG emissions from the combustion vehicle fleet, as discussed in Section VI.A), it is likely that the levels of BEVs would be lower in the real-world than EPA projected as automakers employ such technologies to comply with the final standards. That is because making even minor improvements in combustion vehicle GHG emissions—or even simply holding the average emissions of the combustion vehicle fleet constant—or manufacturing PHEVs will allow automakers to achieve compliance with relatively fewer levels of ZEVs than EPA projected. [EPA-HQ-OAR-2022-0829-0759, p. 26]

Bartlett & Ben Preston, Automakers are Adding Electric Vehicles to Their Lineups. Her''s Wha''s Coming, Consumer Reports (Jan. 6, 2023),https://www.consumerreports.org/hybrids-evs/why-electric-cars-may-soon-flood-the-us-market-a9006292675/.

V. Outside Analysis Demonstrates the Significant Benefits of Stronger Emission Standards, Particularly Alternative 1 with a Steeper Increase in Stringency After 2030.

Outside analysis also shows the benefits of adopting final standards stronger than EPA proposed. Environmental Resources Management, Inc (ERM), one of the largest sustainability consultancies globally, was commissioned by NRDC to provide an independent, third-party analysis of EPA's proposed standards and alternative proposals, as well as a recommended approach. ERM's methodology, assumptions, and results are described throughout this section, and the ERM report is attached to this comment letter.104 ERM's analysis shows that Alternative 1 with a steeper increase in stringency after 2030 would produce significant societal benefits. [EPA-HQ-OAR-2022-0829-0759, p. 26]

104 Dave Seamonds, et al., ERM, Impacts of EPA Light-& Medium-Duty Multi-Pollutant Standards: National Scenario Results, June 2023 [hereinafter ERM, Impacts Report] (attached to this comment letter).

ERM's analysis employed a modeling framework that leveraged EPA's tools to inform and develop inputs to ERM's Benefit-Cost Analysis (BCA) framework. It is important to note that while this analysis is based on EPA's "baseline" scenario, we believe this "baseline" is ultimately not an accurate reflection of a "No Action" scenario, as it is overly conservative. We explore this further in Section XV, but ultimately the most relevant of the analyses that EPA considered supports baseline ZEV sales greater than the baseline levels projected in the "EPA No Action" scenario. [EPA-HQ-OAR-2022-0829-0759, p. 26]

Where possible, ERM mirrored EPA's methodology to keep its analytical approach and resultant comparisons consistent with EPA's approach in the Proposal, and to allow for an apples-to-apples comparison. [EPA-HQ-OAR-2022-0829-0759, p. 26]

Policy Scenarios

ERM investigated five different policy scenarios: EPA's no action "baseline" ("EPA No Action"); EPA's preferred approach ("EPA Main Proposal"); our recommended approach, which reflects greater increases in stringency after model year 2030 ("Alternative 1+"); EPA's strongest option ("EPA Alternative 1"); and EPA's weakest option ("EPA Alternative 3"). [EPA-HQ-OAR-2022-0829-0759, p. 27] Modeling Background

EPA's updated MOVES model (MOVES3.R3105) was utilized to model electric vehicle (EV) adoption rates (sales and in-use), vehicle miles traveled (VMT), and pollutant emissions by vehicle type. Cost assumptions (battery costs, incremental vehicle costs, charging equipment costs, etc.) and vehicle classification/identification information and sales shares were incorporated into both ERM's BCA framework and its modification and application of MOVES3.R3 data outputs. ERM's BCA framework was applied to compare and evaluate the impacts across several policy scenarios as compared to the EPA No Action case. [EPA-HQ-OAR-2022-0829-0759, p. 27]

105 Although MOVES3.R1 was used for L/MD rulemaking, MOVES3.R3 reflects an updated version of MOVES3.R1 but maintains relevant L/MDV data and assumptions.

SEE ORIGINAL COMMENT FOR PIE CHART–- Figure V.B-1: National Light- and Medium-Duty Vehicle Fleet106. [EPA-HQ-OAR-2022-0829-0759, p. 28]

106 ERM, Impacts Report at 6.

This pie chart is based on EPA's modified version of MOVES. EPA projects that the majority of vehicles subject to the rule will be SUVs and light trucks (~160 million), followed by passenger cars (i.e., sedans), which are projected to number just over 100 million vehicles. The remainder is made up of Class 2b (chassis-certified only) and Class 3 medium-duty vehicles, projected to number around 14 million vehicles nationwide; note that "incomplete" class 2b/3 vehicles covered by the proposed Phase 3 heavy-duty rulemaking were not included in this analysis. [EPA-HQ-OAR-2022-0829-0759, p. 28]

1. Reductions in greenhouse gas emissions will bring climate change benefits to environmental justice communities.

Reducing GHG emissions from light- and medium-duty vehicles will help reduce the significant harm that climate change inflicts on environmental justice communities. By 2055, the Proposed Standards would avoid 7,300 million metric tons (MMT) of CO2 emissions, 88 Fed. Reg. at 29198, tbl. 3, and EPA's calculations show the Proposal would produce climate benefits of between $82 and $1,000 billion in 2020 dollars by 2055, depending on the values used for GHG emission reductions. Id. at 29200, tbl. 6 (using a 3% discount rate). As compared to the Proposed Standards, by 2055 Alternative 1 would achieve an additional 800 MMT of CO2 savings, 88 Fed. Reg. at 29203, tbl. 14, and increase climate benefits by between $9 and $100 billion. Id. at 29205, tbl. 17. And adopting Alternative 1 with a faster ramp rate after 2030 would bring even more climate benefits to environmental justice communities. See infra Section V (detailing the societal benefits of more stringent standards). [EPA-HQ-OAR-2022-0829-0759, p. 19]

D. Alternative 1+ Results in Greater Emissions Reductions and Public Health Impacts than EPA's Preferred Approach

The ERM modeling results regarding GHG tailpipe and upstream emissions, shown below in Figure V.E-1, show the emissions reductions possible by taking an Alternative 1+ approach from 2026-2040, as well as the cumulative reductions from the other policy scenarios and the monetized value of these reductions (shown in Table V.E-1). These benefits are compared to EPA's No Action scenario, which is quite conservative in its projections for what market conditions are expected to be in a no action scenario. [EPA-HQ-OAR-2022-0829-0759, p. 30]

A final rule aligned with our recommended approach would be expected to achieve more than a 52% reduction in emissions of CO2 by 2040 compared to 2026 and result in almost $148 billion in climate benefits by 2040 – approximately $35 billion more than would be possible from an EPA Main Proposal approach during the same timeframe. Accordingly, EPA's failure to finalize a rule that aligns with our recommended approach would unnecessarily leave significant climate benefits on the table. [EPA-HQ-OAR-2022-0829-0759, pp. 30-31]

SEE ORIGINAL COMMENT FOR Figure V.E-1: Comparison of Projected Climate Benefits110 [EPA-HQ-OAR-2022-0829-0759, p. 31]

110 Id. at 11.

SEE ORIGINAL COMMENT FOR Table V.E-1: Projected Cumulative Reduction and Monetized Value (per policy scenario)111 [EPA-HQ-OAR-2022-0829-0759, p. 31]

111 Id.

ERM analysis used EPA's identified Social Cost of Carbon as the basis for monetized social benefits. This analysis also used a 3% average discount rate and escalated the monetary values to 2021 levels to be consistent with other costs contained within the benefit cost model. [EPA-HQ-OAR-2022-0829-0759, pp. 30-31]

1. Comparison of Overall Societal Benefits

The results from ERM's analysis (depicted in Figure V.I-1) show that on a net societal basis––inclusive of the costs to fleets as well as air quality benefits, climate benefits, and reduced utility bills—the greatest benefits are seen with Alternative 1+ at about $125.7 billion through the 2040 timeframe. [EPA-HQ-OAR-2022-0829-0759, p. 35]

SEE ORIGINAL COMMENT FOR Figure V.I-1: Comparison of Possible Annual Net Societal Benefits119 [EPA-HQ-OAR-2022-0829-0759, p. 36]

119 Id. at 15.

This figure depicts net annual societal benefits (which incorporates net incremental fleet cost savings, climate benefits, air quality benefits, and reduced utility bills). [EPA-HQ-OAR-2022-0829-0759, p. 36]

XXIX. Conclusion

EPA should finalize emission standards for light- and medium-duty vehicles that are at least as stringent as Alternative 1 but with increasing stringency from 2030 to 2032 to put the country on track for 100% new ZEV sales by 2035. EPA can and must go further than it has proposed. Adopting the recommendations set forth in this comment letter would result in feasible, cost-beneficial emission standards that would better serve EPA's statutory mandate to protect public health and welfare. [EPA-HQ-OAR-2022-0829-0759, p. 205]

Organization: Environmental Defense Fund (EDF) (1of 2)

III. EPA's final light-duty standards should deliver pollution reductions at least at the level of the proposal.

In this section, we outline the breadth of factors supporting the feasibility and cost-effectiveness of protective pollution standards. We recommend that EPA strengthen the standards in a manner that delivers pollution reductions at least as great as the proposal that EPA is considering. We also highlight the importance of adjustments that could secure even greater pollution reductions by including in the final rule a voluntary (but once chosen, enforceable) alternative leadership pathway that, for manufacturers choosing the pathway, would ensure ACC II levels of ZEV deployment nationwide. In addition, especially if EPA modifies the proposal's phase-in of the standards in the early years of the program as indicated in Alternative 3, we recommend that EPA consider increasing the stringency of the 2031-2032 standards to potentially increase cumulative GHG reductions relative to the proposal, and at minimum, protect the benefits achieved under the standards as proposed. [EPA-HQ-OAR-2022-0829-0786, p. 16]

A. Feasibility, cost, and lead time support final standards at least as protective as the proposal.

In this section, we examine a series of interlocking analyses and factors that support standards at least as protective as EPA's proposed emissions standards, including 1) extensive independent analysis related to rapidly-declining ZEV costs, including the impacts of the IRA in further advancing ZEV cost declines and accelerating ZEV deployment; 2) manufacturers' projections of battery cost declines; 3) an assessment of market indicators, including manufacturer investments and commitments, which are broadly consistent with and reinforce these study findings; 4) a discussion of leading state actions, including the ACC II rule; and 5) presentation of a revised baseline analysis, which synthesizes and quantifies each of these factors. Each of these factors, both individually and when taken together, demonstrate that EPA's proposed standards are feasible and cost-effective. [EPA-HQ-OAR-2022-0829-0786, p. 16]

B. EPA should strengthen standards in a manner that delivers pollution reductions at least as great as the proposal.

The above analysis demonstrates the feasibility of standards that deliver pollution reductions at least as great as EPA's proposal. In this section we offer two suggested approaches EPA should pursue to further strengthen the standards: 1) adopting stronger standards in later model years of the program, reflecting additional ZEV deployment; and 2) finalizing a voluntary (but once chosen, enforceable) leadership pathway that incentivizes ACC II levels of ZEV deployment nationwide. [EPA-HQ-OAR-2022-0829-0786, p. 37]

i. Primary standards should be strengthened to reflect additional ZEV deployment in later years of the program.

The foregoing factors support protective standards. They also especially underscore the opportunities to strengthen the later model years of the program, similar to EPA's decision in its MY 2023-2026 standards to strengthen the MY 2026 standards. Even more so here, manufacturers have substantial lead-time, and most cost assessments project both upfront cost-parity (or savings) and substantial savings on a total cost of ownership basis in that timeframe. IRA credits will still apply, delivering further cost savings. Moreover, though our comments show that EPA has reasonably considered infrastructure, grid-related issues, supply and critical mineral considerations in both the near and long term, even stakeholders raising concerns about those considerations have focused most on perceived near-term constraints. And California's ACC II program will be delivering 76% ZEVs in 2031 and 82% in 2032. In summary, in the 2031-32 timeframe, there is broad consensus that ZEVs will be cheaper to purchase, own, and operate, will be produced at significant volumes relying on supply chains that have been strengthened and secured, and will be sold at percentages significantly greater than EPA's proposal in the states that have adopted ACC II standards. [EPA-HQ-OAR-2022-0829-0786, pp. 38-41]

In addition to being feasible, strengthening standards in later model years of the program is critical to delivering additional pollution reductions and important to ensure we are firmly on the pathway to ensuring all new vehicles sold by 2035 are zero-emitting. In this section, we have demonstrated how adjustments in stringency in these later model years will deliver significant emissions reductions. EPA should consider strengthening the later model years of the program across all of its proposed alternatives, but we underscore the vital importance of such strengthening in circumstances that would ensure any finalized alternative delivers pollution reductions at least as great as the proposal. To illustrate this, we have examined EPA's proposed Alternative 3 and examined how EPA might strengthen the later model years to ensure modified standards would deliver emission reductions at least as great as the proposal and, separately, at least as great as Alternative 1. [EPA-HQ-OAR-2022-0829-0786, pp. 38-41]

Table 5, below, shows the fleetwide targets for EPA's no action case, as well as the Proposal and Alternatives 1 and 3. [EPA-HQ-OAR-2022-0829-0786, pp. 38-41]

[See original attachment for Table 5: Fleetwide Certification CO2 Targets Sales Under Certain EPA Options (g/mi)] [EPA-HQ-OAR-2022-0829-0786, pp. 38-41]

As the table demonstrates, GHG standards under the EPA Proposal and Alternative 1 are front- loaded, with the largest year over year reductions occurring between 2026 and 2029. In contrast, Alternative 3 achieves roughly the same GHG target as the Proposal in 2032, but achieves this level more gradually. In terms of "cumulative 2027-2032 MY grams per mile", Alternative 1 achieves 60 gram-years per mile more control than the Proposal, while Alternative 3 achieves 27 gram-years per mile less control than the Proposal. In other words, the slower decrease means cumulative GHG reductions from Alternative 3 are lower than the Proposal even though they reach the same standard by 2032. [EPA-HQ-OAR-2022-0829-0786, pp. 38-41]

As described above, we have combined the slower, but steadier levels of GHG reductions reflected in Alternative 3 with greater levels of GHG reductions in the later MYs so that the overall level of GHG reductions afforded in one scenario by the Proposal and the other, by Alternative 1, are achieved. EDF selected cumulative GHG emission reductions through CY 2055 as a reasonable metric for overall GHG reduction potential. To do this, we used a spreadsheet model that reflects the basic scrappage and annual mileage versus age distributions used in EPA's OMEGA 2 model. EDF assumed constant vehicle sales between 2027 and 2055, which is consistent with the results of EPA's OMEGA modeling. We also ignored VMT rebound, which is again reasonable given the small changes in ICEV CO2 emissions projected in EPA's OMEGA modeling.110 [EPA-HQ-OAR-2022-0829-0786, pp. 38-41]

110 EPA assumed that BEVs would be driven the same number of miles as the ICEVs they replaced, so electrification produced no change in fleet VMT.

Using this model, EDF found that reducing the fleetwide GHG targets of Alternative 3 in MYs 2031 and 2032 by 2.1 and 4.2 g/mi, respectively, would match the Proposal's cumulative 2055 GHG emission reduction. Analogously, reducing the fleetwide GHG targets of Alternative 3 by 8.7 and 17.4 g/mi in MYs 2031 and 2032 would match Alternative 1's cumulative 2055 GHG emission reductions. The CO2 emission targets under these amended scenarios are shown in Table 6. EPA assumed that BEVs would be driven the same number of miles as the ICEVs they replaced, so electrification produced no change in fleet VMT. [EPA-HQ-OAR-2022-0829-0786, pp. 38-41]

[See original attachment for Table 6: Fleetwide Certification CO2 Targets Sales Under Certain EPA Options and Two New Scenarios (g/mi)] [EPA-HQ-OAR-2022-0829-0786, pp. 38-41]

EDF also estimated the level of BEV sales under the two new control scenarios by assuming that ICEV emissions in 2032 continue through 2055 (roughly 250 g/mi CO2 for average ICEV). The results are shown in Table 7. [EPA-HQ-OAR-2022-0829-0786, pp. 38-41]

[See original attachment for Table 7: BEV Sales Under Various EPA Options and Two New Scenarios] [EPA-HQ-OAR-2022-0829-0786, pp. 38-41]

The increased level of BEV sales in the last two years of Alternative 3 in order to match the performance of the Proposal are modest: less than 1% increase in MY 2031 and 3% points in MY 2032. The increases in BEV sales required to match the performance of Alternative 1 are more substantial but still reasonable: 3% points in MY 2031 and 7% points in MY 2032. [EPA-HQ-OAR-2022-0829-0786, pp. 38-41]

Moreover, as we discuss earlier in these comments, automakers can also choose to meet standards through additional ICEV reductions and deployment of PHEVs. [EPA-HQ-OAR-2022-0829-0786, pp. 38-41]

EDF used the OMEGA 2 and OMEGA Effects models to project the cumulative benefits of the Proposal, Alternative 1 and the two other scenarios based on Alternative 3. The emission reductions projected for the four scenarios are summarized in Table 8. [EPA-HQ-OAR-2022-0829-0786, pp. 38-41]

[See original attachment for Table 8: Cumulative Emission Reductions for Calendar Years 2027-2055 (Million metric tons for GHG, metric tons for criteria pollutants)] [EPA-HQ-OAR-2022-0829-0786, pp. 38-41]

The GHG emission reductions for the two scenarios with strengthened later year standards either exceed those of the Proposal and Alternative 1 or are within 1%. The same relationship holds for emissions of fine PM and NOx. However, the sOx emission reductions for the two scenarios with strengthened later year standards are much larger than those for the Proposal and Alternative 1, likely due to the fact that vehicle electrification is larger in the later years when the electrical grid is cleaner. [EPA-HQ-OAR-2022-0829-0786, pp. 38-41]

Accordingly, we encourage EPA to consider strengthening standards in later model years of the program (2031 and 2032), which can deliver important, additional emission reductions regardless of the alternative EPA finalizes. It is especially vital that the agency do so to ensure any final rule delivers emission reductions at least as great as the proposal, should EPA otherwise choose to pursue a pathway like Alternative 3 that, absent strengthening, would not deliver these benefits. [EPA-HQ-OAR-2022-0829-0786, pp. 38-41]

Organization: Ford Motor Company

Ford supports the 2032 endpoint of the Multi-Pollutant Proposal which may result in approximately 67 percent of new light- and medium-duty vehicles being ZEVs. As summarized here and detailed in the Attachment, the most reliable way to reach that endpoint is for the EPA to adopt the "Alternative 3" GHG standards with several, modest adjustments. [EPA-HQ-OAR-2022-0829-0605, p. 2]

To achieve the 2032MY goals EPA has proposed and Ford supports, the final regulation must have the following elements. First, regarding the stringency of the GHG standards, the EPA should finalize the Alternative 3 standards with minor adjustments to the utility allowance inherent in the truck curves and provide a phase-out for refrigerant credits (rather than eliminate all at once). The Alternative 3 standards effectively draw a straight line from 2026 to 2032; that is, they would require roughly equal reductions in absolute grams-per-mile targets over the duration of the program. Alternative 3 reaches the same endpoint in 2032 as the EPA's main proposal, and therefore would achieve the primary goal shared by Ford and EPA—widespread adoption of ZEVs. In contrast, EPA's main proposal, Alternative 1, and Alternative 2 each would require precipitous reductions in 2027 – 2029; this is not feasible and does not align with the anticipated scaling of the EV supply chain and manufacturing base. Similarly, the EPA's proposal to end refrigerant credits altogether in 2027 would be abrupt and have the effect of standards being even more strict; EPA should phase these credits out over time. Lastly, EPA's final regulations must continue to recognize the utility provided by trucks. Although electrified vehicles hold promise for all vehicles classes, ICE-powered trucks will continue to provide unique capability and utility for many years. The EPA proposal (and Alternative 3) would reduce the existing truck utility allowance too severely. [EPA-HQ-OAR-2022-0829-0605, p. 3]

As the EPA and others consider the many trade-offs in this rulemaking, Ford must emphasize that investments in EVs will yield far greater emissions reductions than investments toward incremental improvements to already-advanced ICE technologies. These considerations are particularly important in the early years of the EPA program, where the EV market must reach critical mass. Accordingly, we encourage EPA to avoid setting criteria emissions requirements that will force unnecessarily large or ill-timed investments and distract both automakers and the supply base with little air quality benefit. [EPA-HQ-OAR-2022-0829-0605, p. 4]

Light-Duty GHG Stringency and Alternatives

Ford commends EPA staff for recognizing the uncertainty and challenges associated with such a transformation rulemaking effort by including alternatives to the main proposal. Ford believes that Alternative 3 represents the most feasible pathway toward achieving a successful program, and considers the following aspects of Alternative 3 to be essential elements of a final rule: [EPA-HQ-OAR-2022-0829-0605, p. 5]

1) Alternative 3 includes a more feasible, uniform ramp rate across the 2027 – 2032MY program timeframe while reaching the same endpoint as the main proposal. In contrast, the main proposal, and Alternatives 1 and 2 are impractically “front-loaded”, with higher year-over-year stringency increases in the early years of the program. [EPA-HQ-OAR-2022-0829-0605, p. 5]

2) Alternative 3 also distributes a change in the relative stringency of the car and truck curves over the 2027 – 2032MY timeframe. The main proposal and Alternatives 1 and 2 apply this adjustment all in one year (2027MY) creating a step-change in the truck stringency that is infeasible for full-line OEMs. It should be noted that while Ford supports the distributed approach of such a rebalancing as implemented in Alternative 3, Ford disagrees with the magnitude of this rebalancing as described in the following section. [EPA-HQ-OAR-2022-0829-0605, p. 5]

Organization: Hyundai Motor America

President Biden’s Executive Order 14037 – setting an EV penetration target of 50% in MY 2030 – Should Guide the Final Rule.

Hyundai supports EPA’s overall emissions reduction goals and, as a legacy automaker with a high share of EV sales compared to our peers, we understand EPA’s goal of the NPRM to aggressively accelerate penetration of BEVs. Hyundai continues to support the already aggressive goal set by the Biden Administration on August 5, 2021, in the “Executive Order on Strengthening American Leadership in Clean Cars and Trucks” (“Executive Order 14037”) that 50 percent of all new passenger car and light truck sales in MY 2030 be battery, fuel cell, and plug-in hybrid electric vehicles. [EPA-HQ-OAR-2022-0829-0599, p. 2]

However, the Proposed Alternative deviates in substantial ways from Executive Order 14037. First, the Proposed Alternative not only significantly increases the penetration rates, but also ignores the PHEVs and FCEVs that were previously included in that calculation, and which are critical to facilitating a safe and reliable transition to EVs. These adjustments are premised on overly- optimistic assumptions and do not account for the numerous hurdles facing implementation of such an aggressive transition timeline. As described in more detail in this comment and in the comments of the Alliance for Automotive Innovation (“AFAI”), the Proposed Alternative does not adequately consider significant challenges faced by all aspects of the market when forcing such transformational change. For example, the Proposed Alternative insufficiently accounts for supply chain constraints, availability of safe and responsibly sourced critical minerals (which are essential for battery production), manufacturing limitations, inadequate charging infrastructure, and significantly lagging consumer acceptance. In light of these challenges, the ambitious timelines proposed by EPA will likely further drive up the cost of EVs, making these vehicles less available to the mass market consumers and priority communities who arguably need them the most. [EPA-HQ-OAR-2022-0829-0599, p. 2]

Accordingly, we request that EPA modify the final standard to appropriately consider these significant challenges, and encourage EPA to adopt the proposal put forward by AFAI. We look forward to working with EPA in finalizing a rule that achieves historic emission reductions and fortifies our path toward full electrification while also allowing for a safe, affordable, and reliable transition for US consumers. [EPA-HQ-OAR-2022-0829-0599, p. 2]

We appreciate EPA's efforts to finalize a rule that achieves historic emissions reductions and puts industry on a firm path toward full electrification. However, the Proposed Alternative goes beyond what was already an aggressive target set by the Biden Administration, setting a drastically steep ramp for compliance while simultaneously removing much needed flexibilities. The current proposal inadequately accounts for real-world challenges, including the short lead time provided to vastly improve charging infrastructure, significant supply chain challenges, availability of safe and reliable supply of critical minerals, manufacturing limitations, and significantly lagging consumer acceptance rates. In addition, the true cost to consumers and automakers resulting from the IRA provisions is not fully reflected in the NPRM. We encourage the EPA to work directly with industry to better understand and analyze these challenges. For these reasons, we believe the Proposed Alternative may not be achievable and therefore support the AFAI Proposal which – while it is ambitious – better reflects real-world challenges and opportunities. [EPA-HQ-OAR-2022-0829-0599, p. 10]

Organization: Institute for Policy Integrity at New York University School of Law

IV. Barring a Compelling Reason Otherwise, EPA Should Select the Alternative That Will Maximize Net Social Welfare

Section 202 of the Clean Air Act instructs EPA to balance its mandate to safeguard "public health and welfare" with an "appropriate" consideration of costs.198 In the Proposed Rule, EPA "finds that the expected compliance costs for automakers are reasonable in light of the emissions reductions in air pollutants and the resulting benefits for public health and welfare" and recognizes that a finding of significant net benefits "reinforces" its conviction that the proposed standards are "appropriate."199 Moreover, President Biden has reaffirmed the principles of Executive Order 12866,200 which include a mandate that each agency, "in choosing among alternative regulatory approaches, . . . should select those approaches that maximize net benefits," including "distributive impacts" and "equity," to the extent permitted by law.201 EPA should follow these principles in setting these standards. [EPA-HQ-OAR-2022-0829-0601, pp. 29-30]

198 42 U.S.C. §§ 7521(a)(1)–(2).

199 Proposed Rule, 88 Fed Reg. at 29,198, 29,344.

200 Exec. Order 14,094 § 1, 88 Fed. Reg. 21,879 (Apr. 11, 2023).

201 Exec. Order 12,866 § 1(a), 58 Fed. Reg. 51,735, 51,735 (Oct. 4, 1993).

Applying these standards, EPA should more strongly consider Alternative 1 (the most stringent among the options analyzed), particularly in light of the economic recommendations and analysis presented in this letter. EPA's proposed program would reduce emissions and increase net social welfare and so is justifiable,202 yet the analysis accompanying the Proposed Rule shows that Alternative 1 would result in $200 billion more net benefits through 2055.203 Critically, EPA concludes that Alternative 1 is "anticipated to be feasible."204 Alternative 1 is more net beneficial than the proposed program in part because of greater reductions in air pollution,205 which EPA describes as "[a]n essential factor . . . in determining the appropriate level of the proposed standards."206 Moreover, the $200 billion figure does not take into account significant unmonetized benefits that would likely further increase Alternative 1's relative advantages.207 [EPA-HQ-OAR-2022-0829-0601, pp. 29-30]

202 Proposed Rule, 88 Fed. Reg. at 29,200 tbl.6.

203 Compare Proposed Rule at 29,200 tbl.6, with id. at 29,200 tbl.17 (at a 3% discount rate and the 9[5t]h percentile values for the SC-GHG at a 3% discount rate).

204 Proposed Rule, 88 Fed Reg. at 29,280. EPA concludes that "standards substantially more stringent than Alternative 1 would not be appropriate because of uncertainties concerning the cost and feasibility of such standards." Id. at 29,201.

205 Compare Proposed Rule, 88 Fed Reg. at 29,348 tbl.135, and id. at 29,355–56 tbl.147, with id. at 29,348 tbl.136, and id. at 29,356 tbl.148.

206 Proposed Rule, 88 Fed Reg. at 29,344.

207 See Proposed Rule, 88 Fed Reg. at 29,380 (noting that the Proposed Rule does not monetize the benefits associated with reducing ambient concentrations of ozone, reductions in direct exposure to NO2 and mobile source air toxics, improved ecosystem effects, or visibility); id. at 29,389 (noting that the Proposed Rule does not monetize military benefits as a result of reductions in U.S. oil imports); RIA at 7-38 tbl.7-1 (showing that the Proposed Rule does not monetize numerous adverse impacts of PM2.5, including certain cardiovascular, respiratory, cancer, nervous system, metabolic, reproductive, and developmental effects).

Additionally, further analysis shows that Alternative 1 is likely even more net beneficial versus the proposed program than EPA currently acknowledges. Applying updated discount rates and climate-damage valuations shows that Alternative 1 is $300 billion more net beneficial than the proposed program.208 Furthermore, approval of the preemption waiver for California's Advanced Clean Cars II (ACC II)—which could occur before this rule is finalized, and thereby shift the analytical baseline—may further reinforce the conclusion that Alternative 1 is most net-beneficial.209 According to EPA's analysis, selecting Alternative 1 in the absence of the waiver would increase BEV penetration relative to the proposed program by 2 percentage points and increase per-vehicle cost by $611 in 2032.210 In contrast, selecting Alternative 1 with the waiver already in place would increase BEV penetration relative to the proposed program by 4 percentage points (i.e., doubling the incremental effect) while increasing per-vehicle cost by $763 in 2032 (a far more modest increase on a percentage basis).211 This suggests that Alternative 1 may be even more net beneficial compared to the proposed program with ACC II in place. [EPA-HQ-OAR-2022-0829-0601, pp. 29-30]

208 See supra p. 12 tbl.3.

209 EPA conducts sensitivity analysis that considers how approval of the ACC II preemption waiver would affect the agency's regulatory impact analysis but does not present the benefits, cost, or net benefits under that scenario. Nor was Policy Integrity able to determine the benefits, cost, and net benefits under this sensitivity in OMEGA.

210 Proposed Rule, 88 Fed Reg. at 29,333 tbl.99; id. at 29,203 tbl.12.

211 Id. at 29,355 tbl.108; id. at 29,355 tbl.109.

For the reasons discussed in supra Section I and elsewhere in this letter, Alternative 1 would not substantially increase legal risk under the major questions doctrine. Alternative 1 relies on the same regulatory approaches that have considerable precedent in prior EPA tailpipe rules.212 It also has similar effects on BEV penetration.213 [EPA-HQ-OAR-2022-0829-0601, pp. 29-30]

212 See generally supra Part I.B.

213 See supra p. 10 tbl.2.

Accordingly, barring a compelling reason otherwise, EPA should select the regulatory alternative that maximizes net benefits—according to EPA's current analysis, Alternative 1. [EPA-HQ-OAR-2022-0829-0601, pp. 30-31]

Organization: International Council on Clean Transportation (ICCT)

ICCT recommends the adoption of Alternative 1, the most stringent option EPA presents in its proposal for the light-duty vehicle (LDV) GHG standards. We believe even greater GHG reductions than laid out in Alternative 1 would be feasible because today's technology, policy, and market landscape have primed the market for a rapid transition to cleaner vehicles. Substantial public and private sector investments and a comprehensive package of federal and state level policies make the timing and stringency of the proposed rule achievable, feasible, and cost-effective. At the federal level, the combination of substantial consumer and industry incentives from the $370 billion allocated to climate and clean energy investments through the Inflation Reduction Act of 2022 (IRA) will accelerate the shift to electric vehicles while supporting a domestic supply chain and charging infrastructure buildout. In parallel, the Bipartisan Infrastructure Law complements the IRA by investing $7.5 billion in electric vehicle charging infrastructure, $10 billion in clean transportation, and more than $7 billion in battery components, critical minerals, and materials. [EPA-HQ-OAR-2022-0829-0569, p. 3]

At the state level, policymakers are charging ahead with their own zero-emission vehicle regulations, investments, consumer incentives, planning, and infrastructure deployment. California's Advanced Clean Cars II (ACC II) regulations will require dramatic reductions in light-duty vehicle emissions to 100% zero-emissions by 2035 through the Zero-Emission Vehicle Regulation and the Low-emission Vehicle Regulations. Many other U.S. states follow California's leadership on automotive emissions regulations. As of May 2023, 7 states have adopted ACC II and it is likely that others will follow. By adopting its proposal, EPA can build on ACC II and expand access to cleaner vehicles more broadly across the U.S. [EPA-HQ-OAR-2022-0829-0569, p. 3]

Globally, automakers have already announced over $1.2 trillion in investments in electrification. These investments will lead to greatly expanded model line-ups and production volumes, technological advancements, and reduced costs. [EPA-HQ-OAR-2022-0829-0569, p. 3]

ICCT recommends EPA finalize Alternative 1 for the greenhouse gas (GHG) emissions standards for light-duty vehicles (LDV) and believes the GHG standards for medium-duty vehicles (MDV) could also be strengthened. These recommendations are based on thorough and clear evidence (detailed in the sections below) that additional GHG reductions could be possible through continued and cost-effective internal combustion engine (ICE) technology improvements and battery electric vehicle (BEV) penetration at lower costs than EPA estimates in its modeling. [EPA-HQ-OAR-2022-0829-0569, p. 4]

ICCT strongly supports the proposed multi-pollutant emission standards for light-and medium-duty vehicles for model years 2027-2032 and recommends its finalization as quickly as possible. Doing so will provide a clear long-term signal that automakers, suppliers, charging companies, and utilities need to make needed investments with confidence. [EPA-HQ-OAR-2022-0829-0569, p. 5]

PROPOSED STRINGENCY

ICCT supports the proposed standards and recommends EPA finalize Alternative 1. Our research shows that the proposed standards are likely less costly than estimated and can be met with a variety of technological approaches and pathways, evidenced by the BEV and ICE technology updates discussed above. Alternative 1 is even more cost-effective and delivers greater environmental and health benefits than the proposed standards. [EPA-HQ-OAR-2022-0829-0569, pp. 55-56]

Comparing Tables 6, 17-19 of the Preamble, Alternative 1 is projected to result in higher net benefits than any other standards contained in the proposal. Moreover, fuel savings alone offset increased technology costs several times over. As discussed above, BEV and ICE technology cost, effectiveness, and availability that has yet to be incorporated by EPA's modeling will make complying with Alternative 1 standards easier and less costly than currently modeled. Furthermore, with widespread adoption of California's ACC II program in other states, the cost of Alternative 1 decreases substantially. Comparing DRIA Tables 13-45 and 13-49, by MY2032 the projected manufacturing cost under Alternative 1 (versus the ACC II adoption sensitivity baseline) are nearly identical to the costs of the proposed standards (versus the central analysis baseline without ACCII adoption). [EPA-HQ-OAR-2022-0829-0569, pp. 55-56]

Organization: Jaguar Land Rover NA, LLC (JLR)

To support the transition to a zero-emission future, JLR would welcome EPA's consideration of our following recommendations:

1) An Alternative Glidepath to Reaching the 2032MY Target

Disconnect between Targets Set by U.S. Blueprint for Transportation Decarbonization, Biden Executive Order (E.O. 14037) and EPA Proposed Standards [EPA-HQ-OAR-2022-0829-0744, pp. 4-5]

Despite being one of the four agencies who created the U.S. Blueprint for Transportation Decarbonization, published in early 2023, there is a disconnect between the goals identified in the roadmap and EPA proposed standards. [EPA-HQ-OAR-2022-0829-0744, pp. 4-5]

The actions highlighted in the Blueprint build on the August 2021 E.O. 14037 4 which set an ambitious goal for:

"50 percent of all new passenger cars and light trucks sold in 2030 be zero-emission vehicles, including battery electric, plug-in hybrid electric, or fuel cell electric vehicles." [EPA-HQ-OAR-2022-0829-0744, pp. 4-5]

4 Executive Order 14037 of August 5, 2021 - Federal Register: Strengthening American Leadership in Clean Cars and Trucks

The Blueprint specifically calls to:
"Continue to provide funding and policy incentives to accelerate the uptake of low- or zero-emission vehicles and invest in supporting infrastructure…Achieve 50% of electric light-duty vehicle sales by 2030". [EPA-HQ-OAR-2022-0829-0744, pp. 4-5]

EPA's proposal is significantly more aggressive than the above targets, with a total fleet projected BEV rate of 60% in 2030MY to achieve the new standards, which would require coordination and investment above and beyond that already accounted for within the Blueprint to achieve. The true delta between the targets cannot be quantified fully, as EPA's analysis does not include PHEVs, and we would like to highlight the comment made by EPA that they "recognize that the inclusion of PHEVs could potentially increase the combined ZEV share projection beyond the BEV penetration levels shown...". If PHEV share remained constant at 20% of the ZEV fleet (including PHEV) as per 2022 sales,5 the 60% BEV share required to achieve standards could rise to 72% ZEV share in 2030MY, 22% greater than the E.O. 14037 and Blueprint goals. [EPA-HQ-OAR-2022-0829-0744, pp. 4-5]

5 S&P Global Mobility (IHS Markit) - Automotive Global Vehicle Registrations - https://www.marketplace.spglobal.com/en/datasets/automotive-global-vehicle-registrations-(248) (subscription)

JLR suggests that EPA's 2030MY target reflects a maximum projected ZEV share of 50%, aligning with both the Blueprint and E.O. 14037 which JLR supports. [EPA-HQ-OAR-2022-0829-0744, p. 5]

We need less stringent targets in the early years and then, based on our plan, we expect to achieve the more ambitious targets in the outer years which will allow us to meet EPA's 2032MY target. The front-loaded stringency in the NPRM, drives tough targets before 2030MY and could divert investment away from this journey. This could drive us to accrue large liabilities for 2024 and 2025MY as we begin to transition our fleet. [EPA-HQ-OAR-2022-0829-0744, pp. 5-7]

The difficulty in the beginning of the regulation is compounded by the extremely high step change between 2026 and 2027MY standards (when adjusted to reflect the proposed reduction in allowable AC and off-cycle credits.) Due to the changes to the footprint curves, light truck standards increase at almost double the rate of passenger car (21% vs 12%). This particularly impacts JLR as an OEM with a high percentage of off-cycle technologies (OCT) and air conditioning (A/C) featured in our vehicles, as noted in the 2022 EPA Automotive Trends Report8. Reaching the 10 g/mile OCT cap and with the highest reported A/C credit (24.2 g/mile), equivalent to an 8% reduction from tailpipe emissions for A/C credits alone in 2021. [EPA-HQ-OAR-2022-0829-0744, pp. 5-7]

8 The 2022 EPA Automotive Trends Report–- https://www.epa.gov/system/files/documents/2022-12/420s22001.pdf

[See original for graph, "Figure 2–- See appendix A1 for more details"] [EPA-HQ-OAR-2022-0829-0744, pp. 5-7]

Our alternative proposal for the standards as illustrated in Figure 2 above includes a lower rate of stringency increase in the earlier years (MYs 2027-2030) than in the later years. The 2027MY combined fleet target is identical to the proposed target for EPA's Alternative 3 scenario. Although this is less stringent than the central EPA proposal, we propose from 2030MY onwards an increased ramp rate to match the central proposed target of 82 g/mile in 2032MY. [EPA-HQ-OAR-2022-0829-0744, pp. 5-7]

Setting targets out to 2032MY, eight years in advance, is appreciated from a planning perspective, and we support the end goal, however it is difficult to predict what will happen with regards to the EV transition and we need time to develop the fleet and grow the EV market sustainably. This suggested amendment to the stringency rates will not affect the overall aim of the regulation as our proposed end target is equivalent to EPA's goal. [EPA-HQ-OAR-2022-0829-0744, pp. 5-7]

We believe that reduced stringency in the earlier years of the regulation is essential and JLR requests that EPA adopt our alternative stringency proposal. [EPA-HQ-OAR-2022-0829-0744, pp. 5-7]

Appendix A1

To generate our alternative proposal, we have taken the projected BEV penetration values for the NPRM Proposed Alternatives 2 and 3 in 2029MY, (46%, 52%) and the corresponding proposed combined fleet targets in g/mile. (132, 122) [EPA-HQ-OAR-2022-0829-0744, p. 13]

The JLR Alternative Proposal is based on a 50% BEV penetration rate at 2030MY. To find the corresponding appropriate target in g/mile, the fleet target change between Alternative 2 and 3 (10) is divided by the difference in proposed BEV rates (6%). This increment is multiplied by four to find the step change between Alternative 3 and JLR Alternative Proposal. This value is subtracted from the Alternative 3 target to give the new JLR combined fleet target in g/mile as stated in the table below. [EPA-HQ-OAR-2022-0829-0744, p. 13]

2029MY Standards	Alternative 3	JLR Alternative Proposal	Alternative 2
Proposed Combined Fleet Target (g/mile)	132	125.3	122
Projected BEV Penetration (%)	46	50	52

In terms of YoY stringency increases, the JLR Alternative proposal:

- 2027MY matches Alternative 3,
- 2028 and 2029MY have identical stringency increases compared to the NPRM Proposal for 2030 and 2031MY,
- 2030MY increase is equal to the 2028MY Alternative 3 step change,
- 2031MY jump aligns with Alternative 3 in 2032MY,
- 2032MY increase is slightly higher than proposed in both NPRM and Alternative 3 to reach the same end point.

Stringency	NPRM Proposal	Alternative 3	JLR Alternative Proposal
2027MY	18%	11%	11%
2028MY	14%	10%	8%
2029MY	15%	11%	9%
2030MY	8%	13%	10%
2031MY	9%	14%	17%
2032MY	12%	17%	21%

[EPA-HQ-OAR-2022-0829-0744, p. 13]

Organization: Kia Corporation

- Kia strongly recommends EPA reevaluate its proposed GHG standards and instead align closer with the 2030 goal set in President Biden's Executive Order (EO) 14037.2 Kia supports a goal of 40-50 percent zero emission vehicles (ZEVs) – battery electric vehicles (BEVs), plug-in hybrid electric vehicles (PHEVs), and fuel cell electric vehicles (FCEVs) by model year (MY) 2030 with continued increases through MY2032, coupled with appropriate supporting policies. [EPA-HQ-OAR-2022-0829-0555, pp. 2-3]

2 "Strengthening American Leadership in Clean Cars and Trucks," Executive Order 14037, August 5, 2021, 86 Fed Reg 43,583.

EPA discusses that standards substantially more stringent than Alternative 1 would be inappropriate "because of the uncertainties concerning the cost and feasibility of such standards."10 Kia argues that proposing requirements above 40-50 percent ZEV penetration by 2030 would be inappropriate. [EPA-HQ-OAR-2022-0829-0555, pp. 5-6]

10 88 Fed. Reg. 29,201.

If EPA finalizes any of the proposed GHG standards included in the NPRM, it could have harmful consequences to the EV market by going too far too fast by forcing EVs at a rate that outpaces EV affordability, EV infrastructure, and critical mineral supply chain. Going too fast could end in consumer rejection of EVs that will be difficult to ever overcome. [EPA-HQ-OAR-2022-0829-0555, pp. 5-6]

However, out of EPA's proposed standards, Alternative 3 would be harmful, but the least harmful, to automakers, the EV market, and consumers. To be clear, Alternative 3 proposed standard, achieving the same stringencies as the proposed standards in MY2032, is still grossly overly optimistic. However, Alternative 3 at least provides for a more consistent rate of stringency and a more realistic slope of consumer acceptance over MYs 2027 - 2031 than EPA's other proposals. [EPA-HQ-OAR-2022-0829-0555, pp. 5-6]

Kia is staunchly committed to electrification. But regulation of the vehicle industry alone will not create a dramatic increase in demand for electric vehicles or smooth supply chain volatilities. [EPA-HQ-OAR-2022-0829-0555, pp. 5-6]

Organization: Lucid Group, Inc.

Support for the Cleanest Alternative

As proposed, GHG standards would increase in stringency each year over a six-year period starting in MY 2027, targeting a resulting industry-wide light-duty fleet average of 82 grams/mile (g/mi) of CO_2 in MY 2032. Lucid recognizes the significance of a 56% reduction in the projected fleet average GHG emissions target levels from the existing MY 2026 standards, however, we believe we face an existential crisis from climate change and industry needs to do their part to address this threat. As such, Lucid strongly encourages the agency to adopt Alternative 1, which is estimated to lead to CO_2 targets that are 10 g/mi lower on average than the proposed rule. We find that Alternative 1 is consistent with actions from this Administration to combat the climate crisis and ramps up the nation's progress toward a zero-emission future and its benefits sooner. [EPA-HQ-OAR-2022-0829-0664, pp. 3-5]

Of the alternatives provided by EPA alongside the proposed standards, Lucid finds that Alternative 1, which is projected to result in an average light-duty target of 72g/mi and EPA has determined to be feasible in terms of cost and highly protective of human health and the environment, provides the most appropriate and immediate response to the tailpipe emissions that are attributable to light-duty combustion vehicles on our roadways. However, an updated assessment that includes current production EVs in the market would further affirm EPA's feasibility findings. EPA cited Ward's Automotive Intelligence data that portrays U.S. electrified new sales percentages implied by OEM announcements for 2030 or before, yet the dataset omitted several EV market participants that could have further influenced EPA's findings. EPA used MY 2019 as the basis for their analysis in the proposed rulemaking, which is not reflective of the tremendous strides that yielded the EV marketplace of today. [EPA-HQ-OAR-2022-0829-0664, pp. 3-5]

The benefits of stringent tailpipe emissions standards are widespread. One such example can be found in the health disparities between communities that are close in proximity to major roadways and arteries and those that aren't, as these locations often exhibit high concentrations of air pollutants from motor vehicles. Populations who live, work, or go to school near high-traffic roadways experience higher rates of adverse health effects as compared to populations that are located away from major roads.7 Relatedly, EPA regulations for vehicles have lowered the near-road concentrations and gradients of traffic-related air pollution around major roads.8 This impact demonstrates that tailpipe emission standards go beyond combatting the climate crisis and directly impact the health of communities today, an output that EPA has stated each of the alternatives must reflect. [EPA-HQ-OAR-2022-0829-0664, pp. 3-5]

7 In the widely-used PubMed database of health publications, between January 1, 1990 and December 31, 2021, 1,979 publications contained the keywords "traffic, pollution, epidemiology," with approximately half the studies published after 2015.

Organization: Maryland Department of the Environment (MDE)

The Maryland Department of the Environment (MDE) is writing to express our support for the above proposed rule to establish Multi-Pollutant Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles. MDE agrees that this comprehensive federal program would achieve significant greenhouse gas (GHG) and criteria pollutant emissions reductions, improve air quality, and result in substantial public health benefits while helping us meet our climate and air quality goals. MDE urges the Environmental Protection Agency (EPA) to adopt the proposed criteria pollutant standards. MDE also urges EPA to adopt the most stringent, technologically feasible Alternative 1 GHG emissions standards. Alternative 1 is the closest to being in alignment with the California Advanced Clean Cars II (ACC II) regulations, which Maryland is in the process of adopting. [EPA-HQ-OAR-2022-0829-0698, pp. 1-3]

Maryland has made a lot of progress over the past few decades towards clean air. The improvements have been so substantial that the EPA has proposed to determine that the Washington, District of Columbia-Maryland-Virginia nonattainment area has clean data for the 2015 8-hour ozone national ambient air quality standard (2015 ozone NAAQS). A Clean Data Determination (CDD) is the first step in being redesignated from nonattainment to attainment. The Baltimore nonattainment area will also be eligible for a CDD in the near future if the area continues to stay at or below the ozone standard. Nitrogen oxides (NOx) are a precursor pollutant of ground-level ozone and are also precursors to secondary small particulate matter (PM2.5). Exposures to these two pollutants are associated with premature death, increased hospitalizations, and emergency visits due to exacerbation of chronic heart and lung diseases and other serious health impacts. Some areas of the state experience higher rates of illnesses such as asthma than average, and these illnesses are aggravated by these pollutants. [EPA-HQ-OAR-2022-0829-0698, pp. 1-3]

While significant progress has been made statewide, continuing to reduce NOx emissions, especially those from the transportation sector, is critical to our efforts to attain and maintain the ozone NAAQS. Regional modeling shows that a significant portion of the ozone-forming pollutants are transported into Maryland from upwind states. EPA estimates that strengthening these standards will reduce NOx and PM2.5 emissions nationally by 41% and 35% in 2055, respectively, which combined with state reductions can provide cleaner air for Marylanders. [EPA-HQ-OAR-2022-0829-0698, pp. 1-3]

Maryland is working hard to reduce in-state emissions from the transportation sector. Efforts include the Maryland Clean Cars Act that instructed MDE to adopt the California Advanced Clean Car (ACC I) regulations that require manufacturers of passenger cars and light-duty trucks to sell increasing percentages of zero-emission vehicles (ZEVs). The regulations also include low-emission vehicle (LEV) standards to reduce criteria pollutants and GHG emissions from new gasoline powered vehicles. As noted above, Maryland is in the process of adopting California's ACC II regulations. The ACC II regulations require auto manufacturers to sell an increasing percentage of ZEVs over time, with a phase in of a 100 percent sales target by 2035. ACC II also established increasingly more stringent exhaust and evaporative emissions standards for criteria pollutants from these vehicles. Maryland's recently enacted Clean Trucks Act of 2023 requires MDE to adopt California's Advanced Clean Trucks (ACT) regulations that require manufacturers of medium-and heavy-duty vehicles to sell increasing percentages of ZEVs by 2035. Maryland is also a signatory to both the 2013 Multi-State Zero-Emission Vehicle Memorandum of Understanding and the 2020 Multi-State Medium-and Heavy-Duty ZEV Memorandum of Understanding under which the signatory states are working collaboratively to accelerate ZEV adoption, coordinate ZEV policy, develop the ZEV market, and build out infrastructure. The recently enacted Bipartisan Infrastructure Law (BIL) and the Inflation Reduction Act (IRA) will provide significant funding to advance electrification and charging infrastructure that will enable the widespread electrification of this vehicle market. [EPA-HQ-OAR-2022-0829-0698, pp. 1-3]

Adopting the most stringent, technically technical feasible Alternative 1 GHG emissions standards at the federal level will provide considerable support for Maryland's efforts to meet our GHG reduction goals. Transportation accounts for almost half of all GHG emissions generated in the State. The Climate Solutions Now Act of 2022 (CSNA) established a statewide goal of a 60 percent reduction in GHG emissions from 2006 levels by 2031. The CSNA requires more stringent GHG emission reductions economy wide and requires state agencies execute plans, programs, and policies in order to achieve these goals. Enacting the most stringent GHG emissions standards that are technologically feasible will complement the many strategies being implemented under the CSNA. [EPA-HQ-OAR-2022-0829-0698, pp. 1-3]

Maryland has implemented emissions reduction measures across all sectors, including on-road transportation to reduce the state's GHG and NOx emissions. Federal programs such as these standards are needed to provide significant additional reductions of these pollutants as they also provide benefits across the economy. The EPA's leadership in strong regulatory GHG limits from motor vehicles could also help reduce ozone and PM2.5 precursors, providing further reductions to help meet our climate and air quality goals. [EPA-HQ-OAR-2022-0829-0698, pp. 1-3]

For these reasons, MDE supports the EPA's proposal to adopt the proposed criteria pollutant standards and the most stringent, technologically feasible Alternative 1 GHG emissions standards for model year 2027 and later light-duty and medium-duty vehicles. [EPA-HQ-OAR-2022-0829-0698, pp. 1-3]

Organization: Mayor Becky Daggett, City of Flagstaff, Arizona et al.

On behalf of the 52 undersigned local officials, we urge the EPA to protect the health of our cities' residents and fight climate change by finalizing the strongest clean car and truck vehicle emission standards before the end of 2023. [EPA-HQ-OAR-2022-0829-0732, p. 1]

EPA should finalize the most stringent standards possible for the Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles (LDV) and the Greenhouse Gas Emissions Standards for Heavy-Duty Engines and Vehicles Phase 3 (HDV). We recommend these car and truck standards: [EPA-HQ-OAR-2022-0829-0732, p. 1]

- Be aligned on rulemaking timelines; [EPA-HQ-OAR-2022-0829-0732, p. 1]

- Account for technological advances and cost-savings in zero-emission technologies, including those made possible by recent legislation; [EPA-HQ-OAR-2022-0829-0732, p. 1]

- Achieve critically necessary reductions in greenhouse gases (GHGs) and other pollutants; and [EPA-HQ-OAR-2022-0829-0732, p. 1]

- Be developed with thorough stakeholder involvement that ensures all affected communities can engage in the rulemaking process. [EPA-HQ-OAR-2022-0829-0732, p. 1]

Ambitious federal standards, coupled with actions we are taking in our cities and towns to accelerate the use of clean vehicles, will enable our localities to more quickly cut transportation pollution and help ensure our residents and businesses have access to zero-emission technologies. [EPA-HQ-OAR-2022-0829-0732, p. 1]

By implementing these recommendations, we believe that the resultant standards will not only meet the Clean Air Act's statutory command to protect public health, but will also help lower fuel costs for consumers, create good, green jobs, and reduce burden on frontline communities. [EPA-HQ-OAR-2022-0829-0732, p. 2]

Outcomes

The final standards should [EPA-HQ-OAR-2022-0829-0547, p. 8]:

- Ensure the LDV and HDV standards support greater zero-emission vehicle adoption by considering market growth expected from IRA and IIJA investments (which will surpass existing commitments outlined in Executive Order 14037); [EPA-HQ-OAR-2022-0829-0547, p. 8]

- Put the nation on a trajectory to ensure 100 percent of all LDVs and HDVs sold in 2035 are zero-emission vehicles including pathway milestones assuring continuous progress; and [EPA-HQ-OAR-2022-0829-0547, p. 8]

- Reflect recently adopted state LDV and HDV emissions standards, consistent with state authority under the Clean Air Act. [EPA-HQ-OAR-2022-0829-0547, p. 8]

Organization: Mazda North American Operations

GHG

The CO2 fleet average standard reductions go well beyond what Mazda and the rest of the industry expected from this rule. President Biden's Executive Order 14037 targeted a goal of 50% new EV (BEV and PHEV) sales by 2030. The auto industry also publicly committed to a similar 40-50% EV target by 2030 (BEV and PHEV). The standards proposed under this rule would result in a requirement of 60% new BEV sales in 2030, and 67% by 2032. Not only are we concerned about the exceptional stringency of the proposed rule but also very concerned that these targets do not include PHEVs in any way: Mazda believes strongly that PHEVs are part of the solution as we undergo the largest vehicle powertrain transformation since the ICE became dominant in about 1920. [EPA-HQ-OAR-2022-0829-0595, p. 2]

In addition, the standards immediately increase dramatically in stringency beginning in 27MY, with a resulting 36% BEV requirement. These standards are particularly accelerated for vehicles classified as light trucks, since the gap between passenger cars and light trucks is reduced. Mazda believes it is very important that the ramp-up and the light truck gap reduction should be slower in the early years of the program, as the industry, consumers, and suppliers adapt to this new reality. EPA's proposed “Alternative 3” is a step in the right direction, but the linear reduction in standards is insufficient to alleviate the harsh early years when the long-term targets are so aggressive. [EPA-HQ-OAR-2022-0829-0595, pp. 2-3]

Organization: Mercedes-Benz AG

we recommend EPA seek a more modest ramp-up, similar to Alternative 3, to appropriately provide flexibility in the early years of the greenhouse gas (“GHG”) program. [EPA-HQ-OAR-2022-0829-0623, p. 2]

Organization: Minnesota Pollution Control Agency (MPCA)

The MPCA has supported EPA's previous efforts to strengthen vehicle emissions standards and appreciates the opportunity to comment on the proposed rule. We see the proposed rulemaking as an opportunity to advance climate action, reduce harm to Minnesotans from criteria pollutants and air toxics, and accelerate the transition to electric vehicles in our state. [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

Importance of new federal greenhouse gas standards for climate action

The transportation sector represents the largest source of greenhouse gas emissions in Minnesota. The top three sources in the transportation sector are light-duty trucks, heavy-duty trucks, and passenger cars.1 These categories are inclusive of light and medium-duty vehicles discussed in this proposal. [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

Stronger vehicle emissions standards at the federal level have lowered greenhouse gas emissions from vehicles generally. However, the long-term consumer trend of choosing larger vehicles and the general trend of more miles driven (except during the pandemic) are counteracting more significant emissions reductions in this sector. Increased emissions stringency at the federal level is critical to continuing the trend of emission reductions in this sector. Accelerating light-and medium-duty vehicle electrification is vital for Minnesota to meet its climate and air pollution goals. Specifically, adopting new light-and medium-duty vehicle emissions standards would: [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

1 Greenhouse gas emissions in Minnesota 2005-2020, https://www.pca.state.mn.us/sites/default/files/lraq-2sy23.pdf.

-Help the state meet economy-wide greenhouse gas emissions reduction goals.

In 2022, as part of the publication of the state's Climate Action Framework,2 Governor Walz and Lieutenant Governor Flanagan endorsed the economy-wide greenhouse gas emissions reduction goal for the state to reduce emissions by 50% by 2030 and to become carbon-neutral by 2050. In May 2023, Minnesota codified these targets in statute. Achieving these goals will require action at all levels of government, across businesses, and by individuals. The proposed multipollutant standards will be critical for reducing emissions from the transportation sector. [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

2 Minnesota's Climate Action Framework, https://climate.state.mn.us/minnesotas-climate-action-framework.

-Advance transportation actions and targets in the state's Climate Action Framework.

Minnesota's Climate Action Framework is a plan that sets a vision for how the state will address and prepare for climate change. The framework broadly guides the direction of climate action toward a carbon-neutral, resilient, and equitable future for Minnesota and contains immediate, near-term actions, as well as key progress indicators with measurable targets. The framework was developed based on significant input from stakeholders, the public, and the Tribal Nations located within Minnesota's modern borders. [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

The proposed light-and medium-duty vehicle standards would advance the following actions in the Clean Transportation goal: [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

--Increase the use of clean fuels, including lower-carbon biofuels (Sub-initiative 1.2.1)

--Expand electric vehicle (EV) charging infrastructure (Sub-initiative 1.2.2)

--Increase EV availability and access (Sub-initiative 1.2.3)

--Accelerate the transition to EVs and clean transportation (Sub-initiative 1.2.4)

--Improve vehicle efficiency and emissions standards (Sub-initiative 1.2.5)

Additionally, the proposed standards would advance the following targets for the Clean Transportation goal:

--Reduce greenhouse gas emissions from the transportation sector 80% by 2040

--Reach 20% electric vehicles on Minnesota roads by 2030 [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

Importance of new federal standards in accelerating vehicle electrification efforts in Minnesota

The MPCA agrees that zero emission vehicle technology is available and viable in many use cases, and the technology is rapidly advancing. Vehicle manufacturers have made major commitments to electrification. However, to address its regulatory obligations to reduce harmful climate-changing pollutants, EPA must lock in those commitments, ensure all manufacturers act, and push the manufacturers to go farther faster. The significant investments that Minnesota is making, as well as the investments from the Bipartisan Infrastructure Law and Inflation Reduction Act will support the industry's transition to electrification and its ability to achieve stringent emissions standards. [EPA-HQ-OAR-2022-0829-0557, p. 3]

The proposed standards would provide more certainty in these efforts and help Minnesota transition more quickly to electric vehicles, achieving earlier reductions in greenhouse gas emissions, criteria air pollutants, and air toxics. Minnesota has made significant efforts toward electrification; now we need EPA to adopt stringent vehicle emissions standards that will drive manufacturers to produce these vehicles at the scale needed to address climate change. [EPA-HQ-OAR-2022-0829-0557, p. 4]

MPCA comments and recommendations

The following are Minnesota's comments and recommendations on the proposed rulemaking:

- Set greenhouse gas emissions standards that are at least as stringent as Alternative 1 [EPA-HQ-OAR-2022-0829-0557, p. 4]

The MPCA strongly supports EPA's initiative to develop greenhouse gas emissions standards for light- and medium-duty vehicles. Specifically, MPCA supports standards that are at least as stringent as Alternative 1. The MPCA recognizes the regulation of greenhouse gases as an important role for the EPA and sees the proposed rule as an important step forward for climate action and pollution reduction. While states have the right under Section 177 of the Clean Air Act to adopt the more stringent alternative emissions standards adopted by California, it remains critical that the federal government meet its obligation to implement strong national standards. MPCA encourages EPA to adopt the most stringent standards that are technologically feasible. [EPA-HQ-OAR-2022-0829-0557, p. 4]

Organization: Mitsubishi Motors North America, Inc. (MMNA)

To determine a realistic maximum volume of EVs the market can support for each of the model years covered by the rule, we believe EPA should consider certain critical factors. Among these factors, we believe EPA must make a thorough and realistic year-by-year assessment of key factors like projected battery costs, projected supply of battery critical-minerals, projected residential and public charging infrastructure availability, projected electrical grid capacity, and consumer acceptance of BEV technology in the broader arena. [EPA-HQ-OAR-2022-0829-0682, p. 2]

Mitsubishi participated in the development of -and supports -the comments submitted by Auto Innovators. [EPA-HQ-OAR-2022-0829-0682, p. 2]

In addition, based on its considerable experience discussed previously with BEV and PHEV leadership, Mitsubishi provides the following recommendations to supplement the comments of Auto Innovators [EPA-HQ-OAR-2022-0829-0682, p. 2] :

1. Closely align the multi-pollutant emissions standards with President Biden's 2030 goal by assuming no more than 40-50% PHEVs and FCEVs by 2030, even though our experience leads us to caution that this itself is very ambitious, and is predicated on the assumption that the necessary supportive policies will be effectively implemented. [EPA-HQ-OAR-2022-0829-0682, p. 2]
2. Consider the many benefits of PHEVs to consumers and the environment during the expected period of constrained battery critical minerals production capacity, and how PHEVs are the perfect stepping-stone to full BEV acceptance. [EPA-HQ-OAR-2022-0829-0682, p. 2]
3. Maintain the current PHEV Utility Factor (UF) and work with industry to identify opportunities to increase PHEV electric operation. This is the ideal stepping-stone technology to encourage long-term BEV acceptance and utilization. [EPA-HQ-OAR-2022-0829-0682, p. 2]
4. Keep the proposed approach to determine the passenger car curves, and consider adjusting the cutpoint and stringency levels of the light-duty trucks during the early years of the program. [EPA-HQ-OAR-2022-0829-0682, p. 2]
5. Maintain the existing GHG program flexibilities, such as Air Conditioning and Off-Cycle technologies credits (including the alternative method to apply off-cycle credits), and allow previously approved technologies to continue receiving credits. [EPA-HQ-OAR-2022-0829-0682, p. 2]
6. Align the Tier-4 (criteria pollutants) with CARB's LEV-IV criteria test procedures and standards. [EPA-HQ-OAR-2022-0829-0682, p. 2]
7. Consider the impact that very aggressive GHG standards will have on vehicle affordability, and especially the detrimental impact to low-to-moderate income families. Regardless of the vehicles that regulation may require us to produce, it is critical that regulators always keep the accessibility of consumers in mind. [EPA-HQ-OAR-2022-0829-0682, p. 2]

The rationale for each one of these recommendations is further explained below. [EPA-HQ-OAR-2022-0829-0682, p. 2]

1. Overall GHG Stringency

Mitsubishi shares the views expressed by Auto Innovators regarding stringency of the GHG standards from MY27 through MY32. In particular, Mitsubishi is concerned that the BEV shares needed for compliance and the accelerated rate of increasing stringency proposed by EPA will create considerable risk based on factors outside the control of the industry. [EPA-HQ-OAR-2022-0829-0682, pp. 2-3]

The White House, on August 5, 2021, announced Executive Order 14037 which set a target of 50% electric vehicles by 2030. In this NPRM, EPA is estimating a BEV share of 60% by 2030, and 67% by 2032, well beyond the 50% goal of EO 14037, which included BEVs, PHEVs, and FCEVs. EPA justifies this, in part, due to manufacturer announcements and recent policies such and the Inflation Reduction Act (IRA) and Infrastructure Investment and Jobs Act (IIJA). However, similar analysis by the Energy Information Administration (EIA) in May 2023, projects such programs will result in an EV share between 11 and 26 percent by 2050. [EPA-HQ-OAR-2022-0829-0682, pp. 2-3]

In its paper, the EIA acknowledges, "…significant uncertainties are inherent to projecting the rate…" of EV adoption. Among the factors EIA includes for this uncertainty are future policies, technology advancement, availability and access to EV infrastructure, consumer behavior, and mineral supply chains. Even with the most optimistic assumptions, the EIA only projected a 26% share of new sales coming from EVs, and that is at nearly thirty years from now3. The wide range of projected EV market shares by two government agencies within the same Administration illustrates the uncertainty of EV market drivers, yet this proposal offers no opportunities for course correction should market conditions, which are outside the control of automakers, fall short of EPA's optimistic assumptions. This, of course, leads to questions on the methodology of this NPRM. [EPA-HQ-OAR-2022-0829-0682, pp. 2-3]

3 https://www.eia.gov/todayinenergy/detail.php?id=56480, Accessed June 23, 2023

EPA included three alternatives to the proposed standard: Alternative 1 is more stringent by 10 g/mi, Alternative 2 is less stringent by 10 g/mi, and Alternative 3 proposes a linear reduction in GHG emissions starting with the MY26 standard and ending with the proposed GHG standard in MY32. While Alternative 3 reduces the stringency burden in the early years of the program, it would still require over 50% BEVs by MY30. Mitsubishi supports Auto Innovators' proposed approach to overall stringency, as, regardless of early-adopter acceptance of BEVs, we question the penetration of this technology into the mass-market approaching 50% by 2030. [EPA-HQ-OAR-2022-0829-0682, pp. 2-3]

Organization: National Association of Clean Air Agencies (NACAA)

GHG Emission Standards and Related Issues [EPA-HQ-OAR-2022-0829-0559, pp. 7-8]

NACAA supports the strongest LMDV CO2 emission standards that are technologically feasible. EPA proposes progressively more effective performance-based CO2 emission standards for MY 2027 through 2032 LDVs and MDVs. The proposed standards do not mandate the use of any specific technology, nor do they mandate that any percentage of vehicle production be ZEVs. Instead, each manufacturer may choose what mix of emission control technologies is best suited for its fleet to meet the standards. [EPA-HQ-OAR-2022-0829-0559, pp. 7-8]

The proposed LDV standards are projected to result in an industry-wide average target for the light-duty fleet of 82 gm/mi of CO2 in MY 2032, which represents a 56-percent reduction in projected fleet average GHG emissions target levels from the existing MY 2026 standards. EPA also puts forth three LDV alternatives for comment. Alternative 1 has more rigorous LDV CO2 standards than the proposal; Alternative 2 has weaker LDVs CO2 standards than the proposal; and Alternative 3 culminates with the same MY 2032 LDV CO2 standard as the proposal but reaches that standard at a more gradual rate. [EPA-HQ-OAR-2022-0829-0559, pp. 7-8]

For LDVs, NACAA supports, at a minimum, EPA's proposed CO2 standards with the addition of anti-backsliding requirements to ensure that non-ZEV vehicle emissions do not increase over time. NACAA firmly opposes Alternative 2 or any final program that is weaker than the proposal. Also, EPA should not pursue a more gradual rate of phase in for any standards it finalizes, such as under Alternative 3, unless the agency tightens the standards in MYs 2031 and 2032 to make up in full for the loss of the emission reductions that would occur from the less protective standards in the earlier years of the program. [EPA-HQ-OAR-2022-0829-0559, pp. 7-8]

For MDVs, NACAA supports EPA's proposed CO2 standards including the proposal to revise the existing MY 2027 CO2 standard because of the increased feasibility of GHG emission-reducing technologies for this sector in this time frame. EPA's proposed MDV CO2 standards would increase in stringency from MY 2027 through MY 2032, when the standards are projected to result in an average target of 275 gm/mi of CO2, representing a reduction of 44 percent from the current MY 2026 standard. [EPA-HQ-OAR-2022-0829-0559, pp. 7-8]

Organization: National Parks Conservation Association (NPCA)

First and foremost, NPCA urges EPA to move forward with Alternative 1 for light-duty vehicles instead of proceeding with other less stringent alternatives included in the proposal. We further urge EPA to increase the stringency of Alternative 1 starting in 2030 to require additional ZEV sales and ensure a greater degree of certainty in achieving one hundred percent ZEV LDV sales by no later than 2035. We firmly believe a strengthened Alternative 1 provides the greatest degree of emission reductions, the highest level of health, climate, and cost benefits, and is both technologically and economically feasible. A more stringent Alternative 1 is also necessary to keep the U.S. in line with the administration's stated 50% ZEV sales by 2030 vehicle electrification goal, as well as follow what many experts say is needed to stay under the 2° C warming threshold.18 NPCA, moreover requests that for non-ZEV vehicles sold post 2027, EPA improve upon Alternative 1 to include additional emission reduction controls for the remaining fossil fuel powered vehicles on the market. [EPA-HQ-OAR-2022-0829-0607, p. 4]

> 18 See, The White House, FACT SHEET: President Biden Announces Steps to Drive American Leadership Forward on Clean Cars and Trucks, (August 5, 2021), available at, www.whitehouse.gov/briefing-room/statements-releases/2021/08/05/fact- sheet-president-biden-announces-steps-to-drive-american-leadership-forward-on-clean-cars-and-trucks/.

Organization: Nissan North America, Inc..Nissan appreciates the Administration's focus on and support for advancing electrification and carbon neutrality and shares the same long-term goal of transitioning to zero emission vehicle society. However, Nissan believes that market realities, infrastructure needs, consumer impacts, and lack of battery critical mineral availability necessitate an adjustment of the GHG standard stringency in this rulemaking timeframe. [EPA-HQ-OAR-2022-0829-0594, p. 1]

Nissan is committed to transitioning its vehicle portfolio to EVs over time and intends to remain an industry leader in EV and related battery technology innovations. Nissan supports President Biden's overall efforts to increase sales of battery, fuel cell, or plug-in hybrid electric vehicles (BEVs, FCEVs, and PHEVs, respectively) over the next decade. The Administration already announced aggressive penetration targets in the August 5, 2021 "Executive Order on Strengthening American Leadership in Clean Cars and Trucks" (hereinafter "Clean Cars EO"). The Proposed Multi-Pollutant Rule, however, goes well beyond the already ambitious goals announced in President Biden's Clean Cars EO. Not only has the penetration percentage been significantly increased (jumping from 50 percent to 60 percent in 2030), but the make-up of that percentage has drastically changed: EPA's Proposed Multi-Pollutant Rule would require a 60 percent penetration rate for BEVs only, excluding the FCEV and PHEV technologies that are critical to shepherding a safe, affordable, and reliable transition to clean vehicles. EPA has moved the goalpost, not by a few feet but by miles.

In light of these myriad challenges, EPA should adjust the proposed GHG standards set forth in the Proposed Multi-Pollutant Rule. Nissan supports a final rule that takes these realities into consideration and seeks an ambitious yet achievable target for plug-in electric vehicle (“PEV”)penetration, closer to the already ambitious targets set in the Clean Cars EO. At a minimum, Nissan requests that EPA adjust the proposed GHG standards and targets to account for a blended PEV percentage, taking into consideration emissions reductions from PHEVs and BEVs collectively. EPA has historically considered the emissions benefits of both groups of advanced technology vehicles, acknowledging the importance and need of PHEVs in the consumer shift towards clean vehicles. Nissan and others in the industry are committed to transforming the industry and have already invested significantly in pressing forward on the transition to EVs. The Proposed Multi-Pollutant Rule goes beyond what is achievable and simply forces too much too quickly. There simply is not a realistic path to achieve the level of accelerated shift in the proposed timeframe. More time is needed for such extensive and transformational change.

VII. Endorsement of Comments from the Alliance for Automotive Innovation

As a member of the Alliance for Automotive Innovation (“the Alliance”), Nissan fully endorses the comments on the Proposed Multi-Pollutant Rule submitted separately by the Alliance. In particular, Nissan highlights several points from the Alliance’s comments, including: [EPA-HQ-OAR-2022-0829-0594, p. 9]

- Support realigning the GHG standard stringency ramp up rates with market reality and uncertainties. [EPA-HQ-OAR-2022-0829-0594, p. 9]

- Support realigning the Federal criteria emission standards with California’s program. [EPA-HQ-OAR-2022-0829-0594, p. 9]

- Emphasis regarding the industry’s commitment to work towards electrification as quickly as practicable, while also taking into consideration resource availability, technological capabilities, market challenges and limitations, and consumer adoption hurdles. [EPA-HQ-OAR-2022-0829-0594, p. 9]

- Support continuation of tailpipe-based program and treatment of 0 g/mi for EVs [EPA-HQ-OAR-2022-0829-0594, p. 9]

- Request reconsideration of the proposed changes in the AC and off-cycle credit programs: [EPA-HQ-OAR-2022-0829-0594, p. 9]

- Request continuing AC and off-cycle credit eligibility for EVs that are part of mixed fleets [EPA-HQ-OAR-2022-0829-0594, p. 9]

- Oppose phase-out of off-cycle credits and request the off-cycle credit cap be maintained at 15 g/mi [EPA-HQ-OAR-2022-0829-0594, p. 9]

Organization: Nissan North America, Inc.

These new proposed targets lose sight of the transformational change that is needed from all sectors of the U.S. economy. Automobile manufacturers such as Nissan have made and will continue to make significant investments to push the industry forward; however, such drastic and front-loaded timelines require significant changes and investments from suppliers, energy providers, mineral extraction and processing industries, battery and charging equipment manufacturers, etc. Such drastic changes to the market are nearly impossible on such a compressed timeline, particularly given the current market constraints affecting nearly all impacted sectors, such as supply-chain complications and limited availability of raw materials. This is especially true with respect to the critical minerals that are essential to battery production for EV expansion and development; EPA has not demonstrated that the critical minerals needed to meet the extremely aggressive EV penetration rates are available to be extracted in a safe, responsible, and reliable manner. Significant cooperation and organization from federal, state, and local governments will also be required to facilitate the roll-out and adoption of EVs and related charging infrastructure. [EPA-HQ-OAR-2022-0829-0594, p. 4]

Beyond the significant market and governmental challenges posed by such a drastic implementation timeline, consumer adoption will be critical to success. Consumer adoption of EVs has historically lagged behind expectations, leaving a significant hurdle to encourage a large and swift shift to EVs. Consumers need to be convinced not only of the appeal, safety, affordability, and reliability of EVs themselves, but they need to adopt the necessary community and home charging equipment to facilitate their use. Consumers will need to adapt their trip planning and driving behavior to allow for vehicle charging needs. The only way to drive these significant behavioral changes is to assure consumers that charging infrastructure is available and reliable. This is simply not a reality today and is unlikely to be a reality in time to drive such a significant shift within the timeline of the Proposed Multi-Pollutant Rule. These challenges are magnified due to the unclear and uncertain benefits under the Inflation Reduction Act, which place significant limitations on EV consumer incentive programs and charging infrastructure programs. Moreover, many consumers are reluctant or unable to purchase EVs due to their significant price premium. The Proposed Multi-Pollutant Rule will only exacerbate these inequalities, with EV prices likely to increase even more due to extreme investments required by all market sectors involved. Driving too much change too quickly will shut out many communities who need clean vehicles the most. It will likely force consumers who are uncertain about ZEV adoption to continue to operate aging ICE vehicles much longer. This is contrary to the intent of the proposal. [EPA-HQ-OAR-2022-0829-0594, p. 5]

VII. Endorsement of Comments from the Alliance for Automotive Innovation

As a member of the Alliance for Automotive Innovation ("the Alliance"), Nissan fully endorses the comments on the Proposed Multi-Pollutant Rule submitted separately by the Alliance. In particular, Nissan highlights several points from the Alliance's comments, including [EPA-HQ-OAR-2022-0829-0594, p. 9]:

- Support realigning the GHG standard stringency ramp up rates with market reality and uncertainties. [EPA-HQ-OAR-2022-0829-0594, p. 9]

- Support realigning the Federal criteria emission standards with California's program. [EPA-HQ-OAR-2022-0829-0594, p. 9]

- Emphasis regarding the industry's commitment to work towards electrification as quickly as practicable, while also taking into consideration resource availability, technological capabilities, market challenges and limitations, and consumer adoption hurdles. [EPA-HQ-OAR-2022-0829-0594, p. 9]

- Support continuation of tailpipe-based program and treatment of 0 g/mi for EVs [EPA-HQ-OAR-2022-0829-0594, p. 9]

- Request reconsideration of the proposed changes in the AC and off-cycle credit programs: [EPA-HQ-OAR-2022-0829-0594, p. 9]

- Request continuing AC and off-cycle credit eligibility for EVs that are part of mixed fleets [EPA-HQ-OAR-2022-0829-0594, p. 9]

- Oppose phase-out of off-cycle credits and request the off-cycle credit cap be maintained at 15 g/mi [EPA-HQ-OAR-2022-0829-0594, p. 9]

- Support coordination and harmonization between EPA, NHTSA, and CARB. One fleet should meet all programs with a common goal. [EPA-HQ-OAR-2022-0829-0594, p. 9]

While Nissan understands and supports the Administration's efforts to push for progress in EV penetration, the current proposal goes well beyond the already aggressive goals set in President Biden's Clean Cars EO. The current proposal is not achievable for numerous reasons, including technology and resource limitations, limited availability of safe and responsibly-sourced critical minerals, supply chain and manufacturing constraints, insufficient charging and energy infrastructure, and significantly lagging consumer adoption, among other reasons. In order to allow for a safe, reliable, and equitable transition to EVs, the proposal must be modified to take these factors into consideration. [EPA-HQ-OAR-2022-0829-0594, pp. 9-10]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC)

NESCAUM and the OTC offer the following specific comments on the NPRM.

A. Proposed LDV and MDV GHG Emissions Standards

NESCAUM and the OTC strongly support EPA's proposal to establish CO_2 emissions standards for LDVs and MDVs that would increase in stringency each year from MYs 2027–2032. EPA should adopt the most stringent standards that are technologically feasible. [EPA-HQ-OAR-2022-0829-0584, pp. 8-9]

EPA's proposed LDV standards are projected to result in an industry-wide average target for the light-duty fleet of 82 g/mi of CO_2 in MY 2032, representing a 56 percent reduction in projected fleet average GHG emissions target levels from existing MY 2026 federal standards. EPA's proposed MDV standards are projected to result in an average target of 275 g/mi of CO_2 by MY 2032, which would represent a reduction of 44 percent compared to the current MY 2026 standards. EPA also proposes to revise the existing standard for MY 2027 given the increased feasibility of GHG emissions reducing technologies in this time frame. [EPA-HQ-OAR-2022-0829-0584, pp. 8-9]

EPA's analysis finds that the proposed LDV and MDV standards could reduce net CO_2 emissions by 7.3 billion metric tons through 2055. EPA estimates the cumulative monetized climate benefits of the standards through 2055 to be $330–$500 billion (2020 $US) depending on upstream emissions and the selected discount rate.24 [EPA-HQ-OAR-2022-0829-0584, pp. 8-9]

24 See EPA, DRIA, EPA-420-D-23-003 (Apr. 14, 2023), https://www.regulations.gov/document/EPA-HQ-OAR-2022-0829-0360.

Considering the state of the U.S. and global LDV and MDV markets, NESCAUM and the OTC believe that GHG standards more stringent than EPA's proposal are technologically feasible. [EPA-HQ-OAR-2022-0829-0584, pp. 8-9]

B. Multi-State Collaboration

The NESCAUM and OTC states have long understood the benefits of a coordinated approach to transportation electrification policy development and implementation. Many are signatories to the 2013 Multi-State Zero-Emission Vehicle Memorandum of Understanding,17 which set light-duty ZEV sales targets for ten states to achieve by 2025; memorialized their commitment to work together to develop policies and programs to achieve those targets; and created the Multi-State ZEV Task Force, facilitated by NESCAUM, to enable states to collaborate and coordinate on ZEV policy. NESCAUM and the Task Force have developed two action plans with recommendations for states to accelerate light-duty ZEV adoption18 and policy guidance on a wide range of related issues and topics. [EPA-HQ-OAR-2022-0829-0584, pp. 5-6]

17 Multi-State Zero-Emission Vehicles Program Memorandum of Understanding (Oct. 2013), https://www.nescaum.org/documents/zev-mou-10-governors-signed-20191120.pdf/.

18 See, e.g., Multi-State ZEV Task Force, Multi-State ZEV Action Plan 2018-2021: Accelerating the Adoption of Zero Emission Vehicles (June 2018), https://www.nescaum.org/topics/zero-emission-vehicles/multi-state-zev-action-plan-2018-2021-accelerating-the-adoption-of-zero-emission-vehicles; Multi-State ZEV Action Plan (May 2014).

Most of the NESCAUM and OTC states are also signatories to the 2020 Multi-State Medium-and Heavy-Duty ZEV Memorandum of Understanding,19 now signed by a diverse coalition of 17 states, the District of Columbia, and the Canadian province of Quebec. Collectively, the U.S. signatories represent 43 percent of the U.S. population, 49 percent of the U.S. economy, and 36 percent of the nation's medium-and heavy-duty vehicles.20 The 2020 MOU commits the signatories to collaborate to accelerate the market for zero-emission trucks, vans, and buses, and sets targets to achieve at least 30 percent medium-and heavy-duty ZEV sales by 2030 and 100 percent ZEV sales by no later than 2050. Some of the signatories have established more ambitious targets. In July 2022, NESCAUM and the Task Force released an action plan with more than 65 strategies and recommendations for state policymakers to support the rapid, equitable, and widespread electrification of MHD vehicles.21 The signatories and other Task Force states are currently working to implement these recommendations. [EPA-HQ-OAR-2022-0829-0584, pp. 5-6]

21 See Multi-State ZEV Task Force, Multi-State Medium-and Heavy-Duty Zero-Emission Vehicle Action Plan: A Policy Framework to Eliminate Harmful Truck and Bus Emissions (July 27, 2022), https://www.nescaum.org/documents/multi-state-medium-and-heavy-duty-zero-emission-vehicle-action-plan/.

NESCAUM and the OTC strongly support EPA's proposal to establish CO2 emissions standards for LDVs and MDVs that would increase in stringency each year from MYs 2027–2032. EPA should adopt the most stringent standards that are technologically feasible. [EPA-HQ-OAR-2022-0829-0584, pp. 8-9]

EPA's proposed LDV standards are projected to result in an industry-wide average target for the light-duty fleet of 82 g/mi of CO2 in MY 2032, representing a 56 percent reduction in projected fleet average GHG emissions target levels from existing MY 2026 federal standards. EPA's proposed MDV standards are projected to result in an average target of 275 g/mi of CO2 by MY 2032, which would represent a reduction of 44 percent compared to the current MY 2026 standards. EPA also proposes to revise the existing standard for MY 2027 given the increased feasibility of GHG emissions reducing technologies in this time frame. [EPA-HQ-OAR-2022-0829-0584, pp. 8-9]

EPA's analysis finds that the proposed LDV and MDV standards could reduce net CO2 emissions by 7.3 billion metric tons through 2055. EPA estimates the cumulative monetized climate benefits of the standards through 2055 to be $330–$500 billion (2020 $US) depending on upstream emissions and the selected discount rate.24 [EPA-HQ-OAR-2022-0829-0584, pp. 8-9]

24 See EPA, DRIA, EPA-420-D-23-003 (Apr. 14, 2023), https://www.regulations.gov/document/EPA-HQ-OAR-2022-0829-0360.

Considering the state of the U.S. and global LDV and MDV markets, NESCAUM and the OTC believe that GHG standards more stringent than EPA's proposal are technologically feasible. [EPA-HQ-OAR-2022-0829-0584, pp. 8-9]

Organization: Our Children's Trust (OCT)

On behalf of America's youth, Our Children's Trust respectfully provides these comments on the U.S. Environmental Protection Agency's ("EPA") proposed Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles. As the Nation's only law firm dedicated to representing youth whose constitutional rights are being infringed by their government's conduct that causes climate change, we write to advise EPA to strengthen the federal emission standards for light- and medium-duty vehicles so that they meet the urgency of the climate crisis and align with the deep emission reductions scientists say are needed to protect the climate system and the constitutional rights of youth. We also ask that the EPA revise its Draft Regulatory Impacts Analysis so that it reflects the true costs of climate change, the true benefits of more swiftly electrifying the transportation sector, and utilizes no discount rate or a discount rate that does not discriminate against children and future generations. EPA must align its rulemaking with the best available science to protect children. [EPA-HQ-OAR-2022-0829-0542, p. 1]

We are well beyond the time for incremental measures. These rules need to go further, faster and across a longer time horizon so that the entire transportation sector, and supporting industrial sectors, can plan and respond as quickly as feasible. The technology is there to expedite the transition away from the internal combustion engine and eliminate their sales by 2030 for passenger cars and light duty trucks. This is not only economically feasible, it is enormously beneficial. [EPA-HQ-OAR-2022-0829-0542, p. 1] Wim Thiery et al., Intergenerational Inequities in Exposure to Climate Extremes, 374 Science 158 (2021).

Organization: Porsche Cars North America (PCNA)

Porsche provides the following comments in support of and in conjunction with the AFAI. These comments seek to define a more achievable regulatory package that makes meaningful progress towards decarbonization goals. Furthermore, Porsche supports the concept of broadly monitoring our collective progress across all sectors involved in the march towards electrification. [EPA-HQ-OAR-2022-0829-0637, p. 19]1. Porsche supports the AFAI proposal for an annual GHG reduction goal that aligns with the 40-50% electrification industry position.

As described within the AFAI comments, Porsche is supportive of a piecewise linear annual compliance pathway that is a logical extension of the three alternative pathways proposed within the NPRM. The piecewise linear pathway could be designed with stringency levels that reflect the industrywide anticipated levels of electrification at various years from 2027-2032MY. The estimated annual compliance curve (reflecting industry average annual fleet average targets) would consist of two linear phases. The phases would essentially reflect industry wide annual percent levels of electrification that would include both pure battery electric and plug-in hybrid electric. The first phase of the piecewise linear curve defining stringency for MY2027-2030 would extend from MY2026 estimated levels of industrywide electrification and arrive at GHG targets that reflect 40-50% of industrywide electrification. The second phase of the piecewise curve could then extend from those targets in MY2030 to a more ambitious level of stringency in MY2032 that best reflects an achievable level of industrywide electrification. [EPA-HQ-OAR-2022-0829-0637, p. 19]

The importance of having a clear touch point in 2030 model year is that it reflects general industry wide positioning regarding support for an ambitious goal of 40-50% of new electrified vehicle sales at that time. This goal is aligned with the President's Executive Order and with the National Blueprint for Electrification. The range of 40 to 50% reflects a reasonable variance for such an ambitious transformative goal and as such Porsche believes that it would be reasonable to select the midpoint of this range to inform the program stringency in MY2030. In addition, Porsche believes it is reasonable for the 40-50% to include within it a mix of BEVs and PHEVs that reflects the anticipated allowance of PHEVs within CARB’s ACC2 ZEV mandate (i.e., approximately 20% PHEV within the 40-50% of total BEV/FCV/PHEV portion of new vehicle sales). [EPA-HQ-OAR-2022-0829-0637, p. 19]

Beyond 2030, the pathway should again use a linear progression, but towards a more ambitious level of electrification. The appropriate level of electrification should reflect a reasonable assessment of consumer adoption and industry readiness that pushes electrification. This target could again include a mix of BEV and PHEV vehicles consistent with the consideration during the initial phase and reflective of the continued allowance for PHEVs within CARB's ACC2 ZEV mandate (i.e., 20% PHEV of the total % of BEV/FCV/PHEV). [EPA-HQ-OAR-2022-0829-0637, p. 19]

Organization: Rivian Automotive, LLC

EPA's proposal is clearly a big step toward a fully decarbonized L/MDV sector. Nonetheless, Rivian believes an even stronger rule is possible and appropriate. Our analysis of the NPRM identified opportunities to strengthen the standards further with the adoption of Alternative 1 and targeted adjustments to certain flexibility provisions. We also offer various comments in response to other proposed changes in the discussion below. [EPA-HQ-OAR-2022-0829-0653, pp. 2-7]

EPA Should Select Alternative 1 and Make Other Changes to Strengthen the Rule

EPA should select Alternative 1—and weigh the feasibility of even more stringent targets—for three key reasons. [EPA-HQ-OAR-2022-0829-0653, pp. 2-7]

EPA shows that, of the alternatives considered, Alternative 1 delivers the greatest net benefits. Agency modeling demonstrates that Alternative 1 rests on realistic assumptions of improvement in emissions from ICE vehicles. [EPA-HQ-OAR-2022-0829-0653, pp. 2-7]

Alternative 1 Offers the Greatest Net Benefits

In the documents introducing and accompanying the proposed rule, agency staff detailed the results of an extensive cost-benefit analysis performed as part of its deliberations. EPA's own calculations show that Alternative 1, of the proposed alternatives, will deliver the greatest net benefits to Americans, including an array of monetized climate and public health benefits. Specifically, the agency found that their main proposal would result in present value net benefits ranging from $850 billion to $1.6 trillion (7 percent and 3 percent discount rates, respectively; SC-GHG at 3 percent) while Alternative 1 would result in benefits ranging from $930 billion to $1.8 trillion (using the same the discount rates and SC-GHG).7 Despite these clear findings, EPA initially proposed a less beneficial alternative without a compelling justification. This is inconsistent with both the Biden Administration's stated goals and priorities and, perhaps most importantly, with the directive of Executive Order 12866, later reaffirmed by Executive Order 13563, that "in choosing among alternative regulatory approaches, agencies should select those approaches that maximize net benefits..."8 Accordingly, Rivian believes EPA should, and is obligated to, select Alternative 1 in its final determination. Finalizing any of the other proposed alternatives would not be justifiable on cost- benefit grounds. [EPA-HQ-OAR-2022-0829-0653, pp. 2-7]

7 U.S. Environmental Protection Agency, Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light- Duty and Medium-Duty Vehicles: Draft Regulatory Impact Analysis (April 2023), 10-30 – 10-31.

8 Exec. Order No. 12,866, 58 Fed. Reg. 190 (Oct. 4, 1993); Exec. Order No. 13,563, 76 Fed. Reg. 14 (Jan. 21, 2011).

Finalize Standards at Least as Stringent as Alternative 1 to Put the U.S. on the Path to 100 Percent EV Sales

With the multi-pollutant emissions standards proposal for MY27 and later, EPA rose to the occasion. The standards as proposed are well calibrated to industry's investments in vehicle electrification. With the growing focus on EV development and sales, automakers can achieve deep cuts to vehicles emissions in the next decade. Indeed, Rivian finds that the available evidence supports at least the most stringent of the alternatives EPA considered. While some stakeholders argue for softening the requirements, Rivian's analysis shows that tighter standards are feasible. We call on the agency to finalize Alternative 1. EPA should strengthen its analysis with full inclusion of Rivian's production volumes, which we believe will further support the case for Alternative 1 and a second look at the MDV standards. We also recommend sunsetting the off-cycle program for all vehicle types earlier than proposed and phasing out MDV ATV multipliers. We generally support battery durability and warranty standards aligned with GTR 22 but offer some considerations regarding implementation. [EPA-HQ-OAR-2022-0829-0653, p. 17]

The need for urgent action on climate change has never been greater. We have also never before seen such a committed partner in the federal government. With some modifications and the selection of Alternative 1, the proposed regulations could mark a true turning point in our industry's journey toward a fully decarbonized future. [EPA-HQ-OAR-2022-0829-0653, p. 17]

Organization: Sierra Club et al.

We appreciate the EPA's proposal, which moves our vehicles in the right direction. However, the final emissions standard for light-duty vehicles should: [EPA-HQ-OAR-2022-0829-0668, p. 2]

-Secure greater pollution reductions with a focus on strengthening the later model years of the program, reflecting the cost-effective availability of greater zero-emission vehicle adoption due to market growth expected from IRA and IIJA investments (which will surpass existing commitments outlined in Executive Order 14037) and state leadership; [EPA-HQ-OAR-2022-0829-0668, p. 2]

-Put the nation on a trajectory to ensure 100 percent of all light- and medium-duty vehicles sold in 2035 are zero-emission vehicles including pathway milestones assuring continuous progress; [EPA-HQ-OAR-2022-0829-0668, p. 2]

-Appropriately take advantage of available cost-effective improvements to new fossil-fuel vehicles; [EPA-HQ-OAR-2022-0829-0668, p. 2]

-Leverage the growth in ZEV deployment associated with state clean car standards adopted under state authority granted by the Clean Air Act; and [EPA-HQ-OAR-2022-0829-0668, p. 2]

-Establish protective zero-emission vehicle durability and warranty requirements [EPA-HQ-OAR-2022-0829-0668, p. 2]

We appreciate the EPA's proposal, which moves our vehicles in the right direction. However, the final emissions standard for light-duty vehicles should: [EPA-HQ-OAR-2022-0829-0668, p. 2]

-Secure greater pollution reductions with a focus on strengthening the later model years of the program, reflecting the cost-effective availability of greater zero-emission

vehicle adoption due to market growth expected from IRA and IIJA investments (which will surpass existing commitments outlined in Executive Order 14037) and state leadership; [EPA-HQ-OAR-2022-0829-0668, p. 2]

-Put the nation on a trajectory to ensure 100 percent of all light- and medium-duty vehicles sold in 2035 are zero-emission vehicles including pathway milestones assuring continuous progress; [EPA-HQ-OAR-2022-0829-0668, p. 2]

Organization: South Coast Air Quality Management District

There are five key issues we request U.S. EPA address before finalizing the rule.1. Extend the phase-in period and adopt more stringent standards to align with California's ACC II regulation. The proposed standards will be phased in over a six-year period from model year (MY) 2027 through 2032 with increasing stringency each year. We recommend that the phase-in period be extended to 2035 and later model years to better align with the ACC II implementation schedule which extends out to MY 2035 and subsequent years. [EPA-HQ-OAR-2022-0829-0659, p. 2]

In terms of stringency, the proposed non-methane organic gases plus nitrogen oxides (NMOG+NOx) standard would phase down to 12 mg/mi by MY 2032 for light-duty vehicles (LDVs), a 60 percent reduction from the Tier 3 standard of 30 mg/mi. For medium-duty vehicles (MDVs), the NMOG+NOx standard would phase down to 60 mg/mi by MY 2032, representing 66 percent to 76 percent reduction from the Tier 3 standard of 178 mg/mi for Class 2b and 247 mg/mi for Class 3 vehicles, respectively. While these standards represent substantial progress, we urge U.S. EPA to consider more stringent standards for CO2 and criteria pollutants to help our region achieve the national ambient air quality standards. We therefore support the adoption of the Alternative 1 stringency level for greater reductions of emissions, including NOx (47,000 tons vs 44,000 tons in 2055) as well as a higher BEV (Battery Electric Vehicle) penetration rate compared to the proposed standards (69% vs 67% in MY 2032). [EPA-HQ-OAR-2022-0829-0659, p. 2]

Furthermore, U.S. EPA should consider additional measures that are technically and economically feasible. For example, the ACC II requires manufacturers to comply with an annual zero emission vehicle (ZEV) sales percentage requirement that scales up from 35 percent in MY 2026 to 100 percent by MY 2035 (including up to 20% PHEVs). CARB's analysis supports this requirement to be both technically and economically feasible based on projected technology advancements. In comparison, the projected 69 percent BEV penetration rate in MY 2032 for Alternative 1 falls short of the ACC II requirements. We understand the proposed standards are performance-based without any mandate on ZEV sales percentages, however, U.S. EPA should conduct an additional feasibility analysis for more stringent standards that will achieve higher BEV penetration rates. [EPA-HQ-OAR-2022-0829-0659, p. 2]

Organization: Southern Environmental Law Center (SELC)

This means EPA must adopt standards that are least as strong as those it has identified as Alternative 1—the most stringent alternative analyzed as part of this proposal and a standard that EPA itself notes is "anticipated to be feasible."52 Alternative 1 will result in significant benefits compared to the current proposal, and these benefits add up. The Alternative 1 standards are projected to result in fleet-wide CO2 targets that are on average 10 g/mi lower than the current proposal,53 resulting in 800 million metric tons fewer CO_2 emissions through 2055.54 This is an approximately 61 percent reduction in projected fleet average GHG emissions target levels from the existing model year 2026 standards,55 and the Alternative 1 standards are expected to result in an approximately 69 percent battery-electric vehicle (BEV) penetration—one of the main ZEV technologies—in 2032.56 Alternative 1 also results in significantly fewer emissions of criteria pollutants and other air toxics through 2055.57 Together, these and other benefits from the stronger Alternative 1 standards are projected to deliver between $20 and $30 billion more in net benefits in calendar year 2055 than the current proposal.58 [EPA-HQ-OAR-2022-0829-0591, pp. 6-7]

58 Id. at tbls. 156, 157.

Ultimately, these and other factors suggest that EPA should consider adopting even stronger standards than Alternative 1. Standards that put the United States on the path of achieving 100 percent ZEV sales by 2035 should be feasible and have the potential to result in significant benefits for communities and the environment. For example, it has been estimated that standards ensuring that all passenger vehicle sales are zero-emission by 2035 could "avoid more than 600 million metric tons of greenhouse gas emissions every year by 2040 and a total of more than 11.5 billion tons by 2050."64 Studies have projected that the widespread transition to ZEVs coupled with a shift to non-combustion electricity would result in over $978 billion in cumulative public health benefits by 2050 nationwide,65 and 40 percent of these benefits would be experienced by the 500 counties with the highest populations of color.66 [EPA-HQ-OAR-2022-0829-0591, p. 8]

Organization: Stellantis

Greenhouse Gas Reductions are Front-Loaded

EPA proposes stringent standards for the 2027-2032MY that achieve ambitious GHG reductions. As shown in Figure 5 below, even the least stringent alternative (Alternative 2) proposed by EPA achieves a 50% reduction in GHG emissions by 2032 compared to 2026, while

EPA's proposed or preferred stringency achieves 56% total reduction by 2032 compared to 2026. [EPA-HQ-OAR-2022-0829-0678, pp. 7-9]

SEE ORIGINAL COMMENT FOR Table 10. Comparison of proposed combined fleet standards to alternatives. Figure 5 -Comparison of alternatives proposed in the EPA NPRM [EPA-HQ-OAR-2022-0829-0678, pp. 7-9]

In addition to setting ambitious overall targets for CO2 reduction, EPA's proposed rule demands that these reductions are primarily achieved early in the program with less reduction required in later years. In the proposed standards, the stringency jump required in the first year of the program (2027MY) is close to double that of stringency change in later years. This "front-loaded" stringency is even more evident when looking at the different fleets. Figure 6 below shows that in EPA's proposed stringency, pickup trucks must reduce GHG emissions by 14% per year in the initial 3 years in 2027-2029MY of the program followed by 10% per year reduction required in 2030-2032MY. [EPA-HQ-OAR-2022-0829-0678, pp. 7-9]

SEE ORIGINAL COMMENT FOR Graph Industry Fleet Targets by MY (Preferred Alternative) Figure 6 -Standards are much more stringent in the early years of the program – especially for trucks [EPA-HQ-OAR-2022-0829-0678, pp. 7-9]

Figure 7 below summarizes output from EPA's OMEGA model estimating the millions of megagrams of CO2 saved under the proposed rule and Alternative 3, which is a more linear alternative that EPA also included the proposed rule that does not front load reductions. [EPA-HQ-OAR-2022-0829-0678, pp. 7-9]

SEE ORIGINAL COMMENT FOR GRAPH CO2 Saved vs 2026MY Figure 7-Proposed cumulative GHG savings are significantly front-loaded [EPA-HQ-OAR-2022-0829-0678, pp. 7-9]

This analysis shows that under the EPA's proposed rule 63% of the CO2 saved would be achieved in the first 3 years of the program with the remaining approximately 35% being saved in the back end of the new program. Alternative 3 (or the more linear alternative) takes a more rational approach to realizing aggressive GHG reductions driven by a dramatic technology transformation. Stellantis shares AAI concerns that Alternative 3 exceeds the 40-50% EV commitment in 2030, however at least the CO2 savings under Alternative 3 are spread out more evenly over the entire rulemaking period allowing more time early on to address market concerns. [EPA-HQ-OAR-2022-0829-0678, pp. 7-9]

Stellantis (and industry) have made bold commitments supporting an electrified future, but time and flexibility are needed to transition from an automotive market that today is less than 10% BEV and PHEV combined to a future that is dominated by electric vehicles. EPA's proposed rule significantly front loads stringency and GHG savings during this critical time of transition in a way that overlooks the needed market enablers. EPA should deploy a stringency that allows the time needed for a more practical transition to an EV dominated market. Stringency and GHG reductions should not be front-loaded but, instead, should ramp up and increase as the market increases. [EPA-HQ-OAR-2022-0829-0678, pp. 7-9]

EPA Needs to Address EV Market Uncertainty & GHG Stringency Concerns [EPA-HQ-OAR-2022-0829-0678, pp. 13-14]

As discussed above, EPA has erred by assuming an overly optimistic market adoption of a single EV technology justified by policies that represent partial solutions. The GHG targets justified by these assumptions exceed what industry and the Biden administration jointly agreed to and likely exceed what reasonably can be achieved in a 50-state market. Targets are front-loaded and biased against the most popular trucks and SUVs that customers demand today. [EPA-HQ-OAR-2022-0829-0678, pp. 13-14]

Stellantis believes that EPA can address these concerns by incorporating key changes into the GHG footprint targets in the final rule. [EPA-HQ-OAR-2022-0829-0678, pp. 13-14]

First, EPA should finalize a fleet GHG target that can be achieved with a combined BEV, PHEV, and fuel cell electric vehicle (FCEV) penetration rate of 40-50% in 2030MY. This would align EPA to the ambitious and unprecedented transformation of the market that was jointly agreed to by the Biden administration, the UAW, Stellantis and other OEMs. [EPA-HQ-OAR-2022-0829-0678, pp. 13-14]

Second, EPA should set a footprint stringency that does not front-load the needed EV penetration rates and GHG savings by adopting a profile like Alternative 3 proposed in the NPRM. Alternative 3 (unlike the proposed scenario) is less stringent earlier in the program when new products and supply chains are critically coming “online”. The Alternative 3 profile makes up for this early relief with increased stringency over the proposed option in later years. This strategy of “back loading” stringency ultimately delivers the same GHG savings as the proposed standards but does so in a way that recognizes the needed transition the market and industry need to make. [EPA-HQ-OAR-2022-0829-0678, pp. 13-14]

Figure 12 below demonstrates the approach Stellantis believes EPA should take when finalizing these targets. It is important to note that penetration rates and GHG targets beyond 2030 are uncertain as we remain focused on achieving the ambitious levels in 2030 jointly committed to by the Biden administration and industry. [EPA-HQ-OAR-2022-0829-0678, pp. 13-14]

SEE ORIGINAL COMMENT FOR FIGURE 12–- EPA should set linear stringency through 2030 that can be achieved with 40-50% BEV+PHEV+FCEV penetration [EPA-HQ-OAR-2022-0829-0678, pp. 13-14]

Organization: Tesla, Inc.

Tesla supports the proposed Alternative 1 with added stringency so that the final performance standards achieves a fleet BEV penetration rate greater than 69% in MY 2032.2 Alternative 1 is estimated to provide greater CO2 emissions reduction of -51% from no action by 2050 compared to -46% under EPA’s proposal, and the additional stringency will result in even greater emission reductions.3 Accordingly, Tesla asserts the EPA should amend its proposal with a more stringent version of Alternative 1 and take, inter alia, the following additional steps to increase the performance and overall stringency of the proposed standards: [EPA-HQ-OAR-2022-0829-0792, p. 2]

2 See, 88 Fed. Reg. 29332-33, Table 96.

3 Id., at 29348 (comparing Tables 135 and 136).

-Eliminate off-cycle crediting for all types of vehicles; [EPA-HQ-OAR-2022-0829-0792, p. 2]

-Revisit the plug-in hybrid electric vehicle (PHEV) utility factor to accurately reflect real world emissions; [EPA-HQ-OAR-2022-0829-0792, p. 2]

-Amend the proposal to create parity in promoting motor vehicle air conditioning (MVAC) efficiency adoption; [EPA-HQ-OAR-2022-0829-0792, p. 2]

-Maintain the existing zero emissions upstream approach for BEVs; [EPA-HQ-OAR-2022-0829-0792, p. 2]

-Eliminate credit multipliers for all vehicles; and [EPA-HQ-OAR-2022-0829-0792, p. 2]

-Ensure BEVs continue to be accounted for, and participate in, the NMOG + NOx reduction standard. [EPA-HQ-OAR-2022-0829-0792, p. 2]

EPA has long considered BEVs to be the most effective mobile source pollution mitigating technology, stating over a decade ago, “From a vehicle tailpipe perspective, EVs are a game-changing technology.”38 Additionally, study after study shows BEVs are a superior technology for reducing air pollution and GHG emissions over their lifetime.39 On a well to wheels analysis including upstream emissions, the U.S. Department of Energy (DOE) has repeatedly found BEVs to be far superior in emission performance than internal combustion engine (ICE) technology.40 For example, a Tesla Model 3 or Model Y charging on the U.S. grid has average lifecycle emissions almost 3.5 times less than an average premium ICE vehicle.41 As a result, over a 17-year lifetime, a Tesla vehicle driver can avoid emitting over 55 tons of CO2e.42 [EPA-HQ-OAR-2022-0829-0792, pp. 6-7]

41 Tesla, Impact Report 2022 at 31-34.

42 Tesla, Impact Report 2022 at 22, 149.

First, Tesla modelling points toward a significant overcompliance with the existing MY 2023-26 standards. Tesla's internal modeling projects 28% ZEV sales in MY 2026. See Figure 2 – Projected U.S. BEV Market Share. This represents an 11% over EPA's earlier predicted MY 2026 ZEV sales level (17%) resulting from the amendments to the MY 2023-26 standards.116 Indeed, there are 206 different BEVs announced for the market in 2027. See Figure 3 – BEV Model Availability in the U.S. Thus, this expected overcompliance carries into future model years as Tesla projects business as usual BEV market share sales to be above those projected by EPA under its proposal. See Figure 2 – Projected U.S. BEV Market Share. [EPA-HQ-OAR-2022-0829-0792, pp. 16-17]

116 EPA, EPA Finalizes Greenhouse Gas Standards for Passenger Vehicles, Paving Way for a Zero-Emissions Future (Dec. 20, 2021) available at h ttps://www.epa.gov/newsreleases/epa-finalizes-greenhouse-gas-standards-passenger-vehicles-paving- way-zero-emissions

SEE ORIGINAL COMMENT FOR Figure 2 – Projected U.S. BEV Market Share [EPA-HQ-OAR-2022-0829-0792, pp. 16-17]

Figure 3 – BEV Model Availability in the U.S. [EPA-HQ-OAR-2022-0829-0792, pp. 16-17]

Second, the overcompliance with the existing standards should be a precursor to the EPA's modelling of the proposed alternatives. The agency's own modelling shows significant overcompliance with both the proposed standard and Alternative 1 in MY 2032. EPA indicates the proposed standard results in a cumulative credit surplus of over 36.8M Mg representing almost 1.6M BEVs that will not be sold.117 See Figure 4. EPA's Projected Credit Surpluses in MY 2032. [EPA-HQ-OAR-2022-0829-0792, pp. 17-18]

117 Draft RIA at 13-13, Table 13-23. See EPA, The 2022 EPA Automotive Trends Report (Dec. 2022) at 79 (calculation utilizing conversion table to back out production Annual Implied Missing BEVs = (Net credits * 1,000,000) / (Tesla Annual 2027-2032 Weighted g/mi Target * Weighted VMT)).

Similarly, the agency finds that Alternative 1 still results in a credit surplus of over 18.5M Mg.118 As provide in Figure 4, this credit surplus represents the credit value of approximately 1.3M BEVs that would not be sold over the 2027-32 period.119 See Figure 4. EPA's Projected Credit Surpluses in MY 2032. This oversupply of credits in My 2032 indicates that manufacturers have the capability to comply with a standard that is more stringent than Alternative 1. [EPA-HQ-OAR-2022-0829-0792, pp. 17-18]

118 Id., at 13-17, Table 13-30.

119 See, footnote 117.

Organization: Toyota Motor North America, Inc.

2. The annual stringency increases in the first three years of the proposed rule are extreme and outside historical norms. EPA has historically recognized that technology penetration is slower in early stages of market development and increases more rapidly over time. The proposed early ramp rates run directly contrary to this reality. We are also concerned that this extreme rate may have a paradoxical effect on CO_2 emissions – lowering the volume of older, higher polluting vehicles replaced because artificial shortages will be created of low-carbon non-BEV vehicles that many customers prefer. Automakers need time to invest in EV and battery production capacity, for the charging infrastructure to develop across the country, and for the market to mature. To reduce carbon dioxide emissions as much as possible, as soon as possible, customers need choices that encourage replacement of high-CO_2 emitting vehicles with low-or zero-CO_2 emitting vehicles. EPA should smooth the early rates of increase in recognition of these factors. [EPA-HQ-OAR-2022-0829-0620, p. 2]

5. GHG Program

The Proposed Rule fails to demonstrate the penetration of BEVs assumed for compliance with the proposed standards is feasible. The proposal notes “While emission standards set by the EPA under CAA section 202(a)(1) generally do not mandate use of particular technologies, they are technology-based, as the levels chosen must be premised on a finding of technological feasibility.”17 CAA section 202(a)(1) states “Any regulation prescribed under paragraph (1) of this subsection (and any revision thereof) shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.”18 [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

17 88 Fed. Reg at 29232.

18 42 U.S.C. § 7521(a)(2).

The aggressive ramp up of BEVs (see Table 1) required to comply forces a rapid transformation of how vehicles are manufactured, driven, fueled, and serviced. As such, “leadtime and requisite technology” must extend to the availability of critical minerals, the readiness of a sustainable battery supply chain and fueling infrastructure, as well as other market-related factors that will affect the price and consumer demand of BEVs. [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

[Table 1 Annual BEV Penetration Assume for Compliance w/ Proposed Standards] [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

MY 2027: BEV Share 36

MY 2028: BEV Share 45

MY 2029: BEV Share 55

MY 2030: BEV Share 60

MY 2031: BEV Share 63

MY 2032: BEV Share 67]

[EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

Today's PEV support system clearly cannot meet the needs of the future envisioned by the proposal. Our comments explain why the proposal lacks a clear justification for how the support system will be in place over the period of the proposed standards. Neither EPA nor auto manufactures can control the timing or outcomes of these essential support measures. [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

Finally, EPA has taken a more measured view of technology risk and uncertainty in past vehicle emissions rulemakings in which technology costs were lower and automakers had significantly more direct control over managing their technology development, deployment, and sales mix to comply. In this Proposed Rule, EPA appears to be taking a much more cavalier approach to risk, lead time, and ensuring the "requisite technology" is available, despite the high cost of BEVs, the massive uncertainty around mineral supplies, the significant investment needed in charging infrastructure and the power grid, and the uncertain market demand for BEVs. The standards in the Final Rule should be adjusted to better account for market uncertainties. [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

Organization: Volkswagen Group of America, Inc.

Supporting President Biden's Goal

Together with many other manufacturers, Volkswagen remains committed to President Biden's goal to reach 40- 50% EV sales by 2030. Taking into account the concerns for the current and future market situation and the uncertainties not in our control, we expect achieving these targets will be a stretch goal for the industry. To establish a feasible pathway into e-mobility for the entire automotive industry, we recommend making the NPRM's targeted EV share consistent with President Biden's Executive Order 14037 on Strengthening American Leadership in Clean Cars and Trucks and to ensure they are safeguarded by similar ambitious EV ecosystems. [EPA-HQ-OAR-2022-0829-0669, p. 2]

GHG Standards

GHG Alternative Target Curves – Aligned with AFAI (Section III.E.)

The EPA has proposed three alternative light-duty GHG standards. AFAI has suggested a logical outgrowth of Alternatives 2 and 3. Volkswagen agrees with the linear Alternative 3 with the combined goal of 50% Plug-in electric vehicles (PEVs), which includes plug-in hybrid electric vehicles (PHEVs) and battery-electric vehicles (BEVs), penetration by 2030. Volkswagen prefers the AFAI aligned proposal. However, if EPA seeks input only on the proposed Alternatives, Volkswagen then prefers Alternative 3. [EPA-HQ-OAR-2022-0829-0669, p. 4]

Alternative 3 has consumer-based advantages from cost, product availability perspective, and better aligns with the regulatory aims toward improving human health and environment protection. Alternative 3 is characterized by similar year-over-year reduction rates (as compared to Alternatives 1 and 2) with all targets converging and achieving the same overall results by MY2032. [EPA-HQ-OAR-2022-0829-0669, p. 4]

Volkswagen believes that Alternatives 1 and 2, both having high reduction rates in the earlier years, do not align with projections of consumer adoption of EVs in the market. Furthermore, when additional EV models are available in the market with improved range, consumer acceptance and demand is expected to improve more linearly. EPA also recognizes that the Alternative 1 and 2 are not recommended due to feasibility, cost, public health and welfare. [EPA-HQ-OAR-2022-0829-0669, p. 4]

Organization: Wisconsin Department of Natural Resources

In this action, EPA is proposing new, more stringent emissions standards for criteria pollutants and greenhouse gases (GHG) for light-duty vehicles and medium-duty vehicles that would phase-in over model years 2027 through 2032. [EPA-HQ-OAR-2022-0829-0507, p. 1]

The WDNR offers the following specific comments on the proposal:

Proposed standards. EPA's proposed GHG standards for light-duty vehicles will result in a 56% increase in stringency of CO2 standard from model year (MY) 2026 to 2032. EPA is proposing three alternatives to this standard (one more stringent, one less stringent, and one with the same final stringency as the proposal, but with a different rate of increase). EPA is not proposing specific alternatives to its proposed GHG standards for medium duty vehicles or the criteria pollutant standards. [EPA-HQ-OAR-2022-0829-0507, p. 2]

Both the proposal and the alternatives presented by EPA will result in substantial decreases in CO2 and criteria pollutant emissions. As such, EPA should finalize standards within this range that best reflect the technology available to manufacturers in the timeframe of the affected model years and that will be achievable in practice. [EPA-HQ-OAR-2022-0829-0507, p. 2]

Organization: World Resources Institute (WRI)

We applaud the Biden administration for acting swiftly and using the full force of Clean Air Act authorities to propose new, more stringent vehicle emissions standards to reduce criteria pollutants and greenhouse gas (GHG) emissions from passenger (and other) vehicles to address climate pollution and public health impacts. [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

Transportation accounted for the largest portion (29%) of total U.S. greenhouse gas emissions in 2021, and light duty vehicles [Link: https://www.epa.gov/greenvehicles/fast-facts-transportation-greenhouse-gas-emissions] (including passenger cars and light-duty trucks) represent the largest category with 58% of the transportation sector's GHG emissions. Furthermore, studies (such as the recent 'Zeroing in on Healthy Air' [Link: https://www.lung.org/getmedia/13248145-06f0-4e35-b79b-6dfacfd29a71/zeroing-in-on-healthy-air-report-2022.pdf] from the American Lung Association) show that regulations and policies designed to reduce GHG emissions, such as through accelerating electric transportation, will have the added benefit of reducing other forms of pollution -including air toxics and particulate matter -that impact public health and disproportionately impact overburdened communities. [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

To address these significant sources of transportation pollution and its legacy of disproportionate impacts, we express our support for EPA's proposed "Alternative 1," which would set the most stringent emissions reduction standards. While these proposed standards are technology neutral, electric vehicles present the best option for compliance as they emit zero tailpipe pollution, resulting in improved public health and climate outcomes. [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

Thus, we urge EPA to strengthen and finalize the strongest rule possible as [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

1. Complementary policies provide incentives for vehicle manufacturers and consumers in the transition; and
2. Strong private investments are rapidly expanding supply chains and manufacturing, helping to accelerate the transition to cleaner, electric vehicles.

[EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

Organization: Zero Emission Transportation Association (ZETA)

We thank the U.S. Environmental Protection Agency (EPA) for the opportunity to comment on its notice of proposed rulemaking to set multipollutant emission standards for model years 2027 and later light- and medium-duty vehicles. ZETA encourages the agency to finalize more stringent standards than Alternative One for light-duty greenhouse gas emissions and finalize light-duty multipollutant standards that are equally as stringent. We also encourage the agency to finalize medium-duty GHG and multipollutant standards that are as stringent as possible. We believe these standards are achievable and will ensure the supply chain has the regulatory certainty needed to protect the investments being made today that will put the sector on a path to a ze–-emission future. [EPA-HQ-OAR-2022-0829-0638, p. 1]

1. Introduction

The Zero Emission Transportation Association (ZETA) appreciates the opportunity to comment on EPA's proposed rulemaking1 to set multi-pollutant emission standards for model years 2027-2032 light- and medium-duty vehicles (LMDVs), consistent with Executive Order 14037.2 ZETA applauds EPA's ambition shown in these proposed standards and we believe EPA should finalize more stringent standards than Alternative One to further incentivize zero emission vehicle deployment and improve local health outcomes. This proposed rulemaking offers an opportunity to begin to phase out internal combustion engine vehicles (ICEVs)—thereby locking in significant emissions reductions, protecting public health and the environment, and backstopping the industry's investments in electrification technologies. These standards will also play a key role in helping achieve the Biden-Harris Administration's blueprint for decarbonizing the transportation sector while adhering to U.S. commitments under the Paris Climate Agreement.3 The blueprint calls for continuously strengthened vehicle emissions standards through the next two decades as a central pillar of the U.S. GHG reduction strategy. [EPA-HQ-OAR-2022-0829-0638, p. 5]

5. ZETA Comments on the Proposed Emission Standards for LDVs

ZETA and its member companies appreciate the opportunity to submit comments on EPA's proposed rule to set multipollutant and GHG emission standards for class 1-2a LDVs. We urge the agency to finalize standards more stringent than Alternative One for LDV GHG emissions and to finalize LDV multipollutant standards that are equally as stringent. For reasons discussed throughout these comments, we believe such stringency is feasible and finalizing such standards will ensure the supply chain has the regulatory certainty needed to protect the investments being made today that will put the sector on a glide path to a zero-emission future. Backtracking on the stringency of these proposed standards in the final rule will not only jeopardize the health, climate, and environmental benefits but would create regulatory uncertainty. [EPA-HQ-OAR-2022-0829-0638, p. 26]

6. ZETA Comments on the Proposed Emission Standards for MDVs

In regards to the proposed GHG and multipollutant emission standards for class 2b-3 MDVs, we encourage EPA to finalize standards that are as stringent as possible. ZETA supports the proposed revisions to the work factor curves, including the cutpoints and slope changes over time, for the same reasons discussed above in the LDV footprint curve context. Ultimately, we believe EPA's proposed changes to the work factor curves will more accurately capture the benefits of EVs and drive greater emissions reductions over the MY 2027-2032 time frame covered by these standards. We encourage EPA to finalize these changes as proposed. [EPA-HQ-OAR-2022-0829-0638, pp. 27-28]

EPA Summary and Response

EPA received many comments supporting, opposing, or recommending changes to the proposed standards or the alternatives on which EPA sought comment. As discussed in greater detail in preamble sections III.D and V, in evaluating the proposal and alternatives in arriving at a decision on the appropriateness of final standards, EPA considered several factors, including differences in manufacturer costs and lead time, CO_2 emissions reductions and technology penetration projections.

The following summary addresses similar comments made by multiple commenters.

EPA received many comments in support of either the proposed standards, or of the more stringent light-duty GHG standard, Alternative 1. Several stakeholders (the American Lung Association, the California Attorney General's Office, CALSTART, Ceres BICEP, Ceres CEVA, Colorado Energy Office et. al, DOEE, Energy Innovation, Institute for Policy Integrity at NYU Law, ICCT, Lucid, MDE, MPCA, Southern Env. Law Center, Tesla, WRI) supported the most stringent alternative – Alternative 1 – or recommended that EPA finalize standards "at least as strong as Alternative 1." More commenters (CAP, Environmental and Public Health Organizations, NPCA, Rivian, South Coast Air Quality Management District) recommended that EPA modify Alternative 1, predominantly by increasing the stringency in the later years to ensure that the US is on a path to full electrification by 2035. Other groups (EC, NACAA, NESCAUM, Our Children's Trust, Sierra Club) requested that EPA strengthen the standards beyond the proposed levels, or that EPA make the standards the "strongest possible." The Sierra Club supported the proposed standards, but analogous to other stakeholders, recommended greater stringency in the later model years (2030-2032).

While many traditional OEMs commented that the stringency of the proposed standards was too stringent, only one manufacturer (Honda) overtly rejected all of the stringency options presented in the NPRM. In fact, several automakers commented in support of Alternative 3, albeit with some modifications. In its comments (which member companies Hyundai, Kia, Mazda, Mitsubishi, Nissan, Porsche, Stellantis, Toyota and Volkswagen endorsed), the Alliance for Automotive Innovation highlighted concerns with front-loading of the proposed standards and Alternatives 1 and 2 while preferring the less steep ramp rate of Alternative 3 in the early years of the program. However, they recommended that EPA adjust the stringency in MY 2030 to align with a projected market share of 40-50% EVs (which includes BEVs, PHEVs and FCEVs), and then adjust standards with stringency increases from MY 2030 to 2032 "that are supported by reasonably certain projections of EV supply chain, manufacturing, market and infrastructure in that timeframe." Several auto manufacturers suggested that, in additional to the Alternative 3's more linear year-over-year phase-in of the standards and its lesser stringency prior to 2032 compared to the proposal, that EPA also consider a slower phase-down or phase-out of some of the credit flexibilities, such as off-cycle credits and air conditioning leakage credits. Those credit provisions are further discussed in Sections 3.1.3 and 3.1.4 of this RTC. Generally, the auto manufacturer comments noted that additional lead time was needed, especially in the early years of the program, in order to provide time for the scale up of battery supply chains and for the production of PEVs. Many individual auto manufacturers provided specific examples of such lead time and feasibility issues, especially for the early years of the standards phase-in.

After carefully reviewing all comments, combined with our updated technical analysis, EPA selected the Alternative 3 footprint curves for its final standards. As EPA explains in Sections III.C and V of the preamble, Alternative 3 strikes a balance by allowing for a more linear stringency increase in the early years (which will help to address concerns over lead time) while ending at the same numerical stringency in MY 2032 as the proposed standards. Moreover, the delayed phase-out of the A/C refrigerant and off-cycle credits described in Section III.C.5 and III.C.6 of the preamble (and Sections 3.1.3 and 3.1.4 of this RTC) address automaker concerns about lead time and the transition to the more stringent standards in the later years. See Sections I.B and III.C.1 of the preamble for further details on the final standards and their basis. For the final rulemaking, EPA considered two new alternatives to the final standards (Alternative A, which were the proposed standards as presented in the NPRM, and Alternative B, less stringent than the final standards). A more detailed discussion of the alternatives for the final rule is provided in Section IV.E of the preamble. In order to assess feasibility in light of uncertainties in our assumptions, EPA conducted multiple sensitivity analyses. These are described in Section IV.F of the preamble.

In response to commenters who recommended Alternative 1, upon considering the entirety of the comments and record, especially in light of the auto manufacturers comments and in consideration of our updated analysis including higher battery costs for PEVs, and for the reasons discussed in section V of the preamble, EPA concluded that the proposed standards would present challenging issues of feasibility and lead time. In light of the fact that Alternative 1 was more stringent than the proposed standards, we concluded, without undertaking further final rule analysis, that the Alternative 1 standards would present even greater issues of feasibility and lead time. As we discussed above, several commenters requested that EPA strengthen the standards beyond the proposed levels, or that EPA make the standards the "strongest possible." In consideration of emission reductions, technological feasibility, costs, lead time concerns (including scale up of battery supply chains and PEV production capacity) and other factors, EPA believes the final standards are appropriate as discussed at length in section V of the preamble. As shown in Table 8-23 and Table 8-24 in RIA Chapter 8.6.6.1, EPA projects that the final rule with the more gradual year-over-year stringency but landing with the same stringency in MY2032 as the proposal will achieve 98% of the cumulative emissions reductions of the proposed standards (Alternative A) by 2055. A more detailed comparison of the per-vehicle incremental costs (12.1.2), and technology penetrations (12.1.3) for each alternative can be found in the RIA. We also discuss some related comments in Section 2.3 of this RTC.

The following is a summary of unique comments related to stringency:

In comments, Ford expressed support for Alternative 3 and its 2032 MY endpoint (which is equal to the MY 2032 stringency of the proposed standards). Additionally, Ford suggested its own modifications to Alternative 3, including a phase-out for refrigerant credits and an increase in the utility allowance in the truck curve which would effectively increases the slope (and thus decrease the stringency) of the truck curve. These structural modifications are addressed in more detail in RTC Sections 3.1.3 and 3.2.1, respectively.

In its comments, Honda opposed the three alternatives presented in the NPRM, pointing to market uncertainties and potential for noncompliance. While not providing specifics, Honda requested a "more reasonable" emissions reduction trajectory and a broader array of compliance flexibilities. EPA believes that the final standards (i.e., the CO2 footprint curves of Alternative 3), when combined with the slower phase-down of A/C and off-cycle credits, addresses Honda's request for a more reasonable trajectory of stringency increase. We believe these standards to be appropriate as we discuss in preamble Section III.C and V.

Separately, Jaguar Land Rover (JLR) recommended an alternative trajectory to that of Alternative 3 which would relax the stringency in years 2028 through 2031, in part to offset EPA's proposed reduction in allowable A/C and off-cycle credits. JLR suggested targets of approximately 150 g/mi in 2028 and roughly 140 g/mi in 2029 (both by visual inspection of Figure 2 in its comments [EPA-HQ-OAR-2022-0829-0744]), 125.3 g/mi in 2030, and approximately 104 g/mi in 2031. Upon review, the difference in JLR's suggested stringency from the updated Alternative 3 targets (updated in the final rulemaking to reflect the MY 2022 base year fleet and AEO 2023 car/truck shares) is minimal. In MY 2030, the stringency that JLR is requesting is more than offset by the delayed phase down of potential A/C and off-cycle credits that we have included in the final standards, and thus should largely address the numerical stringency adjustments to Alternative 3 that JLR has requested in its comments. EPA provides a summary of the A/C and off-cycle credits available in the final standards in Section III.C.2.iv, Table 21 of the preamble.

Arconic, which advocated for inclusion of upstream power generation emissions in compliance calculations for electric vehicles, acknowledged that the numerical standards would have to be modified if such an approach were taken, but did not take a position on the trajectory/stringency rates in this rulemaking. We address comments received on the compliance treatment for BEVs in Section 3.1.5 of this RTC.

In its comments, Darius opposed all three alternatives and while not specifying a recommended level of stringency, requested that the rulemaking be technology-neutral and account for lifecycle emissions. As these are fleet-averaging, performance-based standards, this is a technology-neutral rulemaking. However, consistent with past rulemakings, we are not adopting a lifecycle emissions approach, as we discuss in greater detail in Chapter 19.2 of this RTC.

EDF supported Alternative 3 although it recommended an increase in stringency beyond MY 2030 by reducing fleetwide GHG targets of Alternative 3 in MYs 2031 and 2032 by 2.1 and 4.2 g/mi, respectively, so that this revised trajectory would match the cumulative 2055 GHG emissions reductions projected for the proposed standards. In response, the stringency of our final standards is based on our updated analysis which considers technology feasibility, lead time and cost. The emissions reductions which we discuss in the preamble are an outcome of our analysis; in summary, we are not trying to maintain the reductions of the proposed standards (or any other predetermined future cumulative GHG reduction goal). EDF also recommended that EPA finalize a voluntary leadership pathway that incentivizes ACC II levels of ZEV deployment nationwide; that comment is addressed in RTC Section 3.1.10.

Elders Climate Action, while not commenting on the proposed standards or the three alternatives, recommended that EPA include ZEV sales targets for MYs 2027-29 that are the same as the CARB ACT rule, and set a zero emissions standard by 2035. We disagree with this approach. We are adopting fleet average performance-based standards through MY 2032 as described in section I.B. of the preamble, we do not believe it is appropriate to set minimum sales targets for any technology. We address this comment and additional comments on the timeframe for the standards in RTC Section 3.1.9.

In addition to its comments on overall stringency, Tesla also made recommendations to several program structure elements which we address in the appropriate subsections of RTC Section 3.1.

Some commenters explicitly requested that EPA add anti-backsliding requirements for non-ZEVs: these comments are addressed within RTC Section 12.3.

Additionally, the Alliance urged that the final standards should be based on an assumption of little to no improvement in ICE vehicle emission reductions due to required investments in BEV development. In preamble I.B and as discussed in RTC Section 12.5.3, EPA presents multiple pathways available to manufacturers to comply with the final standards. Several commenters pointed out that ICE improvements are available (addressed in RTC Section 12.3). Each manufacturer may choose the technologies and compliance path most appropriate for their situation.

3.3.2 - Lead time

<u>Comments by Organizations</u>

Organization: 25x'25 Alliance, et al.

The undersigned parties offer the following comments on EPA's proposed rule, "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty

Vehicles." We write these comments because we believe that the proposed rules would establish an overly aggressive, high-risk program that would be counterproductive in achieving the agency's environmental and health objectives. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

In establishing or revising Clean Air Act Section 202(a) standards, EPA must consider issues of technological feasibility, cost of compliance, and lead time. Among other things, that means the agency must look closely at the impact of its proposed standards on net emissions of air pollutants and their associated public health effects, impacts on the automotive industry, impacts on the vehicle purchasers/consumers, energy security, and safety, and how the proposed approach would compare to other possible rulemakings. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

EPA's review of relevant factors in the current proposal is seriously deficient. The chief failure comes because the agency elides two distinct types of feasibility: the technological feasibility of electric vehicles as a part of the fleet and the technological feasibility of electric vehicles as the whole of the fleet. We do not dispute the former, but overwhelming evidence disproves the latter. First, there are no established supply chains capable of supplying the raw materials to manufacture the millions of vehicles needed—just over the next decade—to supply the projected market. Second, the infrastructure necessary to support these vehicles, particularly recharging infrastructure, is not and will not be available in the necessary timescales. The high density of chargers needed in major metropolitan areas and vast web of chargers needed to span the rural areas of the Country will require tremendous planning and investment. The long lead times associated with new renewable generation means that this added marginal electric load will be powered by natural gas and coal for the foreseeable future. And current prices, lack of infrastructure, and public opinion militate strongly against the conclusion that a ten-fold increase in the annual sales of electric vehicles will occur in the next eight years. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

And current prices, lack of infrastructure, and public opinion militate strongly against the conclusion that a ten-fold increase in the annual sales of electric vehicles will occur in the next eight years. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

Organization: Alliance for Automotive Innovation

Neither reasonable nor achievable in the timeframe provided

With that said, as proposed, the NPRM standards—both greenhouse gas (GHG) and criteria—are neither reasonable nor achievable in the timeframe covered in this proposal. Auto Innovators does not believe they can be met without substantially increasing the cost of vehicles, reducing consumer choice, and disadvantaging major portions of the United States population and territory. EPA's proposed rules effectively assume that everything will go perfectly in the transformation to electric vehicles (EVs)3 between now and 2032. For example, the NPRM appears to assume that: [EPA-HQ-OAR-2022-0829-0701, pp. 2-3]

3 The term "electric vehicles" as used herein refers collectively to battery electric, plug-in hybrid electric, and fuel cell electric vehicles.

- An over-abundance of battery critical mineral mines, critical mineral processing capacity, and battery component, cell, and pack production facilities leads to continued battery price reductions. [EPA-HQ-OAR-2022-0829-0701, pp. 2-3]

- Most critical minerals for light- and medium-duty vehicles (LDVs and MDVs) are sourced and processed from the U.S. or countries with which we have a free trade agreement (FTA). [EPA-HQ-OAR-2022-0829-0701, pp. 2-3]

- Every EV battery is produced in the U.S. by 2027 and receives the maximum Inflation Reduction Act (IRA)4 Section 45X manufacturing tax credit. [EPA-HQ-OAR-2022-0829-0701, pp. 2-3]

- Most battery electric vehicle (BEV) and most BEV buyers qualify for maximum tax credits when purchasing or leasing a BEV under the IRA 30D and 45W. [EPA-HQ-OAR-2022-0829-0701, pp. 2-3]

- Congress makes no future changes to the federal law that reduces tax credits for BEVs or BEV batteries. [EPA-HQ-OAR-2022-0829-0701, pp. 2-3]

- Apartments, condominiums, and residential street parking throughout the U.S. (roughly half of the U.S. housin858loomberg858858re retrofited to provide convenient, low- cost, reliable BEV charging. [EPA-HQ-OAR-2022-0829-0701, pp. 2-3]

- Public and workplace charging infrastructure deployment keeps pace with vastly increased BEV deployments. [EPA-HQ-OAR-2022-0829-0701, pp. 2-3]

- Utilities and their regulators in all 50 states request, approve, and build out the needed power generation, service lines, and the corresponding connections to charge not only the proposed light-duty BEVs but also medium-duty and heavy-duty BEVs required in this proposal and other state regulations. [EPA-HQ-OAR-2022-0829-0701, pp. 2-3]

- Electricians and construction professionals are available nationwide to install, maintain, and repair electric vehicle chargers. [EPA-HQ-OAR-2022-0829-0701, pp. 2-3]

- New criteria emission requirements involve “off the shelf” technology and will not draw resources away from the industry transformation to EVs. [EPA-HQ-OAR-2022-0829-0701, pp. 2-3–

4 H.R.5376 - 117th Congress (2021-2022): Inflation Reduction Act (Aug. 16, 2022), available at htps://www.congress.gov/bill/117th-congress/house-bill/5376/text.

GHG Standards

Leap-frogs Biden administration’s own 50% executive order [EPA-HQ-OAR-2022-0829-0701, pp. 3-4]

The stringency of the NPRM proposed standards increases faster than at any time in history. In fact, by assuming BEVs alone will make up 60% of the new vehicles sold in 2030 and 67% of new vehicles just two years later, the proposed requirements leap-frog even President Biden’s ambitious 2030 target of 50%, which included BEVs, fuel cell electric vehicles (FCEVs), and plug- in hybrid electric vehicles (PHEVs) by 2030. The 60% BEV-only proposal also goes beyond the same goal of 50% electric vehicles by 2030 (which again included BEVs, PHEVs, and FCEVs) described in The U.S. National Blueprint for Transportation Decarbonization, authored by four cabinet level agencies including EPA and issued in January 2023 – just a few months before this proposal was published. [EPA-HQ-OAR-2022-0829-0701, pp. 3-4]

Unlike EPA's past regulations that could be met by automaker action alone and without consumer participation or even knowledge, these standards require large numbers of BEVs and are based on many assumptions that are largely outside the control of either EPA or individual automakers. Getting these standards right is critical not only to the automakers that must comply with them, but also to the U.S. global competitiveness and the U.S. economy. If the standards push too fast, too soon, we risk relying on other nations to supply the minerals and batteries needed to produce more EVs. If the standards push too slowly, there is less incentive to develop the necessary supply chain capacity in the U.S. Balancing the requirements with the realities of the marketplace and the supply chain will be key to a successful rule that also solidifies our nation's electric vehicle competitiveness and leadership. [EPA-HQ-OAR-2022-0829-0701, pp. 3-4]

Successfully transitioning from ICE vehicles to electric vehicles—a goal we share with EPA— requires massive changes from all sectors of the U.S. economy: from automotive suppliers to home builders to utilities, labor to mining to mineral processing. Successful implementation also requires substantial consumer changes such as installing home charging and pre-planning long trips to ensure adequate fueling infrastructure along the way. [EPA-HQ-OAR-2022-0829-0701, pp. 3-4]

For our part, automakers can produce electric vehicles, but the proposed regulations are only feasible if we can address and affrmatively answer these questions:

1. Can people afford EVs? [EPA-HQ-OAR-2022-0829-0701, pp. 3-4]

2. Can people fuel EVs? [EPA-HQ-OAR-2022-0829-0701, pp. 3-4]

3. Can automakers obtain the battery critical minerals to power EVs? [EPA-HQ-OAR-2022-0829-0701, pp. 3-4]

4. Will customers embrace the technology on such a large scale in such a short time? [EPA-HQ-OAR-2022-0829-0701, pp. 3-4]

The answers to these questions are not yet known, but lead to the fundamental question and the substance of these comments: Is the U.S. ready for the transformation in the timeframe the NPRM lays out? No. We are not. [EPA-HQ-OAR-2022-0829-0701, pp. 3-4]

Automakers are committed to electrification. The industry publicly agreed in August 2021 that BEVs, PHEVs, and FCEVs could constitute 40 to 50% of new vehicle sales by 2030 with the right combination of supportive measures. Some, but not all, of those supportive measures have started, but they are nowhere near complete and certainly not suffcient to support the even higher requirements in the proposed regulations that substantially leapfrog that target. [EPA-HQ-OAR-2022-0829-0701, p. 5]

I. EV Feasibility

A. Overview

EPA proposes to set transformat ive greenhouse gas (GHG) standards that are projected to require reaching 55% battery electric vehicle (BEV) sales by calendar year (CY) 2028 (model year 2029),7 63% sales by CY 2030 (MY 2031), and 67% sales by the end of this rule (MY 2032).8 It is also proposing criteria pollutant standards that are generally premised on the same or similar BEV sales. By the time these regulations are finalized, MY 2027 will be less than two years away, and MY 2032 seven years away.9 The projected levels of BEV market share are a substantial increase over the 50% EV sales by 2030 described in Executive Order 14037 (which included plug-in hybrid electric vehicles (PHEVs) and fuel cell electric vehicles (FCEVs) in addition to BEVs)10 and reafirmed by EPA and three other cabinet-level agencies in The U.S. National Blueprint for Transportation Decarbonization in January 2023.11 Although EPA's analysis attempts to demonstrate the possibility of achieving such lofty goals, EPA fails to demonstrate a reasonable probability of doing so in the timeframe of its proposal. [EPA-HQ-OAR-2022-0829-0701, pp. 24-25]

7 Model years can begin as early as January 2 of the calendar year preceding the model year designation. (40 C.F.R. § 86.1803-01, definition of "model year"; § 85.2304, definition of "annual production period".) Therefore, model year 2029 can begin as early as January 2, 2028, effectively making a model year 2029 standard a calendar year 2028 requirement.

8 NPRM at 29329. (Table 80.)

9 EPA anticipates finalizing this rulemaking in March 2024. (Spring 2023 Unified Agenda of Regulatory and Deregulatory Actions, RIN 2060-AV49.) Model year 2025 can begin as early as January 2, 2024, making the lead-time of this rule less than two to seven years.

11 U.S. Department of Energy, Department of Transportation, Department of Housing and Urban Development, and Environmental Protection Agency, The U.S. National Blueprint for Transportation Decarbonization (Jan. 2023). Available at htps://www.energy.gov/sites/default/files/2023-01/the-us-national-blueprint-for-transportation- decarbonization.pdf. (Retrieved Jun. 20, 2023).

Technological feasibility is a cornerstone of rulemaking under section 202(a) of the Clean Air Act. Regulations promulgated under section 202 "shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period."12 As EPA acknowledges, this means that emission standards "must be premised on a finding of technological feasibility."13 EPA's conclusions regarding technological feasibility are subject to review under the Administrative Procedure Act; they must be the "product of reasoned decision making," and the agency must provide a reasoned explanation for its projections of feasibility.14 [EPA-HQ-OAR-2022-0829-0701, pp. 24-25]

12 42 U.S.C. § 7521(a)(2).

13 NPRM at 29232; see also Nat. Res. Defense Council v. E.P.A., 655 F.2d 318, 322 (D.C. Cir. 1981)

14 Nat. Res. Defense Council, 655 F.2d at 328.

The Proposed Rule requires an aggressive ramp-up in BEV sales, forcing a staggering increase in the use of a nascent technology at unprecedented levels and on an expedited timeframe. This Proposed Rule will constitute a transformative shift in the makeup of the nation's vehicle fleet. In this context, EPA must take a holistic approach in evaluating technological feasibility, considering not just whether BEV technology presently exists in a vacuum, but also weighing whether the market is able to support the level of BEVs demanded by the rule—that is, whether the "application of the requisite technology" (here BEVs), to the extent required by the Proposed Rule and on the timeline required, is feasible. This assessment must include full and adequate consideration of important factors including, but not limited to, the availability of adequate charging infrastructure, consumer acceptance of BEV technology, electricity generation and capacity concerns, and issues related to battery manufacturing and supply chains.15 [EPA-HQ-OAR-2022-0829-0701, pp. 24-25]

15 See NPRM at 29297-324, 29341-42 (acknowledging that it is appropriate to consider such issues in discussing feasibility); see also, e.g., Bluewater Network v. E.P.A., 370 F.3d 1, 22 (D.C. Cir. 2004) (considering whether EPA had adequately explained the basis of its “prediction of the feasible pace of implementation”).

Additionally, regulations issued under section 202 of the Clean Air Act must not be arbitrary and capricious, a standard identical to the one imposed by the Administrative Procedure Act.16 This standard requires that EPA consider all “important aspect[s] of the problem” and engage in “reasoned decision making,” and that it “consider[] the relevant factors and articulate[] a rational connection between the facts found and the choice made.’”17 [EPA-HQ-OAR-2022-0829-0701, pp. 24-25]

16 See 42 U.S.C. § 7607(d)(9)(A); see also Nat’l Petrochem. & Refiners Ass’n v. E.P.A., 287 F.3d 1130, 1135 (D.C. Cir. 2002).

17 Motor Vehicle Mfrs. Ass’n v. State Farm Mut. Auto. Ins. Co., 463 U.S. 29, 43, 53 (1983); Nat’l Ass’n of Clean Air Agencies v. E.P.A., 489 F.3d 1221, 1229 (D.C. Cir. 2007).

With respect to the Proposed Rule, we are concerned that EPA has fallen short of these legal and procedural obligations. We are seriously concerned that the requirements of the Proposed Rule go beyond what is technologically feasible, contrary to the requirements of the statute, when these important feasibility factors are taken into account.18 We are also concerned that the Proposed Rule fails to consider—or inadequately considers—crucial issues and evidence, and the standards contained in the Proposed Rule do not bear a rational connection to the facts in the record. We outline our concerns as to feasibility below. [EPA-HQ-OAR-2022-0829-0701, pp. 25-26]

18 EPA states that it selected the range of alternatives presented in the Proposed Rule “because they represent a range of standards that are anticipated to be feasible and are highly protective of human health and the environment.” NPRM at 29201; See also id. at 29280 (same). To the extent that EPA is determining section 202 standards based on which standards are “highly protective of human health and the environment,” this is goes beyond what is legally required. This language is absent from section 202(a), which simply instructs EPA to “prescribe . . . standards applicable to the emission of any air pollutant,” subject to the considerations of feasibility and cost of compliance. 42 U.S.C. § 7521(a).

The NPRM, which aims to establish stringent emission standards for light-duty automotive vehicles, including EVs, highlights the complex challenges that lie ahead. While this Proposed Rule represents a crucial step toward a cleaner and more sustainable transportation sector, its implementation poses unique hurdles and underestimates the actions needed to realize the targeted EV market share. Addressing concerns such as manufacturing capacity, battery production, charging infrastructure, and consumer acceptance of EVs are paramount to the success of this ambitious proposed regulation. [EPA-HQ-OAR-2022-0829-0701, pp. 25-26]

Despite these major gaps, the EPA in its Proposed Rule incorrectly assumes these policy actions represent a complete answer to achieve not just a 40-50% EV market in the U.S., but in fact go well beyond this level by assuming a perfect transition to a BEV market of 60% in MY 2030. This incredibly aggressive technology diffusion curve for BEV adoption is faster than any new automotive technology to date, even exceeding the adoption rate targeted by California (the most mature EV market in the U.S.). Moreover, EPA's reliance on its model projections depends heavily on factors beyond the control of it and the automakers. [EPA-HQ-OAR-2022-0829-0701, pp. 27-28]

Although the push toward electrification to combat climate change and reduce greenhouse gas emissions is moving forward, implementing a nationwide regulation that essentially requires automakers to produce and sell a certain percentage of EVs poses significant obstacles. From technological limitations to infrastructure gaps and consumer adoption barr'ers, the EPA's electric vehicle mandate is poised to encounter numerous hurdles that will inhibit successful implementation. Affordability, charging and refueling infrastructure, permitting reform, and critical mineral supply chains are significant challenges that need to be addressed for the widespread adoption of EVs to be feasible at the levels contained in EPA's proposal. [EPA-HQ-OAR-2022-0829-0701, pp. 27-28]

In the following subsections, Auto Innovators provides perspective on the multitude of market enablers needed to support a mature EV market and show how EPA's assumptions take an overly optimistic, if not infeasible, approach to technology adoption and EV market growth. [EPA-HQ-OAR-2022-0829-0701, pp. 27-28]

C. Historical Technology Adoption Versus EV Penetration Assumptions

Figure 2 shows the penetration rate of automotive technologies that have been introduced in the last nineteen years. Technologies that follow the most aggressive growth curve are those that are generally transparent to the customer. Eight speed transmissions, gasoline direct injection (GDI) engines, and stop-start have become standard features, and have little or no impact on customer driving behaviors. BEVs, on the other hand, require drivers to make active changes to their driving habits and potentially additional investments (e.g., home charging equipment). In short, BEVs require change, whereas many of the most successful automotive technologies do not. [EPA-HQ-OAR-2022-0829-0701, pp. 29-30]

EPA is assuming that automobile manufacturers can increase BEV production as quickly as they have adopted new transmission or engine technologies, despite the need to build entirely new supply chains and manufacturing facilities. Underlying such rapid growth is also an assumption that the majority of new vehicle buyers will accept BEVs and their inherent changes to driving habits. [EPA-HQ-OAR-2022-0829-0701, pp. 29-30]

[See original comment for Figure 2: Examples of historical automotive technology adoption29 compared to projected BEV market share under the EPA proposal.30] [EPA-HQ-OAR-2022-0829-0701, pp. 29-30]

29 U.S. Environmental Protection Agency, Automotive Trends Report (Mar. 2023), Detailed data. Available at https://www.epa.gov/automotive-trends/explore-automotive-trends-data#DetailedData. See Detailed Real-World Fuel Economy, CO2 Emissions, and Vehicle Attribute and Technology data.

30 Reflects EPA proposal, central analysis.

EPA has assumed a steep growth in BEV adoption at rates typically only seen in the evolution of disruptive technologies such as the cell phone, the television and microwave ovens, all of which added significant direct convenience and other benefits to customers and that cost substantially less at the time of purchase than an automobile. BEVs, on the other hand, have not thus far experienced such rapid adoption. In terms of convenience or additional new utility, BEVs offer generally superior acceleration performance, home refueling (a convenience not available to all customers), potentially lower fuel costs (that are dependent on where and when a vehicle is charged), and environmental benefits (important to some, but transparent to many). [EPA-HQ-OAR-2022-0829-0701, p. 31]

Thus, EPA makes an extremely aggressive assumption for a nascent technology that has not been fully embraced by the consumer and that faces many additional industrial and market challenges. [EPA-HQ-OAR-2022-0829-0701, p. 31]

J. Conclusion

EPA suggests that reaching a U.S. light-duty battery electric vehicle market share 60% by MY 2030 and two-thirds of all light-duty vehicle sales by MY 2032 is feasible and practicable. The conditions which would enable such a high level of BEV market share are not present today and are highly questionable based on the estimates that EPA relied on in this proposed rulemaking. [EPA-HQ-OAR-2022-0829-0701, p. 83]

III. Light-Duty Vehicle Greenhouse Gas Standards

In 2021, Auto Innovators accepted the challenge of driving light-duty EV purchases (including BEVs, PHEVs, and FCEVs) to between 40 and 50% of new vehicle sales by 2030.145 This commitment was, and remains, premised on having the necessary complementary policies in place to support the 40-50% goal. The Inflation Reduction Act and the Infrastructure Investment and Jobs Act are steps in the right direction, which industry had identified as critical to meeting, not exceeding, our goal of 40-50% EVs by 2030. However, these policies are not a guarantee of the future state of the U.S. EV market and are only part of the coordinated and parallel actions that will be necessary to expand EV sales. [EPA-HQ-OAR-2022-0829-0701, p. 88]

145 Alliance for Automotive Innovation (Aug. 5, 2021), “Auto Innovators: Aligning Policies for a Cleaner Future.” https://bit.ly/45GXdC5.

Concurrent with Auto Innovators announcement, President Biden signed Executive Order 14037 calling for 50% of all new passenger car and light truck sales to be EVs, including BEVs, PHEVs, and FCEVs.146 This policy direction was again affirmed by four cabinet level agencies, including EPA, in The U.S. National Blueprint for Transportation Decarbonization in early 2023.147 [EPA-HQ-OAR-2022-0829-0701, p. 88]

146 Executive Order 14037, “Strengthening American Leadership in Clean Cars and Trucks” (Aug. 5, 2021). 86 Fed. Reg. 43583 (Aug. 10, 2021).

147 U.S. Departments of Energy, Transportation, and Housing and Urban Development; U.S. Environmental Protection Agency, The U.S. National Blueprint for Transportation Decarbonization (Jan. 2023) at 9.

EPA’s proposed rule for MY 2027 to 2032 unilaterally moves those goal posts, requiring approximately 60% BEV sales by 2030.148 The proposed rule also excludes consideration of PHEVs, a technology that is readily available, comprises 1.4% of today’s overall EV sales,149 and that serves an important role in advancing consumer acceptance of EVs. If manufacturers were to substitute PHEVs for some of those BEVs, the overall EV market share would increase further. [EPA-HQ-OAR-2022-0829-0701, p. 88]

148 NPRM at 29333. (Table 99, Proposed standards, 2030.)

149 Alliance for Automotive Innovation (2023), Advanced Technology Sales Dashboard, calendar year 2022. Data compiled by the Alliance for Automotive Innovation using information provided by S&P Global Mobility (formerly IHS Markit). Last updated Mar. 3, 2023; retrieved Jun. 23, 2023.

Auto Innovators does not believe the GHG standards, as proposed, are feasible for the industry as a whole given the lead-time provided to apply the necessary technologies (electric vehicles) to meet them. Our specific concerns with EPA's analysis vis-à-vis electric vehicles are focused on the lack of assessment of necessary and critical market, supply chain, and infrastructure development as described in more detail in Section I (EV Feasibility). Our comments here focus more specifically on the proposed light-duty vehicle greenhouse gas standards. [EPA-HQ-OAR-2022-0829-0701, p. 88]

As EPA notes, BEVs accounted for 5.8% of the new U.S. light-duty passenger vehicle market in 2022.153 Moreover, EPA's MY 2023-2026 GHG emissions standards that were finalized at the end of 2021 projected only a 17% light-duty penetration rate for both BEVs and PHEVs by MY 2026.154 Despite this low rate of consumer acceptance, the Proposed Rule projects a light-duty BEV penetration rate of 67% by MY 2032, up from 36% in MY 2027.155 Importantly, in the absence of these and other strict regulatory programs (such as California's ZEV mandate), EPA projects a significantly lower MY 2032 BEV penetration rate of only 39%.156 It is unclear from EPA's analysis how the regulations alone justify a 28 percentage point increase in BEV market between having regulations versus not. This is particularly concerning given that EPA's no- action analysis presumably includes the same level of existing supportive mechanisms such as the IRA and IIJA, assumptions for infrastructure development, and other market-enabling features. [EPA-HQ-OAR-2022-0829-0701, pp. 89-92]

154 See Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards, 86 Fed. Reg. 74434, 74485, Table 33 (Dec. 30, 2021).

155 NPRM at 29329, Table 80.

156 Id. at 29329, Table 81.

In other words, a staggering increase in the implementation and adoption of BEV technology underpins the Proposed Rule and is the central means by which the rule effectuates its contemplated emissions reductions. But this shift to electrification is not a simple matter of swapping one technology for another. The mass adoption of BEVs on the scale required for compliance with the Proposed Rule's standards requires a much broader transformation in the way vehicles are manufactured, purchased, fueled, serviced, and disposed of. Indeed, the Proposed Rule would reorder much of the U.S. automobile industry—which supports roughly 10.3 million American jobs and $558 billion in annual car sales, and about 6% of the U.S.'s Gross Domestic Product (GDP).157 Consumers must be willing to purchase BEVs at mass scale; the power sector must be able to generate and deliver adequate electricity158—which itself will contribute to emissions—while maintaining grid reliability and otherwise meeting consumer and industrial demand; adequate charging infrastructure must be available; batteries and other components must be manufactured at an increasing rate, critical minerals sourced, and supply chains developed. These needs must be met not only for light-duty vehicles, but also for medium- and heavy-duty vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 89-92]

157 See Economic Insights, Alliance for Automotive Innovation, htps://www.autosinnovate.org/resources/insights.

158 In addition to increasing electricity capacity, utilities are also facing a transition in technology types and more renewable sources, as proposed under the “Greenhouse Gas Standards and Guidelines for Fossil Fuel-Fired Power Plants” [88 FR 33240, May 23, 2023].

As expressed throughout this comment, we have serious concerns that the market will not be able to bear the requirements of the Proposed Rule and that those requirements will not be feasible given these considerations. Compliance will impose significant costs, and require extraordinary effort, on the part of regulated parties—costs which will be passed along to consumers. Setting such stringent standards has the potential to create a significant market disruption, with consequences not only for the automobile industry but for the entire U.S. economy. [EPA-HQ-OAR-2022-0829-0701, pp. 89-92]

3. Front-Loading of the Proposed Standards

The proposed standards are heavily front-loaded, seeking over half of the required GHG emissions improvements in the first two years, and nearly three-quarters of the improvements in the first three years.166 [EPA-HQ-OAR-2022-0829-0701, pp. 92-93]

166 Calculation by Auto Innovators based on EPA-estimated fleetwide CO2 targets corresponding to the proposed standards (NPRM at 29240, Table 29).

The proposed front-loading of the standards increases the risk to the feasibility of the standards since they are largely premised on widespread fleet electrification. As noted, it will take time to develop the supply chains, infrastructure, and market for EVs, and the proposed front-loading further limits recovery opportunities if everything doesn’t go exactly as planned. [EPA-HQ-OAR-2022-0829-0701, pp. 92-93]

While both passenger car and light truck standards are front-loaded in general, the proposed MY 2027 standard stringency increase for trucks (21%) is almost double that of cars (12%).167 Although these reductions become more balanced over the course of the proposed MY 2027-2032 program, light-duty trucks would shoulder more of the burden with a 52% stringency increase between MY 2026 and 2032 as compared to cars with a 45% stringency increase.168 [EPA-HQ-OAR-2022-0829-0701, pp. 92-93]

167 Calculation by Auto Innovators based on EPA-estimated fleetwide CO2 targets corresponding to the proposed standards (NPRM at 29240, Table 29).

168 Calculation by Auto Innovators based on EPA-estimated fleetwide CO2 targets corresponding to the proposed standards (NPRM at 29240, Table 29).

Much of this difference between passenger car and light-duty truck stringency increases (particularly in MY 2027) likely stems from EPA’s proposal to move away from its historic approach to setting standards (a set percentage reduction to an existing footprint target curve) toward setting light-duty truck standards based on passenger car standards.169 EPA proposes to make this switch in a single year (MY 2027), which results in a large step change in light-duty truck stringency, which should be reassessed on whether such a jump is feasible. [EPA-HQ-OAR-2022-0829-0701, pp. 92-93]

169 See DRIA at 1-8 et seq. (Development of truck curve.)

Organization: Alliance for Vehicle Efficiency (AVE)

Evaluation of feasibility

In contrast to previous rulemakings, EPA's assessment of the proposed standards' feasibility must account for a major transformation of the automotive market, its supply chains, technical workers, and the materials needed to produce a compliant fleet. EPA should also account for ZEV production volatility based on China's ability to withhold critical minerals which are not mined in the U.S. [EPA-HQ-OAR-2022-0829-0631, pp. 2-4]

Many of the estimates for future compliance in the Proposal assume that within four years, all the following requirements will be in place: that significant quantities of critical minerals and materials will be available, that the nation's electrical grid will be reliable (and cleaner), that new supply chains will be established, and that all the necessary technology and components needed for zero- emission vehicles (ZEVs) will be mass produced. [EPA-HQ-OAR-2022-0829-0631, pp. 2-4]

Should any of these assumptions be inaccurate, automotive manufacturers will likely assume significant financial risks as they modify their operations and production. The Proposal also assumes that consumers will purchase enough of these new vehicles for manufacturers to meet sales volumes for compliance levels. To reduce these risks, EPA should re-evaluate the ZEV marketplace to determine the new standards' feasibility prior to the effective date. [EPA-HQ-OAR-2022-0829-0631, pp. 2-4]

Technology integration across the U.S. fleet does not happen quickly

EPA is predicting a very significant number of battery electric vehicles (BEVs) to be available to consumers.5 Advanced vehicle technology integrations, however, are historically slow to take effect. As indicated in EPA's 2020 Trends Report, "…it has taken, on average, approximately 15- 20 years for new technologies to reach maximum penetration across the industry." 6 [EPA-HQ-OAR-2022-0829-06, pp. 2-4]

12 5 Federal Register / Vol. 88, No. 87 / Friday, May 5, 2023 / at 29188

6 EPA 2020 Trends Report at p.63

Eleven years ago, EPA made similar predictions about the increased use of then-available technologies to meet future standards, many of which never came close to EPA's predictions. [EPA-HQ-OAR-2022-0829-0631, pp. 2-4]

"The agencies believe that advances in gasoline engines and transmissions will continue for the foreseeable future, and that there will be continual improvement in other technologies, including vehicle weight reduction, lower tire rolling resistance, improvements in vehicle aerodynamics, diesel engines, and more efficient vehicle accessories." 7 [EPA-HQ-OAR-2022-0829-0631, pp. 2-4]

7 Federal Register / Vol. 77, No. 199 / October 15, 2012 / at 62631

Indeed, broad acceptance of BEVs by consumers is still a question for large portions of the country, and the Proposal does not fully address this issue. [EPA-HQ-OAR-2022-0829-0631, pp. 2-4]

Organization: American Coalition for Ethanol (ACE)

Hurdles to Arbitrarily Regulating BEVs as the Only Way to Reduce Vehicle GHG Emissions

According to the U.S. Energy Information Administration, BEVs will comprise about 17% of all vehicle sales by 2030.1 EPA's proposal aims to force an astonishing transition requiring BEVs to represent an average of 78% of all sales of sedans, 68% of all pickup sales, and 62% of all crossover and SUV sales by 2032.2 [EPA-HQ-OAR-2022-0829-0613, pp. 2-3]

1 https://www.eia.gov/outlooks/aeo/narrative/consumption/sub-topic-01.php.

2 Table 80 of EPA's Proposed Rule.

On the surface, this transition does not seem feasible, and in the draft regulatory impact analysis, the Agency itself admits that prior tailpipe GHG emission standards have underperformed relative to what was originally projected. [EPA-HQ-OAR-2022-0829-0613, pp. 2-3]

Automakers are highly skeptical of the feasibility of reaching this immense level of BEV sales in EPA's proposed timeframe. According to John Bozzella, the President and CEO of the Alliance for Automotive Innovation, "a lot has to go right for this massive – and unprecedented – change in our automotive market and industrial base to succeed, especially as 284 million light-duty vehicles across the country (that average 12 years in age) remain on the roads. As of last year, EVs accounted for just over 1% of all light-duty vehicles."3 [EPA-HQ-OAR-2022-0829-0613, pp. 2-3]

3 April 12, 2023 blogpost by John Bozzella, President and CEO of the Alliance of Automotive Innovation.

The Auto Innovators have pointed out President Biden's 2021 Executive Order (EO 14037), which seeks 40 to 50% electric vehicle sales by 2030, was always a "stretch goal," and it includes plug-in hybrids, fuel cell, and BEVs and depends upon complimentary policy relating to dozens of factors outside of the vehicle, such as charging station availability, mineral availability, and grid capacity.4 EPA's proposal represents a "significant movement of the country's electrification goal posts – not by a little, but by a lot" according to Auto Innovators testimony from Mike Hartrick. [EPA-HQ-OAR-2022-0829-06, pp. 2-3]

12 4 https://www.whitehouse.gov/briefing-room/presidential-actions/2021/08/05/executive-order-on-strengthening-american- leadership-in-clean-cars-and-trucks/.

Setting aside whether this proposal is feasible or not from an automaker standpoint, the fact is the Agency is relying on dozens of factors outside of the direct control of automakers and their suppliers for the proposal to come to fruition. In fact, EPA itself lacks the jurisdiction to regulate or control complimentary polices needed to solve for many of these needs, such as securing foreign supplies of raw materials and minerals to make batteries, access to home and public charging infrastructure, state and local building codes, grid capacity and reliability, and perhaps most importantly, consumer preferences and fears associated with such a monumentally fast transition to BEVs. [EPA-HQ-OAR-2022-0829-0613, pp. 2-3]

In response to these practical hurdles, testimony from Mr. Hartrick of the Auto Innovators goes on to say "…there is no clear pathway to meet the totality of these needs in the timeframe considered in the proposed rulemaking without significant impacts to automakers, workers, consumers, and ultimately the availability of vehicles that meet the needs of individuals, families, and businesses across the country." [EPA-HQ-OAR-2022-0829-0613, pp. 2-3]

Non-binding company commitments about BEV production and EPA's reliance upon them does not prove the proposal is feasible. The number of these non-binding commitments and projections relied upon by the Agency is astounding and unprecedented. Indeed, recently in setting final 2023 through 2025 renewable volume obligations (RVOs) for advanced biofuel, EPA specifically chose not to rely on the non-binding production capacity forecasts and commitments of prospective advanced fuel producers. As a result, the final advanced biofuel RVOs are lower than desired by many of these prospective producers, but achievable in EPA's view. Why would the Agency abandon that logic for this rulemaking and put all its faith in similarly non-binding commitments from BEV enthusiasts when proposing these ambitious tailpipe standards for vehicles? [EPA-HQ-OAR-2022-0829-0613, pp. 2-3]

Mr. Bozzella, the President and CEO of the Auto Innovators, sums it up this way: "The administration's 50% (electric vehicle) goal in 2021 was aspirational, but it was also based on clearly defined climate goals, credible assumptions, and data. The 60+% BEVs by 2030 plan, on the other hand, is a house of cards. It rolls up rosy forecasts (like EV batteries will eventually cost automakers nothing) and other hopeful assumptions."5 [EPA-HQ-OAR-2022-0829-06, pp. 2-3]

12 5 June 28, 2023 blogpost by John Bozzella, President and CEO of the Alliance of Automotive Innovation.

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

The proposed light- and medium-duty rule is also arbitrary and irrational in many ways. The Clean Air Act and common sense alike require that EPA adopt regulations only if the agency first determines that compliance will be feasible. The proposed rule flunks that core criterion many times over. Electric vehicles are barely in use today, and the numbers needed to meet EPA's new emissions standards are many times higher than current levels. As EPA admits, compliance with its proposed rule depends on a drastic increase in the number of electric vehicles produced and purchased by 2032. Sales of battery-electric light-duty vehicles, for example, would likely have to jump tenfold or more. Achieving such a surge in the availability and adoption of electric vehicles would present grave challenges in any circumstance, but it is especially implau- sible given EPA's arbitrary and unjustifiably truncated timeline. [EPA-HQ-OAR-2022-0829-0683, pp. 3-4]

EPA predicts that such a sea change would occur, but its forecast fails on its own terms: it relies heavily on manufacturers' nonbinding and aspirational announcements of future plans, oversimplified and illogical assumptions about the purchasing decisions of light- and medium-duty vehicle owners, and unreliable estimates of the costs that electric-vehicle users will incur. [EPA-HQ-OAR-2022-0829-0683, pp. 3-4]

Moreover, EPA's feasibility analysis fails to meaningfully confront multiple serious obstacles to the widespread adoption of electric vehicles on which its proposed rule depends. Increased production of electric vehicles is constrained by the supply of certain minerals critical to manufacturing batteries. That supply is sharply limited; mining and processing operations are nowhere near the levels needed to support the expansion of electric vehicles EPA's proposed rule would require. The supply chain is subject to serious disruptions, as other fed- eral agencies have underscored. For example, nearly all existing supply of several critical minerals is controlled by a small number of foreign and unfriendly nations. The insufficiency of these essential inputs will only become more acute as worldwide demand for them increases. And developing new operations would be a decades-long process that extends far beyond the compliance period for the proposed rule. On average, it takes 16 years to move mining projects from discovery to first production, and another ten to begin producing at max- imum capacity. EPA barely addresses this problem in its proposed rule and offers no plausible solution. [EPA-HQ-OAR-2022-0829-0683, p. 4]

Section 202(a) requires EPA to consider whether compliance with the proposed emissions standards is feasible, giving appropriate consideration to the cost of compliance. 42 U.S.C. § 7521(a)(2) ("Any regulation prescribed . . . shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period."). While the agency may take future advances into account, it may not promulgate rules on the basis of "crystal ball" prognostications. NRDC v. EPA, 655 F.2d 318, 328 (D.C. Cir. 1981) (internal quotation marks omitted). Instead, the agency must explain why its projections are "reason[able]" and defend "its methodology for arriving at numerical estimates." Id. Here, that includes answering theoretical objec-tions to widespread electrification, identifying the major steps necessary to achieve that objective, and offering plausible reasons for believing that each of those steps can be completed in the time available. Id. at 331–32. [EPA-HQ-OAR-2022-0829-0683, p. 18]

EPA's proposed rule is not feasible for multiple independent reasons. Over- all, EPA's conclusion that compliance with its proposed standards is possible assumes a drastic increase in the adoption of light- and medium-duty electric vehicles that is implausible and unrealistic within the proposed rule's con- strained timetable. In addition, EPA has failed to confront several specific im- pediments to the expanded availability and adoption of light- and medium-duty electric vehicles, including serious threats to the supply of minerals critical to manufacturing batteries; the Nation's inadequate charging and refueling infra- structure and limitations of its electricity grid; and safety concerns with electric vehicles that will deter uptake by users and may prompt intervention by other regulators. EPA cannot rationally conclude that compliance with its proposed emission standards is feasible without demonstrating how these obstacles will be overcome. [EPA-HQ-OAR-2022-0829-0683, p. 18]

The agency's conclusion that compliance with the proposed rule is feasible critically depends on the electric-vehicle adoption rates it projects for model years 2027 through 2032. EPA expects that by 2032, 67 percent of light-duty vehicles and 46 percent of medium-duty vehicles will be battery-electric. 88 Fed. Reg. at 29,329, 29,331. Those numbers are staggering. Current adoption rates are much lower, and the assumptions that EPA makes to project such sizeable increases are unwarranted. [EPA-HQ-OAR-2022-0829-0683, p. 19]

a. Current Adoption Of Electric Vehicles

Today, battery-electric vehicles make up a small minority of vehicles in both the light- and medium-duty categories. Manufacturers offer a limited number of models, and relatively few consumers buy them. [EPA-HQ-OAR-2022-0829-0683, p. 19]

Although EPA claims that the production of electric vehicles is growing rapidly, see 88 Fed. Reg. at 29,188–89, the U.S. Department of Energy reports that there are only 68 models of light- and medium-duty battery-electric vehicles available for the current model year. See U.S. Dep't of Energy, Alternative Fuels Data Ctr., Alternative Fuel and Advanced Vehicle Search, https://tinyurl.com/y853dwvt (last accessed June 26, 2023). Thirty-five of them are se- dans or wagons; twenty-nine are SUVs; four are pickup trucks; and none are vans. Id. This limited number of options may be a result of exceedingly low demand. According to the agency, in 2022, battery-electric vehicles accounted for only 807,000 new car sales, or about 5.8 percent of the new light-duty passenger-vehicle market. 88 Fed. Reg. at 29,346. Currently, "in most of the United States, the share of EVs is zero or near-zero." Kenneth T. Gillingham et al., Has Consumer Acceptance of Electric Vehicles Been Increasing?, Forthcoming, Am. Econ. Ass'n, at 6 (Jan. 2023) ("Consumer Acceptance"). This is particularly true in rural areas. In Wyoming for example, there were "only 456 electric cars and light trucks registered statewide as of March 2022." Robert N. Charette, The EV Transition Explained: Converting Gasoline Superusers, IEEE Spectrum (Dec. 11, 2022) ("EV Transition"), https://tinyurl.com/5dnry66s. [EPA-HQ-OAR-2022-0829-0683, p. 19]

By and large, the light- and medium-duty sectors have not embraced a shift from internal-combustion-engine vehicles to electric ones. [EPA-HQ-OAR-2022-0829-0683, p. 19]

To reach EPA's projected rates of adoption, the manufacture and sale of electric vehicles would have to experience rampant growth. EPA has identified no evidence to demonstrate that this will occur, let alone on the constrained timetable of its proposed rule. Instead, the agency relies on speculation and ignores important and relevant data. [EPA-HQ-OAR-2022-0829-0683, p. 20]

Organization: American Fuel & Petrochemical Manufacturers

C. The Proposal's Deployment Timeline is Impracticable

EPA's emissions standards rely on the unsubstantiated assumption that the U.S. electricity and transmission grid and ZEV charging infrastructure will be available to charge the massive numbers of ZEVs that will enter the market. As outlined below, available data supports the Alliance for Automotive Innovation's conclusion that the timeline for EPA's standard is infeasible.36 [EPA-HQ-OAR-2022-0829-0733, p. 13]

36 Alliance for Automotive Innovation, Comments to the Environmental Protection Agency, Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, Proposed Rule, Docket No. EPA-HQ-OAR-2022-0829 (hereinafter AAI Comments) at iv.

B. The Proposed Rule Contravenes the Clean Air Act's Direction that EPA's Regulations be Technologically Feasible

Section 202(a)(2) requires EPA to provide lead time to "permit the development and application of the requisite technology."104 But, as discussed in Section IV.B, EPA's overly-aggressive demands for electrification cannot be supported—there will not be sufficient infrastructure to generate and transmit electricity and charge the vehicles EPA is requiring OEMs to produce. EPA has simply failed to provide both the OEMs, as well as the ancillary services required to sustain an electrified fleet, with enough time to develop the necessary infrastructure.105 EPA's failure to adequately ensure sufficient infrastructure demonstrates that it is not providing sufficient lead time to "permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period."106 [EPA-HQ-OAR-2022-0829-0733, p. 25]

104 42 U.S.C. § 7521(a)(2).

105 See AAI Comments at ii-iv.

106 Id. (emphasis added).

As EPA considers the technological feasibility of its Proposal, it should further consider the OEMs' position that they will not possess adequate resources to adapt to these stringent requirements within the prescribed timeframe, especially in light of increasing global supply chain issues and price increases associated with battery demand.110 EPA's proposal will require an unprecedented rate of vehicle technology change that the nation and OEMs have never experienced before. [EPA-HQ-OAR-2022-0829-0733, pp. 25-26]

110 AAI Comments at ii-iv.

B. The Proposed Rule is Impracticable

1. EPA's Proposed Rule Ignores the Reality of Current ZEV Production.

In describing the need for this regulatory action, EPA suggests that rapid electrification resulting from the Proposed Rule either is already in progress or aligned with the automotive industry. In support, EPA cites public statements of the automotive industry to justify the proposed standards.124 Representing 42 car companies, automotive suppliers, and automotive technology companies that produce about 97 percent of the new vehicles sold in the United States, the Alliance for Automotive Innovation (AAI) submitted the following comments on this Proposal: [EPA-HQ-OAR-2022-0829-0733, pp. 28-29]

124 Proposed Rule at 29,329.

- The proposed GHG and criteria pollutant standards "are neither reasonable nor achievable in the timeframe covered in this proposal";125 [EPA-HQ-OAR-2022-0829-0733, pp. 28-29]

125 Alliance for Automotive Innovation, Comments to the Environmental Protection Agency, Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, Proposed Rule, Docket No. EPA-HQ-OAR-2022-0829 (hereinafter AAI Comments) at ii.

- EPA's proposal cannot be met "without substantially increasing the cost of vehicles, reducing consumer choice, and disadvantaging major portions of the United States population and territory";126 [EPA-HQ-OAR-2022-0829-0733, pp. 28-29]

126 Id.

The Proposed Rule's standards exceed even the public aspirations of OEMs' vehicle and market share targets. [EPA-HQ-OAR-2022-0829-0733, pp. 28-29]

2. EPA's Proposed Rule Commands Impractical Adoption Rates.

Automakers may be publicly acquiescing to government demands, but this does not demonstrate that the technology and infrastructure will be available in the stated period and, most critically, that consumers are ready and willing to adopt electric vehicles. Indeed, many of the automakers have set "goals" for their electrification, premised explicitly on a litany of federal and state subsidies for purchase and infrastructure assistance. And these government demands, and indeed government subsidies, can vanish in an instant, through changes in administrations or judicial challenges. [EPA-HQ-OAR-2022-0829-0733, pp. 30-31]

Organization: American Highway Users Alliance

Key Concerns with the Proposed Rule

The Highway Users is deeply concerned that the proposed requirements for significant reduction in GHG emissions from new light-duty and medium-duty vehicles are very, very possibly not achievable by manufacturers in the limited time frame provided to achieve such significant reductions in emissions. The Alliance for Automotive Innovation has already submitted testimony in this docket that the proposed rule would require 2/3 of vehicles covered by this docket to be battery electric vehicles by 2032. In today's market the share of new light-duty and medium-duty vehicles that are electric vehicles (EVs) is one-tenth of that share nationally, and far, far lower in many regions of the country. So, the rule essentially calls for an industrial transformation, something more easily said than done, not to mention the proposed rule's impacts on consumers and vehicle choice. [EPA-HQ-OAR-2022-0829-0696, p. 2]

More specifically, EPA's proposal in this docket appears to be premised on huge and rapid growth in the portion of light-duty and medium-duty vehicles that are electric powered (EVs) as well as on rapid transformation of the marketplace in a number of related areas that are not the subject of the proposed regulation. EPA seems to have made favorable assumptions on many issues bearing on the feasibility of the proposal, including as to the issues set forth below. The Highway Users, on the other hand, drawing on the expertise of its members, questions that, within the MY 2027 – 2032 timeframe of the proposed rule, all or most of the following will– ccur, that -- [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

- high-speed and other electric charging stations will be sufficiently available to service light- duty and medium-duty EVs in quantities and locations sufficient to encourage customers to buy EVs, [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

- electric utilities can timely provide connections from the electric grid to those charging stations, or hydrogen fueling stations – and provide the refueling and charging connections at reasonable cost, [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

- the electric grid will have the capacity to meet the demand for electricity that will be required to support increased electrification of trucks, buses, and passenger cars, even if the connections can be timely made to charging stations (both public and private) that do not yet exist in sufficient numbers, [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

- charging times can be reduced sufficiently to encourage customers to buy these EVs, [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

- major industries, including vehicle manufacturers and their suppliers, can implement major changes in vehicles as rapidly as the NPRM assumes (given the limited current market penetration of these EVs), [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

- there will be an adequate supply of rare earth and other critical minerals, and the ability to process them, with those minerals being so essential to the manufacture of EVs and batteries, [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

- with a large portion of such minerals being sourced and/or processed overseas, including in China and Africa, whether the national interest in sourcing and processing such minerals in the United States can be met, and [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

- potential customers of these EVs will proceed to purchase them in sufficient quantity, notwithstanding significantly higher up-front costs, uncertain availability of charging facilities, and other concerns. [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

This last consideration is highly important because if the potential customers of these EVs do not become actual customers to a sufficient extent, the manufacturers are unlikely to produce the vehicles in the quantities EPA has estimated will be required to be compliant with the regulations, in turn greatly reducing the benefits of the proposal as EPA estimated. [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

Significantly, at the same time that EPA has issued this NPRM, it has also issued a major proposal calling for reduced tailpipe emissions of CO2, other GHGs, and other substances from heavy-duty vehicles. See 88 Fed. Reg. 25926 (April 27, 2023). That proposed rule, similar to the one in this docket, assumes astronomical growth in EVs as a percentage of new heavy-duty vehicles. That rule faces similar questions regarding feasibility due to, among other uncertainties, the availability of charging infrastructure that is sufficiently fast, the cost of such heavy duty EVs, the ability of the electric grid to provide electricity to support the growth in those EVs, the ability of the electric utilities to provide connections from the grid to charging facilities, and the availability of critical minerals, processing facilities and battery components, and electrical steel, widely used in transformers, electric vehicle chargers and other products important to the widespread adoption of electric vehicles.2 [EPA-HQ-OAR-2022-0829-0696, pp. 3-4]

2 A May 22, 2023 letter from nine major organizations to President Biden expressed concern over the "skyrocketing demand and limited availability of domestically produced electrical steel. Signatories included the Alliance for Automotive Innovation, the Edison Electric Institute and the International Brotherhood of Electrical Workers.

With these two large-scale rules being advanced at the same time, the feasibility of the proposals is even more challenging. It is not as if manufacturing charging stations for heavy-duty, light-duty, and medium-duty vehicles is unrelated. At least some supplies and components are relevant to all; the critical minerals and related processing are needed for all. But suppliers and electric utilities can only gear up so quickly. This confluence of proposed regulations (further combined with separate and significant regulatory actions by the California Air Resources Board) compounds the challenges for relevant industries to comply. It makes it harder to make favorable assumptions on how quickly changes can be made to facilitate marketplace acceptance of EVs. [EPA-HQ-OAR-2022-0829-0696, pp. 3-4]

For reasons including those outlined above, the proposed rule should be revised to provide more time for vehicles to achieve the proposed emission reductions A revised proposal should not only provide more time to achieve a given level of emission reductions but, while still calling for reductions, should call for achievable reductions. The need for revision of the proposal is so significant that EPA should not proceed directly to a final rule after considering comments in this docket. [EPA-HQ-OAR-2022-0829-0696, p. 4]

Instead, EPA should issue a revised NPRM so the public can have the opportunity to comment on a more realistic approach to the effort to reduce GHG and criteria emissions from light-duty and medium-duty vehicles. Such a solution would reduce emissions but more gradually, over a longer period of time than the model years that are the subject of the proposed rule. [EPA-HQ-OAR-2022-0829-0696, p. 4]

Feasibility of the proposal is highly questionable and benefits are likely overestimated [EPA-HQ-OAR-2022-0829-0696, pp. 4-5]

We are skeptical that the GHG and criteria reductions estimated by EPA can be realized in the proposed rule's timeframe. [EPA-HQ-OAR-2022-0829-0696, pp. 4-5]

Organization: American Honda Motor Co., Inc.

Achieving these goals will not be easy, requiring (among other activities) new technology and vehicle development, factory renovations, battery and auto assembly factories, realignment of the supply network, the existence of a vast, well-functioning public charging infrastructure, and the formation of joint ventures and alliances. It was with such considerations in mind that, in our comments to the agency regarding proposed MY2023-2026 vehicle greenhouse gas (GHG) standards, Honda specifically cautioned EPA that "it is important that the agencies not approach such [electrification target] announcements as foregone conclusions."4 Unfortunately, in this rulemaking the agency did just that – set aggressive targets while pointing to industry statements as a basis for the feasibility of its proposed standards. It is worth noting that the agency's proposed level of electrification just six years from now – barely one product design cycle away – is a full 50% higher than Honda's publicly stated target.5 [EPA-HQ-OAR-2022-0829-06, pp. 4-5]

12 4 American Honda Motor Co., Inc. comments on Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions. September 27, 2021. Docket ID No. EPA–HQ–OA2021–0208.

12 5 60% in 2030, versus Honda's publicly stated goal of 40% in 2030

Pointing to complementary policies, including those in the Inflation Reduction Act (IRA), the agency has characterized its standards as "readily achievable,"6 a position that suggests the agency believes all major stakeholders (including consumers, the critical minerals supply chain, utilities, state and local governments, charging infrastructure providers, parts suppliers, battery manufacturers and automakers, among others) are "ready" to effectuate an electrified transportation system in line with the agency's proposed stringency and timeline. Honda respectfully disagrees. Based on our experience in creating and marketing battery electric vehicles over the past 25 years, we believe the agency has significantly underestimated the numerous intertwined external challenges that lie ahead – and, moreover, the fact that a missed target in any one of these areas has significant potential to derail not only our shared decarbonization goals, but also the compliance status of regulated parties. [EPA-HQ-OAR-2022-0829-0652, p. 5]

6 https://www.epa.gov/newsreleases/biden-harris-administration-proposes-strongest-ever-pollution-standards- cars-and

In the auto industry, internal forecasts of future environmental regulations are a necessity, as multi-year planning timelines for products often dictate that development decisions be made well in advance of full clarity on the status of a given future regulation. [EPA-HQ-OAR-2022-0829-0652, p. 10]

E. Agency Faith in a Swift and Seamless EV Market Transition

As noted earlier in these comments, one of the more troubling aspects of the NPRM is the agency's assumed fast and smooth market transition to widespread electric vehicle adoption. This assumption permeates numerous regulatory requirements and key parameters in the proposal, including fleet average GHG stringency, fleet average NMOG+NOx stringency, and overall cost of the regulation to consumers. While major automakers, including Honda, have announced significant targets for levels of vehicle electrification in the coming years, those intentions have also been sincerely caveated – not as excuses or planned off-ramps, but rather to acknowledge the many uncertainties that remain about consumer adoption, a substantial number of which hinge on the development of a full and robust vehicle electrification ecosystem which includes numerous factors outside of Honda's control. [EPA-HQ-OAR-2022-0829-0652, p. 22]

iv. Feasibility and Modeling.

A review of EPA's modeling cost and assumptions for battery costs, critical minerals, battery raw materials, and impacts of federal incentives calls into question EPA's approach and conclusions regarding feasibility of the proposed standards. [EPA-HQ-OAR-2022-0829-0641, pp. 22-23]

- The cost reduction model used in the analysis seems to be based on a model used for part cost reductions driven by improved economies of scale on fixed capital equipment. Given that raw materials make up a significant portion of battery costs, EPA should also use a raw material supply cost model that considers the increasing costs for raw materials with increased supply. [EPA-HQ-OAR-2022-0829-0641, pp. 22-23]

- Cost and price are concepts that the agency uses interchangeably in the regulation. The true cost of the regulation is not fully calculated since the portion of the consumer- facing price is paid for by the government. The agency should fully account for the technical feasibility of any CO2-reducing technology on a cost basis as defined in the CAA regardless of governmental taxation breaks for electric vehicle technology production and sale. [EPA-HQ-OAR-2022-0829-0641, pp. 22-23]

- The cost impact of "fueling" the significant number of electric vehicles assumed in the regulation (67% implied EV share by 2032) is not fully calculated or considered as part of the technical feasibility analysis and cost for the technology. The costs of adding additional solar, wind, and hydropower plants should be considered in the regulation as they are a necessary part of bringing electric vehicles to market. [EPA-HQ-OAR-2022-0829-0641, pp. 22-23]

These topics are further addressed in Appendix B. [EPA-HQ-OAR-2022-0829-0641, pp. 22-23]

Organization: BlueGreen Alliance (BGA)

Automakers have announced $120 billion in new investments in clean vehicle manufacturing in the last eight years, with over 40% of those investments occurring in the six months following the passage of the Inflation Reduction Act in August 2022.8 Domestic automakers' 2023 Q3 profits were the highest they have been since 2016.9 Moreover, due to the passage of transformative programs in the Infiation Reduction Act and the Bipartisan Infrastructure Law, automakers and their suppliers have more federal resources than ever before to support the transition to cleaner vehicles in ways that do not shortchange their workers, their communities, or the environment. [EPA-HQ-OAR-2022-0829-0667, p. 7]

8 Environmental Defense Fund, "Report finds U.S. investments in electric vehicle manufacturing reach $120 billion, create 143,000 new jobs," March 2023. Available Online: https://www.edf.org/media/report-finds-investments-us-electric-vehicle-manufacturing-reach-120-billion- create-143000.

9 U.S. Bureau of Economic Analysis, Corporate profits with inventory valuation adjustments: Domestic industries: Nonfinancial: Manufacturing: Durable goods: Motor vehicles, bodies and trailers, and parts, March 2023. Available Online: https://fred.stlouisfed.org/series/N411RC1Q027SBEA.

Organization: BMW of North America, LLC (BMW NA)

Ultimately, BMW NA believes that the 'roposed Rule's target of 67% EV share by MY32 is overly ambitious and cannot reasonably be achieved given the short amount of remaining time that is left to resolve the outstanding challenges. [EPA-HQ-OAR-2022-0829-0677, p. 2]

BMW NA does have concerns and questions regardi'g the Agency's basis for proposing the massive jump in stringency, particularly for the light truck fleet, from MY26 to MY27. An increase in the BEV market share from 17% to 36% within one year, as predicted by EPA, is impractical to achieve. BMW NA has no indication that the light truck segment will change dramatically in 2027. Therefore, an incremental increase of BEV share is more appropriate. [EPA-HQ-OAR-2022-0829-0677, p. 3]

Organization: BorgWarner Inc.

BorgWarner supports the goals of EPA's proposal. [EPA-HQ-OAR-2022-0829-0640, pp. 3-4]

BorgWarner supports EPA's approach to decarbonize the light-and medium-duty vehicle sectors. However, the proposed pace for battery electric vehicle (BEV) adoption requires continued significant support and incentives from state and federal regulators. [EPA-HQ-OAR-2022-0829-0640, pp. 3-4]

The demand for BEVs across all vehicles sectors is rising. Critical mineral supply will need to increase significantly to support the growth of the BEV market. Battery production, along with the necessary charging infrastructure, will ultimately depend on suppliers and manufacturers having access to increasingly domestically sourced and processed critical materials and minerals in sufficient quantities. Automotive suppliers operate in an integrated, complex worldwide supply chain and access to international markets is critical to our ability to meet production demands. [EPA-HQ-OAR-2022-0829-0640, pp. 3-4]

The Infrastructure Investment and Jobs Act (IIJA), the Inflation Reduction Act (IRA), and CHIPS & Science Act were each important initial steps to enable industry, consumers, and communities to make the EV transition across the U.S. These significant investments are critical in supporting the continued growth of U.S. manufacturing and ensuring the initial transition results in affordable EVs for consumers and profitability for manufacturers. EPA should recognize that a majority of the programs needed to help achieve the EV transformation are still awaiting regulations and guidelines. In addition, the supplier industry, along with automakers and communities, will need time to implement the necessary investments in supply chains, infrastructure, and workforce to make the shift to electrification successful. [EPA-HQ-OAR-2022-0829-0640, pp. 3-4]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

The technologies to meet and exceed the proposed standards are available today. U.S. EPA's analysis finds that zero-emission vehicle (ZEV) technologies are cost-effective compliance options that manufacturers will increasingly deploy. With the rapid development of ZEV technology—supported by commitments from automobile manufacturers, unprecedented public investments in vehicles and infrastructure, and growing consumer demand—the U.S. market is poised to adopt these clean vehicle technologies at scale. The two most common examples of ZEVs are battery electric vehicles (BEV) and fuel cell electric vehicles (FCEV), which rely on different control technologies to eliminate vehicle emissions. BEVs use batteries with an on-board charger to store energy from the electrical grid to power electric motors. Fuel cell electric vehicles are full electric drive vehicles where the propulsion energy is supplied by hydrogen stored on board and a fuel cell stack that transforms the chemical energy stored in hydrogen into electricity for the drive motor. Although not fully zero-emission because of the use of internal combustion engines, plug-in hybrid electric vehicles (PHEV) also use battery packs to power electric motors. [EPA-HQ-OAR-2022-0829-0780, pp. 7-8]

The Proposal Will Deliver Urgently Needed Emission Reductions and is Technologically Feasible

The proposed standards at a minimum are technologically feasible with significant net benefits. The proposal is consistent with U.S. EPA's clear authority to regulate motor vehicle emissions, and manufacturers have control technologies available and in use today to meet and exceed the proposed standards. [EPA-HQ-OAR-2022-0829-0780, pp. 11-12]

The ACC II regulations and U.S. EPA's proposed standards both address multiple pollutants, including GHGs, particulate matter (PM), and non-methane organic gas (NMOG) and nitrogen oxides (NOx), from light- and medium-duty vehicles. Control technologies are available today to meet and exceed the proposed standards. Although ZEV technologies are not the only approach manufacturers can use to comply with the proposed standards, U.S. EPA's analysis concludes that they are one of the most cost-effective and thus will play a large role. ZEVs are especially beneficial and effective because they eliminate vehicle tailpipe emissions across all pollutants, and many manufacturers are actively supporting ZEV market expansion and have publicly committed to significantly increase ZEV production. This is being driven in large part by technology improvements such as declining battery costs, dedicated electric vehicle platform design enabling lower manufacturing costs and reduced vehicle energy consumption, improvements in battery pack capacity and energy efficiency, and fuel cell system improvements. 6 In response, the market has grown significantly with the availability of numerous BEV and FCEV models that meet consumer preferences and operational needs. A variety of state and federal programs, including California and Section 177 state regulatory actions and incentive programs, the federal Inflation Reduction Act, and the federal Infrastructure Investment and Jobs Act are supporting ZEV penetration, building the necessary infrastructure, and providing a backbone for the successful implementation of U.S. EPA's proposed standards. [EPA-HQ-OAR-2022-0829-0780, pp. 11-12]

6 For additional discussion on zero-emission vehicle (ZEV) technology improvements, see: CARB. Advanced Clean Cars II, Staff Report: Initial Statement of Reasons (ISOR). April 2022. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/accii/isor.pdf.

CARB has reviewed the proposed standards and finds that they are technically feasible within the proposal's timeframe. CARB also finds that more stringent standards are technically feasible and offers recommendations to that end. CARB also reviewed the draft regulatory impact analysis (DRIA) and finds that U.S. EPA has taken an appropriate but generally conservative approach to estimating costs, suggesting that the net benefits are likely understated. This section summarizes CARB's review and offers specific recommendations to strengthen the proposal to: achieve additional emission reductions and public health benefits; advance equity and environmental justice; ensure ZEVs meet the needs of drivers, including those who purchase vehicles in the used car market; and provide as consistent a set of standards for ZEVs nationwide as possible, reducing complexity for manufacturers and consumers alike. [EPA-HQ-OAR-2022-0829-0780, pp. 11-12]

Feasibility of proposed standards

California's effective vehicle GHG fleet average emission rate for new vehicles is similar to U.S. EPA's proposal due to similar expected shares of ZEVs entering the market in the 2026 through 2032 MYs and beyond. California's ACC II regulations require that an increasing share of new vehicle sales be zero-emission, ramping up from 35 percent for the 2026 MY to 100 percent for the 2035 MY. As part of the ACC II rulemaking, CARB estimated that 75 percent of new car sales in California in 2032 will be BEVs to comply with the ACC II regulations (with a small percentage of additional fuel cell and plug-in hybrid electric vehicles). In comparison, U.S. EPA projects a 67 percent BEV market share nationwide to comply with the proposed federal GHG standards in the same year. [EPA-HQ-OAR-2022-0829-0780, pp. 12-13]

In establishing its ZEV sales requirement, CARB assessed the technical feasibility and cost of ZEV technologies to determine a feasible pace of ZEV introduction in California. 7 This assessment found several market trends that will drive widespread ZEV penetration in the coming years, including a rapidly expanding number of ZEV models, increasing all-electric range, technological battery and fuel cell advancements, energy efficiency improvements, and declining battery costs. These market trends are also occurring at the national and international levels, and they underpin the technical feasibility of U.S. EPA's proposed standards. Further, as U.S. EPA notes in its proposal, every manufacturer has a public commitment to significant if not full electrification in the next 20 years. 8 Based on public announcements, it is expected that over 100 ZEV and PHEV models will be available to consumers before the 2026 MY. [EPA-HQ-OAR-2022-0829-0780, pp. 12-13]

7 CARB. ACC II ISOR. Appendix G: ACC II ZEV Technology Assessment. April 2022. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/accii/appg.pdf.

8 87 Fed. Re–. at 29,191 - 192.

In addition to these existing market trends, the implementation of ACC II in California and an expanding number of other states will further spur technological development, supporting widespread ZEV deployment and providing additional support that the proposal is not only achievable, but that manufacturers could exceed the standards as proposed. [EPA-HQ-OAR-2022-0829-0780, pp. 12-13]

U.S. EPA's modeling shows that the lowest cost compliance option to meet the proposed standards would result in 46 percent of medium-duty vehicles being battery-electric by the 2032 MY, relying primarily on zero-emission van technologies. Under California's ACT regulation, 40 percent of a manufacturer's medium-duty vehicle sales will be required to be zero-emission in the 2032 MY, increasing up to 45 percent the following MY. In its 2023 ACF rulemaking, CARB identified at least ten zero-emission Class 2b-3 van and pick-up truck models that are commercially available, up from only two manufacturers offering zero- emission Class 2b and 3 vehicles when CARB developed ACT. 10, 11 As in the light-duty sector, manufacturers are investing and will continue to invest in new technologies to comply with California's regulations, providing support that U.S. EPA's proposed standards are technically feasible. In the van category, four of the largest medium-duty van manufacturers—Ford, GM, Stellantis, and Daimler—have announced product availability by 2024 in the U.S.. 12, 13, 14, 15 For pickups, numerous zero-emission models are coming to market as some pickups designed for the passenger vehicle market are now being certified as medium-duty pickups, including the Ford F150 Lightning, the Rivian R1T, and the Tesla Cybertruck. 16 , 17 , 18 [EPA-HQ-OAR-2022-0829-0780, pp. 16-17]

18 Tesla. Re: Support for a Strengthened Advanced Clean Truck Rule. December 9, 2019. https://www.arb.ca.gov/lists/com-attach/120-act2019-VyMFZlAiWWYEYwdY.pdf

As with ACC II, many other states have adopted or announced plans to adopt CARB's regulations on medium- and heavy-duty vehicles, including the ACT rule. This broader adoption of ZEV technologies in the medium-duty sector will continue to drive technological advancement and support compliance with the proposed standards, further illustrating the technical feasibility of the proposal. [EPA-HQ-OAR-2022-0829-0780, pp. 16-17]

The U.S. has no choice but to take bold action to dramatically reduce GHG emissions across the economy. Motor vehicles are a key GHG emissions source, and U.S. EPA's proposal represents an absolutely critical step towards reducing transportation emissions and stabilizing the climate. However, there are opportunities to do more, particularly protecting or insuring against conventional vehicles increasing their GHG emissions. Motor vehicles also continue to contribute to poor air quality for millions of people across the country. The public health benefits from the suite of proposed standards will reduce healthcare costs and improve quality of life. These benefits are especially important for our country's most vulnerable residents, many of whom face disproportionate exposure to air pollution and are the first to suffer the effects of climate change. [EPA-HQ-OAR-2022-0829-0780, p. 67]

CARB finds that a more stringent set of standards, and thus certainly the proposed standards as well, are technically feasible and cost-effective and recommends that U.S. EPA incorporate CARB's recommendations and adopt the most stringent standards feasible. [EPA-HQ-OAR-2022-0829-0780, p. 67]

Organization: California Attorney General's Office, et al.

Recent congressional actions demonstrate the federal commitment to substantial electrification of the transportation sector. In 2021, Congress passed the Bipartisan Infrastructure Law, which allocates $7.5 billion to building out a national network of electric vehicle chargers, $7 billion to ensure domestic manufacturers have the critical minerals and other components necessary to make electric vehicle batteries, and $10 billion for clean transit and school buses.110 In 2022, Congress passed the CHIPS and Science Act, which invests $52.7 billion in America's manufacturing capacity for the semiconductors used in electric vehicles and chargers.111 Later in 2022, Congress passed the Inflation Reduction Act, which provides $7,500 to buyers of new electric vehicles and $4,000 to purchasers of pre-owned electric vehicles.112 Additionally, the Inflation Reduction Act provides billions of dollars to support vehicle manufacturers' expansion of their domestic production of clean vehicles,113 and billions to support battery production in the United States and mining and processing of critical minerals needed for battery cells and electric motors.114 The Inflation Reduction Act also allocates billions to upgrade the nation's power grid in order to help address the new surge in grid demand from electric vehicles.115 [EPA-HQ-OAR-2022-0829-0746, pp. 18-19]

In the Bipartisan Infrastructure Law, Congress directed $5 billion toward States to expand charging infrastructure under the National Electric Vehicle Infrastructure ("NEVI") Formula Program.134 To date, all 50 States have submitted and received approval for their NEVI plans.135 These plans detail the considerable resources and local expertise that state transportation, energy, and environmental agencies bring in support of Congress's vision of a "national network of electric vehicle charging infrastructure."136 Those resources include the mobilization of significant public and private nonfederal monies,137 the strategic siting of EVSE infrastructure in high-demand areas and major transportation corridors,138 designing resilience strategies to pair chargers with distributed generation and storage resources,139 and providing model ordinances for municipal governments to support EVSE expansion.140 These plans also illustrate the importance of greater EV adoption to States' climate targets.141 [EPA-HQ-OAR-2022-0829-0746, pp. 22-24]

B. The Proposed Standards Allow Adequate Lead Time to Apply the Requisite Technologies, and the Costs of Compliance Are Reasonable

Section 202(a) requires EPA to afford manufacturers the lead time necessary for the "development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period." 42 U.S.C. § 7521(a)(2). Given that the requisite technologies needed to satisfy the proposed standards (as well as the more stringent alternative) have already been developed and are widely used today, EPA need only provide the lead time necessary for manufacturers to continue deploying these technologies across their vehicle fleets. Indeed, the ALPHA and OMEGA models that EPA used to model manufacturer compliance with the proposed standards utilized a menu of only existing technologies. 88 Fed. Reg. at 29,294. In addition to Section 202(a)'s general lead time requirement, for criteria pollutant standards applicable to medium-duty vehicles with gross vehicle weight over 6,000 pounds, the Clean Air Act further requires EPA to provide a minimum of four years' lead time and three years' stability, because it defines these vehicles as "heavy-duty" for purposes of Section 202(a)(3)(C). 42 U.S.C. § 7521(b)(3)(C). [EPA-HQ-OAR-2022-0829-0746, pp. 32-33]

Our States and Cities believe that EPA's proposed standards, as well as standards more stringent than EPA's proposed standards, satisfy these statutory requirements. EPA estimates the proposed standards per-vehicle cost to industry as ranging from $401 (for model-year 2029) to $1,164 (for model-year 2032) relative to the no-action scenario. 88 Fed. Reg. at 29,328 (Tables 77 & 78). These are in line with or lower than the per-vehicle costs of previous GHG standards EPA has adopted. 75 Fed. Reg. 25,324, 25,463 (May 7, 2010) (Table III.D.6-4) ($948 for model year 2016); 77 Fed. Reg. 62,624, 62,865 (Oct. 15, 2012) (Table III-34) ($1,836 for model year 2025); 86 Fed. Reg. 74,434, 74,483 (Table 30) (Dec. 30, 2021) ($1,000 for model year 2026).184 Likewise, these projected costs are in line with historical exercises of EPA's Section 202(a) authority.185 [EPA-HQ-OAR-2022-0829-0746, pp. 32-33]

184 The per-vehicle costs for Alternative 1's standards are similarly comparable to the per-vehicle costs of the 2012 rulemaking. Draft RIA, at 13-29 ($1,775 for model year 2032).

185 See, e.g., J.R. Mondt, Cleaner Cars: The History & Technology of Emission Control Since the 1960s (2000), at 214 ("[W]hen three-way catalytic converters were implemented in 1980-83, the additional cost increment [per vehicle, in 1996 dollars] amounted to approximately $1200").

Organization: CALSTART

2. Expected EV Deployment Timelines

One commonly discussed concern is the timeline related to EV deployments and whether there will be a sufficient number of EV options to justify more ambitious standards. The U.S. EV market is significantly more robust than it was only a few years ago. IHS Markit predicts that by 2026, there will be 130 available models offered by 43 brands.2 Having over 43 brands offering over 130 models by 2026 supports the argument that we do not need a delayed ramp up of standards (Alternative 3), and rather the market will be prepared by 2027 to meet Alternative 1's accelerated timeline. Additionally, numerous OEMs have committed to an all-electric lineup in the coming decade. This includes General Motors, Ford, Nissan, Volkswagen, and others.3 Helping guide all OEMs towards 100% zero-emission vehicle sales by 2035 with Alternative 1 and extending the timeline through 2035 would lead more OEMs to plan for this benchmark, increasing competition and decreasing costs. [EPA-HQ-OAR-2022-0829-0618, p. 4]

Organization: Clean Fuels Development Coalition et al.

II. The Proposed Rule in Infeasible Because it Dramatically Underestimates the Cost of Electric Vehicles.

Section 202(a) requires that standards under that provision cannot take effect until “after such period as [EPA] finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.” 42 U.S.C. § 7521(a)(2). This consideration is commonly known as the “feasibility” requirement. See 88 Fed. Reg. 29,232. If the “cost of compliance” would discourage the adoption of the “requisite technology,” then the rule is not feasible. [EPA-HQ-OAR-2022-0829-0712, p. 15]

The proposal suggests that compliance with its proposed standards is fIe only because it anticipates that the share of electric vehicles will increase dramatically, “by almost 30 percentage points over [a] 6-year period, from 36 percent in MY 2027 up to 67 percent of overall vehicle production in MY 2032.” 88 Fed. Reg. 29,329. As a result, the cost of electric vehicles is the linchpin of this plan. If electric vehicles cost too much, consumers will buy fewer, and proposed standards will become infeasible. While the exact costs are difficult to disentangle, the proposal’s estimated vehicle technology costs suggest that electrifying the fleet comes with a price tag of about $3,900 per added electric vehicle sold.9 But these estimates are flawed in at least three ways: they underestimate current electric vehicle costs, they underestimate future electric battery costs, and overestimate the availability of Clean Vehicle Tax credits. [EPA-HQ-OAR-2022-0829-0712, p. 15]

9 This is based on $59.6 billion in vehicle technology costs between 2027 and 2032, divided by the approximately 15 million additional electric vehicles EPA expects its proposal to require over the same time span. This neglects that some of the vehicle technology costs are incurred by the adoption of new technology for internal combustion engine vehicles. It is also only the cost incurred for the additional electric vehicles EPA projects to be sold only as a result of its regulation. In the agency’s projected “no-action” scenario, the share of electric vehicles rises from 27 percent in 2027 to 39 percent in 2032. See Table 129, 88 Fed. Reg. 29,340. These “baseline” electric vehicle penetrations are calculated using the same vehicle technology costs discussed below, and thus represent inflated numbers. If electric vehicle costs are recalculated appropriately, the baseline share of electric vehicles would decrease, the number of additional electric vehicles over this baseline to comply with EPA’s proposed standards would increase, and the cost of compliance with EPA’s proposal would riseortionately.

12. B. The non-binding company commitments and projections EPA cites do not prove feasibility.

The non-binding company commitments and projections EPA cites do not prove feasibility See 88 Fed. Reg. 29,190-93 (“While manufacturer announcements such as these are not binding, and often are conditioned as forward-looking and subject to uncertainty, they indicate that manufacturers are confident in the suitability of PEV technology as an effective and attractive option that can serve the functional needs of a large portion of light-duty vehicle buyers.”). The auto manufacturers’ statements are not binding, and these companies could change their mind at any time. Many of these statements were made in response to the in direct response to the Biden Administrations urging.16 Further, many of these statements were made with the expectation that EPA would continue to provide various compliance flexibilities—like multipliers—that reduce the real-world stringency of the standards. As noted, the proposed rule would cut these avoidance strategies. [EPA-HQ-OAR-2022-0829-0712, p. 27]

16 Compare FACT SHEET: President Biden Announces Steps to Drive American Leadership Forward on Clean Cars and Trucks, White House Briefing Room (Aug. 5, 2021), https://www.whitehouse.gov/briefing-room/statements-releases/2021/08/05/fact-sheet-president- biden-announces-steps-to-drive-american-leadership-forward-on-clean-cars-and-trucks/ ("[T]he Presi dent will sign an Executive Order that sets an ambitious new target to make half of all new vehicles sold in 2030 zero-emissions vehicles, including battery electric, plug-in hybrid electric, or fuel cell electric vehicles…. That is why today, American automakers Ford, GM, and Stellantis and the United Auto Workers (UAW), will stand with President Biden at the White House with aligned ambition.") with Fred Lambert, Ford, GM, and Stellantis announce joint 40-50% EV sale goal in 2030, Electrek (Aug. 5, 2021), https://electrek.co/2021/08/05/ford-gm-stellantis-joint-40-50-ev-sale-goal-2030/. ("To- day, Ford, GM and Stellantis announce their shared aspiration to achieve sales of 40-50% of annual U.S. volumes of electric vehicles (battery electric, fuel cell and plug-in hybrid vehicles) by 2030 in order to move the nation closer to a zero-emissions future.").

Organization: Consumer Energy Alliance (CEA)

As consumers become more accepting of electric vehicles (EV), taxpayer-funded incentives expand, and automobile manufacturers produce a greater variety of models, EV purchases are expected to keep growing. Policymakers, however, should be increasingly mindful not to put the cart before the horse when it comes to attempting to drive consumers to purchase'products they aren't ready 'o accept, they can't afford to purchase, and that face significant supply-chain bottlenecks that are already limiting supply and increasing costs. This is an area which we explored in-depth in our report Freedom to Fuel: Consumer Choice in the Automotive Marketplace.1 [EPA-HQ-OAR-2022-0829-0788, pp. 1-2]

1 https://consumerenergvalliance.org/cms/wp-content/uploads/2023/06/CEA EV REPORT 2023.pdf

Should this rule be adopted i– its current form - lacking both technological feasibility and eco–omic practicality - the result will be limiting consumer options and thwarting environmental progress through depressing innovation. [EPA-HQ-OAR-2022-0829-0788, pp. 1-2]

Organization: Consumer Reports (CR)

2. The Proposed EPA GHG Standards for MYs 2027+ are Achievable

Transportation accounts for 28% of GHG emissions in the United States7—more than any other sector. EPA's GHG Standards for Light- and Medium-Duty vehicles offer a cost-effective way to reduce these emissions and criteria pollutants, while maintaining a technology-neutral approach. [EPA-HQ-OAR-2022-0829-0728, pp. 7-8]

7 Sources of Greenhouse Gas Emissions, U.S. Environmental Protection Agency, 2021, https://www.epa.gov/ghgemissions/sources-greenhouse-gas-emissions.

2.1. Automakers Have Multiple Options for Compliance

EPA's proposal for MY27+ Light- and Medium-Duty vehicle GHG standards are strong, achievable, technology-neutral performance standards. EPA's analysis found that electric vehicles (EVs) are likely to be the most cost-effective compliance pathway for automakers to meet these standards, but they are not the only option. EPA estimated that an EV-only compliance pathway would require 67% of vehicles sold to be EVs by 2032. However, automakers can also use a mix of improvements in internal combustion engine (ICE) fuel efficiency, conventional hybrids, plug-in hybrids (PHEV), and even hydrogen fuel cell electric vehicles (FCEV) to comply with these standards. CR's modeling presented in Section 6.2 shows that automakers can utilize a wide range of options to comply with these rules. Most automakers will be able to comply with these rules while only selling between 50-60% battery electric vehicles (BEVs) by using a mix of widely available and cost effective technologies. Automakers that invest heavily in conventional and plug-in hybrids will be able to comply while selling as few as 40% BEVs in 2032. [EPA-HQ-OAR-2022-0829-0728, pp. 7-8]

CR estimates that an EV-only compliance pathway would result in the production of enough EVs for approximately 25% of Americans to own one by the end of 2032. In a 2022 nationally representative survey of 8,027 US adults, CR found that 36% of Americans were already “definitely” or “seriously considering” an electric vehicle if they were to buy or lease a vehicle today, indicating that consumer demand may already exceed what is needed to comply with these standards.8 This demand will also increase as consumers see the benefits from recently enacted investments in public charging infrastructure. A deeper dive on consumer demand dynamics can be found in Section 4 of this comment. [EPA-HQ-OAR-2022-0829-0728, pp. 7-8]

8 More Americans Would “Definitely” Get Electric Vehicles, Consumer Reports, July 7, 2022, https://advocacy.consumerreports.org/press_release/more-americans-would-definitely-get-electric-vehicles/.

2.2. The Proposal is in Line With Automakers Commitments

EPA’s analysis of existing automaker EV commitments shows that the industry was already on track to deliver around 50% EVs by 2030. The proposed standards simply reflect a slight boost to the trajectory the industry was on according to public commitments by automakers.9 Since these are technology-neutral standards automakers can adjust to this either by slightly increasing their electrification plans or by deploying existing, cost-effective efficiency technology to their remaining ICE vehicle fleets. As of January 2023, automakers and battery makers planned to invest $860 billion in the transition to EVs by 2030, including $210 billion in the U.S, according to an analysis by Atlas Public Policy.10 [EPA-HQ-OAR-2022-0829-0728, pp. 7-8]

9 Automakers Are Adding Electric Vehicles to ’heir L’neups. Here's What's Coming., Consumer Reports, March 10, 2023, https://www.consumerreports.org/cars/hybrids-evs/why-electric-cars-may-soon-flood-the-us-market-a9006 292675/.

10 $210 Billion of Announced Investments in Electric Vehicle Manufacturing Headed for the U.S., Atlas EV Hub, January 12, 2023, https://www.atlasevhub.com/data_story/210-billion-of-announced-investments-in-electric-vehicle-manufact uring-headed-for-the-u-s/.

6.2. Modeling of Compliance Pathways

EPA’s compliance modeling estimates the single most cost-effective compliance pathway for the vehicle fleet under the proposed regulation. However, it is not the only possible compliance pathway automakers can take. Different automakers are likely to take wildly different compliance pathways, with some automakers going all in on EVs, while other automakers may hedge their bets with more hybrids and PHEVs. [EPA-HQ-OAR-2022-0829-0728, pp. 20-21]

CR modeled a range of reasonable alternative compliance pathways that automakers might consider. The modeling considers different levels of continued ICE improvement and deployment of PHEVs as a percentage of all plug-in vehicles.43 The results of this analysis for model year 2032 are shown in Table 6.1. They show that a wide range of compliance pathways are available to automakers that can reduce the required BEV sales market share for model year

2032 to between 50-60% with varying levels of ICE improvement and PHEV deployment. There is even a feasible compliance option which would allow compliance with only 40% BEVs with heavy investment in hybrid and PHEV technology. [EPA-HQ-OAR-2022-0829-0728, pp. 20-21]

43 ICE improvements of 1% (low), 3.5% (medium) and 5% (high) are modeled. PHEV market share was modeled as a percentage of all plug-in vehicles with values of 0%, 10%, 20% and 40% modeled.

[See original com–ent for Table 6.1 - Modeling of Compliance Alternatives for EPA's Proposed Standards for MY2032] [EPA-HQ-OAR-2022-0829-0728, pp. 20-21]

A few scenarios were also modeled for EPA's Alternative 1. These results are shown in Table 6.2. They find that with only a small improvement in ICE vehicles (1% per year reduction in emissions), automakers can comply with these stronger standards with a minimal increase in BEV market share from 67% to 68% compared to EPA's modeling of the proposed standards. Further reductions in BEV market share are also possible with further investment in ICE improvement and PHEV deployment. [EPA-HQ-OAR-2022-0829-0728, pp. 20-21]

[See original com–ent for Table 6.2 - Modeling of Compliance Alternatives for EPA's Alternative 1 for MY 2032] [EPA-HQ-OAR-2022-0829-0728, pp. 20-21]

Overall these results show that automakers have many potential reasonable compliance pathways to comply with either EPA's proposed standards or the stronger Alternative 1. [EPA-HQ-OAR-2022-0829-0728, pp. 20-21]

Organization: Cummins Inc.

II. General Principles

Aligned with Cummins' commitments described above, Cummins offer these principles for consideration as EPA develops its Final Rule addressing criteria pollutant and GHG emissions for light-duty (LD) and medium-duty vehicles (MDV): [EPA-HQ-OAR-2022-0829-0645, pp. 2-3]

- A harmonized national program for criteria pollutant, GHG, and fuel efficiency standards by EPA, the California Air Resources Board (CARB), and the National Highway Traffic Safety Administration (NHTSA) is essential to assure the greatest improvements are achieved in the most cost-efficient manner and to provide vehicle and engine manufacturers, suppliers, and end-users with the certainty necessary for investment in technologies to improve emissions. We urge the agencies to work together towards a single, nationwide program. [EPA-HQ-OAR-2022-0829-0645, pp. 2-3]

- Sufficient regulatory lead time and stability should be provided to allow manufacturers to develop and implement the technologies needed to improve emissions and spread investments over time to minimize cost to customers. [EPA-HQ-OAR-2022-0829-0645, pp. 2-3]

- Standards should be performance-based and technology neutral, as opposed to standards which mandate a specific technology, to allow manufacturers to innovate across a broad range of technologies to meet customers' diverse needs. [EPA-HQ-OAR-2022-0829-0645, pp. 2-3]

• Standards should be fuel neutral (i.e., same stringency regardless of fuel type) to ensure the environmental benefits of the regulation are achieved regardless of the fuel type chosen by customers. [EPA-HQ-OAR-2022-0829-0645, pp. 2-3]

• The tradeoff between oxides of nitrogen (NOx) and carbon dioxide (CO2) reductions must be considered when setting the stringency of standards. Also, linkage of criteria pollutant and GHG certification and compliance protocols is important so that improvement in one type of pollutant is not achieved at the expense of the other. [EPA-HQ-OAR-2022-0829-0645, pp. 2-3]

• Well-to-wheels emissions should be considered in assessing technology effectiveness to ensure alignment of the standards with the most beneficial path to zero emissions. [EPA-HQ-OAR-2022-0829-0645, pp. 2-3]

Cummins currently certifies heavy-duty (HD) pickup trucks with gross vehicle weight ratings (GVWR) between 8,501 and 14,000 pounds, also known as Class 2b and 3 vehicles, meeting EPA's Tier 3 criteria pollutant emissions standards and Phase 2 GHG standards. Diesel Class 2b and 3 pickup trucks can have significant towing capability and are used in applications going beyond personal use such as construction and agriculture, and as such, do vital work for America. Our additional comments detailed below pertain to those vehicles. [EPA-HQ-OAR-2022-0829-0645, pp. 2-3]

Organization: Delek Holdings, Inc.

I. EPA's Proposed Rule is Based on Flawed Market Projections.

EPA's proposed standards are based on ZEV adoption rates that are unrealistic and unsupported by any concrete evidence. Because higher rates of ZEV adoption are essentially required for engine manufacturers to even come close to meeting the proposed standards, EPA projects adoption rates for MY2027 through MY2032 will be: 45–78% for sedans, 38–62% for SUVs, and 11–68% for pickups, totaling an adoption rate of 36–67% fleet-wide.3 These MY27 estimates are essentially required, despite the reality of the current ZEV market: for MY21, only 4.4% of the U.S. light-duty vehicles produced were PEVs (including both BEVs and plug-in hybrid electric vehicles).4 But EPA does little to acknowledge this reality, much less account for the true feasibility of ZEV penetration into the LD/MD vehicle market. [EPA-HQ-OAR-2022-0829-0527, p. 2]

3 Proposed Rule at ,329 (Table 80).

12 4 Proposed Rule at 29,189 (BEVs alone made up only 5.8% in MY22).

Organization: Environmental. and Public Health Organizations

VI. EPA's Proposed Standards Are Technologically Feasible at Reasonable Cost, as Are Alternative 1 Standards with a Faster Ramp Rate After 2030.

Not only does Alternative 1 with increasing stringency after 2030 yield significant societal benefits, it is also technologically feasible at reasonable cost. In this section, we detail the combustion vehicle and zero-emission technologies that can secure additional emissions reductions from the light-duty fleet, comment on EPA's modeling, and address technology costs.

We also offer recommendations for the Tier 4 NMOG+NOx standards and PM requirements. [EPA-HQ-OAR-2022-0829-0759, p. 36]

2. The electrification technology pathway shows the feasibility of stronger standards.

When it comes to electrification, EPA's OMEGA2 modeling applies electrification almost exclusively to commercial vans, with the model assuming just 236,000 Class 2b-3 electric pickups will be sold out of more than 5.2 million Class 2b-3 pickups sold between 2022-2032

(4.5%). On the other end of the spectrum, the model shows sales of just over 1.2 million electric vans out of just under 2.8 million total sales over the same period (43.4%), with electric vans achieving a 98% market share by 2032. The reasons for such a broad disparity are entirely artificial—for example, the model's 25% cap on production of Class 2b-3 BEV pickups—and do not reflect the latest available data on technology or cost. 187 [EPA-HQ-OAR-2022-0829-0759, pp. 68-69]

187 In its OMEGA2 modeling, EPA has set an artificial cap of 25% on the maximum production of Class 2b-3 BEV pickups, identified in the production_constraints-body_style_MD.csv input file. There is no sufficient justification for this cap in the DRIA or preamble, with the exclusive reference found on p. 1-21 of the DRIA, for which the Agency writes: "The primary assumptions within the work factor based GHG standards for MDV from 2028 to 2032 include an approximately 8 percent year over year improvement, to a large degree from electrification of MDV vans and to a lesser degree electrification of a small fraction (<##########25 percent) of MDV pickups and adoption of other technologies."

a.EPA's modeling should better reflect the favorable economic case for electric pickup trucks.

A recent report by Roush examined the potential for electrification of MDVs under a range of scenarios, finding that electrification is cost-competitive in the great majority of them. 188 It is clear that some amount of the difference between the uptake of Class 2b-3 pickups and vans in the OMEGA2 modeling stems from the far lower range assumed for vans (150 miles) compared to that of pickups (300 miles). But as illustrated in Table VI.A-1 below, 189 Roush finds that by 2030, even when comparing a low-cost combustion powertrain to the most costly battery chemistry (NMC811) deployed in a 400-mile electric Class 3 pickup, 190 the electric pickup still achieves total cost of ownership (TCO) parity within the typical loan length for a new vehicle (7 years). And when comparing a Class 3 pickup with a low-cost battery (LFP) to a high-cost internal combustion engine powertrain, a 400-mile electric pickup would pay off within 1 year, well within the payback period assumed for consumers by manufacturers within EPA's OMEGA2 model. [EPA-HQ-OAR-2022-0829-0759, p. 69]

188 Saxena et al., Electrification Cost Evaluation at 26.

189 Table VI.A-1 is adapted from Saxena et al., Electrification Cost Evaluation, Tbl. 24, at 145. Scenario 1 represents the adoption of low-cost BEV and high-cost combustion vehicle technologies; Scenario 2, medium-cost BEV and combustion vehicle technologies; and Scenario 3, high-cost BEV and low-cost combustion vehicle technologies. Id. at 28-29.

190 Roush used an LFP battery for its low-cost BEV, an NMC811 battery for its medium-cost BEV, and a "10% costlier" NMC811 battery for its High-bost BEV. Id. at 30-31.

Table VIII.A-1. Time to achieve TCO parity for Class 2b-3 BEVs with a 2027 and 2030 purchase timeframe [EPA-HQ-OAR-2022-0829-0759, p. 69]

[See original comment for Table VIII.A-1.].

When accounting for the impacts of the IRA, the economic case for electrification of Class 2b-3 pickups is even clearer, as shown in Table VI.A-2. Here the impact of the full § 30D credit is shown, which is also the maximum allowable limit of the § 45W (commercial clean vehicle) credit for Class 2b-3 vehicles. 191 Roush's analysis finds that purchase price parity is achieved for virtually all BEV classes in the timeframe of the analysis, so the § 45W commercial vehicle credit is not applicable in the later years of their analysis. 192 In fact, Roush finds that, with the application of IRA credits, by MY 2027 all BEVs except the 400-mile pickup will be priced at or below a comparable combustion vehicle 193; and that all MY 2027 BEVs will achieve TCO parity within the first two years of vehicle ownership. 194 Here it is worth noting that, despite the large share of MDVs that are purchased for commercial fleets, EPA did not directly include the § 45W credit in its analysis, instead applying the same combination of the § 30D and § 45W credit as it did for LDVs. 195 Because the § 45W credit is based on the lesser of $7500 or the difference in purchase price, this credit should act to hedge uncertainty in the Agency's analysis, though that is not how it was treated within the OMEGA2 modeling runs. [EPA-HQ-OAR-2022-0829-0759, p. 70]

191 Id. at 175-79. The § 45W credit is based on 30% of the basis of a vehicle not powered by a gasoline or diesel internal combustion engine, or the difference in purchase price between a qualified clean vehicle and a comparable combustion vehicle. In the case of vehicles that have a GVWR less than 14,000 pounds (which includes Class 2b-3 vehicles), the total credit is capped at $7500.

192 Id. at 195.

193 Id.

194 Id. at 197-98.

195 This is not immediately apparent in the text of the preamble or DRIA but can be assessed by comparing the contents of the vehicle_price_modifications_20230314b.csv input files from the LDV and MDV modeling runs, which are identical.

Table VIII.A-2. Time to achieve TCO parity with IRA § 30D credits for MYs 2023 and 2027 196 [EPA-HQ-OAR-2022-0829-0759, pp. 69-71]

196 This table is adapted from Saxena et al., Electrification Cost Evaluation, Tbl. 30, at 193.

[See original comment for Table VIII.A-2.].

The Roush report is not the only analysis to find a strong economic rationale for the adoption of zero-emission MDVs. A recent report from the National Renewable Energy Laboratory (NREL) found that cost parity will be achieved before 2035 (even in the absence of the IRA) for medium- and heavy-duty vehicles, including Class 3 vans and Class 4-5 vehicles that share a platform with Class 2b-3 pickups (which were not part of that analysis).197 Similarly, a recent International Council on Clean Transportation (ICCT) report on electric MDVs finds that purchase price parity with diesel MDVs will be achieved prior to 2032 for 300-mile and lower BEVs, even in the absence of IRA funding.198 And when IRA funding is considered, even 400-mile BEV pickups would achieve purchase price parity in the timeframe of this rule.199 [EPA-HQ-OAR-2022-0829-0759, p. 71]

197 Catherine Ledna et al., NREL, Decarbonizing medium- and heavy-duty on-road vehicles: Zero-emission vehicles cost analysis, Mar. 2022, at 2, 46 https://www.nrel.gov/docs/fy22osti/82081.pdf.

198 Eamonn Mulholland, ICCT, Cost of electric commercial vans and pickup trucks in the United States through 2040 (Working Paper 2022-01), Jan. 2022, at 11 (Fig. 5), https://theicct.org/wp-content/uploads/2022/01/cost-ev-vans-pickups-us-2040-jan22.pdf.

199 See id.

There is some difference in costs between EPA's assessment and other studies such as those described above: on average, according to EPA, Class 2b-3 combustion pickups will cost about $5,000 less (from a purchase price standpoint) than a comparable electric pickup.

However, with the Agency's application of an average IRA credit of $6,000 in 2032, this would still yield cost parity, on average, so even EPA's higher cost assessment cannot fully explain the reason for Class 2b-3 pickups electrifying at such a reduced rate in the Agency's modeling. Even more than that, this disparity is almost entirely influenced by the relative price difference of gasoline and diesel pickups in EPA's modeling, with the Agency's BEV300 pickups just $1,100 more expensive than diesel pickups without the IRA incentives, not far off ICCT's conclusion that BEV300 pickups will achieve cost parity with diesel pickups by 2031.200 Despite this, the model's conversion rate of combustion vehicle sales to electric vehicle sales is virtually indistinguishable between gasoline and diesel pickups, at roughly 20% for each, seemingly indicating that neither purchase price nor TCO parity have a significant impact on sales. Given that many Class 2b-3 vehicles are purchased for commercial use,201 such modeling behavior is inconsistent with the economically-driven decisionmaking that would be expected to occur in the real world.202 [EPA-HQ-OAR-2022-0829-0759, p. 71]

200 Id.

201 See id. at 1; Saxena et al., Electrification Cost Evaluation, at 49.

202 For example, EPA's own analysis of the heavy-duty market assumed a conversion rate of 80% when cost parity is achieved. 88 Fed. Reg. at 25992, Tbl. II-23. And analysis from NREL finds this number to be nearly 100%; see comparison at pp. 59-60 of EDF, Comment Letter on GHG Standards for HD Vehicles, June 16, 2023, https://downloads.regulations.gov/EPA-HQ-OAR-2022-0985-1644/attachment_1.pdf (data from Ledna et al. 2022).

Based on EPA's own modeling, BEV variants for over 71% of the Class 2b-3 market achieve first cost parity with their combustion-powered equivalent by 2032 when including IRA incentives, including 57% of the Class 2b-3 pickup truck market.203 This is a substantially higher share of vehicles than the model assumes will be deployed. [EPA-HQ-OAR-2022-0829-0759, p. 72]

203 This was established using the output files for the OMEGA2 MDV runs, using the vehicles file (2023_03_14_22_42_30_central_3alts_20230314_Proposal_vehicles.csv) to compare in a given model year BEV variants with their combustion equivalent, sharing a base-year vehicle ID.

For all of these reasons, EPA's modeling does not accurately reflect the favorable economic case for commercial MDV electrification, particularly for pickups. While some of these modeling problems can be ascribed to differences in battery costs and EPA's unreasonable choice to include an artificial 25% production cap on BEV pickups, other problems are intrinsic to assumptions made within the model that do not reflect the Agency's own assessment of likely adoption of electrification for commercial vehicles, particularly considering the incentives available under the IRA. [EPA-HQ-OAR-2022-0829-0759, p. 72]

XVI. EPA Should Not Repeat Its Past Pattern of Underestimating ZEV Technology Advancements and ZEV Deployment Within the Fleet.

The regulatory history shows that EPA's projections of ZEV technology advancements and overall ZEV deployment within the fleet routinely prove too conservative. EPA should not repeat those same mistakes in this rulemaking. For example, EPA's light-duty GHG rule finalized in 2012 set standards for MYs 2017–2025 and projected "very small" numbers of electric vehicles in the light-duty fleet through MY 2025. 77 Fed. Reg. at 62917. In the 2012 rule, EPA projected combined PHEV and BEV penetration of only 1% for the MY 2021 car fleet. Id. at 62872. Yet BEV sales alone accounted for at least 3.2% of all vehicle sales in MY 2021.278 In the 2012 rule, EPA did not even project combined BEV and PHEV sales that high by MY 2025. For the combined car and truck fleet, EPA projected BEV and PHEV penetration of only 2% by MY 2025, and for the car fleet alone, BEV and PHEV penetration of only 3% by MY 2025. Id. at 62874, 62875 Tbl. III-52. EPA re-evaluated those projections in 2016 and 2017, again projecting MY 2025 technology penetrations of around 3% or less for BEVs.279 And EPA's 2020 rule still projected only 3.4% BEVs by MY 2025. 85 Fed. Reg. at 24936 Tbl. VII-29. [EPA-HQ-OAR-2022-0829-0759, pp. 106-107]

278 Cox Automotive, In a Down Market, EV Sales Soar to New Record (Jan. 13, 2023), https://www.coxautoinc.com/market-insights/in-a-down-market-ev-sales-soar-to-new-record/; EPA, The 2022 Automotive Trends Report, at 74. See also Ilma Fadhil et al., ICCT, Electric Vehicles Market Monitor for Light-Duty Vehicles: China, Europe, United States, and India, 2020 and 2021, at 6 (2023), https://theicct.org/publication/ev-ldv-major-markets-monitor-jan23/ (estimating nearly 5% total U.S. BEV and PHEV sales in MY 2021).

279 See EPA, Draft Technical Assessment Report: Midterm Evaluation of Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards for Model Years 2022–2025, at ES-10 (2016) https://www.nhtsa.gov/sites/nhtsa.gov/files/draft-tar-final.pdf; EPA, Final Determination on the Appropriateness of the Model Year 2022–2025 Light-Duty Vehicle Greenhouse Gas Emissions Standards under the Midterm Evaluation, at 4-5, 21 (2017), https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P100QQ91.pdf.

In the 2012 rulemaking, EPA also considered a more stringent alternative projecting a 5% combined BEV and PHEV penetration for MY 2025 for the car fleet, but it rejected this alternative based on "serious concerns about the ability and likelihood manufacturers can smoothly implement [that level of] increased technology penetration." 77 Fed. Reg. at 62877. Yet automakers ultimately surpassed that "serious[ly] concern[ing]" electrification penetration level in MY 2022 with BEVs alone. In MY 2022, BEV sales reached at least 5.8% of total light-duty vehicle sales,280 and this growth has continued, with the United States on track to vastly outpace EPA's previous projections of MY 2025 light-duty vehicle electrification. In Q1 of 2023, for example, U.S. light-duty BEV sales alone reached 7.2% of total vehicle sales.281 [EPA-HQ-OAR-2022-0829-0759, p. 107]

280 Cox Automotive, In a Down Market, EV Sales Soar to New Record. See also EPA, The 2022 Automotive Trends Report, at 74 (preliminary report that electric vehicle sales, including both BEVs and PHEVs, were 7.2% of total sales in 2022).

281 Cox Automotive, Another Record Broken: Q1 Electric Vehicle Sales Surpass 250,000, as EV Market Share in the U.S. Jumps to 7.2% of Total Sales (Apr. 12, 2023), https://www.coxautoinc.com/market-insights/q1-2023-ev-sales/.

EPA's projections of ZEV technology advancements and deployment have also proven too conservative in the heavy-duty sector. In the 2016 Phase 2 Final Rule, for example, EPA projected very small levels of HD ZEV penetration through MY 2027. In that rule, EPA projected "limited adoption of all-electric vehicles into the market," and stated that the Agency "do[es] not project fully electric vocational vehicles to be widely commercially available in the time frame of the final rules." 81 Fed. Reg. at 73500, 73704.282 By the time EPA proposed a new rule in 2022, however, the Agency recognized that its 2016 projections were underestimates. See, e.g., 87 Fed. Reg. at 17595 ("Several factors have changed our outlook for heavy-duty electric vehicles since 2016. First, the heavy-duty market has evolved such that in 2021, there are a number of manufacturers producing fully electric heavy-duty vehicles in several applications."). Despite having predicted very limited HD ZEV penetration through MY 2027 in 2016, EPA noted that by 2019, there were already approximately 60 makes and models of HD BEVs available for purchase, "with additional product lines in prototype or other early development stages." Id. EPA explained that "manufacturers and U.S. states have announced plans to shift the heavy-duty fleet toward zero-emissions technology beyond levels we accounted for in setting the existing HD GHG Phase 2 standards in 2016," and recognized the need "[t]o update the MY 2027 vehicle CO2 standards from the HD GHG Phase 2 rulemaking to reflect the recent and projected trends in the electrification of the HD market." Id. at 17598. EPA acknowledged its 2016 under-projections again in the Phase 3 proposal, stating that the Agency has "considered new data and recent policy changes," and is "now projecting that ZEV technologies will be readily available and technologically feasible much sooner than we had projected." 88 Fed. Reg. at 25939. In both the light- and heavy-duty sectors, then, EPA's previous projections of ZEV deployment have proven far too conservative, and automakers have repeatedly shown they can deploy zero-emission technologies on a scale and at a pace far greater than EPA originally predicted. [EPA-HQ-OAR-2022-0829-0759, pp. 107-108]

282 See also 81 Fed. Reg. at 73818 ("As we look to the future, we are not projecting the adoption of electric HD pickups and vans into the heavy duty market…we believe there is no need to a cap for HD pickups and vans because of the infrequent projected use of EV technologies in the Phaseeframe.").

12. A. EPA has broad discretion in considering consumer preferences when promulgating emission standards but should not give undue weight to that factor.

As explained in EPA's Proposal and Section II of these comments, when promulgating new emissions standards under Clean Air Act § 202(a), EPA must consider the statutory criteria of technological feasibility, cost of compliance, and lead time.412 EPA may consider other factors, and in the past has considered a rule's various impacts on vehicle purchasers.413 [EPA-HQ-OAR-2022-0829-0759, p. 152]

412 42 U.S.C. § 7521(a); 88 Fed. Reg. at 29186.

413 88 Fed. Reg. at 29186.

While EPA has often considered consumer acceptance in its Section 202 rulemakings, the Agency may not let the unique preferences of each and every consumer dictate its consideration of the appropriateness or feasibility of emission standards. In International Harvester Company. v. Ruckelshaus, 478 F.2d 615, 640 (D.C. Cir. 1973), the D.C. Circuit Court of Appeals concluded: [EPA-HQ-OAR-2022-0829-0759, p. 152]

We are inclined to agree with the Administrator that as long as feasible technology permits the demand for new passenger automobiles to be generally met, the basic requirements of the Act would be satisfied, even though this might occasion fewer models and a more limited choice of engine types. The driver preferences of hot rodders are not to outweigh the goal of a clean environment. [EPA-HQ-OAR-2022-0829-0759, p. 152]

While International Harvester involved emission requirements for light-duty vehicles under a provision of the 1970 Amendments, the principles the court expressed apply just as well to standards under Section 202(a)(1). As detailed in Section II, Congress intended EPA's standards to push the industry toward greater emission reductions and did not expect them to preserve the market dominance of any particular type of powertrain or power source. EPA should not give oversized weight to arguments questioning consumer preferences, which is not a factor Congress identified in Section 202(a)(1). [EPA-HQ-OAR-2022-0829-0759, p. 152]

While EPA has discretion whether to consider and how much weight to give purchaser acceptance in setting emission standards, that discretion is limited by EPA's primary statutory duty to set standards that adequately protect public health and welfare. An understanding of consumers' willingness to purchase and drive PEVs could inform the feasibility and effectiveness of EPA's regulations. EPA's attention to consumer preferences, however, cannot compromise its overall Clean Air Act mandate to mitigate the automobile's "devastating impact on the American environment," International Harvester, 478 F.2d at 622, or the Agency's primary duty to protect public health and welfare by minimizing harmful air pollution. Most importantly here, however, is that consumer acceptance of PEVs is widespread and growing, and PEVs provide the vehicle features and characteristics that drivers want and need. Thus, as this section will explain, consumer acceptance is not a barrier to PEV penetration at the levels projected by EPA's Proposal or at levels consistent with Alternative 1 with increasing stringency after 2030. [EPA-HQ-OAR-2022-0829-0759, pp. 152-153]

Organization: Environmental Defense Fund (EDF) (1of 2)

Executive Summary

EPA's primary proposal is eminently feasible and consistent with the automakers own publicly announced product plans. In fact, EPA's proposed standards, in certain aspects, reflect a conservative assessment of zero-emitting vehicle (ZEV) deployment in the coming years. [EPA-HQ-OAR-202829-0786, p. 2]

12. C. EPA's proposal is performance-based and can be cost-effectively met with a range of different technologies.

As with EPA's decades-long reliance on the ABT provisions described above, EPA has likewise long established performance-based standards that can be met with a range of emissions- improving technologies. EPA's proposed standards are no exception – they are performance- based and can be met using a range of ZEV and ICEV improvements. [EPA-HQ-OAR-2022-0829-0786, p. 12]III. EPA's final light-duty standards should deliver pollution reductions at least at the level of the proposal.

In this section, we outline the breadth of factors supporting the feasibility and cost-effectiveness of protective pollution standards. We recommend that EPA strengthen the standards in a manner that delivers pollution reductions at least as great as the proposal that EPA is considering. We also highlight the importance of adjustments that could secure even greater pollution reductions by including in the final rule a voluntary (but once chosen, enforceable) alternative leadership pathway that, for manufacturers choosing the pathway, would ensure ACC II levels of ZEV deployment nationwide. In addition, especially if EPA modifies the proposal's phase-in of the standards in the early years of the program as indicated in Alternative 3, we recommend that EPA consider increasing the stringency of the 2031-2032 standards to potentially increase cumulative GHG reductions relative to the proposal, and at minimum, protect the benefits achieved under the standards as proposed. [EPA-HQ-OAR-2022-0829-0786, p. 16]

A. Feasibility, cost, and lead time support final standards at least as protective as the proposal.

In this section, we examine a series of interlocking analyses and factors that support standards at least as protective as EPA's proposed emissions standards, including 1) extensive independent analysis related to rapidly-declining ZEV costs, including the impacts of the IRA in further advancing ZEV cost declines and accelerating ZEV deployment; 2) manufacturers' projections of battery cost declines; 3) an assessment of market indicators, including manufacturer investments and commitments, which are broadly consistent with and reinforce these study findings; 4) a discussion of leading state actions, including the ACC II rule; and 5) presentation of a revised baseline analysis, which synthesizes and quantifies each of these factors. Each of these factors, both individually and when taken together, demonstrate that EPA's proposed standards are feasible and cost-effective. [EPA-HQ-OAR-2022-0829-0786, p. 16]

ii. Market developments further support the feasibility and lead time reflected in EPA's proposal.

Market developments, including manufacturer plans to introduce new BEVs, concrete investments to produce these and other vehicles at volume, and future commitments for significant BEV sales are all consistent with and reinforce the conclusions of the above-described analyses and likewise support the feasibility of protective EPA standards. In fact, these market developments in many cases show manufacturers' plans to produce BEVs at even greater volumes than EPA has assumed. [EPA-HQ-OAR-2022-0829-0786, pp. 23-26]

Increasing BEV Availability and Sales Volumes. An updated report by ERM, based on announcements by major auto manufacturers, finds the number of electrified models available in the U.S. is projected to dramatically increase, reaching 197 by the end of 2025, with over 58 new models slated to launch in model years 2022-2025 (Figure 5).58 As Figure 6 shows, these vehicles will be available across all vehicle types and classes, and, as a result of IRA tax incentives, there will be five light-duty EV models available with a net cost of under $30,000 manufacturer's suggested retail price (MSRP) by the end of 2023 and 15 models available for under $40,000.59 In the United States, more than 800,000 light-duty EVs were purchased in 2022, a 65 percent increase from 2021. The first quarter of 2023 saw EV sales reach over 258,000 units, almost a 45 percent year over year increase.60 [EPA-HQ-OAR-2022-0829-0786, pp. 23-26]

58 Electric Vehicle Market Update: Manufacturer and Commercial Fleet Electrification Commitments Supporting Electric Mobility in the United States. April 2023. ERM for EDF. https://www.edf.org/sites/default/files/2023-05/Electric%20Vehicle%20Market%20Update%20April%202023.pdf (Attachment S)

Source: ERM, EV Market Update (April 2023) [EPA-HQ-OAR-2022-0829-0786, pp. 23-26]

Near-Term Investments Dramatically Increase Production Capacity. In addition to introducing new electric vehicles, manufacturers are investing billions of dollars to produce them at volume. As noted above, a report by WSP for EDF found over $120 billion in private EV supply ecosystem investments and 143,000 new jobs announced in the last eight years. That analysis also evaluated the production capacity of announced facilities with concrete investments. [EPA-HQ-OAR-2022-0829-0786, pp. 23-26]

As shown in the Figures below, by 2026, U.S. manufacturing facilities will be capable of producing an estimated 4.3 million new electric passenger vehicles each year, which represents about 33 percent of all new vehicles sold in 2022. And by 2026, battery manufacturing facilities will be capable of producing more than 1,000 gigawatt hours (GWh) in battery capacity, sufficient to supply up to 11.2 million new passenger vehicles each year, which represents an estimated 84 percent of new vehicle sold in 2022. Both of these levels far exceed EPA’s projections for BEV deployment. [EPA-HQ-OAR-2022-0829-0786, pp. 23-26]

Manufacturer Commitments. In addition to near-term model availability and supporting production investments, vehicle manufacturers have articulated medium- to long-term commitments to even more substantially grow ZEV sales with many working toward a full ZEV fleet within the next decade. For instance, according to the recent market update from ERM, Ford expects 50 percent of its global vehicle volume, and 100 percent of its European volume, to be fully electric by 2030 with a goal of producing 2 million EVs annually by 2026; GM plans to offer a lineup of electric-only models by 2035; Honda has a goal of achieving carbon neutrality by 2050 and 100 percent ZEV sales in North America by 2040—with interim sales goals of 40 percent by 2030 and 80 percent by 2035; Volvo has committed to becoming a fully electric car company by 2030—with an interim goal of reaching 50 percent of global EV car sales and having one million EVs on the road by 2025; and Stellantis aims for 100 percent of sales in

Europe and 50 percent of sales in the U.S. to be BEVs by the end of the decade,61 As EPA notes in the preamble to this proposal, virtually every major automaker is already planning on widespread electrification across global fleets. Figure 9, below, is an updated synthesis of these manufacturer commitments. [EPA-HQ-OAR-2022-0829-0786, pp. 23-26]

[See original attachment for Figure 9: Global Sales Goals by Manufacturers]

Source: ERM, EV Market Update (April 2023) [EPA-HQ-OAR-2022-0829-0786, pp. 23-26]

Market indicators are consistent with and strongly support protective standards. Manufacturers have (and are planning to continue to) offer new vehicles. They have invested billions of dollars to produce these vehicles at near term volumes that far exceed EPA's projections. And almost every company has articulated medium- to longer term ZEV commitments that are broadly consistent with levels in EPA's proposal. [EPA-HQ-OAR-2022-0829-0786, pp. 23-26]

Vehicle Manufacturer EV Commitments

Many vehicle manufacturers have made commitments to transition a significant portion of their sales to ZEVs. While many of the commitments are for a share of manufacturers' global sales, several OEMs have made U.S. specific commitments or have committed to transition their entire fleet which would mean all of their U.S. sales would be ZEV as well. Even for global commitments, manufacturers with significant U.S. sales volumes will nonetheless need to sell meaningful ZEVs to meet their commitments. Because some sales might exceed these global commitments while others fall short, we used global commitments as a reasonable proxy for U.S. sales share. Table 4 below shows OEM commitments and includes a total using 2022 manufacturer sales shares to calculate a weighted ZEV commitment. [EPA-HQ-OAR-2022-0829-0786, pp. 31-34]

[See original attachment for Table 4: Manufacturer ZEV Commitments as Share of Total Sales] [EPA-HQ-OAR-2022-0829-0786, pp. 31-34]

*Due to rounding, the sum of the market share may not equal the total

All major OEMs have set ZEV targets of at least 30% sales starting in 2030. Considering both U.S.-specific and global commitments would result in 47% of new vehicles sold in the U.S. in 2030 being ZEVs. Even unrealistically assuming only the US-specific commitments and the 100% commitments apply, at least 29% of LDV sales in 2030 would be ZEVs growing to 44% in 2035 and 48% in 2040. The 2030 value is plotted above in Figure 12. We also note that the 2035 and 2040 estimates using both approaches are perhaps significantly understated given that some manufacturers with commitments in 2030 have not made 2035 or later commitments but will nonetheless likely increase ZEV sales during that timeframe. [EPA-HQ-OAR-2022-0829-0786, pp. 31-34]

EV Manufacturing Investment Announcements

As discussed above, in their March 2023 report, WSP analyzed investment announcements for domestic EV manufacturing. Their analysis found that announced investments amount to the production of 4.4 million EVs per year by 2026 in the U.S.99 This equals roughly a third (31%) of all LDVs sold in the U.S. last year. Vehicle manufacturers have already committed to manufacturing these vehicles and it provides a lower bound for what might be expected as more manufacturers make EV investment announcements, and the industry continues to grow. [EPA-HQ-OAR-2022-0829-0786, pp. 34-35]

99 U.S. Electric Vehicle Manufacturing Investments and Jobs, Characterizing the Impacts of the Inflation Reduction Act after 6 Months, WSP for EDF, (March 2023). https://blogs.edf.org/climate411/files/2023/03/State-Electric- Vehicle-Policy-Landscape.pdf.

Over the past ten years, between 60% and 70% of the LDVs sold in the U.S. were domestically manufactured with imports accounting for the remaining 30% to 40%.100,101 It is reasonable to expect that not all EVs purchased in the U.S. will be domestically produced. To scale the vehicles, we have assumed that the proportion of EVs within the pool of domestically produced vehicles will be the same as those imported. [EPA-HQ-OAR-2022-0829-0786, pp. 34-35]

100 Board of Governors of the Federal Reserve System. Industrial Production and Capacity Utilization– G.17 Table 3. Originally from Ward's Communications, Chrysler, and GM. 16 Nov 2022. https://www.federalreserve.gov/releases/g17/current/table3.htm.

101 Bureau of Economic Analysis. Motor Vehicle Unit Retail Sales, Table 6. 2023, https://apps.bea.gov/national/xls/gap_hist.xlsx

If the U.S. imported 35% of its vehicles, the average of the last ten years, the EV manufacturing investments have been made already account for 48% of domestically made vehicles sold in the U.S. If the trend of more domestically produced EVs continues and only 20% of sales are imports, the U.S. produced 4.4 million EVs would result in 39% of LDV sales being EVs. [EPA-HQ-OAR-2022-0829-0786, pp. 34-35]

For this analysis, we chose an assumption of 80% domestically produced EVs. While this number is higher than the current share of domestic production, it is in line with the recent trend of onshoring EV manufacturing.102 There are significant incentives and funding opportunities to make domestically producing EVs more attractive to manufacturers. [EPA-HQ-OAR-2022-0829-0786, pp. 34-35]

102 David Gohlke, Zhou, Yan, Wu, Xinyi, and Courtn“y, Calista. 2022. "Assessment of Light-Duty Plug-in Electric Vehicles in the United ”tates, 2010 – 2021". United States. https://doi.org/10.2172/1898424. https://www.osti.gov/servlets/purl/1898424. (Attachment Z)

Manufacturers only make announcements for facilities a few years in advance of production. As such, this gives a glimpse into the near future but should the general trend in announcements continue, tremendous growth would be expected for domestic EV manufacturing. To that end, WSP's analysis is current only through March of 2023. Since that time, manufacturers have announced billions of dollars in additional investment and production capacity, which reinforces the likelihood that these trends will continue to grow and accelerate over time. [EPA-HQ-OAR-2022-0829-0786, pp. 34-35]

ii. Market developments further support the feasibility and lead time reflected in EPA's proposal for Class 2b and 3 vehicles.

Automakers have already begun producing electric versions of Class 2b and 3 cargo vans, step vans, box trucks, large SUVs and pickup trucks. According to ERM, there are currently 13 automakers – including Ford, GM, Daimler, Lightning, Rivian and VW – with plans to produce or already producing 17 models of medium-duty ZEVs with battery ranges up to 500 miles.117 And fleets have already started ordering and implementing these ZEVs. USPS announced that it will purchase 9,250 Ford E-Transit electric delivery vans, which will contribute to USPS' pledge to buy at least 66,000 electric vehicles through 2028.118 In just two years since its launch in 2021, General Motors' BrightDrop has secured more than 30 commercial customers across industries like retail, rental, parcel delivery and service-based utilities, including FedEx, Walmart, Hertz, DHL Express and Purolator.119 The company anticipates accelerating production of its electric delivery vans to reach a 50,000-unit annual volume capacity by 2025.120 Amazon signed a deal with Rivian in 2019 to buy 100,000 Rivian step vans by 2030. Thousands of the delivery vans had been delivered to Amazon and put in circulation in cities across the nation by the end of 2022.121 New York City announced it will purchase 925 EVs, including 382 Chevy Bolts, 360 Ford E-Transit vans, 150 Ford F-150 E-Lightning pickup trucks, 25 PHEV street sweepers, and seven Mack LR BEV garbage trucks.122 These fleet and automaker commitments and investments are another clear indication that EPA's proposed standards for Class 2b and 3 vehicles are feasible. Organization: Ford Motor Company

To achieve the 2032MY goals EPA has proposed and Ford supports, the final regulation must have the following elements. First, regarding the stringency of the GHG standards, the EPA should finalize the Alternative 3 standards with minor adjustments to the utility allowance inherent in the truck curves and provide a phase-out for refrigerant credits (rather than eliminate all at once). The Alternative 3 standards effectively draw a straight line from 2026 to 2032; that is, they would require roughly equal reductions in absolute grams-per-mile targets over the duration of the program. Alternative 3 reaches the same endpoint in 2032 as the EPA's main proposal, and therefore would achieve the primary goal shared by Ford and EPA—widespread adoption of ZEVs. In contrast, EPA's main proposal, Alternative 1, and Alternative 2 each would require precipitous reductions in 2027 – 2029; this is not feasible and does not align with the anticipated scaling of the EV supply chain and manufacturing base. Similarly, the EPA's proposal to end refrigerant credits altogether in 2027 would be abrupt and have the effect of standards being even more strict; EPA should phase these credits out over time. Lastly, EPA's final regulations must continue to recognize the utility provided by trucks. Although electrified vehicles hold promise for all vehicles classes, ICE-powered trucks will continue to provide unique capability and utility for many years. The EPA proposal (and Alternative 3) would reduce the existing truck utility allowance too severely. [EPA-HQ-OAR-2022-0829-0605, p. 3]

As the EPA and others consider the many trade-offs in this rulemaking, Ford must emphasize that investments in EVs will yield far greater emissions reductions than investments toward incremental improvements to already-advanced ICE technologies. These considerations are particularly important in the early years of the EPA program, where the EV market must reach critical mass. Accordingly, we encourage EPA to avoid setting criteria emissions requirements that will force unnecessarily large or ill-timed investments and distract both automakers and the supply base with little air quality benefit. [EPA-HQ-OAR-2022-0829-0605, p. 4]

Standards Continuation Beyond 2032MY

In multiple areas of the NPRM the EPA has requested comment on continuation of light- and medium-duty GHG and criteria pollutant standards beyond 2032MY. Ford opposes continuation of any of the standards beyond the 2032MY. Industry already faces substantial uncertainty before 2032MY, and it is not feasible to establish a robust program beyond that time. [EPA-HQ-OAR-2022-0829-0605, p. 8]

Organization: Governing for Impact and Evergreen Action (GFI)

Fortunately, technological solutions to combat the rising emissions have become more abundant and more affordable.22 Electric vehicles represent the most promising technology to reduce vehicle emissions at the scale needed, as major automakers and fleet owners are aware. Many have made commitments to transition to exclusively manufacturing or buying EVs by the end of the next decade, as noted in the Proposed Rule.23 These automaker commitments come at a time when clear market demand — the number of EVs sold in the US jumped from 1.7% of new car sales in 2020 to a startling 5.7% in 202224 — is supported by an abundance of new federal funding incentives, thanks to the Infrastructure Investment and Jobs Act and the Inflation Reduction Act ("IRA"). So far in 2023, EV demand continues to grow: EVs made up 7% of new cars sales in the first quarter.25 [EPA-HQ-OAR-2022-0829-0621, p. 3]

22 Jack Ewing, "Electric Vehicles Could Match Gasoline Cars on Price This Year," N.Y. Times, https://www.nytimes.com/2023/02/10/business/electric-vehicles-price-cost.html (Feb. 10, 2023).

23 Proposed Rule at 29296 (citing International Energy Agency, "Global EV Outlook 2022," p. 107, May 2022, https://iea.blob.core.windows.net/assets/e0d2081d-487d-4818-8c59-69b638969f9e/GlobalElectricVehicleOutlook2022.pdf).

24 Zachary Shahan, "US Electric Car Sales Increased 65% in 2022," CleanTechnica, https://cleantechnica.com/2023/02/25/us-electric-car-sales-increased-65-in-2022/ (Feb. 25, 2023).

Outside analyses pre-dating the Proposed Rule have also proved more bullish than the EPA's central No Action scenario. In 2021 — prior to the IRA's passage — IHS Markit "predicted a nearly 40 percent U.S. [Private] EV share" of car sales in 2030, according to the Proposed Rule's literature review.65 (In other words, what the EPA projects will occur after accounting for generous IRA tax credits, IHS Markit estimated would take place even without those historic incentives.) Post-IRA, Bloomberg New Energy Finances estimates the 2030 EV share of new car sales at 52 percent by 2030.66 The International Council on Clean Transportation and Energy Innovation concluded that share will reach between 56-67 percent by 2032.67 Indeed, the Proposed Rule acknowledges the inherent uncertainty involved in projecting into the future.68 As a result, the agency conducted several sensitivity cases beyond the central No Action baseline, modeling various alternate "No Action" assumptions (for example, likely forthcoming state policies) that predicted a range of EV shares—in one of these alternate No Action cases, EV penetration reached as high as 66 percent in MY 2032.69 [EPA-HQ-OAR-2022-0829-0621, pp. 8-9]

65 Proposed Rule at 29189 (citing IHS Markit, "US EPA Proposed Greenhouse Gas Emissions Standards for Model Years 2023–2026; What to Expect," August 9, 2021. c. The Proposed Rule Is Not Technologically Feasible Within the Required extend

The Clean Air Act does not direct EPA to drive emission standards for regulated pollutants to zero as quickly as possible. Rather, under section 202(a)(2), EPA must ensure that any standards are issued with sufficient lead time "to permit the development and application of the requisite technology, given appropriate consideration to the cost of compliance within such period."40 For EPA's aggressive PEV mandates, the "requisite technology" not only includes manufacturing the vehicles themselves but also the underlying charging infrastructure necessary to power these vehicles. Here, EPA has not demonstrated that sufficient charging stations, utilities, and other infrastructure needed to support the deployment of an electrified fleet within the Proposed Rule's contemplated timeline is possible. Without the ability to charge the PEVs EPA will be requiring OEMs to produce, the Proposed Rule is nonsensical. Furthermore, according to a recent study, 23% of 657 public charging stations in the San Francisco Bay area were broken, and a big charging company, ChargePoint, had an operational success rate of just 61%.41 [EPA-HQ-OAR-2022-0829-0579, pp. 10-11]

40 42 U.S.C. § 7521(a)(2).

41 NYT, "A Frustrating Hassle Holding Electric Cars Back: Broken Chargers," (Aug 16, 2022), available at https://www.nytimes.com/2022/08/16/business/energy-environment/electric-vehicles-broken-chargers.html.

Take Virginia as a representative example highlighting the gap between the Proposed Rule's required infrastructure and that which is actually feasible. According to a report by the Consumer Energy Alliance, attached herein, Virginia currently has 7.6 million light-duty vehicles on the road. Assuming Virginia transitions to 100% PEV by 2035, the state would need an additional 35.5 billion kWh of generation – equivalent to the generation required to power almost 70% of the homes in the state. And to maximize the zero-emission benefit of PEVs, this generation would need to come from zero-emitting sources such as nuclear or renewables (ignoring, for a moment, the energy intensity required to construct these resources). But 35.5 billion kWh corresponds to either 4 new nuclear reactors in the state or over 450,000 acres of off-shore windfarms. Neither of which is remotely feasible under the Proposed Rule.42 [EPA-HQ-OAR-2022-0829-0579, pp. 11-12]

42 CONSUMER ENERGY ALLIANCE, "Freedom to Fuel: Consumer Choice in the Automotive Marketplace," August 2023 [hereinafter, "CEA Study"]. Nor has EPA shown that the electric grid itself can meet this increased demand. As highlighted by the North American Electric Reliability Corporation ("NERC"), certain high-risk areas do not today meet resource adequacy criteria, posing significant concern about adding even more demand to the grid.43 This risk is further exacerbated by EPA's new carbon dioxide standards for fossil-fuel fired power plants, proposed shortly after the Proposed Rule and not otherwise considered in the Proposed Rule, that may rapidly phase out affordable base-load generation.44 Far from what the Proposed Rule requires, the infrastructure upgrades to support a U.S. LD fleet that is only 7% PEV would require an additional $75-125 billion, which would be passed on from utilities directly to customers.45 Today, energy insecure households, defined as those that are unable to adequately meet basic household energy needs because of cost, pay 26 cents more per square foot in energy costs as compared to energy secure households.46 This disparity will only increase as infrastructure upgrades to accommodate the increased load from PEVs is passed along to ratepayers.

43 North American Electric Reliability Corporation, 2022 Long-Term Reliability Assessment (Dec. 2022), 21, available at https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2022.pdf (indicating that increased demand projections may lead to reliability concerns for the electric grid, especially as dual-peaking or seasonal peaking times change with increased electrification).

44 See Proposed Rule, "New Source Performance Standards for Greenhouse Gas Emissions From New, Modified, and Reconstructed Fossil Fuel-Fired Electric Generating Units; Emission Guidelines for Greenhouse Gas Emissions From Existing Fossil Fuel-Fired Electric Generating Units; and Repeal of the Affordable Clean Energy Rule," 88 Fed. Reg. 33,240 (May 23, 2023).

45 CEA Study at 8 (noting that the average price to consumers in New Mexico would be $117-195 per year).

46 EIA, "U.S. energy insecure households were billed more for energy than other households," (May 30, 2023) available at https://www.eia.gov/todayinenergy/detail.php?id=56640.

Absent a comprehensive understanding of the interplay between PEV manufacturing and charging infrastructure, vehicle manufacturers are left in vulnerable position. If the underlying infrastructure cannot support the influx of PEVs, or if consumers perceive the requisite infrastructure is not available or reliable, consumers will simply not purchase PEVs in the quantities requires for OEMs to meet the proposed standards. Case in point, Toyota has publicly stated that given the three major barriers to widespread PEV adoption—1) the availability of sufficient critical minerals; 2) a sufficient nation-wide charging infrastructure; and 3) overall affordability—"the most immediate way to reduce carbon emissions is through a mix of electrified options, which includes battery electric, plug-in hybrid, and hybrid vehicles."47 [EPA-HQ-OAR-2022-0829-0579, pp. 11-12]

47 Forbes, "Toyota Says Public Charging Not Ready for Pure EVs," (May 20, 2023) available at https://www.forbes.com/sites/brookecrothers/2023/05/20/toyota-admits-inconvenient-truth-about-electric-vehicle-ev-charging-time-prius-prime-rav4-prime/?sh=2b7ed7ab38b1.

Organization: Hyundai America Technical Center, Inc. (HATCI)

Overal', HMG supports EPA's push toward a ZEV future. However, we find elements of the Proposed Rule to be not only challenging, but in some cases, infeasible a nd thus counterproduct've to our (and EPA' s) ultimate goal of 100% ZEVs in the future. HMG believes that if the Proposed Rule is implemented as written, it will have significant negative impacts on the transition to ZEVs by forcing manufacturers to devote considerable resources into short-term, temporary compliance strategies with relatively little overall benefit. HATCI is also a member of the Alliance for Automotive Innovation (AFAI) and further supports the positions and comments the AFAI submitted for the Proposed Rule. [EPA-HQ-OAR-2022-0829-0554, p. 1]

HMG is concerned that the Proposed Rule will require re-prioritizing ICE instead of EV technology investments [EPA-HQ-OAR-2022-0829-0554, p. 2]

HMG has made considerable investments and changes to its business consistent with its focus on the transition to vehicle electrification and goal to achieve carbon neutrality by 2045. With these objectives in mind, HMG has proactively moved its work force over the last five years from ICE development and manufacturer to ZEV development. Such changes have been necessary to expedite the transition to 100 percent ZEVs. [EPA-HQ-OAR-2022-0829-0554, p. 2]'Unfortunately, EPA's proposed Tier 4 regulations would require extensive changes to our current ICE engines, and thus a shift in our plans back to ICE development, and consequently away from ZEV acceleration. Essentially, the Proposed Rule is likely to cause a backslide in ZEV development in order to address a short-term focus on bridge ICE technologies. [EPA-HQ-OAR-2022-0829-0554, p. 2]

Moreover, if the Proposed Rule goes into effect as of model year (MY) 2027, HMG would need to start work in calendar year 2024 to implement the extensive new engine re-developments required to comply with the Proposed Rule. The work force available to respond to the proposed Tier 4 regulations is limited due to the proactive re-organization efforts the company made to transition towards electrification, and HMG staff would have to be transitioned away from ZEV and back to ICE development. [EPA-HQ-OAR-2022-0829-0554, p. 2]

The Tier 4 regulations would also require an excessive investment in new facilities and equipment. Specifically, for just the proposed 0.5mg particulate matter (PM) requirement, HMG would need to invest in Cold FTP and PM measurable equipment and facilities. This large investment in technology for ICE vehicles would be an additional delay in our desired ZEV transformation and would likely be unavailable in time to support MY 2027 vehicle design timing. [EPA-HQ-OAR-2022-0829-0554, p. 2]

As previously noted, the Proposed Rule provides a woefully inadequate amount of lead-time to develop, prepare for, and secure the needed equipment, plus the construction and operation of new facilities to be compliant with the proposed regulations. [EPA-HQ-OAR-2022-0829-0554, p. 2]

HMG believe' the Proposed Rule's criteria pollutant standards for particulate matter (PM) of 0.5 mg/mi across FTP, 20F and US06 are technically infeasible and financially impracticable [EPA-HQ-OAR-2022-0829-0554, p. 4]

The EPA proposed a PM standard of0.5 mg/mi for LDV and MDV that must be met across three test cycles (-7°C FTP, 25°C FTP, US06), a requirement for PM certification tests at the test group level, and a requirement that every in-use vehicle program (IUVP) test vehicle is tested for PM. The 0.5 mg/mi standard is a per-vehicle cap, not a fleet average. [EPA-HQ-OAR-2022-0829-0554, p.'4]

HMG opposes EPA's proposed PM standard for LDVs and MDVs as technically infeasible and financially'impracticable. HMG's positi'n aligns with AFAl's recommendation that EPA instead adopt ACC II PM standards. HMG also recommends eliminating the proposed Cold FTP PM standards. [EPA-HQ-OAR-2022-0829-0554, p. 4]

Organization: Illinois Corn Growers Association

In the current rulemaking, there is only one technology that could achieve the standards in the current rulemaking: electric vehicles. EPA estimates that it will be necessary for automakers to electrify over half of the light and medium duty vehicles they produce and sell by the 2032 model year. This is less than nine years from now. [EPA-HQ-OAR-2022-0829-0756, p. 1]

Moreover, successful electrification of the transportation sector involves sweeping changes in other sectors, such as power generation, energy distribution and the extraction of rare materials essential to maki904loombergthing from bateries to computer chips. There is no guarantee these changes will be in place by 2032. [EPA-HQ-OAR-2022-0829-0756, p. 1]

The standards being proposed in the current rulemaking are at least as difficult to achieve as those promulgated by the U.S. Environmental Protection Agency (EPA) for criteria pollutants for the 1975 model year. Meeting those standards required the adoption of catalytic converters, unleaded gasoline detuned engines and ultimately on-board computer control. [EPA-HQ-OAR-2022-0829-0756, p. 2]

Today, EPA is proposing even more stringent standards for criteria pollutants and Carbon Dioxide (CO2), the most significant of the greenhouse gases that are altering the global climate. It is estimated that the rise in CO2 levels since the 1950's has largely been the result of the burning of fossil fuels such as gasoline. [EPA-HQ-OAR-2022-0829-0756, p. 2]

[See original attachment for table titled "Table 1. Fuel Consumption Impact Due to Proposed Standards"] [EPA-HQ-OAR-2022-0829-0756, p. 2]

Table 1 is reproduced from EPA's Draft Regulatory Impact Analysis for the proposed Multi-Pollutant Emissions Standards.1 According to this table, EPA expects the consumption of liquid fuel in the U.S. (primarily gasoline, diesel and biofuels) to drop by 50% and electrical use to increase by 110% as a result of these rules. Clearly this will result in sweeping changes to the transportation system even greater than the emission standards enacted in the 1970's. [EPA-HQ-OAR-2022-0829-0756, p. 2]

1 "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles Draft Regulatory Impact Analysis," EPA-420-D-23-003 April 2023

In justifying the technological feasibility of the standards, the Technical Support Document3 supporting the rulemaking listed 34 technologies automakers could potentially use to comply with the standards. [EPA-HQ-OAR-2022-0829-0756, pp. 4-5]

3 "Draft Joint Technical Support Document: Proposed Rulemaking for 2017-2025 Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards Office of Transportation and Air Quality, U.S. Environmental Protection Agency and National Highway Trafic Safety Administration, U.S. Department of Transportation EPA- 420-D-11-901,November 2011

By contrast, in support of the proposed Multi-Pollutant Emissions Standards, EPA listed only 9 potential technologies that they believe could be employed to meet the proposed standards. As shown on Table 2, page 5, the twelve automakers with the most U.S. sales have already significantly adopted these technologies on the vehicles they are producing today. [EPA-HQ-OAR-2022-0829-0756, pp. 4-5]

For instance:

-9 of the 12 automakers have employed at least one of the technologies on 70% or more of their products sold in the U.S. [EPA-HQ-OAR-2022-0829-0756, pp. 4-5]

-5 of the 12 automakers have employed at least three of the technologies on at least 70% of their products sold in the U.S. [EPA-HQ-OAR-2022-0829-0756, pp. 4-5]

-One manufacturer has employed three of these technologies on over 90% of their products sold in the U.S. [EPA-HQ-OAR-2022-0829-0756, pp. 4-5]

It appears that automakers have already widely utilized those technologies that work best with their company's vehicles and powertrains while meeting the needs of their customers. Technologies that have not found favor with multiple manufacturers are likely to have been found to be ineffective, overly expensive or failure prone. [EPA-HQ-OAR-2022-0829-0756, pp. 4-5]

Thus, electric vehicles are the only technology on the list that remains largely unutilized and can deliver the massive reductions in tailpipe emissions required to meet the standards. Given the uncertainty associated with this technology, however, it seems reasonable to make other approaches to meeting the standards available to automakers. [EPA-HQ-OAR-2022-0829-0756, pp. 4-5]

[See original attachment for figure "Table 2. Manufacturers Utilization of Proven Technologies"] [EPA-HQ-OAR-2022-0829-0756, pp. 4-5]

Organization: International Council on Clean Transportation (ICCT)

ICCT recommends the adoption of Alternative 1, the most stringent option EPA presents in its proposal for the light-duty vehicle (LDV) GHG standards. We believe even greater GHG reductions than laid out in Alternative 1 would be feasible because today's technology, policy, and market landscape have primed the market for a rapid transition to cleaner vehicles. Substantial public and private sector investments and a comprehensive package of federal and state level policies make the timing and stringency of the proposed rule achievable, feasible, and cost-effective. At the federal level, the combination of substantial consumer and industry incentives from the $370 billion allocated to climate and clean energy investments through the Inflation Reduction Act of 2022 (IRA) will accelerate the shift to electric vehicles while supporting a domestic supply chain and charging infrastructure buildout. In parallel, the Bipartisan Infrastructure Law complements the IRA by investing $7.5 billion in electric vehicle charging infrastructure, $10 billion in clean transportation, and more than $7 billion in battery components, critical minerals, and materials. [EPA-HQ-OAR-2022-0829-0569, p. 3]

Organization: International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

We encourage the EPA to calibrate the proposed standards to an alternative set of strong standards that better reflect the feasibility of compliance so that the projected adoption of ZEVs is set to feasible levels, increases stringency more gradually, and occurs over a greater period of time. [EPA-HQ-OAR-2022-0829-0614, pp. 1-2]

II. Barriers to Compliance

The EPA's proposed GHG emissions standards for light- and medium-duty vehicles set out an ambitious target for ZEV adoption. While the proposed standards are performance-based and do not mandate the use of a specific technology, compliance all but requires the increased adoption of ZEV technologies. The EPA projects that one potential pathway for the industry to meet the proposed standards would be through the following mix of ZEV and ICE vehicles: [EPA-HQ-OAR-2022-0829-0614, p. 7]

ZEV Share Projection.17

17 Supra note 1 at 29329.

Vehicle Class	MY 2027	MY 2028	MY 2029	MY 2030	MY 2031	MY 2032
Sedans	45%	53%	61%	69%	73%	78%
Crossovers/SUVs	38%	46%	56%	59%	61%	62%
Pickups	11%	23%	37%	45%	55%	68%
Total	36%	45%	55%	60%	63%	67%

[EPA-HQ-OAR-2022-0829-0614, p. 7]

While GHG emissions standards seek to hold manufacturers accountable, many of the factors that make compliance feasible are outside of the control of manufacturers. These factors include consumer demand for EVs (market penetration), reliable charging infrastructure, grid capacity, energy costs, or the costs of key inputs, such as batteries or critical minerals. Together, under the proposed standards, these variables will serve as substantial obstacles to OEM compliance. The UAW supports using regulation to bring new technology to the auto industry, so long as the technology is proven and cost effective; regulatory timelines are feasible; and manufacturers have flexibility to meet stringency requirements through multiple technology paths. Through balanced rules, it is possible to take feasibility into account while still making substantial reductions in GHG emissions and meeting key long-term targets. As the EPA highlights, manufacturers have declared their commitment to long-term emissions reductions and electrification targets, but the pathway to those targets must be feasible and strengthen domestic manufacturing. Therefore, we encourage the EPA to recalibrate the standards so that the projected adoption of ZEVs reflects more feasible alternatives, increases more gradually, and occurs over a greater period of time. [EPA-HQ-OAR-2022-0829-0614, p. 7]

A. ICE Sales Fund EV Transition

The proposed standards must reflect what is feasible for manufacturers to produce and sell to consumers and promote domestic production of cleaner technologies. The continued production of ICE vehicles, particularly light trucks (pickup trucks, sport utility vehicles, vans, and minivans), must be supported by proposed standards. The EV industry is in its infancy. On their own, EVs are not yet profitable.18 Some automakers will lose billions producing EVs and don't expect to reach profitability any time soon.19 Therefore, federal programs and regulation must work in concert to incentivize the production of EVs. While the transition is progressing, the auto industry relies on the continued production of ICE vehicles to reach profitability and fund required investments in electrification. Domestic automakers specifically rely on the sale of light trucks to fund investment into the EV transition. [EPA-HQ-OAR-2022-0829-0614, p. 8]

18 Yeon Baik, Russell Hensley, et. al., "Making electric vehicles profitable", (McKinsey and Company, Mar. 8, 2019), https://www.mckinsey.com/industries/automotive-and-assembly/our-insights/making-electric-vehicles-profitable.

19 Chris Bibey, "Electric Vehicles Are Draining Billions From Profitable ICE Legacy Automakers With Ford Projecting $3 Billion in Losses" (Yahoo Finance, Mar. 30, 2023), https://finance.yahoo.com/news/electric-vehicles-draining-billions-profitable-151050558.html.

Organization: Jaguar Land Rover NA, LLC (JLR)

JLR would like to highlight our concerns over EPA's plans to incorporate PHEVs into their analysis for the final rule. If EPA proceeds with the planned changes to the certified PHEV CO2 value, namely through the adjustment of the utility factor, they must acknowledge the impact this will have on fleet compliance, greatly reducing their contribution to the fleet. As such, the baseline GHG target and projected ZEV share should also be adjusted by an equal amount, to avoid an increase in target stringency by stealth. [EPA-HQ-OAR-2022-0829-0744, pp. 4-5]

We would like to comment on the statement made by EPA that "this is a projection and represents one out of many possible compliance pathways for the industry. The proposed standards are performance-based and do not mandate any specific technology for any manufacturer or any vehicle type." Due to the multitude of changes including those to PHEVs and reduction in credit flexibilities, there is very little choice with regards to technologies that will meet the incredibly challenging standards set. [REDACTED]CBI [EPA-HQ-OAR-2022-0829-0744, pp. 4-5]

In addition, the goals set out in the E.O. 14037 and Blueprint refer to vehicles sales in 2030 Calendar Year (CY), whereas the ambitious target set by EPA refers to the 2030MY fleet, which will contain a combination of vehicles sold in 2029 and 2030CY, effectively bringing the target forward by six months. [EPA-HQ-OAR-2022-0829-0744, pp. 4-5]

Increased Lead Time

Automakers need to fund their transition to electrification with their sales today. In today's extremely challenging environment, this transition is being impacted in real terms. To account for this, whilst JLR strongly supports the goals of EPA, the early years of the proposed regulation represent a considerable challenge, particularly for smaller OEMs, and should be tempered to allow for automakers to catch up following the recent stresses on industry. [EPA-HQ-OAR-2022-0829-0744, pp. 5-7]

JLR is very familiar with the challenge to traditional ICE manufacturers of transitioning to zero emission vehicles. We launched the first all-electric SUV by a luxury manufacturer, the Jaguar I-PACE, in 2018. Since its debut, it has won more than 90 global awards, including World Car of the Year Award 2019. Despite this, sales peaked at only 2.1% of the JLR fleet in 2019MY in the US. [REDACTED]CBI This is our starting point today. [EPA-HQ-OAR-2022-0829-0744, pp. 5-7]

We're taking our lessons from the Jaguar I-PACE as we radically redesign and launch our future fleet. Jaguar Land Rover is transforming into a sustainability-rich, electric-first business; however, we need the increased lead time to successfully execute the transformation. [EPA-HQ-OAR-2022-0829-0744, pp. 5-7]

JLR made difficult decisions to launch a superior "BEV first" architecture. We relinquished two flex platforms (platform prioritizing ICE but could support BEV options), which has had subsequent timing implications. While it was a difficult decision to make, the product strategy decisions related to our Reimagine Strategy will unquestionably accelerate Jaguar Land Rover's electrified future. We support the ambition of EPA but need time to pivot our fleet to achieve the goal. [EPA-HQ-OAR-2022-0829-0744, pp. 5-7]

[REDACTED]CBI Despite this aggressive electrification strategy, the proposed GHG targets will be extremely challenging to meet, especially in the beginning years as we ramp up production of our new BEV models. Our manufacturing facilities need to go through an unprecedented transformation. Our largest facility (~8000 employees) where Velar and F- PACE nameplates are built on a flex ICE/PHEV platform will be repurposed to accommodate the new all-electric Jaguar platform. Our next largest facility (~3500 employees) which currently builds our Evoque and Discovery Sport nameplates on a flex ICE/PHEV platform will become JLR's first all-electric manufacturing facility for our EMA platform. Changes to the manufacturing facilities are complex and require time to execute while old products are still being produced. [EPA-HQ-OAR-2022-0829-0744, pp. 5-7]

Additionally, with the significant uncertainty around enabling conditions (e.g., infrastructure, consumer acceptance, market readiness and critical mineral supply chains) the transition period will be difficult to navigate. Due to the large number of factors outside of OEMs control, we propose that the agency take inspiration from other global legislation and commit to formal monitoring points every two years similar to the reports featured in Article 14a in the EU 2023/851 CO2 emission regulation7. Such formal monitoring points form regulatory good practice and can examine the progress of the regulation and whether any aspects need revising. The report should also take into account the progress made with factors outside industry and agency control including: [EPA-HQ-OAR-2022-0829-0744, pp. 5-7]

7 REGULATION (EU) 2023/851 amending Regulation (EU) 2019/631 (CO2 emission perf–rmance standards) - Article 14a https://eur-lex.europa.eu/legal-content/EN/TXT/PDF/?uri=CELEX:32023R0851

- EV adoption rates
- Charging infrastructure deployment
- Battery costs (including critical minerals)
- Consumer impact

The reports will provide an objective assessment of the effectiveness of the regulation and a basis for any changes should they be required. [EPA-HQ-OAR-2022-0829-0744, pp. 5-7]

We need less stringent targets in the early years and then, based on our plan, we expect to achieve the more ambitious targets in the outer years which will allow us to meet EPA's 2032MY target. The front-loaded stringency in the NPRM, drives tough targets before 2030MY and could divert investment away from this journey. This could drive us to accrue large liabilities for 2024 and 2025MY as we begin to transition our fleet. [EPA-HQ-OAR-2022-0829-0744, pp. 5-7]

The difficulty in the beginning of the regulation is compounded by the extremely high step change between 2026 and 2027MY standards (when adjusted to reflect the proposed reduction in allowable AC and off-cycle credits.) Due to the changes to the footprint curves, light truck standards increase at almost double the rate of passenger car (21% vs 12%). This particularly impacts JLR as an OEM with a high percentage of off-cycle technologies (OCT) and air conditioning (A/C) featured in our vehicles, as noted in the 2022 EPA Automotive Trends Report8. Reaching the 10 g/mile OCT cap and with the highest reported A/C credit (24.2 g/mile), equivalent to an 8% reduction from tailpipe emissions for A/C credits alone in 2021. [EPA-HQ-OAR-2022-0829-0744, pp. 5-7]

8 The 2022 EPA Automo–ive Trends Report - https://www.epa.gov/system/files/documents/2022-12/420s22001.pdf

[See original fo– graph, "Figure 2 - See appendix A1 for more details"] [EPA-HQ-OAR-2022-0829-0744, pp. 5-7]

Although there is significant uncertainty in how the ZEV market will develop in this regulatory time period, JLR supports EPA's goals. We are committed to investing in reducing our greenhouse gas footprint and making a positive societal impact on our journey to net zero carbon emissions. [EPA-HQ-OAR-2022-0829-0744, p. 11]

The past few difficult trading years have left a tangible impact on this journey. We had to make business decisions in light of this reduced cashflow, which means we need more time to transition. The end goal is the same. We ask for the agency's support in allowing us to meet it, by giving us enough time to successfully transition our fleet to an electric future. [EPA-HQ-OAR-2022-0829-0744, p. 11]

Organization: Job Creators Network Foundation (JCNF)

EPA's Proposed Rule Is Not Feasible [EPA-HQ-OAR-2022-0829-0709, pp. 2-3]

In addition to being illegal, the proposal is not technically feasible. Daniel Yergi', one of the world's leading energy experts, highlights how electric cars have 2.5 times more copper in them than regular vehicles.6 He cites the Internat'onal Monetary Fund's warning that such environme"tal policies will "spur unprecedented demand for some of the m"st crucial metals," with pr"ce increases that "could derail or delay the energy transition itself."7 [EPA-HQ-OAR-2022-0829-0709, pp. 2-3]

6 Daniel Yergin, "'Net Zero' Will Mean a Mining Boom," (Link: https://www.wsj.com/articles/net-zero-will-mean-a-mining-boom-electric-cars-minerals-oil-fossil-fuels-climate-change-policy-cb8d5137) Wall Street Journal (April 12, 2023).

7 Lukas Boer, Andrea Pescatori, Martin Stuermer, Nico Valckx, "Soaring Metal Prices May Delay Energy Transition," (Link: https://www.imf.org/en/Blogs/Articles/2021/11/10/soaring-metal-prices-may-delay-energy-transition) IMF Blog (Nov. 10,2021).

Organization: Kentucky Office of the Attorney General et al.

As discussed below, the automotive supply chain is nowhere close to ready when it comes to meeting the production demands that the Proposed Rule forces through it. And even if it were, the scope and speed of the Proposed Rule requires automakers to devote every last resource they have to keeping up with that pace—including precious resources they would have spent on the development of more innovative EV technology than we have right now. This sacrifice of innovation at the altar of speed will lead to disastrous consequences down the line as the demand grows for later generations of EVs and their component parts. [EPA-HQ-OAR-2022-0829-0649, p. 4]

Start with what the Proposed Rule aims to do: restructure the American car industry around EVs in under a decade. Specifically, the Agency is pressing to grow today's 8.4% share of light-duty new EV sales to 67% by 2032. 88 Fed. Reg. at 29,189, 29,329. That allows just eight years from when the proposal will likely be finalized to achieve an eight-fold increase. How? By altering emission assessments and imposing the harshest emissions standards the Agency has ever promulgated—on the heels of what are already the "most stringent GHG standards . . . to date" for 2023–2026 model year light-Duty vehicles. Id. at 29,227 (citing 86 Fed. Reg. at 74,434). [EPA-HQ-OAR-2022-0829-0649, p. 6]

EPA tries to disclaim how extreme this proposal is by saying that the Agency is responding to "[r]ecent trends and developments in emissions control technology, including vehicle electrification and other advanced vehicle technologies," that make the "stringent emissions standards . . . feasible at reasonable cost." 88 Fed. Reg. at 29,186. But it also admits, as it must, that the Proposed Rule will forcibly accelerate market transformations—or in the Agency's more euphemistic terms, require "an increasing pace" across more of manufacturers' "vehicle fleets," id. at 29,341. Indeed, far from being "technologically neutral," the proposal's "dramatic reductions in emissions" means that the "only automaker that would meet" them right now is Tesla, which produces only EVs. See Riley Beggin, Proposed Emission Rules That Favor EVs Face Political Blowback, Government Technology (May 23, 2023), https://bit.ly/3qIesCH. [EPA-HQ-OAR-2022-0829-0649, p. 6]

Organization: Kia Corporation

EPA's proposed standards, requiring 60 percent of new vehicle sales be EVs by 2030 and 67 percent by 2032, are unrealistic in the proposed timeframe because of the vast number of market risks, consumer EV demand uncertainty, and multiple external challenges. Neither the current trajectory of consumer adoption of EVs, nor existing levels of complementary government policies are robust enough to meet the target in the timeframe outlined. EPA discusses "uncertainties" several times in the proposal, but the proposed standards do not reflect the uncertainties industry will face in transitioning our powertrain to electrification. [EPA-HQ-OAR-2022-0829-0555, p. 2]

Kia is committed to speeding the transition by investing billions in popularizing EVs to all consumers up and down the market. We urge the agency to work with stakeholders on a reasonable path forward that will result in a balanced set of standards that are achievable for automakers, workers, and consumers. A rule that is set at a more reasonable pace will ensure this transition to EVs is successful for the country. [EPA-HQ-OAR-2022-0829-0555, p. 2]

EPA's Proposed GHG Standards Are Unrealistic in the Timeframe Proposed

EPA requests comment on its proposed light-duty GHG standards that would require a 60 percent EV penetration by 2030 and 67 percent EV penetration by 2032. Alternative 3 achieves the same stringency as the proposed standards in MY2032 but provides for a more consistent rate of stringency inc–ease for MYs 2027 - 2031.7 Importantly, EPA asserts that standards substantially more stringent than Alternative 1, which is more stringent than the proposal, would be inappropriate "because of the uncertainties concerning the cost and feasibility."8 [EPA-HQ-OAR-2022-0829-0555, pp. 4-5]

7 88 Fed. Reg. 29,201.

8 88 Fed. Reg. 29,201.

Kia continues to make dramatic investments in electrification and shares EPA's goal of fully transitioning to electrification. The EPA-proposed GHG standards in the timeframe proposed, however, are not realistic given the vast uncertainties in the market. While Kia is optimistic that we can get to 60 percent electric vehicle penetration in the future, the proposed time frame of 2030 is not realistic. This timeframe is too fast given the uncertainties around EV affordability, EV charging infrastructure, and EV battery critical mineral supplies. [EPA-HQ-OAR-2022-0829-0555, pp. 4-5]

The proposed rule of requiring 60 percent BEVs of new vehicles sold in 2030 has gone well beyond President Biden's 2021 EO14037 goal of 50 percent ZEVs. As it stands today, the national BEV percentage stands at 8.6 percent market share.9 EPA is assuming aggressive penetration for EV adoption, a new technology that has not been fully embraced by consumers yet, more than any new automotive technology to date. Electric powertrain technology is not seamless to the customer like all other recent technologies have been. Additionally, the new EV powertrain technology can be upwards to +$20,000 more than competing ICE models. Affordability, EV charging infrastructure, and EV battery critical minerals are significant challenges that need to be addressed for the widespread adoption of EVs. [EPA-HQ-OAR-2022-0829-0555, pp. 4-5]

9 https://www.autosinnovate.org/resources/electric-vehicle-sales-dashboard

Because of all these factors, Kia strongly recommends that EPA reevaluates the GHG standards proposed. Kia recommends EPA align standards more closely with President Biden's 2021 goal set in the EO14037. Kia can support a target of 40-50 percent ZEVs – BEVs, PHEVs, and FCEVs by 2030 with continued increases through 2032 coupled with the right supporting policies. Even this 40-50 percent ZEVs penetration goal by 2030 was and still is an extremely challenging goal. A goal that will hinge on whether there is (1) sustained and supportive policies from the government supporting a successful EV market; (2) consumers continue to demand this new technology; and, (3) other industries outside the automotive industry make supporting market investments. [EPA-HQ-OAR-2022-0829-0555, pp. 4-5]

EPA Underestimates Market and External Challenges

EPA's proposed rule highlights the very complex challenges that lie ahead for the EV market. There are an enormous number of factors that are outside the control of automakers including manufacturing capacity, battery production, charging infrastructure, critical mineral supply, and consumer acceptance. A successful transition in the timeframe proposed will require massive changes in commitments from all sectors of the economy: vehicle suppliers, labor, utilities, charging infrastructure, home builders, mining, and mineral processing. Consumer behavior and acceptance also needs to significantly change. [EPA-HQ-OAR-2022-0829-0555, p. 6]

EPA's proposal requires automakers to sell EVs but does not propose any requirements to ensure adequate charging infrastructure to homes, highways, or businesses, or mandate utilities to have adequate capacity or provide reasonably priced high-power charging, or mandate easily accessible and affordable battery critical minerals for EV batteries. Government policies need to start today to ensure there are enough critical minerals for batteries and high-power charging. Unfortunately, there is not yet a roadmap to developing these and other essential pieces to the transition. [EPA-HQ-OAR-2022-0829-0555, p. 6]

All of the above market challenges will need to have complementary policies supporting all of the sectors outside the vehicle industry including utilities, mining, charging companies and will require them to meet targets too. It is critical that EPA take these factors into consideration when setting standards. [EPA-HQ-OAR-2022-0829-0555, p. 6]

EPA's Analysis of Supporting Government Policies is Extremely Optimistic

EPA over-estimates the utility of the Infrastructure Investment and Jobs Act (IIJA) and Inflation Reduction Act (IRA) that have started but are nowhere near complete. And we certainly cannot tell yet if these programs will be successful. Kia is also hopeful that the IIJA and IRA clean vehicle tax credit can help expedite the sales of EVs, but EPA justifies its proposal with overly optimistic forecasts about these programs. [EPA-HQ-OAR-2022-0829-0555, p. 6]

As an example, EPA forecasts that the average IRA clean vehicle credit amount (30D) will be $6000 across all EV purchases by 2032.11 Currently, there are 91 ZEVs available to purchase but only ten vehicles qualified for the tax credits in February 2023. The Internal Revenue Service (IRS) proposed rules released in March 2023 further decreased the vehicles eligible and will continue to decrease the vehicles eligible, at least in the short-term. [EPA-HQ-OAR-2022-0829-0555, p. 6]

11 88 Fed. Reg. 29,201.

Organization: Lucid Group, Inc.

Lucid agrees with EPA's finding from its technology feasibility assessment—the increasing availability of zero and near-zero tailpipe emissions technologies not only makes it ripe, but critical, to strengthen emissions standards. EV sales in the U.S. are increasing at a rapid pace. When coupled with the historic level of investment from the Biden Administration through the Bipartisan Infrastructure Law, CHIPS and Science Act, and Inflation Reduction Act, this moment is opportune to complement those incentives with cleaner tailpipe standards. Industry is currently demonstrating the feasibility of a zero-emission transition. Lucid is a modern-day example in its ability to develop the most advanced EV technology with a fraction of the capital available to larger automakers. Industry capital can similarly be redeployed to zero- emission vehicles thus transforming an original equipment manufacturers (OEM) fleet. [EPA-HQ-OAR-2022-0829-0664, pp. 2-3]

The Zero Emission Transportation Association (ZETA) and its members have found that electricity providers and grid-readiness will keep pace with the transition to zero-emission vehicles. In 2021, the U.S. fleet of electric vehicles used 6.1 terawatt hours (TWhs) of electricity, accounting for 0.15% of the total national energy generation that year.2, 3 It's estimated that an additional 15-27 TWh of annual new power generation will be needed to service EVs and related technologies. In the past, nearly 100 TWh have been added in a single year, demonstrating that such an increase is accomplishable.4 [EPA-HQ-OAR-2022-0829-0664, pp. 2-3]

2 "Assessment of Light-Duty Plug-in Electric Vehicles in the United States, 2010–2021," Argonne National Lab, November 2022, available at https://publications.anl.gov/anlpubs/2022/11/178584.pdf.

3 "Monthly Energy Review May 2023," EIA, available at https://www.eia.gov/totalenergy/data/month/pdf/sec7_3.pdf.

Transmission of the energy generated is another key component, and one that this Administration has begun to address. This year, the Administration published its plan to decrease permitting timelines, including those for new transmission projects.5 Additionally, the U.S. Department of Energy proposed a rule on designating National Interest Electric Transmission Corridors.6 The Federal government is demonstrating its intent to bolster grid resilience, which in part will ensure electricity demand is met. [EPA-HQ-OAR-2022-09-0664, pp. 2-3]

6 Notice of Intent and Request for Information: Designation of National Interest Electric Transmission Corridors, 88 FR 30956 (May 15, 2023).

Organization: Mass Comment Campaign sponsoring organization unknown'(513 signatures)

I'm writing to express my concern about the new proposed EPA emissions rules on light and medium-duty vehicles and heavy-d'ty trucks. The EPA's recent proposals to effectively require up to 60% heavy-duty and 70% light and medium-duty vehicles s“les by 2032 t” be "zero emission" is very concerning to me. Among other defects, the proposals fail to consider lifecycle emissions and overlooks the potential for internal combustion vehicles and liquid fuels, such as biofuels, to continue improving and reducing carbon intensity. [EPA-HQ-OAR-2022-0829-1717]

Specifically, I have the following concerns with the proposals:

• Limits consumer choice and increases cost: The proposals may limit choices and increase costs for consumers, including those in economically disadvantaged groups. Many people can not afford to buy new cars already let alone top end model EVs which also require modifications to home to enable charging. [EPA-HQ-OAR-2022-0829-1717]

• Potentially affects U.S. energy security and use of biofuels: These proposals do not address the potential for biofuel to be used to create energy security benefits. [EPA-HQ-OAR-2022-0829-1717]

• Potentially provides a too optimistic forecast for EV Sales: Projected EV sales rates may be optimistic and may overstate the benefits of the proposals. [EPA-HQ-OAR-2022-0829-1717]

• The lack of infrastructure for EVs: Increased sales of EVs may rely on optimistic forecasts of increased electricity generation and charging infrastructure. [EPA-HQ-OAR-2022-0829-1717]

• The lack of critical materials: There is concern about the supply and availability of critical minerals and supply chains for battery manufacturing. The increased environmental impact of mineral mining has not been considered. Lanscape impacts to large scale surface mining operations far outweigh impacts of oil and gas drilling. [EPA-HQ-OAR-2022-0829-1717]

• Provides no incentives for existing vehicles to reduce greenhouse gas (GHG) emissions: This is a missed opportunity to accelerate GHG reduction in the early years of the program. [EPA-HQ-OAR-2022-0829-1717]

• Fails to consider electric vehicles are not zero emissions: The proposals are focused on tailpipe GHG emissions rather than life cycle emissions. Therefore, upstream GHG emissions for fuel and vehicle manufacturing and electricity generation are not included in the analysis. Maintaining an existing vehicle consumes far less energy and thus generates less overall emissions than the emissions generated by manufacturing new fleets of vehicles. [EPA-HQ-OAR-2022-0829-1717]

The EPA is not acknowledging how these proposals would trade our hard-earned U.S. energy security for mineral dependence on China. It is not in our strategic interest to ban cars that run on fuels extracted, refined, and grown in the United States, especially considering all the work that is being done here to lower the carbon intensity of those fuels. To do so would leave us more dependent on and beholden'to China and I don't think the EPA is the entity that should be making such critical economic and geopolitical decisions. [EPA-HQ-OAR-2022-0829-1717]

The EPA's proposals take the misguided position that only emissions from the vehicle tailpipes are worth counting. In doing so, the proposals do not consider internal combustion engine vehicles as a factor in lowering carbon right now using existing technologies. Consumers should have the greatest number of choices to meet their needs and budget. The final standards need to take a tech and fuel neutral approach. [EPA-HQ-OAR-2022-0829-1717]

Therefore, I ask that you do not support the new proposed EPA emissions rules on light and medium-duty vehicles and heavy-duty trucks. [EPA-HQ-OAR-2022-0829-1717]

Organization: Mayor Becky Daggett, City of Flagstaff, Arizona et al.

Technological advances and cost savings

> EPA should ensure the LDV and HDV standards reflect major advancements in zero-emission technologies. Globally, there are more than 839 different models of zero-emission vans, trucks and buses commercially available with new models being introduced at an unprecedented rate.1 [EPA-HQ-OAR-2022-//globaldrivetozero.org/tools/zeti-data-explorer (Accessed March 15, 2023).

Timelines

The sooner that long-term LDV and HDV standards are in place, the sooner that vehicle manufacturers and related companies will have the regulatory certainty needed to plan their decision-making, product development, and rollout. We urge the EPA to finalize both standards by the end of 2023. [EPA-HQ-OAR-2022-0829-0732, p. 1]

Organization: Mazda North American Operations

In addition, the standards immediately increase dramatically in stringency beginning in 27MY, with a resulting 36% BEV requirement. These standards are particularly accelerated for vehicles classified as light trucks, since the gap between passenger cars and light trucks is reduced. Mazda believes it is very important that the ramp-up and the light truck gap reduction should be slower in the early years of the program, as the industry, consumers, and suppliers adapt to th’s new reali“y. EPA's prop”sed "Alternative 3" is a step in the right direction, but the linear reduction in standards is insufficient to alleviate the harsh early years when the long-term targets are so aggressive. [EPA-HQ-OAR-2022-0829-0595, pp. 2-3]

Summary

Mazda is proud of its heritage and contributions to personal mobility, and we celebrated our 100th anniversary in 2020. Mazda has also long been an engineering leader known for innovative powertrains like the rotary engine and Skyactiv technology. [EPA-HQ-OAR-2022-0829-0595, pp. ’-4]

We look at EPA's NPRM and its preferred option through the lens of a company that is already working towards an ele’trified future. It's not a matter of if this transformation will happen, but when and how. Mazda, like the rest of the industry, faces many challenges: [EPA-HQ-OAR-2022-0829-0595, pp. 3-4]

- Will charging infrastructure be sufficient?

- Can the electric grid handle the increased demands?

- How will EV incentives on the federal and state level impact this shift?

- Will suppliers be able to develop and produce components like batteries (that currently require critical minerals, many from China) quickly enough and in enough volume?

- How might future laws or regulations in trade and re-shoring impact our ability to meet goals?

- Are consumers ready and willing“to move away f”om "tried and true" internal combustion engines in numbers sufficient to meet these goals?

- Can OEMs remain sufficiently profitable to fuel the transition to EVs? [EPA-HQ-OAR-2022-0829-0595, pp. 3-4]

Mazda strongly requests that EPA take these considerations into account and make necessary adjustments to the proposed rule as it works towards a Final Rule. We feel the Final Rule should have more realistic targets and associated ramp ups, include PH’Vs, and adopt CARB's current LEV IV for criteria emissions. [EPA-HQ-OAR-2022-0829-0595, pp. 3-4]

Organization: Mclaren Automotive, McLaren Group

Given the challenges we have highlighted in moving towards greater electrification for SVMs like McLaren, EPA is effectively relying on credit trading flexibility as the means by which SVMs will maintain compliance with GHG standards. We believe this is inappropriate for several reasons and demonstrates that the proposed alternative standards do not meet the requirements of CAA§ 202“a) that standards "take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance w”thin such a period". First, we believe it is inappropriate to set a standard so stringent as to effectively require a manufacturer to entirely rely on another manufacturer to maintain compliance. Additionally, there is an inherent risk that even if a credit-generating manufacturer is willing to sell credits, the credits may be purchased by other parties before SVMs can access them. Having to purchase credits to comply with the proposed GHG standard would also divert resources away from electrification challenges. [EPA-HQ-OAR-2022-0829-0748, p. 3]

As stated, allowing for certainty and time to adjust to changes remains important for SVM like McLaren. An SVM standard also must take into account that engines and vehicles already developed will have to company with a standard in MY2024 which is currently unknown. Allowing for early years less stringent targets is essential given that design decisions which have already been made. It is also important for GHG policy to be fair and equitable. The EPA SVM proposal would require over 50% BEV mix in MY2026, based on McLaren analysis, far higher than Primary Standards requirements and effectively impossible given the lack of technology available to electrify high performance supercars. [EPA-HQ-OAR-2022-0829-0748, p. 3]

Organization: MECA Clean Mobility

EPA should try to finalize this proposed rule by the end of 2023 in order to provide lead time that would enable implementation of the medium-duty vehicle requirements prior to MY 2030. [EPA-HQ-OAR-2022-0829-0564, p. 4]

MECA appreciates the need for EPA to set standards respective to the lead time requirements stipulated in section 202(a)(3)(C) of the Clean Air Act. For this reason, the NPRM proposes new requirements for vehicles with GVWR > 6,000 lbs. to begin with MY 2030. We support EPA's inclusion of multiple voluntary early compliance pathways for vehicles with GVWR > 6,000 lbs offered in the proposed rule. Our analysis concludes that technologies are commercially available to enable phase-in of proposed medium-duty vehicle criteria pollutant standards starting with MY 2028, which EPA recognized in the proposal by allowing for alternative early compliance pathways. Therefore, we request EPA work to finalize this proposed rule by the end of 2023. We believe this will provide the necessary lead time to begin the required phase-in of criteria pollutant standards for vehicles with GVWR > 6,000 lbs starting with MY 2028. [EPA-HQ-OAR-2022-0829-0564, p. 4]

The previous light-duty GHG and CAFE regulations covering MY 2017-2025 included provisions for mid-term evaluation or review. These regulations were designed to set emission standards further into the future than this regulation proposes. In addition, significant uncertainty existed during the handling of the previous mid-term review. For these reasons, MECA does not support a similar mid-term evaluation provision in this proposal nor compliance "off-ramps" that would be triggered by results of a review. [EPA-HQ-OAR-2022-0829-0564, p. 4]

MECA members are commercializing components for electric and hydrogen fuel cell vehicles. This includes battery materials for the manufacture of both cathode and anodes utilizing unique macrostructure and composite formulations to improve efficiency and energy density. Electric component manufacturers are using state of the art transistor materials in their motors and power electronics that operate at higher voltages and temperatures thus requiring simpler cooling strategies. These next generation component designs reduce switching losses and improve electric efficiency of the system architecture in electric powertrains. To facilitate integration, component suppliers are integrating the motor, inverter and transmission into electric drive units to simplify the thermal management of the electric components and ease integration into vehicles. [EPA-HQ-OAR-2022-0829-0564, pp. 31-32]

As demonstrated for combustion vehicles over the past 50 years, the market can not always be relied upon to drive innovation towards conservation of critical resources and energy security by improving the efficiency of vehicles. This has led agencies to set fuel efficiency and GHG standards. There is a significant disparity in the electric efficiency of similarly sized passenger electric vehicles today, as shown in Table 4. [See original comment for Table 4. Comparison of Energy Efficiency of BEV and PHEV Models] We urge EPA to begin compiling electric efficiency information and consider setting a minimum efficiency or energy consumption by weight class in a future rulemaking. [EPA-HQ-OAR-2022-0829-0564, pp. 31-32]

Organization: MEMA, The Vehicle Suppliers Associated

The success of our industry is interwoven with the success of this proposal and the ability of the government to work with industry and other stakeholders to meet significant challenges. Therefore, the rule must address: [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

• The need for regulatory certainty. The final rule must contain an effective mix of feasible, demonstrated technology along with emerging technology, leaving options to improve emissions ’eductions in today's advanced propulsion designs. This will foster innovation in a coordinated direction, aligned with U.S. policy, but not mandate application of a narrowly defined technology path to make a positive im’act on the country's urgent environmental goals. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- The influence of –ther technologies - including internal combustion engines fueled by hydrogen and other renewable ca–bon-neutral fuels - which can impact measurable environmental improvements at scale technologies can provide immediate improvement to the environment. This is important not only for environmental improvements but for environmental justice in providing cleaner consumer vehicles immediately to communities living and working close to busy streets, highways, and other transportation networks. Inclusion of all technologies that can decarbonize the transportation sector will foster the necessary growth in manufacturing capacity, vocational performance, infrastructure improvements, and consumer acceptance. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Technology Neutrality and BEV Emissions. EPA should ensure that battery electric vehicles (BEV) are included in metrics for vehicle-to-vehicle comparison by assigning a metric that captures the pollutant emissions related to BEV operation, aligned with national electricity generation figures. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Chall’nges in our nation's infrastructure and power grid. MEMA appreciates the significant public investments being made to support clean transportation infrastructure. As these new investments in highways and main corridors are deployed, federal and state incentives are needed to further expand the EV charging and refueling infrastructure in areas that connect these major thoroughfares. Urban industrial centers will need focused buildout while rural areas will need thoughtful rollouts to achieve an effective EV charging infrastructure. These buildouts must include Direct Current Fast Charge (DCFC) and vehicle-to-grid (V2G) bidirectional charging. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Supply chain challenges. The proposed rule assumes that all materials advanced vehicles, which are not available today in the quantities needed to support the massive growth in vehicle construction, will become available within sufficient time. This places a significant and unnecessary risk on manufacturers and suppliers. Furthermore, once a company has converted production to new technology lines, that company cannot easily pivot its facilities and workforce back to the previous technology if EPA projections are not realized by the mid-to-late-2020s. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Workforce challenges. A significant increase in skilled workers will be needed to support the implementation of this rule and long-term success thereof [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Extended warranty. The necessity to clearly define the applicability of the extended warranty and the need to provide repair access to service these new vehicles. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

MEMA members are working to accelerate the performance and availability of clean-operating vehicle technologies and are directly contributing to their realization. Besides battery electric options, effective low- and zero-carbon technologies for future and current in-use vehicles also exist and can readily be put to use to reduce nationwide emissions and help EPA meet its climate goals. The success of this rule depends on greater inclusion of all available emissions reduction technologies, significant investment in infrastructure, careful understanding and investment in the domestic and global supply chain and ensured repair access to serve the improved and enhanced domestic vehicle fleet. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

Detailed MEMA Comments and Concerns on our Shared Challenges [EPA-HQ-OAR-2022-0829-0644, p. 4]

The Final Rule Must Reflect Regulatory Certainty Paired with Technology Neutrality [EPA-HQ-OAR-2022-0829-0644, p. 4]

EPA must provide sufficient regulatory certainty to manufacturers and consumers to ensure the most favorable outcome of this ambitious market transformation. The final rule must contain an effective mix of feasible, demonstrable technology along with emerging technology, and leverage all available options to improve emissions ’eductions in today's advanced propulsion designs. At the same time, the final rule must encourage innovation in clean transportation, including more advanced low- and zero-emissions technology. Conversely, a 100% ZEV mandate is not realistic, would stifle innovation and would disallow technologies that could address the urgent need to decarbonize applications for LD and MD vehicles. [EPA-HQ-OAR-2022-0829-0644, p. 4]

Technology Neutrality Pairs with Regulatory Certainty

The proposed rule disproportionally favors battery electric propulsion, which in turn discourages any further advancements for internal combustion technology, including carbon-neutral renewable fuels. Emerging innovations and recent technologies offer significant reduction in emissions from ICE vehicles, in both future and current fleets. [EPA-HQ-OAR-2022-0829-0644, pp. 5-6]

Technology-forcing regulations that foster innovation aligned with policy, rather than regulations that mandate a narrowly defined technology path, will lead to a more positive national outcome. [EPA-HQ-OAR-2022-0829-0644, pp. 5-6]

MEMA recognizes that the proposal attempts a performance-based standard, and the agency makes forecasts that estimate a variety of technology combinations in future fleets. By accepting the potential for technologies other than battery electric and hydrogen fuel cell, EPA can make a more immediate, widespread, positive impact on nationwide emissions reductions. Therefore, EPA must incent the development and deployment of advanced technology options to include advanced internal combustion (ICE) technologies, renewable fuels, and post-combustion CO2 capture (known as mobile carbon capture). These incentives will assist in accelerating the necessary infrastructure improvements needed to support advanced technology vehicles. [EPA-HQ-OAR-2022-0829-0644, pp. 5-6]

Organization: Mercedes-Benz AG

Now more than ever, it is critical that EPA strike the right balance between regulatory objectives, supportive policies, and feasibility. As Mercedes-Benz assesses global trends and our company’s commitments, we believe that, even with funding under the Bipartisan Infrastructure Law and the Inflation Reduction Act, there remain many challenges and unknowns regarding the development of the U.S. EV market – charging infrastructure, the supply chain, battery critical minerals availability, electric grid capacity, customer acceptance, etc. It is thus uncertain how

EV sales will keep pace with the agency's NPRM targets. [EPA-HQ-OAR-2022-0829-0623, p. 2]

We would like to emphasize the importance of setting feasible and achievable standards for Class 2b and Class 3 vehicles. Similar to light-duty vehicles ("LDVs"), there remain many uncertainties in customer uptake and acceptance of medium-duty electric vehicles. Moreover, electrification in this segment lags that of light-duty, as production of these vehicles is only just beginning. As a result, there are currently limited options available to consumers, and medium-duty charging infrastructure requires additional attention, funding, and considerations appropriate for medium-duty vehicle usage. Medium-duty vans are being increasingly swept into pick-up truck focused regulations, as well as EPA's intent to treat medium-duty more like light-duty. Yet, medium-duty vans remain fundamentally different than either pick-ups or light-duty, and therefore warrant specific consideration of their technologies, customer uses, and corresponding regulatory requirements. [EPA-HQ-OAR-2022-0829-0623, pp. 2-3]

Organization: Minnesota Corn Growers Association (MCGA)

The proposed EPA standards for 2027 and later set very aggressive goals for reducing GHG and criteria emissions. Achieving these goals will require dramatic changes not only in vehicle design, but in the entire automotive supply chain. While the U.S. market share of BEVs will continue to expand, establishing regulations where success is solely contingent upon an unattainable tenfold increase in the production and sales of BEVs over the next eight years represents an avoidable mistake. The proposed rule would require huge investments and rapid growth in many industries, including the mining and processing of key minerals, the generation and distribution of electricity, and the recharging of electric vehicles. [EPA-HQ-OAR-2022-0829-0612, p. 3]

The proposed rulemaking assumes that BEVs will be the dominant technology for future emissions reductions. But relying on a single technology is a risky strategy; many factors could interfere including the supply and/or cost of critical minerals, lack of BEV recharging infrastructure, slow ramp-up of wind and solar power, poor customer acceptance of BEVs in some market segments, etc. EPA estimates that 67% of U.S. vehicles sales will be BEVs in 2032, but most major automakers predict much lower BEV sales, and the world's largest automaker predicts only 20% in 2030. For comparison, MIT predicts9 that China will achieve only 40% in 2030 despite a head start and extremely strong government interventions. EPA should not base mandatory emissions standards on unrealistic predictions of BEV sales. [EPA-HQ-OAR-2022-0829-0612, pp. 5-6]

9 https://news.mit.edu/2021/chinas-transition-electric-vehicles-0429.

Organization: Minnesota Pollution Control Agency (MPCA)

MPCA believes the proposed standards are technologically feasible and necessary and urges EPA to adopt them. [EPA-HQ-OAR-2022-0829-0557, p. 5]

Organization: Missouri Corn Growers Association (MCGA)

Monumental challenges in implementing this rule.

Notwithstanding the vast challenges to everyday Americans, the aggressiveness of EPA's proposal raises immediate doubt about whether such targets are feasible within the required timeframe. The rule gives a wholly unrealistic and false impression the U.S. has a robust and reliable public EV charging infrastructure ready to accommodate the vast number of BEVs. MCGA members driving Missouri's rural roads know this is not the case. In addition, most American families will find BEVs' dismal range, extended charge time, shortage of maintenance technicians, and poor performance under heavy loads and extreme temperatures both frustrating and entirely impractical for everyday personal and business needs. [EPA-HQ-OAR-2022-0829-0578, p. 2]

Organization: National Association of Clean Air Agencies (NACAA)

Feasibility of More Protective Federal Standards for LDV and MDV Emissions of Multiple Pollutants

The evolution of light- and medium-duty zero-emission vehicles (ZEVs) and charging infrastructure is the result of leadership, commitment and innovation on numerous fronts and, by all accounts, this evolution will continue on an upward trajectory further increasing the feasibility, availability and cost competitiveness of ZEV technologies. [EPA-HQ-OAR-2022-0829-0559, pp. 4-5]

Electric vehicle (EV) sales and model availability continue to grow.11 In 2022, one in seven (10 million) light-duty vehicles sold worldwide was an EV.12 More than 800,000 of those sales were in the U.S., representing a 65-percent increase over 2021,13 and the first quarter of 2023 saw nearly 260,000 EV sales in the U.S.14 Cox Automotive has forecast that U.S. EV sales will reach 1 million in 2023.15 Further, a study prepared by ERM reports that, "Based on announcements by major automakers, the number of electrified models available in the U.S. is projected to reach 187 by the end of 2025, with over 58 new models slated to launch in model years 2022-2025."16 [EPA-HQ-OAR-2022-0829-0559, pp. 4-5]

16 Supra note 11, at 36

Most light- and some medium-duty vehicle manufacturers have publicly announced commitments or goals to increase ZEV sales between now and 204017 and demand by commercial fleet owners is on the rise as are their commitments to fleet electrification.18 Meanwhile, vehicle manufacturers are investing heavily in EVs. According to an October 2022 Reuters analysis of public data and projections released by 37 global automobile manufacturers, "The world's top automakers are planning an extraordinary level of spending to develop and produce millions of electric vehicles, along with the batteries and raw materials to support that production, over the next eight years. Reuters calculates that global automakers expect to spend nearly $1.2 trillion through 2030 on EVs, batteries and materials. The number, which has not previously been published, dwarfs previous investment estimates by the industry and is more than twice the previous calculation published just a year ago."19 [EPA-HQ-OAR-2022-0829-0559, pp. 4-5]

17 Id at 38.

18 Id at 41.

19 https://www.reuters.com/graphics/AUTOS-INVESTMENT/ELECTRIC/akpeqgzqypr/

The federal government is demonstrating its deep commitment to accelerating ZEV deployment. The Bipartisan Infrastructure Law (BIL) and the Inflation Reduction Act (IRA) enacted by Congress and signed by President Biden in 2021 and 2022, respectively, infuse unprecedented funding into EV charging infrastructure and tax credits for commercial and personal ZEVs and battery manufacturing. As EPA acknowledges in its proposal, "These measures represent significant Congressional support for investment in expanding the manufacture, sale, and use of zero-emission vehicles by addressing elements critical to the advancement of clean transportation and clean electricity generation in ways that will facilitate and accelerate the development, production and adoption of zero-emission technology during the time frame of the rule."20 Moreover, EPA states, "Congressional passage of the BIL and IRA represent pivotal milestones in the creation of a broad-based infrastructure instrumental to the expansion of clean transportation, including light- and medium-duty zero-emission vehicles, and we have taken these developments into account in our assessment of the feasibility of the proposed standards."21 NACAA notes that given the importance of this federal funding EPA should ensure that it is allocated equitably across the country. [EPA-HQ-OAR-2022-0829-0559, pp. 4-5]

20 Supra note 1, at 29,195

21 Id at 29,196

State leadership is also playing a pivotal role in rapidly ramping up light- and medium-duty ZEV adoption. A number of states have established ambitious GHG emission reduction targets – some economy-wide and others transportation-specific – requiring aggressive reductions by as soon as 2030. States have also chosen to exercise their authority under CAA section 177 and adopt portions of the California Advanced Clean Cars (ACC) Regulation, which requires light-duty car and truck manufacturers to sell increasing percentages of ZEVs. The regulation also includes low-emission vehicle (LEV) standards to reduce criteria pollutant and GHG emissions from new cars and trucks with internal combustion engines. [EPA-HQ-OAR-2022-0829-0559, pp. 4-5]

Seventeen states have adopted the LEV standards and 15 states have adopted the LEV standards and ZEV sales requirements. Additional states have efforts underway regarding LEV and/or ZEV adoption and with each additional adopting state comes a greater share of the national light-duty vehicle market. Last year, California finalized its Advanced Clean Cars II (ACC II) Regulation, requiring manufacturers of passenger cars and light trucks to produce and deliver for sale increasing percentages of ZEVs overtime culminating with 100 percent ZEVs by 2035. Six states have adopted ACC II, six more have announced that they are pursuing adoption and still others are contemplating such action. With each additional adopting state comes a greater share of the national LDV market. [EPA-HQ-OAR-2022-0829-0559, pp. 4-5]

Regarding MDVs, in the summer of 2020, 17 states and the District of Columbia entered into the Multi-State Medium- and Heavy-Duty Zero Emission Vehicle Memorandum of Understanding (MOU), including specific goals and targets, agreeing to collaborate “to foster a self-sustaining market for zero emission medium- and heavy-duty vehicles.”22 In July 2022, this group reaffirmed and strengthened its commitment to the MOU by releasing an Action Plan for accelerating a transition to zero-emission trucks and buses.23 Eight of these states have chosen to exercise their authority under CAA section 177 to adopt the California Advanced Clean Trucks (ACT) Regulation requiring manufacturers that certify Class 2b through Class 8 chassis or complete vehicles with internal combustion engines (ICE)24 to sell increasing (through MY 2032) percentages of ZEVs as part of their annual sales through 2035, with 60 percent ZEVs for vocational vehicles and 40 percent ZEVs for tractors (short-haul and long-haul combined). Additional states have efforts underway regarding ACT and, as with LDVs, with each additional adopting state comes a greater share of the national MDV (and heavy-duty vehicle) market. [EPA-HQ-OAR-2022-0829-0559, pp. 4-5]

23 https://www.nescaum.org/documents/multi-state-medium-and-heavy-duty-zev-action-plan.pdf

24 For the first time, EPA’s proposes to group Class 2b and Class 3 MDVs with LDVs in the LMDV rule (historically these vehicles have been grouped with heavy-duty vehicles).

In September 2021, five states signed the Regional Electric Vehicle Midwest Coalition Memorandum of Understanding “to accelerate vehicle electrification in the Midwest” and provide “the foundation for cooperation on fleet electrification along key commercial corridors to safeguard economic security, reduce harmful emissions, improve public health, and advance innovation” while positioning the region “to realize additional economic opportunity in clean energy manufacturing and deployment.”25 [EPA-HQ-OAR-2022-0829-0559, pp. 4-5]

25 https://www.michigan.gov/-/media/Project/Websites/leo/REV_Midwest_MOU_master.pdf?rev=6dd781b5a4eb4551b3b3a5b875d67fb9

Finally, NACAA recommends that EPA include provisions in the final rule that align with ACC II regarding data standardization, durability, warranty, minimum mileage range labeling, charging and serviceability requirements. [EPA-HQ-OAR-2022-0829-0559, p. 8]

Organization: National Association of Convenience Stores (NACS) et al.

II. Proposed Electrification Timelines are Unworkable.

The challenges associated with electrifying the light- and medium-duty fleet cannot be understated. EPA projects that the Proposed Rule will result in 67 percent of light-duty vehicles sold in 2032 being electric. That figure is an average of 78 percent electric sedans, 68 percent electric pickups and 62 percent electric crossover and SUVs.3 Conversely, EPA estimates that in the absence of any regulations, electric vehicles would make up only 39 percent of new sales in 2032.4 [EPA-HQ-OAR-2022-0829-0628, pp. 3-4]

3 Proposed Rule at ,329 (Table 80).

4 Reputable estimates on how quickly EV sales will increase vary widely. S&P Global Mobility estimates that by 2030, EVs will be 40 percent of new vehicle sales. The Energy Information Administration, on the other hand, estimates that EVs will be 17 percent of new vehicle sales by 2030. McKinsey has the highest

estimate and projects that EVs will be 48 percent of new vehicle sales by 2030. Given these varying estimates – all from highly respected sources – the Agency should exercise caution about consumers' willingness to purchase, and manufacturers' ability to deliver, EVs at the rates required by the Proposed Rule. Writing rules on its own does not mean that challenges related to supply chains for making the vehicles or consumer sentiment will change.

These timelines are entirely untethered from the market's capabilities. Most prospective EV drivers will need fast, high-powered on-the-go charging solutions before they're comfortable buying an EV.5 Although fuel retailers are very active in the National Electric Vehicle Infrastructure Program ("NEVI" Program) and other federal and state funding opportunities, it remains unacceptably difficult to identify a viable business case for installing EV charging stations. Unless those obstacles are permanently removed, these challenges will remain regardless of what the final rule demands. [EPA-HQ-OAR-2022-09-0628, pp. 3-4]

5 Consumer Reports, "Battery Electric Vehicles and Low Carbon Fuel: Overview of Methodology," April 2022,
https://article.images.consumerreports.org/prod/content/dam/surveys/Consumer_Reports_BEV%20AND%20LCF% 20SURVEY_18_FEBRUARY_2022.

Most of these impediments involve an electricity market structure that was not designed for – and is thus incompatible with – the retail fuel market. Many fuel retailers have installed EV charging stations at their outlets, utilizing any number of business models and ownership structures. Very few, if any, of these investments are profitable on a self-sustaining basis. The structural impediments to the profitability of public EV charging are too significant to overcome. These existing investments should therefore be interpreted as "beta tests" by companies exploring the charging space, rather than indicators of a viable, sustainable business model. [EPA-HQ-OAR-2022-0829-0628, pp. 3-4]

We are confident that the right combination of policy incentives and signals will enable the market to overcome any barriers that exist today. We simply fail to understand the rationale for leaving emission reduction opportunities on the table while we work toward those aspirational objectives. The best way to address practical impediments to electrification is to inject flexibility into the Proposed Rule while simultaneously promoting near-term emissions reductions through the use of multiple technologies, including renewable liquid fuels. [EPA-HQ-OAR-2022-0829-0628, pp. 3-4]

No one solution will decarbonize transportation energy. What policymakers think is the best solution today may be surpassed by subsequent ingenuity and innovation. Sound policy should not stifle innovation by mandating specific solutions. Instead, policy should set performance goals and let the market – guided by consumers – innovate to find the best way to meet those goals. [EPA-HQ-OAR-2022-0829-0628, pp. 3-4]

II. Electrification Timelines Proposed Under the Rule are Divorced from Reality.

EPA projects that the Proposed Rule will result in 67 percent of light-duty vehicles sold in 2032 being electric. That figure is an average of 78 percent electric sedans, 68 percent electric pickups and 62 percent electric crossover and SUVs.5 Conversely, EPA estimates that in the absence of any regulations, electric vehicles would make up only 39 percent of new sales in 2032.6 The extraordinary pace of electrification mandated under this rulemaking is entirely divorced from the world in which consumers and the broader marketplace operate. [EPA-HQ-OAR-2020829-0648, p. 4]

5 Proposed Rule at 29,329 (Table 80).

6 Reputable estimates on how quickly EV sales will increase vary widely. S&P Global Mobility estimates that by 2030, EVs will be 40% of new vehicle sales. The Energy Information Administration, on the other hand, estimates that EVs will be 17% of new vehicle sales by 2030. McKinsey has the highest estimate and projects that EVs will be 48% of new vehicle sales by 2030. Given these varying estimates—all from highly respected sources—the Agency should exercise caution about consumers' willingness to purchase, and manufacturers' ability to deliver, EVs at the rates required by the Proposed Rule. Promulgation of this Proposed Rule, alone, does not mean that challenges related to supply chains for making the vehicles or consumer sentiment will change.

The challenges to electrification cannot be overstated and will require an unprecedented effort irrespective of regulatory mandates. Public charging deployment is a principal obstacle. In the Proposed Rule, EPA catalogs many of the federal incentives currently in place for charging infrastructure, suggesting that these policies may ameliorate many of these challenges.7 This suggestion is short-sighted and incorrect. Subsidies alone will not create a long-term, sustainable proliferation of EV charging stations. For electrification policies to succeed in the long term, there must be a competitive, public charging market to refuel electric vehicles.8 Cars will need places to refuel, and private companies need a financial justification to spend capital to install charging stations. [EPA-HQ-OAR-2022-0829-0648, p. 4]

7 Proposed Rule at 29,307.

8 EV charging policy should promote competitive market dynamics and work with consumers' existing behavior and fuel retailers' real estate and business infrastructure. In a competitive market, private dollars will make sure infrastructure is there to meet consumers' needs. Without these market-oriented policies in place as a foundation for any public investment, there is a very real risk that public dollars spent will be stranded and wasted in ways that do not serve an appreciable number of consumers and ultimately do little to combat EV range anxiety.

c. Supply Chain and Market-Related Barriers to EV Adoption

Various other barriers to EV adoption exist beyond public charging, including consumer skepticism toward new technology, higher costs than internal combustion engine ("ICE") vehicles, limited range, lack of convenient public charging infrastructure, uncertain battery aging and resale value, dismissive or deceptive car dealerships, lack of available models, and other supply constraints.29 [EPA-HQ-OAR-2022-0829-0648, p. 9]

29 Matteo Muratori et al., PROG. ENERGY 3 022002 "The rise of electric vehicles—2020 status and future expectations" (Mar. 25, 2021) available at https://doi.org/10.1088/2516-1083/abe0ad.

EPA acknowledges, though does not meaningfully address, many of the barriers to EV adoption.30 If the Agency is interested in electrifying light-duty transportation in the United States, it should proactively redress these obstacles rather than assume they will dissipate on their own under the full weight of unachievable mandates. [EPA-HQ-OAR-2022-0829-0648, p. 9]

30 Proposed Rule at 29,311.

Organization: National Automobile Dealers Association (NADA)

II. Proposal Overview

Earlier this year, EPA proposed to revise its multipollutant emissions standards for light-duty passenger cars and trucks and light medium-duty vehicles (defined as classes 2b and 3).1 EPA states that the proposal is authorized under section 202(a) of the Clean Air Act (CAA),2 and was issued in response to Executive Order (E.O.) 14037, "Strengthening American Leadership in Clean Cars and Trucks" (Aug. 5, 2021), which set a U.S. new vehicle sales goal of 50 percent zero-emission vehicles by 2030.3 [EPA-HQ-OAR-2022-0829-0656, pp. 2-5]

1 88 Fed. Reg. 29184 et seq. (May 5, 2023).
2 42 U.S.C. § 7521(a).
3 88 Fed. Reg. at 29186, 29187, 29231-33.

The proposal seeks to establish more stringent standards for light- and medium-duty vehicles beginning with MY 2027 and to progressively tighten them through MY 2032.4 For light-duty vehicles, EPA proposes a 56 percent reduction in combined fleet average greenhouse gas (GHG) emission target levels compared to the existing MY 2026 standards.5 For medium-duty vehicles, EPA proposes a 44 percent GHG emissions reduction compared to existing MY 2026 standards, and a 37 percent reduction compared to MY 2027 standards.6 EPA also proposes non-methane organic gases plus nitrogen oxides (NMOG+NOx) standards that represent a 60 percent reduction from the existing MY 2025 light-duty standards and a 66 to 76 percent reduction for medium-duty vehicles.7 And for both light- and medium-duty vehicles, EPA's proposed standards project to reduce particulate matter emissions by more than 95 percent.8 [EPA-HQ-OAR-2022-09-0656, pp. 2-5]

4 88 Fed. Reg. at 296, 29234, 29257.
5 88 Fed. Reg. at 29196, 29234, 29239-40.
6 88 Fed. Reg. at 29196, 29234.
7 88 Fed. Reg. at 29197.
8 Id

The proposal would maintain the footprint structure of the existing light-duty standards, but update the footprint standard curves "to flatten the slope of each curve and to narrow the numerical stringency difference between the car and truck curves" based on the vehicle technologies EPA projects automakers will use to comply.9 It would also revise the air conditioning credit program by limiting credit eligibility to light-duty internal combustion engine (ICE) vehicles for tailpipe CO2 emissions control beginning in MY 2027, and remove refrigerant- based air conditioning provisions for both light- and medium-duty vehicles to maintain consistency with a separate proposal to disallow their use.10 EPA also proposes to sunset the off-cycle credits program for both light- and medium-duty vehicles by: (i) reducing the menu credit cap annually until its unavailable in MY 2031; (ii) eliminating the 5-cycle and public process pathways starting in MY 2027; and (iii) limiting eligibility for off-cycle credits to vehicles with tailpipe emissions greater than zero starting in MY 2027.11 [EPA-HQ-OAR-2022-0829-0656, pp. 2-5]

9 88 Fed. Reg. at 29196, 29234.
10 88 Fed. Reg. 29196, 29246-48.
11 88 Fed. Reg. 29196, 29249-52.

EPA forecasts that the average marginal per-vehicle cost for regulated manufacturers (OEMs) to comply with its proposed light-duty mandates will rise from $633 in MY 2027 to $944 in MY 2031, and projects that the marginal per vehicle cost of compliance will jump to approximately

$1,200 in MY 2032.12 For medium-duty vehicles, EPA's estimated average marginal per vehicle OEM cost of compliance ranges from $364 in MY 2027 to approximately $1,800 in MY 2032.13 [EPA-HQ-OAR-2022-0829-0656, pp. 2-5]

12 88 Fed. Reg. at 29201, 29328, 29343; See also EPA's Draft Regulatory Impact Analysis (DRIA) at l (able 11), 4-17, 13-25 (Table 13-45).

Importantly, these costs are in addition to those imposed by EPA in prior rules, which are necessarily built into the cost of MY 2027 and later vehicles. EPA asserts, however, that higher light- and medium-duty costs will be offset by purchase incentives arising from the Inflation Reduction Act (IRA), and by lower EV operating costs.14 [EPA-HQ-OAR-2022-0829-0656, pp. 2-5]

14 88 Fed. Reg. at 29201, 29328-29, 29344, 29364.

Based on OEM fleet electrification investment and production plan announcements and federal subsidies in the Infrastructure Investment and Jobs Act (IIJA) and the IRA, EPA contends that EV technologies have advanced to such a degree that EVs now "are a feasible way to greatly reduce emissions" and can be used "as an emissions control technology to comply with" the proposed standards.15 EPA projects that, although "[t]he proposed standards are performance- based and do not mandate any specific technology...or any vehicle type[,]" new light-duty EV sales will increase from 36 percent in MY 2027 to 67 percent in MY 2032.16 EPA also projects new medium-duty EV sales ranging from 17 percent in MY 2027 to 46 percent in MY 2032.17 [EPA-HQ-OAR-2022-0829-0656, pp. 2-5]

15 88 Fed. Reg. at 29194, 29284, 29341-44.
16 88 Fed. Reg. at 29329.
17 88 Fed. Reg. at 29331.

EPA also projects that its proposed standards will cause new light-duty vehicle sales to decrease a small amount during the first two years, increase a small amount in the next two years, and then decrease by a small amount in the final two years.18 EPA projects no change in new medium-duty vehicle sales as a result of its proposed standards based on an assumption that, because commercial buyers "are less sensitive to changes in vehicle prices than personal vehicle owners[,]" they will not "change purchase decisions if the price of the vehicle changes" and "will still purchase the vehicle that fts their needs."19 [EPA-HQ-OAR-2022-0829-0656, pp. 2-5]

18 88 Fed. Reg. at 29370.
19 88 Fed. Reg. at 29371.

The following NADA comments focus on the potential impacts of EPA's proposal on new light- and medium-duty sales, and on fleet turnover. [EPA-HQ-OAR-2022-0829-0656, pp. 2-5]

III. EPA Has Not Demonstrated That Its Proposed Standards Are Technologically Feasible, Economically Practical, or Cost Beneficial.

Of the 285 million vehicles on U.S. roads today, only 2.1 million (less than one percent) are EVs,20 but OEMs are investing and preparing significantly for the production and deployment of EVs. Indeed, 800,000 EVs were sold in 2022, capturing 5.8% of total new vehicle sales, up from 3.2% in 2021.21 And EV market share is generally expected to increase significantly over time. [EPA-HQ-OAR-2022-0829-0656, pp. 2-5]

20 See Global EV Data Explorer – Data Tools - IEA. A recently-issued Alliance for Automotive Innovation (AAI) report indicates that 3.3 million EVs—or 1.17 percent—are today operating on U.S. roads. See Get Connected EV Quarterly Report 2023 Q1.pdf (autosinnovate.org) ("Registration and Infrastructure").

21 See In a Down Market, EV Sales Soar to New Record - Cox Automotive Inc. (coxautoinc.com).

Since EPA began regulating tailpipe emissions, OEMs have successfully made incremental but affordable ICE vehicle emissions improvements while simultaneously developing and bringing new alternative technologies and fuels to market. But OEMs are limited in their ability to further improve ICE vehicle emissions in conformity with EPA's proposed standards without substantial cost increases. Consequently, it is concerning that EPA's proposed standards, if adopted, will increase the cost of covered new motor vehicles, and hinder the deployment of EVs at a critical juncture for this emerging market. [EPA-HQ-OAR-2022-0829-0656, pp. 2-5]

NADA has long supported continuous vehicle emissions improvements that are technologically achievable and affordable for household and commercial new vehicle customers. As noted above, NADA's franchised dealer members are "all-in" with selling and servicing the new EVs being produced by the OEMs they represent. In fact, nationwide, NADA expects franchised dealers to spend some $5 billion installing EV chargers, buying EV-related equipment, parts, and tools, and investing in EV training for sales and service personnel. As evidenced by these investments and by the EV-related activities at the 2022 and 2023 NADA Shows,22 America's new motor vehicle dealers recognize their importance to the broad, mass market adoption of EVs. However, they also are concerned that EPA's proposal could undermine that adoption. [EPA-HQ-OAR-2022-0829-0656, pp. 2-5]

22 See Exhibit A: "Everything Electric" at NADA Show 2022-2023.

Appropriately structured standards must involve a national, holistic approach to improving tailpipe emissions. EPA claims that it is not proposing to mandate specific technologies or the production of specific vehicle types, but its proposal is anything but technology neutral. Unlike prior rules governing tailpipe emissions, EPA's proposed standards cannot be met by ICE vehicles alone and would phase-out existing credits for ICE vehicle and hybrid technologies that have to date helped OEMs to achieve better emissions compliance. Moreover, they are premised on overly aggressive assumptions regarding future EV market penetration. If adopted, the cumulative practical effect of the proposal would be to greatly reduce the market availability of new ICE vehicles. This "if you build them, they will come" approach ignores the fact that, while franchised dealers are the OEMs' primary customers, actual emission reductions cannot be achieved unless and until new EVs take to the road. [EPA-HQ-OAR-2022-0829-0656, pp. 2-5]

Unlike for many regulated goods, prospective purchasers of new light-duty vehicles have transportation options, including the used vehicle marketplace, the service and repair of existing vehicles, and alternatives like public transit and micro-mobility. Consequently, vehicle consumer purchase behaviors must be viewed through the lens of an ever-changing marketplace that hinges on the willingness and ability of prospective purchasers to buy ever more expensive new vehicles with enhanced emissions performance. Similarly, new commercial medium-duty vehicle purchase decisions hinge on affordability, cost-efficiency, and reliability (i.e., uptime). At bottom, the market will avoid new vehicles that are too costly, that offer performance comprises, or that pose unacceptable downtime risks. [EPA-HQ-OAR-2022-0829-0656, pp. 2-5]

EPA's current proposal is flawed in that it disregards these critical demand-side marketplace factors. It also appears aimed at promoting EVs to the exclusion of ICE, hybrid, and other alternative fuel vehicles. It will likely cause OEMs to produce fewer new technology ICE and alternative fueled vehicles and will increase their cost, thereby dissuading consumers from considering their purchase. EPA's final rule should set truly technology-neutral emissions standards that maximize, not inhibit, fleet turnover. Doing so is critical to maximizing emissions reduction given that, as noted above, regulatory objectives will not be achieved unless and until new vehicles subject to more stringent emissions standards are bought. [EPA-HQ-OAR-2022-0829-0656, pp. 2-5]

Organization: National Corn Growers Association (NCGA)

The proposed EPA standards for 2027 and later set very aggressive goals for reducing GHG and criteria emissions. Achieving these goals will require dramatic changes not only in vehicle design, but in the entire automotive supply chain. While the U.S. market share of BEVs will continue to expand, establishing regulations where success is solely contingent upon an unattainable tenfold increase in the production and sales of BEVs over the next eight years represents an avoidable mistake. The proposed rule would require huge investments and rapid growth in many industries, including the mining and processing of key minerals, the generation and distribution of electricity, and the recharging of electric vehicles. [EPA-HQ-OAR-2022-0829-0643, p. 2]

There are many obstacles to this shift including geopolitics, long lead times, capital investments, and consumer acceptance. [EPA-HQ-OAR-2022-0829-0643, p. 2]

Organization: National Fers Union (NFU)

I. Executive Summary

The proposed EPA standards for 2027 and later set very aggressive goals for reducing GHG and criteria emissions. Achieving these goals will require dramatic changes not only in vehicle design, but in the entire automotive supply chain. Battery electric vehicles will play a large role in achieving the goals, but this will require huge investments and rapid growth in many industries including the mining and processing of key minerals, the generation and distribution of electricity, and the recharging of electric vehicles. [EPA-HQ-OAR-2022-0829-0581, p. 2]

It would be naive to believe that these dramatic changes will be achieved smoothly and quickly. There are many obstacles including geopolitics, long lead times, capital investments, and consumer acceptance. In order to achieve emissions goals in the most robust, rapid, and affordable way, EPA should encourage multiple additional solutions such as hybrid electric vehicles (including plug-in hybrids), biofuels, and E-Fuels. [EPA-HQ-OAR-2022-0829-0581, p. 2]

Organization: National Propane Gas Association (NPGA)

The EPA's goals in reducing GHGs and other pollutants is laudable, but its timeline is unachievable. [EPA-HQ-OAR-2022-0829-0634, p. 2]

Organization: Nebraska Corn Board (NCB) and Nebraska Corn Growers Association

The EPA's proposed rule is a pre-mature way to ensure electric vehicles (EV) are a part of the Biden Administration's plan for EV sales to be 50% of all vehicle sales by 2030. The "most stringent emissions proposal to date" is pushing to exceed that plan to implement around 69% acceptance by the proposed deadline. This is not feasible for rural America. [EPA-HQ-OAR-2022-0829-0583, p. 1]

Organization: Nissan North America, Inc.

III. GHG Proposal

Thanks to the leadership and early investment of Nissan, the EV market has steadily grown over the last 10 years, albeit slower than many expected. Transitioning from long-existing and established technology takes time and significant financial investment. This responsibility must be shared among the industry, its customers, and governmental entities. Widespread adoption of EVs requires not only that the automotive industry broadly embrace investment in this technology, but also that consumers show willingness to adopt the new technology. Nissan has invested billions of dollars in an effort to stimulate growth, not only investing in technology and product development but also in infrastructure and consumer outreach/education. Nissan strongly supports federal, state, and local investment in market measures to complement the efforts already in place by industry leaders such as Nissan to further encourage this shift towards EVs. [EPA-HQ-OAR-2022-0829-0594, pp. 3-4]

Nissan is committed to transitioning its vehicle portfolio to EVs over time and intends to remain an industry leader in EV and related battery technology innovations. Nissan supports President Biden's overall efforts to increase sales of battery, fuel cell, or plug-in hybrid electric vehicles (BEVs, FCEVs, and PHEVs, respectively) over the next decade. The Administration already announced aggressive penetration targets in the August 5, 2021 "Executive Order on Strengthening American Leadership in Clean Cars and Trucks" (hereinafter "Clean Cars EO"). The Proposed Multi-Pollutant Rule, however, goes well beyond the already ambitious goals announced in President Biden's Clean Cars EO. Not only has the penetration percentage been significantly increased (jumping from 50 percent to 60 percent in 2030), but the make-up of that percentage has drastically changed: EPA's Proposed Multi-Pollutant Rule would require a 60 percent penetration rate for BEVs only, excluding the FCEV and PHEV technologies that are critical to shepherding a safe, affordable, and reliable transition to clean vehicles. EPA has moved the goalpost, not by a few feet but by miles. [EPA-HQ-OAR-2022-0829-0594, pp. 3-4]

In light of these myriad challenges, EPA should adjust the proposed GHG standards set forth in the Proposed Multi-Pollutant Rule. Nissan supports a final rule that takes these realities into consideration and seeks an ambitious yet achievable target for plug-in electric vehicle ("PEV") penetration, closer to the already ambitious targets set in the Clean Cars EO. At a minimum, Nissan requests that EPA adjust the proposed GHG standards and targets to account for a blended PEV percentage, taking into consideration emissions reductions from PHEVs and BEVs collectively. EPA has historically considered the emissions benefits of both groups of advanced technology vehicles, acknowledging the importance and need of PHEVs in the consumer shift towards clean vehicles. Nissan and others in the industry are committed to transforming the industry and have already invested significantly in pressing forward on the transition to EVs. The

Proposed Multi-Pollutant Rule goes beyond what is achievable and simply forces too much too quickly. There simply is not a realistic path to achieve the level of accelerated shift in the proposed timeframe. More time is needed for such extensive and transformational change. [EPA-HQ-OAR-2022-0829-0594, p. 5]

IV. EPA Tier 4 Proposal

Nissan has continued to improve ICE vehicle technologies and steadily reduce corresponding criteria pollutant emissions. While Nissan is committed to achieving emissions reductions on all fronts – GHG and criteria pollutants – the Proposed Multi-Pollutant Rule would set criteria pollutant standards that require significant investment of financial and research and development resources to ICE technologies, thereby diverting these limited resources that are critical to achieving the Administration’s aggressive electrification goals. EPA should encourage and allow manufacturers to invest their available resources towards the ultimate goal of transitioning to EVs, which mitigates the criteria pollutant emissions as fleet electrification continues to ramp up. [EPA-HQ-OAR-2022-0829-0594, pp. 6-7]

The standards and requirements set out in the proposal are costly and inconsistent with already established standards under California’s Advanced Clean Cars (“ACC”) II program. The stringency and accelerated timeline for implementation as proposed are technically, economically, and logistically unrealistic. In particular, the proposed PM standards and elimination of commanded enrichment strategies for component protection will pose significant challenges for the industry. [EPA-HQ-OAR-2022-0829-0594, pp. 6-7]

- The proposed PM standard and accompanying phase-in schedule are not feasible given current technology and lead time considerations. The proposed new 0.5 mg/mile standard would require the installation of a gasoline particulate filter (GPF) on every vehicle in order to comply. While GPFs are not new technology, they are relatively new to the U.S. market and the proposed requirements are unique globally. Adding an emission control component such as a GPF is no simple task and requires significant research, development, and testing, as well as re-calibration of relevant software systems to account for new systems, components, and monitors within the overall vehicle software architecture. Such hardware and software changes require sufficient lead time, which is not provided under the proposal. EPA’s proposed new standard would also be implemented in the middle of the phase-in period for California’s new PM standards. EPA should align its proposal with the standard recently finalized in California, for which manufacturers have already started planning. [EPA-HQ-OAR-2022-0829-0594, pp. 6-7]

Organization: North American Suba’u, Inc.

The agency's proposed MY2027-2032 GHG standards aim to front-load standards in the early years, starting at an 18 percent increase in stringency in 2027 and declining to eight percent in 2030, nine percent in 2031, and 11 percent in 2032. While Subaru shares the goal of making significant reductions in greenhouse gas emissions, the feasibility of achieving the standards, particula’ly in the proposal's early years, must be considered particula“ly noting various "outside the vehic’e" factors (addressed below) needed to support a more aggressive EV posture. [EPA-HQ-OAR-2022-0829-0576, p. 2]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC)

Collectively, California and the 15 Section 177 ZEV states account for roughly 35 percent of U.S. sales of new light-duty ZEVs.12 The ZEV sales requirements in these states have helped to create a national market that enables ZEV automakers, suppliers, and charging providers to achieve economies of scale, lowers consumer costs, and promotes job creation in automotive, manufacturing, infrastructure, and supporting industries. Experience proves that ZEV sales requirements provide the regulatory certainty needed to drive public and private investment in deployment of ZEVs and charging infrastructure. Indeed, states with these requirements consistently outperform the national average for light-duty ZEV sales. From 2019 to 2022, light-duty ZEV market penetration in the Section 177 ZEV states more than quadrupled, exceeding 10 percent of total LDV sales.13 [EPA-HQ-OAR-2022-0829-0584, pp. 4-5]

12 National Automobile Dealers Association, NADA Data 2021 (2022), https://www.nada.org/media/4695/download?inline.

13 Atlas Public Policy, EV Hub, https://www.atlasevhub.com/ materials/automakers-dashboard/ (2023 IHS data) (visited Feb. 23, 2023).

Outside of California, nearly half of the nation’s public charging infrastructure has been deployed in states with ZEV sales requirements. These states also account for roughly three quarters—nearly $5 billion—of all utility funding for transportation electrification approved by state public utility commissions.14 [EPA-HQ-OAR-2022-0829-0584, pp. 4-5]

14 U.S. Department of Energy, Alternative Fuels Data Center, Alternative Fueling Station Counts by State, https://afdc.energy.gov/stations/states (visited June 9, 2023).

California’s ACC II program, finalized in 2022, requires manufacturers of passenger vehicles (designed to transport 12 persons or less) and light-duty trucks (gross vehicle weight rating less than 8,500 pounds) to produce and deliver for sale an increasing percentage of ZEVs over time and 100 percent ZEVs by 2035. ACC II also establishes increasingly more stringent exhaust and evaporative emission standards for light- and medium-duty ICE vehicles. To date, California, Massachusetts, New York, Oregon, Vermont, Virginia, and Washington have adopted ACC II. These seven states represent over 20 percent of the LDV market.15 Six more jurisdictions—Colorado, Delaware, the District of Columbia, Maryland, New Jersey, and Rhode Island—have announced their intentions to adopt ACC II. More are expected to follow given the anticipated climate, air quality, and economic benefits of the program.16 [EPA-HQ-OAR-2022-0829-0584, p. 5]

15 Recent modeling for select Section 177 states shows that adopting ACC II will result in even greater cumulative NOx and GHG emissions reductions than EPA’s proposed standards between 2025 and 2040. Across all of the states modeled, ACC II achieved 30 percent greater well-to-wheel CO2 equivalent reductions and 75 percent greater NOx reductions than EPA’s proposed standards. Some states modeled saw even greater reductions. In Connecticut and New Jersey, for example, ACC II would provide an incremental benefit of roughly two times more than EPA’s proposal. See Sonoma Technology, ACC II Program – EPA 2027 Proposal Comparison (June 8, 2013), [LINK TO NESCAUM WEBSITE WHEN POSTED].

16 National Automobile Dealers Association, NADA Data 2021 (2022), https://www.nada.org/media/4695/download?inline.

California's Advanced Clean Trucks (ACT) regulation requires manufacturers of Class 2b-8 on- road medium- and heavy-duty vehicles to sell increasing percentages of ZEVs. By model year 2035, 55 percent of sales of Class 2b-3 vehicle sales, 75 percent of class 4-8 vehicle sales, and 40 percent of Class 7-8 truck tractor sales must be ZEVs. In addition to California, seven states— Colorado, Massachusetts, New Jersey, New York, Oregon, Vermont, and Washington—have adopted the ACT regulation. These states have also adopted California's Heavy-Duty Low NOx and Phase II GHG regulations, which are designed to reduce emissions from new diesel fueled heavy-duty vehicles while the market transitions to ZEVs. Many more states are expected to follow. Like the ACC II regulation, state adoption of the ACT regulation creates economies of scale, lowers costs, promotes job creation, and provides the regulatory certainty needed to drive investment in ZEVs and infrastructure. [EPA-HQ-OAR-2022-0829-0584, p. 5]

C. Market-Enabling Complementary Policies

Many of the NESCAUM and OTC states have state-specific plans to reduce GHGs and air pollution from on-road transportation and have adopted a diverse set of market-enabling policies and programs designed to advance the market for light-, medium, and heavy-duty ZEVs. Examples include ZEV sales and purchase requirements as discussed above; ZEV and infrastructure purchase incentives; utility programs and investments in ZEV infrastructure; consumer and fleet outreach and education programs; innovative financing mechanisms; multi-family dwelling and workplace charging programs; and deployment of public charging in communities and along major travel corridors. Many states have established requirements or goals to transition state vehicles and transit fleets to ZEVs. In addition, most states have adopted clean energy or renewable portfolio standards, which require a share of power sold by their utilities to come from renewable sources. Some states have adopted 100 percent renewable energy goals. States recognize that transitioning to renewable energy sources will maximize emissions reductions from ZEVs over time. [EPA-HQ-OAR-2022-0829-0584, p. 7]

III. NESCAUM and OTC Comments on the NPRM

For the reasons carefully considered and articulated in the NPRM, and those discussed above, NESCAUM and the OTC strongly support EPA's exercise of its authority under CAA Section 202(a) to establish new and more stringent criteria pollutant and GHG emissions standards for MYs 2027 and later LDVs and Class 2b and 3 MDVs. As an initial matter, we agree with EPA's conclusion that the standards it proposes are technologically feasible and that the costs of compliance for manufacturers would be reasonable. The proposed standards would generate substantial reductions in emissions of GHGs, criteria pollutants, and air toxics, creating significant benefits for public health and welfare. We also agree that the proposal would result in reduced vehicle operating and maintenance costs for consumers. Moreover, the benefits of the regulation would far exceed its costs. EPA estimates the cumulative monetized benefits of the GHG and criteria pollutant standards through 2055, considering both upstream and downstream emissions, to be between $850 billion and $1.6 trillion (2020 $US) depending on the selected discount rate.23 [EPA-HQ-OAR-2022-0829-0584, pp. 7-8]

23 See EPA, Draft Regulatory Impact Analysis (DRIA), EPA-420-D-23-003 (Apr. 14, 2023), https://www.regulations.gov/document/EPA-HQ-OAR-2022-0829-0360.

Considering the state of the U.S. and global LDV and MDV markets, NESCAUM and the OTC believe that GHG standards more stringent than EPA's proposal are technologically feasible. [EPA-HQ-OAR-2022-0829-0584, pp. 8-9]

Announcements by major manufacturers to transition their vehicles to ZEVs, agreements by large public and private fleets to purchase ZEVs, the deployment and rapid expansion of charging infrastructure networks across the country, an increasing number of states adopting the ACC II and ACT programs, and accelerating global momentum, all support the conclusion that the LDV and MDV markets are ready for rapid and widespread electrification. Alternative 1 in the NPRM is projected to result in an industry-wide average target of 72 g/mi of CO2 in MY 2032, representing a 61 percent reduction in projected fleet average GHG emissions target levels from the existing MY 2026 standards. NESCAUM and the OTC believe the standards described in Alternative 1 are technologically feasible. [EPA-HQ-OAR-2022-0829-0584, p. 9]

Organization: Office of Wyoming Governor Mark Gordon

Wyoming has a vested interest in the proposed rule. Wyoming stands to feel significant negative impacts from this rule, including: consumer costs, supply chain effects, our nation's energy security, highway funding shifts, electric vehicle (EV) charging infrastructure realities, rural population accessibility, and state vehicle fleets. It is important that the EPA not mandate that the personal vehicle and transportation market move to EVs through a rushed and backdoor emissions approach. Programs such as the Federal Highway Administration's National Electric Vehicle Infrastructure (NEVI) program illustrates how difficult a compulsory shift to EVs is to implement in rural states such as Wyoming. [EPA-HQ-OAR-2022-0829-0675, p. 1]

Organization: POET, LLC

EPA also assumes that, provided batteries are available, automakers will be able to manufacture BEVs in essentially unlimited quantities.83 EPA simply states that "vehicle assembly capacity" can "respond relatively quickly to the necessary investment commitments," because it is a "relatively well understood process."84 The situation, however, is far more complex. As the Trinity report explains, "MY 2024 is beginning which means there is at most three years of lead time remaining before automakers would be required to comply."85 EPA fails to justify its assumption of unlimited production capacity given that short lead time. EPA also fails to explain why it has assumed that vehicle redesign schedules for shifting from conventional vehicles to BEVs would be essentially identical to such schedules for conventional vehicles: [EPA-HQ-OAR-2022-0829-0609, p. 22]

83 Id. at 4.

84 Id. (quotations omitted).

85 Id. at 5.

Given the radical nature of the changes in chassis design, powertrain components, tooling, availability of components and supply chain issues, the need for new vehicle control strategies and components, and other challenges specific to electrification, it is far from clear that the existing redesign schedules are valid and likely that they need to be longer than the existing schedules.86 [EPA-HQ-OAR-2022-0829-0609, p. 22]

86 Id.

Uncertainty in BEV Penetration Rate

In its proposal, EPA forecasts almost 70% BEV penetration will occur in MY 2032 across the light duty categories (passenger car, crossover/SUV, and light truck), or over 10 million BEVs. In addition, this compliance pathway would require almost 40% BEV penetration in the medium-duty van and pickup truck categories. By comparison, EIA projects approximately 1.5 million BEVs in 2050, with only 1.2 million in 2032.2 Thus, EPA's projections of sales of approximately 11 million BEVs are almost nine times higher than those of EIA, the leading U.S. governmental source for independent energy statistics and analysis.3 [EPA-HQ-OAR-2022-0829-0609, p. 36]

2 Annual Energy Outlook (AEO) 2023 Reference Table 38, https://www.eia.gov/outlooks/aeo/tables_ref.php

3 Regarding BEV sales in EPA's analysis, EPA finds 15,834,010 total light duty vehicle sales in 2032 (Draft Regulatory Impact Analysis Table 4-18) multiplied by 70% BEV penetration (Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles Fact Sheet, EPA-420-F-23-009 pg. 5).

1. The analysis U.S. EPA has performed to "demonstrate" the feasibility of a dramatic increase in BEV penetration into the light-duty vehicle fleet is based on a number of unreasonable and/or unsupported assumptions that cause the agency to substantially overstate the likely penetration rate and underestimate the cost of compliance with the Proposed Rule. [EPA-HQ-OAR-2022-0829-0609, p. 53]

Review of U.S. EPA's BEV Technology Assessment

In both the Proposed Rule and the Draft Regulatory Impact Analysis (DRIA), U.S. EPA projects that manufacturer compliance will require dramatic increases in the sale of new battery electric vehicles (BEVs). In the Fact Sheet1 accompanying the publication of the Proposed Rule, U.S. EPA states that compliance will require "…nearly 70 percent BEV penetration in MY 2032 across the combined light- duty passenger car, crossover/SUV, and pickup truck categories." This 70 percent BEV penetration value can be compared to the present (MY 2022) BEV penetration which is less than 5 percent and the 20 to 40 BEV percent rate in MY 2032 that U.S. EPA assumes will be achieved in the absence of the proposed rule even without accounting for the Proposed Rule (See DRIA Figures 4-2 and 4-3). [EPA-HQ-OAR-2022-0829-0609, pp. 53-54]

1 https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P1017626.pdf.

The first step in a review of the agency's BEV technology assessment needs to focus on the dramatic increase in BEV penetration forecast to occur even in the absence of the Proposed Rule. As noted above, U.S. EPA expects BEV penetration to increase by 4 to 10 times over the period of only ten years from MY 2022 to MY 2032 without the Proposed Rule. The agency also points out (DRIA Chapter 3.1.3.1) that worldwide demand for BEVs is expected to grow dramatically again in the absence of the Proposed Rule because of actions taken by other jurisdictions. However, despite the fact that a radical transformation of the auto industry and the vehicle battery industry will be required to achieve even these highly optimistic levels, U.S. EPA assumes that both BEV supply and demand in the U.S. can be accelerated by only the Proposed Rule to 2 to 3 times by MY 2032 relative to the aggressive growth already represented in the No

Action Case. Further, in its analyses of the Proposed Rule, U.S. EPA assumes that this high level of demand for BEVs will continue unchanged through MY 2055. A more reasonable assumption given U.S. EPA's apparent position that transformation of the new light- and medium-duty vehicle market to BEVs is inevitable would be to assume much slower growth in the near term along with a continuation in growth into the future. [EPA-HQ-OAR-2022-0829-0609, pp. 53-54]

U.S. EPA's overall forecast of BEV penetration into the vehicle fleet with and without the Proposed Rule can be seen in Figure 9-2 of the DRIA which is reproduced below. [See original attachment for Figure 9-2 BEV stock used in OMEGA effects calculations] As shown, even without the Proposed Rule, the fraction of BEVs in the overall light-duty vehicle fleet is projected, relative to 2027 levels, to double by 2032, triple by 2037, and reach four times by about 2050. In contrast, the agency assumes the Proposed Rule will force BEV penetration rates up by another 50% in 2032, almost double them in 2037, and more than double them by 2050. Although U.S. EPA purports that its analyses support these forecasts of incredible growth in BEV penetration, those analyses rest on a series of unreasonable, unsupported, and highly optimistic assumptions regarding BEVs as discussed below. As a result, the conclusions drawn by U.S. EPA regarding BEV penetration cannot be relied on. [EPA-HQ-OAR-2022-0829-0609, pp. 53-54]

In addition to making optimistic assumptions regarding the availability of batteries for BEVs, U.S. EPA has also assumed that even as early as MY 2027 there will be no limit to the number of BEVs that automakers can produce provided that batteries are available. More specifically, U.S. EPA states (DRIA Chapter 2.6.5) that: [EPA-HQ-OAR-2022-0829-0609, pp. 56-57]

…vehicle assembly capacity is a relatively well understood process that can respond relatively quickly to the necessary investment commitments. Given the existing activities among automakers in this area, and the relatively long lead time before MY 2027 when the proposed rule would begin, EPA did not specifically impose a limit on vehicle assembly capacity. [EPA-HQ-OAR-2022-0829-0609, pp. 56-57]

The reference to the amount of lead time prior to MY 2027 is an example of the disingenuous nature of U.S. EPA's analysis. At present, MY 2024 is beginning which means there is at most three years of lead time remaining before automakers would be required to comply with the new regulatory requirements. Another issue with the U.S. EPA analysis is that while it does purport to account for vehicle redesign schedules (DIRA Chapter 2.6.4.1), it does so based on the unsupported assumption that schedules that have applied for the redesign of conventional vehicles also apply to the transformation of a conventional vehicle platform to a BEV platform. Given the radical nature of the changes in chassis design, powertrain components, tooling, availability of components and supply chain issues, the need for new vehicle control strategies and components, and other challenges specific to electrification, it is far from clear that the existing redesign schedules are valid and likely that they need to be longer than the existing schedules. [EPA-HQ-OAR-2022-0829-0609, pp. 56-57]

Overall, U.S. EPA's analysis fails to provide convincing support for the agency's position that it is technically feasible and reasonable to expect BEV penetration to increase by 14 times current levels (e.g. ~5% to ~70%) in the space of only ten years given the complete transformation that the auto industry. U.S. EPA has failed to demonstrate that there will be a sufficient supply of batteries and then relied on the unsupported assumption that battery supply is the only factor limiting the number of BEVs that can be produced even over a very short period of time. [EPA-HQ-OAR-2022-0829-0609, p. 57]

In summary, U.S. EPA's conclusions regarding the technical feasibility and costs of achieving the BEV penetration rates associated with compliance with the Proposed rest on a set of unreasonable and unsupported assumptions. These assumptions include: [EPA-HQ-OAR-2022-0829-0609, p. 61]

1. The auto industry can switch from making primarily conventional vehicles to making primarily BEVs in under ten years; [EPA-HQ-OAR-2022-0829-0609, p. 61]

2. Sufficient quantities of batteries for BEVs will be available to automakers at costs that will drop by 50% or more from current levels within a few years despite the fact that plants needed to produce those batteries largely have not yet been built; [EPA-HQ-OAR-2022-0829-0609, p. 61]

3. Costs of BEV componentry will drop by approximately 40% in under ten years; [EPA-HQ-OAR-2022-0829-0609, p. 61]

4. Automakers will not incur significant costs associated with redesigning conventional vehicles to BEVs and in reconfiguring manufacturing facilities to produce BEVs [EPA-HQ-OAR-2022-0829-0609, p. 61]

5. Large federal purchase incentives will be available to all consumers who wish to purchase BEVs; [EPA-HQ-OAR-2022-0829-0609, p. 61]

6. Likely higher insurance costs and lower resale values for BEVs will not deter consumers from purchasing BEVs; [EPA-HQ-OAR-2022-0829-0609, p. 61]

7. Despite the fact that the Proposed Rule is forecast to double the number of BEVs in operation in the U.S. by 2055 relative to the no action case, only minimal increases in BEV infrastructure will be required to support that larger population of BEVs; and [EPA-HQ-OAR-2022-0829-0609, p. 61]

8. Consumers will prefer to purchase BEVs rather than conventional vehicles; [EPA-HQ-OAR-2022-0829-0609, p. 61]

These assumptions appear to be designed to allow the agency to reach the conclusion that the large reductions in GHG emissions required for compliance with the Proposed Rule can be easily achieved through dramatic growth in BEV penetration that will save automakers and consumers considerable amounts of money. However, they also raise the question of "if the transformation of the auto industry from conventional vehicles to BEVs is both inevitable due2 to consumer demand and will save the auto industry and consumers billions of dollars, then why is the Proposed Rule necessary? A directly related question given that the period of benefit analysis of the Proposed Rule spans the period from 2027 to 2055 is why the standards proposed by U.S. EPA which increase in stringency over the period from the MY 2027 to MY 2032 are so aggressive. If the effective date of the most-stringent standard were pushed back from MY 2032 to MY 2037, that would still provide for 18 years of full benefit compared to 23 years (80%) [EPA-HQ-OAR-2022-0829-0609, p. 61]

Organization: Porsche Cars North America (PCNA)

EPA's proposal reflects a historic level of ambition for low-carbon, low-emission mobility. [EPA-HQ-OAR-2022-0829-0637, p. 2]

EPA has proposed ambitious targets within this NPRM for the accelerated decarbonization of the light- and medium- duty vehicle segments, in addition to incremental reductions in criteria pollutants from remaining combustion models. This proposal represents one of the most stringent and technologically demanding regulatory frameworks in the history of US automotive emissions regulations. EPA projects that to achieve these requirements, consumer adoption of electric vehicles must quadruple over the next 3-4 model years from current rates of approximately 8% to nearly one-third of new vehicle sales by 2027. Over the next six model years, this growth must double again, with electric vehicles comprising of over two-thirds of annual new vehicle sales by 2032. The extent of this proposal reflects the urgency and magnitude in carbon reductions being sought by EPA to address potential impacts of climate change. [EPA-HQ-OAR-2022-0829-0637, p. 2]

EPA's proposal also reflects the historic and transformative investments being made across the auto industry by OEMs like Porsche into electromobility. As noted in the comments from AFAI, the auto industry is projected to invest over $1.2 trillion in the development and production of electric vehicles by 2030. As AFAI outlines, this investment and commitment must be matched by an equal level of effort from segments outside of the auto industry for the range of electrification goals within this proposal to have a chance at being successfully achieved. Many other sectors will play an increasingly important role in enabling the electric vehicle transition. Utilities, charging infrastructure providers, and raw material suppliers will need to execute their own transformative plans at unprecedented speed. Sustained, supportive public policy will be critical in forming a robust foundation across many sectors that need to scale up growth and capacity. [EPA-HQ-OAR-2022-0829-0637, p. 2]

Comments specific to the proposed Light-Duty Vehicle and Light-Duty Truck Greenhouse Gas Standards for MY2027 and Later [EPA-HQ-OAR-2022-0829-0637, p. 18]

As noted in the opening section of these comments, Porsche views EPA's proposed GHG standards for MY2027-2032 as a highly ambitious package of increasing annual stringency combined with overall reductions in program flexibilities. In total this proposal presents a highly challenging set of standards for the industry that will demand an unprecedented rate of electrified vehicle development, production, and consumer adoption. This proposal appears to exceed what may be achievable for the light-duty industry as a whole across all vehicle segments, price points, and utility. [EPA-HQ-OAR-2022-0829-0637, p. 18]

In less than 10 years, EPA projects that 2 out of 3 new vehicles sold to American individuals, families and businesses will need to be fully electric. The importance of this statement cannot be underestimated as vehicle purchases remain one of the most, if not the most, expensive purchase that a consumer will ever make in their lifetime. In 10 years, two out of three customers must view electrification as a completely superior mobility choice that outshines any competitive combustion vehicle in the class in which that customer is shopping. EPA's regulations create no binding obligation on consumer adoption or on matching policy requirements of other sectors who will contribute to the success of electrification. Customers cannot broadly be expected to adopt technologies that are inconvenient, difficult to live with, or ultimately more expensive to own and operate. Auto manufacturers like Porsche are investing unprecedented levels of funding to provide exciting, electrified vehicle products to meet the needs of our customers. However, manufacturers will in part be reliant on the action of other sectors to help reduce the cost of electrification and to ensure that once a consumer purchases an EV that they are supported with a reliable, convenient, and affordable charging ecosystem. [EPA-HQ-OAR-2022-0829-0637, p. 18]

EPA has described throughout the NPRM and its supporting materials, that the agency believes these standards to be achievable based upon assumptions that outline ambitious improvements in electrification costs and supply chain readiness and in the rapid deployment of affordable, accessible nationwide charging infrastructure. These assumptions are being used by EPA to justify legally binding, regulatory compliance obligations on the auto industry. Obligations that rely significantly on the successful execution of policy and development by sectors outside of the auto industry's control. Shortfalls in any number of these underlying assumptions could have direct influence on future electrified vehicle costs and readiness which in turn would negatively impact consumer adoption and future compliance. Given the extent to which the standards are premised on high levels of electrification, it is unlikely that non-electrified technologies could be deployed to make up a significant compliance shortfall should EVs fail to achieve the levels of adoption assumed by EPA. [EPA-HQ-OAR-2022-0829-0637, p. 18]

Porsche recognizes the urgency underlying t'e magnitude of EPA's proposal to'address the agency's concerns related to the effects of climate change. Porsche, like many other manufacturers, has established holistic decarbonization goals throughout our products and business operations. Porsche supports the goal of increasing the level of electrification within the light duty car park and views electrification as a key enabler for achieving climate and energy security benefits. Nevertheless, the rate of transformation inherent within regional regulations must ultimately be achievable within the boundary conditions of each market. [EPA-HQ-OAR-2022-0829-0637, p. 18]

Organization: Renewable Fuels Association (RFA)

I. Executive Summary

EPA's proposed tailpipe emissions standards for 2027 and later years set extremely aggressive goals for reducing vehicular greenhouse gas (GHG) and criteria pollutant emissions. Achieving these goals would require dramatic changes not only in vehicle design, but also in the entire transportation energy supply chain. In addition, meeting the proposed emissions standards in the manner envisioned by EPA would require a massive and rapid shift in the vehicle purchasing and refueling behavior of American consumers. Indeed, if the rule is finalized as proposed, EPA projects that electric vehicles (EVs) "could account for 67% of new light-duty vehicle sales and 46% of new medium-duty vehicle sales in MY 2032."1 By comparison, EVs accounted for just 5.8% of new light-duty vehicle sales in 2022 and accounted for just 1% of total registered light-duty vehicles.2 [EPA-HQ-OAR-2022-0829-0602, pp. 3-4]

1 U.S. Environmental Protection Agency. "Biden-Harris Administration Proposed Strongest-Ever Pollution Standards for Cars and Trucks to Accelerate Transition to a Clean-Transportation Future." April 12, 2023. https://www.epa.gov/newsreleases/biden-harris-administration-proposes-strongest-ever-pollution-standards-cars-and.

2 Kelly Blue Book. “America Splits Into Thirds on Electric Cars.” (March 22, 2023). https://www.kbb.com/car- news/america-splits-into-thirds-on-electric-cars/.

While EVs are likely to play an important role in achieving emissions reductions goals, the growth in EVs projected by EPA would require enormous investment and rapid expansion in many global industrial sectors. Such a transition would require immediate and dramatic growth in the mining and processing of critical minerals, a massive increase in the generation and distribution of lower-carbon electricity, and the rapid buildout of a nationwide infrastructure network for recharging EVs. [EPA-HQ-OAR-2022-0829-0602, pp. 3-4]

It would be naïve and unrealistic to believe that such extraordinary changes in the marketplace can be achieved smoothly and quickly. There are numerous obstacles involved in a transition of this scale, including geopolitical and national security concerns; long lead times in permitting, material supply, design, and manufacturing; substantial capital investments; safety considerations; and unprecedented changes in consumer behavior and purchasing habits. [EPA-HQ-OAR-2022-0829-0602, pp. 3-4]

Organization: Rivian Automotive, LLC

Alternative 1 is Feasible

We find that EPA’s compliance modeling and other evidence demonstrates the feasibility of this target. The agency modeled average vehicle certification values in a scenario compliant with Alternative 1. In this scenario, it appears that ICE vehicles in MY32 average approximately 230 g/mi (see Figure 2 below). (Unless otherwise specified, all emissions rates quoted in this section refer to 2-cycle test values.) Several automakers already perform at a similar standard. For example, in MY21 Mitsubishi reported average emissions of 218 g/mi while Subaru reported 238 g/mi.9 Neither manufacturer made significant use of electrification technologies in that MY.10 [EPA-HQ-OAR-2022-0829-0653, pp. 2-7]

9 U.S. Environmental Protection Agency, The 2022 EPA Automotive Trends Report: Greenhouse Gas Emissions, Fuel Economy, and Technology since 1975 (December 2022), 85.

10 Id. at 88.

See original attachment for: Figure 2. Outputs from EPA’s modeling show an Alternative 1 compliance scenario in which the remaining ICE vehicles emit approximately 230 g/mi on average in MY32 (the chart’s legend somewhat obscures the blue ICE line). [EPA-HQ-OAR-2022-0829-0653, pp. 2-7]

Going forward, evidence suggests that automakers could improve fleet average ICE emissions commensurate with the targets of Alternative 1—and perhaps achieve even deeper reductions. For example, the International Council on Clean Transportation (“ICCT”) projects that the gasoline vehicle fleet can achieve average emissions of 168 g/mi by 2030, well below the ICE-only performance modeled in the Alternative 1 scenario.11 This would allow industry to comply with fewer BEV sales than EPA currently projects—or to achieve an even more stringent fleet average target by MY32. Certainly, several non- electrification emissions reduction technologies are still far from full or even majority utilization across the current fleet.12 [EPA-HQ-OAR-2022-0829-0653, pp. 2-7]

11 Stephanie Searle and Josh Miller, The International Council on Clean Transportation, “To Put the United States on Track to Reach 50% Electric Vehicle Sales in 2030, Cut the Greenhouse Gas Target in Half,” September 7, 2022, available at www.theicct.org/us-ghg-standards-ev-sales-sep22/.

12 U.S. Environmental Protection Agency, Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light- Duty and Medium-Duty Vehicles: Draft Regulatory Impact Analysis (April 2023), 3-1 – 3-6.

Large credit banks also continue to characterize the program, indicating that some degree of emissions reduction “slack” exists in the industry. Manufacturers ended MY21 with 131 Tg of GHG credit. Of that total, 24 Tg do not expire until MY25. Another 33 Tg will remain in banks until MY26.13 [EPA-HQ-OAR-2022-0829-0653, pp. 2-7]

13 U.S. Environmental Protection Agency, The 2022 EPA Automotive Trends Report: Greenhouse Gas Emissions, Fuel Economy, and Technology since 1975 (December 2022), 123-124.

Booming EV sales in the coming years could further strengthen industry’s compliance position entering the MY27+ program. When EPA finalized GHG standards for MY23 and beyond in 2021, it projected that automakers could meet the requirements with EV sales of approximately 17 percent in MY26.14 To the extent that manufacturers exceed that figure by MY26—and with EV sales already at approximately 8 percent in MY22, the treId is positive—the industry might enter the new regulatory window in MY27 well positioned to comply with more stringent targets.15 [EPA-HQ-OAR-2022-0829-0653, pp. 2-7]

Organization: RV Industry Association (RVIA)

RVIA strongly opposes EPA’s overreaching proposed rule for the reasons discussed below and requests the agency exclude motor homes from having to comply with the proposed medium- duty vehicle standards. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

In contradiction to this NPRM, the EPA has already proposed, in the Phase 3 GHG rule (see 88 FR 25996), to establish standards for motor homes that correctly acknowledge the reality that motor homes are not well-suited for electrification. Under the proposed Phase 3 GHG rules, the EPA would establish a CO2 standard of 226 g/mi for MY2027 and later motor homes. As discussed in the Phase 3 GHG NPRM, the agency has proposed this standard given the negative implications of electrifying the motor home chassis. To power a motor home, the batteries would take up space that is otherwise necessary for housing the various elements of a motor home. It would also add significant amounts of weight to the motor home making it no longer capable of being equipped with the components typically found in a motor home. It makes no difference whether a motor home falls under the MD/HD Phase 3 GHG rules or the LD/MD rules, the issues are the same. Standards which can only be met by battery-powered vehicles are not practicable for motor homes. EPA staff who authored the Phase 3 GHG rule have acknowledged this. In establishing standards for medium-duty vehicles within this rule, staff need to be consistent and exclude motor homes from standards that would force them to be electrified. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

Motor homes are often operated in locations where there is no electricity. This is known as "boondocking." Frequently, motor homes will be operated for weeks at a time at such locations. When motor homes are operated in a boondocking scenario, there is no possibility of EV charging. Electrification simply does not work for this operating use case. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

Unlike medium-duty vehicles that might be conveniently recharged overnight, motor homes are routinely driven 500 miles or more a day making it necessary to fully recharge mid-trip. A multi- hour charging event is simply not something the typical motor home driver would find acceptable. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

Motor homes are typically a discretionary purchase by families who tend to be very cost sensitive. Large increases in price for a vehicle that is operated on average only 20 days per year and that travels on average only 4,000 miles will not be viewed favorably by potential buyers. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

The ability to recoup higher vehicle costs through refueling savings is minimal given motor homes are driven sparingly by their owners. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

If finalized, EPA's rule will severely limit the use and affordability of motor homes. As a result, it will severely hurt motor home manufacturers, dealers, their employees and their families. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

Regarding the certification of medium-duty motor homes powered by internal combustion engines, as well as vehicles used to tow RVs, RVIA supports the concerns raised by the Alliance for Automotive Innovation in its comment letter. Such concerns include: [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

• EPA's proposed rule is neither reasonable nor achievable in the timeframe provided. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

• EPA's proposed rule is a de facto battery electric vehicle mandate. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

• EPA outstrips Biden administration's own 50 percent light-duty electrification executive order from 2021. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

• EPA underestimates battery costs and makes unrealistic battery electric vehicle (BEV) sales assumptions. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

• EPA makes no concurrent requirements to support the infrastructure and battery critical minerals for the required EVs or the drivers that must buy them. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

Organization: Scott Wilson

By now, you will have read in public comments that this proposed regulation will transform the way people have lived, worked, and played for over 100 years" (Alliance for Automotive Innovation) and "If finalized as proposed, the proposals would have a very significant impact on all segments of the fuels and vehicle industries and the entire U.S. economy" (American Petroleum Institute). While these statements are hyperbolic, the rule will indeed lead to significant changes to our vehicle fleet, spread over many years. That's the whole point. We've just begun taking the first few steps needed to eventually bring the Gasoline Age to an end. We have a long way to travel on this road. But, it's clear that the best way to achieve the emission targets, which even the Texas Public Policy Foundation acknowledges are under EPA's authority, is to take the combustion out of vehicles. [EPA-HQ-OAR-2022-0829-0515, p. 1]

The automaker's position (Alliance for Automotive Innovation) is that the proposed rule is overly-ambitious and that it requires "stepped-up efforts at the state and local level when it comes to building codes, permitting, and approval from public utility commissions". That is true, and is an ongoing effort, however, we cannot wait until the entire EV ecosystem is in place before ramping up vehicle production. Vehicles and their supporting social and physical infrastructure must develop together, hand-in-hand, just like the fuel, repair, and dealer systems did for gasoline vehicles. We would do well to learn from societies that are successfully transitioning to EVs, like Norway, and the EU more broadly. [EPA-HQ-OAR-2022-0829-0515, p. 1]

Organization: Sierra Club et al.

A strong LDV rule is technologically feasible and achievable because we are seeing dramatic cost and performance improvements in zero emission electric vehicle technology. This is bolstered by the availability of significant federal financial incentives, and affirmed by existing automaker commitments to deploy ZEV technologies and the adoption of state clean car standards across the country. A strong emissions standard can position the United States as a leader in ZEV technology development and manufacturing and create high-quality jobs. [EPA-HQ-OAR-2022-0829-0668, p. 2]

Organization: Stellantis

Electrification Rates Misaligned to Market and Exceed Commitments

Stellantis fully supports comments submitted through The Alliance for Automotive Innovation (AAI or the Auto Innovators) detailing the challenges associated with EPA's overly optimistic expectation for EV market growth. Stellantis remains steadfast to delivering on our commitments to achieve an electrified future, and we acknowledge EPA's efforts with this rulemaking to help support this difficult yet critical transition. However, the proposed rule significantly underestimates the actions needed to build the targeted EV market. Addressing concerns such as manufacturing capacity, battery production, charging infrastructure, and consumer acceptance of EVs will be paramount to the success of this ambitious proposed regulation. [EPA-HQ-OAR-2022-0829-0678, pp. 2-3]

- The Inflation Reduction Act (IRA) committed significant funds to incentivize the purchase of EVs [EPA-HQ-OAR-2022-0829-0678, pp. 3-4]

– however these incentives come with criteria that exclude many EV models today, and pending guidance from the IRS likely could exclude more in the future. [EPA-HQ-OAR-2022-0829-0678, pp. 3-4]

- The IRA also provides an incentive to produce the needed batteries helping to offset their cost – however this only applies to the U.S., ignoring the global supply chain needed to support a 40- 50% U.S. EV market. [EPA-HQ-OAR-2022-0829-0678, pp. 3-4]

Despite these major gaps, the EPA in its proposed rule incorrectly assumes these policy actions represent a complete answer to achieve a 40-50% market. EPA's proposed rule extends even further by assuming a "perfect" transition to a battery electric vehicle (BEV) only market at 60% in 2030MY – exceeding the commitment made to President Biden, the Administration's National Blueprint for Transport Decarbonization, and the Stellantis Dare Forward commitment. [EPA-HQ-OAR-2022-0829-0678, pp. 3-4]

These EV penetrations are greater than those of the most mature and forward leaning EV markets in the U.S. Figure 1 below summarizes the electrification rates projected by the EPA proposed rule against the penetration rates required in California's ZEV mandate as part of their recent Advanced Clean Cars II (ACC II) program. California, the most mature EV market in the U.S., will require at least 34% BEVs in 2027, increasing to 54% in 2030, and reaching 66% in 2032. EPA's proposed rule exceeds these California rates in every year from 2027-2032 and by as much as 6% in 2030. [EPA-HQ-OAR-2022-0829-0678, pp. 3-4]

SEE ORIGINAL COMMENT FOR TABLE Industry Average Electrification Rates Figure 1- EV Requirements of EPA NPRM vs. CARB ZEV Mandate and Biden Executive Order [EPA-HQ-OAR-2022-0829-0678, pp. 3-4]

EPA projects BEV rates that exceed Biden EO and the penetration of California's ZEV mandate [EPA-HQ-OAR-2022-0829-0678, p. 4]

Overly optimistic EV penetration assumptions are especially evident in the high-capability pickup segment as shown in Figure 2 below. EPA projects a 60% BEV penetration of pickup trucks by 2032MY, completely ignoring the market benefit of plug-in hybrid electric vehicle (PHEV), while assuming an "ideal" transition to BEVs despite the technology challenges to maintain range while providing the towing and hauling capabilities of today's ICE trucks. [EPA-HQ-OAR-2022-0829-0678, p. 4]

SEE ORIGINAL COMMENT FOR NPRM Share of Light-Duty Pickups that are BEV* Figure 2- Pickup truck BEV penetration of the proposed rule [EPA-HQ-OAR-2022-0829-0678, p. 4]

Stellantis supports Auto Innovators' comments recommending that EPA take a less optimistic approach in applying IRA incentives incorporating a more realistic price influence on future EV market projections. [EPA-HQ-OAR-2022-0829-0678, pp. 5-6]

This incredibly aggressive assumption for BEV adoption is faster than any new automotive technology to date, even exceeding the adoption rate targeted by California (the most mature EV market in the U.S.). This adoption rate far exceeds what is supported by the policy actions in place and adds significant risk to the automotive industry who must comply with these standards whether these assumptions hold true or not. [EPA-HQ-OAR-2022-0829-0678, pp. 5-6]

12 Stellantis supports the concerns the Auto Innovators raise that the NPRM mandates a very aggressive ramp-up in BEV sales and forces new technology at unprecedented levels in an expedited timeframe such that it may go beyond what is technically feasible, contrary to

section 202 of the Clean Air Act (CAA).4 The stringency of the proposed standards for greenhouse gas (GHG) emissions and criteria pollutants, as well as its restrictions on credit programs and other flexibilities, all would force automakers to convert to BEV fleets on a massive scale. In short, there is concern that the NPRM is seeking a transformative shift to electrification beyond what is feasible for the industry or market to bear – and beyond what Congress has provided. [EPA-HQ-OAR-20-0829-0678, p. 6]

4 42 U.S.C. §7521.

Stellantis also supports the Auto Innovators' concerns raised regarding the proposed rule's reliance on the BIL and the IRA to support the Agency's feasibility determination. In particular, EPA's reliance on these statutes as proposed to support projected BEV infrastructure, battery production and consumer demand, may be speculative and therefore call into question EPA's feasibility determination. [EPA-HQ-OAR-2022-0829-0678, p. 6]Criteria Emissions Requirements are Infeasible & Distract from Electrification

Separate from the proposed GHG standards, EPA is proposing dramatic criteria emission reductions. Left unchanged, these reductions will force OEMs to divert engineering and financial resources from our march to electrification and refocus those resources on improvements to our shrinking ICE fleet. The rationale for these proposed actions now is difficult to fathom. EV technology greatly reduces or eliminates criteria emissions – and Stellantis has committed to 50% EV technology by 2030. EPA actions exceed aggressive CARB ACCII LEV IV requirements that could provide a large benefit over EPA's existing criteria standards (e.g., CARB PM standards are a 10-fold improvement over current EPA standards) while still maintaining an EV-focused plan. Below are the most critical changes EPA is proposing. [EPA-HQ-OAR-2022-0829-0678, p. 15]

EPA should maintain previously defined EV Multipliers

EPA is proposing to end advanced technology (BEV, FCEV, and PHEV) multipliers for medium-duty vehicles in 2027MY, one year earlier than scheduled. The agency also seeks comment on reducing the magnitude of the multipliers for 2025-26MY. Aligned with Auto Innovators, Stellantis does not believe the advanced technology credit multipliers should be adjusted or reduced in the 2025-27MY timeframe. The Phase 2 rule was finalized in 2016, and [redacted text.] We believe the proposal to change or end advanced technology multipliers in the 2025-27MY does not provide sufficient lead time as required by the Clean Air Act. [EPA-HQ-OAR-2022-0829-0678, p. 22]

Recommendations and Conclusion

The standards proposed in the 2027-2032MY Multi-pollutant NPRM represent a focus on electrification of the automotive market that directionally Stellantis supports. However, the rate at which EPA has projected this transition far exceeds the ambitious targets the Biden administration and industry jointly agreed to, and even exceeds penetrations of the most mature EV markets in the U.S. The EPA bases these EV penetrations on an overly optimistic outcome of policy actions that represent only a fraction of what is needed to support a mature EV market. EPA compounds these errors by removing compliance flexibilities that have successfully incentivized proliferation of GHG saving technologies throughout the fleet. [EPA-HQ-OAR-2022-0829-0678, pp. 23-24]

Organization: Tesla, Inc.

Given the acceleration of public health and welfare impacts associated with climate change, it is incumbent upon the EPA to recognize the crucial role battery electric vehicle (BEV) technology plays today and how widespread commercial availability of BEVs in the U.S. today should inform the implementation of a more stringent finalized standard as part of this rulemaking. In designing new standards that increasingly depend upon achieving reductions of tailpipe conventional criteria pollutant emissions and ever-enhanced efficiency to reduce greenhouse gas emissions, it is fully appropriate for the agency to recognize that while the industry may be nearing the limits of incumbent internal comb–tion technologies -- or those additional gains may occur at ever greater costs per gram of –llutant reduction -- alternative technologies are increasingly available with competitive cost and performance capabilities. [EPA-HQ-OAR-2022-0829-0792, p. 1]

As provided below, the rapid pace of light-duty vehicle electrification strongly supports efforts to address the significant public health and community impacts of air pollution associated with the current light-duty vehicle fleet. This transformative technology has been amply demonstrated, is being rapidly deployed, and has significantly decreasing competitive costs. Tesla believes it is essential for EPA to establish stringent longer-term light-duty multi-pollutant emission standards that actively embrace a more rapid transition to BEVs. Such standards are well within EPA’s long-standing and well- established authority and are compelled by the record before the agency. Accordingly, Tesla encourages the agency to finalize multi-pollutant light-duty standards that are more stringent than the preferred proposed emission reduction standards. [EPA-HQ-OAR-2022-0829-0792, p. 1]

A number of studies show that the light-duty sector must rapidly decarbonize beginning this decade to meet the U.S. commitments. Further, the need for the rapid deployment of light-duty BEVs is even more critical given the lengthening time it takes to turn over the light-duty fleet. Currently, the average age of light-duty vehicles on the road in the U.S. is now at an all-time high of 12.5 years compared to two decades ago when the average age was 9.7 years.58 To meet the goal of limiting global warming for below 1.5 degrees C the passenger fleet must primarily be composed of BEVs by 2050.59 Given the aging vehicle fleet, this requires vehicles sales consisting of 100% BEVs in the early 2030s.60 Other studies have similarly highlighted BEV sales need to reach 95% by 2035 to meet the 1.5 degree C target.61 Still others have found that in order to meet net-zero emission by 2050 60% of vehicle sales must be BEVs in 2030 with no new ICE vehicle sales occurring after 2035.62 [EPA-HQ-OAR-2022-0829-0792, p. 9]

In general, EPA appropriately recognizes the acceleration of electrification technology being developed and deployed throughout the auto industry.75 Indeed, the agency points toward the numerous manufacturer statements announcing BEV production goals that encompass the timeframe of the proposed standard. These announcements have continued to expand during the process of this rulemaking with Toyota, Hyundai, JLR, and Subaru, among others, announcing new commitments on BEVs.76 Correctly, EPA utilizes these public commitments in its analysis of the industry, and they reflect manufacturers' ability to meet stringent multi- pollutant emissions standards.77 [EPA-HQ-OAR-2022-0829-0792, pp. 11-12]

77 See generally, BNEF, Zero Emission Vehicle Factbook: A BloombergNEF Special Report for COP 27 (Nov. 2022) (finding automakers have collectively committed to sell around 43 million EVs per year by 2030, and automakers with planned phase-outs of combustion engines now account for 30% of the global auto market.) available at h ttps://assets.bbhub.io/professional/sites/24/2022-COP27-ZEV-T ransition_Factbook.pdf?utm_source=newsletter&utm_medium=email&utm_campaign=newsletter_axiosgenerate&stream =top. It should be note that even this figure from less than a year ago is already outdated.

Nonetheless, EPA's proposed standards are set at a level less stringent than the depth and pace of electrification technology deployment that has already occurred and will be accelerated through market forces and numerous other state and federal policies. BEV deployment, like other technologies, will follow a S curve leading to a much more rapid pace of adoption between now and when the proposed regulations take hold. Indeed, many manufacturers have rapidly placed innovative technology across major portions of their new vehicle offerings in only a few model years.78 BEV technology will continue to follow similar paths, and deployment has already been shown to outperform the traditional S curve.79 [EPA-HQ-OAR-2022-0829-0792, p. 12]

78 See e.g., Hula, et al, Analysis of Technology Adoption Rates in New Vehicles, SAE International (April 1, 2014) available at h ttps://www.epa.gov/sites/default/files/2016-10/documents/2014-01-0781_0.pdf

As EPA recognizes, “zero and near-zero emission technologies are more feasible and cost-effective now than at the time of prior rulemakings.”87. To address this Tesla has been a leader in reducing the costs of high- performance BEVs. A Tesla Model 3’s starting price is $40,240 and, inclusive of individual qualification with the current U.S. 30D tax credit, can reach an equivalent price of $32,740.88 As recently reported, the Model 3 sells for now sells for $4,930 less than the average new vehicle sold in the U.S.89 Tesla has further outlined a pathway to reducing the production cost of its next generation vehicle by 50%.90 As evidenced by the popularity of its Model Y and Model 3 vehicles, Tesla has also demonstrated that increases in production volumes can reduce BEV costs to levels favoring them in the marketplace and facilitating broad consumer acceptance.91 [EPA-HQ-OAR-2022-0829-0792, p. 13]

Furthermore, the time frames for which these standards are being now proposed and will be set are ones that are perfectly appropriate under the Act. As we have repeatedly noted in comments to the Agency, auto manufacturers have acknowledged that, “integrating technologies that improve fuel economy across multiple product lines requires several years of lead time and a substantial investment of capital and engineering resources.”141 Further, “once a vehicle redesign incorporating a new vehicle technology is planned, [i]t takes a significant amount of time to retool a factory and smoothly validate the tooling and processes to mass produce a replacement technology.”142 It is critical that the rules be set now, which will provide the regulatory certainty that companies need to make these investments. [EPA-HQ-OAR-2022-0829-0792, p. 23]

141 Brief of the Association of Global Automakers and the Alliance Of Automobile Manufacturers in Opposition, Coalition for Responsible Regulation v. EPA, No. 12-1253 (Sup, Ct,, July 22, 2013) at 4 available at h ttp://www.edf.org/sites/default/files/12-1253-Brief-in-Opposition-Auto-Manufacturers.pdf.

142 Id., at 5, quoting 75 Fed. Reg. 25324, 25468.

Consistent with this approach, EPA appropriately states “While standards promulgated pursuant to CAA section 202(a) are based on application of technology, the statute does not specify a particular technology or technologies that must be used to set such standards; rather, Congress has authorized and directed EPA to adapt its standards to emerging technologies.”146 Furthermore, as the agency recognizes, “This forward-looking regulatory approach keeps pace with real-world technological developments and comports with Congressional intent.”147 [EPA-HQ-OAR-2022-0829-0792, p. 23]

146 88 Fed. Reg. at 29187 (emphasis added).

147 Id., at 29232.

Lead Time and Rapid Deployment Mean Other Factors Are Not Barriers to More Stringent Standards

While Section 202(a) directs the agency to have the proposed emission standards take effect after such period found necessary to permit the development and application of the requisite technology, these considerations must take place under the same technology forcing context utilized in assessing the vehicle technology. Under this rubric, any assessment of BEV charging infrastructure adequacy should not, based upon the extensive record available to the agency, dampen the agency’s move forward with a more a stringent standard. First and foremost, all levels of light-duty BEV charging utilize proven and demonstrably effective technology that have been applied for years. Second, economics dictate that increased build out of charging infrastructure follows deployment of BEVs, as without adequate vehicles on the road investment in such infrastructure risks becoming a stranded asset. Third, new charging technologies and solutions will continue to develop.183 [EPA-HQ-OAR-2022-0829-0792, pp. 29-30]

183 See, S&P Global, EV Chargers: How many do we need? (Jan. 9, 2023) (discussing battery swapping, wireless charging, and increased deployment of DC wallbox solutions) available at h ttps://press.spglobal.com/2023-01-09-EV-Chargers-How-m any-do-we-need

Organization: Toyota Motor North America, Inc.

2. The annual stringency increases in the first three years of the proposed rule are extreme and outside historical norms. EPA has historically recognized that technology penetration is slower in early stages of market development and increases more rapidly over time. The proposed early ramp rates run directly contrary to this reality. We are also concerned that this extreme rate may have a paradoxical effect on CO_2 emissions – lowering the volume of older, higher polluting vehicles replaced because artificial shortages will be created of low- carbon non-BEV vehicles that many customers prefer. Automakers need time to invest in EV and battery production capacity, for the charging infrastructure to develop across the country, and for the market to mature. To reduce carbon dioxide emissions as much as possible, as soon as possible, customers need choices that encourage replacement of high-CO_2 emitting vehicles with low- or zero- CO_2 emitting vehicles. EPA should smooth the early rates of increase in recognition of these factors. [EPA-HQ-OAR-2022-0829-0620, p. 2]

1. Overview

When President Biden issued Executive Order 14037 in 2021 calling for 50% electrified vehicles (defined then as battery electrics (BEVs), plug-in hybrids (PHEVs) and fuel cell hybrid electrics (FCHVs), Toyota publicly committed to making every effort to achieve those targets. However, the Proposed Rule would force about 60% BEVs alone by 2030, and 67% by 2032. This significantly moves the goal line on electrification and is paramount to a BEV mandate on an incredibly aggressive timeline. Taken separately, the proposed GHG standards and the proposed tailpipe/criteria standards each attempts to steer the future toward a BEV-only vehicle market. Together they do that and impose significant costs on internal combustion engine (ICE) vehicles currently accounting for about 94% of the new vehicle market. Toyota shares the administration's goal to decarbonize transportation, but believes the Proposed Rule requires significant adjustments. [EPA-HQ-OAR-2022-0829-0620, p. 8]

Data show that a portfolio approach to electrification which includes the technologies above plus hybrid electrics (HEVs), provides the same or greater carbon reductions as an approach that focuses exclusively on BEVs. A portfolio approach utilizing scarce critical minerals in the most effective manner to remove more traditional ICE vehicles from the road more quickly. It also provides consumers with more carbon-reducing options that fit their lifestyles and purchasing power. [EPA-HQ-OAR-2022-0829-0620, p. 8]

The Proposed Rule also for the first time imposes standards on automakers for which compliance requires significant actions by third parties over which we (or EPA) have no control. First, achieving the level of BEVs required by the Proposed Rule will require massive new supplies of critical minerals, the mines to extract them, and the refining facilities to turn ore into battery-grade material. Currently, virtually the entire mineral and battery supply chain is outside the U.S. Second, it requires massive investments in home and public charging infrastructure, as well as upgrades to the electrical grid throughout the U.S. and an accelerated shift to renewable power generation. Various provisions of the IIJA and IRA directionally support some of these areas but fall significantly short of what will be needed for the expected level of electrification. And finally, the ultimate impact of these factors on vehicle costs and consumer demand are unclear, at best. The are few contingencies for automakers and our customers in the event any or all these factors stand in the way of complying with the Proposed Rule. Our comments below address these and other issues. [EPA-HQ-OAR-2022-0829-0620, pp. 8-9]

We are prepared to follow up with additional information beyond these comments. We look forward to collaborating toward a more workable Final Rule. [EPA-HQ-OAR-2022-0829-0620, pp. 8-9]

5. GHG Program

The Proposed Rule fails to demonstrate the penetration of BEVs assumed for compliance with the proposed standards is feasible. The proposal notes "While emission standards set by the EPA under CAA section 202(a)(1) generally do not mandate use of particular technologies, they are technology-based, as the levels chosen must be premised on a finding of technological feasibility."17 CAA section 202(a)(1) states "Any regulation prescribed under paragraph (1) of this subsection (and any revision thereof) shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period."18 [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

17 88 Fed. Reg at 29232.

18 42 U.S.C. § 7521(a)(2).

The aggressive ramp up of BEVs (see Table 1) required to comply forces a rapid transformation of how vehicles are manufactured, driven, fueled, and serviced. As such, “leadtime and requisite technology” must extend to the availability of critical minerals, the readiness of a sustainable battery supply chain and fueling infrastructure, as well as other market-related factors that will affect the price and consumer demand of BEVs. [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

[Table 1 Annual BEV Penetration Assume for Compliance w/ Proposed Standards

MY 2027: BEV Share 36

MY 2028: BEV Share 45

MY 2029: BEV Share 55

MY 2030: BEV Share 60

MY 2031: BEV Share 63

MY 2032: BEV Share 67]

[EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

Today’s PEV support system clearly cannot meet the needs of the future envisioned by the proposal. Our comments explain why the proposal lacks a clear justification for how the support system will be in place over the period of the proposed standards. Neither EPA nor auto manufactures can control the timing or outcomes of these essential support measures. [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

Therefore, it is disappointing that EPA removed the e-RIN proposal from the RFS set rule as it is one of the few measures for which EPA has direct authority to provide at least some level of assistance in supporting the EV shares required in the GHG proposal. After a muti-year collaboration with the auto industry, a valuable policy tool for establishing PEV markets and promoting clean energy has been lost. [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

Finally, EPA has taken a more measured view of technology risk and uncertainty in past vehicle emissions rulemakings in which technology costs were lower and automakers had significantly more direct control over managing their technology development, deployment, and sales mix to comply. In this Proposed Rule, EPA appears to be taking a much more cavalier approach to risk, lead time, and ensuring the “requisite technology” is available, despite the high cost of BEVs, the massive uncertainty around mineral supplies, the significant investment needed in charging infrastructure and the power grid, and the uncertain market demand for BEVs. The standards in the Final Rule should be adjusted to better account for market uncertainties. [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

5.1. Annual Stringency Increase

The greatest rate of emissions reductions is required over the first three years of the proposed standards with annual rates of improvement is as high as 16% (compared to a maximum of 12%

annual rate over the final three years) (see Figure 8). This front-loaded stringency runs contrary to the longstanding recognition that technology penetration is slower in early stages of market development and accelerates with continuous refinements and growing consumer awareness and acceptance. The situation is made worse by the BEV-forcing nature of the proposal and the requisite need to establish battery supply chains, production capacity, and charging infrastructure. [EPA-HQ-OAR-2022-0829-0620, pp. 26-27]

[See original for graphs, Figure 8 Required PEV Growth Versus Infrastructure Ramp Up] [EPA-HQ-OAR-2022-0829-0620, pp. 26-27]

Organization: Valero Energy Corporation

II. EPA unreasonably relies on unreliable information and speculation to conclude that the proposed rule is feasible.

EPA cites to numerous sources in support of the feasibility of its proposal, such as the proposition that many OEMs have announced investments in ZEV technologies and have released projections for additional makes and models of LD ZEVs. However, EPA does not account for the fact that these projections are contingent on a multitude of best-case assumptions and market factors that EPA's own sources caveat heavily. Although EPA could have obtained specific data and credible information regarding manufacturers' investments and capabilities and infrastructure buildout, EPA chose not to do so. By cherry-picking headlines that appear to support the Administration's policy objectives, meanwhile disregarding material assumptions and contingencies outside the control of regulators and OEMs alike that are relevant to its analysis, EPA unreasonably relies on optimistic projections that have no basis in actual fact while overlooking the large body of credible evidence that strongly indicates that EPA's proposed standards are infeasible. [EPA-HQ-OAR-2022-0829-0707, p. 18]

This approach is inexplicably at odds with the approach EPA takes in the recently announced "RFS Set" rule, in which EPA expressly declined to rely upon fuel producers' announcements of anticipated renewable diesel production capacity in establishing the renewable fuel volumes for 2023-2025.91 Consequently, EPA's proposed rule is unsupported, arbitrary, and exceeds EPA's statutory authority. [EPA-HQ-OAR-2022-0829-0707, p. 18]

91 Renewable Fuels Standard (RFS) Program: Standards for 2023-2025 and Other Changes, announced June 21, 2023, pre-publication version available at https://www.epa.gov/renewable-fuel-standard-program/final-renewable- fuels-standards-rule-and-2025.

B. EPA disregards caveats regarding ZEV production capabilities.

EPA cites to "[a] proliferation of announcements by automakers in the past two years[,] signal[ing] a rapidly growing shift in product development focus among automakers away from internal-combustion technologies and toward electrification."118 Drawing support from these announcements, EPA concludes that it is feasible within the next decade to force transition of the domestic LDV fleet to BEV largely on the basis of third-hand sources and news articles taken out of context. Though EPA acknowledges in passing that "manufacturer announcements such as these are not binding, and often are conditioned as forward-looking and subject to uncertainty[,]"119, EPA's proposed rule is not characterized by any reciprocal flexibilities to adjust ambitious targets in order to accommodate material realities and uncertainties impacting BEV production. In contrast to EPA's projections, the same OEMs EPA cites to for support of the Proposed Rule have raised material concerns with an accelerated transition to LD BEVs. [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

118 EPA's Proposed Rule at 29190.

119 EPA's Proposed Rule at 29193.

For example, EPA cites to a May 2021 announcement from Ford, providing that "they expect 40 percent of their global sales will be all-electric by 2030."120 However, the Ford press release EPA cites to also contains the following laundry list of caveats:121 [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

120 EPA's Proposed Rule at 29190 (citing to Ford Motor Company, ''Superior Value From EVs, Commercial Business, Connected Services is Strategic Focus of Today's 'Delivering Ford+' Capital Markets Day,'' Press Release, May 26, 2021).

"Cautionary Note on Forward-Looking Statements

Statements included or incorporated by reference herein may constitute 'forward- looking statements' within the meaning of the Private Securities Litigation Reform Act of 1995. Forward-looking statements are based on expectations, forecasts, and assumptions by our management and involve a number of risks, uncertainties, and other factors that could cause actual results to differ materially from those stated, including, without limitation: [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford and Ford Credit's financial condition and results of operations have been and may continue to be adversely affected by public health issues, including epidemics or pandemics such as COVID-19; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford is highly dependent on its suppliers to deliver components in accordance with Ford's production schedule, and a shortage of key components, such as semiconductors, can disrupt Ford's production of vehicles; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford's long-term competitiveness depends on the successful execution of its Plan;

- Ford's vehicles could be affected by defects that result in delays in new model launches, recall campaigns, or increased warranty costs; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford may not realize the anticipated benefits of existing or pending strategic alliances, joint ventures, acquisitions, divestitures, or new business strategies; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Operational systems, security systems, and vehicles could be affected by cyber incidents and other disruptions; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford's production, as well as Ford's suppliers' production, could be disrupted by labor issues, natural or man-made disasters, financial distress, production difficulties, or other factors; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford's ability to maintain a competitive cost structure could be affected by labor or other constraints; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford's ability to attract and retain talented, diverse, and highly skilled employees is critical to its success and competitiveness; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford's new and existing products and mobility services are subject to market acceptance and face significant competition from existing and new entrants in the automotive and mobility industries; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford's results are dependent on sales of larger, more profitable vehicles, particularly in the United States; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- With a global footprint, Ford's results could be adversely affected by economic, geopolitical, protectionist trade policies, or other events, including tariffs; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Industry sales volume in any of Ford's key markets can be volatile and could decline if there is a financial crisis, recession, or significant geopolitical event; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford may face increased price competition or a reduction in demand for its products resulting from industry excess capacity, currency fluctuations, competitive actions, or other factors; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Fluctuations in commodity prices, foreign currency exchange rates, interest rates, and market value of Ford or Ford Credit's investments can have a significant effect on results; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford and Ford Credit's access to debt, securitization, or derivative markets around the world at competitive rates or in sufficient amounts could be affected by credit rating downgrades, market volatility, market disruption, regulatory requirements, or other factors; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford's receipt of government incentives could be subject to reduction, termination, or clawback; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford Credit could experience higher-than-expected credit losses, lower-than-anticipated residual values, or higher-than-expected return volumes for leased vehicles; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Economic and demographic experience for pension and other postretirement benefit plans (e.g., discount rates or investment returns) could be worse than Ford has assumed; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Pension and other postretirement liabilities could adversely affect Ford's liquidity and financial condition; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford could experience unusual or significant litigation, governmental investigations, or adverse publicity arising out of alleged defects in products, perceived environmental impacts, or otherwise; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

• Ford may need to substantially modify its product plans to comply with safety, emissions, fuel economy, autonomous vehicle, and other regulations; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

• Ford and Ford Credit could be affected by the continued development of more stringent privacy, data use, and data protection laws and regulations as well as consumers' heightened expectations to safeguard their personal information; and [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

• Ford Credit could be subject to new or increased credit regulations, consumer protection regulations, or other regulations. [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

• We cannot be certain that any expectation, forecast, or assumption made in preparing forward-looking statements will prove accurate, or that any projection will be realized. It is to be expected that there may be differences between projected and actual results. Our forward-looking statements speak only as of the date of their initial issuance, and we do not undertake any obligation to update or revise publicly any forward-looking statement, whether as a result of new information, future events, or otherwise. For additional discussion, see "Item 1A. Risk Factors" in our Annual Report on Form 10-K for the year ended December 31, 2020, as updated by subsequent Quarterly Reports on Form 10-Q and Current Reports on Form 8-K." [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

Moreover, in March 2023, figures released by Ford highlighted that Ford Motor Co.'s EV business had lost $3 billion before taxes during the past two years and will lose a similar amount this year as the company invests heavily in EV technology.122 Ford's 10-K filed in February 2023 further disclosed: [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

122 Krishner, Tom, Associated Press, "Ford's electricitv vehicle unit losing billions, as company invests in new technolo23, 2023), https://www.pbs.org/newshour/economy/fords-electric-vehicle-unit-losing-billions-as-company-invests-in-new-technology; see also Ford News Release, "'Refounded' Ford to Show How Customer-Focused Segments Will Drive Value and Growth, Changes in Financial Repor3, 2023) https://media.ford.com/content/fordmedia/fna/us/en/news/2023/03/23/_refounded_-ford-to-show-how-customer-focused-segments-will-driv.html.

• "We have announced plans to significantly increase our electric vehicle production volumes; however, our ability to produce higher volumes of electric vehicles is dependent upon the availability of raw materials necessary for the production of batteries, e.g., lithium, cobalt, nickel, graphite, and manganese, among others."123 [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

123 Ford 10-K Annual 3) https://shareholder.ford.com/Investors/financials/sec-filings/sec-filings-details/default.aspx?FilingId=16361873 (emphasis added).

• "As a result of the competition for and limited availability of the raw materials needed for our electric vehicle business, the costs of such materials are difficult to accurately forecast as they may fluctuate during the term of the offtake agreements and other long-term purchase contracts based on market conditions. Accordingly, we may be subject to increases in the prices we pay for those raw materials, and our ability to recoup such costs through increased pricing to our customers may be limited. As a result, our margins, results of operations, financial condition, and reputation may be adversely impacted by commitments we make pursuant to offtake agreements and other long-term purchase contracts."124 [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

124 Ford 10-K Annual 3) https://shareholder.ford.com/Investors/financials/sec-filings/sec-filings-details/default.aspx?FilingId=16361873 (emphasis added).

III. EPA fails to adequately consider important aspects and consequences of the proposed rule.

EPA's claims in the preamble seeking to distance itself from the policy directives established by the Biden Administration in Executive Order 14037 are belied by the numerous specific instances in the preamble in which EPA assumes without serious, critical, and independent analysis that the LMD vehicle fleet should be forced to transition to BEV and FCEV technologies. In its haste to fulfill the Administration's predetermined policy objectives, EPA fails to adequately consider important aspects of the rule and overlooks significant impacts and consequences that will inevitably result if the rule is adopted as proposed. [EPA-HQ-OAR-2022-0829-0707, p. 29]

The lack of rigor and discipline in EPA's methodology stands in stark contrast with EPA's typical approach to rulemaking and defies the general assessment factors for evaluating the quality of scientific and technical information that the Science Policy Council (SPC) has issued.140 In particular, this rulemaking does not have the hallmarks of the "weight-of-evidence" approach which "considers all relevant information in an integrative assessment that takes into account the kinds of evidence available, the quality and quantity of the evidence, the strengths and limitations associated with each type of evidence."141 Nor does this proposal comport with the Action Development Process outlined by EPA, which states that rules should be "based on sound scientific, economic, legal, and policy analyses" and "reflect appropriate solicitation and consideration of views outside EPA." 142 [EPA-HQ-OAR-2022-0829-0707, pp. 28-29]

140 EPA, Science Policy Council, A Summary of General Assessment Factors for Evaluating the Quality of Scientific and Technical Informationailable at https://www.epa.gov/sites/default/files/2015-01/documents/assess2.pdf.

141 Id. at p. 2.

142 EPA, Action Development Process: Guidance for EPA Staff on Developing Quality Actions (2011)lable at https://nepis.epa.gov/.

Additionally, rulemaking under the CAA almost always starts with EPA gathering and analyzing relevant information from various sources included regulated entities and other impacted entities and suppliers of controls. EPA could have requested information from vehicle manufacturers, battery manufacturers, mineral suppliers, auto dealers, insurance carriers, consumer organizations, small businesses, and others in order to obtain credible, verifiable, and standardized information in order to support a thoughtful and critical analysis of its projections regarding vehicle availability, purchase costs, battery availability, battery performance, charging infrastructure availability and performance, and other aspects of this proposal. EPA should not rely on self-serving OEM announcements as a shortcut to using its authority to gather data and complete analysis for an action with vast economic consequences. [EPA-HQ-OAR-2022-0829-0707, pp. 28-29]

2. The statutory structure of the Clean Air Act further confirms that EPA is not authorized to mandate the sale of ZEVs.

i. The statutory structure confirms Congress' focus on technologically achievable emission controls.

Several provisions of Section 202 of the Clean Air Act confirm that Congress focused on technologically feasible standards for vehicles deemed to emit pollutants that actually cause or contribute to pollution. Section 202(a)(2) requires EPA to provide manufacturers with lead time to comply with the " standards, in order "to permit the development and application of requisite technology." 42 U.S.C. § 7521(a)(2). Similarly, Section 202(a)(3)(A)(i) provides that EPA's HDV standards for certain criteria pollutants should reflect the "greatest degree of emission reduction achievable through the application of technology which the [EPA] determines will be available" during the relevant model year. Id. § 7521(a)(3)(A)(i). Those provisions contemplate that technological feasibility will meaningfully constrain the emission standards that EPA sets under Section 202(a). EPA cannot ignore technological feasibility and simply decide to require production of fewer internal combustion vehicles. [EPA-HQ-OAR-2022-0829-0707, p. 78]

Other provisions show the type of "technology" that Congress contemplated vehicle manufacturers would develop to meet those standards. Section 202(m) requires EPA to command manufacturers to install on "all" new light-duty vehicles and trucks "diagnostic systems" that identify "emission-related systems deterioration or malfunction ... which could ... result in failure of the vehicles to comply with emission standards established under this section." 42 U.S.C. § 7521(m)(l). The required diagnostic systems must monitor, "at a minimum, the catalytic converter and oxygen sensor." Id. [EPA-HQ-OAR-2022-0829-0707, p. 78]

In other words, to ensure compliance with emission standards under Section 202(a), Congress required "emissions-related systems" and accompanying "diagnostic systems" on each vehicle—again underscoring Congress's view that the vehicles subject to an emission standard actually emit the relevant pollutant in EPA's judgment. [EPA-HQ-OAR-2022-0829-0707, p. 78]

As the statutory structure demonstrates, EPA may set standards that are "technology-forcing," because they require manufacturers to adopt nascent technology that may not yet be "adequately demonstrated." NRDC, 805 F .2d at 419. EPA's rules thus have promoted the development of "automotive technologies, such as on-board computers and fuel injection systems" that improve emissions from combustion engines. 86 Fed. Reg. at 74,451. But the statute does not permit what EPA proposes here: enacting "average" standards divorced from technologically achievable limits on emitting vehicles, which instead force manufacturers to produce a different type of supposedly non-emitting vehicle altogether. [EPA-HQ-OAR-2022-0829-0707, p. 78]

Organization: Volkswagen Group of America, Inc.

Ambitious and Stringent Standards Proposed

EPA's NPRM proposes historically ambitious and stringent targets towards carbon neutrality for the light-duty and medium-duty transportation sector. Significantly noted by AFAI, the automotive industry is committing resources and investments of $1.2 trillion by 2030, while Volkswagen estimates our worldwide digitalization and electrification investment around $130 billion1 between 2023 and 2027. The ambition must be met equally by commitment of segments outside the automotive Industry. [EPA-HQ-OAR-2022-0829-0669, p. 2]

1 120 Billion Euro; Exchange rate: 1.09 USD to 1 EUR

To that end, Volkswagen supports continuous reductions in vehicle fleet average GHG emissions and criteria pollutants. Volkswagen is committed to work with U.S. agencies, utilities, charging infrastructure providers, raw material suppliers and additional stakeholders in partnership with AFAI on reasonable and achievable pathways for all manufacturers for 2027 and beyond. Sustained, complementary and supportive policy is paramount in forming a cross-sector foundation required to scale up growth and infrastructure. To achieve the shared vision of zero emission mobility, solutions must be instituted in these sectors to allow Volkswagen to provide customers with a “People’s Car” of superior utility and affordability. [EPA-HQ-OAR-2022-0829-0669, p. 2]

Organization: Volvo Car Corporation (VCC)

Particulate Matter (PM)

For several reasons, VCC is opposed to EPA’s proposal on particulate matter. Implementing the PM requirements as proposed in the NPRM is just not feasible. The EPA proposal differs from the CARB approach on PM and it is also more stringent than ACCII. Therefore, it will cause a lot of additional burden on manufacturers that are spending most of their resources on electrification. It is not just a matter of adding the gasoline particulate filter, rather it includes substantial development and investments. Such massive hardware changes are just not possible by 2027MY. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

If CARB and EPA are not harmonized then VCC would need to have two sets of hardware in the US market, one Federal and one California + S177 states. This would be very costly for a small OEM like VCC. In 2027MY VCC will only have few engine families in production according to our current plan, but this approach would mean VCC needs to double its engine programs. In addition, VCC has already decided on a hardware technical solution that meets CARB ACCII for 2026 MY and beyond but a final EPA rule is not expected until spring 2024. So it will be very difficult to implement an EPA specific hardware technical solution in time for the 2027 MY. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

VCC’s recommendation is that EPA align with CARB with regards to PM. EPA should follow the CARB ACCII PM-regulations and the CARB phase-in plan that is already in effect. This is fully consistent with the way that CARB ACC1 (LEV III) and EPA Tier3 was synchronized in the prior set of regulations. So, there is a precedent for this approach, and given that California and 177 states make up over 40% of the US car market, this approach is efficient and consistent with those regulations already in place. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

EPA’s proposal on particulate matter would create a stringent standard that requires additional hardware which is much worse for a small OEM like VCC due to our small fleets. This means investment costs need to be split on much smaller fleets. In addition, there are major development costs which would put VCC at a significant disadvantage. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

VCC has invested substantially to upgrade our dynos used for US certification testing to the latest 1066 standard. VCC did not anticipate any further upgrades to these dynos because VCC will be all electric in 2030MY. Therefore, the EPA proposal would require upgrades for one market (USA) for only 3 model years and then VCC would discontinue the whole emission measurement system in 2030. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

The proposal would also necessitate additional test capacity and different separate tests for EPA and CARB. So, it would mean doubling the number of the tests and this would create additional administrative burden in order to implement. Increasing test cells does not happen overnight and it would likely not be feasible for VCC to get the additional test cells needed for MY 2027 testing. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

In addition to separate tests, the EPA proposal differs from CARB requirements on emission and OBD certifications. If CARB and EPA are not harmonized VCC must submit two OBD applications for each engine, one for CARB and one for EPA. Many OEMs are likely in a similar position, but the implication to small volume manufacturers is much more significant than it is to the larger OEMs. VCC encourages EPA to harmonize with CARB and not require separate EPA certifications. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

New certification and compliance programs will likely be costly, especially with new tightened criteria that is proposed. VCC believes measurement accuracy is a concern at this low level. See the section on tunnel blank PM testing contained in the Alliance for Auto Innovation comments. In addition, it is not feasible with current existing sensor technology to monitor and detect the proposed requirement of 30% efficiency (See appendix for technical comments on the OBD proposal). It is also important to note that active regeneration is very infrequent on petrol engines and happens only during extreme conditions. This would make it problematic to consistently detect frequent or incomplete regeneration (See appendix for technical comments on the OBD proposal). [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

The NPRM proposed PM standard alone would mean the few remaining HEVs in Volvo Cars' cycle plan 2027MY-2029MY would likely need new hardware to accommodate a new gasoline particulate filter (GPF). For a small manufacturer like VCC, this would be necessary for 3 years only for vehicles with short life span and it would be challenging and costly. It would result in very little environmental benefit. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

EPA should consider requiring more stringent fuel requirements which would have a more significant environmental impact at a lower cost. Although changes to fuel standards are outside the scope of this NPRM, VCC believes that fuels which contain reduced particulate formation can be utilized in today's vehicles and future vehicle fleets. This would have faster and greater environmental benefit without all the burden and investment of PM filters which would be utilized for future vehicles only. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

Rather than the EPA proposed particulate matter requirements in the NPRM, VCC strongly encourages EPA adopt the CARB PM1 Regulation and allow for a Phase-In for these requirements. This is best pathway for harmonization and will deliver environmental benefits without unnecessary additional costs. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

Organization: Western Energy Alliance

it is hard to fathom how EPA comes to that conclusion. The electric grid is in no way capable of handling the huge increase in electricity demand that the rule would require, the United States does not have access to the critical minerals required for such a high market penetration of EVs, nor is the increased wind and solar energy generation available now nor in the foreseeable future to make supposedly ZEVs actually ZEVs. EPA has failed to adequately consider the impact of this rule on grid reliability. EPA should analyze grid reliability in this rulemaking and reference the large body of work raising concerns about how increased EVs will destabilize the grid.1 Without the grid capability and the critical minerals, EPA's EPA Proposed Rule on Light-Duty Vehicle Emissions Standards July 5, 2023 statement on technical feasibility is logically flawed, as current and projected grid infrastructure cannot support the goal of the proposed rule. [EPA-HQ-OAR-2022-0829-0679, pp. 2-3]

1 For example see E lectric Vehicle Dynamic Charging Performance Characteristics during Bulk Power System D isturbances, North American Electric Grid Reliability Corp. et al., April 2023; T estimony of Federal Energy Regulatory Commissioners Willie Phillips, Mark Christie, and James Danly before the Senate Energy & Natural Resources Committee, May 4, 2023, warning: "We face unprecedented challenges to the reliability of our nation's electric system."…the U.S. electric grid is "heading for a very catastrophic situation in terms of reliability…" and there is a "looming reliability crisis in our electricity markets."

EPA must reconsider its analysis on technical feasibility by considering a full range of data on grid reliability. The Rapid Energy Policy Evaluation and Analysis Toolkit Domestic, a project of Princeton University, projects electricity demand would need to increase 18% by 2030 and 38% by 2035 to meet the president's EV goals.2 Many are warning of the lack of infrastructure to support the EV goals. The nation would need to spend $20 billion to $30 billion annually on new transmission lines for the increased demand, but is spending next to nothing.3 [EPA-HQ-OAR-2022-0829-0679, p. 3]

2 Preview: Final REPEAT Project Findings on the Emissions Impacts of the Inflation Reduction Act and Infrastructure Investment and Jobs Act, Rapid Energy Policy Evaluation and Analysis Toolkit, Princeton University, April 2023.

3 Rob Gramlich, founder and president of Grid Strategies, a transmission policy group, as quoted in "Why the electric vehicle boom could put a major strain on the U.S. power grid," CNBC, July 1, 2023.

Technical Infeasibility and Impracticalities for Consumers: EPA uses flawed analysis about the technical feasibility of the rule, but the behavior aspects are also seriously deficient. There is little evidence that EVs are being accepted by consumers other than a small niche of high-end, wealthy individuals who can afford to purchase an expensive vehicle with limited range.11 Given the long refueling times and battery drain when operating the heater or air conditioning, only those who can afford a second or third vehicle for exclusive use in-town are currently purchasing EVs. There has been no evidence to date that these problems of limited range and functionality will be overcome soon to achieve the high market penetration EPA hopes with this rule. [EPA-HQ-OAR-2022-0829-0679, p. 6]

11 The Energy Information Administration (EIA) shows that 2/3 of households with EVs have incomes over $100,000. Electrified vehicles continue to see slow growth and less use than conventional vehicles, EIA, May 2018

EPA's assertion is simply not supported by facts:

“The year-over-year growth in U.S. PEV sales suggests that an increasing share of new vehicle buyers are concluding that a PEV is the best vehicle to meet their needs. Many of the zero-emission vehicles already on the market today cost less to operate than ICE vehicles, offer improved performance and handling, have a driving range similar to that of ICE vehicles, and can be charged at a growing network of public chargers as well as at home.” (p. 29189) [EPA-HQ-OAR-2022-0829-0679, p. 6]

At only 5.8% of new vehicle sales, EVs has a long way to go to meet the targets EPA is setting of 67%, a more than ten-fold increase that is a far goal from the “increasing share of new vehicle buyers…” Further, asserting that the range is similar to an ICEV is preposterous, especially in anything less than the most favorable mild weather conditions, as EVs lose range in cold and hot weather.12 [EPA-HQ-OAR-2022-0829-0679, p. 6]

12 Winter & Cold Weather EV Range Loss in 7,000 Cars, Recurrent, December 12, 2022.

The most fuel-efficient car on the market is the Toyota Prius, but even it would not meet the proposed standards. With this proposed rule EPA is squeezing out the Prius’ successful hybrid technology. The Prius MY 2032 standard is less than half the CO_2 emissions per mile of MY 2023, which range from 155 g/mi to 179 g/mi. To comply with the proposed rule, the fleet-average CO_2 emissions of Toyotas in MY 2032 would have to be 52 to 60% lower than that of today’s Prius, forcing Toyota to rapidly increase the percentage of EVs sells, regardless of consumer choice. Clearly EPA is stepping well beyond its authority by advancing a technically infeasible rule that attempts to reshape the entire vehicle marketplace. The historical record of governments attempting to plan an entire economy or sector has not been a successful one. EPA should abandon this rule. [EPA-HQ-OAR-2022-0829-0679, pp. 6-7]

Organization: World Resources Institute (WRI)

Locking in cleaner vehicle standards, and potentially extending them through 2035 as requested by auto manufacturers, will create market stability and will give manufacturers, investors, and consumers greater confidence in the direction of the vehicle market. [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

Based on the current and growing uptake of electric vehicles, paired with public and private investments in charging, purchasing, and manufacturing from the Inflation Reduction Act and the Infrastructure Investment and Jobs Act, these standards would be achievable under the model years proposed. Public investments from recent legislation include but are not limited to: [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

- National Electric Vehicle Infrastructure Program [Link: https://www.fhwa.dot.gov/environment/nevi/]

- Electric Vehicle Tax Credit [Link: https://www.irs.gov/credits-deductions/credits-for-new-clean-vehicles-purchased-in-2023-or-after]

- Commercial Clean Vehicle Credit (45W) [Link: https://www.irs.gov/credits-deductions/commercial-clean-vehicle-credit]

- Used Clean Vehicle Credit [Link: https://www.irs.gov/credits-deductions/used-clean-vehicle-credit]

• Advanced Manufacturing Production Credit (45X) [Link: https://www.irs.gov/instructions/i7207]

[EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

Complementary policies provide incentives

By leveraging the billions of dollars in new federal investments in electric vehicle charging in the Infrastructure Investment and Jobs Act and the hundreds of millions of dollars of clean transportation incentives in the Inflation Reduction Act these standards have the potential to be the floor not the ceiling for transportation emissions reductions. [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

These policies provide unprecedented levels of public support for electric vehicles specifically including at least $83 billion of loans, grants, and tax credits that could support the production of low or zero-emission vehicles, batteries, or chargers according to a recent analysis [Link: https://www.atlasevhub.com/data_story/210-billion-of-announced-investments-in-electric-vehicle-manufacturing-headed-for-the-u-s/#_ftn4] by Atlas Public Policy. [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

Complemented by existing state policies like the Advanced Clean Trucks and Advanced Clean Fleets rules, which require manufacturers to begin selling an increasing percentage of zero-emission vehicles starting in 2024, EPA's proposed rules can help to accelerate the transition to zero-emission transportation while improving public health and reducing climate pollution. [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

Private investments are rapidly expanding supply chains and manufacturing [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

Since the passage of the Inflation Reduction Act less than one year ago, companies have announced tens of billions of dollars in renewable energy, battery, and electric vehicle projects across the country. From the announcement that Our Next Energy [Link: https://www.michiganbusiness.org/press-releases/2022/10/whitmer-announces-2000-jobs-investment-of-$1.6-billion-michigan-based-our-next-energy-builds-battery-manufacturing-campus-wayne-county/] has invested $1.6 billion in their first battery manufacturing campus in Wayne County, Michigan to the news that Hyundai Motor Group and SK On [Link: https://fortune.com/2022/12/08/hyundai-new-5-billion-electric-battery-plant-georgia-atlanta-biden-inflation-reduction-act/] are jointly investing $4-$5 billion to build electric battery plants outside of Atlanta, Georgia to BMW's [Link: https://apnews.com/article/technology-north-america-spartanburg-south-carolina-climate-and-environment-96753f092b29e0d384903591b5221f13] recent announcement of their $1.7 billion investment near Spartanburg, South Carolina in their shift to EV manufacturing there is ample evidence that recent policies are helping to drive substantial private investments. [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

These investments are leading to rapidly developing supply chains, domestic battery production capacity, and increased manufacturing which will lead to further reductions in the cost and increases in the availability of zero-emission vehicles. This market growth will continue to increase with additional supportive policies and regulations, such as these proposed rules. [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

EPA Summary and Response

EPA appreciates the comments received on the topic of the lead time needed to reduce emissions from light- and medium-duty vehicles in order to comply with the proposed GHG standards. A number of commenters shared the view that the existence of vehicle technologies for reducing GHG emissions was not in question. However, many of those same commenters objected to the pace of the standards under EPA's proposal, and specifically EPA's modeled projection of the year-over-year increases in BEV penetrations to meet the proposed standards, as well as the projected level of BEVs in MY 2032.

The feasibility of complying with GHG standards in a given future model year is closely related to the level of stringency of the standards. EPA's responses to comments on the topic of stringency/level of the GHG standards are provided in RTC Section 3.3.1. This section contains EPA responses to comments regarding the year-over-year trajectory of the ramp down of the standards, and the associated lead time available to meet the level of standards for each year – including MY 2032 when the most stringent level of standards is reached. Comments specifically related to the lead time needed to build up the PEV supply chain and secure critical materials are addressed in RTC Section 15. Comments related to the lead time needed to build out charging infrastructure and prepare electricity generation for greater numbers of PEVs are addressed in RTC Sections 17 and 18, respectively. Comments related to the rate of growth of consumer markets for light- and medium-duty vehicles are addressed in RTC Sections 13 and 14.

Various commenters (25 x '25 Alliance, AAI, AVE, ACE, AmFree, American Highway Users Alliance, BMW, Delek Holdings) asserted that the rate of ramp-up of BEV's projected through MY 2032 by EPA in the proposal does not provide sufficient lead-time for the industry and supporting developments in infrastructure, critical material supply and vehicle market. The commenters cite the NPRM's central case BEV penetration value of 67 percent in 2032, and note that value is substantially higher than today. In response, EPA does not agree that level of proposed and final standards in 2032 provides insufficient lead-time to introduce emissions-reducing technology needed to for compliance. As discussed in more detail in Preamble Section V.B, EPA's central case analysis for this final rulemaking, consistent with the NRPM analysis, considers the constraints on the ramp-up of vehicle technologies and the required lead time to introduce technologies into the new vehicle fleet. Specifically, EPA's compliance analysis accounts for the time required between vehicle redesign cycles, limits to the rate at which a manufacturer can alter its technology mix, limits to the ramp up of battery production and the availability of critical materials, and limits related to consumer acceptance as described in Chapters 2.6 and 4 of the RIA, and Section IV.C.5 of the preamble. These explicit limits are applied along with the feasibility assessment of the available technologies, which is described in RIA Chapter 3. While EPA has concluded that the central case trajectory for compliance provides sufficient lead-time, we note that it is not necessary for every manufacturer to reach the technology penetrations that EPA has presented for the industry overall. For example, because several manufacturers already produce 100 percent PEVs, or plan to do so prior to MY 2032, remaining manufacturers will necessarily have a PEV penetration rate below the industry overall rate (assuming the industry does not overcomply as a whole). Furthermore, EPA agrees with, and would like to emphasize here a comment received from Consumer Reports that the overall industry penetration rate projected for the central case is only one of many possible feasible pathways for compliance. As discussed further in RTC Section 12.5.3, for this final rulemaking analysis EPA is presenting multiple feasible pathways for compliance, which span a wide range of technology penetrations as described in the Preamble Executive Summary, and RIA Chapter 12.

Multiple commenters (AAI, AVE, Honda) asserted that the EPA's lead-time assessment for the NPRM was based on various optimistic assumptions and that the increase in vehicle electrification projected in the central analysis by 2032 was infeasible. AAI asserted that EPA effectively assumed that "that everything will go perfectly in the transformation to electric vehicles between now and 2032", while Honda commented that "a missed target in any one of these areas has significant potential to derail… the compliance status of regulated parties." EPA does not agree that the determination of compliance lead time and feasibility in the NPRM, or for these final standards, is based on assumptions that either overly optimistic or overly pessimistic. Instead, EPA's central case assumptions are derived using central estimates of important trends projected into the future from the best available sources, taking into account a wide range of potential limitations. At the same time, after considering comments and updating our data with the latest available information, EPA has adjusted both some of its cost estimates, e.g. higher estimated battery costs, and the stringency of the standards, particularly in the early years.

The two key examples of battery costs and consumer acceptance illustrate the approach used by EPA. As described in RIA Chapters 12.2.1 and 4.1, EPA did not make the most optimistic assumptions, but instead chose scenarios between a high and low range of feasible scenarios. Furthermore, EPA again notes that the central analysis is only one many feasible pathways for compliance. The various sensitivities presented in RIA Chapter 12 are selected, in part, to illustrate what might happen if key assumptions do not follow the trajectories projected for the central case analysis. These sensitivity results demonstrate that there is sufficient lead time for manufacturers to comply with these final standards using alternative pathways that reflect different combinations of compliance strategies and market conditions.

AAI, BMW, and Toyota raised a concern that the proposed light-duty GHG standards are heavily front-loaded, and have greater reductions in GHG emissions in the earlier years of the 2027-2032 timeframe. These commenters noted that supply chains, infrastructure, and market for BEVs takes time to develop, and that front-loading makes it more difficult to recover if future conditions depart significantly from projections. To illustrate, AAI notes that the initial increases in car and truck stringencies between MYs 2026 and 2027 are 12 percent and 21 percent, respectively, noting that the truck increase is significantly more than for cars. BMW noted the increase in EPA's projected BEV market share for the light-duty truck regulatory class from MY 2026 to MY 2027. Other commenters asserted that the proposed standards provided an appropriate ramp up in stringency from 2027 onward. CALSTART commented in support of the front-loaded ramp up of the proposed standards, and stated that the market would be prepared to support the proposal's Alternative 1. Overall, in response to the range of comments on the trajectory of stringency increases between MYs 2027 and 2032, EPA maintains that the proposed standards are technically feasible. However, taking into account the comments expressing concern about the relatively large portion of stringency increase that occurs before MY 2030, and between MYs 2026 and 2027 in particular, EPA concludes that compared to the proposed standards, a more gradual ramp-in of GHG stringency would be appropriate. EPA is finalizing standards that are less stringent than the proposed standards for each year from 2027 through 2031. This stringency reduction is the result of changes to several program elements in this final rule compared to the proposal, including a more gradual ramp down of the footprint standard curve (i.e., Alternative 3), an extended phase-out period for off-cycle credits a ramp down of A/C credits to a non-zero value, and a delay in the transition to the revised PHEV utility factor. For 2032, the GHG footprint standard curves are the same as the proposed standards. The overall result is that compared to the proposed standards, manufacturers will be able to deploy GHG emissions reducing technology more gradually in the early years of the program. Manufacturers will also have more time take advantage of ongoing development in the consumer market and charging infrastructure for PEVs. EPA believes that collectively all of these changes from the proposal to the final rule will be adequate to address the lead time issues raised by auto manufacturers.

CARB and the California Attorney General's Office et al. commented that the proposed standards are technically feasible, and control technologies already exist to achieve compliance in the rulemaking timeframe. The California Attorney General's Office et al. also noted that EPA's modeling included a "menu of only existing technologies" to show feasible compliance pathways. These commenters generally noted also the important role that the IRA and other incentives will have in enabling the production and market adoption of vehicles equipped with emissions-reducing technology. CARB cited several market trends that support a positive feasibility assessment, including the rapid expansion of available ZEV models, increasing all-electric range, technological advancements in batteries, declining battery costs, and improved energy efficiency. EPA acknowledges and agrees with these comments. EPA further notes that our judgement of the technical feasibility of these standards is standards is not dependent on the development of new technology, but instead is based on the increased production and adoption of technologies that have already been demonstrated at scale today.

AFPM commented specifically on the lead time needed for the development of the electrical grid and charging infrastructure needed to support the levels of BEVs projected in the NPRM's central case analysis. EPA's discussion of preparedness of infrastructure is provided in RIA Chapter 5 and RTC Sections 17 and 18.

ACE, AmFree, AFPM, and Clean Fuels Development Coalition et al. commented that the non-binding commitments of automakers for future BEV production cited by EPA in the NPRM does not prove that the proposed standards are feasible. In response, EPA notes that we chose to document automaker commitments and plans as supporting evidence for our underlying feasibility assessment. We agree with the commenter that by themselves, such statements from automakers do not, by themselves, prove that the standards are feasible.

Borg Warner commented on the importance of continued support and incentives from state and federal entities and specifically cited the importance of The Infrastructure Investment and Jobs Act (IIJA), the Inflation Reduction Act (IRA), and CHIPS & Science Act. The BlueGreen Alliance provided a description of industry investments that have already been made as a result of these incentives. EPA acknowledges and appreciates comments received about the necessary investments needed to support continued GHG reductions needed, even in the absence of new GHG standards, but also as a result of the proposed and final standards for MY 2032.

The American Highway Users Alliance commented that the concurrence of new and more stringent light and medium duty rule standards together with heavy duty standards would place additional pressure on the electrical grid and charging infrastructure, and the supply of critical materials and production capacity for batteries. This issue is addressed in RTC Sections 15 and 18.

3.4 – Other

<u>Comments by Organizations</u>

Organization: Alliance for Automotive Innovation

II. Adjustments to Address EV Market Uncertainties

As demonstrated in Section I (EV feasibility) of these comments, there is a great deal of uncertainty in EPA's projections including the ability to use the various federal tax incentives, battery cost improvements, and infrastructure development. In particular, charging/refueling infrastructure and supply of critical minerals and raw materials from IRA-compliant sources are well outside the control of either EPA or automakers. We understand EPA must use projections in its modeling. But with all of the uncertainty around these items, large inaccuracies can lead to a final rule that is grossly misaligned with the market. We propose the following conceptual market-based target adjustment system to allow for year-by-year adjustments to be made within the framework of a rule that can be finalized on EPA's desired timeline and will minimize the potential need to be reopened to react to real-world market conditions. These market- based adjustments are proposed to work in conjunction with whatever combination of target stringencies and flexibilities is promulgated in a final rule. [EPA-HQ-OAR-2022-0829-0701, pp. 84-85]

A. Critical Mineral Availability

There are many different ways to attempt to measure or evaluate the supply of critical minerals and raw materials needed for battery production. We believe the simplest and most direct way is to look at the total percentage battery capacity across the entire U.S. market per model year that is able to qualify for the full $3,750 30D tax credit tied to extracting and processing critical minerals in the U.S. or a country with which we have a free trade agreement. If the supply of critical minerals from these countries is sufficient, then the IRA will have done the job EPA claims it will do. But if these materials are not available from qualifying sources, then the IRA will not have accomplished what EPA projected through no fault of the automakers. [EPA-HQ-OAR-2022-0829-0701, pp. 84-85]

Automakers cannot build batteries with materials that don't exist or that are unavailable. [EPA-HQ-OAR-2022-0829-0701, pp. 84-85]

An adjustment mechanism would be applied as follows. For MY 2027, each automaker will submit a pre-model year report by December 2025. Within this report, battery capacity of each EV model could be detailed, along with planned volumes and whether or not each will qualify for the critical mineral portion of 30D. Material sourcing contracts will be executed for MY 2027 by that time. EPA can aggregate this data from all manufacturers. For example, if a total of 2,000 GWh of battery capacity is planned for sale in MY 2027 according to the combined pre- model year reports, and 1,200 GWh of this capacity will qualify for the $3,750 30D credit based on sourcing and processing countries of origin, a 10 g/mi (for example) maximum potential target adjustment would be scaled according to this formula: [EPA-HQ-OAR-2022-0829-0701, pp. 84-85]

Adjustment (CM) = Adjustment (Max) * (MY (capacity) – MY (qualifying)) / (MY (capacity))

Where

Adjustment (CM) = Critical material adjustment (g/mi)

Adjustment (Max) = 10 g/mi

MY (capacity) = Industry total battery per model year (GWh)

MY (qualifying) = Industry total battery capacity (GWh) per model year qualifying for the full $3750 tax credit

Using the example data from above,

Adjustment (CM) 10 g/mi * (2,000 GWh – 1,200 GWh) / (2,000 GWh) = 4 g/mi

[EPA-HQ-OAR-2022-0829-0701, pp. 84-85]

This simple calculation could be published by EPA in the second quarter of calendar year 2026, giving automakers time to react for the bulk of MY 2027 production. This appears to be the best compromise for getting accurate information to EPA close enough to a given model year to be more accurate than projections made over three years in advance, while also providing enough time in advance to be of use for a given model year without having to be retroactively applied. [EPA-HQ-OAR-2022-0829-0701, pp. 84-85]

These challenges and the need for additional flexibility remain pertinent for MY 2027 and later regulations. The customers of these companies will still demand high performance from any vehicle sold by these manufacturers. The challenges of limited, highly focused product lines will not be eased by vehicle electrification. Limited product portfolio and product development cycles mean the ability to make regular improvements is a challenge. Battery technology has not developed enough for application within high-performance supercars. Technology is developing and SVMs have plans to electrify further; however, time is needed. Supply chain access and lead-time challenges will continue and potentially grow given rapidly rising global demand for lithium-ion batteries and trends toward vertical integration by larger companies to secure critical mineral supplies. Furthermore, given low production volumes there is also limited ability to amortize expensive product development across a volume of products – R&D and investment payback is longer. This leads to SVMs having different investment cycles which will mean they will require additional time to comply with GHG and criteria pollutant regulations. [EPA-HQ-OAR-2022-0829-0701, pp. 207-208]

With this backdrop, we are concerned that EPA appears to now dismiss these challenges in general, proposing much reduced flexibility in MY 2027 and later. [EPA-HQ-OAR-2022-0829-0701, pp. 207-208]

B. Battery Cost Reductions

There is great uncertainty as to whether battery costs will fall significantly during the time frame of this rule, as projected by EPA. While battery costs have dropped over the last decade, they appear to have plateaued around $150/kWh. With dramatic increases in demand coming and high inflation in recent years, battery costs appear to even be trending upward recently. We propose that battery pack costs could also be disclosed to EPA at the time of the pre-model year reports. EPA could then aggregate data from all automakers to develop a volume-weighted average battery pack cost per kWh for a given model year. Costs for all these battery packs will be locked in by this point in time, so there is no uncertainty in actual costs. The cost delta between EPA's projected cost estimate used as the basis for the rule and the actual cost would be used to calculate a target adjustment using, for example, the following formula: [EPA-HQ-OAR-2022-0829-0701, pp. 85-86]

Adjustment (BC) = Scaler * (Cost (actual) – Cost (estimate))

Where

Adjustment (BC) = Battery cost adjustment (g/mi)

Scaler = 0.2 g/mi/$

Cost (actual) = Industry total battery cost per model year ($/kWh)

Cost (estimate) = EPA estimated total battery cost per model year ($/kWh)

Using MY 2029 as an example with an EPA projected cost of $90/kWh and an actual industry cost of $105/kWh:

Adjustment (BC) = 0.2 g/mi * ($105/kwh) – ($90/kWh) = 3 g/mi [EPA-HQ-OAR-2022-0829-0701, pp. 85-86]

This target adjustment would be published at the same time as the critical mineral adjustment in Q2 of the calendar year preceding the model year. [EPA-HQ-OAR-2022-0829-0701, pp. 85-86]

Organization: American Petroleum Institute (API)

g. Program Review.

i. Assessment of both vehicle and infrastructure development/deployment progress.

The design of a program with heavy reliance on infrastructure that may not be widely available on the timeline proposed is optimistic at best. The proposal appears premature on the stated timeline, and essentially in conjunction with the HD GHG Phase 3 program, which would be competing for the same resources. If EPA is not willing to adjust the timeline and/or standards of the proposed programs, API requests that the agency consider incorporating a pre-program assessment as well as a program progress assessment. It is imperative that EPA provide a real-world evaluation, with an honest assessment provided to the public, regarding progress on infrastructure readiness and ZEV technology deployment. The opportunity for stranded investments by all stakeholders impacted by this program is just too great not to incorporate pre- and mid-program reviews. [EPA-HQ-OAR-2022-0829-0641, p. 23]

For a mid-program assessment, EPA could consider something akin to the Midterm Evaluation that was finalized in the 2012 joint agency rulemaking establishing the MY 2017-2025 LD GHG standards.77 Further, we recommend that EPA engage a broad stakeholder community to identify necessary elements to incorporate into such an assessment. [EPA-HQ-OAR-2022-0829-0641, p. 23]

77 “Midterm Evaluation of Light-Duty Vehicle Greenhouse Gas Emissions Standards for Model Years 2022-2025.” https://www.epa.gov/regulations-emissions-vehicles-and-engines/midterm-evaluation-light-duty-vehicle-greenhouse-gas.

ii. Future program incentives and program adjustment of standards.

In addition, we also request that the agency report on the findings following review with enough time to adjust the standards if needed. Adequate lead time must be provided to the regulated community to allow for necessary adjustments to regulatory compliance strategies, and to avoid stranded investments as much as possible. A proposal based on stretch goals must incorporate an “offramp” or some opportunity to pivot if the essential elements of the program, such as charging/fueling infrastructure, do not materialize. [EPA-HQ-OAR-2022-0829-0641, p. 23]

Organization: Jaguar Land Rover NA, LLC (JLR)

EPA should consider formal monitoring points every two years to evaluate the effectiveness of the regulation given the uncertainty in how the market will develop [EPA-HQ-OAR-2022-0829-0744, pp. 5-7]

Organization: Kia Corporation

The government’s ability to implement the right complementary policies and monitoring these factors will be paramount to the success of this ambitious rulemaking. EPA standards alone cannot and will not create demand or infrastructure for EVs. [EPA-HQ-OAR-2022-0829-0555, pp. 6-7]

EPA’s Program Should Include Mechanism to Adjust Standards if Necessary

EPA’s proposal does not include any mechanism to adjust standards or correct course if the various assumptions in the model do not materialize. Market assumptions in EPA’s model include adequate charging infrastructure, consumer acceptance and demand, critical mineral supply, manufacturing capacity, power capacity, power rates, and low cost discrepancy between ICE and EVs. All of these elements – market realities and external challenges – are outside the control of automakers. There needs to be a mechanism that allows or requires EPA to revise standards if certain market conditions do not materialize at the level necessary to increase demand for EVs. [EPA-HQ-OAR-2022-0829-0555, p. 7]

Organization: Lucid Group, Inc.

Battery/Vehicle Efficiency is Critical to Long-Term Viability of EVs

EPA solicited input on additional ways the program could provide alternative pathways encouraging manufacturers to achieve lower CO_2 emissions earlier than projected in the proposal. Incentivizing EV efficiency measured by either miles/kWh or miles per gallon equivalent (MPGe) would help achieve lower CO_2 emissions and reduce the demand for raw materials and on the grid. We must ensure that we do not electrify for the sake of electrification, but instead establish policies and programs that prioritize efficient use of electricity and resources, yielding benefits such as: [EPA-HQ-OAR-2022-0829-0664, pp. 7-9]

-Reduced upstream emissions: Most EVs are charged from the power grid, which, while rapidly becoming cleaner, still includes emitting sources. More efficient EVs would use less grid electricity, thereby reducing the upstream emissions associated with their charging and vehicles miles traveled. [EPA-HQ-OAR-2022-0829-0664, pp. 7-9]

-Conservation of critical minerals and associated de-risking of the supply chain: Using fewer batteries reduces the demand per vehicle for lithium and other critical materials. Reducing the use of these materials reduces supply chain bottlenecks and enhances national security. [EPA-HQ-OAR-2022-0829-0664, pp. 7-9]

-Reduced consumer purchase costs: EV efficiency speeds mass adoption by reducing vehicle prices. It seeds a virtuous cycle—efficiency lowers vehicle production costs and purchase prices by reducing the number of batteries (the largest cost input for EVs) needed to achieve a targeted range. Fewer batteries lower the vehicle curb weight thereby further reducing the required cell count to achieve a desired range. [EPA-HQ-OAR-2022-0829-0664, pp. 7-9]

-Reduced consumer energy costs: Efficient vehicles require less energy to travel a given distance. More efficient ICE vehicles have demonstrably reduced the gas bill for consumers, and more efficient BEVs reduce consumers' electric bill. [EPA-HQ-OAR-2022-0829-0664, pp. 7-9]

-A more resilient grid through smarter energy consumption: While government programs have been known to encourage the use of electricity and have even extended to promote energy derived from wind, solar, and renewables, there exists a common denominator—use of energy. By focusing on increasing efficiency, we can foster smarter energy consumption easing the resources necessary for the grid’s clean energy transition. [EPA-HQ-OAR-2022-0829-0664, pp. 7-9]

-Environmental Justice benefit: The U.S. Department of Transportation (DOT) states "low income and minority communities are more likely to be located near highways and other transportation facilities that produce local reduced air quality, and to suffer from negative health effects such as asthma." Addressing environmental inequality goes beyond roadway design and extends to the vehicles on the roads. Zero-emission vehicles (ZEVs) are a first line of defense in addressing respiratory and cardiovascular disease and other pollution-related health disparities by improving air quality in communities located in or near traffic-dense areas. Efficiency brings down the costs of such vehicles and will help increase equitable adoption of medium-and heavy-duty electric vehicles. [EPA-HQ-OAR-2022-0829-0664, pp. 7-9]

-Higher overall vehicle performance: There is a misconception regarding the correlation between vehicle efficiency and vehicle performance. Traditionally, fuel efficient vehicles were not associated with high performance. However, Lucid's vehicles demonstrate that increased efficiency in EVs yields faster charging, increased power density, and higher output power derived from the same energy input providing faster acceleration capability. With higher vehicle performance often comes increased consumer interest, which in the case of electrification supports consumer adoption. [EPA-HQ-OAR-2022-0829-0664, pp. 7-9]

The National Highway Traffic Safety Administration’s (NHTSA) CAFE and EPA GHG programs already apply standards to ICE vehicles for efficiency, measured by MPG and g/mi respectively. Instituting a similar standard to EVs would apply the same expectations of efficiency to all surface transportation. Vehicle efficiency is determined by several systems and how well they've been optimized to work together. In EVs this includes but is not limited to the battery pack, drive motors, power train, and aerodynamics of the vehicle itself. The overall efficiency in EVs can be measured by MPGe or miles per kWh. EPA has the authority to establish multiplier incentives for EVs and advanced technologies to encourage such technologies in the market.10 Using this authority to implement standards for EV efficiency will encourage manufacturers to not only electrify their fleets, but also prioritize efficiency. [EPA-HQ-OAR-2022-0829-0664, p. 9]

10 "EPA also believed that the temporary regulatory incentives may help bring some technologies to market more quickly than in the absence of incentives Since the GHG performance for these vehicle types is significantly better than that of conventional vehicles, the multiplier provides a significant benefit to the manufacturer." 86 Fed. Reg. 74458-59 (Dec. 30, 2021).

Organization: MECA Clean Mobility

EPA should consider incentives and potential future requirements that advance efficiency of electric vehicles. [EPA-HQ-OAR-2022-0829-0564, pp. 31-32]

Efficiency incentives and regulations have historically driven vehicle manufacturers and technology suppliers to continue to innovate and develop better materials, components, and vehicle systems to reduce energy demand, operating costs and related emissions of vehicles. Electric vehicle efficiency does not provide large benefits at today's EV sales penetration rates. However, if the goals of this rule are met by 2032, electric vehicle sales will be over 60% and EVs will make up a much larger fraction of the in-use passenger car fleet. Therefore, small improvements in efficiency will result in large reductions in grid demand. MECA suggest that EPA consider a range of both incentives and requirements to advance the efficiency of technologies that reduce the emissions footprint of all mobile sources, regardless of the source of propulsion energy. As noted above, setting non-zero certification values for battery electric and fuel cell vehicles will continue to motivate vehicle manufacturers to work with suppliers to improve vehicle efficiency. [EPA-HQ-OAR-2022-0829-0564, pp. 31-32]

MECA requests that EPA explore additional incentivization structures that would allow consumers to make informed choices when purchasing electric and fuel cell vehicles. For example, EPA could institute a labeling requirement for electric vehicles with similarities to Energy Star and displaying how an electric vehicle compares to other similar electric vehicles in its class. The simplified Energy Star graphic is recognizable and understood by the majority of consumers who might not be able to interpret the value of an electric vehicle efficiency in kilowatt-hours per 100 miles, which is currently on the window sticker. [EPA-HQ-OAR-2022-0829-0564, pp. 31-32]

MECA members are commercializing components for electric and hydrogen fuel cell vehicles. This includes battery materials for the manufacture of both cathode and anodes utilizing unique macrostructure and composite formulations to improve efficiency and energy density. Electric component manufacturers are using state of the art transistor materials in their motors and power electronics that operate at higher voltages and temperatures thus requiring simpler cooling strategies. These next generation component designs reduce switching losses and improve electric efficiency of the system architecture in electric powertrains. To facilitate integration, component suppliers are integrating the motor, inverter and transmission into electric drive units to simplify the thermal management of the electric components and ease integration into vehicles. [EPA-HQ-OAR-2022-0829-0564, pp. 31-32]

As demonstrated for combustion vehicles over the past 50 years, the market can not always be relied upon to drive innovation towards conservation of critical resources and energy security by improving the efficiency of vehicles. This has led agencies to set fuel efficiency and GHG standards. There is a significant disparity in the electric efficiency of similarly sized passenger electric vehicles today, as shown in Table 4. [See original comment for Table 4. Comparison of Energy Efficiency of BEV and PHEV Models] We urge EPA to begin compiling electric efficiency information and consider setting a minimum efficiency or energy consumption by weight class in a future rulemaking. [EPA-HQ-OAR-2022-0829-0564, pp. 33-34]

Organization: Porsche Cars North America (PCNA)

Porsche's double-E strategy of electromobility and near carbon-neutral combustion

As stated above, Porsche has established an ambitious goal for the electrification of our cars and trucks over the next several years. This goal builds upon the range of electrified models that Porsche has offered in the United States for the past decade. Within the premium, high-performance and luxury segments in which Porsche competes, Porsche has delivered almost 45,000 BEVs and PHEVs to our US customers. These vehicles have brought a new level of complexity in development and manufacturing and continue to incur higher costs associated with batteries and electric drive componentry. Nevertheless, with continued innovation, Porsche is confident that the expanding range of electrified models, with continuously improving technical performance, will meet the needs and desires of many of our customers for the high degree of utility and performance that they demand. [EPA-HQ-OAR-2022-0829-0637, p. 4]

Importance of Monitoring Progress on the Advancement of Electrification

EPA's proposal includes a wide array of assumptions related to the development of the electrification market, costs of components, supply chain readiness, and charging infrastructure. These assumptions each contribute towards the percent of electrification that was used to inform the overall stringency of the targets. As outlined by the AFAI, Porsche supports the concept of a holistic program to monitor the overall progress of each of these assumptions and their related impacts on electrification readiness and adoption. Monitoring progress with transparent reporting is a pragmatic policy decision that does not cast doubt on the success of each of the assumptions. Rather, monitoring and reporting establishes a clear and transparent basis for ongoing dialogue between stakeholders and the EPA. This type of monitoring can provide early awareness of unexpected challenges or disruption and allow stakeholders to understand how requirements may need to be adjusted to help ensure that the requirements remain achievable. [EPA-HQ-OAR-2022-0829-0637, p. 7]

Organization: Stellantis

Target Adjustment Mechanisms Needed Based on Market Enablers

Stellantis fully supports the Auto Innovators' comments proposing a target adjustment mechanism based on key EV market enablers. This mechanism is in addition to making the other revisions needed to address concerns raised with the standards. There is a great deal of uncertainty with how critical mineral and raw material supplies, battery cost improvements, and charging/refueling infrastructure will develop over the next decade. In particular, charging/refueling infrastructure and supply of critical minerals and raw materials from non-countries of concern are well outside the control of either EPA or automakers. We understand EPA must use projections in its modeling. However, given the uncertainty around these items, large inaccuracies can lead to a final rule that is grossly misaligned with the market. The Auto Innovators' proposal of a market-based target adjustment system would allow for year-by-year adjustments to be made within the framework of a rule that can be finalized on EPA's desired timeline and will minimize the need to be reopened to react to real-world market conditions. [EPA-HQ-OAR-2022-0829-0678, p. 7]

This proposal contains three individual adjustment mechanisms of roughly equivalent magnitude. The first is based on the percentage of the entire U.S. light-duty fleet qualifying for the full $3,750 30D retail tax credit which is tied to extracting and processing critical minerals in the U.S. or a country with a free trade agreement. This is the most simple and direct way to assess whether or not raw material supplies are developing adequately. The second adjustment mechanism is based on actual EV battery costs that could be confidentially disclosed to the EPA by each automaker every model year and compared with EPA's projected battery costs used in the development of this rule. The third mechanism is simply tracking the ratio of public charging/refueling points to the number of light-duty EVs registered and on the road. As the total size of the on-road EV fleet grows, so does the amount of charging/refueling infrastructure. If these three key market enablers develop as envisioned by EPA in this rule, then the impact of these adjustments will be negligible. But if one or more of these key enablers do not develop quickly enough, then this proposed system will allow for simple, objective, and transparent metric-based adjustments to be applied equally to all of industry. These are industry-wide issues and thus should be resolved on an industry-wide basis. [EPA-HQ-OAR-2022-0829-0678, p. 7]

At a House Committee on Energy and Commerce hearing on driving affordability held on June 22, 2023, Rep. Dingell (D-MI) raised concerns with EPA Principal Deputy Administrator Goffman on what happens under the NPRM if companies cannot reach BEV as 67% of new vehicle sales in 2032, consumers cannot afford EVs, the charging stations aren't there, and the assumptions and forecasting EPA relies upon are not viable. Mr. Goffman's response included a reference to a possible market assessment review. Stellantis believes the Auto Innovators' recommended ongoing market-based target adjustment system to be the best embodiment of a direct market review. However, Stellantis could support an additional market-based review that is both objective and transparent in reaching the necessary adjustments to allow this rule to be reasonable and achievable given the large amount of uncertainty with how these key market enablers will develop over the next decade. At a minimum, Stellantis supports EPA adding modules to its annual EPA Automotive Trends Reports that capture important metrics such as the number of public EV charging stations deployed and percent of EVs purchased. [EPA-HQ-OAR-2022-0829-0678, p. 7]

EPA Summary and Response

Some manufacturers suggested that one response to the uncertainty and risk surrounding supply chain, critical minerals, manufacturing costs and charging infrastructure would be to implement a stringency adjustment mechanism based, for example, on an assessment of progress in domestic critical mineral sourcing, PEV infrastructure, or other developments the commenters deem necessary to accompany increased penetration of PEVs under the standards.

EPA notes that we have assessed issues such as the supply chain (including critical minerals), charging infrastructure needs and development, and manufacturing costs as part of our assessment of the feasibility of these standards, although actual implementation of specific measures to advance issues such as infrastructure, mining, supply chain development etc. are largely outside of EPA's statutory authority to control and are outside the scope of this rulemaking. Regarding the implementation of a stringency adjustment mechanism, EPA disagrees with this recommendation.

As we discuss in Section I.B.1 of the preamble, our final standards have been adjusted (with the more linear Alternative 3 from the proposal, combined with a slower phase-down of several credit provisions) in response to concerns about lead time and feasibility. Our technical assessment, as discussed in Sections IV and V of the preamble, is that the final standards are feasible and appropriate for the years at issue. Despite commenters' concerns over uncertainty and risk in the development of the market for electric vehicles, feasibility is not dependent on one singular technology pathway (such as BEVs): the final standards, as in previous rulemakings, are performance-based and do not require any particular technology to meet the standards. Manufacturers may choose many potential pathways to compliance that involve different mixtures of vehicle technologies. Table 4 in Section I.B of the preamble gives examples of technology pathways for compliance (with varying levels of BEV penetration, as well as varying levels of PHEVs, HEVs and non-hybrid ICE technologies) based on OMEGA modeling. Additionally, we have run sensitivity analyses (Section IV.F of the preamble) addressing low critical mineral availability, higher battery costs, and lower consumer acceptance (for any particular reason, including a lack of optimal number of chargers). In Section IV.F.4 of the preamble, we discuss a sensitivity and path to compliance in which no additional BEV models are produced that are not currently in production.

Finally, EPA notes that an automatic stringency adjustment would eliminate the predictability and certainty of the standards, which in turn would make it more likely that developments in these areas would not occur. EPA finds that making the standards contingent on future developments is unlikely to provide the appropriate signal to both the automotive industry and to those in related industries to make the investments (e.g., in development of the supply chain by the automotive industry and further deployment of charging infrastructure) about which the commenters are concerned. Many commenters (e.g., CALSTART, NESCAUM, Environmental and Public Health Organizations, ICCT) have expressed the need for clear market signals to drive these necessary investments.

Instead of introducing additional uncertainty into automakers' long-term planning, EPA has chosen to adopt standards that can reasonably be met with a variety of technology paths under a variety of potential future circumstances.

In their comments, both Lucid and MECA recommended that EPA include some mechanisms to incentivize the efficiency of electric vehicles. While EPA does recognize several goals commenters have in supporting such an idea (reduced upstream emissions, reduced demand for critical minerals, reduced purchase and operating costs, decreased grid demand, etc), – we do not agree it is appropriate to establish regulatory incentives for more efficient EVs in this final rule. However, we do note that there should be a considerable business case for manufacturers to improve EV efficiency as it will have a direct impact on required battery size, weight, range and resulting battery costs. Manufacturers that can design more efficient BEVs may benefit from a market advantage over competing vehicles in the same segment with lower efficiency. We also note that the fuel economy and environment labels on new vehicles provide information related to efficiency, including EV range and annual operating costs. To the extent that consumers demand more efficient EVs, the label is a source of information that may help consumers identify the most efficient EVs.

4 - Criteria pollutant standards

Comments by Organizations

Organization: Alliance for Automotive Innovation

Criteria – Adopt California's LEV IV Standards

For the Tier 4 criteria pollution standards, we recommend that EPA adopt California's LEV IV exhaust and evaporative emission standards adopted just seven months ago and begin in 2026MY. LEV IV standards were adopted by California last year as an effective and appropriate path forward to address the toughest in the nation air quality challenges. EPA should align with this comprehensive strategy to enable a nationwide criteria emissions program. [EPA-HQ-OAR-2022-0829-0701, pp. 7-8]

If EPA finalized the multi-pollutant regulations with these two recommendations, the final regulations would still be the most aggressive and challenging in U.S. history, and they would provide dramatic reductions in GHG and criteria emissions. However, EPA would reduce the risk of potential harmful consequences to both the EV market, and the new vehicle market in general, by forcing BEVs at a rate that outpaces the EV supply chain, infrastructure, critical mineral supplies, and customer acceptance. Getting the pace right is critical to the success of the automakers and to U.S. leadership and competitiveness. [EPA-HQ-OAR-2022-0829-0701, pp. 7-8]

2. Proposed 40 C.F.R. § 86.1811-27(c)

The proposed 40 C.F.R. § 86.1811-27(c)(1) specifies to "Measure emissions as described in paragraph (b)(1) of this section, but use the driving cycle identified in 40 CFR 1066.801(c)(5)."294 The driving cycle identified in the proposed 40 CFR § 1066.801(c)(5) is the HFFET.295 [EPA-HQ-OAR-2022-0829-0701, p. 189]

294 NPRM at 29420.

295 NPRM at 29444.

IV. Light-Duty Criteria and Toxic Pollutant Standards

Automakers are committed to ultimately achieving net-zero transportation carbon emissions and electrification of the light-duty vehicle fleet. However, this transformation requires massive investment in EV technology and supporting mechanisms such as infrastructure, all involving many stakeholders. To be successful, automakers must primarily focus resources on the transformation rather than incremental changes to existing internal combustion engine (ICE) vehicles, which are already very near zero. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

The focus of EPA and the automakers is and should be on electrification. Thus, Auto Innovators supports changes to traditional criteria emission (e.g., NMOG, NOx, and PM) standards that measurably reduce emissions, but do not add substantial additional hardware or capital costs to ICE vehicles that will soon be retired. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

Unfortunately, EPA proposes to adopt new requirements that will divert resources from our shared goal of widespread electrification. Prohibiting enrichment could require complete engine redesigns and possibly larger displacement engines to provide customers with the capability they demand. The proposed PM standards substantially increase costs and vehicle development complexity in addition to adding testing requirements. Finally, in several cases, EPA provides less flexibility and/or chooses not to align with ACC II. This lack of alignment is particularly troubling as automakers and suppliers have already developed product plans and spent resources toward meeting the ACC II regulations, and in some cases, EPA's proposal would require substantial changes during the middle of ACC II regulatory phase-ins. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

3.NMOG+NOx Cold FTP Fleet Average

EPA proposes to set a cold FTP NMOG+NOx fleet average requirement of 300 mg/mile, excluding ZEVs.258 EPA requests comment on whether a 400 mg/mile vehicle cap should be used instead of a fleet average.259 [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

258 NPRM at 29262.

259 NPRM at 29262.

Auto Innovators prefers a fleet average requirement, but requests a value of 300mg/mi for LDV+LDT1 and 400mg/mi for LDT2+HLTD+MDPV for the following reasons: [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

At -7 °C, emission reduction right after engine start-up and during catalyst warm-up is the key factor. Large displacement engines (V6, V8, etc.) inevitably have substantially higher emissions at engine startup before the catalyst is warmed up. For downsized turbocharged engines, the amount of heat supplied to the catalyst decreases due to the relationship between the recovery of the exhaust energy by the turbocharger and the heat capacity of the turbocharger itself; thus, the warm-up time tends to be longer than that of an engine without a turbocharger. During this longer warm-up time when the catalyst is in a semi-active state, the heavier vehicle with a turbocharger under high running load conditions has much higher emissions than other vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

According to the DRIA, EPA developed the proposal based on the test results of three models. The results of these three models certainly meet 300 mg/mi. However, due to differences in exhaust system layout (i.e., front catalyst distance from the engine) and engine control from these models, there are some models that cannot achieve both emission reduction before catalyst warm-up and early catalyst warm-up at a high level under -7 °C condition. There are also vehicles that are heavier than the vehicles EPA tested. [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

Developing technology to adapt these vehicles to 300 mg/mi would require diverting substantial resources from electrification [EPA-HQ-OAR-2022-0829-0701, pp. 147-148] :

1.For emission systems development and evaluation, update and/or increase of chassis dynamometer system testing to make it possible to reproduce cold temperature condition is necessary. [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

2.Development of pistons and injectors for better combustion and designing arrangement of emission purification devices are necessary. When changing the catalyst system (increase in the amount of precious metals, increase in the number of cells), increase in costs occurs. [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

Regarding the 300 mg/mile fleet average, EPA proposes that the family emission limit (FEL) be set to a resolution of 0.1 g/mile (100 mg/mile).260 An FEL set to only a single decimal place (i.e., 0.x g/mile) provides very little flexibility among different vehicles. We recommend that EPA allow an FEL resolution to three decimal places (i.e., 0.xxx g/mile). [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

260 NPRM at 29436.

We also note that although EPA describes the 300 mg/mile fleet average as excluding ZEVs in the preamble,261 the proposed 40 C.F.R. § 86.1811-27(c)(3)(i) regulatory text does not reflect that exclusion.262 Auto Innovators agrees with the exclusion and recommends updating the regulatory text accordingly. [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

261 NPRM at 29262.

262 NPRM at 29420.

Organization: American Honda Motor Co., Inc.

Unlike with previous automotive emissions regulations, in which an OEM had numerous compliance technology pathways and could strategically invest in a package of technologies that best suited its customers' needs, this proposal sets stringencies at such a level where there is just one way to comply: significant levels of electrification. Yet should the market not pan out within the agency's ambitious timeline – even for reasons entirely beyond an automaker's control, such as a slower-than-expected rollout of public charging infrastructure that has a chilling effect on consumer interest in EVs – there is no safety net, no alternate package of technologies to which an OEM can pivot and maintain compliance. Regulated parties will simply fall short, facing a profoundly disruptive and costly set of noncompliance obligations. [EPA-HQ-OAR-2022-0829-0652, p. 5]

Further complicating matters, the agency has also chosen to propose criteria emissions standards and engine operation requirements that surpass even California's stringent LEV IV tailpipe pollution standards (part of the Advanced Clean Cars II regulation) finalized just last year. As proposed, EPA's requirements will necessitate significant new internal combustion engine (ICE) development which, in turn, diverts critical resources previously allocated for vehicle electrification that would have served the very same air quality goals. [EPA-HQ-OAR-2022-0829-0652, pp. 5-6]

Recognizing California's longstanding leadership in air quality management and the historical relationship between California and federal emissions standards (where California sets a vanguard target, automakers invest to meet that requirement, and EPA subsequently accommodates a national compliance pathway by setting federal regulations similar to California upon its next round of standards), it is not an unreasonable notion for automakers to theorize that EPA's upcoming PM emissions standards might land in a similar place to California's LEV IV program. [EPA-HQ-OAR-2022-0829-0652, p. 10]

We thoroughly support the decarbonization and air quality improvement objectives promoted by the agency, as well as various elements pertaining to this regulatory proposal's design. We share the agency's desire for widespread adoption of vehicle electrification in the U.S., accelerating our mutual goal of broad transportation decarbonization. [EPA-HQ-OAR-2022-0829-0652, p. 32]

In our view, neither the proposed standards nor any of the three alternatives adequately address the inherent market uncertainties and potential for noncompliance that exists within the agency's ambitious timeline. Rather, the proposal sets the stage for what may be a profoundly disruptive and costly set of noncompliance obligations across the industry. We respectfully urge the agency to finalize a more reasonable emissions reduction trajectory, along with a broader array of compliance flexibilities. We believe that standards in line with Honda's publicly stated electrification targets are representative of a challenging but workable requirement. [EPA-HQ-OAR-2022-0829-0652, pp. 32-33]

Moreover, the emissions inventory will naturally improve as older, dirtier vehicles age out of the car parc and are replaced by cleaner, potentially even zero-emission technologies. EPA's Mobile Sources Technical Review Subcommittee (MSTRS), a diversely represented advisory group to both EPA's Clean Air Act Advisory Committee and staff from EPA's Office of Transportation and Air Quality, made similar observations to the agency in an October 2021 report: [EPA-HQ-OAR-2022-0829-0652, p. 16]

It is expected that the most meaningful reductions in criteria emissions moving forward will come not from further incremental ratcheting of standards, but rather from the ongoing process of fleet turnover: the routine replacement of old (dirty) vehicles with new (clean) vehicles. [EPA-HQ-OAR-2022-0829-0652, p. 16]

Recent research supports this understanding. 29 [EPA-HQ-OAR-2022-0829-0652, p. 16]

> 29 The Future of Mobility: A Report by the EPA Mobile Sources Technical Review Subcommittee. Available online at https://www.epa.gov/system/files/documents/2022-01/mstrs-10-14-2021-meeting-future-of-mobility-report.pdf

Recommendation: Honda strongly urges the agency to include, as part of its Final Rule, feasible GHG and NMOG+NOx standards that properly reflect risk and uncertainty associated with the electrification transition, including a possible removal or substantial weakening of IRA and BIL incentives. [EPA-HQ-OAR-2022-0829-0652, p. 24]

we understand and appreciate the agency's desire to further reduce criteria emissions from the fleet. While we support this goal in principle, we disagree with the agency's suggested approach. The NPRM's proposed PM and commanded enrichment requisites would offer only marginal emissions benefit while forcing costly new engine development (and possibly even chassis development) activities. These aspects of the proposal are highly disruptive to Honda's efforts to focus resources as we pivot to vehicle electrification. We strongly encourage the agency to adopt a federal criteria emissions program aligned with California's recently finalized LEV IV emissions standards and testing regimens. Doing so would deliver continued criteria emissions reductions for all Americans, while sidestepping unnecessary and costly regulatory inefficiencies. [EPA-HQ-OAR-2022-0829-0652, p. 33]

Organization: BlueGreen Alliance (BGA)

[Automakers have historically succeeded at reducing criteria pollutants from their ICE fleets while investing in their ZEV production capacities. EPA's light- and medium-duty standards must incentivize them to continue to achieve gains in reducing tailpipe pollutants and in their ZEV offerings. Reducing tailpipe pollution emissions from ICE vehicles is technologically feasible and affordable; there are off-the-shelf technologies like GFPs that automakers are already applying to their vehicles sold in Europe and Asia in order to comply with emission regulations there. Such technologies could easily and affordably be applied to light- and medium- duty vehicles sold in the United States, with no additional research and development needed. Because EPA's standards are performance-based and technology-agnostic, automakers can and will employ a combination of ZEV and ICE vehicle improvement technologies to comply, while supporting a range of auto manufacturing supply chain jobs. [EPA-HQ-OAR-2022-0829-0667, p. 5]

Organization: BMW of North America, LLC (BMW NA)

BMW NA supports the comments filed by the Alliance of Auto Innovators to the EPA docket. Our main concern is that a diverging approach in the United States between Federal regulations and California's regulations will substantially increase the hurdles to fulfill fleet and vehicle standards. BMW NA is aiming for one single US fleet and therefore would like to motivate EPA to align the Tier 4 rules with LEV IV as much as possible. This is referring to the rules for the NMOG+NOx fleet (bin structure and EV treatment) as well as to the vehicle standards. [EPA-HQ-OAR-2022-0829-0677, p. 4]

The fleet regulation should be harmonized, so that the same fleet composition should lead to compliance in both regulations. Other than the CARB approach, the Tier 4 fleet regulation is heavily dependent on the BEV share. As mentioned above, there is a high uncertainty what BEV share could be reached in each single year. From our perspective, the Tier 4 regulation should focus on regulating pollutant emissions of ICE vehicles. [EPA-HQ-OAR-2022-0829-0677, p. 4]

There should be no additional burdens on top of CARB vehicle standards, which are leading to additional substantial investments for a mature technology in its phase-out - e.g. for test labs or completely new after-treatment systems beyond the CARB standard. [EPA-HQ-OAR-2022-0829-0677, p. 4]

Organization: BorgWarner Inc.

BorgWarner supports EPA's proposal for a lower criteria pollutant standard. BorgWarner supports increased stringency for criteria pollutants on new LD and MD vehicles. BorgWarner produces cost-effective technology that can meet or even exceed the tighter stringency limits. We also support the gradual phase-in of these standards to allow manufacturers to develop and test the new design architectures before installing the necessary emission systems. [EPA-HQ-OAR-2022-0829-0640, pp. 6-7]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

CARB supports U.S. EPA's proposal to tighten criteria air pollutant emission standards, particularly given the continued role that internal combustion engine vehicles will play in the national fleet over the regulatory timeframe and beyond. Reducing exposure to harmful air pollution is a key element of the proposed standards, and the proposals to tighten criteria air pollutant emissions are needed to protect public health, especially in communities with disproportionate exposure to air pollution. Because U.S. EPA's proposal does not require ZEV sales, as California's rules do, the tightening of criteria air pollutant emission standards is even more critical to ensure that the internal combustion engine vehicles that will continue to be sold are becoming cleaner. [EPA-HQ-OAR-2022-0829-0780, pp. 26-27]

As part of its ACC II rulemaking, CARB adopted its fourth iteration of its Low Emission Vehicle (LEV) standards, referred to as LEV IV. CARB finds that U.S. EPA's proposals are appropriate and largely consistent with the LEV IV standards. CARB has documented our analysis and recommends strengthening the proposal to realize the greatest degree of emission reductions achievable, considering cost and technology availability, to further protect public health. [EPA-HQ-OAR-2022-0829-0780, pp. 26-27]

Organization: Center for Biological Diversity et al.

As environmental, community, and health organizations, we call on you to take more aggressive action to clean up the gas-powered car and truck fleet that will be polluting our nation's air and communities for decades to come. EPA's latest round of emissions reductions standards, covering Model Years 2027 through 2032, focuses on the rise of zero-emission technologies, including electrification, and the growing number of electric vehicle (EV) models that already have or will soon enter the market. While electrification is undoubtedly an effective and important means of securing emissions reductions, there will also be tens of millions of gas guzzlers that will be sold before EVs become dominant. EPA's rule should focus on curbing emissions from these vehicles as well, as they fuel climate change and needlessly pollute low-income and communities of color. [EPA-HQ-OAR-2022-0829-0671, p. 1]

Organization: Ceres Corporate Electric Vehicle Alliance (CEVA)

The Alliance applauds the Environmental Protection Agency (EPA) for its commitment to adopting multi-pollutant emissions standards for Model Years (MY) 2027 and later light- and medium- duty vehicles and greenhouse gas (GHG) emissions standards for heavy-duty vehicles, and urges EPA to align these standards with U.S. climate and public health goals.1 Specifically, the Alliance supports: [EPA-HQ-OAR-2022-0829-0511, p. 1]

1 https://www.energy.gov/sites/default/files/2023-01/the-us-national-blueprint-for-transportation-decarbonization.pdf

-Light-duty vehicle GHG emissions standards aligned with Alternative 1, the strongest standard proposed in this rulemaking, which will result in a 59% reduction in average fleetwide carbon dioxide emissions by MY2032 from a MY2026 baseline. The Alliance also encourages EPA to move forward with its proposed criteria pollutant emissions standards for light-duty vehicles, reducing fleetwide average MY2032 criteria pollutant emissions 60% from MY2025 levels.2 [EPA-HQ-OAR-2022-0829-0511, p. 1]

2 https://www.epa.gov/system/files/documents/2023-04/lmdv-multi-pollutant-emissions-my-2027-nprm-2023-04.pdf (p.42)

-Medium-duty vehicle (Class 2b and 3) multi-pollutant emissions standards aligned with its current proposal, which will ensure a 44% reduction in average fleetwide GHG emissions by MY2032 from a MY2026 baseline, and a 66 76% reduction in criteria pollutant emissions by MY2032 from a MY2025 baseline.3 [EPA-HQ-OAR-2022-0829-0511, p. 1]

3 Ibid. (p.42)

Organization: Colorado Energy Office, Colorado Department of Transportation, and Colorado Department of Public Health and Environment

In response to EPA's request for comments on specific aspects of the rule, we offer the following suggestions to ensure the rule is as successful as possible: [EPA-HQ-OAR-2022-0829-0694, pp. 2-3]

- Regarding criteria pollutants, we urge EPA to consider ways to align these proposed standards with California, and in doing so to avoid any backsliding in remaining conventional vehicles sold, while avoiding a scenario in which OEMs are forced to divert investment away from transportation electrification and towards technology advancement on conventional vehicles. We are concerned that the criteria standards in the EPA draft rule could have this unintended effect. [EPA-HQ-OAR-2022-0829-0694, pp. 2-3]

Organization: General Motors, LLC (GM)

In many cases, an EPA final rule aligned with CARB's LEV IV in internal combustion engine criteria emission stringency and the associated test and certification procedure s will help GM achieve significant emissions reductions for internal combustion engine products as soon as MY 2027 despite limited lead time, while continuing to transition to zero-emission vehicle technologies. [EPA-HQ-OAR-2022-0829-0700, p. 6]

Considering the unprecedented nature of EPA concurrently proposing GHG and criteria pollutant standards for light-duty and medium-duty vehicles, we urge EPA to carefully align the standard stringency, phase-in percentages, assumed EV shares, and vehicle categories applicable to Tier 4 standards and the GHG standards. [EPA-HQ-OAR-2022-0829-0700, p. 5]

Organization: Hyundai America Technical Center, Inc. (HATCI)

HMG strongly supports AFAl's call for the harmonization of California Air Resources Board (CARB) and EPA requirements to avoid the need for separate software for each. It is crucial to streamline the regulatory framework and establish consistent guidelines to facilitate compliance for automotive manufacturers, as well as ensure cost-effective compliance, again resulting in benefits to the environment and consumers. [EPA-HQ-OAR-2022-0829-0554, p. 9]

Organization: Kia Corporation

- Kia recommends EPA adopt the criteria emission standards the California Air Resources Board (CARB) adopted under the Advanced Clean Cars II (ACC II)(i.e., Low Emission Vehicle IV (LEV IV)). California's final standards significantly reduce criteria pollutants quickly - Particulate matter (PM), Nitrogen Oxide (NOx), Non-methane organic gasses (NMOG) - but does not divert critical resources needed to increase EV market penetration. It is critical that the criteria emissions regulatory framework is streamlined. [EPA-HQ-OAR-2022-0829-0555, p. 3]

Kia Supports Aligning with CARB's Criteria Emissions Standards Under ACC II

Kia supports a tightening of criteria emissions standards that can be accomplished cost-effectively through vehicle software calibration changes. EPA's proposed changes to criteria emissions standards would require large capital improvements, additional hardware on vehicles, and/or complete engine redesigns to maintain capability. [EPA-HQ-OAR-2022-0829-0555, pp. 9-10]

Kia recommends EPA adopt the criteria emission standards CARB adopted under the ACC II (i.e., LEV IV) as well as harmonization with CARB's phase-in schedule. Industry negotiated with California in a transparent process over years in several workshop and comment periods to develop final standards. California's final standards significantly reduce criteria pollutants – PM, NOx, MNOG – quickly but does not strand technologies or divert much needed resources. [EPA-HQ-OAR-2022-0829-0555, pp. 9-10]

While EPA is proposing a 10-fold increase in electric vehicles sales, EPA is proposing automakers redesign ICEs to meet new criteria emission standards. EPA's proposed requirements will divert the much-needed capital away from vehicle electrification. If EPA wants the vehicle industry to succeed in increasing new vehicle sales to 50-60 percent in seven years, EPA must allow automakers to focus resources on the full transformation to EVs – an expensive and monumental task. Not on incremental changes to near-zero criteria emissions on ICE vehicles. As discussed above, Kia will invest $36.3 billion by 2027 in EVs and other advanced vehicle technologies. This is a downpayment as Kia continues our aggressive EV transition to perfect our electric powertrain technology. Focusing resources on EVs is critical to ensure electrification transition is successful. [EPA-HQ-OAR-2022-0829-0555, pp. 9-10]

EPA proposes bins that are slightly different from bins finalized in ACC II. Specifically, EPA is not proposing Bin 125, Bin 25, or Bin 15, as found in ACC II, and instead is proposing a Bin 10. Kia recommends aligning EPA's new bin structure with CARB's bin structure. While Kia has no issue with the stringency of EPA's proposed bins, it would be beneficial for the bin structure to be harmonized between CARB and EPA as this would eliminate compliance and testing complexity. [EPA-HQ-OAR-2022-0829-0555, pp. 9-10]

Organization: Maryland Department of the Environment (MDE)

The Maryland Department of the Environment (MDE) is writing to express our support for the above proposed rule to establish Multi-Pollutant Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles. MDE agrees that this comprehensive federal program would achieve significant greenhouse gas (GHG) and criteria pollutant emissions reductions, improve air quality, and result in substantial public health benefits while helping us meet our climate and air quality goals. MDE urges the Environmental Protection Agency (EPA) to adopt the proposed criteria pollutant standards. MDE also urges EPA to adopt the most stringent, technologically feasible Alternative 1 GHG emissions standards. Alternative 1 is the closest to being in alignment with the California Advanced Clean Cars II (ACC II) regulations, which Maryland is in the process of adopting. [EPA-HQ-OAR-2022-0829-0698, pp. 1-3]

Maryland has made a lot of progress over the past few decades towards clean air. The improvements have been so substantial that the EPA has proposed to determine that the Washington, District of Columbia-Maryland-Virginia nonattainment area has clean data for the 2015 8-hour ozone national ambient air quality standard (2015 ozone NAAQS). A Clean Data Determination (CDD) is the first step in being redesignated from nonattainment to attainment. The Baltimore nonattainment area will also be eligible for a CDD in the near future if the area continues to stay at or below the ozone standard. Nitrogen oxides (NOx) are a precursor pollutant of ground-level ozone and are also precursors to secondary small particulate matter (PM2.5). Exposures to these two pollutants are associated with premature death, increased hospitalizations, and emergency visits due to exacerbation of chronic heart and lung diseases and other serious health impacts. Some areas of the state experience higher rates of illnesses such as asthma than average, and these illnesses are aggravated by these pollutants. [EPA-HQ-OAR-2022-0829-0698, pp. 1-3]

While significant progress has been made statewide, continuing to reduce NOx emissions, especially those from the transportation sector, is critical to our efforts to attain and maintain the ozone NAAQS. Regional modeling shows that a significant portion of the ozone-forming pollutants are transported into Maryland from upwind states. EPA estimates that strengthening these standards will reduce NOx and PM2.5 emissions nationally by 41% and 35% in 2055, respectively, which combined with state reductions can provide cleaner air for Marylanders. [EPA-HQ-OAR-2022-0829-0698, pp. 1-3]

Maryland is working hard to reduce in-state emissions from the transportation sector. Efforts include the Maryland Clean Cars Act that instructed MDE to adopt the California Advanced Clean Car (ACC I) regulations that require manufacturers of passenger cars and light-duty trucks to sell increasing percentages of zero-emission vehicles (ZEVs). The regulations also include low-emission vehicle (LEV) standards to reduce criteria pollutants and GHG emissions from new gasoline powered vehicles. As noted above, Maryland is in the process of adopting California’s ACC II regulations. The ACC II regulations require auto manufacturers to sell an increasing percentage of ZEVs over time, with a phase in of a 100 percent sales target by 2035. ACC II also established increasingly more stringent exhaust and evaporative emissions standards for criteria pollutants from these vehicles. Maryland’s recently enacted Clean Trucks Act of 2023 requires MDE to adopt California’s Advanced Clean Trucks (ACT) regulations that require manufacturers of medium-and heavy-duty vehicles to sell increasing percentages of ZEVs by 2035. Maryland is also a signatory to both the 2013 Multi-State Zero-Emission Vehicle

Memorandum of Understanding and the 2020 Multi-State Medium-and Heavy-Duty ZEV Memorandum of Understanding under which the signatory states are working collaboratively to accelerate ZEV adoption, coordinate ZEV policy, develop the ZEV market, and build out infrastructure. The recently enacted Bipartisan Infrastructure Law (BIL) and the Inflation Reduction Act (IRA) will provide significant funding to advance electrification and charging infrastructure that will enable the widespread electrification of this vehicle market. [EPA-HQ-OAR-2022-0829-0698, pp. 1-3]

Adopting the most stringent, technically technical feasible Alternative 1 GHG emissions standards at the federal level will provide considerable support for Maryland's efforts to meet our GHG reduction goals. Transportation accounts for almost half of all GHG emissions generated in the State. The Climate Solutions Now Act of 2022 (CSNA) established a statewide goal of a 60 percent reduction in GHG emissions from 2006 levels by 2031. The CSNA requires more stringent GHG emission reductions economy wide and requires state agencies execute plans, programs, and policies in order to achieve these goals. Enacting the most stringent GHG emissions standards that are technologically feasible will complement the many strategies being implemented under the CSNA. [EPA-HQ-OAR-2022-0829-0698, pp. 1-3]

Maryland has implemented emissions reduction measures across all sectors, including on-road transportation to reduce the state's GHG and NOx emissions. Federal programs such as these standards are needed to provide significant additional reductions of these pollutants as they also provide benefits across the economy. The EPA's leadership in strong regulatory GHG limits from motor vehicles could also help reduce ozone and PM2.5 precursors, providing further reductions to help meet our climate and air quality goals. [EPA-HQ-OAR-2022-0829-0698, pp. 1-3]

For these reasons, MDE supports the EPA's proposal to adopt the proposed criteria pollutant standards and the most stringent, technologically feasible Alternative 1 GHG emissions standards for model year 2027 and later light-duty and medium-duty vehicles. [EPA-HQ-OAR-2022-0829-0698, pp. 1-3]

Organization: Mazda North American Operations

Mazda strongly requests that EPA take these considerations into account and make necessary adjustments to the proposed rule as it works towards a Final Rule. We feel the Final Rule should have more realistic targets and associated ramp ups, include PHEVs, and adopt CARB's current LEV IV for criteria emissions. [EPA-HQ-OAR-2022-0829-0595, pp. 3-4]

Organization: Mercedes-Benz AG

Furthermore, we emphasize the need for flexibility in the rulemaking, particularly related to the criteria emissions. We recommend EPA align its criteria emissions standards to those adopted in California's Advanced Clean Cars II ("ACCII") Low Emission Vehicle IV ("LEV IV") standards. The ACCII program, including ZEV and LEV IV, was designed purposefully to advance electric vehicles and secure important, additional criteria emissions improvements from internal combustion engines. Aligning Tier 4's light-duty and medium-duty bins, levels of the standards, and phase-in commensurate with LEV IV will provide significant nationwide air quality benefits. To the extent EPA deviates from the LEV IV pathway, Mercedes-Benz is prepared to work with the agency to identify more appropriate pathways and timelines that maximize technology development underway for the worldwide market. We further implore EPA to use this rulemaking to seek additional areas that reduce burden, without compromising environmental benefits; as proposed, the rule significantly increases testing burden and likely requires investments in lab upgrades that detract from ongoing and necessary EV investment. [EPA-HQ-OAR-2022-0829-0623, p. 2]

The EPA NPRM contains aggressive criteria emissions standards that push the bounds of current technologies, and also rely heavily on the sale of electric vehicles. In addition, these criteria emissions standards do not properly account for the proceeding three to four years of work with the California Air Resources Board ("CARB") to develop and implement the ACCII LEV IV standards. LEV IV was developed under a mutual understanding that important and real criteria emissions controls could and should be implemented, and at the same time, as auto industry investments increasingly shift into electrification, a balance must be struck. LEV IV therefore provides air quality and health benefits without requiring automakers to divert electric vehicles investments into internal combustion engine technology upgrades and expanded testing. Additionally, Mercedes-Benz has already begun development efforts for LEV IV, and EPA's proposed standards would in many cases negate the research and development dollars already committed. [EPA-HQ-OAR-2022-0829-0623, p. 4]

Thus, Mercedes-Benz's recommends that EPA align its Tier 4 standards with the LEV IV standards, which includes adoption of the same bins used in LEV IV [EPA-HQ-OAR-2022-0829-0623, p. 4]

Organization: Minnesota Pollution Control Agency (MPCA)

- Adopt the proposed criteria pollutant standards for light- and medium-duty vehicles

MPCA also strongly supports EPA's proposal to establish more stringent emissions standards for criteria pollutants for both light- and medium-duty vehicles. EPA's modeling suggests the proposed standards would result in significant criteria pollutant and air toxics emissions reductions, which would provide substantial health and air quality benefits to Minnesotans. [EPA-HQ-OAR-2022-0829-0557, p. 4]

Organization: Mitsubishi Motors North America, Inc. (MMNA)

Align the Tier-4 (criteria pollutants) with CARB's LEV-IV criteria test procedures and standards. [EPA-HQ-OAR-2022-0829-0682, p. 2]

Organization: Porsche Cars North America (PCNA)

Comments specific to the proposed Criteria Exhaust Emission Standards for Model Years 2027 and Later [EPA-HQ-OAR-2022-0829-0637, p. 8]

Porsche provides the following comments in supplement to the comments from the AFAI specific to the proposed Tier- 4 standards for light-duty vehicles. As noted earlier, Porsche does not currently market medium-duty vehicles in the United States and offers no input for those regulatory requirements. [EPA-HQ-OAR-2022-0829-0637, p. 8]

In general, Porsche continues to maintain that the vast majority of emission reduction opportunity will be realized through the deployment of zero- and near-zero emission technology vehicles. As projected within the NPRM and the support documents, the bulk of emissions benefits should be achieved through the significant growth in electric vehicles projected by EPA for the US market. [EPA-HQ-OAR-2022-0829-0637, p. 8]

While focusing on a majority electrification strategy, Porsche continues to see a role for future advanced combustion engines in limited applications. As such, Porsche appreciates the sections of the proposal that align with California's recently adopted Advanced Clean Cars II LEV-IV program and supports comments that seek additional alignment between the two programs. This alignment will help manufacturers optimize resources and streamline planning. [EPA-HQ-OAR-2022-0829-0637, p. 8]

Organization: Stellantis

From a criteria emissions standpoint, not only did EPA assume the same optimistic EV penetrations, it also proposes tailpipe requirements on ICE products that demand significant levels of all-new technology investment on a shrinking ICE fleet. Again, EPA chooses to exceed even the most forward-leaning precedent of California driving new requirements and development that distracts from the focus needed to execute on our commitment to transition to an EV dominated market by 2035. [EPA-HQ-OAR-2022-0829-0678, pp. 23-24]

Adopt the aggressive CARB ACC II LEV IV criteria emission standards recently finalized by California. Specifically, EPA should: [EPA-HQ-OAR-2022-0829-0678, pp. 24-25]

EPA Should Adopt Stringent CARB ACCII LEV IV Criteria Emissions Standards

Stellantis fully supports AAI's comments and the recommendation to align to CARB ACC II LEV IV criteria emissions requirements. EPA should either adopt or align with California's stringent ACCII LEV IV criteria requirements, avoiding the unnecessary development of all new technology to apply to a shrinking ICE fleet (distracting from EV focus). As highlighted in the examples above, the California standards still provide significant improvements over EPA's Tier 3 standards. EPA must also continue to allow enrichment for component protection which is critically needed for continued use of highly efficient downsized turbocharged powertrains and avoid PM requirements that mandate development of all-new GPF systems and/or extraneous new testing. [EPA-HQ-OAR-2022-0829-0678, pp. 16-17]

Also, vehicles over 22,000 lb. GCWR will be forced to certify on an engine dyno for criteria emissions. Because this is misaligned with California's ACC II LEV IV rules, it forces dual certification efforts, different hardware and uncertain impacts on GHG performance. Stellantis believes the 22,000 lb. GCWR proposed requirement should not be implemented for determination of criteria emissions standards, nor should it be used to alter the GHG stringency. To address EPA concerns, criteria emissions standards should be aligned with CARB's ACC II LEV IV rules instead. [EPA-HQ-OAR-2022-0829-0678, p. 19]

Organization: Toyota Motor North America, Inc.

3. The stringency of the criteria pollutant standards (i.e., tailpipe standards) exceed California's recently finalized LEV 4 standards with little technical or scientific justification. In

fact, the proposed tailpipe standards serve as a de facto BEV mandate. EPA should adopt California's LEV4 standards – the most stringent ever put in place in the U.S. - and not go beyond these. [EPA-HQ-OAR-2022-0829-0620, p. 2]

9.1 Overall comments

Toyota believes that the focus of OEM's efforts should be on electrifying the fleet and that additional and unnecessary provisions with minimal impact on air quality should be reconsidered by the EPA. We believe that the California Air Resources Board (CARB), with their long, collaborative process with all stakeholders, has done a good job of balancing the need to protect human health and with the structure and additional provisions in their LEV IV regulation. Since conventional vehicles will remain in the sales mix though and beyond the timeframe of this Proposed Rule, the unnecessary stringency of certain Tier 4 provisions does not promote more electrification, but rather reduced Toyota's ability to assign resources from conventional engines and hinders EPA's goal of alignment with President Biden's electrification goals. Therefore, we highly recommend that EPA harmonize with the regulatory structure and stringency of the California LEV IV regulation. [EPA-HQ-OAR-2022-0829-0620, p. 48]

Organization: Volvo Car Corporation (VCC)

The proposal if adopted would create unnecessary additional burden on manufacturers that are spending most of their resources on electrification. VCC believes the US government should instead pursue policy that encourages and develops the US electric vehicle market. VCC shares the Biden administration goals on electrification and encourages EPA to implement a rule that does not have unintended consequences like delaying or deterring future electrification plans. [EPA-HQ-OAR-2022-0829-0624, p. 5]

Organization: Wisconsin Department of Natural Resources

4. Alignment with California Air Resources Board (CARB) programs. EPA proposes to align certain program elements with CARB's Advanced Clean Cars II rule (such as accounting for high-powered cold starts in plug-in vehicles) and to update onboard diagnostics (OBD) requirements to reflect CARB's 2022 OBD-II rule. To ensure national consistency and ease compliance requirements for manufacturers, EPA should seek to align such elements with approved CARB regulations whenever possible. [EPA-HQ-OAR-2022-0829-0507, p. 3]

EPA Summary and Response

Summary:

The Alliance for Automotive Innovation (AAI) as well as Ford Motor Company, Kia, Mazda, Mitsubishi, Porsche North America, Stellantis, Aston Martin, BMW and the SVM Ad Hoc group all recommended that EPA adopt CARB's ACC II criteria pollutant program in lieu of EPA's proposal. AAI along with Mitsubishi stated their belief that the proposed criteria pollutant program diverted resources away from EV development and towards ICE technologies. Honda, Mercedes-Benz AG, Porsche, Stellantis and Volvo all commented that the proposed criteria pollutant standards will distract resources from efforts to electrify the fleet and act as an unnecessary burden on the vehicle manufacturers. The Colorado Energy Office, Colorado Department of Transportation, and Colorado Department of Public Health and Environment seemed to echo this comment and expressed concern that the criteria pollutant program could have the unintended effect of delaying electrification. In addition, Honda commented that the criteria pollutant program proposed by EPA is too reliant on electric vehicles and ancillary systems, such as charging infrastructure, to achieve the levels of electrification required to meet the proposed criteria pollutant standards and suggested. “We respectfully urge the agency to finalize a more reasonable emissions reduction trajectory, along with a broader array of compliance flexibilities.” Honda, Mercedes-Benz and Stellantis also commented on the stringency of CARB’s ACC II program and stated that the proposed criteria pollutant program from EPA went beyond the stringency of ACC II.

On the other hand, the California Air Resources Board (CARB), Ceres Corporate Electric Vehicle Alliance (CEVA) and the Center for Biodiversity (CBD) et al. all commented in favor of the proposed criteria pollutant standards, with CBD noting that “While electrification is undoubtedly an effective and important means of securing emissions reductions, there will also be tens of millions of gas guzzlers that will be sold before EVs become dominant.” CARB commented similarly “Because U.S. EPA’s proposal does not require ZEV sales, as California’s rules do, the tightening of criteria air pollutant emission standards is even more critical to ensure that the internal combustion engine vehicles that will continue to be sold are becoming cleaner.”

The Auto Alliance pointed out that the instructions for -7°C testing in 40 CFR 86.1811-27(c)(1) improperly cited a provision describing the Highway Fuel Economy Test.

Response:

EPA thanks all the commenters for providing comments regarding the proposed criteria pollutant standards. EPA believes that the form and the stringency of final criteria pollutant program addresses the comments received, provides additional alignment with the CARB ACC II program in certain respects, and is within EPA’s Clean Air Act statutory authority.

As several commenters noted, there will most likely be over 100 million ICE-based vehicles sold in the U.S. in the coming decades. Under our central case projections nearly 40% of new vehicles sold and 82% of the on-road fleet will have internal combustion engines in 2032. In addition, EPA’s GHG and criteria pollutant programs are performance-based, and vehicle manufacturers will most likely adopt different technology solutions to meet the final standards, some of which could include heavy reliance on a spectrum of ICE-based technologies such as advanced gasoline engines, hybrids and plug-in hybrids. EPA agrees that tightening emission standards for ICE-based vehicles is critically important to ensure that these vehicles continue to become cleaner.

EPA disagrees with comments that the criteria pollutant program is a distraction from electrification and with comments that the criteria pollutant program can only be met with the adoption of BEVs. Several vehicle manufacturers have announced new engine development programs, such as GM’s 6^{th} generation V8, and it seems clear that vehicle manufacturers continue to invest in ICE technology even as they ramp up their EV portfolios. In addition to electrification, manufacturers have the ability to reduce emissions from their ICE-based vehicles through available technologies including better combustion control and improved after-treatment systems allowing them to comply with the final standards with a combination of ICE improvements and electrification. The basis for our technical conclusion that these standards are feasible without the adoption of BEVs is explained further in Chapter 3.2 of the RIA.

Regarding AAI's comment that the instructions for -7°C testing in 40 CFR 86.1811-27(c)(1) improperly cited a provision describing the Highway Fuel Economy Test, we have corrected this for the final rule to refer to the testing instructions for -7°C testing at 40 CFR 1066.801(c)(6).

Many auto industry commenters recommended that EPA adopt the CARB ACC II program in lieu of our proposed criteria pollutant program. While elements of EPA's final standards are consistent with the CARB standards, as discussed further in responses later in this section, and EPA did consider aspects of the CARB standards in evaluating appropriate standards under the Clean Air Act, EPA disagrees with commenters that we should adopt the CARB's ACC II program as recommended by commenters. The CARB ACC II program holistically considers both greenhouse gas and criteria pollutant emissions, with the foundation of the ACC II program being a manufacturers' production requirement for ZEVs. Commenters did not recommend adopting the ZEV requirement provisions of ACC II and instead recommended that EPA only adopt some of the criteria pollutant elements of ACC II. This a la carte approach to emissions standards fails to consider the interdependent nature of CARB's ACC II program. CARB's treatment of ICE-based vehicles is premised on an increasing penetration of ZEVs in the California fleet, and the associated emission reductions that result from an increasing percentage of ZEVs. EPA's program, being performance-based for both GHG and criteria pollutant emissions, relies on increasingly stringent performance-based standards to achieve substantial emissions reductions nationwide. As a result, ICE-based vehicles are anticipated to be part of most manufacturers' product plans under the EPA standards. With ICE-based vehicles representing such a substantial portion of new vehicles sold and the on-road fleet for decades to come, to achieve the necessary emissions reductions for both GHG and criteria pollutant emissions it is important that ICE vehicles, in addition to electric vehicles, continue to reduce emissions. GM supports this position and commented "In many cases, an EPA final rule aligned with CARB's LEV IV in internal combustion engine criteria emission stringency and the associated test and certification procedures will help GM achieve significant emissions reductions for internal combustion engine products as soon as MY 2027 despite limited lead time, while continuing to transition to zero-emission vehicle technologies." EPA is, however, finalizing additional provisions which are responsive to certain comments recommending alignment with ACC II, as discussed further in responses later in this section.

4.1 - Program design and structure

Comments by Organizations

Organization: Cummins

•

• Standards should be fuel neutral (i.e., same stringency regardless of fuel type) to ensure the environmental benefits of the regulation are achieved regardless of the fuel type chosen by customers. [EPA-HQ-OAR-2022-0829-0645, pp. 2-3]

Organization: General Motors, LLC (GM)

The following appendices provide further detailed regulatory and technical comments. Appendix A
provides recommended edits to EPA's proposed regulatory text to clarify various parts of the regu latory language to ensure a successful and aligned set of EPA regulatory requirements. The other appendices provide confidential business information to help inform various technical aspects of the criteria emission and GHG standards. In many cases, an EPA final rule aligned with CARB's LEV IV in internal
combustion engine criteria emission stringency and the associated test and certification procedure s will
help GM achieve significant emissions reductions for internal combustion engine products as soon as MY 2027 despite limited lead time, while continuing to transition to zero-emission vehicle technologies. [EPA-HQ-OAR-2022-0829-0700, p. 6]

[See original attachment for April 7, 2023 EPA Memorandum with subject: Redline Version of EPA's Proposed Regulations to Adopt New Standards for Light-Duty and Medium-Duty Vehicle Standards"] [EPA-HQ-OAR-2022-0829-0700, p. 6]

[See original attachment containing redacted confidential comments titled, "Summary of GM Technical Comments and Recommendations in Response to Environmental Protection Agency's (EPA) Notice of Proposed Rule Making (NPRM) for Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles (Tier IV)" [EPA-HQ-OAR-2022-0829-0700, p. 6]

Organization: KALA Engineering Consultants

Suggested Alternatives

KALA is an engineering firm and would not be making these comments unless we had some alternatives to suggest to EPA. If the EPA does the right thing and makes known the attributable upstream and downstream GHG emissions for both gasoline and BEV vehicles in a straight-forward comparison, the GHG reduction premise for the EPA Docket ID No. EPA–HQ–OAR–2022–0829 would be nullified. That leaves the criteria air pollutant emission reduction premise for the proposed rulemaking. As we stated above, we concur with EPA that BEVs would reduce criteria pollutant levels where they operate. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

However, looking at what has been happening with weather events, forest and wildfire emissions and more frequent flooding events over the last 20 years, the number of lives lost from those Climate Change-related calamities may soon overwhelm any life-saving measures that would stem from implementing the criteria pollution standards proposed in this docket, previous dockets and future dockets. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

Despite that grim assessment, we feel that continuing to try and reduce criteria pollutants is worthwhile, even though massive forest fires in Canada this year seem to have wiped out any progress in that area for the time being. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

Focusing Criteria Pollutant Emission Reductions on Nonattainment Areas

In the Federal Register Text for the EPA–HQ–OAR– 2022–0829, EPA identifies the number of air pollution nonattainment areas around the country. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

From Section I. A. 2, i: “There are currently 15 PM2.5 nonattainment areas with a population of more than 32 million people and 57 ozone nonattainment areas with a population of more than 130 million people.” [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

Each of those PM 2.5 and Ozone nonattainment areas of the country have vehicles that are either registered within the nonattainment area or are registered in surrounding counties that by regularly driving into the nonattainment area contribute to criteria pollutant emissions within the geographic nonattainment area. The vehicles registered outside the nonattainment area itself that contribute to emissions within the actual geographic confines of the defined nonattainment area are probably used to drive to destinations inside the nonattainment area for work or other reasons. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

Our reasoning for what we are about to suggest is based on the question we asked ourselves. “If we really want to make the biggest impact on highly air polluted locations, as defined by nonattainment areas, why require nation-wide criteria pollutant standards when requiring low or no operating emission vehicles to be used within or to enter nonattainment areas might obtain acceptable significant reductions?” We really must agree with the comments from South Dakota Department of Agriculture and Natural Resources (DANR), in which they said, [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

South Dakota is a large state with significant driving distance between many of our communities. Although several new electrical vehicles indicate they have a 200 mile or greater range (note – it is 224 miles one way from Pierre to Sioux Falls), a recent study shows electric vehicles (EVs) do not consistently achieve EPA' s range estimates. In addition, all batteries degrade over time. Reports indicate EV vehicle batteries will degrade between 10 and 40 percent over a 10-year life span. To maintain the battery's life, manufactures recommend batteries are not frequently depleted below 10 percent capacity or charged above 90 percent capacity. This means that an electrical vehicle should be limited to 80 percent of its capacity range to maintain the battery's life. In addition, cold, hot, and windy weather conditions may reduce an EV vehicle's range between 20 to 40 percent and may further impact the reliability of EV. South Dakota is known to have cold and windy winters and hot and windy summers, which, with current EV ranges, batteries conditions, and availability of charging stations, makes widespread use of EV s impractical in South Dakota. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

We believe that a regulatory scheme targeted at vehicles that regularly operate within nonattainment areas, requiring vehicle registrants to use low or no operating emission vehicles if they wish to operate those vehicles inside the nonattainment area on a regular basis would be one approach to reduce criteria emissions in those designated areas. Such a regulatory scheme would require cooperation with the automobile registration agencies, the air quality or resources agencies and potential enforcement agencies within the state where the nonattainment areas are located. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

By shifting focus to nonattainment areas, the efforts underway to add charging stations all over the country could be re-focused to install many more charging stations within nonattainment areas and get more bang for the Federal buck spent. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

Here is how we see such a plan could work. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

A. Vehicle registrants who reside inside the non-attainment area would receive notices that their vehicle(s) do not meet newly promulgated EPA regulations for lowering air pollutant emissions in the local nonattainment area. These of course, would include fleet owners of delivery vans, service vehicles, school busses and other owners of large numbers of vehicles that operate principally inside or very nearby the nonattainment area boundaries. These notices would inform them that one or more of the vehicles they own may no longer be used to drive within the local area because the emissions from the vehicle(s) are too high. The notice would inform the registrants that they can ask for monetary assistance with purchase of a compliant vehicle (sort of like Cash for Clunkers, i.e. high polluting vehicles) or ask for a waiver due to the age of the registrant and/or very low use of the non-complying vehicles (you know, that little old lady who just drives her car to church and the grocery store). [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

B. Since vehicles are re-registered every year, state registration bureaus would ask registrants if they work or travel to destinations inside the nonattainment area on a regular basis. If so and their vehicles are non-compliant, they would receive the same notice that the non-compliant vehicle they drive into the nonattainment area must be changed out to a compliant vehicle by a date certain. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

C. Enforcement could be carried out by application of modern technology. With the advancement of Artificial Intelligence, cameras, many of which are now in place, could be connected to computer systems using software that reads the license plate numbers for vehicles entering the nonattainment area. As time goes by and the same license plates, which of course have vehicle information tied to them including engine type and possibly latest emissions testing data, are read over and over again, the registrant for that vehicle would be notified that the vehicle they are using has been spotted entering the nonattainment area multiple times, enough times to meet criteria for regular entry, and they must switch to a compliant vehicle by a date certain. Warnings and then fines could be levied in stepped amounts against repeat offenders who regularly operate non- compliant vehicles in the nonattainment area. Impoundment would be the final step. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

D. The states where these focused programs would be operating could set up a vehicle connection service similar to or connected to Craig’s List in which non-compliant vehicle owners could sell or swap their vehicles with interested parties within the state or outside of the state. The description of such vehicles would be required to notify potential buyers that the vehicle does not comply with nonattainment area emission requirements and buyers should not attempt to register the vehicle if they will be entering a nonattainment area with it regularly. There should also be a website that will show car buyers where nonattainment areas and possible candidates for nonattainment areas are located and the qualifying vehicles for each, which could be tailored to the particular criteria pollutant group, such as PM2.5 or Ozone, the area falls under. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

E. EPA might require large over-the-road trucks to drive to a central off-loading location where their cargo would be removed in a timely manner from their trailers into covered or enclosed staging platforms where pallets or other items would be re-loaded onto heavy-duty all-electric urban delivery vehicles that would then distribute the goods to various destination points within the nonattainment area (about a 75 mile round trip distance). These truck off-loading facilities would be located downwind of the prevailing winds for the area so that PM and diesel soot would be blown away from the nonattainment area most of the time and be dispersed through dilution. Moving trucks and special loads that require heavy lift machinery to off-load would be exempt from these requirements. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

We believe this sort of regulatory scheme could work better than applying universal, nation-wide criteria pollutant standards for all vehicles, especially in those locations where such standards are not actually required to meet local air quality goals. If the proposed rulemaking standards were revised to apply to nonattainment areas, and major urban corridor areas, such as the more dense parts of the I-95 corridor, the complaints seen in the comments to this rulemaking would be lessened or mitigated. We think most people can agree that vehicle requirements that address the worst air pollution areas in the country should be acceptable to protect the health of those who live and work in those areas. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

Organization: Mitsubishi Motors North America, Inc. (MMNA)

Mitsubishi participated in the development of - and supports - the comments submitted by Auto Innovators. [EPA-HQ-OAR-2022-0829-0682, p. 2]

In addition, based on its considerable experience discussed previously with BEV and PHEV leadership, Mitsubishi provides the following recommendations to supplement the comments of Auto Innovators:

1.

2. Consider the many benefits of PHEVs to consumers and the environment during the expected period of constrained battery critical minerals production capacity, and how PHEVs are the perfect stepping- stone to full BEV acceptance. [EPA-HQ-OAR-2022-0829-0682, p. 2]

3.

4. Keep the proposed approach to determine the passenger car curves, and consider adjusting the cutpoint and stringency levels of the light-duty trucks during the early years of the program. [EPA-HQ-OAR-2022-0829-0682, p. 2]

5. Maintain the existing GHG program flexibilities, such as Air Conditioning and Off-Cycle technologies credits (including the alternative method to apply off-cycle credits), and allow previously approved technologies to continue receiving credits. [EPA-HQ-OAR-2022-0829-0682, p. 2]

6.

7. Consider the impact that very aggressive GHG standards will have on vehicle affordability, and especially the detrimental impact to low-to-moderate income families. Regardless of the vehicles that regulation may require us to produce, it is critical that regulators always keep the accessibility of consumers in mind. [EPA-HQ-OAR-2022-0829-0682, p. 2]

Organization: Stellantis

Eliminate counting vehicles without tail pipes (BEV, FCEVs) as part of a tail pipe emissions fleet [EPA-HQ-OAR-2022-0829-0678, pp. 24-25]

Organization: Toyota Motor North America, Inc.

3. The stringency of the criteria pollutant standards (i.e., tailpipe standards) exceed California's recently finalized LEV 4 standards with little technical or scientific justification. In fact, the proposed tailpipe standards serve as a de facto BEV mandate. EPA should adopt California's LEV4 standards – the most stringent ever put in place in the U.S. - and not go beyond these. [EPA-HQ-OAR-2022-0829-0620, p. 2]

9. Tier 4 Program

Toyota supports the comments by the Alliance for Automotive Innovation by reference. The comments here are to add emphasis or additional perspective to those items. [EPA-HQ-OAR-2022-0829-0620, p. 48]

EPA Summary and Response

Summary:

In addition to the broad comments regarding the proposed criteria pollutant program, EPA also received comments from several stakeholders regarding the overall program design and structure. Mitsubishi Motors recommended that EPA consider the benefits of PHEVs in meeting future standards and that EPA should maintain the existing standards in form and stringency in the early years of this rulemaking. Toyota and Stellantis commented that they felt the stringency of the criteria pollutant program goes beyond the California ACC II program and Toyota also stated that the stringency acts a "de facto BEV mandate." Toyota also recommended that EPA adopt the California ACC II standards.

Kala Engineering Consultants provided detailed comments regarding restricting operation of vehicles with high emissions in non-attainment areas. Kala noted that not all areas in the United States were in non-attainment and recommended that vehicles and/or vehicle operation be controlled within these non-attainment areas to reduce emissions. These recommendations were made as an alternative to nationwide emissions standards that would broadly impact the entire country.

Cummins commented that standards should be fuel-neutral.

Response:

EPA has considered the vehicle manufacturer comments within the context of the overall criteria pollutant design, structure and stringency and concluded that the program design and structure, as proposed and as finalized, is appropriate. While some manufacturers commented that EPA's proposed criteria pollutant program goes beyond the stringency of California's ACC II program, EPA addresses the rationale for final standards and not adopting CARB ACC II in RTC Section 4.1.1 above.

EPA disagrees that the criteria pollutant program is a de facto BEV mandate. Each of the criteria pollutant standards is performance-based. Vehicle manufacturers are anticipated to apply a variety of technologies to meet the standards, including but not limited to BEVs. For example, many ICE-based vehicles are already being certified at or below the final fleet average NMOG+NOX standards being finalized in this rule and vehicle manufacturers have a variety of technologies that can be applied to ICE-based vehicles to reduce their criteria pollutant emissions. For additional detail regarding the current fleet compliance status and technologies that could be applied to reduce criteria pollutant emissions, please refer to RIA Chapter 3.2.

Regarding Kala Engineering Consultants recommendation to limit vehicles and/or vehicle operation to reduce emissions only within non-attainment areas instead of broadly applied national standards, while the concept of "geofencing" vehicle operation is known to EPA, we do not believe it to be an effective approach to ensuring emissions reductions, and such a concept is outside the scope of this rulemaking.

Regarding Cummins comments on fuel neutrality of the standards, the standards are fuel neutral except for medium-duty diesels at low ambient temperatures. Diesel MDV are exempt from the -7°C FTP NMOG+NO_X standard but we are requiring manufacturers to report results from this test cycle in their certifications. We are also applying a NO_X temperature correction to the in-use standards for high GCWR diesel MDV. These differences for diesel MDV are due to current limitations with respect to NO_X control from selective catalytic reduction (SCR) systems at cold ambient temperatures. The Agency will continue to monitor technology developments with respect to diesel SCR system NO_X emissions control at cold ambient temperatures.

4.1.1 - Phase-in of criteria pollutant standards

Comments by Organizations

Organization: Alliance for Automotive Innovation

B. Tier 4 Phase-Ins

1.General Tier 4 Phase-In Approach

EPA proposes to require a general phase-in of Tier 4 provisions, under which 40% (in MY 2027), 80% (in MY 2028) and 100% (in MY 2029) would need to meet all Tier 4 requirements. [EPA-HQ-OAR-2022-0829-0701, pp. 143-145]

If EPA was simply proposing to adopt the same provisions as California adopted in ACC II, a short phase-in such as that proposed might be adequate. However, EPA is proposing more stringent standards, across more test cycles and conditions, than the ACC II program requirements. Manufacturers are likely to encounter technical challenges as they develop solutions to meet these new requirements, particularly if EPA finalizes its proposed general prohibition on enrichment, which will significantly impact vehicle drivability. [EPA-HQ-OAR-2022-0829-0701, pp. 143-145]

Auto Innovators is also concerned that every vehicle and powertrain combination would need to pass all of the new, individual requirements in order to be counted in the phase-in. Should a vehicle that a manufacturer planned to include in a test group in the phase-in encounter unexpected challenges with one or more of the Tier 4 provisions, it would need to be pulled from the test group and would not count in the volume-weighted phase-in calculation. With the short duration provided to comply with the aggressive Tier 4 phase-in, there will likely not be enough time to solve all technical issues while still meeting the proposed phase-in. [EPA-HQ-OAR-2022-0829-0701, pp. 143-145]

To address this concern, we recommend that EPA offer the option of an alternate phase-in plan, similar to what is done with current and CARB ACC II LEV IV regulations. We also recommend that EPA allow credits to be earned for early compliance, and that EPA provide a four-year phase-in period. This will allow OEMs to solve significant technical challenges and procure the hardware needed to address the Tier 4 (unique) proposed requirements. We recommend a 25/50/75/100% (MY 2027-2030) four-year phase-in. [EPA-HQ-OAR-2022-0829-0701, pp. 143-145]

In addition, we request that EPA separate the Tier 4 requirements, similar to CARB's ACC II LEV IV regulation, allowing flexibility to meet different aspects of the Tier 4 regulation (e.g., PM standards vs. enrichment prohibitions), with different vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 143-145]

1.PM Phase-In

As discussed elsewhere, Auto Innovators opposes EPA's proposed PM standards, but would support adoption of the California ACC II PM standards. However, if EPA finalizes its proposals instead of adopting the California PM standards as we recommend, we believe that EPA should reconsider the Tier 4 PM phase-in. [EPA-HQ-OAR-2022-0829-0701, pp. 143-145]

Automakers have already begun research, design, and development of strategies to meet California's phase-in of more stringent PM standards in MYs 2026-2030. EPA's PM standards, if adopted as proposed, would likely strand those investments. Our preferred approach (if EPA proceeds with its proposal) would be to implement the federal standards after completion of the California ACC II PM phase-in. We recommend that any unique EPA PM requirements take effect starting in MY 2030 and phase-in by 40/80/100% through MY 2032. [EPA-HQ-OAR-2022-0829-0701, pp. 143-145]

2. Light- and Heavy-Duty Vehicle Phase-In Split

As required under the Clean Air Act, EPA treats vehicles with a gross vehicle weight rating (GVWR) less than or equal to 6,000 lbs. (light-duty vehicles in this discussion) differently than vehicles with a GVWR greater than 6,000 lbs. (heavy-duty vehicles in this discussion). [EPA-HQ-OAR-2022-0829-0701, pp. 143-145]

Auto Innovators is concerned that EPA does not appear to have considered the implications of electrification on GVWR where some vehicles that have historically been considered light-duty, might become heavy-duty vehicles due to battery weight and no longer count in the light-duty phase-in. [EPA-HQ-OAR-2022-0829-0701, pp. 143-145]

In such a scenario, EPA's assumptions about the market share of BEVs (upon which NMOG+NOx fleet average standards are premised) could be in error. Furthermore, separating the ≤6,000 lb. GVWR fleet from the 6,001 – 8,500 lb. GVWR fleet separates vehicles that are currently being used in a combined "compliant" ≤8,500 lb. fleet. Combined fleets are managed by offsetting less capable vehicles with more capable vehicles, which provides automakers the opportunity to maintain compliance while phasing out legacy vehicles and focusing on the transition to electrification. [EPA-HQ-OAR-2022-0829-0701, pp. 143-145]

We recommend that EPA allow BEV applications to optionally count in the ≤6,000 lb. GVWR fleet phase-in, regardless of GVWR. [EPA-HQ-OAR-2022-0829-0701, pp. 143-145]

3. Enrichment Phase-In

Notwithstanding the above comments on EPA's proposed prohibition on enrichment, if EPA does proceed with its proposal, it should be clear how this provision is phased in. [EPA-HQ-OAR-2022-0829-0701, pp. 143-145]

Auto Innovators suggests a longer phase-in for Tier 4 requirements and that separate, and appropriately timed phase-ins be applied instead of a single vehicle needing to meet all aspects of the Tier 4 requirements. The same should apply to a prohibition on enrichment, if adopted. [EPA-HQ-OAR-2022-0829-0701, pp. 143-145]

Furthermore, we note a lack of clarity in the proposed regulatory text related to the phase-in for prohibition of enrichment. The proposed text at 40 C.F.R. 86.1809-12(d)(2) specifies that "This determination [that enrichment is unnecessary] is effective for all vehicles certified to Tier 4 standards."256 The proposed Tier 4 regulations require all vehicles to meet the Tier 4 NMOG+NOx standards, effective MY 2027, but other provisions of Tier 4 are phased in over three years, and vehicles that do not meet the other provisions are "interim" Tier 4 vehicles. Thus, it is not completely clear whether the proposed general prohibition on enrichment is tied to vehicles that meet the Tier 4 NMOG+NOx standards, or whether it is tied to full Tier 4 vehicles (as opposed to interim Tier 4 vehicles). [EPA-HQ-OAR-2022-0829-0701, pp. 143-145]

256 NPRM at 29418.

We recommend that if EPA adopts its proposal to prohibit enrichment for Tier 4 vehicles, it should then also modify the proposed 40 C.F.R. 86.1809-12(d)(2) text to ensure the text is interpreted as applying to only those vehicles which EPA intends it to apply. [EPA-HQ-OAR-2022-0829-0701, pp. 143-145]

2. Phase-in of Criteria Pollutant Standards and 40 CFR §86.1813-17(b)(1)(i)

Clarification is requested regarding the 8.5K – 14K incomplete vehicle ORVR phase in requirements. Is the ORVR compliance phase-in independent of the exhaust emissions phase-in tables or are the phase-in options associated. I.e., if an OEM uses a model year 2027 exhaust phase-in does that mean the ORVR phase-in must also start in model year 2027? [EPA-HQ-OAR-2022-0829-0701, p. 188]

Auto Innovators disagrees with this approach. The current 2027MY requirements should not be reopened. The 2027MY standards should remain unchanged from the final rule that EPA issued in 2016CY, as that is what OEMs have relied upon to create compliance plans. Further, the Clean Air Act section 202(a)(3)(C) mandates four-year lead time and three-year stability periods. The agency is proposing only three full years of lead time (assuming the Proposed Rule is finalized later this year) and no stability period between any of the proposed annually decreasing GHG standards. EPA's proposal is inconsistent with the CAA and, thus, no change should occur in 2027MY. Finally, OEMs need more time to adapt to a fuel neutral standard.

Therefore, when fuel neutrality is implemented, it should be phased in over several years (30/60/100), and not fully implemented until 2032MY. [EPA-HQ-OAR-2022-0829-0701, pp. 193-194]

K. Technical Issues with Proposed Tier 4 Regulatory Text

1. Proposed 40 C.F.R. § 86.1811-27(b)(6)(i)

The proposed 40 C.F.R. § 86.1811-27(b)(6)(i) specifies to "Include all light-duty program vehicles at or below 6,000 pounds GVWR in the calculation to comply with the Tier 4 fleet average NMOG+NOx standard."293 We believe the preamble text and this command's placement as part of (b)(6) makes it clear that this instruction applies only to the NMOG+NOx standards at (b)(2), and their phase-in at (b)(6)(i). Nevertheless, for the avoidance of any doubt, EPA may want to explicitly describe the standards at (b)(2) and the phase-in at (b)(6)(i) to make clear that the command does not apply to the cold temperature NMOG+NOx fleet average standards at (c)(3)(i). [EPA-HQ-OAR-2022-0829-0701, p. 188]

293 NPRM at 29420.

Organization: Alliance for Vehicle Efficiency (AVE)

AVE supports EPA's proposal for lower criteria pollutants and requests that the EPA accelerate the fleet compliance phase-in requirements for particulate matter. [EPA-HQ-OAR-2022-0829-0631, pp. 7-8]

AVE supports EPA's proposal for a PM standard of 0.5 mg/mi for both LD and all MD vehicles. AVE members produce technologies like gasoline particulate filters (GPFs) that make this stringency level feasible and cost-effective. Furthermore, AVE members are already working with manufacturers to design and install the requisite technology into many of today's vehicles. [EPA-HQ-OAR-2022-0829-0631, pp. 7-8]

AVE is concerned about the longer than necessary phase-in for compliance with the new PM stringency levels and recommends that EPA consider a 60% compliance level in 2027, followed by 90% in 2028, and then 100% in 2029. Delaying implementation appears counterproductive and unnecessary. [EPA-HQ-OAR-2022-0829-0631, pp. 7-8]

The need for quicker action is obvious. The International Coalition for Clean Transportation (ICCT) recently reported that PM emission levels across the U.S. have risen since 2015 and are now back to 2005 levels.19 In the Proposal, EPA strongly emphasizes the significant health benefits that will accrue from the lower PM standard but does not fully justify the basis for a long phase-in period. The American Lung Association reports of a long-term study of people in six U.S. cities from 1974 to 2009 that supports faster action addressing PM. [EPA-HQ-OAR-2022-0829-0631, pp. 7-8]

19 See ICCT https://theicct.org/publication/true-pm-emissions-jun23/

"The findings suggest that cleaning up particle pollution had almost immediate health benefits. The researchers estimated that the U.S. could prevent approximately 34,000 premature deaths a year if the nation could lower annual levels of particle pollution by 1 µg/m3."20 [EPA-HQ-OAR-2022-0829-0631, pp. 7-8]

20 See https://www.lung.org/clean-air/outdoors/what-makes-air-unhealthy/particle-pollution

EPA references the agency's consideration of bringing environmental justice to at-risk communities and AVE supports this effort. Still, a shorter phase-in period for new stringency levels would do a great deal more to accomplish this effort and bring more immediate relief to the communities that bear a disproportionate amount of the country's particulate pollution. [EPA-HQ-OAR-2022-0829-0631, pp. 7-8]

The technologies needed to meet the proposed PM standard have already been deployed on millions of vehicles in Europe and China by the same global manufacturers who sell vehicles in the U.S. market. This experience likely negates the need for a long lead time before MY 2027. Moreover, suppliers stand ready to support manufacturers with cost-effective technology and the experience to meet the proposed standards. [EPA-HQ-OAR-2022-0829-0631, pp. 7-8]

Organization: American Honda Motor Co., Inc.

Phase-in timeline for compliance with 0.5 mg/mi standard is unreasonable [EPA-HQ-OAR-2022-0829-0652, p. 14]

In addition to concern about the agency's proposed 0.5 mg/mi stringency, we are similarly concerned with the agency's proposed phase-in schedule. EPA's proposed phase-in timeline to reach 100% compliance is just three years (from 2027-2029), providing virtually no lead time and forcing unplanned development for technologies the industry is already planning to sunset. Development cycles required by manufacturers would need to be initiated in 2023 to begin the 40% phase-in for MY2027 vehicle production. As this NPRM is unlikely to be finalized until early-to-mid 2024, manufacturers could possibly already be late in being able to meet a 40% compliance requirement for MY2027, as vehicles will already be going down the manufacturing line by late 2026. [EPA-HQ-OAR-2022-0829-0652, p. 14]

Organization: Cummins

- Sufficient regulatory lead time and stability should be provided to allow manufacturers to develop and implement the technologies needed to improve emissions and spread investments over time to minimize cost to customers. [EPA-HQ-OAR-2022-0829-0645, pp. 2-3]

Organization: Energy Innovation

In the EPA's proposed rule, the GHG tailpipe standards for LDVs are "projected to result in an industry-wide average target for the light-duty fleet of 82 grams/mile (g/mile) of carbon dioxide (CO_2) in MY 2032, representing a 56 percent reduction in projected fleet average GHG emissions target levels from the existing MY 2026 standards."12 The proposed GHG standards for MDVs are "projected to result in an average target of 275 grams/mile of CO_2 by MY 2032, which would represent a reduction of 44 percent compared to the current MY 2026 standards."13 The proposed rule will also reduce cumulative GHG emissions between 2027 and 2055: CO_2 by 26 percent, methane (CH_4) by 17 percent, and nitrous oxide (N_2O) by 25 percent, compared to no-action scenario.14 See table 135 below from the proposed rule. [EPA-HQ-OAR-2022-0829-0561, pp. 5-7]

12 U.S. EPA, “Proposed Rules,” May 5, 2023, 29196.

13 U.S. EPA, 29196.

14 U.S. EPA, 29348.

[See original attachment for “Table 135 – Estimated GHG Impacts of the Proposed Standards Relative to the No Action Scenario, Light-Duty and Medium-Duty”] [EPA-HQ-OAR-2022-0829-0561, pp. 5-7]

While the proposed rule is an improvement over the status quo, greater emissions reductions via higher rates of electrification in the LDV and MDV sectors are needed to reduce harmful air pollutants and mitigate climate change. We believe EPA’s alternative to the proposed rule (Alternative 1) is the preferred option (as discussed further below) because it will achieve greater emissions reductions more quickly, while still being technologically feasible and cost-effective. [EPA-HQ-OAR-2022-0829-0561, pp. 5-7]

Organization: Ford Motor Company

Standards Continuation Beyond 2032MY

In multiple areas of the NPRM the EPA has requested comment on continuation of light- and medium-duty GHG and criteria pollutant standards beyond 2032MY. Ford opposes continuation of any of the standards beyond the 2032MY. Industry already faces substantial uncertainty before 2032MY, and it is not feasible to establish a robust program beyond that time. [EPA-HQ-OAR-2022-0829-0605, p. 8]

Finally, Ford recommends that EPA defer the phase-in requirement of the new PM standards to starting in 2029MY, consistent with the Ford recommendation for the new fuel enrichment requirements. [EPA-HQ-OAR-2022-0829-0605, p. 13]

Organization: Mercedes-Benz AG

Mercedes-Benz also requests that EPA provide, at a minimum, a one-year delay and four-year phase- in for these changes in order to allow sufficient engineering development time to update engine strategies for compliance, and time to phase new engines into the fleet. This timing would be consistent with EPA’s own recognition of product cycles: “EPA has also considered vehicle redesign cycles. Based on previous public comments and industry trends, manufacturers generally require about five years to design, develop, and produce a new vehicle model.”5 Application of a new engine would not be incorporated during a vehicle refresh and instead would occur at the time of major redesign. [EPA-HQ-OAR-2022-0829-0623, p. 7]

5 NPRM at 29341.

although EPA provides several different phase-in approaches for the criteria emissions standards to meet the lead-time and stability requirements as obligated by the Clean Air Act, EPA should recognize that the proposed phase-ins do not necessarily follow industry standard product cycles. Particularly in this instance, where standards adopted by CARB have formed the main driver of emission standards since the rulemaking process began in 2020. Powertrain improvement and development of new engine platforms and is a multi-year process. These developments improve emissions performance and customer experience, but the three model year lead-time proposed for the early compliance option may not align with product cycle refreshes in the MDV segment. EPA should alter the phase-in schedule to better align with existing product cycle planning or allow manufacturers to request an alternative early-compliance pathway. This would encourage early compliance and associated emissions benefits as product cycles refresh and evolve. [EPA-HQ-OAR-2022-0829-0623, p. 19]

Organization: Porsche Cars North America (PCNA)

2. Porsche supports an extended phase-in timeline and alternative phase-in for Tier-4 Compliance

Porsche supports the comments from AFAI regarding an extended phase-in for the percentage of projected new vehicles that must comply with Tier-4 standards. As recommended by the AFAI, Porsche supports a revision to the proposed language in 86.1811-27(b)(6)(i) to require 25% in MY2027, 50% in MY2028, 75% in MY2029 and 100% in MY2030. Porsche supports this extension given the requirement in (b)(6)(i) for a vehicle to meet all the proposed standards to be considered within the phase-in. As AFAI notes, manufacturers may have difficulty in meeting narrow elements of the overall proposal, especially elements that are not aligned with California's LEV-IV programs. Because EPA is requiring vehicles to meet Tier-4 in its entirety, regardless of which part is unable to be achieved, the vehicle would not be included in the phase-in. The longer phase-in could provide additional flexibility for vehicles that need time to meet all the requirements, especially the newer requirements being proposed by EPA. [EPA-HQ-OAR-2022-0829-0637, pp. 9-10]

In addition, Porsche supports the addition of a point-based alternative phase-in option available to manufacturers to use for determining compliance with the phase-in in lieu of the annual percent-based compliance. The point-based system could utilize previous examples in which the percentage of a manufacturers fleet that meets the standards is multiplied by a declining annual value, with a minimum points requirement that must be achieved by a future date. The exact function can be developed to ensure that the alternative point-based system delivers consistent emissions reductions with the percent-based system. The opportunity to earn higher points in earlier model years would incentivize early Tier-4 concepts, which could in turn provide additional flexibility for concepts that may need to comply later either due to their redesign cycle, or for concepts which may be having challenges with specific portions of the Tier-4 package and simply need additional development time. [EPA-HQ-OAR-2022-0829-0637, pp. 9-10]

4. In the default pathway, Porsche supports adding the opportunity for early, optional Tier-4 compliance for light-duty program vehicles over 6000 pounds. [EPA-HQ-OAR-2022-0829-0637, pp. 10-11]

Porsche supports the position of the AFAI to include within the default compliance pathway outlined in 86.1811- 27(b)(6)(ii) the ability for LDT3, LDT4, and MDPV vehicles (i.e., vehicles over 6000 pounds) to optionally comply with Tier-4 requirements prior to the 2030 model year requirement. These vehicles could be referred to as "Default Path Early Tier-4" vehicles which could then be included within the Tier-4 phase-in percentages in 86.1811-27 for vehicles under 6000 pounds. The volumes used for determining compliance to the Tier-4 phase-in would include the projected volume for these Default Path Early Tier-4 vehicles and the compliance percentages would be calculated accordingly. [EPA-HQ-OAR-2022-0829-0637, pp. 10-11]

Porsche recognizes that some manufacturers may find that the default pathway better aligns with their future product portfolio versus the alternative early pathway in 86.1811-27(b)(6)(iii) (i.e., including all vehicles under 8500 pounds vehicles together). Porsche appreciates that the default pathway was defined to reflect the Clean Air Act minimum lead time for vehicles over 6000 pounds and thus reflects that there is no obligation for those vehicles to meet Tier-4 standards prior to model year 2030. This proposal for Default Path Early Tier-4 vehicles should continue to align with the Clean Air Act in that manufacturers in the default pathway are not required to choose to declare these vehicles as Default Path Early Tier-4s, but if they do, then the vehicles could be counted in the Tier-4 phase-in. [EPA-HQ-OAR-2022-0829-0637, pp. 10-11]

The option for over 6000 pounds vehicles to be included early could provide manufacturers who have selected the default pathway with some additional flexibility for complying with the Tier-4 phase-in, without having to fully reject the default pathway altogether. As noted by the AFAI, future electric vehicles are likely to incorporate larger traction batteries to meet customer demand for increasing range or utility. A manufacturer in the default pathway may find they are at risk of compliance with the under 6000 pounds Tier-4 phase-in should an electric vehicle that was intended to be part of the phase-in begin to approach the 6000 pounds threshold as product teams demand more range or utility. By allowing over 6000 pounds vehicles to still be counted in the Tier-4 phase-in, this flexibility would provide greater freedom to product teams balancing phase-in compliance with increasing customer needs. [EPA-HQ-OAR-2022-0829-0637, pp. 10-11]

Organization: South Coast Air Quality Management District

There are five key issues we request U.S. EPA address before finalizing the rule. [EPA-HQ-OAR-2022-0829-0659, p. 2]

1. Extend the phase-in period and adopt more stringent standards to align with California's ACC II regulation. The proposed standards will be phased in over a six-year period from model year (MY) 2027 through 2032 with increasing stringency each year. We recommend that the phase-in period be extended to 2035 and later model years to better align with the ACC II implementation schedule which extends out to MY 2035 and subsequent years. [EPA-HQ-OAR-2022-0829-0659, p. 2]

EPA Summary and Response

Summary:

Much like other topics regarding the proposed criteria pollutant program, EPA received several comments regarding the phase-in of the revised standards. EPA received comments that were both supportive of the proposed phase-in and recommended that the agency shorten the window of time for vehicle manufacturers to comply with more stringent requirements and comments that recommended that the agency provide more time and additional flexibility in meeting new requirements.

The Alliance for Automotive Innovation (AAI) commented that the duration of the phase-in might be appropriate had EPA adopted California's ACC II program in lieu of the proposed standards. AAI noted that, due to the differences in the two programs, manufacturers were more likely to experience technical difficulties in meeting the EPA standards. Mercedes commented similarly and stated that the ACC II criteria pollutant planning was the main driver in their product development. Mercedes added that the current phase-in does not recognize vehicle manufacturers product planning cycles. AAI made special note of EPA's proposal to eliminate command enrichment and the potential for vehicle drivability issues as the result of eliminating enrichment. AAI and Porsche also commented on the Tier 4 phase-in requirement by which the EPA proposed that all vehicles brought into Tier 4 as part of the phase-in would be required to meet all the Tier 4 provisions. AAI further noted that meeting all the provisions simultaneously on a single vehicle may increase the risk to vehicle compliance. AAI recommended that EPA allow provisions to be separated, similar to the CARB ACC II program. AAI and Porsche also recommended that EPA allow credits for early compliance and an alternative phase-in of 25/50/75/100% for MY's 2027 through 2030.

AAI also commented on specific criteria pollutant provisions. Regarding the phase-in of PM standards, AAI noted that manufacturers were already working on developing technical solutions to meet the CARB ACC II PM standards. For PM, AAI recommended delaying revised federal standards until after the ACC II program was fully phased-in. The specific recommendation as a PM phase-in of 40/80/100%, starting in MY 2030 and ending in MY 2032. AAI also made recommendations regarding the phase-in of enrichment and ORVR. AAI also suggested clarifying that the NMOG+NOx phase-in proposed at 86.1811-27(b)(6)(i) did not apply for the NMOG+NOx standards for cold temperature testing.

Alliance for Vehicle Efficiency (AVE) commented in support of EPA's PM standards and recommended a more rapid phase-in of the standards noting in the process ICCT's recent assessment the PM emissions have been increasing in the United States since 2015. AVE recommended a phase-in of 60/90/100% from MY 2027 through MY 2029. AVE emphasized the need for PM reductions by noting the impact that PM has on disadvantaged neighborhoods and the prolific application of gasoline particulate filters outside of the United States.

Cummins requested sufficient regulatory lead time and stability in order for manufacturers to develop and implement the technologies needed to improve emissions and spread investments over time to minimize cost to customers.

Ford Motor Company commented that they did not support the EPA programs extending beyond MY 2032 and recommended that the revised PM standards should begin phasing in in MY 2029.

Porsche Cars North America recommended a point-based phase-in in lieu of an annual percentage-based phase-in and noted that previous criteria pollutant programs have adopted a similar strategy for some pollutants.

South Coast Air Quality Management District (SCAQMD) recommended that EPA extend the phase-in period to MY 2035 to align with CARB's ACC II program.

<u>Response:</u>

EPA has carefully considered all the comments received regarding the phase-in for criteria pollutant standards. As a result, the agency is finalizing a phase-in that is about a year slower than proposed. Instead of the 40/80/100% phase-in from MY's 2027 through 2029 that was proposed, EPA is finalizing a 20/40/60/100% phase-in that runs from MY 2027 through MY 2030 for vehicles <6,000 pounds GVWR, maintaining the 100% phase-in for vehicles >6,000 pounds GVWR, and adding one additional year for vehicles >6,000 pounds to meet the final phase-in for criteria pollutant standards. For more information on phase-in see preamble Section III.D.1.

EPA does not believe that creating separate and unique Tier 4 phase-ins for each program provision is required or appropriate. Vehicle emissions control systems are designed and deployed as a system. Changes made to support lower NMOG+NOx standards, certification to lower emissions bins, elimination the SFTP and lower PM standards go together, and the agency feels it is reasonable to expect vehicle manufacturers to design, develop and deploy systems which are optimized to meet all of the criteria pollutant emission requirements simultaneously, just as they are today. Separate phase-ins may result in vehicle manufacturers trading off one pollutant for another to meet individual phase-in requirements.

As responded below, the EPA does not plan to finalize new restrictions on command enrichment so concerns regarding the phase-in of enrichment requirements are no longer valid.

Regarding comments such as those from Alliance for Vehicle Efficiency (AVE) regarding a faster phase-in, while it is true that tens of millions of gasoline particulate filters have been deployed worldwide, very few are commercially available as original equipment on US sold vehicles. Given that the United States has unique, and in many cases more stringent, criteria pollutant emission standards as compared to the rest of the world, the agency believes that it is reasonable to provide vehicle manufacturers with more lead-time to adapt PM control technologies to existing vehicles and calibrations.

Cummins comments regarding standards stability and lead time with respect to their products are entirely directed at vehicles with more than 6,000 pounds GVWR, which are regulatorily defined as "heavy-duty" under the Clean Air Act. EPA's default compliance programs for heavy-light-duty trucks above 6,000 pounds GVWR (e.g., LDT3, LDT4 and MDPV) and for MDV all provide a minimum of 4 years of lead time and 3 years of standards stability, as required by the Clean Air Act for heavy-duty vehicles.

On the other hand, both Ford and AAI recommended that EPA delay phase-in of the final PM standards until after CARB's ACC II PM standards were fully phased in. As EPA's PM standards are more stringent than CARB's this recommendation does not seem to be required or necessary. Given the overlapping timeframe of the two rulemakings, and statements by vehicle manufacturers that they are reducing focus on ICE powertrain development, we expect that vehicle manufacturers will design their systems to meet the most stringent PM standards and will not develop systems twice. Emission control systems that comply with EPA's final PM standards will also be compliant with CARB's ACC II program.

EPA has chosen not to adopt Porsche's recommendation for a point-based phase-in as an alternative to year over year percentage increases. The agency believes that extending the phase-in addresses Porsche's request for additional flexibilities, as well as the ability to apply BEVs to the phase-in requirements.

Regarding the SCAQMD comments regarding extending the phase-in until MY 2035 to better align with the CARB ACC II program, EPA has decided to finalize the proposed rulemaking period that results in a fully phased in program in MY 2032. EPA will continue to monitor technology progress as well as other related regulator actions as it considers potential standards beyond the MY 2032 timeframe.

The final rule includes clarifying language to state that the NMOG+NOx phase-in requirements of 40 CFR 86.1811-27(b)(6)(i) apply for 25°C testing, and not for -7°C testing.

4.1.2 - NMOG+NOx

Comments by Organizations

Organization: Alliance for Automotive Innovation

Criteria Emission Standards

Automakers will spend $1.2 trillion by 2030 as a down payment on a net-zero future, but far more will be needed. If we hope to succeed, automakers must focus resources on the EV transformation rather than incremental changes to existing, very near-zero (criteria) emission ICE vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 5-6]

This should not be interpreted as automakers requesting no criteria emission reductions or regulations. We support changes that can be made cost-effectively through software calibration changes to the vehicle. For example, we support and recommend EPA adopt the criteria emission standards California adopted under Advanced Clean Cars II (i.e., LEV IV). We worked with California over several years to develop these standards that substantially reduce real- world criteria pollutants (nonmethane organic gas (NMOG), nitrogen oxides (NOx), particulate mater (PM)), as rapidly as possible without stranding technology or diverting resources from electrification. [EPA-HQ-OAR-2022-0829-0701, pp. 5-6]

However, some of the changes proposed in the NPRM go far beyond California's LEV IV program and would require large human and capital resources. For example, all-new engine designs, retooling of engine and vehicle production facilities, new hardware on vehicles, and additional testing laboratories are required at the same time the EPA expects 67% of new vehicles to be BEVs. These simultaneous ICE-focused activities will distract from efforts to electrify light-duty vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 5-6]

NMOG + NOx Fleet Average

Unlike California, EPA proposes a performance-based standard that counts zero-emission vehicles in the NMOG+NOx fleet average. While EPA calls this a performance-based standard, it assumes a high BEV penetration rate for setting the standard (i.e., a light-duty vehicle at 12 mg/mi fleet average assumes 60% of the fleet are BEVs). This is more akin to a design requirement. Regulating criteria emissions from vehicles with criteria emissions (i.e., excluding ZEVs from the fleet and regulating that fleet at 30 mg/mile) is a more appropriate performance-based method. Like EPA's proposed GHG requirements, it is unknown if market sales of BEVs will achieve the specified targets. Making up for reduced BEV sales by reducing emissions from ICE vehicles will take years of development and cannot be altered on an annual basis. To avoid risk of an uncertain BEV market, major ICE investments and diverting resources from focused electrification efforts, we recommend EPA adopt the California Air Resources Board's (CARB) stringent LEV IV regulatory framework that phases-out BEVs in the NMOG + NOx fleet average. This will provide planning stability and an insurance policy from market conditions that OEMs have no control over. Adopting CARB's requirements will ensure significant reductions in tailpipe emissions while avoiding major ICE investments and maintaining the focus on electrification that will have a great reduction in criteria emissions over time. [EPA-HQ-OAR-2022-0829-0701, p. 7]

Recommendation

GHG – Better align to President Biden's 2030 electrification goal [EPA-HQ-OAR-2022-0829-0701, pp. 7-8]

To address the concerns identified above, Auto Innovators and our members recommend EPA reevaluate the GHG standards and more closely align with President Biden's 2030 goal. Thus, we recommend adopting requirements for 40 to 50% BEV, PHEV, and FCEVs in 2030 with continued increases through 2032. These standards should be coupled with and connected to regularly measured infrastructure deployment and battery critical mineral supply levels available during this rule. [EPA-HQ-OAR-2022-0829-0701, pp. 7-8]

Criteria – Adopt California's LEV IV Standards [EPA-HQ-OAR-2022-0829-0701, pp. 7-8]

For the Tier 4 criteria pollution standards, we recommend that EPA adopt California's LEV IV exhaust and evaporative emission standards adopted just seven months ago and begin in 2026MY. LEV IV standards were adopted by California last year as an effective and appropriate path forward to address the toughest in the nation air quality challenges. EPA should align with this comprehensive strategy to enable a nationwide criteria emissions program. [EPA-HQ-OAR-2022-0829-0701, pp. 7-8]

If EPA finalized the multi-pollutant regulations with these two recommendations, the final regulations would still be the most aggressive and challenging in U.S. history, and they would provide dramatic reductions in GHG and criteria emissions. However, EPA would reduce the risk of potential harmful consequences to both the EV market, and the new vehicle market in general, by forcing BEVs at a rate that outpaces the EV supply chain, infrastructure, critical mineral supplies, and customer acceptance. Getting the pace right is critical to the success of the automakers and to U.S. leadership and competitiveness. [EPA-HQ-OAR-2022-0829-0701, pp. 7-8]

IV.Light-Duty Criteria and Toxic Pollutant Standards [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

Automakers are committed to ultimately achieving net-zero transportation carbon emissions and electrification of the light-duty vehicle fleet. However, this transformation requires massive investment in EV technology and supporting mechanisms such as infrastructure, all involving many stakeholders. To be successful, automakers must primarily focus resources on the transformation rather than incremental changes to existing internal combustion engine (ICE) vehicles, which are already very near zero. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

The focus of EPA and the automakers is and should be on electrification. Thus, Auto Innovators supports changes to traditional criteria emission (e.g., NMOG, NOx, and PM) standards that measurably reduce emissions, but do not add substantial additional hardware or capital costs to ICE vehicles that will soon be retired. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

Unfortunately, EPA proposes to adopt new requirements that will divert resources from our shared goal of widespread electrification. Prohibiting enrichment could require complete engine redesigns and possibly larger displacement engines to provide customers with the capability they demand. The proposed PM standards substantially increase costs and vehicle development complexity in addition to adding testing requirements. Finally, in several cases, EPA provides less flexibility and/or chooses not to align with ACC II. This lack of alignment is particularly troubling as automakers and suppliers have already developed product plans and spent resources toward meeting the ACC II regulations, and in some cases, EPA's proposal would require substantial changes during the middle of ACC II regulatory phase-ins. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

To reduce costs while still providing similar (and substantial) environmental benefits, the EPA regulations should seek to align with criteria emissions regulations already adopted by California in ACC II. We worked closely with the California Air Resources Board (CARB) and with EPA staff in attendance and participating,255 for the past several years to develop standards that substantially reduce real-world criteria emissions (including NMOG+NOx and PM), as rapidly as possible without stranding technology or diverting resources from electrification. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

255 At no time did EPA staff indicate a different or more stringent pathway was under development federally, while the auto industry provided input, feedback, and technical data to CARB. The California process provided an ideal forum for alignment, even if EPA could not commit to alignment at that stage.

We recommend that EPA adopt the ACC II criteria emission regulations in place of its proposal. This adoption would provide substantial environmental benefits, streamline the regulations, and allow automakers to focus resources on electrification rather than developing and deploying changes to ICE vehicles specific to EPA's proposed new requirements. At a minimum, EPA should align with ACC II through the end of the ACC II phase in periods; in most cases, ACC II regulations are fully phased in by MY 2030. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

A. Consideration of the California ACC II Criteria Pollutant Regulation as an Alternative [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

EPA failed to consider adopting various California ACC II criteria pollutant provisions, and in so doing has also failed to demonstrate the incremental costs and benefits of its proposed program relative to this existing and logical alternative. EPA has also failed to consider the appropriate time to develop and deploy the additional ICE technologies to meet its proposal, particularly in the context of an overlapping and different final state regulation. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

It is no defense to say that EPA has yet to approve a Clean Air Act waiver for these provisions. EPA has yet to reject a waiver request from California, and included the California ACC II program as a sensitivity case to the proposed greenhouse gas regulations. Unfortunately, to the extent that the ACC II sensitivity case provides estimates of criteria emission benefits, it has been challenging, if not impossible, to separate benefits associated with the GHG program from those associated with the criteria pollutant program, and even more difficult to separate the impacts from individual components of the proposed criteria pollutant program. These challenges have been exacerbated by the limited time available to comment on the NPRM. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

If EPA proceeds with its own misaligned proposal to the logical alternative of California's ACC II program, it should at a minimum demonstrate the incremental benefits and costs of each of its unique program aspects relative to the ACC II program. In addition, if EPA proceeds with its own proposal, EPA should also align with ACC II through the end of the ACC II phase in periods before starting new requirements on top of those already under implementation. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

C. NMOG+NOx Standards

We recommend that EPA align its regulations to the California ACC II program. To the extent that EPA proceeds with its original proposal, we provide the following comments on the proposed NMOG+NOx requirements. [EPA-HQ-OAR-2022-0829-0701, pp. 145-147]

1.Electric Vehicles in the FTP NMOG+NOx Fleet Average

a)ZEVs

EPA proposes to include ZEVs in the FTP NMOG+NOx fleet average calculations, and has correspondingly proposed fleet average standards that decline to 12 mg/mile, well below the 30 mg/mile (with ZEVs phased out) fleet average in the California ACC II program. [EPA-HQ-OAR-2022-0829-0701, pp. 145-147]

Consistent with our broader recommendation that EPA align its regulations to the California ACC II program, we recommend that EPA set the Tier 4 FTP NMOG+NOx fleet average requirement at 30 mg/mile and phase-out ZEVs from the fleet average. In addition to our concerns with EPA's projections for electric vehicles, highlighted in Section I of these comments, we are also concerned that the NMOG+NOx fleet average is a second, separate regulation that is generally premised on EV market share projections. With multiple overlapping regulations (in terms of EV dependence) there may be unforeseen conflicts that could create compliance difficulties or raise regulatory costs without providing additional benefits. Even the lack of certainty of EV penetration prior to completion of a model year may cause difficulties. Our suggested approach would remove the dependence on EV market share for compliance with the FTP NMOG+NOx fleet average requirement, addressing these concerns. If EPA instead proceeds with their proposed approach, it should ensure that compliance with the NMOG+NOx fleet average standard is not overly reliant on the assumed penetration rates of electric vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 145-147]

a) PHEVs

If EPA decides to proceed with its proposed approach of including ZEVs in the FTP NMOG+NOx fleet average, we believe that the criteria pollutant emissions of PHEVs should be adjusted for the zero-emission portion of their operation. Such action would recognize the emission benefits of these vehicles and would be consistent with EPA's treatment of BEVs for the purposes of criteria emissions. [EPA-HQ-OAR-2022-0829-0701, pp. 145-147]

2.High-Altitude FTP Bin Standards

EPA is proposing to regulate high-altitude FTP emissions at the same stringency as the low-altitude FTP requirement. EPA states that, “Modern engine management systems can use idle speed, engine spark timing, valve timing, and other controls to offset the effect of lower air density on exhaust catalyst performance at high altitudes.”257 While this is true during warmed-up conditions, cold start emissions are impacted by the lower air density at altitude that cannot be overcome by “modern controls.” [EPA-HQ-OAR-2022-0829-0701, pp. 145-147]

257 DRIA at 3-36.

- Reduced effectiveness of Catalyst Warm up Strategy: The lower air density at high altitude makes it impossible to warm-up the catalyst as quickly as is done at low altitude. [EPA-HQ-OAR-2022-0829-0701, pp. 145-147]

- High Altitude Fuel Volatility: High altitude certification fuel has a lower vapor pressure. For a given engine power, manifold pressure and other operating characteristics are the same, but the fuel vaporization is not, which tends to result in combustion residues, which in turn impact emissions during warm-up. [EPA-HQ-OAR-2022-0829-0701, pp. 145-147]

- Reduced Exhaust Gas Recirculation (EGR): The lower air density at high altitude reduces the amount of EGR, resulting in higher NOx emissions. [EPA-HQ-OAR-2022-0829-0701, pp. 145-147]

For the reasons described above, additional aftertreatment development will be necessary to meet EPA’s proposed standards. The proposed high-altitude standards will, as a result, require improvements to the aftertreatment system (precious metal content, catalyst volume and additional control devices). In addition, automakers would need to increase laboratory capacity, possibly even building additional laboratories at a significant capital cost, for high-altitude testing to develop these improved systems. These resources would be better applied to vehicle electrification. At minimum, EPA should provide a specific assessment of the emissions benefit of this added requirement, along with a full assessment of testing availability, capacity and resources. [EPA-HQ-OAR-2022-0829-0701, pp. 145-147]

We recommend that EPA adopt the high altitude NMOG+NOx standards recently adopted in ACCII as shown in Figure 40 below.

Figure 40: Recommended High-Al□tude Standards

Bin	Low Altitude Standard (g/mi)	High Altitude Standard (g/mi)
BIN 160	160	160
BIN 125	125	160
BIN 70	70	105
BIN 60	60	90
BIN 50	50	70
BIN 40	40	60
BIN 30	30	50
BIN 25*	25	50
BIN 20	20	30
BIN 15*	15	30
BIN 10	10	20**

[EPA-HQ-OAR-2022-0829-0701, pp. 145-147]

3. NMOG+NOx Cold FTP Fleet Average

EPA proposes to set a cold FTP NMOG+NOx fleet average requirement of 300 mg/mile, excluding ZEVs.258 EPA requests comment on whether a 400 mg/mile vehicle cap should be used instead of a fleet average.259 [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

258 NPRM at 29262.

259 NPRM at 29262.

Auto Innovators prefers a fleet average requirement, but requests a value of 300mg/mi for LDV+LDT1 and 400mg/mi for LDT2+HLTD+MDPV for the following reasons: [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

At -7 °C, emission reduction right after engine start-up and during catalyst warm-up is the key factor. Large displacement engines (V6, V8, etc.) inevitably have substantially higher emissions at engine startup before the catalyst is warmed up. For downsized turbocharged engines, the amount of heat supplied to the catalyst decreases due to the relationship between the recovery of the exhaust energy by the turbocharger and the heat capacity of the turbocharger itself; thus, the warm-up time tends to be longer than that of an engine without a turbocharger. During this longer warm-up time when the catalyst is in a semi-active state, the heavier vehicle with a turbocharger under high running load conditions has much higher emissions than other vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

According to the DRIA, EPA developed the proposal based on the test results of three models. The results of these three models certainly meet 300 mg/mi. However, due to differences in exhaust system layout (i.e., front catalyst distance from the engine) and engine control from these models, there are some models that cannot achieve both emission reduction before catalyst warm-up and early catalyst warm-up at a high level under -7 °C condition. There are also vehicles that are heavier than the vehicles EPA tested. [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

Developing technology to adapt these vehicles to 300 mg/mi would require diverting substantial resources from electrification:

1.For emission systems development and evaluation, update and/or increase of chassis dynamometer system testing to make it possible to reproduce cold temperature condition is necessary. [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

2.Development of pistons and injectors for better combustion and designing arrangement of emission purification devices are necessary. When changing the catalyst system (increase in the amount of precious metals, increase in the number of cells), increase in costs occurs. [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

Regarding the 300 mg/mile fleet average, EPA proposes that the family emission limit (FEL) be set to a resolution of 0.1 g/mile (100 mg/mile).260 An FEL set to only a single decimal place (i.e., 0.x g/mile) provides very little flexibility among different vehicles. We recommend that

EPA allow an FEL resolution to three decimal places (i.e., 0.xxx g/mile). [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

260 NPRM at 29436.

We also note that although EPA describes the 300 mg/mile fleet average as excluding ZEVs in the preamble,261 the proposed 40 C.F.R. § 86.1811-27(c)(3)(i) regulatory text does not reflect that exclusion.262 Auto Innovators agrees with the exclusion and recommends updating the regulatory text accordingly. [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

261 NPRM at 29262.

262 NPRM at 29420.

F. Interim In-Use Standards

Auto Innovators recommends EPA provide interim in-use compliance standards for PM, early drive-away, and US06 NMOG+NOx standards, consistent with the approach taken by CARB in its LEV IV program.280 [EPA-HQ-OAR-2022-0829-0701, p. 178]

280 See 13 C.C.R. § 1961.4(d)(2)(A)3., (2)(C)3., (3)(A)5.a., and (3)(A)5.b.

Notwithstanding our comments opposing EPA's proposed PM standards, we recommend that test groups first certified to Tier 4 PM standards in the first four years of the program meet an in-use standard 1 mg/mile higher than the certification standard. [EPA-HQ-OAR-2022-0829-0701, p. 178]

For early drive-away and US06 NMOG+NOx standards, we recommend that test groups first certified to these Tier 4 standards in the first two years of the program meet an in-use standard 1.2 times their certification standard. [EPA-HQ-OAR-2022-0829-0701, p. 178]

Vehicles will still certify to the new standards, but the interim in-use standards reduce the jeopardy associated with new technology and more stringent standards. [EPA-HQ-OAR-2022-0829-0701, p. 178]

G. Tier 4 Emission certification Bins

For several decades, EPA and CARB have provided multiple emission certification bins – from less stringent to more stringent. Automakers can certify vehicles to any bin but must meet a sales-weighted fleet average. The use of bins provides automakers with flexibility to certify some vehicles to higher bins and others to lower bins. At the same time, the fleet average provides assurance of air quality benefits. The number of bins or emission levels associated with bins does not have even a theoretical impact on air quality. In fact, we have recommended allowing automakers to set family emission limits (FELs). Nonetheless, both EPA and CARB have restricted the number of bins in the past. [EPA-HQ-OAR-2022-0829-0701, pp. 178-179]

As we approach zero emissions, flexibility becomes far more important. Unfortunately, as shown below, the NPRM further restricts the number of bins to which vehicles can certify, including eliminating bins allowed under ACC II, and not providing bins that were added under ACC II. For example, ACC II allows Bin 125 through 2028. The inclusion of Bin 125 for a short additional period minimizes the need for additional investments in vehicles that are approaching end-of-life. As a result of fleet averaging, the number of bins has no impact on environmental benefits. [EPA-HQ-OAR-2022-0829-0701, pp. 178-179]

We therefore recommend EPA align the bins in Tier 4 with those in ACC II. We agree with the addition of Bin 10 (10 mg/mile) and plan to request CARB add this bin during their next ACC II regulatory update. We would also recommend that both EPA and CARB consider adding bins 35, 45, and 90 to provide manufacturers with greater flexibility while maintaining environmental benefits. [EPA-HQ-OAR-2022-0829-0701, pp. 178-179]

We also note that, unlike CARB, EPA does not allow a higher US06 standard for bins below 30 mg/mile. The emission variation associated with high-speed, high-load cycles on the US06 are particularly challenging at the very low emission levels (sub-30 mg/mile). Consequently, we recommend EPA align Tier 4 with ACC II and set a 30 mg/mile standard for US06 for all bins below bin 30. [EPA-HQ-OAR-2022-0829-0701, pp. 178-179]

[See original attachment for Figure 66: Comparison of EPA and CARB Bins] [EPA-HQ-OAR-2022-0829-0701, pp. 178-179]

K. Technical Issues with Proposed Tier 4 Regulatory Text

However, when evaluating the existing vehicles pulled into the new MDPV definition and making conclusions that the proposed definition would not affect the classification of existing Class 2b and 3 ICE vehicles, it does not appear that EPA considered the proposed 22,000-pound limit to GCWR in the WF calculation, which is proposed to begin in MY 2030, in combination with the 5,000-pound WF threshold. After the WF GCWR limit, many ICE work trucks in the market today would be classified as MDPV in MY 2030 and beyond (see examples below). Manufacturers encourage EPA to review compliance data submissions to reassess how the proposed MDPV definition may interact with 2023MY and 2024MY ICE products. [EPA-HQ-OAR-2022-0829-0701, pp. 198-200]

[See original attachment for Figure 73: Sample ICE Work Trucks and Classifications]

307 Press Kit: 2023 Ram Heavy Duty, Towing specifications (Public “Base Weight Total” used for example may vary from “EPA Curb” weight) htps://media.stellantisnorthamerica.com/newsrelease.do?id=24053&mid=,

The consequences of shifting ICE work vehicles to the MDPV regulatory class are significant. For criteria emissions, the MDPV NMOG+NOx targets are proposed to be 12 mg/mi in MY 2030 vs. 178 or 247 mg/mi for MDV in MY 2029 in the default compliance pathway308 (see Figure 74 below), and the MDPV definition would preclude these work trucks from certifying to proposed Bin 160 or Bin 125, which are reserved only for MDVs.309 The EPA NPRM analysis does not appear to recognize that many ICE work trucks would switch to MDPV with the proposed new MDPV definition, and no technology pathway is discussed to bring a 2029MY9 MDV work truck into a compliant light-duty averaging set. [EPA-HQ-OAR-2022-0829-0701, pp. 198-200]

308 NPRM at 29261, Table 41.

309 NPRM at 29261, Table 42.

[See original attachment for Figure 74: NPRM Table 41: LDV, LDT, MDPV and MDV Fleet Average NMOG+NOx Standards Under the Default Compliance Pathway] [EPA-HQ-OAR-2022-0829-0701, pp. 198-200]

With the proposed new MDPV definition, after the WF calculation adjustments beginning in MY 2030, many ICE work trucks over 22,000 pounds GCWR would otherwise be required to engine dyno cert if they were not MDPVs. The logic appears paradoxical and unintended. These vehicles cannot be both so alike to passenger vehicles that they should be regulated as passenger vehicles, and so alike to heavy-duty purpose-built work trucks that they should be regulated the same as light-heavy engines. Many of these ICE vehicles pulled into the new MDPV definition in MY 2030 today share engine hardware with vehicles that would be required to engine dyno cert under Part 1036 in MY 2030 due to the 22,000-pound GCWR limit. [EPA-HQ-OAR-2022-0829-0701, p. 200]

There is a stark difference between light-duty chassis dyno certification procedures, required for MDPVs, and engine dyno certification procedures for vehicles over 22,000-pound GCWR. Similar vehicles sharing parts and development resources today could be forced to pursue different development paths based on the proposed MY 2030 class definitions and test procedures. [EPA-HQ-OAR-2022-0829-0701, p. 200]

Complexity with the proposal is not limited to within the EPA program. Department of Transportation, through the Corporate Average Fuel Economy program, may have different regulatory class definitions for fuel consumption regulations than proposed by EPA. California Air Resources Board, through Advanced Clean Cars II, has different NMOG+NOx Bins, and different certification requirements than EPA proposes.310 [EPA-HQ-OAR-2022-0829-0701, p. 200]

F. MDV BINs

13. Background NMOG+NOx Bins

As noted above in Section III.F, EPA and CARB have provided different emission certification bins – from less stringent to more stringent – for several decades. Automakers can certify vehicles to any bin but must meet a sales-weighted fleet average. The use of bins provides automakers substantial flexibility to certify some vehicles to higher bins and others to lower bins. At the same time, the fleet average provides assurance of air quality benefits. The number of bins or emission levels associated with bins does not have even a theoretical impact on air quality. In fact, we have recommended allowing automakers to set family emission limits (FELs). Nonetheless, both EPA and CARB have restricted the number of bins in the past. [EPA-HQ-OAR-2022-0829-0701, pp. 205-206]

Like LDVs, EPA has proposed Bins that do not align with the Bins in California's ACC II. As shown in Figure 75 below, EPA prohibits virtually every bin that is allowed in California's ACC II LEV IV regulations. At the same time, EPA proposes 60 mg/mile fleet average requirement for MDVs, assuming it will be met using a blend of BEVs and ICE vehicles. While EPA does propose additional bins in 10 mg/mile increments from Bin 70 to Bin 0, and we support additional bins, these are unlikely to be used for Class 2b and 3 vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 205-206]

Combined with California's restriction against selling a vehicle in California with a higher emission bin than the one sold federally (see 13 CCR 1961.4(c)(6), Equivalence of Federal Standards), this effectively mandates that every Class 2b and 3 ICE vehicle certify to Bin 125 –

the only common bin between California and EPA. [EPA-HQ-OAR-2022-0829-0701, pp. 205-206]

[See original attachment for Figure 75: MDV Category Bins Tier 4 vs ACC II] [EPA-HQ-OAR-2022-0829-0701, pp. 205-206]

14. Recommendations on MDV Bins and NMOG+NOx stringency

Manufacturers recommend that EPA align with California ACC II stringency for MDV NOx. Manufacturers have plans for ICE vehicles to meet the Bin150 standards for gas, and Bin175 for diesel MDV powertrains, including in use testing at high loads. [EPA-HQ-OAR-2022-0829-0701, pp. 206-207]

To the extent that EPA projects that manufacturers will use ZEVs to meet lower fleet averages, EPA should carefully study which ZEVs would remain as MDVs, and be subject neither to the MDPV definition, nor Part 1036 engine dyno certification requirements, nor migrate to Class 4 to maintain current performance after accounting for the size and weight of ZEV hardware (batteries, etc.). Manufacturers recommend that ZEVs no longer meeting the final MDV definition not be included in the MDV averaging set when EPA sets standards. The NMOG+NOx fleet averages likely need to be adjusted to account for the lower BEV volumes resulting from either (or both) changes in the definitions and market projections for potential BEV sales, similar to our concerns noted with the MDV GHG fleet targets. [EPA-HQ-OAR-2022-0829-0701, pp. 206-207]

We strongly recommend EPA align the bins in Tier 4 with those in ACC II, LEV IV. Otherwise, Tier 4 will eliminate all flexibility associated with the bin system. Additional bins simply provide flexibility for manufacturers to meet the fleet average emission standards in the most cost-effective manner possible. They encourage incremental per vehicle improvements and will provide for a more effective program as BEV technology ramps up and the fleet average NMOG+NOx ramps down. [EPA-HQ-OAR-2022-0829-0701, pp. 206-207]

1. Reduce Refinery Gate and Downstream Sulfur Caps to 10 ppm

When EPA finalized the Tier 3 rules governing gasoline, it lowered the maximum average sulfur level from 30 ppm to 10 ppm. This change was essential to enable advance emissions control technology to achieve the lower tailpipe emissions standards that are part of the Tier 3 standards because, as EPA points out, “any amount of gasoline sulfur will deteriorate catalyst efficiency.”446 However, EPA continues to allow gasoline with 80 ppm sulfur at the refinery gate and 95 ppm downstream. Auto Innovators continues to stand behind previous industry comments on sulfur as detailed in the Auto Alliance Tier 3 comments.447 Refiners and the distribution system have had many years to adjust to lower sulfur standards. [EPA-HQ-OAR-2022-0829-0701, p. 274]

446 Control of Air Pollution from Motor Vehicles: Tier 3 Motor Vehicle Emission and Fuel Standards, Proposed Rule, 78 Fed. Reg. 29816, 29821 (May 21, 2013).

447 Supplemental Comments of the Alliance of Automobile Manufacturers on Market Gasoline Sulfur, Alliance of Automobile Manufacturers (Oct. 31, 2013), Docket ID EPA-HQ-OAR-2011-0135-4950.

If EPA pursues lower Tier 4 emissions standards in the NPRM, we urge EPA to reduce the refinery gate cap to 10 ppm, perhaps with a phase-in period, and at the same time to develop a pathway toward a downstream retail cap of 10 ppm per gallon. The elimination of gasoline with greater than 10 ppm sulfur will enable advanced emissions control technology and will reduce the impact of sulfur on catalyst efficiency. This cap aligns with sulfur caps in the European Union and many parts of Asia, including China. The lower sulfur cap also aligns with the lower NMOG + NOx standards as proposed in the NPRM. [EPA-HQ-OAR-2022-0829-0701, p. 274]

Organization: Alliance for Vehicle Efficiency (AVE)

Finally, AVE supports EPA's proposed stringency level for NMOG + NOx cap for cold testing. The current proposal at 300 mg/mi is feasible and suppliers already manufacture the technology to comply. [EPA-HQ-OAR-2022-0829-0631, p. 8]

Organization: American Lung Association (ALA) et al.

Better Control Fine Particles and Ozone-forming Air Pollutants from New Vehicles
EPA has taken an appropriate multi-pollutant approach to the standards to ensure the cleanup of ozone-forming emissions. To maximize the benefits of the rule, EPA should consider eliminating smog-forming certification levels for higher polluting light-medium vehicles over time. While the proposals intend to push fleet averages of smog-forming emissions down by 60 percent or more, there are still allowances for much higher emitting vehicles through the entirety of the rulemaking. We also encourage EPA to phase out higher-emitting certification levels to drive both fleet average and individual vehicle emissions lower over time. [EPA-HQ-OAR-2022-0829-0745, pp. 2-3]

Organization: American Petroleum Institute (API)

ii. Criteria pollutants proposed stringency of requirements do not factor non-BEV technologies.

EPA proposes to reduce30 the NMOG+NOx standard by 60% from the current 30 mg/mile level to 12 mg/mile in 2032. We do not believe this reduction is justified either on a health benefit or a cost-effectiveness basis. Furthermore, the criteria pollutant proposal for NMOG+NOx is another example of setting a performance standard that can only be met by a specific vehicle technology. EPA has not demonstrated a technically feasible path for OEMs to meet NMOG+NOx standards with a mixed vehicle fleet comprised of large and small light-duty vehicles with ICE technologies. The examples given in the DRIA (Table 3-14) for vehicles that currently meet less than 15 mg/mile NMOG+NOx is limited to sedans and smaller SUVs, but do not include pick-up trucks and full-size SUVs. Trucks and SUVs represent a significant portion of OEM fleets.31 EPA instead anticipates and sets the standard to require the use of BEVs by OEMs to sell large SUVs and trucks, instead of allowing for a choice of technology paths which could include ICE vehicles in the fleet. This is arbitrary and capricious and could likely have implications for consumers choice and costs. Moreover, only 19 vehicles were certified below 15 mg/mi that rely only on ICE technologies out of the approximately 299 carline models certified by EPA in 2021. [EPA-HQ-OAR-2022-0829-0641, pp. 11-12]

30 In its recent Advanced Clean Cars II regulation, the California Air Resources Board has maintained a 30 mg/mile NMOG+NOx standard.

Organization: Aston Martin Lagonda (AML)

- Understanding what SVMs are selling in the US

Neither with regard to criteria emissions nor GHG does EPA explain in the NPRM the paucity (verging on absence) of Small OEM flexibility or additional lead-time. A misstatement in the preamble may shed light on this: in the preamble (88 FR 29405) (May 5, 2023), EPA incorrectly states (as does the Draft Regulatory Impact Analysis) that the "proposed NMOG+NOx standards should have no impact on the existing Small Business manufacturers, which currently produce only electric vehicles." This is simply not so. There most certainly are SVMs that produce internal combustion engine (ICE) vehicles for the US market, AML being one of them. Nowhere in the draft RIA does the term "small volume manufacturer" even appear, and the draft RIA thus fails to address the SVM segment of the industry. Given that the EPA has consistently recognised the SVM category, it is unusual that it would bring forward punitive regulations at those companies less able to deal with heavy sanctions. [EPA-HQ-OAR-2022-0829-0566, p. 4]

B. THERE ARE FOUR SPECIFIC TOPICS IN THE NPRM THAT ARE OF DEEP CONCERN TO SVMs

1. CRITERIA EMISSIONS

- "Moving the goalpost" for MY 27 and 28 makes the trajectory exceptionally challenging for SVMs therefore appropriate derogations are essential. Special accommodation must be made for SVMs that took strategic decisions and made technological and financial commitments more than 5 years ago and are unable to make rapid adjustments to adapt to new regulation at pace. [EPA-HQ-OAR-2022-0829-0566, pp. 6-7]

EPA proposes to abandon the MY 27 and 28 SVM NMOG+NOx standards set forth in Tier 3 (and on which SVMs have been rightfully relying), and to require SVMs to adhere to the Tier 4 large volume (and short) phase-in. [EPA-HQ-OAR-2022-0829-0566, pp. 6-7]

This inequitably conflicts with the already established and in effect SVM phase-in set forth in 40 CFR 86.1811-17 (h)(l), as follows: [EPA-HQ-OAR-2022-0829-0566, pp. 6-7]

SVM Fleet Average NMOG+NOx Standard (mg/mile)

Model year: 2027: In effect Tier 3: 51; In effect Tier 4: 22

Model year: 2028: In effect Tier 3: 30; In effect Tier 4: 20 [EPA-HQ-OAR-2022-0829-0566, pp. 6-7]

The NPRM's proposed change means that in MY 27, SVMs would have to meet a fleet average NMOG+NOx standard that is 57% more stringent than what they have been planning in reliance on 40 CFR 86.1811-17(hl(l). And then, for MY 28, they would have to meet a fleet average NMOG+NOx standard that is 33% lower than what they have been planning in reliance on 40 CFR 86.1811-17(h)(l). This would be an unjust "moving the goalpost".[EPA-HQ-OAR-2022-0829-0566, pp. 6-7]

• The proposed NMOG+NOx requirements are excessively stringent - too stringent, too soon This is especially so considering Tier 3 levels and that the CARB ACCII rulemaking appropriately maintained an SVM NMOG+NOx fleet standard of 51 mg/mi through MY 34, as shown in the graph below. [EPA-HQ-OAR-2022-0829-0566, pp. 6-7]

[See original comment for bar graph of SVM FTP NMOG+NOx LIMIT [g/mi]] [EPA-HQ-OAR-2022-0829-0566, pp. 6-7]

• The Proposed Tier 4 NMOG+NOx fleet average is unrealistic for companies that cannot make use of fleet averaging; SVMs should not have to rely on credit purchasing. [EPA-HQ-OAR-2022-0829-0566, pp. 6-7]

There is no recognition in the NPRM that an SVM may have only one or two ICE test groups, neither of which meets the Tier 4 fleet NMOG+NOx average. The fleet average concept in such a situation offers no flexibility; having nothing to "average", such an SVM would simply have no ability to comply and would fall into a deficit situation. It was precisely to address this type of scenario that the Tier 3 SVM flexibility provisions in 40 CFR 86.1811-17(h) were promulgated. The current rulemaking should follow suit and adopt comparable SVM flexibility. [EPA-HQ-OAR-2022-0829-0566, p. 7]

As regards credit purchasing, we reiterate how it is unfair to force SVMs to rely on risky credit purchasing (with unknown availability and at an unknown cost) to meet criteria emissions requirements. [EPA-HQ-OAR-2022-0829-0566, p. 7]

• The Proposed Interim Tier 4 provision does not provide flexibility to SVMs [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

We note that one general flexibility concession in the NPRM -- the category of "Interim Tier 4 vehicles" -- does not provide relief to SVMs. As proposed, the Interim Tier 4 provision leaves SVMs empty-handed because the benefits of Interim Tier 4 are restricted to OEMs who can otherwise meet the 40% and 80% phase-in percentages with their full Tier 4 test groups (and thus use the Interim Tier 4 category for the remaining 60% and 20% of their fleets during the phase in}. Given that SVMs - particularly those with only one or two test groups -- cannot meet the phase-in percentages with full Tier 4 cars, EPA's proposal unfairly denies SVMs the ability to make use of the benefits of the Interim Tier 4 category. [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

• In sum, as regards criteria emissions, EPA should:

• follow CARB's ACCII rules and continue the availability of Bin 125 to SVMs through MY 2034 and not require NMOG+NOx limits for cold testing.2 [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

2 EPA must justify imposing on SVMs the proposed new cold NMOG+NOx standard. Until EPA can establish that the environmental benefits outweigh the burdens on SVMs, SVMs should be exempted.

• with regard to NMOG+NOx FTP and US06 standards [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

• In order to properly account for the problems facing SVMs with regard to "fleet averaging,, and the risks of credit purchasing, as explained above, set the degree and frequency of SVM step-downs to reflect SVM realities -- limited product lines, longer product development and life cycles [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

- MY 2027 -- Maintain for all SVMs the already-in effect {86-1811-17{h} MY 27 Tier 3 SVM NMOG+NOx standard {51m g/mi} [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

- MY 2028 -- Maintain for all SVMs the already-in effect MY 28 Tier 3 SVM NMOG+NOx standard (30 g/mi) [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

- MY 2029-32 - continue the 30 mg/mi standard for SVMs given that the environmental benefits of a more stringent standard have not been established and are vastly outweighed by the potential burden on SVMs. [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

- Make the Interim Tier 4 category more flexible and available [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

- Add a new paragraph (e} to proposed 40 CFR 86.1811-27 to read as follows: [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

(e) If meeting the standards set forth in this section 40 CFR 86.1811-27 would cause severe economic hardship, small-volume manufacturers may ask us to approve an extended compliance deadline under the provisions of 40 CFR 1068.250, except that the solvency criterion does not apply and there is no maximum duration of the hardship relief [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

This provision would mirror the SVM relief made available under Tier 3 in 40 CFR 86.1811-17. [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

The above steps are necessary to comply with the Clean Air Act's section 202{a} mandate that EPA provide sufficient lead-time "to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such [lead-time]." [EPA-HQ-OAR-2022-0829-0566, pp. 7-8]

Organization: BMW of North America, LLC (BMW NA)

BMW NA supports the comments filed by the Alliance of Auto Innovators to the EPA docket. Our main concern is that a diverging approach in the United States between Federal regulations and California's regulations will substantially increase the hurdles to fulfill fleet and vehicle standards. BMW NA is aiming for one single US fleet and therefore would like to motivate EPA to align the Tier 4 rules with LEV IV as much as possible. This is referring to the rules for the NMOG+NOx fleet (bin structure and EV treatment) as well as to the vehicle standards. [EPA-HQ-OAR-2022-0829-0677, p. 4]

The fleet regulation should be harmonized, so that the same fleet composition should lead to compliance in both regulations. Other than the CARB approach, the Tier 4 fleet regulation is heavily dependent on the BEV share. As mentioned above, there is a high uncertainty what BEV share could be reached in each single year. From our perspective, the Tier 4 regulation should focus on regulating pollutant emissions of ICE vehicles. [EPA-HQ-OAR-2022-0829-0677, p. 4]

There should be no additional burdens on top of CARB vehicle standards, which are leading to additional substantial investments for a mature technology in its phase-out - e.g. for test labs or completely new after-treatment systems beyond the CARB standard. [EPA-HQ-OAR-2022-0829-0677, p. 4]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Criteria Air Pollutant Standards

CARB supports U.S. EPA's proposal to tighten criteria air pollutant emission standards, particularly given the continued role that internal combustion engine vehicles will play in the national fleet over the regulatory timeframe and beyond. Reducing exposure to harmful air pollution is a key element of the proposed standards, and the proposals to tighten criteria air pollutant emissions are needed to protect public health, especially in communities with disproportionate exposure to air pollution. Because U.S. EPA's proposal does not require ZEV sales, as California's rules do, the tightening of criteria air pollutant emission standards is even more critical to ensure that the internal combustion engine vehicles that will continue to be sold are becoming cleaner. [EPA-HQ-OAR-2022-0829-0780, pp. 26-27]

As part of its ACC II rulemaking, CARB adopted its fourth iteration of its Low Emission Vehicle (LEV) standards, referred to as LEV IV. CARB finds that U.S. EPA's proposals are appropriate and largely consistent with the LEV IV standards. CARB has documented our analysis and recommends strengthening the proposal to realize the greatest degree of emission reductions achievable, considering cost and technology availability, to further protect public health. As described further below, CARB recommends that U.S. EPA adopt its proposed NMOG+NOx and PM standards, adopt elements of CARB's evaporative emission standards program, and eliminate the use of commanded enrichment as proposed while collecting additional information on the use of auxiliary emissions control devices to further improve emission standards in the future. [EPA-HQ-OAR-2022-0829-0780, pp. 26-27]

NMOG+NOx Emission Standards for Light-Duty Vehicles

CARB supports U.S. EPA's proposal to reduce the light-duty vehicle NMOG+NOx fleet average standard to 12 milligrams per mile (mg/mi) with ZEVs eligible to be included in the compliance calculation. The proposal assumes that non-ZEVs will reach a fleet average of 30 mg/mi, which is identical to CARB's LEV IV requirements for light-duty vehicles. Both CARB's LEV III requirements and U.S. EPA's Tier 3 requirements previously determined that 30 mg/mi was technologically feasible without heavy reliance on ZEVs. 33 Accordingly, CARB does not project the need for development or deployment of any new technologies but rather the use of the technologies and rate of deployment previously analyzed and determined to be feasible. Technologies relied upon in the LEV III analysis included larger volume catalysts, greater catalyst precious metal loading, more optimized close-coupled catalysts, optimized thermal management, low thermal mass turbochargers, double layer catalyst washcoats, and improved fuel injection control; these technologies are described in more detail in the original LEV III rulemaking package. 34 These are the same technologies that manufacturers have largely deployed to date and can still utilize to convert current and future vehicles that, combined with ZEVs, can meet U.S. EPA's proposed standards. CARB also notes that the ZEV penetration that will help manufacturers comply with the proposed GHG standards also support compliance with the criteria air pollutant standards. [EPA-HQ-OAR-2022-0829-0780, p. 27]

NMOG+NOx Emission Standards for Medium-Duty Vehicles

As under the proposed medium-duty vehicle GHG standards, CARB supports U.S. EPA's decision to better delineate the medium-duty vehicle class from heavy-duty vehicles to enable application of the most rigorous and appropriate criteria air pollutant emission standards and procedures. [EPA-HQ-OAR-2022-0829-0780, pp. 27-28]

CARB supports U.S. EPA's proposal to reduce the medium-duty vehicle NMOG+NOx fleet average standard to 60 mg/mi. As described in greater detail below, U.S. EPA's proposed medium-duty fleet average standards are not directly comparable to CARB's recently adopted LEV IV medium-duty standards for two reasons: first, CARB's standards exclude ZEVs from the fleet average while U.S. EPA's do not, and second, U.S. EPA's proposed standards apply to a different subset of medium-duty vehicles than CARB's standards. CARB has performed its own analysis to compare California's effective stringency for medium-duty vehicles to U.S. EPA's proposed standards and finds that both programs are targeting similar fleet-wide emission levels. As such, CARB expects that manufacturers will be able to use the same technology solutions to meet both the California and the proposed federal emission standards and concludes that the proposed standards are technically feasible with the current technologies available and expected ZEV penetration rates in this sector. [EPA-HQ-OAR-2022-0829-0780, pp. 27-28]

Analysis of CARB's LEV IV requirements relative to U.S. EPA's proposal

Differences in vehicles subject to CARB's LEV IV requirements relative to U.S. EPA's proposal [EPA-HQ-OAR-2022-0829-0780, p. 28]

U.S. EPA proposes to apply a single NMOG+NOx fleet average standard to all medium-duty vehicles at or under 22,000 lbs. gross combined weight rating (GCWR). 35 Based on U.S. EPA certification data, the proposed fleet average standards would apply primarily to all vans and to the gasoline-fueled trucks currently in the medium-duty classes. The proposed standards would move diesel trucks to compliance with heavy-duty engine standards. In contrast, CARB's LEV IV standard applies separate fleet average standards to Class 2b and Class 3 vehicles without regard to their GCWR; therefore, the LEV IV standard applies to both gasoline and diesel vehicles and both vans and trucks. Additionally, the LEV IV fleet average standards do not include ZEVs in the calculation of the fleet average. Thus, the LEV IV medium-duty fleet average standards apply to a different population of vehicles than U.S. EPA's proposed standards and the numeric standards of the two programs cannot be directly compared. [EPA-HQ-OAR-2022-0829-0780, p. 28]

35 Medium-duty vehicles above this GCWR cutoff would separately be required to certify to U.S. EPA's heavy-duty engine standards.

Developing estimated fleet averages to enable comparisons

Given the difference in vehicles covered by the two programs, assessing whether the two regulations are targeting similar emission levels first requires aligning the vehicle populations. CARB developed a compliance scenario to estimate the emissions from its medium-duty fleet under the LEV IV standards, then omitted diesel trucks to develop a gasoline-only fleet estimate for comparisons to U.S. EPA's proposal. [EPA-HQ-OAR-2022-0829-0780, pp. 28-32]

To create this compliance scenario, CARB adjusted the LEV IV fleet average standards by combining the Class 2b and Class 3 fleet based on sales volumes and estimated the least stringent emission "bins" 36 to which manufacturers would likely certify their vehicles to achieve minimum compliance with the respective fleet averages (summarized in Table 3). [EPA-HQ-OAR-2022-0829-0780, pp. 28-32]

36 Manufacturers certify vehicles according to test groups for exhaust emission standards that meet discrete categories or bins based on their emission rates. For instance, there is a bin at the SULEV 125 emission rate, corresponding to 125 milligrams per mile (mg/mi) of NMOG+NOx. The numerical part of the standard category, such as 125 in SULEV 125, refers to the emission standard, in thousandths of a gram per mile of NMOG+NOx emissions on the FTP driving cycle. The highest bin effectively caps the worst-case emissions that could come from some vehicles in a manufacturer's fleet certified to that bin.

Based on past trends and added complexities in diesel emission controls, the analysis estimates that diesel Class 2b vehicles will use the dirtier emission bin of super-ultra-low-emission vehicle (SULEV) 170 37 and gasoline Class 2b vehicles will use the SULEV 150 bin 38 and eventually phase into the SULEV 125 bin. CARB's EMFAC population of on-road emission sources shows that the Class 2b category is made of 61 percent gasoline vehicles and 39 percent diesel vehicles. 39 Because the Class 2b category contains more gasoline vehicles, they can remain in the SULEV 150 and 125 bins without needing to certify to lower emission levels to offset the diesels in this class. For Class 3 vehicles, CARB assumes diesel vehicles will certify to the SULEV 230 and 200 bins, 40 while the gasoline vehicles will have to phase into the SULEV 175, 150, 125, and 100 bins. 41 CARB's EMFAC population shows the Class 3 population is made of 70 percent diesel and 30 percent gasoline vehicles, which means gasoline vehicles will have to certify to the cleaner emission bins to offset the larger population of diesel vehicles using the dirtier emission bins in the Class 3 category. Estimating these phase-in percentages for the bin usage is necessary to estimate the likely emission levels for the subset of medium-duty vehicles subject to both LEV IV and U.S. EPA's proposed standard. [EPA-HQ-OAR-2022-0829-0780, pp. 28-32]

37 CARB expects manufacturers to certify their diesel medium-duty vehicles to the dirtiest emission bins, based on previous certification levels of diesel vehicles which regularly certify to the higher emission bins. For LEV IV, the SULEV 170 bin will be the dirtiest bin available for Class 2b after the SULEV 250 and SULEV 200 bins phase out. Therefore, CARB expects the diesel population of Class 2b vehicles to primarily be certified to the SULEV 170 bin. While this analysis ultimately excludes diesel vehicles, these vehicles are included in California's LEV IV fleet average standards, which means understanding the potential emissions from diesel vehicles in California is necessary to determine the likely certification levels for the gasoline vehicles that are included in the analysis.

38 CARB expects manufacturers to certify their gasoline medium-duty vehicles to cleaner emission bins than their diesel vehicles. The analysis expects all the gasoline vehicles to use the next lowest bin, SULEV 150, from the SULEV 170 bin to offset the emissions from their diesel vehicles in the SULEV 170 bins. For the 2029 MY, when the fleet average reduces to 150 mg/mi, manufacturers will have to additionally rely on vehicles certified to the SULEV 125 bin if they want to continue certifying their diesel vehicles to the SULEV 170 bin.

39 EMFAC is CARB's model that estimates the official emissions inventories of on-road mobile sources in California. It is approved by U.S. EPA for planning required to meet the NAAQS. See 40 C.F.R. §§ 93.110, 93.111; 87 Fed. Reg. 68,483, Nov. 15, 2022. Available at: https://arb.ca.gov/emfac/

40 Similar to the assumption CARB made about diesel Class 2b vehicles, CARB expects Class 3 diesel vehicles to use the dirtiest emission bins available after the SULEV 400 and 270 bins phase out. Based on previous certification levels, most Class 3 vehicles are at these expected levels.

41 Similar to the assumption CARB made about gasoline Class 2b vehicles, CARB expects Class 3 gasoline vehicles to use the next cleanest bins below those used to certify Class 3 diesel vehicles. With a larger population of Class 3 diesel vehicles, the Class 3 gasoline population needs to become much cleaner to offset manufacturers keeping their diesel vehicles certified to the higher emission standards.

[See original for table titled “Table 3. Certification Bin Assumptions for NMOG+NOx Medium-Duty Vehicle Standard Comparison.”] [EPA-HQ-OAR-2022-0829-0780, pp. 28-32]

After applying these assumptions and removing the diesel vehicles, CARB generated estimated emission levels for the gasoline-only medium-duty fleet, shown as the blue line with circles in Figure 3. CARB then developed a second estimated California LEV IV fleet that includes ZEVs, using ZEV penetrations required by CARB’s ACT and ACF regulations, shown as the dashed grey line with circles in Figure 3. [EPA-HQ-OAR-2022-0829-0780, pp. 28-32]

To estimate a version of U.S. EPA’s proposed standard to compare to CARB’s gasoline-only fleet average, CARB removed the expected ZEV penetration rates from the proposed fleet average and calculated the levels to which the remaining medium-duty vehicles would need to certify to meet the proposed fleet average. This estimated standard is shown as the dark blue line with triangles in Figure 3. [EPA-HQ-OAR-2022-0829-0780, pp. 28-32]

[See original for graph titled “Figure 3. Comparison of Proposed Medium-Duty NMOG+NOx Emission Standards to California’s LEV IV Requirements.”] [EPA-HQ-OAR-2022-0829-0780, pp. 28-32]

Comparison between estimated medium-duty vehicle fleet average emission levels under LEV IV and U.S. EPA’s proposed standards [EPA-HQ-OAR-2022-0829-0780, pp. 28-32]

Figure 3 shows the two comparisons between U.S. EPA’s proposed standards and CARB’s estimated LEV IV standards: one including ZEVs as U.S. EPA would apply their proposed Tier 4 standards and another without ZEVs as CARB would apply the LEV IV standards. [EPA-HQ-OAR-2022-0829-0780, pp. 28-32]

First, U.S. EPA’s proposed fleet average (shown as the orange dashed line with triangle markers), which is inclusive of ZEVs and Class 2b and Class 3 medium-duty vehicles, is compared to the estimated comparable LEV IV fleet average with ZEVs (shown as the gray dashed line with circle markers). Through the 2035 MY, the two curves follow similar trajectories and reach identical end points for overall emission levels. Given that both U.S. EPA’s proposed standards and CARB’s standards allow for averaging, banking, and trading of fleet average credits and deficits for vehicle manufacturers to smooth out year-to-year changes, CARB expects manufacturers could readily manage the small deviations between the two programs while deploying identical vehicles in both markets. [EPA-HQ-OAR-2022-0829-0780, pp. 28-32]

Figure 3 also compares the two emission standards for the estimated gasoline-only fleets. The projected LEV IV gasoline-only fleet average (shown as the light blue solid line with circle markers) and the estimated non-ZEV fleet average for U.S. EPA’s proposed fleet average (shown as the dark blue line with triangle markers) show similar, but not identical, trajectories through the 2031 MY. As noted above, manufacturers would be expected to manage slight deviations across MYs through the flexibilities of the program such as averaging, banking, and trading of credits and deficits relative to the fleet average. From the 2032 MY on, while the projected fleet averages are slightly different, the analysis does not account for a few factors that would likely minimize any such difference. As CARB noted in its Final Statement of Reasons for the LEV IV standards, 42 staff expects that a portion of these medium-duty vehicles will also be subject to CARB's heavy-duty in-use standards that make use of a portable emissions measurement system (PEMS) and those standards will likely result in manufacturers meeting more stringent emission levels than the fleet average would theoretically necessitate. When combined with the uncertainty in what each manufacturers' actual ZEV sales share will be (which also affects the resultant emission level their non-ZEVs would have to meet), CARB finds that the proposed standards are similar enough to the LEV IV standards that manufacturers would likely be able to deploy common emission control solutions to simultaneously meet both requirements. [EPA-HQ-OAR-2022-0829-0780, pp. 28-32]

Organization: California Attorney General's Office, et al.

Finally, EPA should evaluate the risk of excess credit generation in the NMOG+NOx program for medium-duty vehicles. Because Section 202(a)(3)(C) requires three years' "stability" for NOx standards for "heavy-duty" vehicles (defined by statute to include some of the vehicles EPA now classifies as medium-duty), but not for GHG standards, the proposed medium-duty GHG standards require year-over-year reductions in model years that the medium-duty NMOG+NOx standards hold constant. Id. at 29,243 (Table 32), 29,261 (Table 41). EPA expects the industry to achieve compliance with the medium-duty GHG standards to a significant extent through electrification, which likewise reduces NMOG+NOx emissions. Id. at 29,244, 29,331. Therefore, the medium-duty fleet will likely achieve NMOG+NOx reductions even in those "stability" years. EPA should clarify whether this discrepancy poses any risk of excessive credit generation and necessitates some action to prevent dilution of the MDV NMOG+NOx standards, such as restricting credit generation under the NMOG+NOx program,191 or calibrating the model- year 2030 standards' stringency to account for such changes in the fleet, see id. at 29,261 (Table 41). [EPA-HQ-OAR-2022-0829-0746, p. 38]

> 191 For example, EPA could make credit generation dependent on manufacturers' participation in the optional early compliance pathway. Id. at 29,260.

Organization: Cummins Inc

The tradeoff between oxides of nitrogen (NOx) and carbon dioxide (CO_2) reductions must be considered when setting the stringency of standards. Also, linkage of criteria pollutant and GHG certification and compliance protocols is important so that improvement in one type of pollutant is not achieved at the expense of the other. [EPA-HQ-OAR-2022-0829-0645, pp. 2-3]

Organization: Environmental. and Public Health Organizations

B. Emissions of criteria pollutants from light- and medium-duty vehicles harm the public health.

EPA's proposed reductions of non-methane organic gases ("NMOG") plus NOx, as well as particulate matter, are crucial to protecting the public from harmful air pollutants. As EPA notes, "[e]mission sources impacted by [its] proposal, including vehicles and power plants, emit pollutants that contribute to ambient concentrations of ozone, PM, NO2, SO2, CO, and air toxics."67 These pollutants are linked to premature death, respiratory illness (including childhood asthma), cardiovascular problems, and other adverse health impacts. In particular, NOx emissions increase levels of ozone, because ground-level ozone forms when there are high concentrations of ambient NOx and VOCs, and when solar radiation is high.68 NOx emissions also impact particulate matter by forming secondary particles through atmospheric chemical reactions.69 Reductions in NOx emitted from LDVs will therefore result in reduced ambient levels of ozone and PM and improved health and environmental outcomes. [EPA-HQ-OAR-2022-0829-0759, p. 17]

69 DRIA at 7-10.

F. EPA should strengthen the Tier 4 NMOG+NOX standards and finalize the proposed PM requirements.

We now turn to EPA's proposed criteria pollutant standards for LDVs. As detailed below, while the proposed PM2.5 requirements are appropriate, EPA should strengthen the NMOG+NOX standards and consider ways to limit over-crediting. [EPA-HQ-OAR-2022-0829-0759, p. 53]

1. EPA should increase the stringency of the proposed NMOG+NOX standards.

a. EPA should strengthen the NMOG+NOx standards to better reflect available, feasible, and cost-effective technologies.

EPA's 2014 Tier 3 emissions standards were set based on the deployment of technologies applicable to combustion vehicles. The NMOG+NOx standards are meant to continuously phase in from 2017-2025, ultimately reaching a fleet average of 30 mg/mile on the FTP and 50 mg/mile on the SFTP. However, over this time period, an increasing share of BEVs will be sold, which are certified to 0 mg/mile NMOG+NOx. While the deployment of BEVs will not alter the tailpipe emissions reductions anticipated under the Tier 3 program, the additional BEVs, counted as 0 mg/mile, substantially reduce manufacturers' incentives to deploy the full extent of technologies EPA identified in the Tier 3 rulemaking to their combustion vehicles. [EPA-HQ-OAR-2022-0829-0759, p. 53]

Two responses are possible from manufacturers: they either (1) deploy the same suite of internal combustion engine technologies to their combustion vehicle fleet, and therefore generate a significant amount of overcompliance credits that can be used to reduce their compliance obligations under the Tier 4 standards EPA is now proposing; or (2) reduce the deployment of technologies as EPA originally envisioned when setting the Tier 3 standards, leaving emissions reductions for their combustion vehicle fleet on the table. Either response weakens compliance with the standards. Strengthening the Tier 4 standards will help avoid these problems. [EPA-HQ-OAR-2022-0829-0759, p. 53]

Therefore, EPA's proposed NMOG+NOx standards leave a significant gap between the feasible deployment of zero-emission technologies (indicated by the share of BEVs modeled for GHG compliance) and the feasible deployment of improvements to combustion vehicles (indicated by the achievement of a Tier 3 fleet average standard without the deployment of BEVs). Figure VI.F-1 illustrates, on the left, the implicit requirements on combustion vehicles under the proposed NMOG+NOx standards with EPA's modeled adoption of BEVs under the GHG standards; and, on the right, the implied share of BEVs required by the proposed Tier 4 standards if combustion vehicles achieve Tier 3 compliance. If BEVs are deployed at levels modeled by the Agency to comply with its GHG Proposal, NMOG+NOx emissions from combustion vehicles would remain about 30% higher than the Tier 3 requirement over the timeframe of the rule. If, instead, the combustion vehicle fleet matches the Tier 3 requirements in 2027-2032, far fewer BEVs would need to be deployed to meet the Tier 4 proposed targets.These scenarios demonstrate that numerous technological pathways are available to manufacturers to comply with the Tier 4 standards and that stronger standards are entirely feasible. [EPA-HQ-OAR-2022-0829-0759, p. 53]

SEE ORIGINAL COMMENT FOR Figure VI.F-1. Emissions performance and ZEV market share implied by the combination of achieving the proposed GHG standards and Tier 3 / Proposed Tier 4 NMOG+NOx standards

If manufacturers deploy ZEVs consistent with EPA's projection of compliance with the GHG standards, tailpipe emissions performance from the remaining combustion vehicles will exceed Tier 3 standards (left). If combustion vehicles instead achieve Tier 3 emissions standards, far fewer ZEVs will be required to meet the proposed Tier 4 fleet average standards than are modeled to comply with the GHG standards (right). [EPA-HQ-OAR-2022-0829-0759, p. 54]

EPA should close this gap in relative stringency by setting a standard that reflects the full emissions reductions of the combustion vehicle technologies it has already identified as feasible (and which are readily available). Aligning the Agency's assessment of ZEV deployment and its analysis (covered primarily in the Tier 3 rulemaking) of what is achievable to reduce NMOG+NOx emissions from combustion vehicles would yield a 2032 target of 10 mg/mi, a 17% reduction from its Proposal. Interim targets would then be adjusted accordingly. [EPA-HQ-OAR-2022-0829-0759, p. 54]

Such a standard for LDVs would still be technology-neutral: The target corresponds to the lowest non-zero bin in the Proposal (Tier 4 Bin 10),137 and the Agency has already identified combustion vehicles that have certified FTP emissions below 10 mg/mi.138 Moreover, we expect that manufacturers seeking to comply with the multipollutant standards primarily through combustion vehicle technologies would be investing in further emission-reduction technologies from those vehicles, such as by ensuring their vehicles are more in line with the emissions profiles of the industry-leading vehicles, including through deployment of hybridization and other EPA-identified strategies to reduce tailpipe emissions. Alternatively, for manufacturers that want to comply with the multipollutant standards through greater deployment of zero-emission technologies, this pathway would still allow flexibility for their combustion vehicle fleet to fall short of the Tier 3 requirements, provided they sell ZEVs beyond EPA's modeled industry average. [EPA-HQ-OAR-2022-0829-0759, pp. 54-55]

137 88 Fed. Reg. at 29419.

138 DRIA at 3-41, Tbl. 3-14.

EPA has embarked on a multipollutant rulemaking precisely because technologies exist to simultaneously achieve reductions in GHGs and criteria pollutants.139 Reducing the stringency of the final standards to 10 mg/mi NMOG+NOx better aligns with the feasible and cost-appropriate technologies already identified by the Agency. [EPA-HQ-OAR-2022-0829-0759, p. 55]

139 88 Fed. Reg. at 29187.

b. EPA should consider ways to limit over-crediting.

Figure VI.F-1 (left side) shows a non-monotonic behavior—that is, the allowable emissions profile of the combustion vehicles (green line) first increases significantly from 2026-2029, then decreases. This is largely due to the delay in increasing stringency for LDT3, LDT4, and MDPV classes (Class 2 light trucks), the result of EPA's interpretation of lead time requirements under the Clean Air Act.140 The Agency has offered an optional "early compliance" pathway for manufacturers; however, this pathway increases the total stringency over the six years covered by the proposal, reducing the likelihood of manufacturers choosing this path to compliance.141[EPA-HQ-OAR-2022-0829-0759, p. 55]

140 See id. at 29258.

141 If EPA sets a 10 mg/mile standard in 2032 as recommended in Section VI.F.1.a, and thus reduces the step for Class 2 light trucks to 10 mg/mile, there would presumably be no such gap in stringency between the early and default compliance pathways.

In an effort to induce manufacturers to align with the early compliance pathway and to acknowledge the reduced emissions benefits of the stagnant standard for Class 2 light trucks from 2025-2029 (a full five-year window corresponding to the lifetime of Tier 3 credits) under the default compliance pathway, EPA should condition manufacturers' full utilization of credits in this time period on their utilization of the early compliance pathway. For example, EPA could set a limit on the amount of averaging, banking, and trading (ABT) credits that could be utilized for compliance, in order to limit windfall credits from reductions in fleet emissions that occur during the 4-year period of stagnation. This would also ensure that manufacturers do not artificially prolong compliance through an overreliance on such credits. [EPA-HQ-OAR-2022-0829-0759, p. 55]

B.EPA should strengthen the Tier 4 NMOG+NOX standards, finalize the proposed PM requirements, and finalize the proposed change to criteria pollution requirements for MDVs with a GCWR above 22,000 pounds, subject to appropriate monitoring. [EPA-HQ-OAR-2022-0829-0759, p. 74]

Consistent with the recently finalized criteria pollutant emission standards for heavy-duty engines (Classes 2b-8) and those that have been proposed for LDVs (Classes 1-2a plus medium-duty passenger vehicles) in this rulemaking, the Agency is proposing standards regulating tailpipe emissions of criteria pollutants from medium-duty vehicles. Under Clean Air Act Section 202(a)(3)(A), these standards must "reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology." 42 U.S.C. § 7521(a)(3)(A) (emphasis added). As described below, EPA should strengthen the Tier 4 NMOG+NOx standards and enact guardrails to ensure that windfall credits earned during a period of required lead time do not undercut the emissions gains possible in the 2027-2032 timeframe. We support the proposed PM2.5 requirements and the proposed change to criteria pollution requirements for MDVs with a gross combined weight rating (GCWR) of more than 22,000 pounds, subject to appropriate monitoring to prevent manipulation.[EPA-HQ-OAR-2022-0829-0759, p. 74]

1. EPA must improve the stringency of the Tier 4 NMOG+NOx standards for MDVs.

Because additional reductions in emissions of NMOG+NOx from MDVs are readily achievable, EPA must strengthen the Proposed Standards to meet its statutory mandate. Figure VIII.B-1 shows the distribution of certification data for MY 2022-2023 gasoline pickups, affirming EPA's observation that the MDV fleet is already capable of achieving levels of NMOG+NOx emissions far below the current standards. In fact, because these data are not sales-weighted and include some share of gasoline pickups that would now be required to certify to the heavy-duty engine standard under the Proposal, this table likely understates the capability of manufacturers to readily achieve reductions of NMOG+NOx emissions from their MDV combustion fleet. [EPA-HQ-OAR-2022-0829-0759, p. 74]

Figure VIII.B-1. Distribution of NMOG+NOx certification values for Class 2b-3 gasoline pickups and vans

[See original attachment for Figure VIII.B-1.].

As in the case of the proposed light-duty NMOG+NOx standards (Section VI.F, supra), EPA's Proposed Standards for MDVs are in tension with its modeling of GHG compliance (Figure VIII.B-2). Here too, the Proposed Standards are well above the average emissions value expected under the conditions that: (1) manufacturers' combustion vehicles achieve Tier 3 standards; and (2) ZEV sales consistent with EPA's GHG modeling are achieved. If EPA's compliance modeling of ZEV sales is accurate and materializes in real-world sales, the remaining combustion fleet would be able to backslide to as much as double the average NMOG+NOx emissions allowed under Tier 3 (Figure VIII.B-2 (left)). Given the danger that these pollutants cause to public health and welfare, including through localized effects, such backsliding would be wholly inappropriate under Section 202. If instead the combustion fleet achieves Tier 3 standards as expected, far fewer ZEVs would be needed to comply with the proposed Tier 4 program or the early compliance pathway. [EPA-HQ-OAR-2022-0829-0759, p. 75]

Figure VIII.B-2. Emissions performance and ZEV market share implied by the combination of achieving the proposed MDV GHG standards and MDV Tier 3 / Proposed Tier 4 NMOG+NOx standards [EPA-HQ-OAR-2022-0829-0759, p. 76]

[See original attachment for Figure VIII.B-2.].

If manufacturers deploy MD ZEVs consistent with EPA's projection of compliance with the GHG standards, tailpipe NMOG+NOx emissions performance from the remaining combustion vehicles will greatly exceed Tier 3 standards (left). If combustion vehicles instead achieve Tier 3 emissions standards, far fewer ZEVs will be required to meet the proposed Tier 4 fleet average standards than are modeled to comply with the GHG standards (right). [EPA-HQ-OAR-2022-0829-0759, p. 76]

> 210 The ZEV market share here appears significantly higher than in the GHG modeling because it excludes combustion vehicles with a gross combined weight rating (GCWR) of more than 22,000 pounds. However, ZEVs with a GCWR greater than 22,000 pounds are included in the MDV fleet in our analysis. This proposed change is further discussed in Section VIII.B.3.

The relationship between the GHG Proposal and the Tier 4 proposal means that a significant amount of NMOG+NOx reductions are left on the table, in conflict with EPA's statutory mandate to achieve the "greatest degree of emission reduction achievable." 42 U.S.C. § 7521(a)(3)(A). As mentioned previously, combustion vehicles can readily reduce emissions below Tier 3 levels, but at a bare minimum, EPA's final standards should reflect the emissions levels that would be achieved by the combustion fleet achieving Tier 3 NMOG+NOx standards with ZEVs deployed to the extent modeled to meet GHG standards. Under this more stringent standard, manufacturers would retain flexibility to invest in greater ZEV deployment or to instead apply existing, feasible, and cost-effective technologies within their combustion fleet. These modifications would better ensure that the Tier 4 MDV standards are consistent with the greatest degree of emissions reduction achievable. [EPA-HQ-OAR-2022-0829-0759, p. 76].

EPA should also take action to prevent the problems caused by a growing bank of emissions credits. Even in the absence of a GHG rule, the expected market-driven deployment of ZEVs would result in a significant bank of credits prior to 2030 under the proposed Tier 4 standard for MDVs (Figure VIII.B-2, right). Those windfall credits would either be used to delay the achievement of Tier 3 standards or to offset required reductions in the MY 2030-2032 period. In an effort to mitigate the impact of the deployment of technology (electrification) that is not required to meet the current standards, EPA should limit the use of credits generated through overcompliance with Tier 3 standards. To encourage manufacturers to adopt the more stringent early compliance pathway, the Agency could (for example) restrict the use of Tier 3 credits in the 2027+ timeframe to only those manufacturers that have elected the early credit pathway. This would be appropriate, since the Tier 3 standards fixed under the proposal through MY 2029 were predicated on the deployment of a reduced suite of emissions reduction technologies. [EPA-HQ-OAR-2022-0829-0759, pp. 76-77]

Organization: Environmental Defense Fund (EDF) (1of 2)

Passenger vehicles also emit harmful pollutants, including fine particulate matter (PM2.5) and oxides of nitrogen (NOx). These pollutants contribute to the formation of soot and smog and contribute to elevated concentrations of pollution near roadways, where millions of people live and go to school, and people of color and people with low income are disproportionately exposed to air pollution from vehicles. [EPA-HQ-OAR-2022-0829-0786, p. 6]

Please see EDF's comments on the Proposed Rule, Revised 2023 and Later Model Year Light- Duty Vehicle Greenhouse Gas Emissions Standards, 86 Fed. Reg. 43726 (August 10, 2021) dated September 27, 2021, and resubmitted to this docket, for a more thorough discussion of the substantial health and environmental harms associated with the pollution and GHG emissions from passenger vehicles.1 [EPA-HQ-OAR-2022-0829-0786, p. 6]

1 EDF's comments on the Proposed Rule, Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards, 86 Fed. Reg. 43726 (August 10, 2021) dated September 27, 2021, at 4-6. Accessible at https://www.regulations.gov/comment/EPA-HQ-OAR-2021-0208-0688. (Attachment A)

VII. Standards must continue to drive reductions from ICEVs and PHEVs.

EDF strongly supports EPA's proposed NMOG + NOX and PM2.5 standards. As our nation transitions to a zero-emitting fleet it is imperative that gasoline and diesel vehicles continue to reduce health-harming air pollutants to protect communities from the harms of vehicle emissions. [EPA-HQ-OAR-2022-0829-0786, p. 62]

A. EDF supports strong NMOG + NOx standards.

EDF supports light-duty vehicle and medium-duty vehicle fleet average FTP NMOG + NOX standards that include both ICEVs and ZEVs in a manufacturer's compliance calculation. We also support the proposed fleet average standards that decline from 2027–2032 in the early compliance program, the elimination of higher certification bins, a requirement for the same fleet average emissions standard to be met across four test cycles (25 °C FTP, HFET, US06, SC03), and one fleet average NMOG + NOX standard in the -7 °C FTP test. These features are important to ensure increasing ZEV deployment results in rigorous air pollution reductions and likewise prevent any offsetting pollution increases from remaining internal combustion engine vehicles. [EPA-HQ-OAR-2022-0829-0786, p. 62]

Organization: Ferrari N.V. and Ferrari North America, Inc.

a) NMOG+NOx Standards

EPA is proposing to remove any NMOG+NOx fleet-average flexibility for SVMs, requiring an alignment to Large Volume Manufacturers (LVMs) targets starting with MY 2027, unreasonably changing the current Tier 3 regulation that allows SVMs to comply with 51 mg/mi standard until MY 2027, and therefore cutting their target by more than half (i.e. 22 mg/mi compared to 51 mg/mi). For later years, EPA is requiring SVMs to comply with an overall 76% standard reduction in just 5 model years. [EPA-HQ-OAR-2022-0829-0572, pp. 5-6]

Ferrari strongly believes this approach is unfair, especially in light of the unexpected change of the Tier 3 regulation and the huge implied percentage of BEVs that manufacturers responsible of high performance vehicles shall include in their fleet. While most LVMs can benefit from a wide range of models to compensate for the few vehicles that pollute the most, independent SVMs like Ferrari have to deal with a huge and unfeasible BEV penetration in their car portfolios since the beginning of the legislation. [EPA-HQ-OAR-2022-0829-0572, pp. 5-6]

Ferrari acknowledges EPA's intention of aligning SVM targets to those of LVMs. However, this sharp reduction in NMOG+NOx standards is not feasible in such a short amount of time. In support of this, California recognized the impracticability of these manufacturers4, allowing them to comply with a fleet-average standard of 51 mg/mi for the entire regulatory period. [EPA-HQ-OAR-2022-0829-0572, pp. 5-6]

4 CARB ACC II Regulations Initial Statement of Reasons (April 12, 2022), chapter III, section C, paragraph 7

Ferrari's commitment to reducing NMOG+NOx emissions is reflected on several of our models (Ferrari Portofino M, Ferrari Roma, 296 GTB, Ferrari Purosangue) which are currently certified as BIN 50. An even more remarkable result has been achieved with our Ferrari Purosangue, the first and only V12 model certified as BIN 50 in the United States. [EPA-HQ-OAR-2022-0829-0572, pp. 5-6]

However, the current state of art does not allow high-performance vehicles with modern passive heating systems to achieve a certification level below BIN 50, and therefore large investments and time-consuming activities on active heating devices (e.g. burner, electric heating catalyst) are required. In addition, the very limited demand of those devices due to mass market focus on electrification will inevitably lead to ad hoc development with related huge costs and times. [EPA-HQ-OAR-2022-0829-0572, pp. 5-6]

Organization: Ford Motor Company

Tier 4 Criteria Emissions Program

Overview

Ford and Industry worked closely with CARB for several years to develop a tough but achievable criteria emission program as part of the Advanced Clean Cars II (ACC2) and Low Emission Vehicle IV (LEV4) rulemaking efforts. Ford believes those programs struck the right balance between reducing high-priority ICE emissions while ensuring that resources were not unduly directed away from the main goal of transitioning to zero-emissions vehicles. [EPA-HQ-OAR-2022-0829-0605, pp. 10-11]

In a departure from historical precedent, the proposed EPA Tier 4 program differs fundamentally from LEV4, and Ford recommends that EPA reconsider this approach and attempt to maximize alignment with the LEV4 program. The following comments outline our recommendations if EPA does not adopt a program that is harmonized with LEV4. [EPA-HQ-OAR-2022-0829-0605, pp. 10-11]

Light-Duty NMOG+NOx Fleet Average

Ford does not believe the NMOG+NOx fleet average associated with the main proposal is feasible. This is primarily a consequence of the direct relationship between the main GHG proposal and the NMOG+NOx fleet average (i.e., we do not find the main GHG proposal to be feasible, therefore the expected NMOG+NOx reductions that would come from such rapid adoption of ZEVs will not be achievable). Ford believes that a revised NMOG+NOx fleet average based on Alternative 3 could be feasible if derived with a sufficient "safety factor" between projected EV volumes and resulting NMOG+NOx fleet average. [EPA-HQ-OAR-2022-0829-0605, pp. 10-11]

NMOG+NOx Bin Structure

EPA has proposed several changes to the NMOG+NOx bin structure from existing Tier 3 bins, adding bins 60, 40 and 10, eliminating bins 160 and 125 for light-duty vehicles (LDVs), and simplifying medium-duty vehicle (MDV) bin structure by aligning class 2b and class 3 bins with LDV bins (retaining bins 160 and 125 for MDVs). Ford supports the addition of these extra bins but also requests several other bins be added at the upper and lower ends of this range. [EPA-HQ-OAR-2022-0829-0605, pp. 10-11]

For LDVs, Ford believes EPA's addition of bin 10 is appropriate given the range of 22 mg/mi to 12 mg/mi of the proposed Tier 4 fleet-average standards. However, we also request that EPA include bins 15 and 25, aligned with SULEV25 and SULEV15 categories in California's LEV4 LDV program. It is appropriate to include more bins in the range of the proposed standards to allow manufacturers greater precision and flexibility in certifying their vehicles given the low level of the proposed standards. [EPA-HQ-OAR-2022-0829-0605, pp. 10-11]

For MDVs, EPA has argued in the Multi-Pollutant Draft Regulatory Impact Analysis (DRIA) Chapter 3.2.1 that 100 mg/mi is a feasible capability for ICE MDVs. Despite this, no bins are proposed near 100 mg/mi capability, only at 70 and 125 mg/mi. Ford requests the inclusion of a bin 100 for MDVs, aligned with the LEV4 SULEV100 category for MDVs, as well as bins 85 and 75 for class 2b MDVs, again aligned with the LEV4 SULEV85 and SULEV75 categories for class 2b MDVs. These additional bins are further supported by figure 3-11 in the DRIA, which shows the current interquartile range of NMOG+NOx certification for gasoline MDVs as roughly 70 to 120 mg/mi (diesel IQRs are higher, from 120 to 180 mg/mi depending on van or pickup vehicle type). More bins in this range would encourage manufacturers to continue to make incremental improvements to NMOG+NOx emissions from ICE vehicles by incentivizing improvements that may be smaller than the 55 mg/mi step between bin 125 and bin 70. [EPA-HQ-OAR-2022-0829-0605, pp. 10-11]

[See original comment for Table 1: NMOG+NOx Bins for EPA Tier 4, CARB ACC II LEV 4 and Ford Proposal] [EPA-HQ-OAR-2022-0829-0605, pp. 10-11]

Organization: Green Diesel Engineering LLC

Alternative Emission Strategy Proposal

1. The Environmental Protection Agency (EPA) has stated that the Clean Air Act (CAA) was created in part "to protect and enhance quality of the Nation's air resources so as to promote public health and welfare and the productive capacity of its population" and "to initiate and accelerate a national research and development program to achieve the prevention and control of air pollution." [EPA-HQ-OAR-2022-0829-0457, pp. 1-4]

- When the CAA was enacted in 1970, our nation had levels of excessive SO2 and NOx emissions. However, changes made to fuel and combustion technology, significantly reduced those pollutants which left the air quality good by 1990. Since that time, the push to further reduce NOx emissions to hundredths of the gram per mile, inevitably resulted in a detrimental increase in CO2 and N2O greenhouse gases. This catch-22 occurs in diesel combustion, because there is a tradeoff. In order to reduce NOx (NO and NO2), the burn cycle must become less efficient and more fuel is needed for the same torque. Ironically, the more fuel that is burnt; the more CO2 is produced which seemingly defeats the purpose of reducing NOx. During the last 28 years our transportation fleet has created almost 20% more CO2 yearly, in comparison to a transportation fleet calibrated for minimum CO2 and increased NO and NO2. The US averages 1800 million metric tons of CO2 formation from the transportation sector on a yearly basis. If the US focused on minimum CO2, we could realize a drop of 450 million metric tons of CO2 per year from this sector. https://www.epa.gov/ghgemissions/sources-greenhouse-gas-emissions [EPA-HQ-OAR-2022-0829-0457, pp. 1-4]

- Controlling air pollution is vital in the US and the entire world. The long- term detriments of increasing CO_2 on this planet, cannot be understated. CO_2 is a stable gas with a 300-year half-life. Once CO_2 is made, it will stay in the atmosphere and continually warm the planet which could lead to environmental problems and strains on our economic systems. NOx on the other hand, is an unstable compound and has roughly a day half-life on this planet. Organically, it breaks down into N and O_2—both elements which are naturally found in our atmosphere. [EPA-HQ-OAR-2022-0829-0457, pp. 1-4]

2. A goal of CAA, is to align emission standards to “reflect the greatest degree of emission reduction achievable through the application of [available] technology.” [EPA-HQ-OAR-2022-0829-0457, pp. 1-4]

- In the transportation sector, we are not achieving the greatest degree of CO_2 reduction. The entire fleet of diesel vehicles in the US could achieve a 20% reduction in CO_2 formation with proper guidance. [EPA-HQ-OAR-2022-0829-0457, pp. 1-4]

- The current technology is focused on minimizing NOx without regard to CO_2. These technologies in Selective Catalytic Reduction (SCR) and Exhaust Gas Recirculation (EGR) are problematic at best and increase the life cycle operating costs. As a result, this increase in “well to wheels” emission levels must be considered in both the manufacturing and recycling processes. [EPA-HQ-OAR-2022-0829-0457, pp. 1-4]

- SCR has been on vehicles for 10-15 years. Though this technology does lower NOx emissions, the by-products it generates include ammonia (NH_3) and nitrous oxide (N_2O). Ammonia is more detrimental for humans than NO or NO_2, and N_2O is a strong greenhouse gas which is roughly 300 times more potent than CO_2. In the long run, increasing these by-products is not a good trade-off for the environment or those concerned about climate change. [EPA-HQ-OAR-2022-0829-0457, pp. 1-4]

3. NO and NO_2 (NOx) have been over-regulated for decades. Yet rather than gaining a better understanding of the chemistry, properties and usefulness of NO and NO_2, issues are being researched in an effort to stimulate further reductions. [EPA-HQ-OAR-2022-0829-0457, pp. 1-4]

- NO and NO_2 are naturally forming compounds on this planet, primarily as a by-product of lightning. NOx formation from lightning is greater than the entire transportation sector on a yearly basis with an estimate of 8.6-34 million metric tons. (https://www.nasa.gov/topics/earth/features/nox_lightning.html) (https://www.epa.gov/report-environment) [EPA-HQ-OAR-2022-0829-0457, pp. 1-4]

- NOx never accumulates on the Earth as it is constantly decomposing into Nitrogen and Oxygen. [EPA-HQ-OAR-2022-0829-0457, pp. 1-4]

- NOx is produced endogenously by humans. This means our lungs produce NOx internally as a by-product of breathing. Human NOx production varies based on food intake, activity level and constituents in the air. More research should be focused here. (Thoraz 1999;54:947-952, Nasal Nitric Oxide in Man, J Lundberg, E Weitzberg), (Integrated Science Assessment for Oxides of

Nitrogen, EPA/600/R-15/068, January 2016. Pg. 351, 356, 360-361.) [EPA-HQ-OAR-2022-0829-0457, pp. 1-4]

- Some research claims NOx leads to asthma; however, the correlation is weak and causation is not apparent. The majority of asthma cases correlate strongly with seasonal mold and pollen airborne allergens. Asthma is most prevalent in spring and fall months. (https://data.web.health.state.mn.us/asthma-charts), (Integrated Science Assessment for Oxides of Nitrogen, EPA/600/R-15/068, January 2016. Pg. 490-500.) [EPA-HQ-OAR-2022-0829-0457, pp. 1-4]

The graph above shows the significant reductions in NO2 across the US in the last 40 years. [See original attachment for graph of ambient annual nitrogen dioxide concentrations in the U.S., 1980-2016] The US has been below the National Ambient Air Quality Standards (NAAQS) safety thresholds for decades, including the 1-hour threshold at 100 ppb. We solved the NOx issue 40 years ago. NOx regulations for combustion engines should be reverted back to acceptable levels to allow for 20% CO2 reduction. Powertrains need to be calibrated for minimum fuel consumption in all operating conditions. [EPA-HQ-OAR-2022-0829-0457, pp. 1-4]

The graph above is from a NASA satellite image which highlights the areas with NOx issues. [See original comment for map of nitrogen dioxide levels throughout the Unites States] Since these areas are predominantly urban vicinities or downstream of power plants, it would be more beneficial to focus on localized efforts to reduce NOx. A good 70% of people live in the urban areas and reducing NOx in these inner cities will provide the most focused assistance. Ideally, most city transportation would be electric to eliminate emissions at source. Cities could build large parking lots outside urban areas for combustion vehicles and mass electric transit into city center. Keep in mind, electric vehicles do not reduce emissions, but rather change where those emissions are produced (battery mining / manufacturing / recycling plants) and electric power-distribution facilities. Moving the emissions away from where most people live would be prudent. Electric transportation does not reduce CO2 emissions over the vehicle life cycle due to battery manufacturing, mining, recycling and charging. Electric vehicles will help reduce smog in LA, Denver, etc. where there is poor airflow, however, they will not reduce carbon emissions when battery recycling/lifespan is incorporated in the well to wheels analysis. (https://climate.mit.edu/ask-mit/are-electric-vehicles-definitely-better- climate-gas-powered-cars),(https://www.iea.org/data-and- statistics/charts/comparative-life-cycle-greenhouse-gas-emissions-of-a-mid-size-bev- and-ice-vehicle),(https://www.epa.gov/greenvehicles/comparison-your-car-vs-electric- vehicle),(https://www.sciencedirect.com/science/article/pii/S1361920921000614). [EPA-HQ-OAR-2022-0829-0457, p. 4]

Proposed Emission Standard Guidelines

- Modify the emission standards on gasoline and diesel with the primary emphasis to be on minimizing CO2. [EPA-HQ-OAR-2022-0829-0457, p. 6]

- Increase NOx limit for diesel engines to 3 gram/mile on EPA emission test cycles. This is still cleaner than 1980 standards. With proper engine tuning, the smaller NOx increase allows for a decrease of 100 gram/mile of CO2. [EPA-HQ-OAR-2022-0829-0457, p. 6]

- Maintain the theme of clean diesel and keep particulate filters to prevent PM (particulate matter) emissions. [EPA-HQ-OAR-2022-0829-0457, p. 6]

- Manufacturers could add GPS software to go into low NOx mode when near NOx abatement zones. [EPA-HQ-OAR-2022-0829-0457, p. 6]

- Re-allocate tax incentives for urban residents to purchase BEV (battery electric vehicle) [EPA-HQ-OAR-2022-0829-0457, p. 6]

- Work with states on regional smog issues as these are very limited in geographical area. The top cities are: Los Angeles, Denver, Miami, New York City, Houston, Atlanta, etc. Moving to primarily electric vehicles in dense population zones eliminates point of use emissions. [EPA-HQ-OAR-2022-0829-0457, p. 6]

- Work with bio-fuel producers, farmers, refineries as needed to promote plant- based fuels that do not impact the food system. Hemp would be a good starting point as the entire plant can be utilized. The seed oil produces bio-diesel and the stalk produces ethanol. A robust bio fuel industry could reduce CO_2 up to 1000 million metric tons yearly. [EPA-HQ-OAR-2022-0829-0457, p. 6]

- Re-calibrating vehicles in the field for low CO_2 will yield the quickest return on investment. [EPA-HQ-OAR-2022-0829-0457, p. 6]

Organization: Hyundai America Technical Center, Inc. (HATCI)

HMG likewise provides comments regarding the Proposed Rule' s proposal to apply the standards equally at high altitude without compliance relief provisions from Tier 3 for certification. HMG suggests removing the high-altitude requirement. If this is not possible, HMG proposes the introduction of a low sales volume threshold as a viable alternative solution. This could involve implementing waivers from high altitude testing for vehicles with sales below a certain threshold. Similar relief provisions are already in place for 50 State/California requirements, where low volume sales of a particular bin result in exemption from testing. This approach would address the burden and cost associated with high altitude testing, while still maintaining appropriate emissions control measures for vehicles sold at larger volumes. Finding low sales volume test groups for testing is extremely challenging. Additionally, high altitude testing is a costly and burdensome process for OEMs. With modem emission controls in place, it is unnecessary and unreasonable to mandate high altitude testing, as acknowledged by the EPA. Removing this requirement or implementing a sales volume threshold would provide relief to manufacturers without compromising environmental standards, which would likewise result in benefits to consumers. [EPA-HQ-OAR-2022-0829-0554, p. 8]

Organization: Interfaith Power & Light

Transportation is currently the single largest source of climate pollution in the United States. In 2020, the national passenger vehicle fleet represented approximately 94% of the nation’s on-road vehicles and generated over one million tons of ozone- and particle-forming NOx emissions, which create dangerous smog. In order for the U.S to meet our Paris Climate Agreement goals we need the strongest possible long-term standards—beyond model year

2026— that will put the country on a path to a 100% zero-emission new vehicle sales target by 2035. [EPA-HQ-OAR-2022-0829-0530, p. 1]

Organization: International Council on Clean Transportation (ICCT)

CRITERIA POLLUTANT EMISSIONS

NMOG and NOx emissions

ICCT supports EPA's move to set more stringent NMOG + NOx emission limit for light-duty vehicle bins and the fleet average. We have observed that these proposed standards are more stringent than the Euro 7 emission regulations for cars and vans. The emission limit for all cars and vans in Euro 7, converted from mg/km, is 206 mg/mile. Meanwhile, in EPA's proposal, Tier 4 emission limit for all LDVs is 70 mg/mile. More details on the difference in emission limits between the two standards are show in Figure 11. Even if the SFTP early driveaway standard has a higher NMOG + NOx emission limit at 82 mg/mile, it is more stringent than the Euro 7 emission limit at 206 mg/mile. [EPA-HQ-OAR-2022-0829-0569, pp. 44-45]

For NMOG + NOx fleet average standards, EPA provides two pathways for automakers: default and early compliance. The default compliance pathway provides a full 4 years of lead time and 3 years of standards stability for LDT3, LDT4, MDPV, MDV class 2b and 3 which are defined as heavy-duty vehicles by the Clean Air Act.113 However, automakers can opt for the early compliance pathway, in which LDT3, LDT3, MDPV meet identical and declining fleet averages like LDV, LDT1, and LDT2. MDV class 2b and 3 also has gradually declining standards every model year. ICCT supports the option of the early compliance pathway that will result in higher reduction in NMOG + NOx emissions and greater environmental and health benefits. ICCT supports EPA encouraging automakers to adopt the early compliance pathway. [EPA-HQ-OAR-2022-0829-0569, pp. 44-45]

113 Emission standards for new motor vehicles or new motor vehicle engines, 42 U.S. Code § 7521, https://www.law.cornell.edu/uscode/text/42/7521

EPA could consider even lower NMOG + NOx fleet average standards for light-duty vehicles. EPA's standards are not as stringent as CARB's. CARB LEV IV phases out ZEV and PHEV in fleet average calculation, at 100% in MY 2025, 60% in MY 2026, 30% in MY2027, 15% in MY2028, to 0% by MY 2029. From MY2029+, the ICE vehicle fleet average is 30 mg/mile. The NMOG + NOx fleet average emissions under Tier 4 in MY 2029 would be higher than 30 mg/mile. For example, the EPA projects BEV penetration rate of light-duty vehicle fleet at 55% in 2029. Assuming the early compliance path, NMOG + NOx fleet average emission of ICE vehicles in 2029 could be 40 mg/mile (18 mg/mile MY2029 standards divided by the ICE vehicle penetration of 45%). Similarly, in 2032, the ICE fleet average emission could be 36 mg/mile (12 mg/mile divided by 33% ICE fleet penetration), still higher than CARB. EPA does not include a PHEV projection in the proposal. If PHEVs that still have tail-pipe emissions are included and the BEV penetration rate is lower than projected, the ICE vehicle NMOG + NOx fleet average could be higher than these calculated values. [EPA-HQ-OAR-2022-0829-0569, pp. 44-45]

However, for MDVs, the ICE fleet average emission projection could be lower than CARB's LEV IV standards for later MY 2030+. EPA projects BEV penetration rate at 46% in MY 2032. Assuming the early compliance path, NMOG + NOx fleet average emission of ICE MDV vehicles in MY 2032 could be 111 mg/mile (60 mg/mile MY 2032 standard divided by the ICE vehicle penetration of 54%), lower than CARB's fleet average of 150 mg/mile for class 2b and 175 mg/mile for class 3. [EPA-HQ-OAR-2022-0829-0569, pp. 44-45]

International comparison on NMOG + NOx emission standards

Figure 11 compares the light-duty vehicle NMOG + NOx emission standards between three authorities: European Union (Europe), CARB, and U.S. EPA. All purple markers represent standards up until MY 2025, and green markers represent MY 2025+ standards. The yellow line represents the Euro emission limits with purple circles illustrating Euro 6 standards that regulate emissions from MY2014 to 2025 cars and vans and green circles for Euro 7. Euro 6 had three separate standards for 3 categories of vehicle classes, based on vehicle weights.114 The blue line represents CARB LEV standards. LEV III had two separate standards, one for Passenger cars and Light-duty truck class 1 (LDT1), and one for LDT 2,3,4 and MDPV.115 These LEV III standards are illustrated by the purple triangles. Green triangles show LEV IV standards that are the same for all LDV vehicle classes. The red line shows the U.S. EPA Tier standards. The purple squares illustrate Tier 3 standards and the green squares Tier 4 standards. The figure also shows that Tier 3 and LEV III share the same emission limit at 0.16 g/mile or 160mg/mile and is lower than Euro 6 limits for all vehicle categories. Similarly, Tier 4 and LEV IV limits are lower than Euro 7 limits, however, Tier 4 emission limit at 70 mg/mile is lower than LEV IV limit at 125 mg/mile. [EPA-HQ-OAR-2022-0829-0569, pp. 45-47]

114 M1 are vehicles that carry passengers and comprise of no more than 8 seats in addition to the driver seats, M2 are vehicles similar to M1 and have a maximum mass not exceeding 5 tons. N1 vehicles are constructed to carry goods with maximum mass not exceeding 1305 kg (class I), 1760 kg (class Ii) and 3,500 kg (class III)

115 LDV are passenger cars with 8,500 lbs GVWr maximum, LDT1 vehicles are trucks with 3,750 lbs LVW maximum, LDT2 vehicles are trucks with 3,750 lbs LVW minimum, LDT3 vehicles are trucks with more than 6,000 lbs GVWR and with an ALVW of 5,757 lbs or less, LDT4 vehicles are trucks with more than 6,000 lbs GVWR and with an ALVW of more than 5,750 lbs. MDPVs are any passenger vehicles at or below 14,000 lbs GVWR with a work factor at or below 5,000 lbs. MDPV also includes pickups with GVWR below 9,900 lbs with an interior bed lengths less than 8 feet regardless of its work factor above 5,000 lbs. Pickups with GVWR between 9,900 and 14,000 lbs with a work factor above 5,000 lbs can be included if the interior bed length is less than 6 feet.

SEE ORIGINAL COMMENT FOR Figure 11. Light-duty vehicle NMOG + NOx emission standard comparison between CARB, EPA, and Euro standards [EPA-HQ-OAR-2022-0829-0569, pp. 45-47]

Notes:

1. EU Euro standards are max-per-vehicle or vehicle limit values that apply both in laboratory testing and real-world emission, while CARB LEV and EPA Tier programs have both limit values and fleet average values that are only laboratory test. [EPA-HQ-OAR-2022-0829-0569, pp. 45-47]

2. CARB LEV III, LEV IV and EPA Tier 3, Tier 4 set NMOG + NOx standards; EU Euro standards are the summation of independent NOx standards and NMHC/NMOG standards. [EPA-HQ-OAR-2022-0829-0569, pp. 45-47]

3. Starting MY 2029, LEV IV phase out ZEV+PHEV in the fleet average calculation, while Tier 4 still includes them. [EPA-HQ-OAR-2022-0829-0569, pp. 45-47]

4. Tier 4 LDT3,4 and MDPV standards are based on the early compliance pathway that is similar to Tier 4 PC + LDT1,2 [EPA-HQ-OAR-2022-0829-0569, pp. 45-47]

As mentioned in the previous section, Tier 4 standards include EV emissions in the NMOG + NOx fleet average calculation, while LEV IV standards gradually phase out EVs in the calculation by MY2029. As a result, even though the figure shows Tier 4 with a lower fleet average value than LEV IV, the projected ICE vehicle fleet average under Tier 4, illustrated as the dash red line, could be higher than LEV IV in MY 2029-2032. [EPA-HQ-OAR-2022-0829-0569, pp. 45-47]

Figure 12 compares the medium-duty vehicle NMOG + NOx emission standards between two authorities: CARB and U.S. EPA. All purple markers represent standards up until MY 2025, and green markers represent MY 2025+ standards. The blue lines represent CARB LEV standards, and the red lines represent EPA Tier standards. Both Tier 3 and LEV III had the same emission limit and fleet average for Class 2b and 3. However, starting with MY 2026, the Tier 4 emission limit is the same for both Class 2b and 3 at 160 mg/mile and lower than LEV IV at 250 mg/mile for Class 2b and 400 mg/mile for Class 3. Tier 4 MDV standards include EV emissions in the NMOG + NOx fleet average calculation, while LEV IV standards do not. The figure also shows that for MY 2030+, the projected ICE fleet average emissions shown as the dash red line could be lower than for the LEV IV Class 2b standards. [EPA-HQ-OAR-2022-0829-0569, pp. 45-47]

SEE ORIGINAL COMMENT FOR Figure 12. Medium-duty vehicle NMOG + NOx emission standard comparison between CARB and EPA [EPA-HQ-OAR-2022-0829-0569, pp. 45-47]

Evaporative emission

ICCT recommends EPA to set stronger running loss standards. The Tier 4 proposal allows vehicles to continue to be subject to Tier 3 evaporative emission standards, which states running loss may not exceed 0.05 g/mile. The running loss is reduced from 0.05 in LEV III to 0.01g/mile in LEV IV. According to CARB's Initial statement of reasons, since 1990, when the LEV emission standards were established, the 0.05 g/mile has not changed. The 2019 models' certification data showed that 87% of vehicles were already emitting at or below 0.01 g/mile. Thus, it is feasible for EPA to set more stringent running loss standards in alignment with CARB.116 [EPA-HQ-OAR-2022-0829-0569, pp. 45-47]

116 CARB. (2022). Initial Statement of Reasons. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/accii/isor.pdf and https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/accii/isor.pdf

Organization: Kia Corporation

Kia does not support a different approach than CARB, basing the standard on a ZEV and non-ZEV fleet average, because of the testing complexity this will add. Further, predicting the portion of ZEVs in the fleet will be difficult, as this will be determined by market conditions, which industry has little control over. It would be impossible for an automaker to adjust its NMOG+NOx fleet emissions if the portion of ZEVs in the fleet is less than predicted. It will also be impossible for an automaker to adjust its NMOG+NOx fleet emissions. Separating ZEVs and non-ZEVs for NMOG+NOx standard will provide needed planning stability. [EPA-HQ-OAR-2022-0829-0555, p. 11]

Kia appreciates the agency's commitment to performance-based standards and remaining technology neutral. However, Adopting CARB's ACC II will provide significant emissions reductions from ICE vehicles while avoiding diverting major resources from EV investments. [EPA-HQ-OAR-2022-0829-0555, p. 11]

Further, if EPA proceeds with its proposed approach, EPA must adjust the EV market share carefully so that projections of the NMOG+NOx standard are not skewed based on unrealistic EV penetration. [EPA-HQ-OAR-2022-0829-0555, p. 11]

Kia also recommends EPA adopt the high-altitude NMOG+NOx standards adopted through ACC II. [EPA-HQ-OAR-2022-0829-0555, p. 11]

Organization: Lucid Group, Inc.

Lucid Supports a Cleaner NMOG+NOx Standard

As mentioned above, tailpipe emissions contribute to adverse public health effects. EPA's proposed rule points out that NOx exposure impairs lung function and plant health and available technologies exist to further reduce NMOG+NOx emissions. For these reasons, Lucid strongly supports EPA's proposal to use a maximum fleet average standard of 300 mg/mi for light duty vehicles, light duty trucks, and medium duty passenger vehicles. [EPA-HQ-OAR-2022-0829-0664, p. 5]

Organization: Mclaren Automotive, McLaren Group

SVM Criteria Pollutant Standards

As outlined above, as a SVM we face unique challenges in meeting very stringent GHG standards, particularly those that rely on electrification. This is also the case for criteria pollutant standards which we are impacted by further, given the reduction in flexibilities proposed by the EPA. The EPA proposes to abandon the MY 27 and 28 SVM NMOG+NOx standards set out in Tier 3 (and on which we have been planning towards), and propose instead to increase stringency and require SVMs to adhere to the primary Tier 4 NMOG+NOx standard. Under the EPA's proposal, we would need to meet the same criteria pollutant and particulate matter emission standards on the same schedule as large manufacturers, despite our much less frequent new model platform introductions and lower fleet diversity, resulting in our corresponding limited ability to utilise average provisions. [EPA-HQ-OAR-2022-0829-0748, p. 4]

Historically, EPA have provided additional flexibilities and provision to SVMs, recognising the challenges we face. Furthermore, these flexibilities have been recognised and provided for in CARB's ACC II LEV IV regulation. With limited engine families, SVMs like McLaren are unable to utilise flexibilities with averaging, unlike mass market OEMs with many product lines. In order to properly account for the unique challenges faced by SVMs with regard to fleet averaging - based standards, it is important to set the degree and frequency of SVM step-downs to reflect SVM realities -- limited product lines, with longer product development and life cycles. We would propose the following alternative to the EPA's proposal: [EPA-HQ-OAR-2022-0829-0748, p. 4]

- MY 2027 -- Maintain for all SVMs the already-in effect MY 27 Tier 3 SVM NMOG+NOx standard (51m g/mi)

- MY 2028 -- Maintain for all SVMs the already-in effect MY 28 Tier 3 SVM NMOG+NOx standard (30 g/mi)

- MY 2029-32 - continue the 30 mg/mi standard for SVMs [EPA-HQ-OAR-2022-0829-0748, p. 4]

Organization: MECA Clean Mobility

Stringent NMOG+NOx requirements will yield substantial air quality benefits.

Assuming roughly 15 million new vehicles are sold per year and EPA's electrification estimates in the proposal, approximately 40 million light-duty ICE vehicles will be sold between MY 2027 and MY 2032. Many of these will remain on the road until 2050. MECA agrees with EPA's technology neutral regulatory approach that considers a combination of technologies from electrification to improved emission controls on ICE vehicles. [EPA-HQ-OAR-2022-0829-0564, pp. 4-5]

Our analysis of currently available certification data supports that vehicle manufacturers are making substantial progress on the path to the SULEV30 fleet average level with only the inclusion of a modest number of HEVs, PHEVs and BEVs. It has now been over twenty years since the first vehicle was certified to the SULEV30 standard and seven years since the first SULEV20. Advances in catalyst technology and honeycomb substrates have evolved to achieve NMOG+NOx emission levels well below 20 mg/mile and supports both the introduction of certification bins below the current lowest level as well as potential to achieve lower fleet average emission levels. Furthermore, catalyst coating technology combined with targeted precious metal placement has been successful in controlling costs in light of rising raw material prices. [EPA-HQ-OAR-2022-0829-0564, pp. 4-5]

The use of existing engine, hybrid powertrains and exhaust emission control architectures have also facilitated achieving the lowest SULEV20 and SULEV30 NMOG+NOx emission levels and significant CO2 reductions cost-effectively. Today, even larger SUVs and mini-vans with conventional and hybrid powertrains are being certified to the SULEV30 limit while further technology improvements continue to be incorporated into new production vehicles to enable compliance with the declining NMOG+NOx fleet average. The introduction of the additional bins as proposed by EPA will provide greater certification flexibilities to manufacturers that will complement increasing sales of electric vehicles to achieve lower fleet average emission targets. [EPA-HQ-OAR-2022-0829-0564, pp. 4-5]

EPA should consider setting a cap of 300 mg/mi for the -7°FTP NMOG+NOx standard rather than a fleet average at that level. [EPA-HQ-OAR-2022-0829-0564, pp. 4-5]

MECA commends EPA's proposal to replace the existing -7°FTP NMHC fleet average standards with a single -7°FTP NMOG+NOx standard of 300 mg/mi for LDV, LDT1 through 4 and MDPVs. We agree with the provisions of not averaging EVs into this fleet average standard, identical useful life coverage, and application of the same standard at high altitude. EPA emissions testing of vehicles in the MY 2019-2021 range at -7°C FTP showed that a 300 mg/mi standard is feasible with a large compliance margin for NMOG+NOx. Furthermore, a combination of revised calibration strategies and heating technologies, available to MY 2027 and later vehicles, could provide additional margin below the 300 mg/mi fleet average. First, vehicles designed for MY 2027 and later standards can incorporate targets based on a new cold temperature standard into new engine calibrations. Second, vehicles could also employ (separately or in tandem with engine calibration changes) electric heat in the exhaust stream via an electric heater or directly to the three-way catalyst (electrically heated catalyst or EHC). For these reasons, MECA suggests EPA consider finalizing a 300 mg/mi cap rather than a fleet average. [EPA-HQ-OAR-2022-0829-0564, pp. 4-5]

Organization: Mercedes-Benz AG

The current EPA Tier 3 rule includes separate NMOG+NOx standards for operation at high altitudes. CARB's LEV IV regulation also accounts for differences in testing at high altitude by providing different emissions standards for higher altitudes. EPA's proposed rule eliminates this allowance, calling for a constant emissions limit up to 1720 meters. EPA premises this decision on the capabilities of modern engines, citing "[m]odern engine management systems can use idle speed, engine spark timing, valve timing, and other controls to offset the effect of lower air density on exhaust catalyst performance at high altitudes."8 EPA does not consider or assess that modern engines are already designed to operate to the fullest extent, leaving little room for additional calibration to address high altitude conditions. [EPA-HQ-OAR-2022-0829-0623, pp. 8-10]

8 NPRM at 29262.

The below plot illustrates this difference with an example of the NMOG+ NOx standards for SULEV/BIN 30 for light-duty vehicles. In this example, EPA Tier 3 and LEV IV both include a standard of 30 mg/mile up to either 1520 or 1219 meters, respectively, and then a 50 mg/mile standard above that altitude point. EPA's proposed rule includes a 30 mg/mile standard for all altitudes up to 1720 meters. [EPA-HQ-OAR-2022-0829-0623, pp. 8-10]

[See original for graphs on NMOG+ NOx standards for SULEV/BIN 30 for light-duty vehicles] [EPA-HQ-OAR-2022-0829-0623, pp. 8-10]

Altitude-based standards are necessary to account for engine operation capabilities. The difference between sea level operation and altitude operation continues to increase as altitude increases. The following plots illustrate the impact of altitude on engine operation. [EPA-HQ-OAR-2022-0829-0623, pp. 8-10]

[See original for diagram on the impact of altitude on engine operation] [EPA-HQ-OAR-2022-0829-0623, pp. 8-10]

The figure above shows engine operation at sea level first and then altitude. When propulsion power is held constant (shown in green), the air available for catalyst heating (shown in red) must be reduced. Reducing the air used for catalyst heating does not allow the engine to operate in an emission-optimal strategy, resulting in higher raw emissions that the catalytic converter must be able to control. [EPA-HQ-OAR-2022-0829-0623, pp. 8-10]

The right figure shows a pair of plots again for sea level and altitude, but in this case, the catalyst heating remains constant in order to preserve efficient engine operation. This can only be accomplished by significantly reducing the power available to move the vehicle. Without an exception for altitude, the resulting situation is that both propulsion power and catalyst heating must be significantly reduced. The results is that the vehicle may not have enough power to drive. This control is physically limited, with little to no opportunity to improve engine calibrations. [EPA-HQ-OAR-2022-0829-0623, pp. 8-10]

To further detail the challenge to engine operation at altitude, note that the turbocharger is only able to compensate for the low air density to a limited extent, especially during transient driving. Using late ignition, the most important catalyst heating action cannot be fully implemented due to the lack of boost pressure, which leads to low cylinder air filling. This constraint results in an increase in raw emissions and slower heating of the catalyst. Additionally, the extent at which optimum catalyst heating operation may be implemented at low atmospheric pressure is limited to ensure combustion stability is sufficient to prevent engine stalling and provide protection of the vehicle from damage or accident. [EPA-HQ-OAR-2022-0829-0623, pp. 10-11]

Finally, real-world data shows the number of miles driven at higher altitudes under these challenging conditions are very limited. [EPA-HQ-OAR-2022-0829-0623, pp. 10-11]

Therefore, Mercedes-Benz recommends that the EPA align the requirements starting in 2027 MY with those in CARB's LEV IV rule, which provides a separate NMOG+NOx standard for vehicle operation at altitude. [EPA-HQ-OAR-2022-0829-0623, pp. 10-11]

Organization: Mitsubishi Motors North America, Inc. (MMNA)

2. Treatment of Plug-in Hybrid Electric Vehicles (PHEVs)

PHEVs offer many benefits and should be an integral part in implementing the proposed Multi-Pollutant Emissions Rule. PHEVs provide environmental benefits and are a viable alternative for vehicle buyers not yet ready or able to own or lease a BEV. PHEVs are a steppingstone to BEV acceptance, teaching consumers the benefits of BEV ownership without the drawbacks – range anxiety, charge anxiety, etc. PHEVs directly address better overall fuel economy, and reduced GHG emissions compared to comparable gasoline-only models, while offering similar utility, comfort, and convenience. [EPA-HQ-OAR-2022-0829-0682, pp. 3-4]

Additionally, PHEVs aid the transition from pure internal-combustion engines to full vehicle electrification, especially during any period when limited battery critical minerals production capacity would not be sufficient to meet the volumes necessary to supply the number of BEVs assumed in EPA's proposal. PHEVs have smaller battery packs that enable clean, electric-only – and, in our case, significant –driving, thereby using less critical minerals than comparable BEVs with bigger battery packs. The All-Electric Range (AER) of today's PHEVs already exceed the average daily commute mileage of most American drivers, and this will only increase in the future. Consumers would also benefit by having less expensive, easier to install, lower amp, home chargers installed to charge their PHEVs, rather than the more expensive, higher amp ones needed to charge larger BEV battery packs. More electrified powertrain options, including PHEVs, support the shift to electrification, reduce the demand for limited critical mineral supply, and enable greater EV access to more consumers. [EPA-HQ-OAR-2022-0829-0682, pp. 3-4]

Mitsubishi supports Auto Innovators' recommendation that EPA include PHEVs in its modeling, as a substitute for some BEVs, so that PHEVs comprise at least 20% of the combined

BEV+PHEV share, based on the availability and benefits of PHEVs and concerns with battery critical minerals supply constraints. [EPA-HQ-OAR-2022-0829-0682, pp. 3-4]

Equally as importantly, we also ask EPA to consider our recommendations regarding the PHEV NMOG+NOx Contribution Factor and the PHEV Utility Factor (UF) as discussed in other sections of our comments. [EPA-HQ-OAR-2022-0829-0682, pp. 3-4]

6. Tier-4 criteria Pollutant Emissions

Mitsubishi echoes Auto Innovators' support for EPA's adoption of the California ACC II (i.e., LEV-IV) criteria test procedures and standards. [EPA-HQ-OAR-2022-0829-0682, p. 9]

Mitsubishi supports cost-effective reductions in criterial pollutant emission from Internal Combustion Engines (ICE). However, some of EPA's proposed changes to the criteria emission standards - like the more stringent Particulate Mass (PM) and NMOG+NOx requirements and the enrichment prohibition - go above and beyond those adopted by CARB in ACC II standards. If finalized as proposed, these changes would require OEMs to divert large resources in time and capital (resources that could otherwise be directed to accelerate EV technology deployment) towards further ICE technology development and additional testing facilities. Mitsubishi believes that allowing OEMs to focus their finite R&D investments on developing EV technologies, rather than having to continue to invest in technology that is being phased out, is the most effective way to reach our shared goal to transition to electrification. [EPA-HQ-OAR-2022-0829-0682, p. 9]

NMOG+NOx Standards:

California LEV-IV regulation, 13CCR 1961.4 (d)(1)(A), phases out Zero Emission Vehicles (ZEVs) from the NMOG+NOx fleet average calculation, reaching 0% inclusion of ZEVs in MY29. The fleet average standard is maintained at 30 mg/mi for MY26 and subsequent model year vehicles. California's approach yields significant environmental benefits while reducing regulatory complexity. EPA's proposal, on the other hand, retains ZEVs in the fleet average and increases NMOG+NOx fleet average stringency to 12 mg/mi in MY32. EPA's proposed approach has significant drawbacks, including: [EPA-HQ-OAR-2022-0829-0682, pp. 9-10]

- Increasing fleet average stringency to 12 mg/mi apparently led EPA to propose one certification Bin below 12 mg/mi: Bin 10. A model certified to Bin 10, however, could not be certified under the California LEV regulation. 13CCR 1961.4 (c)(6)(A) requires the California Bin for a given model be equivalent to, or more stringent than, the federal Bin. Since California has not adopted a Certification Bin equal to or less than 10, EPA's proposed Bin 10 is impractical to implement, even if future technology is developed to make Bin 10 feasible. [EPA-HQ-OAR-2022-0829-0682, pp. 9-10]

- While retaining ZEVs in the fleet average calculation, EPA overlooked the necessity of including PHEV ZEV contribution in the fleet average calculation. [EPA-HQ-OAR-2022-0829-0682, pp. 9-10]

We support the California methodology of calculating PHEV contribution factor as detailed in 13 CCR (d)(4) namely:

PHEV NMOG+NOx Contribution Factor … the PHEV NMOG+NOx contribution factors for LDVs (in g/mi) are calculated as follows.

PHEVfactor = Std – 0.005 x ZVMTF – 0.005 x US06RF; Where:

PHEVfactor = PHEV NMOG+NOx contribution factor, rounded to the nearest 0.001 g/mi.

Std = NMOG+NOx standard, in g/mi, of the FTP emission category the test group is certified to in subsection (d)(2)(A).

ZVMTF = Zero vehicle miles traveled factor, calculated as follows. For purposes of this calculation, the maximum allowable ZVMT F that may be used is 1.0.

ZVMTf = CertRV/100 + 0.2

CertRV = Certification Range Value as defined in title 13, CCR, section 1962.4(l). [EPA-HQ-OAR-2022-0829-0682, pp. 9-10]

US06RF = US06 range factor, which is either equal to 1.0 if US06 All-Electric Range (AER) is at least 10 miles or to zero if US06 AER is less than 10 miles. The US06 AER is defined in the "California Test Procedures for 2026 and Subsequent Model Year Zero-Emission Vehicles and Plug-in Hybrid Electric Vehicles, in the Passenger Car, Light-Duty Truck and Medium-Duty Vehicle Classes. [EPA-HQ-OAR-2022-0829-0682, pp. 9-10]

Although somewhat complex, the CARB methodology for adjusting PHEV NMOG+NOx certification level reasonably characterizes the environmental benefit of PHEV ZEV capability over conventional internal combustion engine only models. [EPA-HQ-OAR-2022-0829-0682, pp. 9-10]

Again, we strongly recommend EPA fully adopt the same NMOG+NOx fleet average standard structure as California LEV-IV. However, if EPA decides to retain ZEVs in the NMOG+NOx fleet average calculation, we recommend the above PHEV NMOG+NOx Contribution Factor methodology be adopted. [EPA-HQ-OAR-2022-0829-0682, pp. 9-10]

Organization: National Association of Clean Air Agencies (NACAA)

Criteria Pollutant Emission Standards and Related Issues [EPA-HQ-OAR-2022-0829-0559, pp. 6-7]

For reasons cited above, NACAA strongly supports EPA's proposal of more protective emission standards for non-methane organic gas (NMOG)+NOx and for PM. [EPA-HQ-OAR-2022-0829-0559, pp. 6-7]

The proposed 12-milligrams-per-mile (mg/mi) NMOG+NOx fleet average standard for LDVs, to be phased in by MY 2032, will reduce emissions by 60 percent relative to the existing 30-mg/mi (Tier 3) MY 2025 standard set in 2014. The proposed 60-mg/mi NMOG+NOx fleet average standard for MDVs, also to be phased in by MY 2032, will reduce emissions by 66 to 76 percent from the Tier 3 standards of 178 mg/mi for Class 2b vehicles and 247 mg/mi for Class 3 vehicles. EPA's proposed cold temperature (-7°C) NMOG+NOx standards will ensure that emissions are controlled over a wide range of operating conditions. [EPA-HQ-OAR-2022-0829-0559, pp. 6-7]

With respect to PM, EPA proposes a standard of 0.5 mg/mi for LDVs and MDVs, with a requirement that this standard be met across three duty cycles, including a cold-temperature (-

7°C) cycle. Such a standard will appropriately drive the use of gasoline particulate filters, which are readily available. EPA projects that making these revisions to the standards set by the agency in the 2014 Tier 3 rule would reduce PM emissions from ICE vehicles by more than 95 percent and also yield reductions in toxic air pollutants. [EPA-HQ-OAR-2022-0829-0559, pp. 6-7]

NACAA also supports EPA's proposal to eliminate commanded enrichment as an auxiliary emission control device on ICE engines used in LDVs and MDVs. Commanded enrichment is an engine operation that overrides the engine management feedback control system by applying extra fuel in order to provide additional power or protect engine or exhaust system components, thereby producing very high levels of excess emissions. This strategy is deployed during normal operation and use (e.g., vehicle speeds, grades of public roads and vehicle loading and towing within manufacturer recommendations, even if the operation occurs infrequently). However, as EPA explains in the proposal," Technologies exist that can prevent thermal damage of engine and/or exhaust system components without the use of enrichment during normal operation and use Modern vehicles have sufficient power without the use of enrichment. [EPA-HQ-OAR-2022-0829-0559, pp. 6-7]

The use of enrichment only has the potential to incrementally increase power but significantly reduces the effectiveness of the catalytic aftertreatment system, resulting in a ten-fold or greater increase of CO and HC emissions."27 NACAA recommends that in addition to eliminating commanded enrichment EPA require that vehicle data related to enrichment be collected and analyzed. [EPA-HQ-OAR-2022-0829-0559, pp. 6-7]

27 Id at 29,277

Organization: National Automobile Dealers Association (NADA)

EPA also proposes non-methane organic gases plus nitrogen oxides (NMOG+NOx) standards that represent a 60 percent reduction from the existing MY 2025 light-duty standards and a 66 to 76 percent reduction for medium-duty vehicles.7 And for both light- and medium-duty vehicles, EPA's proposed standards project to reduce particulate matter emissions by more than 95 percent.8 [EPA-HQ-OAR-2022-0829-0656, p. 2]

V. Criteria Emissions

Air quality in the United States has improved substantially.31 EPA is proposing new NMOG+NOx standards that are 60% stricter than the 2025 standards. "Data and observations indicate ICE vehicle emissions may be approaching a ZEV-equivalent level... Future vehicle emission- reduction efforts might be more profitably targeted on reducing the effect of gross emitters, which represents 2–5% of the fleet but can produce up to half the emissions."32 [EPA-HQ-OAR-2022-0829-0581, p. 13]

31 Timothy Wallington, et al., Vehicle Emissions and Urban Air Quality: 60 Years of Progress, Atmosphere 2022, 13(5), 650, available at https://doi.org/10.3390/atmos13050650.

32 S.L. Winkler, et al., Vehicle criteria pollutant (PM, NOx, CO, HCs) emissions: how low should we go?, Climate and Atmospheric Science (2018), available at https://doi.org/10.1038/s41612-018-0037-5.

Further tightening of criteria emissions standards on new vehicles may not be effective at improving air quality, but it also discourages technologies that can help meet GHG emissions reductions goals—and meet them today. For example, flexible fuel vehicles allow use of greater ethanol blends, which provide increasing GHG emissions reductions. However, overly restrictive criteria emissions standards make it more difficult to design engines, cold start strategies, and catalytic aftertreatment which can handle the wide range of fuel properties required for flex- fuel vehicles. Moreover, higher ethanol blends would reduce air toxic emissions that may be more important to focus on with respect to light-duty and medium-duty vehicles that will continue to use gasoline well into the future. [EPA-HQ-OAR-2022-0829-0581, p. 13]

Organization: National Tribal Air Association (NTAA)

Criteria Pollutant Emissions Standards

Many residents in Indian country continue to be exposed to concentrations of ozone and particulate matter that exceed current National Ambient Air Quality Standards. With a few exceptions, the sources of this pollution are outside the jurisdiction and control of Tribal governments. It is imperative that the EPA and applicable state and local authorities take all necessary measures to return Tribal communities to healthy air quality. [EPA-HQ-OAR-2022-0829-0504, p. 2]

The proposed emissions standards for new light-duty and medium-duty vehicles for non-methane organic gases plus nitrogen oxides (NMOG+NOx) constitute one key step in reducing the impacts from the largest source of these ozone-precursor pollutants. Concurrently, reduced emissions of NMOG+NOx will reduce ambient air concentrations of particulate matter, and PM2.5 more specifically. The NTAA supports the proposed standards for these pollutants across the applicable vehicle categories and looks forward to healthier air quality in our many impacted communities. [EPA-HQ-OAR-2022-0829-0504, p. 2]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC)

The NESCAUM and OTC regions include the New York City (NYC) Combined Statistical Area (CSA) with over 20 million people living across portions of Connecticut, New Jersey, New York, and Pennsylvania. It is the largest CSA by population in the United States. The NYC metropolitan area and surrounding regions continue to persistently exceed federal health-based air quality standards for ground-level ozone. The chronically persistent high concentrations compromise the health and welfare of the citizens living in the NYC CSA and throughout the Northeast Corridor. While ozone is largely a summertime issue, NOx emissions are a year-round problem. NOx emissions contribute to acid deposition, eutrophication, and visibility impairment in the NESCAUM and OTC regions. During colder seasons, NOx emissions play a role in producing secondary PM2.5 through the formation of nitrates. [EPA-HQ-OAR-2022-0829-0584, p. 3]

B. Proposed LDV and MDV Criteria Pollutant Emissions Standards

NESCAUM and the OTC also strongly support EPA's proposal to establish more stringent emissions standards for criteria pollutants for both LDVs and MDVs for MYs 2027–2032. EPA should adopt the standards proposed in the NPRM. [EPA-HQ-OAR-2022-0829-0584, pp. 9-10]

EPA is proposing non-methane organic gas (NMOG) plus NOx standards for LDVs that would phase-down to a fleet average level of 12 mg/mi by MY 2032, representing a 60 percent reduction from the existing standards for MY 2025 established in the Tier 3 rule in 2014. EPA is proposing NMOG plus NOx standards for MDVs that would require a fleet average level of 60 mg/mi by MY 2032, representing a 66–76 percent reduction from the Tier 3 standards for Class 2b and Class 3 vehicles. EPA is proposing cold temperature NMOG plus NOx standards for LDVs and MDVs to ensure robust emissions control over a broad range of operating conditions. [EPA-HQ-OAR-2022-0829-0584, pp. 9-10]

EPA's modeling shows that these proposed standards would reduce NOx emissions by 66,000 tons in 2055, representing a 41 percent reduction compared to the no action scenario. EPA also estimates reductions of 220,000 tons of VOCs, representing a 50 percent reduction, and 12,000 tons of sulfur dioxide, representing a 42 percent reduction, compared to no action. [EPA-HQ-OAR-2022-0829-0584, pp. 9-10]

The NESCAUM and OTC jurisdictions need the greatest possible reductions in NOx emissions from all sectors to meet federal air quality standards. Modeling conducted by NESCAUM and the OTC has demonstrated that, even with a 90 percent reduction in emissions of all regulated pollutants from all on-road mobile sources, the NYC CSA would still benefit from additional NOx reduction strategies to achieve ozone reductions.25 NESCAUM and the OTC believe substantial NOx reductions from transportation can be achieved through the application of ZEV technologies. NESCAUM and the OTC believe EPA's proposed standards are necessary and technologically feasible and we urge EPA to adopt them. [EPA-HQ-OAR-2022-0829-0584, pp. 9-10]

25 See OTC, Modeling Committee Update for OTC and MANEVU Stakeholders Meeting at 10 (Apr. 21, 2023), https://otcair.org/upload/Documents/Meeting%20Materials/3%2020230421%20OTC_Modeling_Comm_final.pdf.

Organization: Porsche Cars North America (PCNA)

1. Porsche seeks to confirm NMOG+NOx fleet average credits continue to act as a single averaging set. [EPA-HQ-OAR-2022-0829-0637, pp. 8-9]

Porsche seeks to confirm it's understanding of the NMOG+NOx credit flexibilities under the default phase-in scenario for vehicles >6000 pounds defined in 86.1811-27(b)(6)(ii). Under this scenario, Porsche recognizes that all Tier-4 and Interim Tier-4 light-duty program vehicles (LDV, LDT1, LDT2) below 6000 pounds would be averaged together to assess compliance with the declining NMOG+NOx fleet average outlined in Table 3 of 86.1811-27(b)(6)(ii) and that this averaging set would only include vehicles below 6000 pounds. Porsche further understands that the default scenario would create a second averaging set for Interim Tier-4 vehicles over 6000 pounds (LDT3, LDT4, and MDPVs) and that these vehicles would be assessed against the Tier-3 fleet average NMOG+NOx standard of 30mg for model years 2027-2029. Porsche recognizes that EPA is not proposing changes to the credit operations outlined in 86.1861- 17(b)(1)(ii) which states that: [EPA-HQ-OAR-2022-0829-0637, pp. 8-9]

“Except as specified in paragraph (b)(1)(iii) of this section, LDV and LDT represent a single averaging set with respect to all emission standards.” [EPA-HQ-OAR-2022-0829-0637, pp. 8-9]

Because EPA is continuing to view the LDV and LDT as a single averaging set for NMOG+NOx fleet average compliance, Porsche seeks to confirm that credits generated within a model year (i.e., for MY2027-2029) in either the under 6000 pound or over 6000 pounds averaging set can be used between the two averaging sets should manufacturers have a deficit in either set. Furthermore, Porsche seeks to confirm that manufacturers can apply carry-forward Tier-3 credits within both the under and over 6000 pounds averaging sets (setting aside the MDV restriction) to also cover any deficits. Finally, Porsche seeks to confirm that any deficit in either the over or under 6000 pounds averaging set would have to be covered with credits earned in the same model year from the other averaging set prior to utilizing banked, carry- forward credits from earlier model years. [EPA-HQ-OAR-2022-0829-0637, pp. 8-9]

3. Porsche supports flexibility to include zero emission vehicles within NMOG+NOx fleet averages as an option

As described within III.C.2.iii. of the preamble,2 EPA has proposed that the declining NMOG+NOx fleet average should continue to include all vehicle types, including BEVs and other Bin 0 powertrains. Consistent with comments from the AFIA, Porsche recognizes that there is value in aligning the Tier-4 structure with CARB’s LEV-IV, which excludes ZEVs from the LEV-IV fleet average, but maintains a consisten annual target of 30mg/mile. Porsche recommends that should EPA considering aligning the Tier-4 fleet average approach with CARB, that EPA offer manufacturers the option to include BEVs within the fleet average and use the declining annual targets similar to as it is proposed in the NPRM. The two options would provide additional flexibility for manufacturers without disrupting the requested alignment with LEV- IV. [EPA-HQ-OAR-2022-0829-0637, p. 10]

Organization: Reginald Modlin and B. Reid Detchon

3. In fact, EPA’s Phase I testing results showed that NOx and PM “have significant decreases in emissions as ethanol levels increase from E0 to E10” – and EPA then “decided to drop the Phase 1 test fuels … from the Phase 3 fuel matrix.” [EPA-HQ-OAR-2022-0829-0570, p. 30]

150 Adam R.F. Gustafson, Boyden Gray & Associates, “EPA Emails Show the Agency Relied on the Oil Industry to Design Anti-Ethanol Fuel Effects Study,” memo to Urban Air Initiative, Nov. 4, 2016: pp. 15, 17: http://cleanfuelsdc.org/wp-content/uploads/2019/04/BGA-FOIA-EPA-EPact-Emails-Nov-4-2016.pdf (accessed Sept. 14, 2021)

4. At a meeting in June 2015 with the Energy Future Coalition, EPA Administrator Gina McCarthy erroneously asserted that her hands were tied on mid-level ethanol blends because they would increase NOx – a comment probably based on the flawed tests and the MOVES model. [EPA-HQ-OAR-2022-0829-0570, p. 30]

151 Reid Detchon, Energy Future Coalition, personal recollection.

ii. Emissions tests by the U.S. Department of Energy have confirmed that “even though ethanol is more catalytically reactive than other gasoline components, ethanol will likely neither help nor hinder compliance with NOx, non-methane organic gases (NMOG), and CO regulations in realistic fuel blends.” [EPA-HQ-OAR-2022-0829-0570, p. 30]

152 Daniel Gaspar, Pacific Northwest National Laboratory, “Top Ten Blendstocks For Turbocharged Gasoline Engines: Bioblendstocks With Potential to Deliver the Highest Engine Efficiency.” PNNL-28713 (2019): p. 34: https://www.osti.gov/servlets/purl/1567705 (accessed June 22, 2021).

iii. Despite repeated calls to fix this clear error, EPA has not done so. [EPA-HQ-OAR-2022-0829-0570, p. 30]

i. Automakers can readily adjust the engine’s air-fuel ratio to keep NOx emissions within permissible levels: A 2014 Ford study of a flexible fuel vehicle found that NOx emissions decreased by approximately 50% as the ethanol content increased from zero to E30-E40. The study pointed to the importance of engine calibration: “Upon sensing greater ethanol content in the fuel, the calibration prescribed different engine operating conditions.” [EPA-HQ-OAR-2022-0829-0570, p. 46]

Organization: Renewable Fuels Association (RFA)

X. Criteria Pollutant Emissions

Sustained efforts to reduce emissions from vehicles and other sources have been highly successful in improving the air quality of cities throughout the U.S., as shown below in plots based on CARB and EPA data.42 Ambient levels of all major pollutants have gone down dramatically, despite large increases in population and GDP. The average values (and in most cases the 90th percentile values) now meet the National Ambient Air Quality Standards. [EPA-HQ-OAR-2022-0829-0602, pp. 19-20]

42 Wallington et al., "Vehicle Emissions and Urban Air Quality: 60 Years of Progress", Atmosphere 2022; https://doi.org/10.3390/atmos13050650.

EPA is proposing new NMOG+NOx standards that are 60% stricter than the 2025 standards. However, vehicles meeting the 2025 standards are already so clean that they do not make any meaningful contribution to air quality problems. Thus, additional reductions required beyond the 2025 levels are unlikely to yield significant air quality benefits but would come at an excessive cost to automakers and ultimately consumers. [EPA-HQ-OAR-2022-0829-0602, pp. 19-20]

A Ford study concluded that “ICE vehicle emissions may be approaching a ZEV- equivalent level...Future vehicle emission-reduction efforts might be more profitably targeted on reducing the effect of gross emitters, which represents 2–5% of the fleet but can produce up to half the emissions.” 43 [EPA-HQ-OAR-2022-0829-0602, pp. 19-20]

43 Winkler et al., "Vehicle criteria pollutant (PM, NOx, CO, HCs) emissions: how low should we go?" Climate and Atmospheric Science (2018); https://doi.org/10.1038/s41612-018-0037-5.

Further tightening of criteria emissions standards on new vehicles is not only ineffective at improving air quality, it also potentially discourages changes that can help meet GHG emissions reductions goals. For example, FFVs are a key enabler for allowing low-carbon E85 to displace gasoline in some applications. But overly restrictive criteria emissions standards may make it more difficult to design engines, cold start strategies, and catalytic aftertreatment that can handle the wide range of fuel properties required for FFVs. [EPA-HQ-OAR-2022-0829-0602, pp. 19-20]

Organization: Satya Consultores

Satya began its DEP work with the goal of solving the tradeoff between reducing diesel soot and NOX emissions. At higher temperatures, diesel engines achieve more complete combustion, and emit less soot and other fine particulate matter as a result. However, under these conditions NOX emissions increase. In turn, lower engine temperatures result in lower NOX emissions but cause soot emissions to increase. This tradeoff is well known among fuel scientists.1 Both pollutants have significant adverse environmental impacts and health effects. [EPA-HQ-OAR-2022-0829-0602, pp. 19-20]

Satya’s DEP resolves this conundrum. We call the resulting fuel “Next Diesel.”

1 See, e.g., Narayan et al., Combustion Monitoring in Engines Using Accelerometer Signals, J. VIBROENGINEERING, Sep. 2019, at 4; Tie Li & Hideyuki Ogawa, Analysis of the Trade-Off between Soot and Nitrogen Oxides in Diesel- Like Combustion by Chemical Kinetic Calculation.

In DEP, two proprietary additives are mixed into the diesel fuel. The first additive (“A1”) is an ethoxylated fatty acid ester, made with a mixture of stearic and palmitic acid esters of sorbitol and its mono- and dianhydrides. The second additive (“A2”) is a complex water-based blend of aromatic solvents with methyl radicals mixed with ethoxylated phenol-derived surfactants. [EPA-HQ-OAR-2022-0829-0602, pp. 19-20]

Diesel fuel flows from a tank at the end of the refining process in a continuous stream through piping to a Shock Wave Power Reactor. En route, A1 is metered into the diesel fuel stream via a Progressive Cavity Injection Pump, and the combination is blended using a static mixer. Once the fuel/A1 mixture is homogenous, A2 is metered in, and that combination is blended in a second static mixer. The resulting diesel fuel/A1/A2 mixture then flows into the Shock Wave Power Reactor where it is subjected to controlled cavitation, a process which creates vapor bubbles in the fuel mixture. As a liquid passes through the SPR it is subjected to “controlled cavitation.” The heart of the reactor is a specially designed rotor. The spinning action generates hydrodynamic cavitation in the rotor cavities away from the rotor to prevent damage to metal surfaces. As microscopic cavitation bubbles are produced and collapse, shockwaves are given off into the liquid which can heat and/or mix.2 [EPA-HQ-OAR-2022-0829-0602, pp. 19-20]

2 Hydro Dynamics, Inc. (n.d.). Retrieved from Harnessing the Power of Cavitation: https://www.hydrodynamics.com/cavitation-technology/.

The resulting diesel fuel exhibits improved properties, including significantly improved ignition characteristics. Its electrical conductivity is more than 1,000 times greater than regular diesel fuel, and the lubricity value is more than 100 times greater. These and other upgraded properties of Next Diesel enable more complete fuel combustion, which in turn results in less soot production and also reduces NOX emissions. The corresponding loss of fuel power, if any, is negligible. [EPA-HQ-OAR-2022-0829-0687, pp. 2-3]

The pilot- scale test results, which followed EPA-specified federal test procedures (or "FTPs"), demonstrated significant reductions in soot with accompanying reductions in NOX emissions. All Next Diesel emissions test results were compared to ultra-low sulfur diesel ("ULSD") emissions tests on the same engines. Only the fuels were changed; all other test parameters were identical. All tests were "engine out;" there was no after-treatment or particulate filtering. Combustion map parameters for both Next Diesel and ULSD were the same. [EPA-HQ-OAR-2022-0829-0687, pp. 3-5]

Satya and SwRI compared Next Diesel with ULSD in extensive tests. Two of the many test results illustrate Next Diesel's potential. As illustrated in Figure 1 below, transient cycle tests on a newer model diesel engine, the Navistar N13, documented a 14% reduction in soot emissions and an 8.6% reduction in NOX: [See original attachment for Navistar N13 Transient Tests] [EPA-HQ-OAR-2022-0829-0687, pp. 3-5]

As shown in Figure 2, on an older model DDC Series 60 engine, the reductions in soot were even more dramatic: a 29% reduction of soot, with no increase in NOX emissions. [See original attachment for DDC Series 60 Transient Tests] [EPA-HQ-OAR-2022-0829-0687, pp. 3-5]

The modified fuels produced by this pilot-scale plant conform to physical, mechanical, rheological, thermal, and chemical fuel standards promulgated by the American Society for Testing and Materials ("ASTM"), including ASTM-D975. The fuel has been tested in real-scale heavy duty certification engines. Based on the success of these evaluations, Satya has worked with SwRI and other internationally recognized research organizations to design a production-scale facility. The facility design meets ASTM and American National Standards Institute ("ANSI") standards and would be capable of processing 12,000 barrels of diesel fuel per day, or 150 million gallons per year. SwRI has concluded (Link: https://www.swri.org/press-release/swri-engineers-help-develop-cleaner-burning-diesel-fuels) that DEP and Next Diesel are ready for commercial development. [EPA-HQ-OAR-2022-0829-0687, pp. 3-5]

All of the testing conducted to date by Satya and SwRI has been conducted with ultra- low sulfur diesel ("ULSD") that meets current EPA fuel composition requirements. The introduction of ULSD in 2006 has led to dramatic reductions in particulate matter and NOX emissions from diesel engines, and the diesel engine requirements proposed by EPA in the current rulemaking promise additional reductions. Satya's DEP demonstrates that even more air quality gains are possible with additional diesel fuel controls. [EPA-HQ-OAR-2022-0829-0687, p. 5]

Emissions of pollutants like soot and NOX are generally highest immediately following a cold engine start because after-treatment systems tend to be inefficient during and just after ignition. Next Diesel reduces emissions during and after a cold engine start, and reductions continue to be achieved even after the engine and after-treatment systems reach steady operating temperatures.

Engine manufacturers may choose to modify or reprogram new engines to maximize benefits of Next Diesel, but such modifications are not necessary. Next Diesel is an improved fuel that does not require modification of any part of a new or existing engine. [EPA-HQ-OAR-2022-0829-0687, p. 5]

Organization: South Coast Air Quality Management District

There are five key issues we request U.S. EPA address before finalizing the rule.

1. Extend the phase-in period and adopt more stringent standards to align with California's ACC II regulation. The proposed standards will be phased in over a six-year period from model year (MY) 2027 through 2032 with increasing stringency each year. We recommend that the phase-in period be extended to 2035 and later model years to better align with the ACC II implementation schedule which extends out to MY 2035 and subsequent years. [EPA-HQ-OAR-2022-0829-0659, p. 2]

In terms of stringency, the proposed non-methane organic gases plus nitrogen oxides (NMOG+NOx) standard would phase down to 12 mg/mi by MY 2032 for light-duty vehicles (LDVs), a 60 percent reduction from the Tier 3 standard of 30 mg/mi. For medium-duty vehicles (MDVs), the NMOG+NOx standard would phase down to 60 mg/mi by MY 2032, representing 66 percent to 76 percent reduction from the Tier 3 standard of 178 mg/mi for Class 2b and 247 mg/mi for Class 3 vehicles, respectively. While these standards represent substantial progress, we urge U.S. EPA to consider more stringent standards for CO2 and criteria pollutants to help our region achieve the national ambient air quality standards. We therefore support the adoption of the Alternative 1 stringency level for greater reductions of emissions, including NOx (47,000 tons vs 44,000 tons in 2055) as well as a higher BEV (Battery Electric Vehicle) penetration rate compared to the proposed standards (69% vs 67% in MY 2032). [EPA-HQ-OAR-2022-0829-0659, p. 2]

Furthermore, U.S. EPA should consider additional measures that are technically and economically feasible. For example, the ACC II requires manufacturers to comply with an annual zero emission vehicle (ZEV) sales percentage requirement that scales up from 35 percent in MY 2026 to 100 percent by MY 2035 (including up to 20% PHEVs). CARB's analysis supports this requirement to be both technically and economically feasible based on projected technology advancements. In comparison, the projected 69 percent BEV penetration rate in MY 2032 for Alternative 1 falls short of the ACC II requirements. We understand the proposed standards are performance-based without any mandate on ZEV sales percentages, however, U.S. EPA should conduct an additional feasibility analysis for more stringent standards that will achieve higher BEV penetration rates. [EPA-HQ-OAR-2022-0829-0659, p. 2]

Organization: Stellantis

Structure of Fleet Average NMOG + NOx Standard Acting as De facto ZEV Mandate [EPA-HQ-OAR-2022-0829-0678, p. 16]

EPA is proposing increasingly stringent light-duty vehicle NMOG+NOx standards for the sales weighted average inclusive of all LDV, LDT and MDPV. The proposed fleet average standards are only feasible if aggressive BEV technology penetration rates are achieved, like those discussed in the GHG section of our comments. [EPA-HQ-OAR-2022-0829-0678, p. 16]

This exposes the criteria emissions compliance to the same market feasibility risks discussed earlier in the context of GHG compliance. Overly optimistic projected policy solutions lead to unrealistic assumptions of BEV market acceptance, along with resource redeployment to electrification and long lead times for ICE hardware changes, creating risk for compliance in the criteria emissions space that is untenable. Additionally, EV technology significantly increases the weight of electric models compared to their ICE counterparts which means that the emissions benefits of EVs may be pushed into higher weight classes, and therefore we are prevented from offsetting the emissions of comparable ICE models in lower weight classes. These issues were discussed and addressed recently during development of ACC II LEV IV criteria emissions rules established by CARB where the ICE fleet complies with criteria emissions requirements independent of BEV sales, allowing manufacturers to maintain compliance regardless of BEV penetration rates and weight class complexities. [EPA-HQ-OAR-2022-0829-0678, p. 16]

EPA should adopt CARB's ACC II LEV IV 30 mg/mi ICE fleet average with BEV phasing out at declining rates, so that compliance is not dependent on BEV market penetration. In addition, one method of compliance (both testing and fleet management) can achieve the same (cleaner air) result and is more efficient. [EPA-HQ-OAR-2022-0829-0678, p. 16]

Organization: Tesla, Inc.

Tesla supports the proposed Alternative 1 with added stringency so that the final performance standards achieves a fleet BEV penetration rate greater than 69% in MY 2032.2 Alternative 1 is estimated to provide greater CO2 emissions reduction of -51% from no action by 2050 compared to -46% under EPA's proposal, and the additional stringency will result in even greater emission reductions.3 Accordingly, Tesla asserts the EPA should amend its proposal with a more stringent version of Alternative 1 and take, inter alia, the following additional steps to increase the performance and overall stringency of the proposed standards: [EPA-HQ-OAR-2022-0829-0792, p. 2]

2 See, 88 Fed. Reg. 29332-33, Table 96.

3 Id., at 29348 (comparing Tables 135 and 136).

- Eliminate off-cycle crediting for all types of vehicles; [EPA-HQ-OAR-2022-0829-0792, p. 2]

- Revisit the plug-in hybrid electric vehicle (PHEV) utility factor to accurately reflect real world emissions; [EPA-HQ-OAR-2022-0829-0792, p. 2]

- Amend the proposal to create parity in promoting motor vehicle air conditioning (MVAC) efficiency adoption; [EPA-HQ-OAR-2022-0829-0792, p. 2]

- Maintain the existing zero emissions upstream approach for BEVs; [EPA-HQ-OAR-2022-0829-0792, p. 2]

- Eliminate credit multipliers for all vehicles; and [EPA-HQ-OAR-2022-0829-0792, p. 2]

- Ensure BEVs continue to be accounted for, and participate in, the NMOG + NOx reduction standard. [EPA-HQ-OAR-2022-0829-0792, p. 2]

BEVs Continue to Be the Most Effective NMOG+ NOx Emission Reduction Technology

An overarching goal of the proposed emission standards regime should be to continue to design them in a manner that incents, accelerates, and rewards the deployment of the best performing vehicles. As noted previously, BEVs represent the best vehicle technology for eliminating tailpipe criteria air pollutants. Tesla believes that the agency should continue to recognize BEVs for this best- in-class performance and the emission reduction contributions. Accordingly, Tesla supports EPA's decision to maintain ZEVs in the baseline of the NMOG + NOx emissions standards.182 Failure to continue this approach would unfairly penalize BEVs by eliminating their NMOG credit generation and the incentive for ZEV adoption that averaging, banking, and trading creates. [EPA-HQ-OAR-2022-0829-0792, p. 29]

Organization: Volkswagen Group of America, Inc.

Criteria Emissions

Volkswagen is in full agreement with AFAI's comments regarding Criteria Emissions, harmonization between EPA regulations and California's Low Emission Vehicle (LEV) regulation to enable manufactures to focus on a single technical solution for the U.S. market. Volkswagen recommends harmonization of EPA regulation with the fully adopted California LEV IV emission regulations. [EPA-HQ-OAR-2022-0829-0669, p. 6]

Harmonization of Bin Structure (Section III.C.2.i.) [EPA-HQ-OAR-2022-0829-0669, p. 6]

Volkswagen suggests inclusion of Bin 15 and Bin 25 stages as implemented in CARB's LEV IV regulation. The NPRM Bin structure does not contain Bin 15 and Bin 25 stages. These emission standards are relevant for the development of future concepts. Smaller increments between Bin 30 and Bin 10 are required to provide manufacturers the flexibility to maximize their fleet's emission performance. Incremental steps below Bin 30 could be implemented in a quick and cost effective manner and will not cause serious challenges in the measurement process at test sites. This suggestion would also solve the challenge of mutual recognition of Tier and LEV certificates and avoid the requirement to certify to a Clean Air standard for the same vehicle test group. [EPA-HQ-OAR-2022-0829-0669, p. 6]

Bin 70 Bin 60 Bin 50 Bin 40 Bin 30 Bin 25 Bin 20 Bin 15 Bin 10 Bin 0

FTP (20-30°C) NMOG+NOx Fleet Average Standard [EPA-HQ-OAR-2022-0829-0669, p. 6]

Volkswagen supports the continuous reduction of the NMOG+NOx fleet average standard to ensure the transition from combustion engines to electrification. The continuous reduction of NMOG+NOx between MY2027 and MY2032 will promote increased offerings of electrified vehicles. If the EPA does not fully adopt CARB's LEV IV for criteria pollutants, Volkswagen recommends that the fleet average targets be adjusted to account for the final changes realized in the GHG PEV final curve. The inclusion of PEV (BEV and PHEV) in the calculation is rational and purposeful. Volkswagen further supports the flexibility to carry-over Tier 3 credits to the Tier 4 program, as well as a Tier 3 credit lifetime of 5 years for all vehicle categories (LDV, LDT1, LDT2, LDT3, LDT4, and MDPV). [EPA-HQ-OAR-2022-0829-0669, p. 6]

FTP -7°C NMOG+NOx Fleet Average Standard (Section III.C.2.iii) [EPA-HQ-OAR-2022-0829-0669, p. 6]

The EPA's proposed transition from -7°C NMHC to a NMOG+NOx fleet requirement will lead to challenges related to measurement processes. The sensitivity of NOx to condensation is very high under such low temperatures. Volkswagen has concerns over test validity due to condensation. This being a cold soak test may significantly increase our testing burden. Volkswagen requests this be taken into account as an increased burden to the manufacturers. [EPA-HQ-OAR-2022-0829-0669, p. 6]

Please also note, if the FTP -7°C NMHC Fleet Average becomes NMOG+NOx requirement, Volkswagen supports the 1:1 transfer of Tier 3 NMHC credits to Tier 4 NMOG+NOx credit account. [EPA-HQ-OAR-2022-0829-0669, p. 6]

Volkswagen agrees with AFAI comments and proposes taking the fleet average of 300 mg/mi target for LDV/LDT1 and a fleet average of 400 gm/mi for LDT2/HLDT, and does not support a 400 mg/mi vehicle cap as EPA had requested comment on this alternative. [EPA-HQ-OAR-2022-0829-0669, p. 6]

Organization: Wisconsin Department of Natural Resources

This rule is critical to improving Wisconsin's air quality. The on-road mobile sector is the largest contributor of nitrogen oxides (NOx) emissions in Wisconsin. The 2020 National Emissions Inventory reported that the on-road mobile sector accounted for 41% of the total NOx inventory in Wisconsin, with light- and medium-duty vehicles constituting at least 30% of those emissions. Wisconsin continues to have multiple areas in nonattainment of the 2015 ozone standard, with NOx emissions from passenger vehicles (especially in the larger metro areas) being a significant contributor. Given limited state authority over this sector, Wisconsin relies upon timely and impactful EPA action to reduce the effect vehicle emissions have on nonattainment. [EPA-HQ-OAR-2022-0829-0507, p. 1]

However, as the emissions benefits from this rule will not begin to accrue until model year 2027, this proposal will not help Wisconsin meet its near-term (2023 and 2026) ozone attainment dates for the 2015 ozone standard. While this rule will be critically important over the long term, it does not relieve EPA of its responsibility as a co-regulator to ensure needed reductions in emissions from the on-road mobile sector sooner. The WDNR expects EPA to take further action to reduce on-road emissions in the next few years to support these upcoming ozone attainment deadlines. [EPA-HQ-OAR-2022-0829-0507, p. 1]

EPA Summary and Response

Summary:

EPA received several comments regarding the proposed NMOG+NOx standards. The comments fall into three broad categories: Comments that support the proposed standards and program architecture, comments that oppose the proposed standards and architecture, and comments which recommended specific changes to the NMOG+NOx program.

EPA received strong support for the proposed standards from the Alliance for Vehicle Efficiency (AVE), the American Lung Association (ALA), California Air Resources Board (CARB), Environmental Defense Fund (EDF), Interfaith Power and Light, International Council on Clean Transportation (ICCT), Lucid Group, Manufacturers of Emissions Controls (MECA), National Association of Clean Air Agencies (NACAA), National Tribal Air Association (NTAA), Northeast States for Coordinated Air Use Management (NESCAUM), Energy Innovation and Tesla. Both CARB and MECA noted the importance of strong criteria pollutant emission standards in the absence of a ZEV mandate, while EDF commented that EPA should adopt standards more stringent than proposed, based on the anticipated BEV penetrations.

CARB provided several focused comments regarding the NMOG+NOx program, stating the proposed Tier 4 standards are appropriate and largely consistent with their recently adopted ACC II program. CARB also commented that they did not anticipate the need for development or deployment of any new technologies to meet the proposed standards and noted that ZEV penetrations as the result of compliance with the California ACC II program would also help contribute to a manufacturer's federal compliance. Overall, CARB commented that they projected that LEV IV and Tier 4 would result in similar emissions reductions. CARB also commented on air quality and human health impacts and noted NMOG and NOx contribute to smog, especially near-roadways and disadvantaged neighborhoods. CARB asked the Agency to clarify the risk of excessive MDV NMOG+NOX credit generation under the default MDV phase-in that may require additional measures such as restricting credits or changing the stringency of the standards.

Vehicle manufacturers provided a wide range of comments. AAI did voice support for reductions in NMOG+NOx emissions that could be gained solely through software and calibration changes. AAI also feels that the proposed program goes "far beyond [CARB's] LEV IV" program. Both AAI and Stellantis commented that proposed NMOG+NOx standards assume a high BEV penetration rate and Kia and Volkswagen, along with AAI and Stellantis, recommended that the NMOG+NOx standards should better align with the Administration's goals. AAI provided further comments with respect to the proposed NMOG+NOx program saying that it represented substantial changes to the CARB ACC II program and that EPA had failed to indicate to stakeholders that it intended to propose a program different from ACC II. AAI also commented that EPA had failed to consider adopting ACC II in lieu of the proposed program, the incremental benefits of adopting the proposal instead of the ACC II requirements and had not considered the lead-time required to develop and deploy the technologies required to meet the revised NMOG+NOx standards. AAI also commented on PHEV compliance contributions and the potential impacts of the expanded MDPV definition on MDV criteria pollutant compliance.

AAI also urged EPA to update sulfur limits for gasoline to provide a downstream retail cap of 10 ppm (versus the current limits of 10 ppm average with 95 ppm cap). They assert that this is necessary to optimize catalyst efficiency and would align with sulfur caps in the European Union and China.

Regarding the effects of electrification on NMOG+NOx standards, AAI recommended removing BEV's from the fleet average while Porsche North America commented that they support the inclusion of BEVs in the NMOG+NOx fleet average. Both AAI and Mitsubishi recommended that EPA adopt a similar criteria pollutant strategy for PHEVs as that adopted by CARB, where NMOG+NOx emissions are discounted using the PHEV utility factor.

AAI, Hyundai North America, Kia Corporation and Mercedes Benz all commented that the proposed high altitude NMOG+NOx standards would require significant additional development and burden as compared to CARB ACC II. AAI recommended that EPA adopt the CARB ACC II high altitude standards in lieu of the program proposed by EPA.

AAI also commented on a variety of related topics and recommended alternatives for the NMOG+NOx cold FTP fleet average, interim standards for US06 NMOG+NOx, higher US06 standards for vehicles certified to Bin 30 and cleaner, and OBD thresholds aligned with ACC II. Both BMW and Volkswagen commented that they supported the AAI comments overall.

Cummins comments regarding a tradeoff between oxides of nitrogen (NOx) and carbon dioxide (CO2) reductions may have been historically true prior to the introduction of catalytic NO_x controls, e.g., SCR, between 2007 and 2010, when the primary NO_x controls relied on combustion phasing and charge dilution. This tradeoff has decreased substantially as diesel applications rely more upon catalytic controls for NO_X emissions. In EPA's 2022 analysis of modern dual-SCR systems and other technologies in support of 2027 and later heavy-duty standards, we found that the combination of active and passive thermal management anticipated for meeting the final 2027 and later heavy-duty standards can be designed and developed in a manner that does not pose an additional burden for meeting heavy-duty engine GHG standards. (U.S. EPA. Regulatory Impact Analysis: Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards Regulatory Impact Analysis, December 2022, EPA-420-R-22-035, https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P1016A9N.pdf). Similarly, as such technologies are applied to light- and medium-duty diesel applications to comply with 2027 and later standards, we do not anticipate any significant impact on GHG emissions from these applications.

EPA also received comments on the proposed bin structure for both light and medium duty vehicles. AAI recommended that EPA adopt the same bin structure as ACC II for both light and medium duty vehicles and noted a lack of overlap between the EPA proposal and ACC II. The SVM Ad Hoc group and Mitsubishi echoed a similar statement and commented that the proposed bin structure was overly restrictive. The SVM Ad Hoc group also specifically recommended that EPA retain Bin 125 throughout the phase-in applied to their standards.

The American Petroleum Institute (API) commented on the final NMOG+NOx fleet average and noted that only a portion of the existing fleet is certified at or below 15 mg/mile. API also commented that EPA had failed to demonstrate the technical feasibility of the final fleet average. On a similar note, Ford Motor company also commented that the proposed NMOG+NOx standards were not feasible and should include a “safety factor”. The National Farmers Union and Renewable Fuels Association (RFA) disagreed with the need or effectiveness of more stringent NMOG+NOx standards. RFA commented further that more stringent NMOG+NOx standards could discourage technologies that reduce CO_2 emissions.

MECA made several comments regarding the proposed NMOG+NOx standards, recommending that EPA adopt a 300 mg/mile cap at -7 degrees C instead of a fleet average. They also noted that ICE-based vehicles could adopt electrically heated catalysts as a means of meeting more stringent NMOG+NOx standards.

Modlin & Detchon, raised concerns with the data and modeling EPA uses to assess emission impacts of ethanol blends, and suggested this has influenced EPA's willingness to promote higher-octane or lower-carbon fuels in the market. This comment is very similar to another in Section 12.5.1 of this RTC document, and we direct the reader there for a response.

Green Diesel Engineering and Cummins recommended that EPA adopt less stringent NOx standards for diesels as a means of reducing CO_2 emissions.

Response:

EPA appreciates all the comments regarding the level of NMOG+NOx standards. As a result of these comments and additional technical analysis performed by EPA to inform both the GHG and criteria pollutant programs, EPA has made several changes to NMOG+NOx standards for the FRM.

EPA is finalizing revised final NMOG+NOx standards for both light and medium duty vehicles that are less stringent than those proposed. There are several factors and comments that have contributed to EPA's decision. EPA received strong support from many commenters recognizing the need and the feasibility of lower emissions standards. As a portion of the fleet moves to zero emission vehicles the Agency believes it is important to also reduce the emissions from the millions of ICE-based vehicles that will continue to be a significant portion of new vehicles sold, and a majority of the on-road fleet, for decades to come. Recognizing that both the GHG and criteria pollutant standards are performance-based, EPA has adjusted the final fleet average NMOG+NOx standards to reflect the anticipated penetration of ICE-equipped and BEV vehicles. The agency believes that the final NMOG+NOx standards strike the appropriate balance between those commenters that noted the importance of strong NMOG+NOx standards to protect human health and those commenters which expressed concern regarding the feasibility of the final fleet average. For additional information regarding the final fleet average standards refer to Sections III.D.2 and V of the preamble.

In finalizing a higher NMOG+NOx final fleet average of 15 mg/mile, EPA is also addressing comments, such as those from Ford, that the proposed fleet average of 12 mg/mi is not feasible and should include a safety margin. EPA, however, disagrees with API's comment that the agency failed to demonstrate that the proposed standards are feasible. Both the NPRM and the FRM note a number of vehicles that are already certified to 15 mg/mi or less NMOG+NOx. In addition, the agency has described in detail technologies that are already being applied by vehicle manufacturers to meet Tier 3 standards and can continue to be developed to result in even lower emissions (see RIA Chapter 3.2.5). EPA's technical judgment is that OEMs can comply with the NMOG+NOx standards using a variety of compliance pathways. The standards are feasible for ICE-based vehicles without taking into consideration the possibility of averaging with zero-emitting vehicles. However it is more likely that manufacturers will sell vehicles with a variety of technologies, including some with improvements in ICE powertrains and at least modest levels of BEVs, and the standards are certainly feasible for manufacturers with such a strategy. AAI recommended that EPA adopt a provision to discount PHEV criteria pollutant emissions based on the utility factor. EPA disagrees with this recommendation and provides the technical basis for the Agency's decision in preamble Section III.D.2.

AAI commented that bin structure and OBD thresholds should align with ACC II. EPA is finalizing a bin structure that is comprehensive of all the bins adopted by CARB in ACC II. The response on OBD is available in RTC Chapter 5.

EPA has decided to not make changes in response to the comment from AAI, Hyundai North America, Kia Corporation and Mercedes Benz regarding high altitude NMOG+NOx standards.

EPA believes that vehicle manufacturers can meet the same standard at altitude. As a result, EPA did not adopt the CARB ACC II high altitude standards in lieu of the program proposed by EPA.

EPA disagrees with AAI's comments regarding the effects on NMOG+NOx compliance of the expanded MDPV definition. EPA is adopting the recommendations from AAI to adjust the work factor and GVWR thresholds for the final MDVP definition. Most of the vehicles currently captured by the final MDPV definition are light-duty EVs with utility that is not representative of medium-duty vehicles. AAI also commented that EPA did not provide a technology pathway for MDVs to comply with the final NMOG+NOx standards. EPA did provide a pathway based on an anticipated growing penetration of electric cargo vans in the MDV fleet. Furthermore, given that the MDV NMOG+NOx standards are performance based, vehicle manufacturers may decide which technologies are best suited for their customers, which may mean improvements in ICE emissions in lieu of electrification.

Regarding the issue of tighter gasoline sulfur limits, EPA believes the proposed emission standards are feasible with current sulfur limits. Moreover, as discussed in RTC Section 19.1, changes to fuels controls are beyond the scope of this rulemaking,

Finally, regarding Cummins and Green Diesel Engineering's recommendation that EPA adopt less stringent NOx standards for diesels as a means of reducing CO_2 emissions, EPA does not believe that it is appropriate or necessary to trade off one pollutant for the other. Many technologies exist in the market today which have low CO_2 emissions and low NOx emissions.

With respect to CARB's comments regarding the potential for excessive MDV NMOG+NO_x credit generation, that concern was shared by the Agency during the development of the MDV program and was taken into consideration for both the proposal and within the final rule. The early compliance program finalized does not allow carry over of Class 2b and Class 3 Tier 3 NMOG+NO_x credit into the new program unless a manufacturer chooses the optional early compliance program for criteria pollutants. Manufacturers would not build large credit banks under Tier 3 by opting for default phase-in since those credits would retire at the beginning of the 2031 model year. The early compliance program does allow Tier 3 NMOG+NO_x credits to be used, but the program also begins to phase-in significantly more stringent standards beginning in 2027, and the declining NMOG+NO_x standards within the early compliance program fully take into consideration year-over-year increases in MDV BEV sales in order to meet MDV criteria pollutant and GHG standards.

4.1.3 - Particulate matter (PM)

<u>Comments by Organizations</u>

Organization: Ad Hoc Small OEM Group

. PARTICULATE MATTER

-EPA's proposed PM reduction to 0.5mg/mi across FTP, US06 and Cold Testing goes too far too soon for Small OEMs [EPA-HQ-OAR-2022-0829-0563, pp. 13-14]

EPA's proposed PM reduction to 0.5mg/mi across FTP, US06 and especially Cold Testing is an enormous increase in stringency over a short period of time. This is a regulatory combination that Small OEMs simply cannot meet. We recognize that the regulation of PM is headed towards necessitating the use of Gasoline Particulate Filters (GPF), but further research and development is needed with respect to GPF aging and monitoring for purposes of California OBD. This issue is not yet fully understood and requires more lead-time under the CAA section 202(a). [EPA-HQ-OAR-2022-0829-0563, pp. 13-14]

In addition, there are also technical issues and costs associated with measuring PM emissions below 1 mg/mile, and specialized, expensive test facilities may be needed to reliably measure PM at such a low level. [EPA-HQ-OAR-2022-0829-0563, pp. 13-14]

It is thus unreasonable to impose the proposed PM standards and timetable on Small OEMs, especially considering the minimal environmental benefit obtained together with how drastic the proposed change is compared to existing Tier 3 levels and the CARB ACCII PM standards, as shown in the graph below. [EPA-HQ-OAR-2022-0829-0563, pp. 13-14]

[See original attachment for graph "Tailpipe PM Limit [mg/mi]] [EPA-HQ-OAR-2022-0829-0563, pp. 13-14]

-In sum, as regards SVMs and PM, EPA should harmonize with the CARB ACCII SVM PM approach as follows:

-FTP

-- For MY 2027-2028 -- 3 mg/mile.

-- For MY 2029 and later — 1 mg/mi. [EPA-HQ-OAR-2022-0829-0563, pp. 13-14]

-SFTP

-- For 2027 – 2029 – 6 mg /mi

-- For 2030 and later – 3 mg/mi [EPA-HQ-OAR-2022-0829-0563, pp. 13-14]

-No Cold Testing for SVMs given that it is not yet fully understood what is needed to meet the 0.5mg standard at 20F with high-performance engines. [EPA-HQ-OAR-2022-0829-0563, pp. 13-14]

We further note the above levels and timetable are consistent with the EU regulation of PM. GPFs will be necessary on all European engines in 2030 with the implementation of EU7's mandating PM measurement for both Port Fuel Injection Engines and Gasoline Direct Injection Engines. [EPA-HQ-OAR-2022-0829-0563, pp. 13-14]

Organization: Ad Hoc Tier 4 Light-Duty Small Manufacturer Group

4. PARTICULATE MATTER

EPA's proposed PM reduction to 0.5mg/mi across the FTP and US06 and Cold Testing also goes too far too soon [EPA-HQ-OAR-2022-0829-0509, pp. 9-10]

EPA's proposed PM reduction to 0.5mg/mi across the FTP and US06 and Cold Testing is an enormous increase in stringency over a short period of time. So much so that it is over-reach, especially considering Tier 3 levels and that CARB has tightened PM standards without going to the extent that EPA proposes, as shown in the graph below. [EPA-HQ-OAR-2022-0829-0509, pp. 9-10]

[See original attachment for "Tailpipe PM Limit [mg/mi]"] [EPA-HQ-OAR-2022-0829-0509, pp. 9-10]

More and more stringent PM standards will lead to the need for Gasoline Particulate Filters (GPFs) as an aftertreatment. One GPF issue which is not currently understood fully is GPF aging and monitoring for purposes of OBD. [EPA-HQ-OAR-2022-0829-0509, pp. 9-10]

In addition, there are also technical issues and costs associated with measuring PM emissions below 1 mg/mile, and specialized, expensive test facilities may be needed to reliably measure PM at such a low level. [EPA-HQ-OAR-2022-0829-0509, pp. 9-10]

In sum, as regards PM, EPA should

- Follow the CARB ACCII SVM PM approach as follows:

- FTP

-For MY 2027 -- 3 mg/mile.

-For MY 2029 and later—1 mg/mi. [EPA-HQ-OAR-2022-0829-0509, pp. 9-10]

We note this is consistent with the EU approach to PM and GPFs: GPFs will be necessary on all engines in 2030 with the implementation of EU7's mandating PM measurement for both Port Fuel Injection Engines and Gasoline Direct Injection Engines [EPA-HQ-OAR-2022-0829-0509, pp. 9-10]

-SFTP

-For MY 2027 – 2029 – 6mg /mi

-For MY 2030 and later – 3mg/mi [EPA-HQ-OAR-2022-0829-0509, pp. 9-10]

-No Cold Testing – no PM standard for cold testing, or at a minimum an SVM exemption (note that what will be needed to meet the 0.5mg standard at 20F has not yet been fully understood). [EPA-HQ-OAR-2022-0829-0509, pp. 9-10]

Organization: Alliance for Automotive Innovation

Criteria Emission Standards

Automakers will spend $1.2 trillion by 2030 as a down payment on a net-zero future, but far more will be needed. If we hope to succeed, automakers must focus resources on the EV transformation rather than incremental changes to existing, very near-zero (criteria) emission ICE vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 5-6]

This should not be interpreted as automakers requesting no criteria emission reductions or regulations. We support changes that can be made cost-effectively through software calibration changes to the vehicle. For example, we support and recommend EPA adopt the criteria emission standards California adopted under Advanced Clean Cars II (i.e., LEV IV). We worked with California over several years to develop these standards that substantially reduce real- world criteria pollutants (nonmethane organic gas (NMOG), nitrogen oxides (NOx), particulate mater (PM)), as rapidly as possible without stranding technology or diverting resources from electrification. [EPA-HQ-OAR-2022-0829-0701, pp. 5-6]

However, some of the changes proposed in the NPRM go far beyond California's LEV IV program and would require large human and capital resources. For example, all-new engine designs, retooling of engine and vehicle production facilities, new hardware on vehicles, and additional testing laboratories are required at the same time the EPA expects 67% of new vehicles to be BEVs. These simultaneous ICE-focused activities will distract from efforts to electrify light-duty vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 5-6]

PM Standards

Auto Innovators and our members understand the importance of particulate mater (PM) standards. In fact, we've worked with both California and EPA to develop and adopt standards as part of ACC II that result in a 90% reduction in PM emissions (from 10 mg/mile to 3 mg/mile to just 1 mg/mile when fully phased in (2028 model year)). However, the NPRM proposes a new standard of 0.5 mg/mile, which will effectively necessitate a gasoline particulate filter (GPF) system with on-board monitoring that is unique to the U.S. on every ICE vehicle. This new standard also takes place in the middle of the phase-in for California's new PM standards. [EPA-HQ-OAR-2022-0829-0701, pp. 6-7]

The NPRM rightly notes that GPFs are not new technology and have been used in China and the EU. However, this is not an apples-to-apples comparison. China and EU PM standards are based on particle count instead of mass. Their NMOG+NOx standards and on-board diagnostic (OBD) requirements are also not as stringent as EPAs (or California's). Moreover, the GPF used elsewhere cannot simply be pulled off the shelf and installed; rather capital resources would be required for re-tooling, redesign, testing and other requirements, including inventing a new sensing technology to address the proposed filtration efficiency monitor requirement and lab testing capabilities at the proposed levels. The significant development time, resources and investment required to meet the proposed PM standard will disrupt the focus on electrification, particularly when adoption of California's LEV IV 1 mg/mile PM standard will provide substantial nationwide benefits. [EPA-HQ-OAR-2022-0829-0701, pp. 6-7]

IV. Light-Duty Criteria and Toxic Pollutant Standards

Automakers are committed to ultimately achieving net-zero transportation carbon emissions and electrification of the light-duty vehicle fleet. However, this transformation requires massive investment in EV technology and supporting mechanisms such as infrastructure, all involving many stakeholders. To be successful, automakers must primarily focus resources on the transformation rather than incremental changes to existing internal combustion engine (ICE) vehicles, which are already very near zero. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

The focus of EPA and the automakers is and should be on electrification. Thus, Auto Innovators supports changes to traditional criteria emission (e.g., NMOG, NOx, and PM) standards that measurably reduce emissions, but do not add substantial additional hardware or capital costs to ICE vehicles that will soon be retired. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

Unfortunately, EPA proposes to adopt new requirements that will divert resources from our shared goal of widespread electrification. Prohibiting enrichment could require complete engine redesigns and possibly larger displacement engines to provide customers with the capability they demand. The proposed PM standards substantially increase costs and vehicle development complexity in addition to adding testing requirements. Finally, in several cases, EPA provides less flexibility and/or chooses not to align with ACC II. This lack of alignment is particularly troubling as automakers and suppliers have already developed product plans and spent resources toward meeting the ACC II regulations, and in some cases, EPA's proposal would require substantial changes during the middle of ACC II regulatory phase-ins. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

To reduce costs while still providing similar (and substantial) environmental benefits, the EPA regulations should seek to align with criteria emissions regulations already adopted by California in ACC II. We worked closely with the California Air Resources Board (CARB) and with EPA staff in attendance and participating,255 for the past several years to develop standards that substantially reduce real-world criteria emissions (including NMOG+NOx and PM), as rapidly as possible without stranding technology or diverting resources from electrification. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

255 At no time did EPA staff indicate a different or more stringent pathway was under development federally, while the auto industry provided input, feedback, and technical data to CARB. The California process provided an ideal forum for alignment, even if EPA could not commit to alignment at that stage.

We recommend that EPA adopt the ACC II criteria emission regulations in place of its proposal. This adoption would provide substantial environmental benefits, streamline the regulations, and allow automakers to focus resources on electrification rather than developing and deploying changes to ICE vehicles specific to EPA's proposed new requirements. At a minimum, EPA should align with ACC II through the end of the ACC II phase in periods; in most cases, ACC II regulations are fully phased in by MY 2030. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

A. Consideration of the California ACC II Criteria Pollutant Regulation as an Alternative

EPA failed to consider adopting various California ACC II criteria pollutant provisions, and in so doing has also failed to demonstrate the incremental costs and benefits of its proposed program relative to this existing and logical alternative. EPA has also failed to consider the appropriate time to develop and deploy the additional ICE technologies to meet its proposal, particularly in the context of an overlapping and different final state regulation. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

It is no defense to say that EPA has yet to approve a Clean Air Act waiver for these provisions. EPA has yet to reject a waiver request from California, and included the California ACC II program as a sensitivity case to the proposed greenhouse gas regulations. Unfortunately, to the extent that the ACC II sensitivity case provides estimates of criteria emission benefits, it has been challenging, if not impossible, to separate benefits associated with the GHG program from those associated with the criteria pollutant program, and even more difficult to separate the impacts from individual components of the proposed criteria pollutant program. These challenges have been exacerbated by the limited time available to comment on the NPRM. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

If EPA proceeds with its own misaligned proposal to the logical alternative of California's ACC II program, it should at a minimum demonstrate the incremental benefits and costs of each of its unique program aspects relative to the ACC II program. In addition, if EPA proceeds with its own proposal, EPA should also align with ACC II through the end of the ACC II phase in periods before starting new requirements on top of those already under implementation. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

D. PM Standards

EPA is proposing PM standards that exceed the stringency of CARB's recently adopted PM standards, to phase them in at the same time as CARB's standards are phased in (creating conflicting state and federal requirements), and to apply them to additional test cycles. EPA's proposed standards would add significant direct costs to vehicles for additional hardware, laboratory test cells (and potential upgrades and/or new build outs), calibration, monitoring, warranty, and customer repair and maintenance. Further, with additional test cycles, stringent OBD requirements, and absence of consideration of additional implementation costs, EPA inappropriately considers the technology additions as a drop-in with little to no cost. [EPA-HQ-OAR-2022-0829-0701, pp. 150-151]

EPA has inadequately considered the exceedingly low contribution of light-duty vehicles to PM emission inventories, has failed to consider adoption of the California standards as an alternative to its proposal, and has not fully assessed costs associated with upgrading laboratories and laboratory practices to precisely and accurately measure PM emissions with statistical certainty. [EPA-HQ-OAR-2022-0829-0701, pp. 150-151]In light of these significant issues, and as described more fully below, we are concerned that EPA has fallen short of its rulemaking obligations to engage in reasoned decision-making and articulate a "rational connection between the facts found and the choice made"266 with regard to the Proposed Rule's PM standards. "[W]hen an agency decides to rely on a cost-benefit analysis as part of its rulemaking, a serious flaw undermining that analysis can render the rule unreasonable."267 Moreover, an agency must undertake a "rational consideration of alternatives," and provide an "adequate explanation when these alternatives are rejected."268 [EPA-HQ-OAR-2022-0829-0701, pp. 150-151]

266 Motor Vehicle Mfrs. Ass'n v. State Farm Mut. Auto. Ins. Co., 463 U.S. 29, 43, 53 (1983); see also Nat'l Ass'n of Clean Air Agencies v. E.P.A., 489 F.3d 1221, 1229 (D.C. Cir. 2007).

267 Nat'l Ass'n of Home Builders v. E.P.A., 682 F.3d 1032, 1040 (D.C. Cir. 2012); see also City of Portland v. E.P.A., 607 F.3d 706, 713 (D.C. Cir. 2007) (noting that the D.C. Circuit "will [not] tolerate rules based on arbitrary and capricious cost-benefit analyses").

268 Int'l Ladies' Garment Workers' Union v. Donovan, 722 F.2d 795, 817 (D.C. Cir. 1983); see also, e.g., Yakima Valley Cablevision, Inc. v. F.C.C., 794 F.2d 737, n.36 (D.C. Cir. 1986) ("The failure of an agency to consider obvious alternatives has uniformly led to reversal.").

Here, based on the record, we believe that EPA has failed to adequately justify the Proposed Rule's PM standards, failed to ensure that the relevant facts support this proposed standard, and failed to ensure that it has considered all reasonable alternatives, including adoption of the California standards as an alternative to its proposal. Moreover, we believe that the proposed PM standards will impose an extremely high cost, but result in little corresponding air quality benefits. [EPA-HQ-OAR-2022-0829-0701, pp. 150-151]

We encourage EPA to carefully evaluate its proposed PM standards and the evidence underlying them, and to ensure that it is adequately accounting for the relevant costs and benefits and fulfilling its statutory obligation to engage in reasoned, evidence-based decision-making. [EPA-HQ-OAR-2022-0829-0701, pp. 150-151]

2.PM Standard Concerns

Increasing stringency for 25 ºC FTP will add additional cost and development work with minimal air quality and will divert OEM resources from fleet electrification. The technical issues are magnified for the US06 proposal because of the necessity of both reductions in engine out emissions and the development of GPF designed for high temperature/high flow rate conditions. In particular: [EPA-HQ-OAR-2022-0829-0701, pp. 153-154]

- Automakers must account for the higher engine out PM (soot) compared to FTP. [EPA-HQ-OAR-2022-0829-0701, pp. 153-154]

- US06 is high flow, and PM collection rate of GPF is lower than FTP. [EPA-HQ-OAR-2022-0829-0701, pp. 153-154]

- US06 is high temperature, and collected PM on GPF is lower. Therefore, the PM collection rate of GPF is lower than FTP. [EPA-HQ-OAR-2022-0829-0701, pp. 153-154]

- US06 has many accelerations and decelerations, PM (SOF) tends to be larger than LA#4. [EPA-HQ-OAR-2022-0829-0701, pp. 153-154]

a) PM Development Burden

To balance both stringent emission level and PM regeneration, the following should be considered: [EPA-HQ-OAR-2022-0829-0701, p. 154]

- EPA has not designed a program that allows for GPF technology from other regions to be simply "dropped in" and thus will require additional development and resources. [EPA-HQ-OAR-2022-0829-0701, p. 154]

- To comply with PM 0.5 mg/mile standard, it takes long lead-time to develop the exhaust system that includes a GPF to balance emission reductions and PM collection/regeneration. It also takes a long lead time to design GPF location on the vehicle. [EPA-HQ-OAR-2022-0829-0701, p. 154]

b) - The lead time for large pickup trucks will be even longer. [EPA-HQ-OAR-2022-0829-0701, p. 154]PM Recommendation

As EPA recognizes in the NPRM, the proposed PM standard will mandate a technology response; namely, installation of a GPF. Effectively mandating a GPF on all gasoline vehicles will require additional costs associated with development, testing, labs, monitoring, warranty, and consumer repair, all of which divert resources away from electrification. Auto Innovators recommends EPA adopt the PM standards in ACC II, shown below, using the ACC II phase-in schedule. [EPA-HQ-OAR-2022-0829-0701, pp. 154-155]

SEE ORIGINAL COMMENT FOR Figure 44: Recommended PM Standards [EPA-HQ-OAR-2022-0829-0701, pp. 154-155]

California's LEV IV includes interim in-use compliance standards of 2 mg/mi for the first two model years that a test group is certified to the LEV IV 25ºC FTP standard. We recommend EPA align with California. [EPA-HQ-OAR-2022-0829-0701, pp. 154-155]

3.PM Measurement Considerations

The following data from laboratories which are ISO 17025 accredited and fully compliant to test procedure requirements and best practices defined in 40 C.F.R. §1066 demonstrates that uncertainty in the PM measurement process can exceed the proposed 0.5 mg/mi standard. [EPA-HQ-OAR-2022-0829-0701, pp. 154-155]

We recommend eliminating the -7 °C FTP PM requirement, because it adds to test burden, requires large investments / upgrades to test facilities, and reduces test validity rate. [EPA-HQ-OAR-2022-0829-0701, pp. 154-155]

a) We also recommend considering laboratory PM measurement variability and allowing re-tests for exceedances during certification, confirmatory or in-use testing, especially for vehicles equipped with diesel or gasoline particulate filters. [EPA-HQ-OAR-2022-0829-0701, pp. 154-155]Challenges in PM Measurement at 0.5 mg/mile

The proposed Tier 4 PM standard of 0.5 mg/mile is a completely new venture beyond the expectations of automotive manufacturers and was not anticipated in the design of their emissions laboratories. The emission laboratories across the industry are still learning how to accurately measure PM at the Tier 3 PM limit of 3 mg/mile due to the uncertainty involved in all of the processes leading to final PM results in mg/mile. 40 C.F.R. Part 1065 and 1066 added many new requirements and recommendations to improve measurement of PM and to reduce variability. Even with all the Part 1065/1066 requirements and recommendations, the PM gravimetric measurement technique at 0.5 mg/mile will still require further scrutiny and refinement to further reduce measurement uncertainty and to improve measurement resolution as the net mass on the filter will approach tunnel background levels especially with larger vehicles that must run at higher constant volume sampler (CVS) flowrates. Test procedure updates may be needed, such as the reference filter validity criteria of +/-10 micrograms, as we demonstrate below is clearly not adequate at this low level. It may be adequate for heavy-duty vehicles, but not for light- or medium-duty vehicles at the 0.5 mg/mile where the net mass on the filter will be less than 10 µg at larger CVS flow rates. The potential sources of variability which contribute to the gravimetric measurement uncertainty include: [EPA-HQ-OAR-2022-0829-0701, pp. 155-156]

- Microbalance stability in weighing PM filters and artifacts at this level; [EPA-HQ-OAR-2022-0829-0701, pp. 155-156]

- Static charge removal from filters at such low mass levels; [EPA-HQ-OAR-2022-0829-0701, pp. 155-156]

- Filter handling by the operators; [EPA-HQ-OAR-2022-0829-0701, pp. 155-156]

- Filter weight gain due to artifacts during transportation from weigh room to test cell; [EPA-HQ-OAR-2022-0829-0701, pp. 155-156]

- Tunnel contamination due to prior testing on the test cell and background correction; [EPA-HQ-OAR-2022-0829-0701, pp. 155-156]

- Test to test and cell to cell variability; [EPA-HQ-OAR-2022-0829-0701, pp. 155-156]

- Laboratory to laboratory offset. [EPA-HQ-OAR-2022-0829-0701, pp. 155-156]

All these individual factors add to the uncertainty and the errors involved can either stack up and lead to large errors or cancel each other and result in lower errors. Unfortunately, manufacturers have no control over the direction of these errors and how they interact throughout the measuring process. It is also noteworthy that even following EPA's regulations, these sources of uncertainty will remain. [EPA-HQ-OAR-2022-0829-0701, pp. 155-156]

In efforts to minimize the impact of these sources of variability, some countermeasures have been identified to reduce the PM measurement uncertainty, but they are not sufficient to ensure that vehicles will pass the proposed PM limit of 0.5 mg/mile with confidence, especially on the US06 and the cold -7 °C FTP test on larger vehicles. Some of the countermeasures being pursued to minimize the uncertainty include using robotic auto handlers to minimize filter handling by the operators; segregating clean, dirty, and cold testing in dedicated test cells; using special lint free laboratory coats; special powder-free gloves; using Polonium strips in the weighing chambers of the microbalance and replacing them regularly every 6 months; and regular cleaning of the weighing room and PM sampling system. [EPA-HQ-OAR-2022-0829-0701, pp. 156-157]

At the 0.5 mg/mile level, the net mass of PM on the filter will be approaching tunnel background levels especially on larger light-duty vehicles and light-duty trucks, which must meet the same 0.5 mg/mile standard. These larger vehicles must run with higher CVS flow rates to meet the C.F.R. dilution factor requirements between 7:1 and 20:1. These larger CVS flowrates dictate large sample ratios which the net mass on the filter is then multiplied by. Any error involved in the process of weighing the filter such as tunnel contamination, filter handling or static charge removal is magnified a few hundred times by the sample ratio. [EPA-HQ-OAR-2022-0829-0701, pp. 156-157]

This will be even worse for medium-duty vehicles, which will need larger CVS flow rates than light-duty vehicles (beyond 1,000 cubic feet per minute (CFM) or 30 m3/min). As a result, medium-duty vehicles will have larger sample ratios, requiring the net mass on the filter to be even lower in order to pass the proposed PM standard. This requires that medium-duty vehicles only emit a few micrograms of PM when the artifact present in the tunnel by itself, when multiplied by the high sample ratio, can exceed the 0.5 mg/mile standard. In this case, the tunnel background might be higher than the net mass of PM on the filter. When net mass on the filter and tunnel background are close in magnitude, the accuracy becomes very poor, making the measurement method inadequate. Correction for tunnel background in this case may lead to negative mass. At this low level, correction is not feasible, pushing the limits and going beyond the capability of the gravimetric measurement technique. [EPA-HQ-OAR-2022-0829-0701, pp. 156-157]

b) Range of Net PM Mass on Filter at 0.5 mg/mile and lower

Figures 45 and 46 provide FTP PM data below 0.5 mg/mile from all test cells capable of PM measurement at an OEM laboratory over four months. It is obvious that as the CVS flow rate increases, the net PM mass on the filter decreases, approaching about 7.5 µg or lower at 550 CFM. Minimal data is available above 550 CFM because the larger vehicles that require higher

CVS flowrates typically exceed the proposed 0.5 mg/mile level. [EPA-HQ-OAR-2022-0829-0701, pp. 157-160]

SEE ORIGINAL COMMENT FOR Figure 45: Net mass on PM filters for FTP tests with results below 0.5 mg PM/mile at various flowrates. [EPA-HQ-OAR-2022-0829-0701, pp. 157-160]

SEE ORIGINAL COMMENT FOR Figure 46: Relationship between net filter mass and CVS flow rate for vehicles with less than 0.5 mg/mile FTP emissions. [EPA-HQ-OAR-2022-0829-0701, pp. 157-160]

c)FTP PM Variability within the Same Laboratory (Test to Test and Cell to Cell)

Figure 47 presents weekly internal cross check data set for all PM measurement-capable test cells within an OEM certification laboratory over a 10-week period. As shown, the overall laboratory average for the tested vehicle is 0.2853 mg PM/mile, represented by the black dotted line in the middle. The upper and lower red lines represent +/- 2 standard deviations around the laboratory mean and the upper and lower pink doted lines represent +/- 3 standard deviations around the laboratory mean. For this data set, 2-standard deviations is: 0.2677 mg/mile (0.553 - 0.2853 mg/mile), or 94% of the mean, which represents the variability with 95% confidence. This is more than 53% of a 0.5 mg/mile standard. The data is corrected for the tunnel background and the tunnels are cleaned regularly to minimize the tunnel background influence with the data. There are also some other measures such as shutting out of intrusive particles by maintenance of dilution air filter to minimize the tunnel background influence. [EPA-HQ-OAR-2022-0829-0701, pp. 157-160]

SEE ORIGINAL COMMENT FOR Figure 47: Intercell correlation of PM results for a singe vehicle over a 10-week period at an OEM emissions laboratory. [EPA-HQ-OAR-2022-0829-0701, pp. 157-160]

d)FTP PM Variability on Round Robin with Industry (Lab to Lab)

Figure 48, below, provides FTP PM data from the first quarter 2023 round robin correlation program between light-duty automaker laboratories and EPA's National Vehicle and Fuel Emissions Laboratory (NVFEL). Within the same laboratory, test-to-test variability seems to be within a reasonable range, but the laboratory-to-laboratory offset is obviously large, ranging from 2.877 to 4.445 mg/mile with a difference of 1.568 mg/mile, which is more than 50% of the current 3 mg/mile standard. These are all certification laboratories that are 40 C.F.R. Part 1066 compliant and ISO 17025 accredited. These laboratories follow very rigorous test procedures and quality checks as recommended by the C.F.R. These laboratories also often go beyond what the C.F.R. recommends for quality assurance, for example by using robotic auto-handlers and regular cleaning of dilution tunnels and sampling systems. [EPA-HQ-OAR-2022-0829-0701, pp. 157-160]

SEE ORIGINAL COMMENT FOR Figure 48: PM data from the 1Q2023 automaker / EPA interlaboratory correlation program. [EPA-HQ-OAR-2022-0829-0701, pp. 157-160]

Below is PM data from another round robin program from 2022 run by the same certification laboratories and EPA (Figure 49). The 2-standard deviation limit around the EPA mean is 0.56 mg/mile. The all-laboratory average 2-standard deviation is 0.48 mg/mile. The variability from laboratory to laboratory at a 95% confidence level is almost as high as the proposed FTP PM standard of 0.5 mg/mile. The offset between the initial baseline tests' average and the confirmatory tests' average is more 0.37 mg/mile, or more than 25% change within the same laboratory. [EPA-HQ-OAR-2022-0829-0701, pp. 160-164]

SEE ORIGINAL COMMENT FOR Figure 49: FTP PM test results from a 2022 automaker/EPA interlaboratory correlation program. [EPA-HQ-OAR-2022-0829-0701, pp. 160-164]

Results from another recent interlaboratory round robin program from 2022 are shown in Figure 50 for a vehicle with a FTP PM emission level below 1 mg/mile. The lab to lab offset is evident here, which cannot be explained. The average 2-standard deviation from all labs is 0.065 mg/mile, or about 13% of the 0.5 mg/mile standard. The offset between Laboratory 2 and Laboratory 1 confirmatory testing at the end is is 0.27 mg/mile, or 54% of a 0.5 mg/mile standard. The offset between the initial baseline tests' average and the confirmatory tests' average is about a 21% change within the same laboratory. [EPA-HQ-OAR-2022-0829-0701, pp. 160-164]

SEE ORIGINAL COMMENT FOR Figure 50: FTP PM test results from a 2022 automaker/EPA interlaboratory correlation program using a vehicle with less than 1 mg/mile PM emissions. [EPA-HQ-OAR-2022-0829-0701, pp. 160-164]

e) US06 PM Testing at 0.5 mg/mile

The US06 test, being an aggressive high speed high load cycle, requires larger CVS flowrates than the FTP to maintain the dilution factor between the required 7:1 and 20:1 ratio. In order to meet the same 0.5 mg/mile standard on the US06, the net PM mass on the filter must be lower than the net mass of PM with the FTP. Below, in Figures 51 and 52, are US06 PM data below 0.5 mg/mile from all PM measurement-capable test cells at an OEM laboratory over four months. It is obvious that as the CVS flow rate increases (going from left to right on the figure below), the net mass of PM on the filter decreases, approaching about 5 µg at 1000 CFM where larger light- duty vehicles and trucks will need to run. There is not much US06 data below 0.5 mg/mile available at CVS flow rates higher than 1000 CFM because the larger vehicles needing those higher CVS flowrates generally have PM emissions higher than 0.5 mg/mile. The US06 data ranges from a CVS flowrate of 400 to 1000 CFM. Medium-duty vehicles, which are not represented here because there is no data available and which must run at higher CVS flow rates above 1000 CFM, will have lower net mass on the filter; lower than the tunnel background on some vehicles, which will likely result in net negative calculated mass. [EPA-HQ-OAR-2022-0829-0701, pp. 160-164]

SEE ORIGINAL COMMENT FOR Figure 51: Net mass on PM filters for FTP tests with results below 0.5 mg PM/mile at various flowrates. [EPA-HQ-OAR-2022-0829-0701, pp. 160-164]

SEE ORIGINAL COMMENT FOR Figure 52: Relationship between net filter mass and CVS flow rate for vehicles with less than 0.5 mg/mile US06 emissions. [EPA-HQ-OAR-2022-0829-0701, pp. 160-164]

f)Variability on US06 from Industry Round Robin (1st Quarter of 2022)

Figure 53 presents PM data from a recent round robin program from 2022 with US06 testing. Most of the laboratories' three-test average fell in between 0.6 and 0.95 mg/mile, except for one laboratory which had two tests between 0.5 and 1.0 mg/mile and one very high test of 3.25 mg/mile. Previous round robin correlation programs have shown that almost all automaker and government emission test laboratories occasionally experience this type of unusually high PM results on US06 tests. The three-test US06 average at the laboratory with the high US06 results was 1.6933 mg/mile and the 2-standard deviation was 2.6864 or 158% variability. The overall laboratories' average was 0.913, the average 2-standard deviation between the labs was 0.862 mg/mile and the variability is 94% in this case. EPA should take this into consideration and allow a re-test in the case when this occasional and exceedingly high US06 test PM result happens during certification or confirmatory testing. [EPA-HQ-OAR-2022-0829-0701, pp. 160-164]

SEE ORIGINAL COMMENT FOR Figure 53: US06 PM test results from the 1Q2022 automaker/EPA interlaboratory correlation program. [EPA-HQ-OAR-2022-0829-0701, pp. 160-164]

g) Variability in Microbalance Filter Weighing

Figure 54, below, shows 25 repeat-weighing of a 100 mg metal mass by a microbalance using a robotic auto-handler. The standard deviation is 0.4 µg and the range between the highest and lowest measured values is 1.5 µg. The uncertainty due to microbalance instability in weighing metal weights can be approximated as 0.8 µg (2-standard deviations), assuming that effects of ambient environmental conditions are negligible, the static charge effect is minimal since the metal weight is made of stainless steel, and the Polonium strips within the weighing chamber are effective at removing any static charge on the metal weight. Removing any static charge on the metal weight is important, but there are ways other than the Polonium strips such as neutralization by ionizer. Any operator handling is not relevant here since these are automatic weight measurements performed by the robotic auto-handler independent of any operator intervention. [EPA-HQ-OAR-2022-0829-0701, pp. 164-169]

A similar test was performed of 25 repeat measurements of the mass of a clean blank filter (Figure 55). The filter was stationed inside the robotic auto-handler, did not leave the weighing room, and was not handled by operators like is typically done on reference filters. The test resulted in a 1.1 µg standard deviation and a range of 4.6 µg. The measurement of the clean PM filter had almost three times the variability as the metal mass and almost three times the standard deviation and range of measured values. This is evidence of the organic artifact compounds present in ambient air which are adsorbed and desorbed by the filter and reported in many studies by several researchers. The two-standard deviation in weighing a clean PTFE filter was 2.2 µg. [EPA-HQ-OAR-2022-0829-0701, pp. 164-169]

SEE ORIGINAL COMMENT FOR Figure 54: Repeated measurements of a 100 mg metal weight. [EPA-HQ-OAR-2022-0829-0701, pp. 164-169]

SEE ORIGINAL COMMENT FOR Figure 55: Repeated measurements of a clean PM measurement filter. [EPA-HQ-OAR-2022-0829-0701, pp. 164-169]

h) PM Testing at -7 °C

The proposed Tier 4 PM standard of 0.5 mg/mile at -7 °C is unprecedented, and was not considered in automaker emissions test laboratory designs. [EPA-HQ-OAR-2022-0829-0701, pp. 164-169]

There are several complications in implementing PM testing at -7 degrees C; measuring PM in an environmental test cell at -7 °C is not an easy task. This may require updated test procedures to prevent condensing water vapor from depositing on the filter face, which can result in high filter weight, leading to invalid tests. The number of invalid tests is expected to increase, resulting in additional testing burden. In addition, -7 °C PM testing requires upgrades to testing facilities to include full dilution tunnels, which were not designed for. In addition, these existing test cells may not have enough space to add a full dilution tunnel, requiring major capital upgrades to build new test cells. Also, commercially available PM samplers are not designed to operate at below freezing temperatures, which will create another complication. [EPA-HQ-OAR-2022-0829-0701, pp. 164-169]

The following Figure 56 shows PM data from five -7 °C FTP tests, collected on a vehicle with a new GPF. The error bar is based on two standard deviations, representing a 95% confidence level. Variability is quite high in the testing, with the two standard deviation error exceeding the average of the five tests. The two standard deviation error is equivalent to 114% of the five test average, which is quite significant. [EPA-HQ-OAR-2022-0829-0701, pp. 164-169]

SEE ORIGINAL COMMENT FOR Figure 56: Results from five FTP tests at -7 °C for the same vehicle with a new GPF. [EPA-HQ-OAR-2022-0829-0701, pp. 164-169]

In addition, five FTP tests at 25 °C and five US06 tests were also run on the same vehicle, in the same test cell, and with the same driver as shown in Figures 57 (FTP) and 58 (US06), below. On the FTP, the two standard deviation level is 48% of the five-test average, which is significant. The US06 data shows a two standard deviation level equivalent to 90% of the five-test average. It is obvious from the three sets of data that the -7 °C testing had the largest amount of variability (114%), followed by the US06 (90%) compared to their respect five-test averages. The data also demonstrates that vehicles equipped with a GPF that pass the 25 °C FTP and US06 mg/mile proposed PM standards are also likely to pass the same standard at -7 °C as shown in the NPRM. [EPA-HQ-OAR-2022-0829-0701, pp. 164-169]

SEE ORIGINAL COMMENT FOR Figure 57: Results from five FTP tests at 25 °C for the same vehicle, same driver, same test cell. [EPA-HQ-OAR-2022-0829-0701, pp. 164-169]

SEE ORIGINAL COMMENT FOR Figure 58: Results from five US06 tests for the same vehicle, same driver, same test cell. [EPA-HQ-OAR-2022-0829-0701, pp. 164-169]

Assuming the purpose of the proposed -7 °C FTP PM standard is to mandate the use of GPFs to minimize PM emissions on all vehicles, vehicles passing the 0.5 mg/mile standard on the 25 °C FTP and US06 tests should also have PM emissions below 0.5 mg/mile on the -7 °C FTP test. Requiring PM testing at -7 °C will add unnecessary and substantial testing burden on OEMs at a time when industry resources are focused on the transitioning to electric vehicles. PM testing -7 °C is very demanding with a low validity rate, and would require most laboratories to undertake expensive test cell upgrades. [EPA-HQ-OAR-2022-0829-0701, pp. 164-169]In summary,

- A -7 °C FTP PM standard will require major laboratory upgrades that EPA has not considered in its proposal. [EPA-HQ-OAR-2022-0829-0701, pp. 164-169]

- A -7 °C FTP PM standard is not necessary and will not provide additional information or emission reductions beyond what the 25 °C FTP and US06 provide. [EPA-HQ-OAR-2022-0829-0701, pp. 164-169]

- PM Testing at -7 °C has a high test-to-test variability and will significantly increase test burden. [EPA-HQ-OAR-2022-0829-0701, pp. 164-169]

We recommend that EPA discard its proposed -7 °C FTP PM standard. If EPA decides to adopt such a standard, we recommend that EPA exempt vehicles with GPFs from the standard. [EPA-HQ-OAR-2022-0829-0701, pp. 164-169]

i) Tunnel Blank Data

Tunnel blank particulate mass tests are performed in the laboratory without a vehicle to characterize the background PM level of the test cell sampling systems as well as the variability caused by artifacts weighed on the filter due to handling, static charge and other factors. [EPA-HQ-OAR-2022-0829-0701, pp. 169-175]

Laboratories following 40 C.F.R. Part 1066 test procedures and PM best practices typically observe average PM filter weight changes of less than 5 µg for tunnel blank tests. [EPA-HQ-OAR-2022-0829-0701, pp. 169-175]

The following Figure 59 shows the results from 836 tunnel blank particulate mass tests from one ISO 17025 accredited laboratory following the 40 C.F.R. Part 1066 PM requirements and best practice recommendations. The overall average tunnel blank filter weight change is 2.6 µg. [EPA-HQ-OAR-2022-0829-0701, pp. 169-175]

While 85% of the filter net weight change are less than 5 µg, 12% were between 5 and 10 µg and 3% were between 10 and 20 µg. [EPA-HQ-OAR-2022-0829-0701, pp. 169-175]

SEE ORIGINAL COMMENT FOR Figure 59: Tunnel blank PM tests for a single laboratory, Feb. 5, 2021 to Apr. 15, 2023. [EPA-HQ-OAR-2022-0829-0701, pp. 169-175]

Other automaker laboratories have similar trends of tunnel background, but with a higher average and with backgrounds exceeding 25 µg as shown in Figure 60, with each bar representing one background test. The figure shows the range of variability of the tunnel background. There are also a few background tests with negative mass which could be due to filter handling by the operators, static charge removal or microbalance instability. The average background is 6.63 µg, and the standard deviation is 4.9 µg which is quite high. The test cells run different types of testing including gasoline, diesel, SCO3 and OBD testing. It is clear whenever there was a high background above 5 µg followed by a lower one below 5 µg, a tunnel cleaning test was run in between and brought the background level down below 5 µg. The buildup of PM background may take a few vehicle tests or may reach very high value in a single test depending on the test type and vehicle. [EPA-HQ-OAR-2022-0829-0701, pp. 169-175]

SEE ORIGINAL COMMENT FOR Figure 60: Tunnel blank PM tests for another laboratory. [EPA-HQ-OAR-2022-0829-0701, pp. 169-175]

j)Constant Volume Sampler (CVS) Flow by Test Weight and its Impact on PM Filter Net Weight Change [EPA-HQ-OAR-2022-0829-0701, pp. 169-175]

40 C.F.R. Part 1066 requires a CVS time-weighted dilution factor between 7:1 and 20:1 for particulate mass sampling. The lower limit of 7:1 is required, in part, to prevent condensation in the sampling system during testing. The upper limit of 20:1 is required to prevent over-dilution, improving the signal to noise ratio for particulate mass measurements. In order to meet the Part 1066 requirements to prevent aqueous condensation and reduce the risk of invalid tests, a mid-point dilution factor of ~ 14:1 is often targeted. The actual dilution factor for each test is difficult to precisely control as it is impacted by many factors such as the actual exhaust flow during the test, CVS flow rates available, CFV inlet temperature during the test and other factors. [EPA-HQ-OAR-2022-0829-0701, pp. 169-175]

FTP test data at 20-30 °C demonstrates CVS flow rates can range from 200 CFM to 800 CFM for light-duty vehicles and 300 CFM to 1100 CFM for medium-duty vehicles. (See Figure 61.) A flowrate of 200 CFM is a typical minimum flow rate supported by laboratory systems. [EPA-HQ-OAR-2022-0829-0701, pp. 169-175]

SEE ORIGINAL COMMENT FOR Figure 61: CVS Flow Rate Data for Light- and Medium-Duty FTP Tests. [EPA-HQ-OAR-2022-0829-0701, pp. 169-175]

CVS flow rates on US06 tests are higher than those of the FTP. Data at 20-30 °C demonstrates CVS flow rates can range from 300 cfm to 1600 cfm for light-duty vehicles (Figure 62). There is limited US06 test data available for medium-duty vehicles >############################ 10,000 lbs. These vehicles are currently required to perform the LA92 cycle instead of the US06 cycle. By using US06 test data available through 9,000 lb. ETW and extrapolating to 14,000 lbs. it is expected that CVS flow rates for medium-duty vehicles on the US06 cycle may range from 600 cfm to over 2000 cfm. [EPA-HQ-OAR-2022-0829-0701, pp. 169-175]

SEE ORIGINAL COMMENT FOR Figure 62: CVS Flow Rate Data for Light- and Medium-Duty US06 Tests. [EPA-HQ-OAR-2022-0829-0701, pp. 169-175]

The particulate filter net weight change at the 0.5 mg/mi standard decreases as the CVS flow rate increases. The following Figure 63 illustrates the filter net weight change at the 0.5 mg/mi standard for the FTP and US06 by CVS flow rate with the following assumptions: (1) for the FTP test, the 40 C.F.R. Part 1066 single filter method with a filter face velocity during phase 2 of 135 cm/sec; (2) for the US06 test, a single particulate mass filter over the test with a filter face velocity of 100 cm/sec. [EPA-HQ-OAR-2022-0829-0701, pp. 169-175]

For the FTP test at the 0.5 mg/mi standard, the filter net weight can be as low as ~13 µg for light-duty vehicles and below 10 µg for medium-duty vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 169-175]

For the US06 test at the 0.5 mg/mi standard, the filter net weight can be as low as ~6 µg for light-duty vehicles and approaches 4 µg for medium duty vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 169-175]

SEE ORIGINAL ATTACHMENT FOR Figure 63: Assessment of net PM filter weight change by CVS flowrate at a 0.5 mg/mile standard. [EPA-HQ-OAR-2022-0829-0701, pp. 169-175]

The tunnel blank PM data above demonstrates that variability in the PM sampling, handling, and weighing process without a vehicle can contribute up to, and periodically exceed, 20 µg to the PM filter. As shown in Figure 64, the tunnel blank PM net weight contribution alone at high CVS flow rates can cause a compliant vehicle to exceed the 0.5 mg/mi standard. [EPA-HQ-OAR-2022-0829-0701, pp. 169-175]

SEE ORIGINAL COMMENT FOR Figure 64: Overlay of tunnel blank PM testing and net filter weight change at a 0.5 mg/mile standard for various by flowrate. [EPA-HQ-OAR-2022-0829-0701, pp. 169-175]

K) Suggestions and Recommendations Based on Analysis of PM Measurement Capability

We recommend that that EPA adopt California LEV IV PM standards in whole. If EPA proceeds with a different standard, then at a minimum, EPA should adopt 1 mg/mi until it is fully phased in under LEV IV. In addition:

- EPA eliminate the requirement for PM testing at -7 °C. [EPA-HQ-OAR-2022-0829-0701, pp. 175-176]

- We recommend considering laboratory measurement variability and allowing re-tests for exceedances during certification, confirmatory and in-use testing, especially for vehicles equipped with diesel particulate filters or gasoline particulate filters. [EPA-HQ-OAR-2022-0829-0701, pp. 175-176]

- Tunnel blank tests or background should be measured weekly. Dilution tunnel conditioning and cleaning should be required to be performed whenever the tunnel blank or background exceeds 5 µg.276 Tunnel contamination and background will be very significant and can be higher than the net mass of PM on the filter, which will affect the PM test results adding to the uncertainty in measurement. Tunnel cleaning is typically a process of using high temperature gasoline exhaust to remove PM entrained on the tunnel surfaces. For example, this can be accomplished by operating a higher mass gasoline vehicle at steady state speeds (e.g., 80 mph) for a period of time. [EPA-HQ-OAR-2022-0829-0701, pp. 175-176]

276 Cleaning could entail running a low emission gasoline vehicle on repeated US06test cycles to heat the tunnel, thereby removing entrained particulate matter.

- Tunnel Background correction should be required given the significant difference it can make on test results, particularly at very low standard levels. [EPA-HQ-OAR-2022-0829-0701, p. 176]

- More appropriate reference filter limits should be required for light- and medium-duty vehicles, for example +/- 5 µg. The current Part 1065 reference filter validity limit of +/- 10 µg may be adequate for heavy-duty vehicles, but it is not adequate for testing at the 0.5 mg/mile standard level for light- and medium-duty vehicles where the net mass on the filter can be less than 10 µg. [EPA-HQ-OAR-2022-0829-0701, p. 176]

- Consider making Robotic auto handlers a requirement to minimize filter handling by operators. This is important, particularly at independent laboratories that perform in- use testing. Requirements should take effect after the appropriate lead time. [EPA-HQ-OAR-2022-0829-0701, p. 176]

- Consider requiring single filter collection with flow weighing on the FTP to minimize the impact of artifacts and to collect more mass on the filter. Requirements should take effect after the appropriate lead time. [EPA-HQ-OAR-2022-0829-0701, p. 176]

- Finally, EPA should adopt interim in-use standards for the first two model years after a test group certifies to a new EPA PM standard. [EPA-HQ-OAR-2022-0829-0701, p. 176]4. PM certification Test Requirements

EPA requests comment on whether pre-production PM certification testing should be performed at the durability group level after lower PM standards are fully phased in.277 Auto Innovators supports this proposal as a common-sense adjustment to test requirements following demonstration of PM control at lower levels across the fleet during the phase-in. With the increasing laboratory burden associated with testing electric vehicles, actions that reduce ICE vehicle test burden while still ensuring emission control system efficacy are appreciated. [EPA-HQ-OAR-2022-0829-0701, p. 176]

277 NPRM at 29269

F. Interim In-Use Standards

Auto Innovators recommends EPA provide interim in-use compliance standards for PM, early drive-away, and US06 NMOG+NOx standards, consistent with the approach taken by CARB in its LEV IV program.280 [EPA-HQ-OAR-2022-0829-0701, p. 178]

280 See 13 C.C.R. § 1961.4(d)(2)(A)3., (2)(C)3., (3)(A)5.a., and (3)(A)5.b.

Notwithstanding our comments opposing EPA's proposed PM standards, we recommend that test groups first certified to Tier 4 PM standards in the first four years of the program meet an in-use standard 1 mg/mile higher than the certification standard. [EPA-HQ-OAR-2022-0829-0701, p. 178]

For early drive-away and US06 NMOG+NOx standards, we recommend that test groups first certified to these Tier 4 standards in the first two years of the program meet an in-use standard 1.2 times their certification standard. [EPA-HQ-OAR-2022-0829-0701, p. 178]

Vehicles will still certify to the new standards, but the interim in-use standards reduce the jeopardy associated with new technology and more stringent standards. [EPA-HQ-OAR-2022-0829-0701, p. 178]

H. -7°C CO standard

EPA proposes a 10.0 mg/mi CO emissions cap for the -7°C FTP. This differs from the current standards in that the same cap applies to all light-duty vehicles. For larger vehicles, CO emission mass is larger and it takes more time to warm up the catalyst. Therefore, we request that EPA maintain the current CO cap of 12.5 mg/mile for LDT2-4 and MDPV. We also note that there are no CO non-attainment areas in the U.S., and vehicle CO emissions are declining.281 [EPA-HQ-OAR-2022-0829-0701, p. 180]

C. Particulate Matter (PM) Requirement for MDVs

4. Standard Alignment

Particulate mater requirements found in the Proposed Rule are misaligned and differ with CARB Advanced Clean Cars II (ACC II) regulation both in standard level and required test cycles. ACC II sets a particulate mater limit of 8 mg/mi and 10 mg/mi for Class 2b and Class 3 vehicles, respectively, on the FTP75 test cycle, whereas the proposed EPA standard is 0.5 mg/mi across the same cycle. The jump in stringency from 8 mg/mi to 0.5 mg/mi represents a 16-20 times jump in stringency, depending on the weight category of vehicle. [EPA-HQ-OAR-2022-0829-0701, pp. 194-195]

Manufacturers have been developing products and product plans to meet the ACC II pPM standard levels since that rulemaking process began in September of 2020. Investments and development are already underway, and these costs should not be stranded. The lack of alignment between standards will waste three years of development work, leaving it largely abandoned. During a time of rapid industry transition, EPA's proposal would siphon funds away from electrification efforts in the MDV segment. [EPA-HQ-OAR-2022-0829-0701, pp. 194-195]

EPA should align the PM stringency for MDVs with the ACC II rules already promulgated by California across the same timeframe of MY2027 to MY2032. This would provide for a reasonable level of stringency in the requirements while allowing investment to continue to be focused on increasing MDV electrification. [EPA-HQ-OAR-2022-0829-0701, pp. 194-195]

Alternatively, if EPA chooses not to align with ACC II PM standards, an alternate standard is needed, because the application of the same stringency level as LDVs for MDVs is neither appropriate nor feasible. As documented in the PM Section above, EPA must recognize the lab measurement limitations (lab-to-lab and test-to-test variability) for larger, heavier vehicles with much higher exhaust flow rates is limited to 4 or 5 mg/mile for Class 2b and 3, respectively. Because vehicles in the Medium-Duty segment are much heavier than LDV vehicles and are used in different ways than their LDV counterparts, it makes sense to have a separate standard level rather than apply one standard to every vehicle from a 2,000-pound subcompact passenger car to a 7,000-pound Class 3 dually pickup truck with a 20,000-pound towing capacity. [EPA-HQ-OAR-2022-0829-0701, pp. 194-195]

5. Test Cycle Alignment

To minimize unnecessary test burden, EPA should align its test cycles with those of ACC II and allow manufacturers to use US06 Bag 2 in place of the full US06 test for Particulate Mater testing. This significantly reduces test burden without impacting environmental benefit. [EPA-HQ-OAR-2022-0829-0701, p. 195]

2. IUMPR Systems with Active Regeneration

For active regeneration of a GPF, we believe that a special denominator is necessary. In addition to the general denominator criteria, the denominator for monitors associated with active regeneration of a GPF should only be incremented if, and only if, an active regeneration event is commanded for a time greater than or equal to ten seconds, where "Active regeneration" of a gasoline particulate filter is defined as the active control of the exhaust system (e.g., to increase the exhaust system temperature) for the purpose of the regeneration of the particulate filter. [EPA-HQ-OAR-2022-0829-0701, pp. 249-250]

Also, we would also like to work with EPA staff to clarify the de-greening process and the starting mileage when the GPF is expected to achieve compliant filtration efficiency. The de-greening of a GPF is directly linked to the clear definition of a proper regeneration (frequency) and the proper detection of defective sensing systems. [EPA-HQ-OAR-2022-0829-0701, pp. 249-250]

3. GPF Monitoring Requirements

a) Detection Requirements

When developing a GPF monitor, manufacturers often target six-sigma separation between worst performing acceptable (WPA or “good parts”) and best performing unacceptable (BPU or “bad parts”). To achieve this separation, there needs to be enough separation in systems that meet the emission standard and those that should turn on the MIL for the OBD threshold. As the emission standards decrease, the OBD threshold multiplier needs to increase to provide necessary separation for a robust monitor. [EPA-HQ-OAR-2022-0829-0701, pp. 250-251]

We propose to revise the language found in (§ 86.1806–27 (h)(2)(i), to read: [EPA-HQ-OAR-2022-0829-0701, pp. 250-251]

If there is no failure or deterioration of the PM filter that could cause a vehicle to exceed the specified PM emission level, [Strikethrough: the system must detect a malfunction if the PM filter allows free flow of exhaust through the PM filter assembly where 30 percent or less of the normal filtration is occurring] [In Red: [Underline: the OBD II system shall detect a malfunction when no detectable amount of PM filtering occurs . . .]] [EPA-HQ-OAR-2022-0829-0701, pp. 250-251]

This revision aligns with CARB’s long-standing precedent for detection requirements and this revision is the only option that is feasible with today’s commercially available sensing technology. Figure 81 below shows delta pressure curves as a function of exhaust flow from a completely intact substrate and completely missing substrate. For a robust diagnostic, manufacturers require at least six-sigma separation between these curves. At low exhaust flows (of the Worldwide Harmonized Light Vehicles Test Procedure (WLTP) or FTP drive cycle), there is practically no separation between a fully intact substrate and a missing substrate. There is more separation at higher exhaust flows, as shown, but most of the higher exhaust flows are off cycle (i.e., higher exhaust flow than a US06). [EPA-HQ-OAR-2022-0829-0701, pp. 250-251]

The below example data with a delta pressure sensor shows the lack separation between an intact and missing substrate. Requiring detection of a filter flowing 30% of normal would further reduce the limited separation between “intact substrate” and “missing substrate”. Therefore, robust detection with this sensing technology is not possible for any partial failure modes of the GPF. [EPA-HQ-OAR-2022-0829-0701, pp. 250-251]

As demonstrated in the graph below, the delta pressure versus exhaust flow curves also illustrates the challenge for meeting In-Use Monitor Performance Ratio (IUMPR) minimum ratios for missing substrate detection. One way to address this could be by defining a special denominator for this monitor. Following previous and current examples from both CARB and European Union (EU) regulations regarding monitoring of Diesel Particulate Filter (DPF), the following special denominator criteria are needed to ensure that the IUMPR requirements can be met. We recommend that EPA add the following GPF special denominator criteria: [EPA-HQ-OAR-2022-0829-0701, pp. 250-251]

- Minimum of 500 miles [EPA-HQ-OAR-2022-0829-0701, pp. 250-251]

- High enough exhaust flow rate is achieved for a specified amount of time, and [EPA-HQ-OAR-2022-0829-0701, pp. 250-251]

- Alternate or additional denominator criteria, with Administrator approval. [EPA-HQ-OAR-2022-0829-0701, pp. 250-251]

[See original for graph. “Figure 81: Delta Pressure vs Exhaust Flow Rate”] [EPA-HQ-OAR-2022-0829-0701, pp. 250-251]

c) Passive Regeneration

As it pertains to regeneration, if a manufacturer designs their GPF system to not require periodic active regenerations (or to not have a “periodically active regenerating system”), then the manufacturer should not be subject to § 86.1806–27(h)(2)(ii), (iii), or Infrequent Regeneration Adjustment Factors (IRAF) during emission demonstration. Auto Innovators proposes to add a definition of a “Periodically regenerating system” to be defined as a system that requires active regeneration less frequently than 4,000 km/2,500 miles on a 25 deg C FTP. [EPA-HQ-OAR-2022-0829-0701, pp. 252-253]

Regen frequency monitoring is required for major monitors for diesel particulate filter (DPF) systems due to infrequent active regeneration, or periodically regenerating system. Diesel aftertreatment systems typically experience much lower exhaust gas temperatures, which limits passive regeneration. GPF systems, on the other hand, often experience exhaust gas temperatures of 600-650 deg C, which promotes passive regeneration. Passive regeneration is a physical phenomenon, not a control strategy or design feature. Passive, or continuous, regeneration is non-intrusive and occurs naturally due to operating conditions without any intervention from the control system and has no emissions impact. This occurs when the temperature inside the GPF is at or above 600C, which is not equal to the inlet temperature of the after-treatment system. As shown in Figure 82 below, the catalytic process increases exhaust temperature so that values greater than 600C commonly occur inside the after- treatment on all regulated driving cycles. In OEMs’ experience, significant passive regeneration occurs not just on the US06, but also on the FTP (i.e., “on all regulated drive cycles”). GPF systems can be regenerated passively (without active regeneration) for thousands of standard drive cycle miles. [EPA-HQ-OAR-2022-0829-0701, pp. 252-253]

[See original for graph, “Figure 82: Exhaust Gas Temperature vs Speed”] [EPA-HQ-OAR-2022-0829-0701, pp. 252-253]

Auto Innovators proposes that manufacturer systems without “periodic regeneration systems” not be subject to § 86.1806–27 (h)(2)(ii) and (iii) since passive regeneration cannot be monitored for too frequent occurrence or inefficiency because it is not intrusive and is not commanded by the control strategy. Additionally, for (iii), because GPFs rely on passive regeneration without intervention from the control system, GPF overloading or clogging is the result of vehicle operation or some other fault, not the regeneration strategy failing to adequately regenerate the filter. [EPA-HQ-OAR-2022-0829-0701, pp. 252-253]

For vehicles that use periodic regeneration, we recommend replacing the "1.5x the applicable FTP standard" with the multipliers that vary based on the certification level (e.g., a Bin15 would have a multiplier of 3.33x the FTP standard) consistent with CARB OBD II thresholds in 13 CCR 1968.2 which are shown in Figures 83-86 below. [EPA-HQ-OAR-2022-0829-0701, pp. 252-253]

Organization: American Fuel & Petrochemical Manufacturers

As previously mentioned, EPA did not fully consider the impact of the rule on fleet turnover. The Agency is aware that the higher purchase price of new ZEVs will keep older cars and trucks on the road longer and that new ZEVs will increase particulate matter ("PM") emissions through increased tire and road wear. In another example of EPA's biased analysis, EPA estimated the value of health benefits from reductions in PM2.5 emissions by multiplying PM2.5-related benefit- per-ton ("BPT") values by the annual reduction in tons of directly emitted PM2.5 and PM2.5 precursor emissions (NOx and SO2) from displaced ICEVs.206 However, EPA ignored the fleet turnover benefit that would result from replacing older ICEVs with new, more efficient, ICEVs. EPA also ignored its own National Emissions Inventory, which shows that roadway dust contributes more PM2.5 emissions than the tailpipe. Roadway dust emissions, including particles from tire wear, are correlated with vehicle weight, so increases in fleet average vehicle weight would be expected to increase roadway dust PM2.5 emissions.207 Converting ICEs to ZEVs under the Proposal would significantly increase the average vehicle weight on U.S. roadways, which in turn would increase the entrained road dust emissions. Yet EPA did not include these PM sources or increases in the analysis. There also exist overall medium-duty truck weight restrictions, which could require a greater number of ZEVs to move the same tonnage of cargo, thus increasing the number of vehicles needed to haul the same amount of freight, vehicle miles traveled, and resulting PM emissions. EPA also ignores the GHG emissions associated with manufacturing more, less dense, remotely located intermittent generation sources and battery back-up, plus the need for more natural gas peaking capacity and massive transmission, substation, and transformer investment to integrate these technologies into the power grid. Those emissions are significant and may offset or eliminate the benefits that EPA calculates. [EPA-HQ-OAR-2022-0829-0733, p. 45]

Organization: American Honda Motor Co., Inc.

B. Particulate Matter Standards

One of the more surprising aspects of the NPRM is the deviation between proposed federal criteria emissions standards and the C alifornia Air Resources Board's LEV IV emissions standards finalized for the state of California just last year. While news coverage of the latter was largely focused on the state's zero emission vehicle requirements, air quality advocates widely hailed California's LEV IV program as a challenging but achievable set of new emissions requirements. Notably, those included phased-in 25°C FTP 1.0 mg/mi particulate matter (PM) standards from LEV III along with US06 3.0 mg/mi PM standards. [EPA-HQ-OAR-2022-0829-0652, p. 10]

Automakers, including Honda, maintained strong dialogue with California regulators during the development of LEV IV, and had a robust understanding of CARB's decision for maintaining 25°C FTP 1.0 mg/mi PM standards. Given the ongoing open dialogue between CARB and EPA technical staff, and traditional close coordination between the two agencies, Honda believed it was reasonable to assume that federal PM emission standards would likely align with CARB's latest program. Development activities for Honda's internal combustion engine products were based on that assumption. [EPA-HQ-OAR-2022-0829-0652, pp. 10-11]

As it turns out, EPA proposed federal PM standards that far exceed even CARB's recently adopted LEV IV requirements. As shown in Table 1 below, not only has the agency proposed a standard that is nominally twice as stringent as California's, but moreover, EPA calls for that stringency to be met under the 25°C FTP test and two additional significantly more challenging test procedures – the US06 high-speed/high- load test cycle, and the -7°C FTP cold test. [EPA-HQ-OAR-2022-0829-0652, pp. 10-11]

SEE ORIGINAL COMMENT FOR Table 1. Comparison of California and Federal PM Standards, including EPA Proposal [EPA-HQ-OAR-2022-0829-0652, pp. 10-11]

Note: The above table is a high-level comparison of PM emissions standards and test procedures across regulatory programs. It should not be considered a comprehensive summary of emissions requirements. [EPA-HQ-OAR-2022-0829-0652, pp. 10-11]

Relative to the meaningful emissions improvements that could be driven by a nationwide adoption of California's LEV IV PM requirements, EPA's proposed PM standards represent a highly disruptive distraction to Honda as we seek to focus our resources on vehicle electrification. Honda strongly urges the agency to reconsider its proposed federal PM requirements, and instead align with California's LEV IV requirements [EPA-HQ-OAR-2022-0829-0652, p. 11]

Difficulty of measuring 0.5 mg/mi using gravimetric filter-based techniques [EPA-HQ-OAR-2022-0829-0652, pp. 11-12]

The exceedingly low PM mass levels proposed by the agency in this rulemaking raise significant concern over whether compliance with such requirements can even be meaningfully ascertained, given the high potential for test-to-test variability. As noted in comments submitted into this rulemaking Docket by our trade association, Auto Innovators, numerous possible sources of variability exist that could contribute to increased measurement uncertainty, including: [EPA-HQ-OAR-2022-0829-0652, pp. 11-12]

- Operator filter handling [EPA-HQ-OAR-2022-0829-0652, pp. 11-12]

- Filter weight gain during movement from weigh room to test cell [EPA-HQ-OAR-2022-0829-0652, pp. 11-12]

- Tunnel contamination due to prior testing in the test cell [EPA-HQ-OAR-2022-0829-0652, pp. 11-12]

- Static charge removal from filters at extremely low mass levels [EPA-HQ-OAR-2022-0829-0652, pp. 11-12]

- Cell-to-cell variability [EPA-HQ-OAR-2022-0829-0652, pp. 11-12]

- Lab-to-lab offsets [EPA-HQ-OAR-2022-0829-0652, pp. 11-12]

- Vehicle variability [EPA-HQ-OAR-2022-0829-0652, pp. 11-12]

- Driver variability [EPA-HQ-OAR-2022-0829-0652, pp. 11-12]

- Fuel differences [EPA-HQ-OAR-2022-0829-0652, pp. 11-12]

With respect to the final bullet above, the lack of a particulate matter index (PMI) standard for certification fuel (see PMI discussion below) means EPA and OEM laboratories could each be using a certification fuel with very different PM-forming propensities. [EPA-HQ-OAR-2022-0829-0652, pp. 11-12]

These concerns notwithstanding, the agency suggests that 0.5 mg/mi standards would not represent a challenge from a measurement and repeatability standpoint: [EPA-HQ-OAR-2022-0829-0652, p. 12]

Current test procedures, as outlined in 40 CFR part 1066, allow robust gravimetric PM measurements well below the proposed PM standard of 0.5 mg/mi. Repeat measurements in EPA laboratories, at different levels of PM below 0.5 mg/mi, are shown in Figure 17. The size of the error bars relative to the measurement averages at and below 0.5 mg/mi demonstrates that the measurement methodology is sufficiently precise to support a 0.5 mg/mi standard. Other than selecting test settings appropriate for quantifying low PM, no test procedure changes are needed.18 [EPA-HQ-OAR-2022-0829-0652, p. 12]

18 88 Fed. Reg. 29268 (May 5, 2023)

The figure referenced in the above quote shows measurements as low as 0.1 mg/mi with extremely tight standard deviations, though based on the agency's explanatory text, it is not even clear an actual vehicle was tested.19 In Honda's view, the agency downplays challenges associated with PM measurement levels this low. An interlaboratory study (ILS) was conducted in 2021 by ASTM under real- world conditions in multiple automaker labs, in which inter- and intra-laboratory precision was investigated for the 1065/66 test methods.20 That is, reproducibility (R) and repeatability (r) were determined. In virtually every instance, the R and r values of the four tested vehicles greatly exceeded the proposed 0.5 mg/mi standard for both the FTP75 and US06 test cycles. [EPA-HQ-OAR-2022-0829-0652, p. 12]

19 The title of Figure 17 suggests the chart may have been generated with tests using an aerosol generator, as opposed to actual vehicle testing. No additional detail is provided by the agency.

20 ASTM, 2021. "Interlaboratory Study to Establish Precision Statements for ASTM D8108-21, Standard Test Method for Determination of Particulate Matter Mass from Light Duty Mobile Sources (Gravimetric Method)." Research Report: D22-2001.

Beyond measurement challenges, the agency's proposed PM standards also present a number of practical challenges. While state-of-the-art research laboratories may be able to yield an exceedingly low emissions measurement (setting aside the accuracy of that measurement), the agency does not appear to recognize that industry labs must have the flexibility to test a range of vehicles. Once dirtier vehicles are tested in a laboratory, the accuracy of any subsequent hyper-stringent PM test would be called into question. The updating of all industry laboratories to achieve such capabilities is unreasonable, particularly within the accelerated compliance timeline proposed by the agency. [EPA-HQ-OAR-2022-0829-0652, pp. 12-13]

Similarly, it is unreasonable for EPA to assume that automakers could dedicate entire laboratories solely to ultra-low PM measurement. [EPA-HQ-OAR-2022-0829-0652, pp. 12-13]

The agency's proposed PM standard would prompt additional system on-cost and require OBD for vehicles containing GPFs. This would require significant investment and coordination with suppliers to achieve a product that meets OBD requirements of light duty vehicles during a time when OEMs are reducing investment and workforce developing vehicles with ICE powertrains. A specific technology is not required to meet 0.5 mg/mi, but it is well known in the industry that GPFs would be required to meet this standard for the three test cycles proposed (-7°C FTP, 25°C FTP, and US06). In addition, the cost analysis done by EPA does not appear to include GPF post-warranty consumer costs, where the consumer may be responsible for an entire GPF replacement later in a vehicle's life. Metallic ash builds up in a GPF (from engine oil, etc.) and cannot be removed via regeneration. This cost may fall to subsequent owners of the vehicle, including used vehicle purchasers. [EPA-HQ-OAR-2022-0829-0652, p. 14]

Further, the agency appears to have ignored many of the costs associated with GPF application on vehicles. The process of applying a GPF to a vehicle for which it was previously not designed requires far more than simply affixing a device on a car or truck. A re-examination of the emissions system must be undertaken, including possible engine redesign, software changes, OBD modifications, and even potential exhaust plumbing modifications, the latter of which would potentially incur frame-related costs as well. Finally, the added exhaust back pressure of adding a GPF will reduce engine output and degrade vehicle performance. [EPA-HQ-OAR-2022-0829-0652, p. 14]

Recommendation: Honda respectfully requests the agency re-examine the full breadth of costs and vehicle performance impacts associated with GPF application as part of its Final Rule. [EPA-HQ-OAR-2022-0829-0652, p. 14]

Proposed federal PM standards would only marginally benefit non-attainment areas [EPA-HQ-OAR-2022-0829-0652, p. 15]

As noted in EPA's Proposed Reconsideration of the National Ambient Air Quality Standards for Particulate Matter (reproduced here as Figure 1), counties still needing reductions to meet 10/35 µg/m3 levels reside almost exclusively in California.25 That state, of course, has an implementation plan to address PM emissions, including the LEV IV emissions package and aggressive electrification mandates. [EPA-HQ-OAR-2022-0829-0652, p. 15]

SEE ORIGINAL COMMENT FOR Figure 1. Counties that Still Need PM2.5 Emissions Reductions for Proposed Alternative Standard Level of 10/35 µg/m3. Source: EPA. The 2022 EPA Automotive Trends Report: Greenhouse Gas Emissions, Fuel Economy, and Technology since 1975, p. 71. [EPA-HQ-OAR-2022-0829-0652, p. 15]

Would a nationwide federal 0.5 mg/mi standard help California achieve its PM2.5 emissions reductions needs? Mathematically, only marginally so: assuming industry compliance with California's ZEV regulation, which calls for EVs to make up 50% of the state's new vehicle sales by 2028, a shift of PM requirements in California from 1.0 mg/mi to 0.5 mg/mi for the remaining ICE fleet (600,000 units) would yield just 65 additional tons over the life of those vehicles – less than 1% of the amount needed to address the state's PM2.5 emissions reduction shortfall, as identified by EPA.26 27 Given the near ubiquitous PM2.5 attainment across the rest of the nation, and the fact that LEV IV will already meaningfully help address PM2.5 emissions in California and elsewhere, it is not clear why EPA is choosing to pursue this costly and highly disruptive policy. [EPA-HQ-OAR-2022-0829-0652, p. 15]

26 EPA, 2023. Reconsideration of the National Ambient Air Quality Standards for Particulate Matter. Available online at https://www.govinfo.gov/content/pkg/FR-2023-01-27/pdf/2023-00269.pdf

27 EPA, 20022. Regulatory Impact Analysis for the Proposed Reconsideration of the National Ambient Air Quality Standards for Particulate Matter, Table ES-4. Available online at https://www.epa.gov/system/files/documents/2023-01/naaqs-pm_ria_proposed_2022-12.pdf

Marginal benefit of PM standards beyond LEV IV is exceedingly limited] [EPA-HQ-OAR-2022-0829-0652, p. 17]

Improving the PM performance of new vehicles from 1.0 mg/mi to 0.5 mg/mi would have a limited, perhaps undetectable, marginal benefit on the PM inventory, which is largely impacted by non-road sources. As shown in Figure 2 below, EPA's own data show that on-road non-diesel light duty vehicles account for less than one percent of PM2.5 emissions in the United States, a level dwarfed by other sources such as wildfires, agriculture and unpaved road dust.30 [EPA-HQ-OAR-2022-0829-0652, p. 17]

30 U.S. EPA, "2017 National Emissions Inventory: January 2021 Updated Release, Technical Support Document," February 2021. Interactive data queries available online at https://www.epa.gov/air-emissions-inventories/2017- national-emissions-inventory-nei-data

SEE ORIGINAL COMMENT FOR Figure 2. 2017 National PM2.5 Emissions, by Source - PM2.5 [EPA-HQ-OAR-2022-0829-0652, p. 17]

By our math, a decision to finalize PM standards as proposed, instead of setting a nationwide standard aligned with California's LEV IV PM requirement, would further improve the PM2.5 inventory a mere 0.05% – even after full turnover of the vehicle fleet. In intervening years, benefits would be even lower, as emissions standards only deliver an improvement on the emissions performance of new vehicles subject to the updated standards. By contrast, a nationwide standard aligned with California's LEV IV PM requirement would deliver reasonable (albeit still modest) PM reductions from vehicles but do so in a far more efficient and less costly manner. [EPA-HQ-OAR-2022-0829-0652, p. 17]

Recommendation: Honda strongly urges the agency to reconsider its decision regarding federal PM stringency and the inclusion of a -7°C FTP PM test requirement, and instead align federal PM emission standards and test procedures with existing California LEV IV requirements. Doing so would deliver continued PM emissions reductions across the country without forcing unnecessary ICE development and test cell upgrade costs upon manufacturers that are seeking to more efficiently direct resources toward vehicle electrification [EPA-HQ-OAR-2022-0829-0652, pp. 17-18]

-7°C FTP 0.5 mg/mi proposed limit [EPA-HQ-OAR-2022-0829-0652, pp. 13-14]

As noted above, EPA proposes that OEMs comply with a 0.5 mg/mi standard not just under the 25°C FTP test, but also under the high-speed US06 and cold -7°C FTP tests. With respect to the latter, there are presently only a modest number of laboratories with a cold chamber test cell capable of testing vehicles at -7°C, and even fewer that are also able to test exceedingly low PM levels. With EPA now proposing stringent PM measurement under these cold temperature test conditions, the availability of those laboratories will be even more limited. Further restricting testing resources is the question of whether such a lab is configured with the dilution tunnel inside or outside the cold chamber. For labs with tunnels inside the chamber, significant investment must be made to reconfigure/insulate/heat the dilution tunnel, and – if not already configured in this manner for PM sampling – possibly add heating and dehumidification to the dilution air to ensure condensation-free dilute exhaust. It does not appear that the agency has quantified the costs associated with industry-wide laboratory and testing upgrades necessary to meet its proposed cold -7°C FTP PM testing regimen. [EPA-HQ-OAR-2022-0829-0652, pp. 13-14]

In order for an engine to have stable combustion at -7°C and avoid misfire, a calibration for slightly rich operation during cold start is required. This is well understood by the agency, as illustrated by the regulation requirements for this test to encompass evaluation of CO and NMHC. During rich operation, particle mass (filter) measurements will include the excess fuel and SVOCs from the cold engine start. This stands in contrast to the European Union's (EU) process for measuring particle number (PN), in which SVOCs are first stripped off, prior to measurement of PN using highly reproducible electronic instrumentation. Significantly, the current (Euro 6d) standard for particle mass is 4.5 mg/km (7.2 mg/mi),21 using a filter method similar to that used in the U.S. in which the SVOCs are not stripped off. As such, EPA's proposal goes well beyond the EU regulation. [EPA-HQ-OAR-2022-0829-0652, pp. 13-14]

21 Euro standards use the Worldwide Harmonized Light Vehicles Test Procedure (WLTP), generally regarded as less onerous than U.S. test procedures.

To be clear, the agency's inclusion of a -7°C FTP PM test amounts to a de facto gasoline particulate filter (GPF) requirement; the proposed stringency, at that temperature, simply cannot be met without such a device. It appears the agency is keenly aware of the presence of GPF technology on vehicles elsewhere in the world and has proposed a testing regimen to force the inclusion of GPFs in the United States as well. Indeed, in the proposal, EPA points to "GPF-forcing" requirements of other countries' regulations: "All pure GDI vehicles in India also have to meet similar GPF-forcing standards starting in 2023."22 Recognizing, as noted above, that regulatory programs around the world have distinct structural and test procedure differences, the presence (or lack) of a technology elsewhere should not be a basis upon which to set emissions standards. [EPA-HQ-OAR-2022-0829-0652, pp. 13-14]

22 88 Fed. Reg. 29268 (May 5, 2023)

Organization: American Lung Association (ALA) et al.

EPA has proposed important reductions in fine particles from new vehicles across various testing cycle to better respond to — and control for — real-world driving conditions. The EPA standards are estimated to result in widespread use of gasoline particle filters to meet the standards. Filters are currently standard equipment on some vehicle models sold in European and Chinese markets and should be the norm to control this carcinogenic pollutant on equivalent models sold in American communities. We support EPA's robust approach to controlling fine particle emissions from new engines and encourage EPA to consider accelerating the phase-in to require 100% of the new vehicle fleet in MY 2027 to use gasoline particle filters and set strong assurances for ongoing function and maintenance of these critical emission controls. [EPA-HQ-OAR-2022-0829-0745, p. 3]

Organization: American Petroleum Institute (API)

EPA has also not demonstrated that a particulate matter (PM) 0.5 mg/mi limit is technologically feasible on the basis of measurement capabilities and test procedure. EPA has stated that the agency is not reopening the test procedures, nor does the agency believe that test procedure changes are required, to PM for the proposed PM standards. The agency fails in justifying this decision. The EPA needs to reconsider if it is possible to measure PM emissions of 0.5 mg/mile accurately with current methods. The test set utilized in the NPRM to suggest that test-to-test repeatability is sufficiently precise to support a 0.5 mg/mile standard was noted to use an aerosol generator, presumably to generate PM. In contrast an actual engine will produce PM with more composition and concentration variability, which could impact repeatability. Further, FCA reported32 the challenges of measuring 1 mg/mile of PM. It can be assumed that these uncertainties would only increase for a PM target of 0.5 mg/mile "[a]s the PM standard is transitioning to 1 mg/mile, this study showed that the net PM mass on the filter will be approaching tunnel ambient background levels. At these net filter PM mass levels, the sources of errors in measurement are numerous. If these sources of errors are not mitigated, the uncertainty can be substantial exceeding the PM limit of 1 mg/mile." It is important to highlight that the 2023 EPA certification vehicle test data shows that there were approximately 83 carline models (out of approximately 376 carlines tested on US06) that achieved a certification level of emissions of 0 gm/mile (and a rounded emission test results level below 0.5 mg/mile) of PM on the US06 drive cycle. [EPA-HQ-OAR-2022-0829-0641, p. 12]

32 Yassine, M., "Challenges in PM Measurement at 1 mg/mile and Tunnel Background Correction," SAE Technical Paper 2023-01-0370, 2023, https://doi.org/10.4271/2023-01-0370.

EPA fails to properly account for all of the cost increases associated with the enforcement of gasoline particulate filter (GPF) technologies. The GPF cost model is described in DRIA Chapter 3.2 and GPF cost is included in the OMEGA model. The model anticipates the direct manufacturing cost (DMC) for a bare downstream GPF, which ranges from $51 dollars for a 1.0-liter engine using a relatively low GPF 249 volume to engine displacement ratio, up to $166 dollars for a 7.0 liter engine using a relatively high GPF volume to engine displacement ratio. In the DRIA (page 3-60) GPF cost is based on the ICCT 2011 work, which is now over 10 years old. Further, the EPA assumes that the GPFs that OEMs will utilize to meet more stringent PM and GHG targets will be those new generation of MY 2022 GPFs with "high filtration efficiencies generally over 95 percent" and low backpressure. The assumed costs for MY 2022 GPF with higher efficiency appear to be unreasonably low and caused the modeling to overestimate feasibility. Furthermore, it is not clear if the associated equipment for effective operation of the GPF such as associated sensors and controllers are included in the cost assessment performed by EPA. The agency should reevaluate its assessment based on more realistic efficiency levels to avoid arbitrary and capricious action. [EPA-HQ-OAR-2022-0829-0641, p. 13]

Another issue with the proposed PM standards is related to the new testing requirement at -7°C in the Federal Test Procedure (FTP) cycle. In the NPRM EPA states "as was the case for light-duty vehicles, the -7°C FTP cycle is crucial because it differentiates Tier 3 levels of PM from GPF-level PM and because -7°C is an important real-world temperature that addresses uncontrolled cold PM emissions in Tier 3.” The temperature selection of -7°C (19.4°F) is arbitrary and capricious because it is not a real-world temperature applicable to a large portion of the U.S. National Oceanic and Atmospheric Administration (NOAA) data of winter temperature averages for every state from 1971 to 2000 33 suggests that only Alaska, North Dakota, Minnesota, Maine, Wisconsin and Vermont have average winter temperatures below -7°C. 34 The winter average of all 50 states is 0.1 °C (32. °F), which further suggests that a temperature of -7°C is not a real-world temperature. [EPA-HQ-OAR-2022-0829-0641, p. 12]

33 “Winter Temperature Averages for Every State”: https://www.currentresults.com/Weather/US/average-state- temperatures-in-winter.php.

34 According to the U.S. Census Bureau, these states account for less than 5% of the population of the United States (“State Population Totals and Components of Change: 2020-2022”: https://www.census.gov/data/tables/time- series/demo/popest/2020s-state-total.html).

Organization: Arizona Department of Environmental Quality (ADEQ)

Additionally, given Arizona's climate, ADEQ is particularly interested in EPA's plans to adopt proven technologies such as Gasoline Particulate Filters (GPF) as part of its proposed pathways for industries. As Arizona has several particulate matter nonattainment areas, ADEQ supports adoption of GPF technology that is proven to reduce combustion engine tail pipe particulate emissions by over 95 percent.2 [EPA-HQ-OAR-2022-0829-0533, p. 1]

4. PARTICULATE MATTER

EPA's proposed PM reduction to 0.5 mg/mi across the FTP and US06 and Cold Testing goes far beyond what SVMs are able to achieve in a short period of time [EPA-HQ-OAR-2022-0829-0566, pp. 11-12]

EPA's proposed PM reduction to 0.5 mg/mi across the FTP and US06 and Cold Testing is an enormous increase in stringency over a short period of time. This is a regulatory combination that SVMs simply cannot meet. We recognize that the regulation of PM is headed towards necessitating the use of Gasoline Particulate Filters (GPF), but further research and development is needed with respect to GPF aging and monitoring for purposes of California OBD. This issue is not yet fully understood and requires more lead-time under the CAA section 202(a). [EPA-HQ-OAR-2022-0829-0566, pp. 11-12]

In addition, there are also technical issues and costs associated with measuring PM emissions below 1 mg/mile, and specialized, expensive test facilities may be needed to reliably measure PM at such a low level. [EPA-HQ-OAR-2022-0829-0566, pp. 11-12]

It is thus unreasonable to impose the proposed PM standards and timetable on SVMs, especially considering the minimal environmental benefit obtained together with how drastic the proposed change is compared to existing Tier 3 levels and the CARB ACCII PM standards, as shown in the graph below. [EPA-HQ-OAR-2022-0829-0566, pp. 11-12]

[See original attachment for bar graph of Tailpipe PM Limit [mg/mi]] [EPA-HQ-OAR-2022-0829-0566, pp. 11-12]

In sum, as regards SVMs and PM, EPA should harmonize with the CARB ACC/1 SVM PM approach as follows:

- FTP

-- For MY 2027-2028 -- 3 mg/mile.

-- For MY 2029 and later - 1 mg/mi. [EPA-HQ-OAR-2022-0829-0566, pp. 11-12]

- SFTP

-- For MY 2027 - 2029 - 6 mg /mi

-- For MY 2030 and later - 3 mg/mi [EPA-HQ-OAR-2022-0829-0566, pp. 11-12]

- No Cold Testing for SVMs given that it is not yet fully understood what is needed to meet the 0.5mg standard at 20F with high-performance engines. [EPA-HQ-OAR-2022-0829-0566, pp. 11-12]

We further note the above levels and timetable are consistent with the EU regulation of PM. GPFs will be necessary on all European engines in 2030 with the implementation of EU7's mandating PM measurement for both Port Fuel Injection Engines and Gasoline Direct Injection Engines. [EPA-HQ-OAR-2022-0829-0566, pp. 11-12]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Criteria Air Pollutant Standards

CARB supports U.S. EPA’s proposal to tighten criteria air pollutant emission standards, particularly given the continued role that internal combustion engine vehicles will play in the national fleet over the regulatory timeframe and beyond. Reducing exposure to harmful air pollution is a key element of the proposed standards, and the proposals to tighten criteria air pollutant emissions are needed to protect public health, especially in communities with disproportionate exposure to air pollution. Because U.S. EPA’s proposal does not require ZEV sales, as California’s rules do, the tightening of criteria air pollutant emission standards is even more critical to ensure that the internal combustion engine vehicles that will continue to be sold are becoming cleaner. [EPA-HQ-OAR-2022-0829-0780, pp. 26-27]

As part of its ACC II rulemaking, CARB adopted its fourth iteration of its Low Emission Vehicle (LEV) standards, referred to as LEV IV. CARB finds that U.S. EPA’s proposals are appropriate and largely consistent with the LEV IV standards. CARB has documented our analysis and recommends strengthening the proposal to realize the greatest degree of emission reductions achievable, considering cost and technology availability, to further protect public health. As described further below, CARB recommends that U.S. EPA adopt its proposed NMOG+NOx and PM standards, adopt elements of CARB’s evaporative emission standards program, and eliminate the use of commanded enrichment as proposed while collecting additional information on the use of auxiliary emissions control devices to further improve emission standards in the future. [EPA-HQ-OAR-2022-0829-0780, pp. 26-27]

Particulate Matter Emission Standards

CARB supports U.S. EPA's proposal to lower the PM emission standards for light- and medium-duty vehicles for all test cycles to ensure robust PM control under broad operating conditions. CARB's ACC I PM standards are lower than U.S. EPA's Tier 3 standards for the FTP cycle, and the ACC II regulations expanded lower PM standards to more test cycles to achieve the same desired outcome of robust PM control. [EPA-HQ-OAR-2022-0829-0780, pp. 33-34]

At the time of CARB's original adoption of its standards in 2012, the gasoline particulate filter technology that U.S. EPA is now relying on was not as well developed to support such stringent levels. Since that time, however, the technology has matured and been deployed industry-wide in the European vehicle fleet, confirming its technology readiness. But under the ACC II regulations, the ZEV requirements necessarily reduce the fraction of conventional vehicles at a pace that minimized the additional benefit from a further reduction in the PM FTP standards in California. [EPA-HQ-OAR-2022-0829-0780, pp. 33-34]

On a national level, in contrast, CARB supports the proposed PM standards given that the proposed standards as a whole do not have a parallel path to effectively eliminate emissions from new vehicles. In the absence of this certainty of future zero-emission standards, the proposed PM standards will ensure over the long term that PM emissions are reduced to the maximum extent feasible from vehicles driven in California (and elsewhere, especially in cold climates) even if they were not originally sold here. U.S. EPA's proposed PM standards are appropriate for protecting public health and reducing exposure to PM, especially for residents of disadvantaged communities that are in close proximity to busy roadways. [EPA-HQ-OAR-2022-0829-0780, pp. 33-34]

Further, on the issue of measurement capabilities of low levels of PM, CARB previously addressed the technical feasibility as part of its LEV III MTR. 44 As a part of the MTR, staff conducted a technical review to determine if the gravimetric PM mass measurement method was appropriate for the 1 mg/mi standard. The technical review was conducted by CARB in collaboration with U.S. EPA, industry, and other stakeholders. The review process included extensive studies, testing, and laboratory evaluation of PM emissions at 1 mg/mi and below. The results of the technical review of the PM standards were presented by staff to the Board in October 2015. [EPA-HQ-OAR-2022-0829-0780, pp. 33-34]

44 CARB. ACC PM Measurement Feasibility. October 2015. https://ww2.arb.ca.gov/sites/default/files/barcu/board/books/2015/102215/15-8-9pres.pdf.

As a result of these studies, CARB concluded that the gravimetric method prescribed for the FTP driving cycle, in conjunction with appropriate laboratory practices, has a measurement precision of 0.1 mg/mi, even when measuring emission rates less than 1 mg/mi. This method can precisely measure PM emissions to determine compliance with a standard of 0.5 mg/mi. 45 It should also be noted that such analysis was conducted on low-PM-emitting vehicles that had a higher level of vehicle test-to-test variability than what is observed in U.S. EPA's test data for vehicles equipped with a gasoline particulate filter. As this technology is a mechanical wall-flow filtering device with a high trapping efficiency, it inherently dampens variations in engine-out

PM emissions and produces more consistent results at very low PM levels, thereby reducing one element of concern regarding measurement precision at low PM levels. This further demonstrates that the proposed PM standard is feasible and appropriate. [EPA-HQ-OAR-2022-0829-0780, pp. 33-34]

45 CARB. An Update on the Measurement of PM Emissions at LEV III Levels. October 2015. p. 23. https://ww2.arb.ca.gov/sites/default/files/2020-01/lev_iii_pm_measurement_feasibility_tsd_20151008_ac.pdf

Organization: David Pedersen

I agree with and support the agency's objective of reducing air-pollutant emissions from internal combustion engines in automobiles. Since there is no safe level of air pollution ("As the author of the Clean Air Act, Senator Edmund Muskie, later admitted, “[o]ur public health scientists and doctors have told us that there is no threshold, that any air pollution is harmful." Susan E. Dudley and Marcus Peacock, "Improving Regulatory Science: A Case Study of the National Ambient Air Quality Standards", https://www.journals.uchicago.edu/doi/full/10.1086/696956), it is critical that emissions from automobiles be reduced as much as possible. [EPA-HQ-OAR-2022-0829-0518, p. 1]

However, I strongly disagree with the proposed standards that would require the use of gasoline particulate filters (GPFs). Back around 2001, the agency promulgated particulate-matter (PM) standards for compression-ignition (i.e. diesel) engines that essentially triggered the use of diesel particulate filters (DPFs), which have been nothing short of disastrous. Independent laboratory testing by Transport and Environment - a renowned European non-governmental organization and environmental group - found that PM emissions from DPFs themselves exceed legal limits by a factor of 1000 (see "New diesels’ particle emissions spike to 1,000 times normal levels in tests", https://www.transportenvironment.org/discover/new-diesels-particle-emissions-spike-1000-times-normal-levels-tests/, or see attachment "New-diesels-new-problems-filters.png"). I myself experienced this firsthand when I was engulfed by a thick plume of smoke from a regenerating particulate filter while walking home one day last year (see screenshot, attachment "Screenshot 2023-06-20 at 16-43-08 Ford Transit 2013 DPF Regen part 2.png", for example). [EPA-HQ-OAR-2022-0829-0518, p. 1]

Additionally, a 2023 study found that exhaust particulate filters don't remove ultrafine particles (UFPs), which are far more hazardous than coarse, fine, and very-fine particulate matter ("Ultrafine particle concentrations remain in the “high” category as defined by WHO." Damayanti et al., Limited impact of diesel particle filters on road traffic emissions of ultrafine particles, https://www.sciencedirect.com/science/article/pii/S0160412023001617). DPFs were also found to increase MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) cytotoxicity compared to non-DPF sources (https://www.sciencedirect.com/science/article/abs/pii/S0269749118332135) - see attachment "CytotoxicityPAHsVariousSources.png". [EPA-HQ-OAR-2022-0829-0518, p. 1]

Multiple vehicle owners have also reported frequent breakdowns as a result of clogged or otherwise-defective particulate filters, while others have experienced vehicle fires (https://dieselnet.com/news/2011/10cleaire.php) and even explosion hazards (https://www.worksafebc.com/en/resources/health-safety/risk-advisory/explosion-or-fire-from-diesel-particulate-filter-dpf-systems?lang=en) as a result of them. This should trigger a prohibition on the use of such filters, as the Clean Air Act prohibits the EPA from considering any control technologies that pose safety hazards; this rule may be struck down if such controls are considered in light of their safety hazards. [EPA-HQ-OAR-2022-0829-0518, p. 1]

It is also worth mentioning that exhaust filters do nothing to address emissions from tires, which are not covered by this proposed rulemaking. [EPA-HQ-OAR-2022-0829-0518, p. 1]

Once again, I reiterate my stance that while PM emissions can and must be reduced as much as possible, the agency should NOT consider - let alone mandate - the use of exhaust particulate filters on new internal-combustion engines. The agency should explore alternative methods for reducing PM emissions instead, including mandatory electric-vehicle sales quotas and tire-design requirements in future rulemakings. [EPA-HQ-OAR-2022-0829-0518, p. 1]

Organization: District of Columbia Department of Energy and Environment (DOEE)

Ultimately, none of the proposed EPA standards are sufficiently protective to promote the health and safety of District residents or achieve clean air in the District as there is no safe level of exposure to vehicle emissions and particulate matter (PM). The Union of Concerned Scientists (UCS) states that, [EPA-HQ-OAR-2022-0829-0550, p. 2]

Passenger vehicles are a major pollution contributor, producing significant amounts of nitrogen oxides, carbon monoxide, and other pollution. In 2013, transportation contributed more than half of the carbon monoxide and nitrogen oxides, and almost a quarter of the hydrocarbons emitted into our air.1 [EPA-HQ-OAR-2022-0829-0550, p. 2]

Organization: Environmental. and Public Health Organizations

B. Emissions of criteria pollutants from light- and medium-duty vehicles harm the public health.

EPA's proposed reductions of non-methane organic gases ("NMOG") plus NOx, as well as particulate matter, are crucial to protecting the public from harmful air pollutants. As EPA notes, "[e]mission sources impacted by [its] proposal, including vehicles and power plants, emit pollutants that contribute to ambient concentrations of ozone, PM, NO2, SO2, CO, and air toxics."67 These pollutants are linked to premature death, respiratory illness (including childhood asthma), cardiovascular problems, and other adverse health impacts. In particular, NOx emissions increase levels of ozone, because ground-level ozone forms when there are high concentrations of ambient NOx and VOCs, and when solar radiation is high.68 NOx emissions also impact particulate matter by forming secondary particles through atmospheric chemical reactions.69 Reductions in NOx emitted from LDVs will therefore result in reduced ambient levels of ozone and PM and improved health and environmental outcomes. [EPA-HQ-OAR-2022-0829-0759, p. 17]

69 DRIA at 7-10.

Air pollution has become so significant that the public health burdens attributable to air pollution are "now estimated to be on a par with other major global health risks such as unhealthy diet and tobacco smoking, and air pollution is now recognized as the single biggest environmental threat to human health."70 Researchers at the University of Chicago studied the impact of air pollution on life expectancy and found that "the impact of particulate pollution on life expectancy is comparable to that of smoking, more than three times that of alcohol and unsafe water and sanitation, six times that of HIV/AIDS, and 89 times that of conflict and terrorism."71 [EPA-HQ-OAR-2022-0829-0759, p. 17]

70 World Health Organization (WHO), WHO Global Air Quality Guidelines (2021) at xiv, https://apps.who.int/iris/bitstream/handle/10665/345329/9789240034228-eng.pdf.

71 Michael Greenstone, Christa Hasenkopf, & Ken Lee, Air Quality Life Index Annual Update, Energy Policy Institute at the University of Chicago (2022) at 6-7, https://aqli.epic.uchicago.edu/wp-content/uploads/2022/06/AQLI_2022_Report-Global.pdf/.

There is consistent evidence showing the relationship between short-term exposure to PM and mortality, particularly cardiovascular and respiratory mortality. Short- and long-term exposure to PM2.5 can cause harmful health impacts such as heart attacks, strokes, worsened asthma, and early death.72 In addition, short-term PM exposure has been linked to increases in infant mortality, hospital admissions for cardiovascular disease, hospital admissions and emergency visits for chronic obstructive pulmonary disease, and severity of asthma attacks and hospitalization for asthma in children. Year-round exposure to PM is associated with elevated risks of early death, primarily from cardiovascular and respiratory problems such as heart disease, stroke, influenza, and pneumonia.73 These findings show the critical need for EPA to minimize the harmful emissions from the transportation sector. Doing so will only improve public health and the environment. [EPA-HQ-OAR-2022-0829-0759, pp. 17-18]

2. The proposed PM2.5 requirements are appropriate.

EPA is also proposing to set a limit on the allowable particulate matter (PM2.5) emissions from all LDVs. This is an appropriate step under the Agency's authority and is well-grounded in both the need for additional emissions reductions and technical feasibility. [EPA-HQ-OAR-2022-0829-0759, p. 55]

Stoichiometric gasoline direct-injection is deployed in over half the new vehicle fleet in the United States and supports the deployment of turbocharged, downsized engines as well as high-compression ratio engines, both of which are key technologies to reduce GHG emissions.142 At the same time, moving from port-fuel injection to direct-injection leads to an increase in both the amount of PM2.5 and the particle count.143 Addressing PM2.5 emissions from the vehicles deploying these technologies is critical as they become a larger share of the on-road fleet. [EPA-HQ-OAR-2022-0829-0759, p. 56]

142 See U.S. EPA, The 2022 Automotive Trends Report: Greenhouse Gas Emissions, Fuel Economy, and Technology Since 1975, EPA-420-R-22-029 (Dec. 2022), Chapter 4, available at https://www.epa.gov/automotive-trends/download-automotive-trends-report.

Gasoline particulate filters (GPFs) have been successfully deployed globally for years to address these emissions, as EPA has documented in the Draft Regulatory Impact Analysis (DRIA).144 Additionally, in-cylinder strategies can help mitigate emissions, including through the design of both the injector and the cylinder surface.145 Aftertreatment design can also be used to mitigate cold-start emissions, in particular.146 All of the technology developments described above are well-established, and many are analogous to technologies that have been deployed to limit PM2.5 emissions from diesel engines. [EPA-HQ-OAR-2022-0829-0759, p. 56]

As part of its Advanced Clean Cars program, California finalized a PM2.5 standard of 1 mg/mile, to begin phasing in with the 2025 model year.147 As part of its review, the California Air Resources Board (CARB) conducted tests demonstrating the feasibility of achieving this standard, including data on particle count, GPF effectiveness, and the ability to measure sub-mg quantities of PM2.5.148 While these standards have not gone into effect, the underlying data support EPA's proposed PM2.5 program. [EPA-HQ-OAR-2022-0829-0759, p. 56]

147 Cal. Code of Regs. Tit. 13, § 1961.2(a)(2)(A).

148 For measurement capability, see CARB, An Update on the Measurement Of PM Emissions at LEV III Levels, (2015), available at https://ww2.arb.ca.gov/sites/default/files/2020-01/lev_iii_pm_measurement_feasibility_tsd_20151008_ac.pdf. For additional tests on GPF capability, see CARB, California[']s Advanced Clean Cars Midterm Review, Appendix K: PM Emission Testing Results (Jan. 8, 2017), available at https://ww2.arb.ca.gov/sites/default/files/2020-01/appendix_k_pm_test_results_ac.pdf.

The benefits of the PM2.5 standards are significant—depending on the assumed rate of deployment, EPA's Proposed Standards could cut tailpipe PM2.5 emissions by up to 90% by 2050.149 This could lead to cumulative health benefits of $85 to $160 billion over that same timeframe, at a 3% discount rate.150 Importantly, it could also lead to measurable improvements in near-roadway air quality,151 which could be significant for the more than 41 million people living within close proximity of high-traffic roadways.152 [EPA-HQ-OAR-2022-0829-0759, pp. 56-57]

2.The proposed PM2.5 requirements are appropriate.

As discussed in Section VI.F.2, proven and cost-effective technology exists to reduce tailpipe PM2.5 levels to the levels required by EPA's proposed standards. MDVs with GCWR over 22,000 pounds (see the section immediately below) will already be required to achieve similar levels of reductions under EPA's proposal to certify these vehicles under the heavy-duty engine requirements, and the data supporting the finalization of those standards include an assessment of technology improvements for both compression-ignition and spark-ignition engines supporting a technology neutral achievement of PM2.5 reductions.211 The test protocols and targets for EPA's proposed PM2.5 standards are achievable, as discussed in Section VI.F.2, and will provide significant health benefits.). [EPA-HQ-OAR-2022-0829-0759, p. 77]

211 U.S. EPA, Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards: Regulatory Impact Analysis, Sections 3.1 & 3.2, EPA-420-R-22-035 (Dec. 2022

Organization: Environmental Defense Fund (EDF) (1of 2)

Passenger vehicles also emit harmful pollutants, including fine particulate matter (PM2.5) and oxides of nitrogen (NOx). These pollutants contribute to the formation of soot and smog and contribute to elevated concentrations of pollution near roadways, where millions of people live and go to school, and people of color and people with low income are disproportionately exposed to air pollution from vehicles. [EPA-HQ-OAR-2022-0829-0786, p. 6]

Please see EDF's comments on the Proposed Rule, Revised 2023 and Later Model Year Light- Duty Vehicle Greenhouse Gas Emissions Standards, 86 Fed. Reg. 43726 (August 10, 2021) dated September 27, 2021, and resubmitted to this docket, for a more thorough discussion of the substantial health and environmental harms associated with the pollution and GHG emissions from passenger vehicles.1 [EPA-HQ-OAR-2022-0829-0786, p. 6]

1 EDF's comments on the Proposed Rule, Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards, 86 Fed. Reg. 43726 (August 10, 2021) dated September 27, 2021, at 4-6. Accessible at https://www.regulations.gov/comment/EPA-HQ-OAR-2021-0208-0688. (Attachment A)

B. Standards that result in use of Gasoline Particulate Filters are vital.

EDF supports the proposed PM standard of 0.5 mg/mi for light-duty vehicles and medium-duty vehicles that must be met across three test cycles (-7 °C FTP, 25 °C FTP, US06), a requirement for PM certification tests at the test group level, and a requirement that every in-use vehicle program (IUVP) test vehicle is tested for PM. EPA must ensure that the 0.5 mg/mi standard is a per-vehicle cap, not a fleet average. [EPA-HQ-OAR-2022-0829-0786, pp. 62-63]

EPA correctly relies on the availability of Gasoline Particulate Filters (GPFs) in setting its PM standard. GPFs are a highly feasible demonstrated technology with a proven track record at reducing pollution. They are already widely available, and are being put to use in other markets, including the European Union, India and China, where more stringent emissions standards have made them necessary.173 [EPA-HQ-OAR-2022-0829-0786, pp. 62-63]

173 Corning, What Emissions Regulations and Standards are Currently in Place?, https://www.corning.com/worldwide/en/products/environmental-technologies/emissions-control/emissions-regulations.html.

i. Additional reductions in PM pollution are urgently needed, especially in communities that have long faced elevated pollution burdens.

Continuing to drive criteria pollutant reductions is particularly important for low-income communities and communities of color, which have historically faced significant and elevated harms from health-harming transportation pollution. As a result of housing discrimination and other unjust policies, communities of color and low-income communities constitute a higher percentage of the population near our roads and highways and therefore suffer disproportionately from associated harmful pollution.174 According to the American Lung Association's 2023 State of the Air report, people of color are almost four times more likely to breathe the most polluted air when compared to white people.175 A report by Moving Forward Network also found that, on average, Asian and Black Americans are exposed to PM2.5 pollution that is 56 and 44 percent higher, respectively, than white Americans.176 And an EDF analysis of the Bay Area in California found that neighborhoods with higher percentages of residents of color experienced double the rate of asthma from nitrogen dioxide (NO2) –a pollutant often used as a marker for transportation-related pollution.177 Moreover, as described above, recent studies have found light- duty vehicles, including light-duty trucks are responsible for a significant share of pm- attributable premature mortalities. [EPA-HQ-OAR-2022-0829-0786, p. 63]

Accordingly, finalizing the criteria standards EPA has proposed, including setting the PM standard at a level that will encourage the use of GPFs, is critical to protecting health and combatting environmental injustice. [EPA-HQ-OAR-2022-0829-0786, p. 63]

Organization: Ferrari N.V. and Ferrari North America, Inc.

b) Other Criteria Pollutant Standards

Under EPA's proposal, SVMs are no longer eligible for special provisions and must meet the criteria emission standards of LVMs with the same phase-in. Ferrari is concerned about the complete elimination of flexibilities granted in current US legislation (which has historically expressed EPA's recognition of the SVM challenges), and the introduction of very demanding PM standard limits. EPA is indeed proposing an 83% reduction in the PM standard (i.e. 0.5 mg/mi rather than 3 mg/mi), while also increasing the number of test procedures for which this limit is applicable. [EPA-HQ-OAR-2022-0829-0572, p. 6]

Ferrari's commitment to reducing PM emissions dates back in 2019, when Ferrari included the GPF (developed also to ensure compliance with European Regulation) in the US, gaining leadership among other manufacturers in this regard. In support of this, the best GPF technologies have already been implemented on our models, and innovative exhaust system configurations are currently being developed to meet the 1 mg/mi PM requirement in MY 20285, as required by California ACC II regulation. [EPA-HQ-OAR-2022-0829-0572, p. 6]

5 as defined in CCR, Title 13, §1961.4(d)(2)(A)(2)(c)

However, we are deeply concerned about the effectiveness of this configuration with a stricter 0.5 mg/mi PM limit, also considering the short time provided by EPA's proposal. Moreover, the measurement variabilities related to the current state of the art of certification testing measurement equipment should also be taken into account. [EPA-HQ-OAR-2022-0829-0572, p. 6]

Therefore, Ferrari suggests that EPA aligns with the current California's emission standards and related phase-in provisions for SVMs. These SVM specific flexibilities should include the possibility for small volume manufacturers to: [EPA-HQ-OAR-2022-0829-0572, p. 6]

- meet alternate fleet-average standards of 0.051 g/mi for model years 2027 through 2032; [EPA-HQ-OAR-2022-0829-0572, p. 6]

- benefit from an alternative phase-in, which allows SVMs to defer 100% compliance with regulatory requirements at the end of the phase-in period granted to LVMs; [EPA-HQ-OAR-2022-0829-0572, p. 6]

- certify vehicles according to BIN 125 until MY 2032. [EPA-HQ-OAR-2022-0829-0572, p. 6]

We strongly believe that an alignment with ACC II criteria emissions standards would allow manufacturers to focus appropriate resources on zero emissions technologies. [EPA-HQ-OAR-2022-0829-0572, p. 6]

Organization: Ford Motor Company

Second, to ensure the final rule does not go too far and too fast, especially in 2027 – 2029, the EPA should adjust two aspects of the proposal regarding criteria emissions: fuel enrichment and particulate matter testing obligations. Although fuel enrichment can lead to higher emissions during brief and infrequent conditions which are disclosed to the EPA, fuel enrichment has been critical for overall emissions reductions. The practice enables automakers to downsize engines while also meeting consumer needs for some of the toughest jobs, without compromising powertrain durability. Removing fuel enrichment, as EPA has proposed, will directly impact customers' acceptance of new products, especially trucks, and they may keep their existing vehicle longer or opt for a larger (i.e., higher emitting) vehicle to be sure they can get the job done. Major powertrain redesigns would be needed to recover this lost utility, and these are not possible within the timeframe defined by the enrichment phase-out proposed by EPA. Next, although Ford supports aspects of EPA's proposed particulate matter (PM) standards which will necessitate the use of gasoline particulate filters, the proposed PM standard will challenge current laboratory equipment and procedures. Ford requests that the EPA eliminate the need to measure PM on the -7°C FTP for vehicles that are equipped with gasoline particulate filters. [EPA-HQ-OAR-2022-0829-0605, p. 3]

Light- and Medium-Duty PM Standards

Ford understands EPA's rationale in proposing a 0.5 mg/mi PM exhaust emission standard across the light-duty and medium-duty vehicle classes that would require gasoline particulate filters (GPFs). Ford does not oppose such a requirement if properly timed and implemented in a way that avoids undue test burden and costs, particularly during the early years of the transition to electrification. [EPA-HQ-OAR-2022-0829-0605, p. 13]

Ford does not support the newly proposed -7°C FTP PM testing requirement. Ford does not believe that the real-world environmental benefits justify the added development and certification test burden that accompanies such a requirement. Environmental test cells are already a facility bottleneck for OEMs, are prohibitively expensive to construct, and are not typically designed or instrumented to conduct gravimetric particulate matter testing. [EPA-HQ-OAR-2022-0829-0605, p. 13]

Furthermore, Ford believes that the benefit of requiring such testing on vehicles equipped with GPFs is de minimis given that the effectiveness of a given GPF technology will be sufficiently demonstrated on the 25°C FTP and US06 test cycles. Therefore, Ford recommends that EPA exempt GPF-equipped vehicles from the -7°C FTP testing requirement. [EPA-HQ-OAR-2022-0829-0605, p. 13]

Additionally, the proposed EPA standard will be at the edge—if not beyond—the capability of existing laboratory equipment and test processes capability. We recommend that EPA consider instituting additional measures to mitigate laboratory measurement variability including allowing re-tests for exceedances during certification, confirmatory and in-use testing. Ford would also like to work with EPA to determine if there is a role for limited application of particulate number measurements to help reduce the variability and test burden concerns related to the new PM standards. [EPA-HQ-OAR-2022-0829-0605, p. 13]

Finally, Ford recommends that EPA defer the phase-in requirement of the new PM standards to starting in 2029MY, consistent with the Ford recommendation for the new fuel enrichment requirements. [EPA-HQ-OAR-2022-0829-0605, p. 13]

Organization: Hyundai America Technical Center, Inc. (HATCI)

HMG emphasizes hardware changes will be necessary for the proposed 0.5mg/mi PM standard, and there will be packaging modification of after-treatment hardware to allow the addition of GPF and pressure sensors. Engine calibration will be required to account for increased backpressure. In fact, HMG estimates that just the additional hardware (cc-GPF, catalyst, sensors, valves, etc.) needed to comply with Tier 4 requirements will range from $500-$800 USD per vehicle. This estimated increase solely accounts for material costs, and does not include the additional costs involved with investments in technology development of the new hardware. The resources required to develop Tier 4 compliant hardware for ICE vehicles will unfortunately be moved away from ZEV development, and the vehicle cost increases caused by these additional components will undoubtedly increase ICE vehicle prices and delay advances in

ZEVs. This is a significant unintended negative consequence of the Proposed Rule. [EPA-HQ-OAR-2022-0829-0554, p. 5]

Finally, HMG is concerned that the global GPF market will be unable to meet increased demand for all original equipment manufacturers (OEMS) to meet this proposed PM requirement, with downstream consequences not for just HMG and other manufacturers, but also for customers and the market more broadly. [EPA-HQ-OAR-2022-0829-0554, p. 5]

Finally, the presence of accumulated PM in the vehicle exhaust system poses a significant challenge in demonstrating regulatory compliance during in-use emission tests. HMG' s thorough investigations have revealed that PM deposits in the vehicle exhaust systems accumulate over time and are subsequently released during aggressive in-use emission tests (US06 for example), resulting in an appearance of a non compliance condition. In-use PM testing without pre-conditioning will yield results that are not representative of the actual PM generated by combustion. [EPA-HQ-OAR-2022-0829-0554, p. 8]

In order to meet the increasingly stringent Tier 4 PM regulations, we strongly recommend that EPA incorporate an additional optional preparation driving mode, such as performing the US06 mode multiple times, prior to conducting the emission testing. This proposal is based on extensive testing and repeated experiments that have consistently demonstrated a noteworthy reduction in PM levels when this approach is implemented. By adopting this crucial change in the testing procedure, we can mitigate inaccurate and unreliable results, thus better confirming compliance with the regulations. [EPA-HQ-OAR-2022-0829-0554, p. 8]

HMG is concerned about the measurement accuracy and repeatability of the proposed 0.5 mg/mi for PM, and therefore opposes the PM requirements at -7°C conditions, or, in the alternative, proposes that at a minimum, vehicles equipped with gasoline particulate filters (GPF) should be exempt from the requirement. There is limited data available on the feasibility of accurately and repeatedly measuring PM at less than 0.5 mg/mi. HMG's own study reveals a test-to-test variation of up to 0.2 mg/mi in PM measurement repeatability, indicating that the proposed standard of 0.5 mg/mi is overly strict. [EPA-HQ-OAR-2022-0829-0554, p. 5]

Additionally, the environmental chamber needed for -7°C FTP testing presents several challenges that will render complying with the proposed PM standard extremely difficult. One major difficulty is that a test facility suitable for the -7°C FTP testing requirements would not be ready before CY2025, one year after the start of development of software and hardware that would comply with the new PM standard. Other issues related to the -7°C FTP are: [EPA-HQ-OAR-2022-0829-0554, p. 5]

Only a fraction of HMG's emission test cells are climate chambers capable of running the -7°C FTP [EPA-HQ-OAR-2022-0829-0554, p. 5]

Under low-temperature conditions, phenomena such as condensation, freezing, and contamination in the sample line and dilution tunnel can reduce accuracy and repeatability of PM filter weighing capability . [EPA-HQ-OAR-2022-0829-0554, p. 5]

It is very difficult to measure PM reliably. Compared to the 25°C FTP, measuring PM on the -7°C FTP test has greater test-to-test variability and will reduce dyno usage efficiency with frequent cleaning to prevent PM accumulated in the equipment from biasing the vehicles ' results. [EPA-HQ-OAR-2022-0829-0554, p. 5]

Significant investment would be required to update measurement systems required to determine compliance with the -7°C FTP testing, with extended lead-time required to complete the changes that are not available given the Proposed Rule's current compliance schedule. Again, these investments will also divert funds and chambers from electrification for little short-term gain. [EPA-HQ-OAR-2022-0829-0554, p. 5]

Due to the higher exhaust temperatures in gasoline engines, HATCI expects active regeneration frequency to be much lower than on diesel engines. As a result, the Infrequent Regeneration Adjustment Factor (IRAF) will be insignificant relative to the baseline emissions. EPA should provide exemption allowances with specific guidance on how to determine if gasoline IRAF is needed and requirements for calculating it to ensure clarity. [EPA-HQ-OAR-2022-0829-0554, p. 9]

Organization: International Council on Clean Transportation (ICCT)

For particulate matter emissions, ICCT strongly support's EPA's proposed PM limit. Fine particulate matter (PM2.5) emissions from vehicles are a major environmental health hazard, and setting a more stringent PM emissions limit is critical for protecting public health. We support EPA's proposed multipollutant rule that sets the PM limit at 0.5 mg/mile on all test cycles with the addition of the cold temperature FTP test cycle, which would help to greatly reduce tailpipe PM emissions from new gasoline vehicles. Based on our review of recent evidence of increasing PM emissions from recent model year gasoline light-duty vehicles and trucks, we find an urgent need to implement a stronger PM standard. Due to the urgent need to address the rise in PM emissions with recent gasoline vehicles, we recommend EPA adopt the accelerated phase-in pathway for the PM standard. [EPA-HQ-OAR-2022-0829-0569, p. 5]

Particulate matter emission [EPA-HQ-OAR-2022-0829-0569, pp. 47-50]

Recent trends in gasoline light-duty PM emissions [EPA-HQ-OAR-2022-0829-0569, pp. 47-50]

ICCT strongly support's EPA's proposed PM limit. Fine particulate matter (PM2.5) emissions from vehicles are a major environmental health hazard, and setting a more stringent PM emissions limit is critical for protecting public health. EPA's proposed multipollutant rule sets the PM limit at 0.5 mg/mile on all test cycles with the addition of the cold temperature FTP test cycle, which would help to greatly reduce tailpipe PM emissions from new gasoline vehicles. In this section, we review recent evidence of increases in PM emissions from recent model year gasoline light-duty vehicles and trucks, highlighting the urgent need to implement a stronger PM standard. [EPA-HQ-OAR-2022-0829-0569, pp. 47-50]

A recent ICCT analysis looking at remote sensing data shows that, for recent model years, light- duty vehicles and trucks show an increase in UV smoke, a proxy for PM.117 While gasoline light- duty vehicles' and trucks' tailpipe carbon monoxide (CO), hydrocarbons (HC), and nitrogen oxides (NOx) measured by remote sensing show clear and consistent downwards trends, UV smoke averages increase starting from model years 2015–2020 (Figure 13). For 2020 model year vehicles, the UV smoke fleet average is similar to that of 2005 model year vehicles, compared to the other three pollutants, which show a 66%–86% decrease from 2005 to 2020 model year vehicles. [EPA-HQ-OAR-2022-0829-0569, pp. 47-50]

117 Particulate matter mass emissions are not measured directly by remote sensing systems; instead, a measurement of UV smoke is recorded as a ratio of exhaust plume opacity measured at a wavelength of 230nm to fuel burned. UV smoke measurements are then used as a proxy for PM emissions to assess long-term relative trends. More detail is available in Meyer, M., Khan, T., Dallmann, T., Yang, Z. Particulate matter emissions from U.S. gasoline light-duty vehicles and trucks: TRUE Initiative U.S. remote sensing database case study. ICCT, June 2023. https://theicct.org/publication/true-pm-emissions-jun23/

SEE ORIGINAL COMMENT FOR Figure 13. Percent change in distance-specific emissions for various pollutants by model year for LDV and LDT combined, compared to model year 2005. Shaded region shows the 95% confidence interval. [EPA-HQ-OAR-2022-0829-0569, pp. 47-50]

The observed increase in model year average UV smoke levels is connected to a shift in fuel injection technologies. Gasoline Direct Injection (GDI) technology was first introduced to the U.S. LDV market in 2008 and gained momentum relatively quickly, largely due to the higher fuel efficiency and power compared to conventional port fuel injection (PFI) vehicles.118 As of 2021, GDI vehicles represent approximately 53% of the US LDV market. [EPA-HQ-OAR-2022-0829-0569, pp. 47-50]

118 U.S. EPA. (2022, December). The 2022 EPA Automotive Trends Report. https://www.epa.gov/system/files/documents/2022-12/420r22029.pdf

Early GDI vehicles (model years 2008-2014) showed at least 2 times higher PM emissions compared to PFI vehicles.119 This issue of elevated PM emissions from GDI vehicles and the need for more stringent regulation of PM emissions has been identified since before EPA finalized its Tier 3 standards in 2014.120 Recent analysis of remote sensing data adds to this evidence, showing that for 2015–2020 model year vehicles, the models showing UV smoke levels above the fleet average are predominantly GDI vehicles.121 [EPA-HQ-OAR-2022-0829-0569, pp. 47-50]

121 Meyer, M., Khan, T., Dallmann, T., Yang, Z. (2023) Particulate matter emissions from U.S. gasoline light-duty vehicles and trucks: TRUE Initiative U.S. remote sensing database case study. International Council on Clean Transportation. https://www.trueinitiative.org/data/publications/particulate-matter-emissions-from-us-gasoline-light- duty-vehicles-and-trucks

Additionally, chassis dynamometer measurements based on the U.S. EPA's certification tests database122 combined with information from the U.S. Department of Energy fuel economy test database123 demonstrate that PM emissions from GDI vehicles are higher than the PFIs on FTP cycle. An analysis by manufacturer for model years 2019–2023, shows that for most of the manufacturers that have sales for both GDI and PFI vehicles, GDIs have significantly higher PM emissions than PFIs on average (Table 9). On the FTP cycle, GDI vehicles emitted 62%–490% higher average emissions than PFI vehicles of the same manufacturer; on the US06 cycle, GDI vehicles emitted 16% lower to 130% higher average emissions than PFI vehicles of the same manufacturer.124 [EPA-HQ-OAR-2022-0829-0569, pp. 47-50]

International Council on Clean Transportation. https://www.trueinitiative.org/data/publications/particulate-matter-emissions-from-us-gasoline-light- duty-vehicles-and-trucks

SEE ORIGINAL COMMENT FOR Table 9. Average PM emissions (mg/mile) for GDI and non-GDI vehicles by manufacturer for 2019-2023 model year vehicles [EPA-HQ-OAR-2022-0829-0569, pp. 47-50]

Additionally, an analysis of certification test data across all light-duty vehicles shows that PM emissions from GDI vehicles have been reducing over the years; however, they still emit higher PM than PFI vehicles on FTP cycle (Figure 14). For 2023 model year vehicles, GDI vehicles emit on average about 3 times more PM emissions than the PFI vehicles on FTP cycle. For both cycles, the trajectory of average PM emissions for GDI vehicles flattens out over the last few years, suggesting that PM emissions from GDIs will not likely reduce substantially any further without the adoption of more stringent emission standards. [EPA-HQ-OAR-2022-0829-0569, pp. 47-50]

SEE ORIGINAL COMMENT FOR Figure 14. Trend of average PM emissions for US LDV based on EPA certification database for GDI and PFI vehicles under the FTP and US06 regulatory cycles. [EPA-HQ-OAR-2022-0829-0569, pp. 47-50]

Evaluation of proposed PM standard [EPA-HQ-OAR-2022-0829-0569, pp. 50-53]

The real-world and laboratory test data analyses presented above show the issue of increased PM emissions from GDI vehicles, highlighting the need for a more stringent standard than the current Tier 3 standard to prevent a continued increase in PM emissions. EPA’s proposal for PM standards aligns with this finding; we strongly support the proposed stringency level of 0.5 mg/mile on all test cycles and the addition of the cold temperature FTP test cycle for regulating PM emissions. [EPA-HQ-OAR-2022-0829-0569, pp. 50-53]

Table 10 shows that EPA’s proposed limit for PM emissions is more stringent than the California’s most recently enacted LEV IV standards and, also, numerically lower than the proposed Euro 7 standards in EU and the existing standards in China and India. However, EU, China, and India have the additional particle number (PN) standards to regulate the ultrafine particulates. [EPA-HQ-OAR-2022-0829-0569, pp. 50-53]

The PN limits in the EU, China, and India regulations, combined with the particle mass limit, effectively regulate both fine particulates (PM2.5) as well as ultrafine particulates (PM0.1).129 These particles, less than 100 nm in size, have been found to be even more dangerous to human health than PM2.5, as they can be inhaled deeper into the lungs, increasing the chances of particles to entering the bloodstream.130 Part of the motivation for the stringent particulate regulations in the EU and China has been the uptake of GDI vehicles, as GDIs have been found to emit more ultrafine particulates down to a size of 23 nm and can emit even smaller particles (sub 23 nm).131 [EPA-HQ-OAR-2022-0829-0569, pp. 50-53]

While EPA's proposed standard does not include a particle number limit, the stringency of the PM emission standard will help address both PM2.5 and PM0.1 through the implementation of gasoline particulate filters (GPFs). EPA suggests that the proposed PM emissions limit, particularly for the cold FTP test, will likely force the installation of gasoline particulate filters (GPF).132 Studies have demonstrated the effectiveness of GPFs for reducing both PM and PN emissions, showing that GPFs can reduce PM emissions by 97% to 100% and PN emissions by 80% to 99% compared to vehicles without GPFs.133 Other major vehicle markets, including the EU and China, have already begun adopting GPFs to meet stringent particulate emission standards, and the proposed standard would help the US vehicle market follow suit. The European Commission (2022) reported that the Euro 6d standards, which has led to the near-universal adoption of GPFs to meet the PN limits for GDI vehicles, reduced the real-world emission factors of exhaust particles by about 86% compared to Euro 5 compliant vehicles.134 The assessment also reported a typical reduction level of PN emissions by 70% to 80% for a Euro 6 GDI installed with a GPF and tested on the Real-Driving Emissions (RDE) test route. 134 European Commission. (2022, October). Euro 6/VI evaluation study: Annexes 1-6.

GPFs are cost-effective devices, with per vehicle manufacturing cost of $51–$166 based on EPA estimates and $50–$184 based on other independent studies.135 Based on the European Commission's Euro 6/VI assessment, the incremental increase in technology cost per vehicle for Euro 6 standards compared to Euro 5 was estimated at $92–$113 for the addition of GPF along with lambda and pressure sensors (currency converted to U.S. dollars, 1 Euro = 1.10 US$ as of June 21, 2023).136 Thus, EPA's proposed PM standard would provide large health benefits through reduced fine and ultrafine particulate matter emissions with a relatively low added manufacturing cost. This is in line with the European Commission's finding that the Euro 6 benefits from PM and PN emissions reduction were significantly higher than the added cost for GPF per vehicle.137 [EPA-HQ-OAR-2022-0829-0569, pp. 50-53]

137 ibid

Testing of recent European petrol cars provides evidence that the proposed PM limit is achievable. Cars certified to recent Euro standards have showed PM levels close to the proposed US 0.5 mg/mile limit. ADAC, a German automobile association, conducted laboratory tests, which showed that out of 177 gasoline vehicles certified to Euro 6d-TEMP and Euro 6d standards, 74 vehicles, or 42%, showed PM emissions below 0.5 mg/mile.138 Additionally, the UK Department for Transport conducted laboratory testing of five 2019 model year petrol vehicles.139 Under the hot start Worldwide Harmonized Light Vehicles Test Cycle (WLTC) test, the cars emitted 0.09–0.28 mg/km (0.14–0.45 mg/mile), all below 0.5 mg/mile. Under the cold start WLTC test, the cars emitted 0.16–0.446 mg/km (0.26–0.72 mg/mile); two cars emitted under 0.5 mg/mile, and the other three showed PM emissions of no more than 44% above 0.5 mg/mile. Although these results are not directly comparable to the US standard due to differences in test cycles (WLTC instead of FTP and US06), this evidence demonstrates that there already exist vehicles with PM emissions levels similar to the proposed US PM limit. [EPA-HQ-OAR-2022-0829-0569, pp. 50-53]

138 These results are based on averages of three tests: hot start Worldwide Harmonized Light Vehicles Test Cycle (WLTC), cold start WLTC, and BAB 130, which is ADAC's highway cycle. Data was kindly provided by ADAC via email correspondence (2023).

(London, UK). https://www.gov.uk/government/publications/vehicle-market-surveillance-unit-programme-results- 2020/vehicle-market-surveillance-unit-results-of-the-2020-programme#results-petrol-cars

We support the EPA's accelerated phase-in option for PM standards relative to other pollutants, particularly considering evidence of rising gasoline light-duty vehicle and truck PM levels. Analysis of remote sensing UV smoke measurements as a proxy for PM shows that reductions since 2005 model year vehicles have been virtually eliminated due to an increase from 2015 to 2020 model year vehicles. Therefore, it is critical that a more stringent PM standard is implemented as soon as possible to drive the uptake of GPFs. GPFs are at a mature phase and in large-scale production in several vehicle markets and thus would be feasible to implement according to EPA's outlined accelerated timeline, which would phase-in the proposed PM standards for 50% or 80% of the manufacturer's fleet by 2027 and 100% by 2028. Due to the urgent need to address the rise in PM emissions with recent gasoline vehicles, we recommend EPA to adopt the accelerated phase-in pathway for the PM standard. [EPA-HQ-OAR-2022-0829-0569, pp. 50-53]

Health benefits and environmental justice modeling recommendations [EPA-HQ-OAR-2022-0829-0569, pp. 53-54]

In evaluating the health benefits of the proposed rule, it is critical to consider the evidence of increases in PM from recent model year vehicles. The health benefits assessment included in EPA's proposal uses emission factors from MOtor Vehicle Emission Simulator (MOVES), which likely underestimates PM emissions from recent model year vehicles. Figure 15 shows a comparison between EPA MOVES emission factors and remote sensing UV smoke averages by model year, shown as a percent change from each sources respective model year 2005 averages.140 From model years 2006–2015, year-to-year changes, shown in the slopes of the lines, are relatively consistent between EPA MOVES and remote sensing data. However, from model year 2015 on, the trends diverge. For light-duty passenger trucks, the EPA MOVES PM emission factors sharply decline while the remote sensing data show an increase in UV smoke averages.141 Though less significant, a similar trend is observed for passenger cars, with the EPA MOVES PM emission factor continuing to decline after 2015 and remote sensing UV smoke averages showing a slight increase. These findings suggest that the modeled air quality and health benefits of the proposed rule may be underestimated when considering the large benefits of replacing 2015–2020 model year vehicles with future vehicles meeting the proposed PM emission limits. [EPA-HQ-OAR-2022-0829-0569, pp. 53-54]

140 EPA MOVES emission factors are converted from fuel-specific to distance-specific emission factors for this comparison. This is done using real-world fuel economy data from EPA Automotive Trends report, the same source used to convert the remote sensing emissions from fuel-specific to distance-specific.

141 Light-duty passenger truck emission trends from EPA MOVES are compared to light-duty truck (LDT) emission trends from remote sensing data. Similarly, passenger car emission trends from EPA MOVES are compared to light-duty vehicle (LDV) emission trends from remote sensing data.

SEE ORIGINAL COMMENT FOR Figure 15. Percent change in distance-specific PM emission factor from EPA MOVES and remote sensing (RS) UV smoke measurements from Colorado (CO) and Virginia (VA) sources by model year, compared to model year 2005. [EPA-HQ-OAR-2022-0829-0569, pp. 53-54]

Additionally, a full assessment of relative air quality and health benefits across demographics, as done for the heavy-duty multi-pollutant rule, is recommended for this light-duty and medium-duty multi-pollutant rule. It is widely understood that heavy-duty vehicles contribute to racial disparities in exposure to air pollution, and EPA reported the projected air quality impacts across demographics in their finalized heavy-duty multi-pollutant rule. Inequities in air pollution exposure exist for light-duty vehicle emissions as well. One study finds that on a national level, people of color are exposed to 46% more ambient PM2.5 from light-duty gasoline vehicles than White people.142 This is a greater disparity than that of HDVs; the same study finds that people of color exposed to 35% higher ambient PM2.5 levels from heavy-duty diesel vehicles compared to White people. Additionally, the health benefits from the heavy-duty multipollutant rule, as projected by the EPA, are on similar scales to that of the proposed light-duty and medium-duty vehicle rule.143 Thus, as the environmental justice and health implications of the light-duty and medium-duty vehicle rule are significant, a full assessment of the projected distribution of changes in PM2.5 and ozone concentrations by geography, race/ethnicity, and income is recommended for the finalized rule. [EPA-HQ-OAR-2022-0829-0569, pp. 53-54]

142 Tessum, C et al. (2021). PM2.5 Polluters Disproportionately and Systemically Affect People of Color in the United States," Science Advances 7, no. 18: eabf4491, https://doi.org/10.1126/sciadv.abf4491.

143 EPA's proposed light-duty and medium-duty rule is estimated to result in $63 billion and $280 billion (for 7% and 3% discount rates, respectively) in total monetized health benefits from 2027 to 2055. EPA's finalized heavy-duty multipollutant rule is projected to result in $53–150 billion and $91–260 billion (for 7% and 3% discount rates, respectively) in total monetized health benefits from 2027 to 2045.

Organization: John Graham

The heavier weight of BEVs not only increases cost, but also generates higher tire wear and brake wear particulate emissions. These impacts were not considered in the proposed rule.32 [EPA-HQ-OAR-2022-0829-0585, p. 21]

32 DRIA Section 9.6 page 9-26 states only, "Using the miles traveled (for tailpipe, tire wear and brake wear emissions) and liquid fuel consumed (for evaporative and fuel spillage emissions), we can then generate sets of emission rates for use in OMEGA." This suggests that weight was not a factor in evaluating tire wear and brake wear emissions.

Organization: Kia Corporation

Kia Urges PM Standards to Align with CARB's PM Emissions Standards Under ACC II

Kia does not support a more stringent PM standard of 0.5 mg/mi that must be met across three test cycles (25 °C Federal Test Procedure (FTP), US06, -7 °C FTP) and is required to be met as a per-vehicle cap, not a fleet average.17 EPA's proposal of 0.5 mg/mi per-vehicle cap will require a gasoline particulate filter (GPF) on every vehicle. Because GPF technology will be necessary for meeting the proposed PM standard, OBD monitoring of the GPF system will be required to detect GPF malfunctions, store trouble codes, and alert operators.18 [EPA-HQ-OAR-2022-0829-0555, pp. 10-11]

17 88 Fed. Reg. 29,264.

18 88 Fed. Reg. 29,269.

Kia strongly urges EPA to align with CARB's PM standards adopted under the ACC II (i.e., LEV program. Kia recommends eliminating the -7°C FTP requirement because it unnecessarily adds to automakers' testing burden, requires large investments, and upgrades, and reduces test validity rate. [EPA-HQ-OAR-2022-0829-0555, pp. 10-11]

Kia understands the importance of PM standards and has invested significantly over the years to ensure our vehicles meet the PM standards that result in 90 percent reduction in PM emissions – from 10 mg/mi to just 1 mg/mi in MY2028. CARB evaluated for years increasing the stringency of their PM standard but decided against it when finalizing a PM standard for ACC II. EPA's proposed PM standard of 0.5 mg/mile is beyond expectation for automotive manufacturers and emissions labs. The emissions labs across the industry are still learning how to accurately measure PM at the 3 mg/mile standard due to the uncertainty involved in all the processes leading to final PM results in mg/mile. [EPA-HQ-OAR-2022-0829-0555, pp. 10-11]

Kia is concerned about the feasibility and repeatability of the measurement accuracy of the proposed 0.5 mg/mi standard. Because of these challenges there will also be challenges and additional cost of OBD-II diagnostic development, implementation, and calibration for meeting the standards. Consequently, Kia recommends considering laboratory PM measurement variability and allowing re-test for exceedances during certification, confirmatory or in-use testing, especially for vehicles equipped with Diesel or GPFs. We urge EPA to finalize reasonable PM standards to allow automakers to focus new capital investments on the transition to vehicle electrification. [EPA-HQ-OAR-2022-0829-0555, pp. 10-11]

Kia urges EPA to adopt CARB's criteria emission standards under the ACC II (i.e., LEV IV) and, similarly, to fully harmonize its OBD-II requirements with CARB's OBD-II requirements. It is critical that the criteria emissions regulatory framework is streamlined. Again, since EPA is requiring a 10-fold increase in EV sales, EPA needs to harmonize and streamline its criteria pollutants standards as much as possible. Resources should not be diverted away from the ultimate goal – transitioning successfully to electrification. [EPA-HQ-OAR-2022-0829-0555, p. 15]

Organization: Marathon Petroleum Corporation (MPC)

EPA should better understand Particulate Matter Index (PMI) correlation by fully researching fuel distillation properties of gasolines available today to consumers. If EPA were to proceed with changes to gasoline distillation properties, this change will limit gasoline production resulting in financial impacts to consumers and refiners. [EPA-HQ-OAR-2022-0829-0593, p. 2]

Organization: Mazda North American Operations

Criteria

Mazda anticipated some changes to EPA's light duty vehicle criteria emissions (i.e., NMOG, CO, NOx, PM) requirements, particularly to align with the new changes in the California Air Resources Board's (CARB) recent Advanced Clean Cars II regulation. However, we did not expect two of the new requirements included in the proposal: the reduction of the PM standard to 0.5 mg/mile, and the ban of enrichment during normal engine operation. [EPA-HQ-OAR-2022-0829-0595, p. 3]

Reducing the PM standard to 0.5 mg/mile is excessive. There was already considerable difficulty and effort put into meeting CARB's planned 1mg/mile PM standard, and there is still uncertainty that the 0.5 mg/mile standard will be measurable using current laboratory technology. It will also make it necessary to have all vehicles equipped with Gasoline Particulate Filters (GPF) and the resulting cost and development resources that come with new hardware. CARB evaluated the PM standards in its ACC II regulation and only reduced them to 1 mg/mile for the US06 cycle. While GPFs are required in some other markets, CARB set the standards with the intention that they would only be necessary for some limited cases. [EPA-HQ-OAR-2022-0829-0595, p. 3]

The enrichment ban will significantly impact the power and robustness of current internal combustion engines and Mazda strongly opposes it. This could force manufacturers such as Mazda to develop new engine designs, or to eliminate certain powertrain or vehicle designs entirely, making it even more difficult to remain profitable at a time when exceptional investment is needed to fuel the transition to EVs and to satisfy consumer needs. Controlling unnecessary or excessive enrichment is already sufficiently covered by EPA's existing AECD certification processes. [EPA-HQ-OAR-2022-0829-0595, p. 3]

For these reasons, Mazda feels that the best course is for EPA to adopt CARB's current LEV IV requirements. Long a leader in regulations that reduce tailpipe emissions, CARB's regulation is challenging on its own and will lead to further improvements in the vehicle fleet. Taking this course will also better align EPA's regulations with CARB's. Since CARB regulations already impact about 40% of nationwide sales, this will also create economies by Mazda having to develop vehicles to only one standard for criteria emissions. In this way, more resources can be focused on the development of EV and PHEV products. [EPA-HQ-OAR-2022-0829-0595, p. 3]

Organization: MECA Clean Mobility

PM requirements should be implemented at a faster pace based on the combination of the predicted rate of electrification alongside a feasible rate of PM emission control technology implementation. [EPA-HQ-OAR-2022-0829-0564, pp. 5-11]

On January 6, 2023, EPA announced its proposed decision to revise the primary (health-based) annual PM2.5 standard from its current level of 12.0 µg/m3 to within the range of 9.0 to 10.0 µg/m3. In September 2021, both the United Nations World Health Organization2 (WHO) and the Health Effects Institute (HEI) concluded that there is no identified safe threshold for PM2.5 or black carbon, at which no damage to health is observed. In particular, the HEI announced3 that a recent European study using state-of- the-art exposure methods and large cohorts in high income countries found that health impact risks were still evident at levels lower than current ambient standards for PM2.5, NO2 and O3. In particular, the study reported that the hazard ratios for natural-cause mortality remained elevated and significant for PM2.5 even when the analyses were restricted to observations below 12 µg/m.3 [EPA-HQ-OAR-2022-0829-0564, pp. 5-11]

2 World Health Organization. (2021). WHO global air quality guidelines: particulate matter (PM2.5 and PM10), ozone, nitrogen dioxide, sulfur dioxide and carbon monoxide. World Health Organization. https://apps.who.int/iris/handle/10665/345329.

3 https://www.healtheffects.org/announcements/hei-study-europe-finds-evidence-health-effects-lower-levels-air-pollution

University researchers in the U.S. have reported that light duty gasoline vehicle emissions remain prominent amongst the emission source sectors that cause the largest absolute disparities for persons of color communities (POCs include Blacks, Hispanics, and Asians).4 These latest developments highlight the importance of continued tightening of the PM2.5 standards to further reduce exposure and the impacts of the remaining light duty gasoline fueled vehicles on underserved communities. [EPA-HQ-OAR-2022-0829-0564, pp. 5-11]

4 https://www.science.org/doi/10.1126/sciadv.abf4491.

To meet tightening particulate standards in other global regions, including Europe, China and India, fuel injection and gasoline particulate filter (GPF) suppliers have continued to improve their commercially available technologies. In fact, nearly every European GDI engine car is currently certified with a GPF, and LDVs in Europe have been required to meet the approximate equivalent of a 0.5 mg/mile standard since 2017 due to the implementation of a particle number standard. This standard applies to nearly all driving conditions and cycles. China has gone as far as requiring all diesel and gasoline cars to be equipped with the best available control technology, based on wall flow filters, that diesels have used in the US since 2007. [EPA-HQ-OAR-2022-0829-0564, pp. 5-11]

By 2023, four years ahead of the start of EPA's proposed PM limit implementation phase-in, two-thirds of the major automotive producing regions of the world will be meeting tighter PM emission standards similar to those now proposed by EPA. Recent in- use particle mass measurements made from four equivalent vehicle pairs compliant with current U.S. and U.K. standards5 illustrate the potential particulate mass reductions that could be obtained from adopting equally protective standards as those in Europe, China and India (Figure 1) [See original comment for Figure 1. In-use Particle Mass Comparison from four equivalent vehicle pairs compliant with current U.S. and U.K.]. [EPA-HQ-OAR-2022-0829-0564, pp. 5-11]

5 https://www.emissionsanalytics.com/news/the-septillion-particle-problem-literally

In addition, future Euro 7 standards are expected to further tighten the particle number limit to 1x10^11 per km (ca. <0.5 mg/mile) and regulate solid ultrafine particles down to 10 nm in diameter7 to reflect the feasibility of the control technologies. Euro 7 regulations will likely also expand the operating window to include lower temperature operation, higher altitude and towing. In anticipation of these tighter limits over extended duty operation, suppliers have improved fuel injection6,7 as well as diesel and gasoline particulate filters8 and some OEMs are already achieving these tighter limits in Europe as presented by the CLOVE consortium to the Advisory Group on Vehicle Emission Standards in 2020.9 [EPA-HQ-OAR-2022-0829-0564, pp. 5-11]

To highlight the air quality benefits of more stringent PM requirements, MECA funded a study10 to model the benefits of a national 0.5 mg/mile PM standard that is approximately equivalent in mass to the particle number standard in other global regions. The environmental impact of the modeled standards was evaluated for the 49-state plus District of Columbia modeling domain using EPA references and tools. The domain was divided into separate certification regions of seventeen Section 177 states (i.e., those that have adopted California standards) and thirty-two states plus DC11 subject solely to federal certification requirements. Importantly, the magnitude of the emission inventory impact of the modeled standards is significantly influenced by the degree to which the light-duty fleet becomes electrified. The rate of future-year electrification, an uncertain modeling variable, was handled as a range by defining the following 3 scenarios. [EPA-HQ-OAR-2022-0829-0564, pp. 5-11]

10 https://www.meca.org/wp-content/uploads/2023/06/LDV_PM_Standard_Final_Report_06272023.pdf

11 DC enacted California standards by December 2022, after the impact assessment had commenced.

- Low range electrification was defined by the electrification forecast of new vehicle sales as completed in the Energy Information Agency (EIA) Annual Energy Outlook 2022 (AEO2022). This represents approximately 17% new vehicle sales in 2050. [EPA-HQ-OAR-2022-0829-0564, pp. 5-11]

- Mid range electrification was defined by a 10 to 15-year delay in achieving the high range scenario targets (by sector) with 100% electrification of all on-road sales by model year 2060. [EPA-HQ-OAR-2022-0829-0564, pp. 5-11]

- High range electrification was defined by the electrification rate if all California zero emission vehicle regulations as well as all federal executive orders and memoranda of understanding were achieved. This scenario achieves 100% electrification of all on-road sales by model year 2050 with key sector sales becoming fully electrified as early as model year 2035 (i.e., light-duty vehicles sold in the California certification region). [EPA-HQ-OAR-2022-0829-0564, pp. 5-11]

Figure 2 [See original comment for Figure 2. Annual Emission Inventory Impact] summarizes the annual PM2.5 and BC inventory impacts for the modeling domain for the years 2025 to 2060. Up to an estimated 7 and 10 thousand tons/year of BC and PM2.5 exhaust from internal combustion engine (ICE) vehicles would be eliminated in each year. In the fully phased-in fleet (i.e., CY2060), the pollutant benefits are equal to reductions in the light-duty fleet of 91 and 85% for exhaust BC and PM2.5, respectively. Moreover, the continuation of benefits to CY2060 results indicate that the environmental impact of emission controls on internal combustion engines will be significant well into the future – independent of the electrification rate scenario. [EPA-HQ-OAR-2022-0829-0564, pp. 5-11]

Cumulative heath impact valuations, based on recently updated EPA data from the 2012 PM National Ambient Air Quality Standards (NAAQS) revision, are summarized in Figures 3, 4 and 5 [See original comment for Figure 3: Cumulative Impact, Low Range Electrification; Figure 4: Cumulative Impact, Mid Range Electrification; and Figure 5: Cumulative Impact, High Range Electrification] for the low, mid and high electrification scenarios, respectively. The total health valuation, due to the reduced frequency of health incidences under the modeled regulatory case, results in estimated health cost savings of between 18 billion and 163 billion dollars (cumulative through 2050). The range in total valuation is due to (1) incidence rates defined as a range, (2) the discount rate defined as a range, (3) monetary benefits by incidence defined as a range, and (4) the range in PM2.5 benefit realized by electrification rate scenario. These health cost savings come from the estimated 58 to 112 thousand tons of cumulative PM2.5 benefits under the modeled regulatory case. [EPA-HQ-OAR-2022-0829-0564, pp. 5-11]

Within these PM2.5 benefits, an estimated 42 to 81 thousand tons of black carbon would be eliminated. Another way to look at the comparative cumulative benefits presented in Figures 2 and 4 suggests that deploying a regulatory control strategy that includes a combination of electric vehicle penetration and best available exhaust controls on the remaining combustion vehicles approximately doubles the PM2.5 reductions achievable by electrification alone (112 versus 58 thousand tons of PM2.5 or 81 versus 42 thousand tons of BC). [EPA-HQ-OAR-2022-0829-0564, pp. 5-11]

Given the majority of the global vehicle market has, for many years, been deploying commercially available technologies to achieve PM standards more stringent than those proposed by EPA, MECA recommends a more rapid phase-in schedule than EPA's proposed rate of 40%/80%/100% in MY 2027/2028/2029. Rather, we support a schedule of 60% in MY 2027, 90% in MY 2028 and 100% in MY 2029. The basis for this phase in rate is a combination of EPA's assumed rate of electric vehicle penetration and EPA's proposed phase-in rate for the remainder of the ICE sales fleet. In MY 2027, EPA assumes 37% BEV sales. If the remaining ICE vehicle share (63%) is multiplied by the 40% phase-in and added to the 37% BEV share, the total feasible rate of PM standard phase-in is 62.2%. In MY 2028, EPA assumes 45% BEV sales. If the remaining ICE vehicle share (55%) is multiplied by the 80% phase-in and added to the 45% BEV share, the total feasible rate of PM standard phase-in is 89%. [EPA-HQ-OAR-2022-0829-0564, pp. 5-11]

Organization: Mercedes-Benz AG

EPA has proposed to issue a near-zero Particulate Matter ("PM") standard of 0.5 mg/mile. This standard goes beyond the already challenging CARB ACCII rule which phases-in to 1.0 mg/mile. A requirement set at this level would force the incorporation of Gas Particulate Filters ("GPFs") in all vehicles, as well as required On-Board Diagnostic ("OBD") GPF monitoring. [EPA-HQ-OAR-2022-0829-0623, p. 4]

Mercedes-Benz is already developing vehicles that will meet the CARB 1.0 mg/mile PM standard and will need to pivot to design to the 0.5 mg/mile standard. Mercedes-Benz recognizes and supports EPA's goal for emissions reductions but are concerned EPA's proposed PM standard will draw funding and attention away from the electrification of our fleet. In particular, it does not allow for a GPF drop-in solution, as EPA suggests, because EPA's proposed standard, OBD requirements, and new testing requirements will require new and additional research and development in order to comply. [EPA-HQ-OAR-2022-0829-0623, p. 4]

Beyond the additional effort needed to incorporate this new GPF hardware on vehicles, there is also a challenge presented from the measurement uncertainty for PM readings during test cycles. It is also worth noting that it is difficult if not impossible to replicate EPA's test conditions, because our dynamometers and test facilities are under high usage, for multiple scenarios (i.e., development, compliance and in-use). The following diagram illustrates this difficulty with PM readings and design thresholds. The figure on the left shows constraints on vehicles' emissions under the CARB ACCII 1.0 mg/mile standard. The background noise and measurement uncertainty take up 0.19 mg/mile at the bottom of the figure while a necessary 30% engineering buffer to the standard claims another 0.3 mg/mile from the top. This leaves just 0.51 mg/mile PM that the vehicle can emit and still confidently comply with a 1.0 mg/mile standard. [EPA-HQ-OAR-2022-0829-0623, pp. 4-5]

The diagram on the right shows how this challenge is magnified under EPA's proposed 0.5 mg/mile standard. The 0.19 mg/mile variability and 30% buffer remain, but the vehicle is now left with only 0.16 mg/mile PM that it can emit and still confidently comply with the standard. Even with application of a GPF that significantly lowers PM emissions, the variability and capabilities of our laboratories to measure to 0.16 mg/mi is likely problematic without significant investments in laboratory facilities, and even new test cells. This type of investment is counter to

EPA's goals to encourage electric vehicles or the intent to provide a drop-in technology. [EPA-HQ-OAR-2022-0829-0623, pp. 4-5]

[See original for graphic on the impact of EPA's 0.5mg/mile standard on vehicles] [EPA-HQ-OAR-2022-0829-0623, pp. 4-5]

Given the difficulty of designing and testing to such a low standard, Mercedes-Benz recommends the EPA align with the CARB ACCII standards for light-duty vehicles. The LEV IV LDV PM standard provides regulatory uniformity between the agencies and aligns with industry efforts, and investments already underway to develop to this standard. [EPA-HQ-OAR-2022-0829-0623, pp. 4-5]

At such a low standard level, high dynamics of some tests and the resulting high exhaust gas mass flow can lead to other particles, such as humidity, diesel exhaust fluid (DEF), and hydrocarbon particles, collecting on the filter plate in addition to soot particles. Due to the amorphous property of soot, the highly volatile particles do not outgas during conditioning. EPA should not apply the -7°C test, which significantly increases test burden and introduces concerns with the influence of humidity on particulate matter detection. Also, this requirement does not provide any additional emissions benefits. [EPA-HQ-OAR-2022-0829-0623, pp. 18-19]

Finally, EPA should not apply the -7°C test, which significantly increases test burden but does not additional emissions benefits. [EPA-HQ-OAR-2022-0829-0623, pp. 5-6]

EPA should adopt the PM limits already established by CARB during their ACCII rulemaking. This adoption would align with research and development dollars already committed in this space, ensure inclusion of all MDV powertrains, and provide real and significant PM reductions in the MDV segment. As importantly, this alignment would also ensure MDV funding for electric vehicle development is not diverted. [EPA-HQ-OAR-2022-0829-0623, pp. 18-19]

If the agency still pursues a GPF requirement, then additional flexibility with the standard level and testing conditions is needed. First, the agency should allow manufacturers to optionally perform multiple tests to determine compliance. For example, using statistical confidence a manufacturer might run five certification tests. If the average of these five tests is below the 0.5 mg/mile standard then the vehicle is considered compliant. Outlier tests may be rejected, considered resulting from the high variability of this testing and measurement process. [EPA-HQ-OAR-2022-0829-0623, pp. 5-6]

Second, EPA should reconsider the level of the standard, taking into consideration testing variability and necessary compliance margins. The agency could also consider incorporating a Conformity Factor ("CF") into the regulation to provide flexibility accounting for the background emissions and variability in testing. As seen in the figure below, the background contamination and inherent process variability could be added to the standard, bringing the requirement up from 0.5 mg/mile + 0.19 mg/mile to ~ 0.7 mg/mile. This adjustment would provide critical compliance room in the standard, avoid costly laboratory upgrades, and more closely align to the drop-in technology solution EPA envisions. At the same, this requirement will still push GPF technologies into the U.S. market. [EPA-HQ-OAR-2022-0829-0623, pp. 5-6]

[See original for graphic on the proposed revisions to the rule] [EPA-HQ-OAR-2022-0829-0623, pp. 5-6]

Vehicles produce extra emissions during a regeneration as the filter is being purged, but this regeneration process does not occur every time a vehicle is driven. For vehicles with infrequent regeneration events, the EPA provides for the use of an Infrequent Regeneration Adjustment Factor ("IRAF"). This factor is calculated by determining the vehicle regeneration interval, or average miles driven between regenerations, and the amount of additional emissions produced during a regeneration event. Those additional emissions are then distributed across the regeneration interval to develop an emissions result for certification purposes. [EPA-HQ-OAR-2022-0829-0623, pp. 11-12]

The situation is more challenging for GPFs. The majority of PM emissions are produced during the cold start portions of testing. And in systems with close-coupled catalysts, the filter temperature is high enough to allow passive regeneration during fuel cut-off. Putting these two conditions together, a standard road cycle can result in negative soot accumulation instead of positive. Negative soot accumulation makes regenerations very rare, and thereby makes it particularly challenging to perform OBD regeneration diagnostics. [EPA-HQ-OAR-2022-0829-0623, pp. 11-12]

Mercedes-Benz requests the agency provide an exemption from both the regeneration diagnostic requirement, as well as the Additive Adjustment Factor ("AAF") for vehicles with passive infrequent regenerations. The EPA might consider reviewing the EU Commission Regulation 2017/1151,9 which exempts vehicles with regeneration intervals exceeding 4000 km from providing an AAF. It is important to note that this European requirement allows for an attestation up to 4000 km. [EPA-HQ-OAR-2022-0829-0623, pp. 11-12]

9 https://eur-lex.europa.eu/legal-content/EN/TXT/?uri=CELEX%3A02017R1151-20200125.

EPA should define IRAF for infrequently regenerating gasoline systems. This definition is critical to recognizing GPF technology functionality and providing clear direction for OBD implementation. [EPA-HQ-OAR-2022-0829-0623, p. 12]

-The agency should also provide clear definitions for both passive and active regeneration for gasoline systems, and details on how to distinguish the two. Mercedes-Benz is currently developing suggested language to provide at a later time. [EPA-HQ-OAR-2022-0829-0623, p. 12]

-While a denominator for regeneration is not needed for gasoline engines, the agency should include one for diesel engines. We suggest the agency include a 500-mile denominator for diesel engines. [EPA-HQ-OAR-2022-0829-0623, p. 12]

-EPA should provide a definition of the difference between periodically regenerating and infrequently regenerating systems, whether this be in number of miles or number of FTPs. [EPA-HQ-OAR-2022-0829-0623, p. 12]

Leaving the testing procedures to each manufacturer to define adds unnecessary complexity and may result in an unlevel playing field if different manufacturers' processes diverge. Therefore, clear definitions and procedures are essential. [EPA-HQ-OAR-2022-0829-0623, p. 12]

Organization: Mitsubishi Motors North America, Inc. (MMNA)

6. Tier-4 criteria Pollutant Emissions

Mitsubishi echoes Auto Innovators' support for EPA's adoption of the California ACC II (i.e., LEV-IV) criteria test procedures and standards. [EPA-HQ-OAR-2022-0829-0682, p. 9]

Mitsubishi supports cost-effective reductions in criterial pollutant emission from Internal Combustion Engines (ICE). However, some of EPA's proposed changes to the criteria emission standards - like the more stringent Particulate Mass (PM) and NMOG+NOx requirements and the enrichment prohibition - go above and beyond those adopted by CARB in ACC II standards. If finalized as proposed, these changes would require OEMs to divert large resources in time and capital (resources that could otherwise be directed to accelerate EV technology deployment) towards further ICE technology development and additional testing facilities. Mitsubishi believes that allowing OEMs to focus their finite R&D investments on developing EV technologies, rather than having to continue to invest in technology that is being phased out, is the most effective way to reach our shared goal to transition to electrification. [EPA-HQ-OAR-2022-0829-0682, p. 9]

Organization: National Association of Clean Air Agencies (NACAA)

Criteria Pollutant Emission Standards and Related Issues

For reasons cited above, NACAA strongly supports EPA's proposal of more protective emission standards for non-methane organic gas (NMOG)+NOx and for PM. [EPA-HQ-OAR-2022-0829-0559, pp. 6-7]

With respect to PM, EPA proposes a standard of 0.5 mg/mi for LDVs and MDVs, with a requirement that this standard be met across three duty cycles, including a cold-temperature (-7°C) cycle. Such a standard will appropriately drive the use of gasoline particulate filters, which are readily available. EPA projects that making these revisions to the standards set by the agency in the 2014 Tier 3 rule would reduce PM emissions from ICE vehicles by more than 95 percent and also yield reductions in toxic air pollutants. [EPA-HQ-OAR-2022-0829-0559, pp. 6-7]

Organization: National Automobile Dealers Association (NADA)

EPA also proposes non-methane organic gases plus nitrogen oxides (NMOG+NOx) standards that represent a 60 percent reduction from the existing MY 2025 light-duty standards and a 66 to 76 percent reduction for medium-duty vehicles.7 And for both light- and medium-duty vehicles, EPA's proposed standards project to reduce particulate matter emissions by more than 95 percent.8 [EPA-HQ-OAR-2022-0829-0656, p. 2]

Organization: National Tribal Air Association (NTAA)

Criteria Pollutant Emissions Standards

Many residents in Indian country continue to be exposed to concentrations of ozone and particulate matter that exceed current National Ambient Air Quality Standards. With a few exceptions, the sources of this pollution are outside the jurisdiction and control of Tribal governments. It is imperative that the EPA and applicable state and local authorities take all necessary measures to return Tribal communities to healthy air quality. [EPA-HQ-OAR-2022-0829-0504, p. 2]

The proposed emissions standards for new light-duty and medium-duty vehicles for non-methane organic gases plus nitrogen oxides (NMOG+NOx) constitute one key step in reducing the impacts from the largest source of these ozone-precursor pollutants. Concurrently, reduced emissions of NMOG+NOx will reduce ambient air concentrations of particulate matter, and PM2.5 more specifically. The NTAA supports the proposed standards for these pollutants across the applicable vehicle categories and looks forward to healthier air quality in our many impacted communities. [EPA-HQ-OAR-2022-0829-0504, p. 2]

Organization: North American Subaru, Inc.

On criteria pollutants, the agency proposes changes to emissions standards that could be better addressed through alignment with the California Advanced Clean Cars II (i.e., LEV IV) program. Of note is the NPRM’s requirement to add new gasoline particulate filters starting in MY27. CARB's regulations still call for challenging reductions in PM emissions while not requiring a particulate filter for gasoline vehicles. The NPRM requirement to install new technology (including on-board diagnostic sensors, hardware, vehicle testing) would add cost to the vehicle for minimal gain in already low emission vehicles. [EPA-HQ-OAR-2022-0829-0576, p. 2]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC)

Decades of research confirms that exposure to criteria pollutant emissions from motor vehicles, including NOx, PM2.5, and air toxics, worsens asthma and other cardio-respiratory illnesses, especially in children and older adults, leading to additional trips to doctors and emergency rooms, missed days of school and work, and thousands of premature deaths each year. Exposure to PM2.5 can trigger heart attacks and strokes, exacerbate obesity and diabetes, and contribute to cognitive challenges.8 This air pollution affects people nationwide, but especially those who live or work near transportation hubs and corridors, often residents of low-income communities and communities of color affected by decades of cumulative impacts of air pollution from mobile and other sources.9 EPA estimates that, in 2023, LDVs and MDVs will account for approximately 20 percent of NOx emissions, 19 percent of direct PM2.5 emissions, and 41 percent of VOC emissions in the United States.10 [EPA-HQ-OAR-2022-0829-0584, p. 3]

10 NPRM, 88 Fed. Reg. at 29186.

EPA is proposing particulate matter (PM) standards for both LDVs and MDVs of 0.5 mg/mi for three test cycles, including cold temperature. EPA projects the new standards will reduce PM2.5 emissions from ICE vehicles by 95 percent and substantially reduce emissions of air toxics. As discussed in the NPRM, the technology needed to achieve these standards is readily available. The NPRM demonstrates both that PM can be controlled down to near zero levels, and also that emissions well below the proposed limit of 0.5 mg/mi can be measured with existing certification procedures.26 [EPA-HQ-OAR-2022-0829-0584, p. 10]

26 As noted in the NPRM, the majority of the global vehicle market outside of the U.S. is subject to more stringent PM standards. Gasoline passenger cars have been regulated on the number of particles they emit since 2015 in Europe and since 2020 in China and India. As a result, the best available PM emission control technologies like gasoline particulate filters (GPF) and high-pressure fuel injectors have been incorporated into vehicles sold in these regions for several years. In fact, nearly identical vehicles produced in the U.S. without a GPF and shipped to Europe can be sold only after a GPF is installed.

We support EPA's inclusion of both standard and cold temperature testing for criteria pollutants across all vehicle categories, as these tests better represent real world operation across much of the United States. [EPA-HQ-OAR-2022-0829-0584, p. 10]

Organization: Porsche Cars North America (PCNA)

8. No projected need for Infrequent Regeneration Adjustment Factor (IRAF) for gasoline particulate filters

Within the DRIA, EPA made mention of adopting IRAF for gasoline combustion GPF equipped vehicles like what is currently required for diesel vehicles. Porsche does not believe at this time that an IRAF is necessary due to the unique characteristics of gasoline versus diesel and the higher control of soot through passive regeneration. Due to the higher exhaust temperature of gasoline otto-cycle engines, the anticipated frequency of active regenerations for gasoline particulate filter (GPF) equipped vehicles is significantly less than diesel fueled compression engines equipped with diesel particulate filters (DPF). Porsche provides confidential test data in Appendix-B to demonstrate anticipated soot loading and burn off over a variety of test cycles for an example GPF equipped vehicle. [EPA-HQ-OAR-2022-0829-0637, p. 15]

Porsche anticipates that active regeneration for gasoline GPF equipped vehicles will be very infrequent, and through vehicle operation on highways and with potential staged regeneration strategies, Porsche does not believe that the heightened emissions released during an active regeneration will occur sufficiently to warrant the need for gasoline GPF IRAF. Porsche recommends EPA continue to monitor the topic as more GPF equipped vehicles enter the US market. [EPA-HQ-OAR-2022-0829-0637, p. 15]

Organization: Reginald Modlin and B. Reid Detchon

The Clean Air Act Amendments of 1990 required control of toxic emissions from motor vehicles. EPA responded in 2001 with standards based on the technologies and understanding of health effects at that time. However, time and science have moved on. Vehicle engine technologies have advanced, the composition of gasoline has changed, and the public health effects of aromatics have become better understood: Carburetors and port fuel injection have largely been replaced by gasoline direct injection (GDI) technology. More than half of the vehicles entering the market use this technology to enhance fuel economy performance. Unfortunately, GDI technology greatly increases emissions of ultrafine particles when using today's gasoline. [EPA-HQ-OAR-2022-0829-0570, p. 5]

It doesn't have to be this way. Technologies and products have come together to define a new solution for what the Clean Air Act requires: "the greatest degree of emission reduction achievable through the application of technology which will be available." Along with a rapid transition to electric vehicles, a complementary program should include adoption of higher ethanol blends, which have been shown by U.S. National Laboratories to enable higher fuel economy and vehicle performance. Such blends would enable a 40% reduction in the use of toxic aromatics in gasoline. An important recent study, co-authored by the Nobel Prize winner Mario Molina, concluded that reducing the smallest (ultrafine) particles "without simultaneously limiting organics from automobile emissions is ineffective and can even exacerbate this problem." [EPA-HQ-OAR-2022-0829-0570, p. 5]

I. Emissions from the use of toxic chemicals in gasoline – aromatic hydrocarbons – are causing thousands of premature deaths annually in the United States and harming the cognitive development of children. [EPA-HQ-OAR-2022-0829-0570, pp. 6-7]

1. The effect on public health in brief [EPA-HQ-OAR-2022-0829-0570, pp. 6-7]

a. Incomplete combustion of the aromatics in gasoline (comprising 20% of every gallon) results in tailpipe emissions of fine particles. Inhalation of fine particles from fossil fuel combustion is the leading cause of premature death in the world, killing more than 8 million people annually. [EPA-HQ-OAR-2022-0829-0570, pp. 6-7]

i. Octane is needed in gasoline to prevent premature combustion of the fuel mixture (“knock”), which can damage engines. [EPA-HQ-OAR-2022-0829-0570, pp. 7-8]

12 “Engine knocking,” in Wikipedia: https://en.wikipedia.org/wiki/Engine_knocking (accessed Feb. 24, 2021).

ii. The level of aromatics in gasoline is capped at 25% in regions required to use reformulated gasoline (areas that have high levels of ozone pollution, roughly 30% of the U.S. market). On average, aromatics comprise 20% of the gasoline sold in the U.S. Levels elsewhere (e.g., in Europe and China) have been as high as 40%, worsening air pollution and public health in those regions. [EPA-HQ-OAR-2022-0829-0570, pp. 7-8]

13 42 U.S. Code, sec.?7545, “Regulation of fuels,” at (k)(3)(A)(ii): P.L. 101-549, sec. 219, enacted Nov. 15, 1990: https://www.law.cornell.edu/uscode/text/42/7545 (accessed June 17, 2021).

15 Guiqian Tang et al., “Organic composition of gasoline and its potential effects on air pollution in North China,” Science China: Chemistry (2015): 58(9): pp. 1416-25: http://engine.scichina.com/publisher/scp/journal/SCC/58/9/10.1007/s11426-015-5464-0?slug=abstract (accessed Feb. 24, 2021).

iii. In the decade from 1997 to 2006, aromatics made up roughly 25% of the U.S. gasoline pool. That level fell to 20% over the next 10 years as ethanol’s share of the market rose from 3% to nearly 10%. This 20% level equates to 25.3 billion gallons of aromatics used in cars and light trucks per year. [EPA-HQ-OAR-2022-0829-0570, pp. 7-8]

16 U.S. EPA, “Fuel Trends Report,” op. cit., supra note 14.

17 U.S. Energy Information Administration, “Gasoline explained – use of gasoline”, online fact sheet: “Light-duty vehicles (cars, sport utility vehicles, and small trucks) account for about 92% of all gasoline consumption in the United States”: https://www.eia.gov/energyexplained/gasoline/use-of-gasoline.php (accessed Feb. 24, 2021). EIA projects gasoline use in 2021 to total 137.5 billion gallons, or 126.5 billion gallons for light-duty vehicles: U.S. Energy Information Administration, “Annual Energy Outlook 2021,” Table 11. Petroleum and Other Liquids Supply and Disposition (Reference case): https://www.eia.gov/outlooks/aeo/data/browser/#/?id=11-AEO2021®ion=0-0&cases=ref2021&start=2019&end=2050&f=A&linechart=ref2021-d113020a.3-11-AEO2021&chartindexed=0&sourcekey=0 (accessed Feb. 24, 2021).

iv. Aromatics have a much higher ratio of carbon to hydrogen than other typical hydrocarbons do, driving up the carbon content of gasoline and producing higher greenhouse gas emissions. [EPA-HQ-OAR-2022-0829-0570, pp. 7-8]

18 U.S. Energy Information Administration, "Emissions of Greenhouse Gases in the United States 1987-1994" (1995), DOE/EIA-0573(87-94), p. 77: https://www.osti.gov/servlets/purl/122288 (accessed Feb. 24, 2021).

v. Aromatics contribute about 10% of global anthropogenic emissions of non-methane organic gases (NMOG), the major source being car exhaust from gasoline-powered vehicles. [EPA-HQ-OAR-2022-0829-0570, pp. 7-8]

19 I. Barnes and K.H. Becker, "Aromatic Hydrocarbons," in Tropospheric Chemistry and Composition, Encyclopedia of Atmospheric Sciences (2003): p. 2376: https://www.sciencedirect.com/science/article/pii/B0122270908004243 (accessed Feb. 24, 2021).

vi. Aromatics are also responsible for an estimated 30-40% of the ozone and other photooxidants in urban atmospheres, making them the most important class of hydrocarbons with regard to photochemical ozone formation. [EPA-HQ-OAR-2022-0829-0570, pp. 7-8]

20 Ibid

c. The BTEX chemicals are characterized as hazardous air pollutants "known or suspected to cause cancer or other serious health or environmental effects." They are identified as mobile source air toxics and formed in four ways, of which the first two are most pertinent. According to EPA: [EPA-HQ-OAR-2022-0829-0570, pp. 8-9]

21 U.S. Environmental Protection Agency, "What are Hazardous Air Pollutants?", online fact sheet: https://www.epa.gov/haps/what-are-hazardous-air-pollutants (accessed Aug. 29, 2021).

22 U.S. Environmental Protection Agency, "Control of Emissions of Hazardous Air Pollutants from Mobile Sources; Final Rule," Federal Register (2001): 66(61): pp. 17235-39: https://www.govinfo.gov/content/pkg/FR-2001-03-29/pdf/01-37.pdf (accessed Feb. 24, 2021).

i. "First, some air toxics are present in fuel and are emitted to the air when it evaporates or passes through the engine as unburned fuel. Benzene, for example, is a component of gasoline. Cars emit small quantities of benzene in unburned fuel, or as vapor when gasoline evaporates. [EPA-HQ-OAR-2022-0829-0570, pp. 8-9]

ii. "Second, mobile source air toxics are formed through engine combustion processes. A significant amount of automotive benzene comes from the incomplete combustion of compounds in gasoline such as toluene and xylene that are chemically very similar to benzene." (emphasis added) [EPA-HQ-OAR-2022-0829-0570, pp. 8-9]

d. According to a review of the literature by a Health Effects Institute panel, "It is estimated that about 50% of the benzene produced in the exhaust is the result of decomposition of aromatic hydrocarbons in the fuel. … [Two] studies showed that lowering aromatic levels in gasoline significantly reduces toxic benzene emissions from vehicle exhausts." [EPA-HQ-OAR-2022-0829-0570, pp. 8-9]

23 Health Effects Institute, Panel on the Health Effects of Traffic-Related Air Pollution, "Traffic-Related Air Pollution: A Critical Review of the Literature on Emissions, Exposure, and Health Effects" (Special Report 17): Chapter 2, "Emissions from Motor Vehicles," Appendix B: "Fuel Composition Changes Related To Emission Controls" (2010): pp. 3-4:

https://www.healtheffects.org/system/files/SR17TrafficReviewChapter2AppendixB.pdf (accessed Aug. 24, 2021).

e. Gasoline-powered vehicles accounted for 69% of all U.S. emissions of single-ring aromatic hydrocarbons, based on source-specific speciation in the 2005 National Emissions Inventory. [EPA-HQ-OAR-2022-0829-0570, pp. 8-9]

24 Katherine von Stackelberg et al., "Public health impacts of secondary particulate formation from aromatic hydrocarbons in gasoline," Table 3, National emissions inventory of single-ring aromatic hydrocarbons, Environmental Health (2013): 12(19): https://ehjournal.biomedcentral.com/articles/10.1186/1476-069X-12-19/tables/3 in https://ehjournal.biomedcentral.com/articles/10.1186/1476-069X-12-19 (accessed Feb. 24, 2021).

3. Emissions from aromatics: Particulate matter (PM) and ultrafine particles (UFPs) [EPA-HQ-OAR-2022-0829-0570, pp. 9-10]

a. When a fuel is burned in a vehicle, its molecules break apart and create particulate matter (PM). PM is usually characterized according to its size – in three categories: [EPA-HQ-OAR-2022-0829-0570, pp. 9-10]

25 Mohsin Raza et al., "A Review of Particulate Number (PN) Emissions from Gasoline Direct Injection (GDI) Engines and Their Control Techniques," Energies (2018): 11(6), 1417: p. 3: https://www.mdpi.com/1996-1073/11/6/1417/htm (accessed Feb. 24, 2021).

i. Some particles, such as dust, dirt, soot, or smoke, are large or dark enough to be seen with the naked eye. These larger particles (2.5 to 10 micrometers in diameter) are called PM10 and are mostly derived from soil and sea salts. Fine particles (PM2.5, 0.1 to 2.5 micrometers in diameter) and ultrafine particles (UFPs, less than 0.1 micrometer) are predominantly derived from combustion of fossil fuel. [EPA-HQ-OAR-2022-0829-0570, pp. 9-10]

26 Andre Nel, "Air Pollution-Related Illness: Effects of Particles," Science (2005): 308(5723): pp. 804-06: https://science.sciencemag.org/content/308/5723/804 (accessed Feb. 24, 2021).

ii. Exposure to PM2.5 from fossil fuel combustion was recently shown to be the leading cause of premature death in the world, killing more than 8 million people annually – double the previous estimate – based on a new risk assessment model that found a higher mortality rate for long-term exposure to fossil fuel emissions, including at lower concentrations. [EPA-HQ-OAR-2022-0829-0570, pp. 9-10]

27 Vohra, op. cit., supra note 1, updating Dean E. Schraufnagel et al., "Air Pollution and Noncommunicable Diseases – A Review by the Forum of International Respiratory Societies' Environmental Committee, Part 1: The Damaging Effects of Air Pollution," CHEST Journal (2019): 155(2): pp. 409-16: https://journal.chestnet.org/article/S0012-3692(18)32723-5/pdf (accessed Feb. 24, 2021).

28 Leah Burrows, "Deaths from fossil fuel emissions higher than previously thought," news release, Harvard John A. Paulson School of Engineering and Applied Sciences, Feb. 9, 2021: https://www.seas.harvard.edu/news/2021/02/deaths-fossil-fuel-emissions-higher-previously-thought (accessed Feb. 24, 2021).

iii. EPA recently announced that it will reconsider its national standards for PM2.5, stating: "The strong body of scientific evidence shows that long- and short-term exposures to fine particles (PM2.5) can harm people's health, leading to heart attacks, asthma attacks, and premature death. Large segments of the U.S. population, including children, people with heart or lung conditions, and people of color, are at risk of health effects from PM2.5." [EPA-HQ-OAR-2022-0829-0570, pp. 9-10]

29 U.S. Environmental Protection Agency, "EPA to Reexamine Health Standards for Harmful Soot that Previous Administration Left Unchanged," news release, June 10, 2021: https://www.epa.gov/newsreleases/epa-reexamine-health-standards-harmful-soot-previous-administration-left-unchanged (accessed June 11, 2021).

1. Children's exposure to air pollution is of special concern because their immune system and lungs are not fully developed. [EPA-HQ-OAR-2022-0829-0570, p. 10]

30 Joel Schwartz, "Air Pollution and Children's Health," Pediatrics (2004): 113(4): pp. 1037-43: https://pediatrics.aappublications.org/content/pediatrics/113/Supplement_3/1037.full.pdf (accessed Feb. 24, 2021).

2. Long-term exposure to PM2.5 has also been associated with a large increase in the COVID-19 death rate. [EPA-HQ-OAR-2022-0829-0570, p. 10]

31 Xiao Wu et al., "Exposure to air pollution and COVID-19 mortality in the United States: A nationwide cross-sectional study," medRxiv preprint (2020): https://www.medrxiv.org/content/10.1101/2020.04.05.20054502v2 (accessed Feb. 24, 2021).

iv. As EPA notes, "While some PM is emitted directly from sources such as construction sites, unpaved roads, fields, smokestacks or fires, most particles form in the atmosphere as a result of complex reactions of chemicals such as sulfur dioxide and nitrogen oxides, which are pollutants emitted from power plants, industrial facilities and vehicles." [EPA-HQ-OAR-2022-0829-0570, p. 10]

32 U.S. EPA, "EPA to Reexamine Health Standards for Harmful Soot," op. cit., supra note 29.

1. A recent General Motors study found that nearly 96% of the PM emissions from gasoline are caused by the aromatics in the fuel. Due to an increase in heavy aromatics in the U.S. gasoline pool in the last three years, the gasoline particulate index has increased by more than 30% since 2016 and now is worse than in the EU and China. The authors observed: "Fuel quality improvements are not only important for new vehicles, which are designed for it, but also will benefit the whole fleet of legacy vehicles in the market and off-highway engines." [EPA-HQ-OAR-2022-0829-0570, pp. 10-12]

33 Elana Chapman et al., "Global Market Gasoline Quality Review: Five Year Trends in Particulate Emission Indices," SAE International (2021): SAE Technical Paper 2021-01-0623: https://saemobilus.sae.org/content/2021-01-0623/ (accessed June 17, 2021).

v. Ultrafine particles (UFPs) are so small that they can only be detected with an electron microscope, and they are more usefully measured by particle number, not mass. They comprise more than 80% of the particles in urban air but are a negligible fraction of PM2.5 mass. [EPA-HQ-OAR-2022-0829-0570, pp. 10-12]

34 Christina H. Fuller et al., "Indoor and outdoor measurements of particle number concentration in near-highway homes," Journal of Exposure Science and Environmental Epidemiology (2013): 23: p. 506: https://www.nature.com/articles/jes2012116.pdf (accessed Feb. 24, 2021).

1. Studies have shown associations between UFPs and increased asthma symptoms, cardiovascular disease markers, and decreased cognitive function. [EPA-HQ-OAR-2022-0829-0570, pp. 10-12]

35 Ibid.

a. In a recent U.S. study, prenatal UFP exposure was linked to asthma development in children: Children whose mothers were exposed to high levels of UFPs during pregnancy were four times more likely to develop asthma than those whose mothers were exposed to lower levels – roughly the difference between a quiet street and a busy road. Most of the diagnoses occurred just after three years of age, and overall 18% of the infants developed asthma. The researchers took account of other factors, including the age of the mothers and obesity, as well as other air pollutants. [EPA-HQ-OAR-2022-0829-0570, pp. 10-12]

36 Rosalind J. Wright et al., "Prenatal Ambient Ultrafine Particle Exposure and Childhood Asthma in the Northeastern United States," American Journal of Respiratory and Critical Care Medicine (2021): https://www.atsjournals.org/doi/abs/10.1164/rccm.202010-3743OC (accessed June 11, 2021).

37 Damian Carrington, "Asthma in toddlers linked to in-utero exposure to air pollution, study finds," The Guardian (May 21, 2021): https://www.theguardian.com/environment/2021/may/21/asthma-in-toddlers-linked-to-in-utero-exposure-to-air-pollution-ufps-study-finds (accessed June 11, 2021).

2. UFPs contain large amounts of toxic components, and their adverse health effects potential would not be predicted from their mass alone. Particle number, surface area, and chemical composition are more important than mass as a health-relevant metric. [EPA-HQ-OAR-2022-0829-0570, pp. 10-12]

38 Paul A. Solomon, U.S. Environmental Protection Agency, "An Overview of Ultrafine Particles in Ambient Air," EM: The Magazine for Environmental Managers (2012): 5: pp. 20-21: https://cfpub.epa.gov/si/si_public_record_report.cfm?Lab=NERL&dirEntryId=241266 (accessed Feb. 24, 2021).

3. There is a growing concern in the public health community about the contribution of UFPs to human health. Despite their modest mass and size, they dominate in terms of the number of particles in the ambient air. A particular concern about UFPs is their ability to reach the most distal lung regions (alveoli) and circumvent primary airway defenses. Moreover, UFPs have a high surface area and a capacity to adsorb a substantial amount of toxic organic compounds. Harmful systemic health effects of PM10 or PM2.5 are often due to the UFP fraction. [EPA-HQ-OAR-2022-0829-0570, pp. 10-12]

39 Hyouk-Soo Kwon et al., "Ultrafine particles: unique physicochemical properties relevant to health and disease," Experimental & Molecular Medicine (2020): 52: pp. 318-28: https://www.nature.com/articles/s12276-020-0405-1.pdf (accessed June 11, 2021).

5. The ability of inhaled particles to be captured within the human body, called the deposition efficiency, is a function of particle size, with the particle deposition efficiency rapidly increasing as the particles become smaller and smaller. [EPA-HQ-OAR-2022-0829-0570, pp. 10-12]

40 Felipe Rodriguez et al., "Recommendations for Post-Euro 6 Standards for Light-Duty Vehicles in the EU" (2019), International Council on Clean Transportation, p. 8: https://theicct.org/sites/default/files/publications/Post_Euro6_standards_report_20191003.pdf (accessed June 11, 2021).

6. UFPs can cross biological membranes, and their mobility within the body is thought to be high. There is considerable evidence to show that inhaled UFPs can gain access to the bloodstream and are then distributed to other organs in the body. They can even cross the placental barrier. [EPA-HQ-OAR-2022-0829-0570, pp. 10-12]

41 Howard, op. cit., supra note 3, pp. 12-15.

7. UFPs have been shown to directly translocate to the brain along the olfactory nerves. In addition, they can pass intact into cells, where they can have direct access to cytoplasmic proteins and organelles – for example, the mitochondria impacting the respiratory chain and DNA in the nucleus – enhancing the toxic potential of these particles. [EPA-HQ-OAR-2022-0829-0570, pp. 12-13]

42 Solomon, op. cit., supra note 38, p. 21.

8. Results indicating that particles may contribute to the overall oxidative stress burden of the brain are particularly troublesome, as these long-term health effects may accumulate over decades. [EPA-HQ-OAR-2022-0829-0570, pp. 12-13]

43 Annette Peters et al., "Translocation and potential neurological effects of fine and ultrafine particles a critical update," Particle and Fibre Toxicology (2006): 3(13): https://pubmed.ncbi.nlm.nih.gov/16961926/ (accessed Feb. 24, 2021).

vi. Research also suggests that the introduction of excessive UFPs into the atmosphere results in surprising side effects, such as changes in the distribution and intensity of rainfall, causing either drought or flooding in extreme cases. Such drastic climate change affects the global hydrological cycle and thereby affects global public health both directly and indirectly. [EPA-HQ-OAR-2022-0829-0570, pp. 12-13]

44 Kwon et al., op. cit., supra note 39.

vii. In most urban areas, on-road vehicles are the primary source of UFP emissions. These areas observe a peak in UFPs in the morning during rush hour associated with motor vehicle emissions and a second peak during the afternoon, enhanced during the summer, associated with photochemistry, or one slightly later in the afternoon due to rush hour traffic that is enhanced during cooler conditions. [EPA-HQ-OAR-2022-0829-0570, pp. 12-13]

45 Ibid.

46 Solomon, op. cit., supra note 38, p.19.

viii.. An important recent study co-authored by Nobel Prize winner Mario Molina found "remarkable formation of UFPs from urban traffic emissions": [EPA-HQ-OAR-2022-0829-0570, pp. 12-13]

47 Guo et al., op. cit., supra note 2.

1. Photooxidation of vehicular exhaust yields abundant UFP precursors, and organics dominate formation of UFPs under urban conditions. Measurements of gaseous species inside the chamber showed high levels of aromatics, including toluene and C8 and C9 aromatics. [EPA-HQ-OAR-2022-0829-0570, pp. 12-13]

48 Ibid.

2. The authors concluded: "Recognition of this source of UFPs is essential to assessing their impacts and developing mitigation policies. Our results imply that reduction of primary particles or removal of existing particles without simultaneously limiting organics from automobile emissions is ineffective and can even exacerbate this problem." (emphasis added) [EPA-HQ-OAR-2022-0829-0570, pp. 12-13]

49 Ibid.

b. The newest generation of efficient engine technology, gasoline direct injection (GDI), increases public exposure to gasoline PM, and thus to UFPs, including PAHs. Uncontrolled GDI engines have been found to emit 10 times more particles (by mass) than previous engines and more than 100 times the number of particles. [EPA-HQ-OAR-2022-0829-0570, pp. 13-14]

50 John M. Storey et al., Oak Ridge National Laboratory, “Novel Characterization of GDI Engine Exhaust for Gasoline and Mid-Level Gasoline-Alcohol Blends,” SAE International Journal of Fuels and Lubricants (2014): 7(2): pp. 571-79: https://www.eenews.net/assets/2014/10/02/document_cw_01.pdf (accessed Feb. 24, 2021).

51 Transport & Environment, “Gasoline particulate emissions: The next auto scandal?” (2016), p. 2: https://www.transportenvironment.org/sites/te/files/publications/2016_10_Gasoline_particulate_emissions_briefing_0.pdf, citing the European Commission’s Joint Research Centre: A. Mamakos et al., “Assessment of particle number limits for petrol vehicles” (2012): https://publications.jrc.ec.europa.eu/repository/handle/JRC76849 (accessed Aug. 18, 2021).

i. Vehicle exhaust, in particular that of gasoline direct injection (GDI) engines, contains copious amounts of particles in the size ranges with high deposition efficiency. GDI engines emit UFPs and PM at levels comparable to diesel engines that do not use diesel particulate filters. [EPA-HQ-OAR-2022-0829-0570, pp. 13-14]

52 Rodriguez et al., op. cit., supra note 40.

53 Rich Kassel et al., Gladstein, Neandross & Associates, “Ultrafine Particulate Matter and the Benefits of Reducing Particle Numbers in the United States,” A Report to the Manufacturers of Emission Controls Association (MECA) (2013): p. 8: http://www.meca.org/resources/meca_ufp_white_paper_0713_final.pdf (accessed Feb. 24, 2021).

54 Kwon et al., op. cit., supra note 39.

1. Unlike conventional port fuel injection engines, which mix fuel and air prior to injection into the engine cylinders, GDI technology involves spraying the fuel directly into the cylinders, allowing for higher compression ratios – which enable higher combustion efficiencies, enhanced fuel economy and reduced CO2 emissions. However, similar to diesel engines, the direct injection of fuel in GDI engines creates fuel-rich pockets near the injection zone, conducive to formation of carbonaceous PM, especially black carbon. GDI engines emit larger amounts of black carbon than conventional engines, as has been confirmed by several laboratory studies [EPA-HQ-OAR-2022-0829-0570, pp. 14-15]

55 Soroush E. Neyestani et al., “Direct Radiative Effect and Public Health Implications of Aerosol Emissions Associated with Shifting to Gasoline Direct Injection (GDI) Technologies in Light-Duty Vehicles in the United States,” Environmental Science & Technology (2020): 54(2): pp. 687-96: https://pubs.acs.org/doi/full/10.1021/acs.est.9b04115 (accessed Feb. 24, 2021), quoted in Green Car Congress, “UGA study finds black carbon aerosols from GDI engines will worsen public health, climate; need for GPFs”: https://www.greencarcongress.com/2020/01/20200125-uga.html (accessed Feb. 24, 2021).

ii. GDI was used in fewer than 3% of vehicles as recently as model year 2008 but was projected to be used in more than 55% of vehicles in model year 2020. [EPA-HQ-OAR-2022-0829-0570, pp. 14-15]

56 U.S. Environmental Protection Agency, “Manufacturers continue to adopt a wide array of advanced technologies,” in “Highlights of the Automotive Trends Report,” online fact sheet:

https://www.epa.gov/automotive-trends/highlights-automotive-trends-report#Highlight5 (accessed Feb. 24, 2021).

This shift to GDI engines is predicted to nearly double annual deaths in the U.S. from gasoline-vehicle particulate emissions – according to one estimate, from 855 to 1,599 deaths a year. [EPA-HQ-OAR-2022-0829-0570, pp. 14-15]

57 Raza et al., op. cit., supra note 25: p. 5.

iii. Emissions from GDI engines can be mitigated by changes in operating parameters, by the addition of gasoline particulate filters (both with potential costs to vehicle efficiency), or by a reduction in aromatic content. [EPA-HQ-OAR-2022-0829-0570, pp. 14-15]

59 Xin He et al., "Effects of Gasoline Direct Injection Engine Operating Parameters on Particle Number Emissions," Energy & Fuels (2012): 26(4): pp. 2014-27: https://pubs.acs.org/doi/pdf/10.1021/ef201917p (accessed Feb. 24, 2021).

59 Ray J Minjares and Francisco Posada Sanchez, The International Council on Clean Transportation, "Estimated Cost of Gasoline Particulate Filters" (2011): p. 1: https://theicct.org/sites/default/files/publications/GFPworkingpaper2011.pdf (accessed Feb. 24, 2021).

c. There is a strong link between PM emissions from GDI engines and the composition and properties of the gasoline, chiefly the aromatic content of the fuel: High levels of aromatics lead to a higher level of PM emissions. [EPA-HQ-OAR-2022-0829-0570, p. 15]

60 Raza et al., op. cit., supra note 25: p. 13.

i. Aromatic compounds are harder to evaporate and slower to decompose than other hydrocarbons. Aromatics also may decompose into compounds such as acetylenes which serve as precursors for the formation of a benzene ring. [EPA-HQ-OAR-2022-0829-0570, p. 15]

61 Mohammad Fatouraie et al., "Investigation of the Impact of Fuel Properties on Particulate Number Emission of a Modern Gasoline Direct Injection Engine," SAE Technical Paper 2018-01-0358 (2018), p. 9: https://www.nrel.gov/docs/fy18osti/71483.pdf (accessed Feb. 24, 2021).

ii. High levels of aromatic components in fuel have been conclusively shown to increase PM emissions measured by particle number, an aromatic ring being an early stage of the fundamental particulate formation process. [EPA-HQ-OAR-2022-0829-0570, p. 15]

62 Raza et al., op. cit., supra note 25: p. 18.

4. Emissions from aromatics: Secondary organic aerosol (SOA)

a. Organic aerosol is a major component of fine particle pollution. Primary organic aerosol (POA) is directly emitted from fossil fuel combustion and other sources, while secondary organic aerosol (SOA) is formed from the oxidation of these emissions in the air. [EPA-HQ-OAR-2022-0829-0570, p. 15]

63 J. L. Jiminez et al., "Evolution of Organic Aerosols in the Atmosphere," Science (2009): 326(5959): pp. 1525-29: https://science.sciencemag.org/content/326/5959/1525 (accessed Feb. 24, 2021).

i. Tailpipe emissions from on-road gasoline vehicles are an important source of SOA in urban environments, where SOA concentrations often exceed POA levels. For most vehicles, SOA formation exceeds POA emissions after a few hours of atmospheric oxidation. Controlling

SOA precursor emissions is necessary to reduce human exposure to fine particulate matter. [EPA-HQ-OAR-2022-0829-0570, p. 15]

64 Yunliang Zhao et al., "Reducing secondary organic aerosol formation from gasoline vehicle exhaust," Proceedings of the National Academy of Sciences of the United States of America (2017): 114(27): pp. 6984–89: https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5502599/ (accessed Feb. 24, 2021).

ii. A study of SOA formation during a severe photochemical smog event in Los Angeles found that exhaust from gasoline engines represented the single-largest anthropogenic source of SOA, and SOA in turn has been shown to be a large fraction, if not the largest, of gasoline vehicular PM. [EPA-HQ-OAR-2022-0829-0570, p. 15]

65 Michael J. Kleeman et al., "Source apportionment of secondary organic aerosol during a severe photochemical smog episode," Atmospheric Environment (2007): 41(3): pp. 576-91: https://www.sciencedirect.com/science/article/abs/pii/S1352231006008582?via%3Dihub (accessed Feb. 24, 2021).

b. According to EPA's 2011 National Air Toxics Assessment,: secondary formation is the largest contributor to cancer risks nationwide, accounting for 47% of the risk. On-road mobile sources contribute the most cancer risk from directly emitted pollutants (about 18%) and the most to non-cancer risks (34%). [EPA-HQ-OAR-2022-0829-0570, pp. 15-16]

66 U.S. Environmental Protection Agency, "Overview of EPA's 2011 National Air Toxics Assessment," online fact sheet (2015): https://www.epa.gov/sites/production/files/2015-12/documents/2011-nata-fact-sheet.pdf (accessed Feb. 24, 2021).

i. A recent study found higher toxicity in combustion aerosols than non-combustion aerosols, with emissions from vehicle engine exhaust scoring higher on overall toxicity than even those from coal combustion. [EPA-HQ-OAR-2022-0829-0570, pp. 15-16]

67 Minhan Park et al., "Differential toxicities of fine particulate matters from various sources," Nature, Scientific Reports (2018): 8(17007): https://www.nature.com/articles/s41598-018-35398-0 (accessed Feb. 24, 2021).

b. In the 30 years since the law was enacted, EPA has issued specific regulations on the subject of mobile source air toxics (MSATs) only twice – putting modest limits on benzene emissions in 2001 and on the benzene content of gasoline in 2007, but largely deferring action on the others. [EPA-HQ-OAR-2022-0829-0570, pp. 25-26]

i. The 2001 rule did list the BTEX aromatics as mobile source air toxics and noted that mobile sources accounted for more than 75% of total national emissions in each instance. Also listed was polycyclic organic matter: A group of seven PAHs, "which have been identified by EPA as probable human carcinogens" – including BaP – were used as surrogates for the larger group of POM compounds. Mobile sources were said to account for only 6% of total national emissions – but as measured by mass, not particle number. [EPA-HQ-OAR-2022-0829-0570, pp. 25-26]

129 U.S. EPA, "Control of Emissions of Hazardous Air Pollutants from Mobile Sources" (2001), op. cit., supra note 22.

c. Congress reiterated its 1990 mandate in the Energy Policy Act of 2005: "Not later than July 1, 2007, the [EPA] Administrator shall promulgate final regulations to control hazardous air pollutants from motor vehicles and motor vehicles fuels ... as authorized under section 202(l) of the Clean Air Act." [EPA-HQ-OAR-2022-0829-0570, pp. 25-26]

130 Energy Policy Act of 2005, P.L. 109-58, "Elimination Of Oxygen Content Requirement For Reformulated Gasoline," sec. 1504(b)(1)(vi): https://www.congress.gov/109/plaws/publ58/PLAW-109publ58.pdf (accessed Feb. 24, 2021). Codified at 42 U.S. Code, sec.?7545(k)(1)(B)(vi), "Regulation of fuels": https://www.law.cornell.edu/uscode/text/42/7545 (accessed Feb. 24, 2021).

i. EPA issued its 2007 mobile-source rule in response to this congressional directive. It acknowledged that "Recent studies have found that maternal exposures to PAHs in a population of pregnant women were associated with several adverse birth outcomes, including low birth weight and reduced length at birth, as well as impaired cognitive development at age three." [EPA-HQ-OAR-2022-0829-0570, pp. 25-26]

131 U.S. Environmental Protection Agency, "Control of Hazardous Air Pollutants From Mobile Sources; Final Rule," Federal Register (2007): 72(37): p. 8439: https://www.govinfo.gov/content/pkg/FR-2007-02-26/pdf/E7-2667.pdf (accessed Feb. 24, 2021).

1. But EPA took no action, saying that, according to its model, emissions of polycyclic organic matter "correlate directly with VOC emissions" and thus would decline as VOC emissions decline – failing to anticipate the contrary effect of new GDI engine technology, noted above. [EPA-HQ-OAR-2022-0829-0570, pp. 25-26]

132 Ibid., p. 8478.

ii. In proposing the rule, the agency also acknowledged "limited data that suggest that aromatic compounds (toluene, xylene, and benzene) react photochemically in the atmosphere to form secondary particulate matter (in the form of secondary organic aerosol (SOA)), although our current modeling tools do not fully reflect this" (emphasis added) [EPA-HQ-OAR-2022-0829-0570, pp. 25-26]

133 U.S. Environmental Protection Agency, "Control of Hazardous Air Pollutants From Mobile Sources; Proposed Rule," Federal Register (2006): 71(60): p. 15864: https://www.govinfo.gov/content/pkg/FR-2006-03-29/pdf/06-2315.pdf#page=62 (accessed Feb. 24, 2021).

1. The rule's Regulatory Impact Analysis said: "The issue of SOA formation from aromatic precursors is an important one to which EPA and others are paying significant attention. Due to the large contribution of mobile source emissions to overall aromatic levels in the atmosphere, this issue is a crucial one for assessing what further reductions are possible in mobile source PM." (emphasis added) [EPA-HQ-OAR-2022-0829-0570, pp. 26-28]

134 U.S. Environmental Protection Agency, "Control of Hazardous Air Pollutants from Mobile Sources: Regulatory Impact Analysis" (2007): p. I-29: https://nepis.epa.gov/Exe/ZyPdf.cgi?Dockey=P1004LNN.PDF (accessed Feb. 24, 2021).

iii. In the final rule, EPA said: "There may be compelling reasons to consider aromatics control in the future, especially regarding reduction in secondary PM2.5 emissions, to the extent that evidence supports a role for aromatics in secondary PM2.5 formation. Unfortunately, there are limitations in both primary and secondary PM science and modeling tools that limit our present ability to quantitatively predict what would happen for a given fuel control. … [M]ore work is underway on how fuel aromatics, including toluene, affect secondary PM formation, and how aromatics control should be incorporated into air quality predictive models. … Thus, we have concluded that additional aromatics control for MSAT purposes is not warranted at this time." (emphasis added) [EPA-HQ-OAR-2022-0829-0570, pp. 26-28]

135 U.S. EPA, “Control of Hazardous Air Pollutants From Mobile Sources” (2007), op. cit., supra note 131: p. 8479.

1. The final rule stated, in summary: “EPA believes that the emission reductions from the standards finalized today for motor vehicles and their fuels, combined with the standards currently in place, represent the maximum achievable reductions of emissions from motor vehicles through the application of technology that will be available, considering costs and the other factors listed in section 202(l)(2).” (emphasis added) [EPA-HQ-OAR-2022-0829-0570, pp. 26-28]

136 Ibid., p. 8460.

- Note: EPA’s conclusion that it had required “the maximum achievable reductions” was wrong then and is even more clearly wrong today, as shown in Section III, below. Additionally, more than 13 years after issuing the 2007 rule, EPA has still not taken action on “assessing what further reductions are possible in mobile source PM” or on “how aromatics control should be incorporated into air quality predictive models.” [EPA-HQ-OAR-2022-0829-0570, pp. 26-28]

d. EPA missed another opportunity to act in 2014, in its rule on Tier 3 Motor Vehicle Emission and Fuel Standards, which it said would result in “significant reductions in pollutants such as ozone, particulate matter, and air toxics.” [EPA-HQ-OAR-2022-0829-0570, pp. 26-28]

137 U.S. Environmental Protection Agency, “Control of Air Pollution From Motor Vehicles: Tier 3 Motor Vehicle Emission and Fuel Standards,” Federal Register (2014): 79(81): p. 23414: https://www.govinfo.gov/content/pkg/FR-2014-04-28/pdf/2014-06954.pdf (accessed Feb. 24, 2021).

i. EPA acknowledged that “the majority of Americans continue to be exposed to ambient concentrations of air toxics at levels which have the potential to cause adverse health effects. … According to the National Air Toxics Assessment (NATA) for 2005, mobile sources were responsible for 43% of outdoor toxic emissions and over 50% of the cancer risk and noncancer hazard associated with primary emissions. Mobile sources are also large contributors to precursor emissions which react to form secondary concentrations of air toxics.” [EPA-HQ-OAR-2022-0829-0570, pp. 26-28]

138 Ibid., p. 23437.

ii. Yet the agency took no direct action to reduce air toxics or even to estimate the benefits of the action it did take: “While there would be impacts associated with reductions in air toxic pollutant emissions that result from the final standards, we do not attempt to quantify and monetize those impacts…. This is primarily because currently available tools and methods to assess air toxics risk from mobile sources at the national scale are not adequate for extrapolation to incidence estimations or benefits assessment.” (emphasis added) [EPA-HQ-OAR-2022-0829-0570, pp. 26-28]

139 Ibid., p. 23608.

iii. The Tier 3 rule lowered the maximum sulfur content in gasoline to avoid the poisoning of emissions catalysts and make emission control systems more effective, but the sulfur reduction produced no benefit for PM emissions: “Unlike the gaseous pollutants, there was no effect of sulfur level found for PM. … As a result, sulfur would not be expected to have a significant effect on directly-emitted PM (other than very small amounts of sulfate).” [EPA-HQ-OAR-2022-0829-0570, pp. 26-28]

140 Ibid., pp. 23420, 23441.

141 U.S. Environmental Protection Agency, “Fuel Effects on Exhaust Emissions from On-road Vehicles in MOVES2014: Final Report” (2016): p. 47: https://nepis.epa.gov/Exe/ZyPDF.cgi/P100O5W2.PDF?Dockey=P100O5W2.PDF (accessed Feb. 24, 2021).

1. In fact, the rule may have had a contrary consequence: For many refiners, operating strategies that reduce sulfur also reduce octane. According to one analysis, “the majority of refiners are meeting the regulations by increasing hydrotreating severity,” which negatively impacts octane – potentially leading to increased use of aromatics to compensate. [EPA-HQ-OAR-2022-0829-0570, pp. 26-28]

142 Andy Huang et al., Grace Catalysts Technologies, “Driving Octane in an Ultra?Low Sulfur Gasoline Market,” AFPM 17?75 (2017), summarized at https://www.catalystgrp.com/driving-octane-ultra%E2%80%90low-sulfur-gasoline-market/ (accessed Aug. 23, 2021).

e. In December 2020 EPA issued a “Fuels Regulatory Streamlining” rule that relieved refineries of their responsibility to report regularly on the aromatics levels in reformulated gasoline (approximately 30% of the national gasoline pool). An industry-led annual sampling program will be used instead. Refineries also are no longer required to estimate emissions of air toxics, including polycyclic organic matter. [EPA-HQ-OAR-2022-0829-0570, pp. 28-29]

143 U.S. Environmental Protection Agency, “Fuels Regulatory Streamlining,” Federal Register (2020): 85(234), “Program Design,” p. 78414, and “Key Differences Between Part 1090 and Part 80,” p. 78436: https://www.govinfo.gov/content/pkg/FR-2020-12-04/pdf/2020-23164.pdf (accessed June 17, 2021).

f. In August 2021, EPA proposed revised greenhouse gas emissions standards for new cars that again failed to address the importance of vehicle fuels. EPA noted only that “in addition to substantially reducing GHG emissions, a longer-term rulemaking could also address criteria pollutant and air toxics emissions from the new light-duty vehicle fleet – especially important considerations during the transition to zero-emission vehicles.” [EPA-HQ-OAR-2022-0829-0570, pp. 28-29]

144 U.S. EPA, “Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards,” op. cit., supra note 128: p. 43730.

i. Indeed, the very basis on which EPA proceeded, according to the Proposed Rule, was the requirement in Section 202(a) “to establish standards for emissions of air pollutants from new motor vehicles which, in the Administrator’s judgment, cause or contribute to air pollution which may reasonably be anticipated to endanger public health or welfare.” The requirements of Section 202(l)(2), cited above, were enacted concurrently and explicitly based on that same provision of Section 202(a). [EPA-HQ-OAR-2022-0829-0570, pp. 28-29]

145 Ibid., p. 43728.

146 42 U.S. Code, sec.?7521, op.cit.,supra note 125.

Organization: Stellantis

Particulate Matter Standards Should Not Drive All New GPF Systems and Diagnostics

The proposed 0.5 mg/mi particulate matter (PM) standard is twice as stringent as California’s recently adopted ACCII LEV IV requirement – a state with the largest number of nonattainment areas for PM 2.5 in the U.S.6 EPA's proposal will force gasoline particulate filters (GPF), driving significant investments in vehicle/engine assembly plants and increasing the cost of vehicles. This incredibly expensive proposal only offers modest reductions in PM compared to the gains that will be achieved with market transition to electrification. The proposed Cold FTP standard will require all new test cells to robustly measure PM at the required low levels. Since the FTP and US06 will already force GPF, the Cold FTP PM standard becomes a very costly requirement that essentially delivers no environmental gain. [EPA-HQ-OAR-2022-0829-0678, pp. 15-16]

6 Counties Designated Nonattainment for PM-2.5 (1997), PM-2.5 (2006), and/or PM-2.5 (2012) | Green Book | US EPA, accessed 06/26/2023

EPA also adds a diagnostic requirement that goes beyond the industry standard detection of a "missing GPF" to solve a theoretical tampering concern. This filtering efficiency requirement will drive sensing technology that does not exist in the market today and will require years to develop. [EPA-HQ-OAR-2022-0829-0678, pp. 15-16]

In lieu of this costly proposal, we recommend that the EPA adopt the PM standards and phase-in schedule that CARB promulgated with the ACC II LEV IV rule. As described in Auto Innovators' comments, PM emissions reductions of 90% will be achieved (from 10 mg/mi to 1 mg/mi) by 2028MY under ACC II LEV IV. In sum, CARB's ACC II LEV IV requirements provide a significant emissions reduction without driving the need for ongoing investments in a shrinking ICE fleet. [EPA-HQ-OAR-2022-0829-0678, pp. 15-16]

Adopt a more realistic PM standard that does not drive invention and development of all- new GPF systems, diagnostics and test requirements that cannot be certified without new facilities [EPA-HQ-OAR-2022-0829-0678, pp. 24-25]

Organization: Volkswagen Group of America, Inc.

Particulate Matter (PM) 0.5 mg/mi standard (Section III.C.1)

EPA is proposing a 0.5 mg/mile standard for light-duty vehicles that must be met across three test cycles (-7°C FTP, 25°C FTP, US06), a requirement for PM certification tests at the test group level, and a requirement that every in- use vehicle program (IUVP) test vehicle is tested for PM. The 0.5 mg/mile standard is a per-vehicle cap, not a fleet average. [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

In alignment with AFAI, Volkswagen requests EPA adopt CARB's LEV IV PM Standards. AFAI comments include a significant body of work, from multiple manufacturers, which supports the high variability and sensitivities of gravimetric filter measurement systems. Volkswagen agrees with the AFAI statement, "PM measurement at 0.5 mg/mile is approaching noise levels and will not be feasible or technically sound to give reliable PM results with high confidence". [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

Particulate Matter (PM) Lab Comparisons

Volkswagen produced data on 3 mg/mile FTP75 compliant GPF equipped vehicles at four separate ISO 17025 accredited and fully compliant to test procedure requirements defined in 40 C.F.R. §1065/§1066 compliant test labs. The data represents over 200 vehicle tests and demonstrates our concern over repeatability. This overall variation will likely increase when applied to the US06 test cycle. [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

Laboratory location: Volkswagen (Wolfsburg)

Standard deviation [mg/mi]: 0.117

2σ Repeatability as described in §1065.305: 0.234 [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

Laboratory location: Audi (Ingolstadt)

Standard deviation [mg/mi]: 0.125

2σ Repeatability as described in §1065.305: 0.250 [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

Laboratory location: Audi (Neckarsulm)

Standard deviation [mg/mi]: 0.146

2σ Repeatability as described in §1065.305: 0.297 [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

Laboratory location: Porsche (Weissach)

Standard deviation [mg/mi]: 0.133

2σ Repeatability as described in §1065.305: 0.266 [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

The average standard deviation (σ) was determined to be approximately 0.15 mg/mile for the Volkswagen's labs. For a vehicle to comply with the limit of 0.5 mg/mile, it is not to emit more than 0.2 mg/mile due to the uncertainty analysis. [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

The detection sensitivity of the PM measuring technique is close to the proposed limit of 0.5mg/mile (FTP75). To guarantee (> 95% confidence level) vehicle compliance at 0.5mg/mile, the test result needs to be 2σ below the limit. [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

The average standard deviation (σ) was determined to be 0.15 mg/mile for the Volkswagen Group's labs. For a vehicle to comply with the limit of 0.5 mg/mi, it is not to emit more than 0.2 mg/mile due to the uncertainty analysis. [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

SEE ORIGINAL COMMENT FOR GRAPH [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

EPA anticipates that the PM standards in the NPRM will require the application of a GPF. Volkswagen believes that CARB's LEV IV US06 3 mg/mile PM Standard already implies a GPF requirement. Volkswagen requests EPA to adopt CARB's LEV IV PM Standards and furthermore allow use of a compliance statement for all cycles, not just for FTP75 (20-30°C) and US06 if ICE vehicles are equipped with a GPF. [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

Particulate Number (PN) and Particulate Matter (PM) Data Comparison [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

Volkswagen performed six FTP75 tests at 73°F under standard lab test conditions on a conventional combustion vehicle equipped with GPF to fulfill LEV IV requirements. The vehicle was LEV IV compliant to the 1.0 mg/mile standard. Data results show wide variability with respect to the particulate mass (up to 50%) while PN integration data shows high correlation and high repeatability. CO2 results were repeatable for the six tests in a range of ± 1%.[EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

SEE ORIGINAL COMMENT FOR BAR GRAPH Of MY25 NAR project (development test results) [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

GPF Infrequent Regeneration Adjustment Factor (IRAF) [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

Volkswagen supports AFAI's position with respect to the infrequent regeneration adjustment factors. [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

Volkswagen believes that lower stage active regeneration modes will not result in non-compliance on any prescribed test cycle. Volkswagen supports the adoption of the European "Ki-Factor approach" for IRAF determination. If soot accumulation over a 2485 miles (4000 km) does not trigger a fully active regeneration, the standard "SI-IRAF" of 1 (multiplicative factor) is assigned (reference European regulation: « VO (EU) 2017/1151 in current version VO (EU) 2023/443 Article 2 », Annex XXI, Sub-annex 6, Appendix 1). [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

Volkswagen requests use of waiver statement: "Based on our GPF passive regeneration strategies, we attest that no fully active regeneration will take place within 2485 miles (4000 km) during normal vehicle operation based on good engineering judgement. Exemptions will be listed on the AECD document." [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

OBD Monitoring Requirements [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

Volkswagen supports the AFAI's recommendation for EPA to harmonize with CARB on OBD Gasoline and Diesel monitor thresholds as written in 13 CCR 1968.2, by revising the 86.1807-27 (a) to reference CARB LEV IV (version November 30, 2022). AFAI recommends that EPA adopt the CARB OBD emission thresholds that allow robust detection while allowing IUMPR requirements to be met. Due to uncertainty about how lower level standards will be affected by OBD monitoring capability, AFAI recommends that EPA include the interim OBD threshold multipliers for Bin20 and below. [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

With respect to PM monitoring, Volkswagen believes that a PM diagnostic of 30% filtration efficiency threshold is not technically feasible with current technology. Diagnosis of a missing substrate has been demonstrated to be feasible by Volkswagen in other markets. [EPA-HQ-OAR-2022-0829-0669, pp. 8-10]

Organization: Porsche Cars North America (PCNA)

7. Porsche recommends aligning with the PM standards of California's Advanced Clean Cars I and II regulations. [EPA-HQ-OAR-2022-0829-0637, pp. 13-15]

Porsche does not support the adoption of EPA's proposal for 0.5mg PM standard starting in MY2027. As outlined in AFAI comments, Porsche does not understand the basis for this acceleration in Federal PM policy especially given California's recent LEV-IV rulemaking which reaffirmed and retained California's previously adopted LEV-III PM roadmap of 1.0mg. Relative to the potential costs and implementation challenges that this all-new proposal could create, it is unclear of the incremental value that EPA's proposal seeks to achieve by surpassing standards that California confirmed as being effective and appropriate in reducing PM. This is especially important considering California being the state which has the most prevalent challenges with PM emissions nationwide. Considering the overall transition towards electrification, the long-standing 1.0mg policy of California, the uncertainty regarding measurement and certification reliability, and in the minority role that new light-duty vehicles play in the overall PM inventory, Porsche is not supportive of EPA's PM proposal. Instead, Porsche recommends EPA transition to adopt the LEV-III 1.0mg in the timing and context of Tier-4. [EPA-HQ-OAR-2022-0829-0637, pp. 13-15]

As shown in Figure 8.1 of the DRIA (captured below in Figure 1), EPA illustrates the counties which are in nonattainment with the variety of PM standards. EPA makes note of the estimated populations that live within these various counties, however as shown in in the illustration below, the vast majority of that population likely reside in California and in several States that already follow California motor vehicle emissions regulations (i.e., Pennsylvania, Oregon, Washington State). Very few of the states with counties highlighted below are in Federal emissions states. As noted previously, the states who are shown in this figure as having the highest proportion of challenges with PM attainment, were the States who maintained the 1.0mg PM roadmap in LEV-III. [EPA-HQ-OAR-2022-0829-0637, pp. 13-15]

[See original attachment for Figure 1 EPA designated PM nonattainment zones (From Section 8 DRIA)] [EPA-HQ-OAR-2022-0829-0637, pp. 13-15]

Over 10 years ago, CARB finalized their landmark Advanced Clean Cars I regulation which included an all-new PM reduction update for light-duty vehicles. The 1.0mg standard was approved by the Board and waived by EPA, thus establishing the 1.0mg roadmap with a 2025MY start date. The timing for the standard was again reviewed as part of a technical assessment by CARB to determine if an accelerated timeline was appropriate. CARB maintained the 2025MY start date and phase-in to provide additional, cost-effective opportunities to develop PM control technologies. In 2022, CARB finalized their Advanced Clean Cars II regulation and once again the 1.0mg PM standard was maintained as being an appropriate balance of air quality improvement, cost and feasibility especially in light of the States roadmap towards electrification. [EPA-HQ-OAR-2022-0829-0637, pp. 13-15]

Considering CARBs leadership and stability in PM requirements for the US, Porsche created a PM control technology roadmap that incorporated CARB's requirements together in consideration with other global PM requirements. CARB's regulatory timeline has influenced the product development timelines for PM control. This is important in light of EPA's previous Tier-3 rulemaking where EPA specifically did not adopt the CARB 1.0mg FTP PM standard at that time. While EPA concluded Tier-3 with the 3.0mg standard, the agency provided clear indication that future work would continue to assess lower standards. EPA concluded that looking ahead "We will continue to work closely with CARB in this area."4 As such, Porsche recommends that EPA can best deliver on the stated intention to "work closely with CARB" by fully align with CARB on a nationwide implementation of the 1.0mg FTP standard for PM. This alignment would maintain the established PM control roadmaps and provide meaningful, cost-effective PM control for the portions of the US who continue to face challenges with PM inventories. [EPA-HQ-OAR-2022-0829-0637, pp. 13-15]

4 79 FR 23454 Tier-3 Final Rule

When looking across the sources of PM emissions within the total inventory, light duty vehicles are by far a minority contributor. As both EPA and CARB have noted in previous rulemakings, achieving broad reductions of PM inventory requires a vast collection of policies aimed at reducing PM emissions from other mobile sources (e.g., heavy-duty and I/M programs) and from non-transportation sectors, such as agriculture. CARB has implemented a broad suite of policies aimed at reducing PM emissions within their state and for light-duty vehicles, recognizes that beyond the 1mg standard from LEV-III, most additional PM reductions will be derived from their aggressive electrification policy. Given that EPA's MPR proposal generally follows California's electrification ambitions, it would make sense for EPA to align on California's 1mg roadmap in the final rule for the MPR. Even if EPA were to finalize lower levels of electrification, the 1mg roadmap continues to make sense given that most of the PM non-attainment areas are in California. EPA does not appear to have provided sufficient evidence that aiming for reductions on a Nationwide basis beyond the reductions sought in California, is cost effective and practicable, and whether after ten years of PM regulatory stability in LEV-III and LEV-IV, that it now makes sense to disrupt the implementation pathway that industry has been aiming for. This sudden acceleration from EPA creates significant compliance risk with many measurement and test repeatability issues still being questioned. California has determined that the 1mg standard, combined with growth in electrification, reflects a good balance in PM air quality improvements and cost-effective control. Porsche recommends EPA align with CARB. [EPA-HQ-OAR-2022-0829-0637, pp. 13-15]

Organization: Volvo Car Corporation (VCC)

VCC estimates that our current product plan likely complies with the GHG stringency requirements proposed in this NPRM. However, the NPRM's proposed requirement on particulate matter could negatively impact our electrification plans. Some of the proposed requirements are extremely challenging and could impact our electrification plans for the USA. VCC is especially concerned about the potential negative impact to our US plant in South Carolina (our only all electric plant globally). [EPA-HQ-OAR-2022-0829-0624, p. 2]

Particulate Matter (PM)

For several reasons, VCC is opposed to EPA's proposal on particulate matter. Implementing the PM requirements as proposed in the NPRM is just not feasible. The EPA proposal differs from the CARB approach on PM and it is also more stringent than ACCII. Therefore, it will cause a lot of additional burden on manufacturers that are spending most of their resources on electrification. It is not just a matter of adding the gasoline particulate filter, rather it includes substantial development and investments. Such massive hardware changes are just not possible by 2027MY. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

If CARB and EPA are not harmonized then VCC would need to have two sets of hardware in the US market, one Federal and one California + S177 states. This would be very costly for a small OEM like VCC. In 2027MY VCC will only have few engine families in production according to our current plan, but this approach would mean VCC needs to double its engine programs. In addition, VCC has already decided on a hardware technical solution that meets CARB ACCII for 2026 MY and beyond but a final EPA rule is not expected until spring 2024. So it will be very difficult to implement an EPA specific hardware technical solution in time for the 2027 MY. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

VCC's recommendation is that EPA align with CARB with regards to PM. EPA should follow the CARB ACCII PM-regulations and the CARB phase-in plan that is already in effect. This is fully consistent with the way that CARB ACC1 (LEV III) and EPA Tier3 was synchronized in the prior set of regulations. So, there is a precedent for this approach, and given that California and 177 states make up over 40% of the US car market, this approach is efficient and consistent with those regulations already in place. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

EPA's proposal on particulate matter would create a stringent standard that requires additional hardware which is much worse for a small OEM like VCC due to our small fleets. This means investment costs need to be split on much smaller fleets. In addition, there are major development costs which would put VCC at a significant disadvantage. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

VCC has invested substantially to upgrade our dynos used for US certification testing to the latest 1066 standard. VCC did not anticipate any further upgrades to these dynos because VCC will be all electric in 2030MY. Therefore, the EPA proposal would require upgrades for one market (USA) for only 3 model years and then VCC would discontinue the whole emission measurement system in 2030. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

The proposal would also necessitate additional test capacity and different separate tests for EPA and CARB. So, it would mean doubling the number of the tests and this would create additional administrative burden in order to implement. Increasing test cells does not happen overnight and it would likely not be feasible for VCC to get the additional test cells needed for MY 2027 testing. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

In addition to separate tests, the EPA proposal differs from CARB requirements on emission and OBD certifications. If CARB and EPA are not harmonized VCC must submit two OBD applications for each engine, one for CARB and one for EPA. Many OEMs are likely in a similar position, but the implication to small volume manufacturers is much more significant than it is to the larger OEMs. VCC encourages EPA to harmonize with CARB and not require separate EPA certifications. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

New certification and compliance programs will likely be costly, especially with new tightened criteria that is proposed. VCC believes measurement accuracy is a concern at this low level. See the section on tunnel blank PM testing contained in the Alliance for Auto Innovation comments. In addition, it is not feasible with current existing sensor technology to monitor and detect the proposed requirement of 30% efficiency (See appendix for technical comments on the OBD proposal). It is also important to note that active regeneration is very infrequent on petrol engines and happens only during extreme conditions. This would make it problematic to consistently detect frequent or incomplete regeneration (See appendix for technical comments on the OBD proposal). [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

The NPRM proposed PM standard alone would mean the few remaining HEVs in Volvo Cars' cycle plan 2027MY-2029MY would likely need new hardware to accommodate a new gasoline particulate filter (GPF). For a small manufacturer like VCC, this would be necessary for 3 years only for vehicles with short life span and it would be challenging and costly. It would result in very little environmental benefit. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

EPA should consider requiring more stringent fuel requirements which would have a more significant environmental impact at a lower cost. Although changes to fuel standards are outside the scope of this NPRM, VCC believes that fuels which contain reduced particulate formation can be utilized in today's vehicles and future vehicle fleets. This would have faster and greater environmental benefit without all the burden and investment of PM filters which would be utilized for future vehicles only. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

Rather than the EPA proposed particulate matter requirements in the NPRM, VCC strongly encourages EPA adopt the CARB PM1 Regulation and allow for a Phase-In for these requirements. This is best pathway for harmonization and will deliver environmental benefits without unnecessary additional costs. [EPA-HQ-OAR-2022-0829-0624, pp. 2-4]

Other Concerns and Uncertainties

Given the short lead time until 2027 model year, we urge EPA to include an alternate phase-in or interim standards, etc. An alternate phase-in for light duty vehicles should allow for PM In-use interim standards for the first year. This was done for Tier3 so there is precedent for setting interim standards at the outset. Given that the alternate in-use FTP standard for PM is 0.006 g/mile for 2021 and earlier model years, VCC encourages EPA to adopt an alternate in use FTP standard for PM of 0.001 g/mile for 2029 and earlier models. [EPA-HQ-OAR-2022-0829-0624, p. 4]

Organization: Wisconsin Department of Natural Resources

EPA estimates that these standards will result in approximately a 95% reduction in particulate matter (PM) emissions from the covered vehicles. This is significant, and will help states attain and maintain both the current PM standard as well as any revised, more stringent standard EPA may set in the future. It will also help states address near-road PM emissions, which will mitigate localized impacts, improve the air quality in near-road communities, and assist agencies with satisfying transportation conformity regulatory requirements. [EPA-HQ-OAR-2022-0829-0507, p. 1]

EPA Summary and Response

Summary of Particulate Matter Comments

The proposed PM standard for LDV and MDV is the subject of myriad supportive, adverse, and nuanced comments from many stakeholders. Stakeholder comments are broadly grouped into four areas: 1) Comments that reference the CARB ACC II PM standard, 2) Comments about the justification of the EPA PM standard including costs and benefits, 3) Comments about technical issues of the EPA PM standard, and 4) Comments about lead time and phase-in of the EPA PM standard.

1) Comments that reference the CARB ACC II PM standard

AAI commented that EPA failed to consider adopting the CARB ACC II PM standard or other alternatives to the EPA PM standard and a number of commentors, including AAI, Stellantis, VW, Mercedes-Benz, Toyota, Honda, AML, Ferrari, and others, recommended that EPA adopt the ACC II PM standard instead. AAI asserted that the EPA PM standard would create conflicting state and federal requirements.

CARB provided strong support for the EPA's federal PM standard, commenting that EPA's proposals are appropriate and largely consistent with the overall CARB standards. CARB pointed out that EPA's rulemaking does not require ZEV sales, as California's rules do, so the tightening of federal PM standards is critical to ensure that internal combustion engine vehicles that will continue to be sold, become cleaner.

Several manufacturers raised concerns that EPA's PM standard is more stringent than CARB's ACC II standard. CARB pointed out that at the time of CARB's original adoption of its standards in 2012, the gasoline particulate filter technology that EPA is now relying on was not as well developed to support such stringent levels. Since that time, however, the technology has matured and been deployed industry-wide in the European vehicle fleet, confirming its technology readiness. Under ACC II regulations, the ZEV requirements necessarily reduce the fraction of conventional vehicles at a pace that minimize the additional benefit from a further reduction in the PM FTP standards in California.

CARB supported the proposed PM standards because EPA's proposed standards as a whole do not have a parallel path to effectively eliminate emissions from new vehicles. "In the absence of this certainty of future zero-emission standards, the proposed PM standards will ensure over the long term that PM emissions are reduced to the maximum extent feasible from vehicles driven in California (and elsewhere, especially in cold climates) even if they were not originally sold here. U.S. EPA's proposed PM standards are appropriate for protecting public health and reducing exposure to PM, especially for residents of disadvantaged communities that are in close proximity to busy roadways." CARB comments that EPA's PM standard is needed to protect public health, especially in communities with disproportionate exposure to air pollution.

2) Comments about the justification of the EPA PM standard including costs and benefits

EPA received strong support for the PM standard from ALA, ADEQ, CARB, EDF, ICCT, MECA, NACAA, NTAA, NESCAUM and OTA, and the Wisconsin Department of Natural Resources. These commenters stressed the importance of the PM standard to human health, and some discussed the need for a strong PM standard since the EPA rule lacks a ZEV mandate, which CARB uses to greatly reduce PM standards.

For example, ALA commented that filters like GPFs should be the norm to control fine particulate, a carcinogenic pollutant, on vehicles sold in American communities. ADEQ commented that Arizona has several PM nonattainment areas and ADEQ supports the adoption of GPF technology that is proven to reduce combustion engine tailpipe emissions by over 95 percent. EDF supported the PM standard as proposed: a 0.5 mg/mi cap for light-duty vehicles and MDV across three test cycles (-7°C FTP, 25°C FTP, US06), PM certification tests at the test group level, and every in-use vehicle should be tested for PM.

ICCT supported the PM standard including the -7°C FTP test. ICCT described a recent remote sensing study performed by ICCT that shows that for recent model years, light-duty vehicles and trucks show an increase in UV smoke, a proxy for PM. While gasoline light-duty vehicle and truck tailpipe CO, HC, and NOx measured by remote sensing show clear and consistent downwards trends, UV smoke averages increase starting from model years 2015–2020. For 2020 model year vehicles, the UV smoke fleet average is similar to that of 2005 model year vehicles, compared to the other three pollutants, which show a 66%–86% decrease from 2005 to 2020 model year vehicles. Further analysis shows the increase is due to increased market fraction of GDI vehicles, which tend to emit more PM than PFI vehicles. An analysis of certification test data shows that PM emissions from GDI vehicles have been reducing over the years; however, they still emit higher PM than PFI vehicles on FTP cycle. For 2023 model year vehicles, GDI vehicles emit on average about 3 times more PM emissions than the PFI vehicles on FTP cycle. For both cycles, the trajectory of average PM emissions for GDI vehicles flattens out over the last few years, suggesting that PM emissions from GDIs will not likely reduce substantially any further without the adoption of more stringent emission standards.

ICCT further comments that while EPA's proposed standard does not include a particle number limit, the stringency of the PM emission standard will address both PM2.5 and PM0.1 through the implementation of GPFs, which can reduce PM emissions by 97% to 100% and PN emissions by 80% to 99%. ICCT also comments that remote sensing data suggest the EPA MOVES model underestimates PM emissions and if the model were improved, the benefits of the rule would increase.

MECA commented that in 2021 the WHO and HEI concluded that there is no identified safe threshold for PM2.5 or black carbon, at which no damage to health is observed; EPA is poised to revise the primary annual PM2.5 standard from 12.0 to within the range of 9.0 to 10.0 $\mu g/m^3$; and that a recent European study using state-of- the-art exposure methods and large cohorts found that health impact risks were still evident at PM levels lower than current ambient standards for PM2.5. In particular, the study reported that the hazard ratios for natural-cause mortality remained elevated and significant for PM2.5 even when the analyses were restricted to observations below 12 μg/m. A MECA study found that deploying a PM regulatory control strategy that includes a combination of electric vehicle penetration and best available exhaust controls on the remaining combustion vehicles approximately doubles the PM2.5 reductions achievable by electrification alone, and cumulative health cost savings from PM2.5 reduction would be between 18 and 163 billion dollars through 2050.

NESCAUM and OTA commented that PM2.5 exposure can trigger heart attacks and strokes, exacerbate obesity and diabetes, and contribute to cognitive challenges.

CARB, EDF, ICCT, MECA, NTAA, NESCAUM and OTA, and the Wisconsin Department of Natural Resources commented on the importance of the PM standard for low-income communities, communities of color, and people that live or work near transportation hubs and corridors. These commenters note that these groups have historically faced significant and elevated harms from transportation pollution and recent studies found that light-duty vehicles and light-duty trucks are responsible for a significant share of PM-attributable premature mortalities. MECA comments that university researchers in the U.S. have reported that light duty gasoline vehicle emissions remain prominent amongst the emission source sectors that cause the largest absolute disparities for persons of color communities. NTAA comments that many residents in Indian country continue to be exposed to concentrations of PM that exceed current National Ambient Air Quality Standards. With a few exceptions, the sources of this pollution are outside the jurisdiction and control of Tribal governments.

ICCT commented on the cost of GPF technology asserting that GPFs are cost-effective devices, with per vehicle manufacturing cost of $51–$166 based on EPA estimates and $50–$184 based on other independent studies. Based on the European Commission's Euro 6/VI assessment, the incremental increase in technology cost per vehicle for Euro 6 standards compared to Euro 5 was estimated at $92–$113 for the addition of GPF along with lambda and pressure sensors. ICCT concludes that EPA's proposed PM standard will provide large health benefits through reduced fine and ultrafine particulate matter emissions with a relatively low added manufacturing cost.

AAI commented that EPA failed to adequately justify the PM standard and failed to ensure that relevant facts support the standard. AAI, Stellantis, Hyundia and AML asserted the PM standard will impose high cost and several of these commentors stated the standard will result in little corresponding air quality benefits. API commented that EPA did not use the most recent cost estimates for GPF technology and questioned whether EPA's cost estimates include associated sensors and controllers. AAI states that the PM standard will add development work, cost, and divert OEM resources from fleet electrification. Mercedes-Benz also commented that the PM standard and proposed OBD requirements would divert resources from fleet electrification. AAI encouraged EPA to adequately account for the relevant costs and benefits to fulfill its statutory obligation to engage in reasoned, evidence-based decision-making. Stellantis and an SVM manufacturer group commented that expensive test facilities will be needed to measure PM for the standard. Stellantis commented that the PM standard offers only modest reductions in PM compared to the gains that will be achieved with market transition to electrification.

3) Comments about technical issues of the EPA PM standard

Many comments focused on technical issues of the EPA PM standard. These comments discuss challenges of PM testing using -7°C FTP and US06 test cycles, the need for the -7°C FTP standard, concern that the PM standard may not allow manufacturers to "drop-in" GPF technology used in other markets, measurement challenges, challenges of OBD monitoring of GPF technology, and challenges of certification test requirements.

CARB, ICCT, NESCAUM and OTA commented on the importance of requiring 0.5 mg/mi PM over three test cycles, including the -7°C FTP but AAI and Ford commented that applying the PM standard to the -7°C FTP adds to test burden and may requires upgrades or investments to test facilities. AAI provided examples which it says may complicate implementing PM testing in the -7°C FTP, like water condensing on the sample filter face or increased variability. An SVM manufacturer group asserted there are technical issues associated with measuring PM below 1 mg/mi and EPA should not require cold testing or exempt SVMs from cold temperature testing. AML commented that it is not yet fully understood what is needed to meet the 0.5 mg standard at -7°C with high-performance engines.

Ford commented that the benefit of requiring the PM standard in the -7°C FTP is de minimis given that GPF technology will be demonstrated on the 25°C FTP and US06 test cycles, and recommends that GPF-equipped vehicles be exempt from the -7°C FTP. Mercedes-Benz commented on the test burden and justification of the -7°C FTP. Stellantis asserted that the 25°C FTP and US06 test cycles will force GPF adoption without needing the -7°C FTP test. API commented that only six states have average winter temperatures below -7°C.

AAI commented that applying the PM standard to the US06 test cycle may require both engine-out emissions reductions and development of GPF technology for high temperature and flow conditions. AAI suggested that EPA should align its test cycles with those of ACC II and allow manufacturers to use US06 bag 2 in place of the full US06 test for PM testing of MDV to reduce test burden.

AAI and Mercedes-Benz commented that EPA has not designed a program that allows GPF technology from other regions to be “dropped in” and this difference to other regions requires additional development and resources. Mercedes-Benz also noted the challenge of the proposed GPF OBD requirements. Stellantis asserted that the PM standard will require all new GPF systems. Industry commenters pointed to challenges of some current vehicle models not having sufficient room to package GPFs today. Ferrari expressed concern about the effectiveness of their existing GPF configuration that was designed to meet the CARB 1 mg/mi standard in meeting the more stringent EPA 0.5 mg/mi standard considering the proposed lead time.

Numerous comments were submitted on the topic of measurement challenges. AAI, Ford, VW, Mercedes-Benz, Honda, API, an SVM small manufacturer group and others wrote that uncertainty in the PM measurement process is too large and AAI explains how measurement challenges increase for large vehicles. Ferrari comments that measurement variabilities should be considered. AAI and Ford recommend allowing re-tests for exceedances during certification, confirmatory or in-use testing, especially for vehicles equipped with diesel or gasoline particulate filters and Mercedes-Benz suggests that EPA allow averaging of PM measurements and including a conformity factor. AAI provides example data from a laboratory where a US06 test resulted in a PM result that was several times higher than other testing in that lab and other labs. AAI also provided data showing greater variability in repeat robot weighings of a clean blank filter to a stainless steel weight of similar mass. Ford commented it would like to work with EPA to determine if there is a role for limited application of PN measurements to help reduce variability and test burden.

CARB commented that it has previously addressed the technical feasibility of gravimetric PM mass measurement at 1 mg/mi and below with a technical review presentation to the Board in October 2015. CARB concluded that the gravimetric method prescribed for the FTP driving cycle, in conjunction with appropriate laboratory practices, has a measurement precision of 0.1 mg/mi, even when measuring emission rates less than 1 mg/mi. The method can precisely measure PM emissions to determine compliance with a standard of 0.5 mg/mi. It should also be noted that such analysis was conducted on low-PM-emitting vehicles that had a higher level of vehicle test-to-test variability than what is observed in U.S. EPA’s test data for vehicles equipped with a gasoline particulate filter. As this technology is a mechanical wall-flow filtering device with a high trapping efficiency, it inherently dampens variations in PM emissions and produces more consistent results at very low PM levels, thereby reducing one element of concern regarding measurement precision at low PM levels.

AAI recommended that EPA require that all labs adopt certain test procedure changes to support measuring PM below 0.5 mg/mi. EPA should require tunnel blanks to be measured weekly. EPA should require that runnel conditioning/cleaning be performed when tunnel background exceeds 5 µg. EPA should require tunnel background correction given the significant difference it can have on test results at low levels of PM. EPA should require the limit of reference filter validity be reduced from 10 to 5 µg. EPA should require that robotic auto handlers should be required especially at independent laboratories that perform in-use testing. EPA should require that single filter collection with flow weighting be used in FTP testing.

Some commenters requested that EPA continue to cooperate with industry to affirm and improve best practices that are not overly burdensome.

ALA commented on the importance ensuring that critical emission controls like GPFs exhibit ongoing functionality. While not disputing the importance of ensuring ongoing functionality, VW, Stellanis and other commenters expressed concern that proposed GPF OBD requirements would be difficult to achieve with currently available sensing technology. An SVM manufacturer group and AML commented that GPF aging and monitoring for OBD purposes is not currently fully understood.

AAI supports pre-production PM certification testing reverting to the durability group level after the lower PM standard is fully phased in, as a common-sense adjustment that would reduce test burden.

4) Comments about lead time and phase-in of the EPA PM standard

Commenters expressed opposing views on the phase-in of the PM standard. ALA encouraged EPA to accelerate the phase-in of the PM standard to require all new vehicles to use GPFs in MY 2027 for the health benefits that this would provide. ICCT recommended that EPA adopt an accelerated phase-in of the PM standard that EPA requested comment on (50 or 80% in 2027 and 100% in 2028 for vehicles at or below 6000 lb GVWR) because GPF is a mature technology in widespread use in other markets. MECA commented that the PM standard should be implemented at a faster pace than proposed based on the combination of the predicted rate of electrification (BEVs count toward compliance) alongside a feasible rate of PM emission control technology implementation. MECA recommended a phase-in for vehicles at or below 6000 lb GVWR of 60/90/100% in 2027/2028/2029.

Other commenters urged EPA to adopt a phase-in that is slower than what was proposed. AAI commented that long lead-time is necessary to develop exhaust systems that include a GPF and that balance emissions reduction and PM collection/regeneration. Ford and other industry commenters requested more time to apply GPF technology across all ICE models than the 40/80/100 percent phase in that was proposed. An SVM small manufacturer group, AML and Ferrari commented that the proposed PM standard goes too far too soon, going farther than the CARB ACC II PM standard and not providing additional lead time for SVMs. The SVM group suggested a phase-in approach that is consistent with Euro 7. AAI recommended that EPA adopt an interim in-use standard for the first two model years after a test group certifies to a new PM standard.

5) Comments about the role of gasoline aromatics in particulate formation

Modlin and Detchon describe how aromatics in gasoline are known air toxics as well as major drivers of direct PM emissions and formation of secondary PM in the atmosphere. They suggest EPA should phase down aromatic content in gasoline, with the expectation that aromatics can be replaced with additional ethanol. They also discuss ultrafine particles and PAHs, noting that GDI-powered vehicles produce much higher levels of these than older technology vehicles, and that these pollutants in combination pose a serious danger to public health. They suggest that reducing gasoline aromatics content and requiring particulate filters on new vehicles will be important mitigation strategies.

Summary of Particulate Matter Responses

1) Responses to comments that reference the CARB ACC II PM standard

EPA carefully considered adopting alternatives to the PM standard, including CARB standards, European standards, and other alternatives not proposed. The CARB ACC II program provides PM reductions relative to Tier 3 through a more stringent PM standard from ICE-based vehicles and very significantly, PM reductions from a ZEV mandate. As noted in RTC Section 4.1, EPA is not adopting a ZEV mandate, as the CARB standards use, and instead allows manufacturers greater flexibilities in the types of vehicles they may produce. Therefore it is important and appropriate for EPA to finalize a PM standard that is aligned with a performance-based standard, i.e., the EPA performance-based standard requires a more protective PM standards, consistent with our expectations that vehicles with ICE will be the majority of the fleet for decades to come. Areas outside of California will likely have many more ICE vehicles than California will, and therefore greater PM control from ICE vehicles is very important. As compared to the CARB PM standard, the EPA PM standard covers more operating conditions (e.g., the CARB standard does not have PM requirements for cold temperatures like -7°C, which is common in many regions). Colder temperatures are common is many regions outside of California and new GPF technology enables effective PM control under all operating conditions, including high load and cold temperatures, as explained in preamble Section III.D.3.iii. As described in RIA Chapter 3.2.6.2, typical reductions in tailpipe emissions from MY 2022 GPF technology are greater than 95% reduction in PM, greater than 98% reduction in EC (elemental carbon), and greater than 99% reduction in filter-collected PAH.

EPA agrees with CARB's comment that EPA's proposals are appropriate and largely consistent with overall CARB standards. CARB pointed out that EPA's rulemaking does not require ZEV sales, as California's rules do, so the tightening of federal PM standards is critical to ensuring that internal combustion engine vehicles that will continue to be sold, become cleaner.

Several manufacturers raised concerns that EPA's PM standard is more stringent than CARB's ACC II standard. EPA agrees with CARB's point that at the time of CARB's original standards adoption in 2012, the gasoline particulate filter technology that EPA is now relying on was not as well developed to support such stringent levels. Since that time, however, the technology has matured and been deployed industry-wide in the European vehicle fleet, confirming its technology readiness. Under ACC II regulations, ZEV requirements necessarily reduce the fraction of conventional vehicles at a pace that minimizes the additional benefit from further reduction in the PM FTP standards in California.

EPA agrees with CARB's comment that because EPA's proposed standards as a whole do not have a parallel path to effectively eliminate emissions from new vehicles, a more protective PM standard is necessary. In the absence of this certainty of future zero-emission standards, EPA's proposed PM standards ensure over the long term that PM emissions are reduced to the maximum extent feasible from vehicles driven in California even if they were not originally sold there. EPA also agrees with CARB's comment that EPA's proposed PM standards are appropriate for protecting public health and reducing exposure to PM, especially for residents of disadvantaged communities that are in close proximity to busy roadways.

After considering submitted comments referencing CARB ACC II PM standard and performing additional analysis, EPA has decided not to finalize the ACC II PM standard, and is finalizing the 0.5 mg/mile PM standard described in the Preamble. EPA believes that the 0.5 mg/mi standard is feasible, both technologically and with respect to measurement. The 0.5 mg/mi standard applied to the FTP, -7°C FTP and US06 test cycles will ensure low PM emissions over the broadest range of environmental and operating conditions. In addition, a mass-based standard is appropriate both because the measurement technology is well-demonstrated and because it will help areas attain and maintain the mass-based PM NAAQS.

EPA disagrees with AAI's suggestion that adopting this standard will create a conflict with state (i.e., CARB) requirements. It is true that this standard is more stringent than the current CARB standard, for the reasons described above, but EPA does not find that in itself creates a conflict. Any vehicle which satisfies EPA's PM standard will also satisfy California's PM standard.

2) *Responses to comments about the justification of the EPA PM standard including costs and benefits*

EPA is setting standards for vehicles under 6,000 lb GVWR pursuant to CAA section 202(a)(1)-(2), and is subject to the requirements of CAA 202(a)(3) for heavier vehicles, including the requirement that standards reflect the greatest degree of emissions reduction achievable, giving appropriate consideration to cost, energy and safety and requirements for lead time and stability. As discussed in Section V of the preamble, EPA finds these standards are appropriate and consistent with these requirements, and will reduce PM emissions over the broadest range of vehicle operating and environmental conditions.

In the Preamble and RIA, EPA documents strong technical support for the PM standard, including feasibility of the standard and comprehensive analyses of benefits, and costs. EPA updated the GPF direct manufacturing cost model for the FRM using the latest information. As described in the RIA, the cost model considers the GPF substrate, housing, accessories, pressure sensor, labor and overhead, machinery, and warranty costs. The updated model uses a larger GPF swept volume ratio (GPF volume to engine displacement volume) of 0.80 instead of 0.55 in the NPRM, and uses 2022 dollars instead of 2021 dollars. The larger swept volume ratio is based on an expanded GPF/vehicle database, input from a GPF supplier, and an ICCT PM/GPF fact sheet released in November 2023.

EPA performed years of vehicle testing with various GPF installations, including PM, EC, PN, filter-collected and gas-phase PAH emissions and documented that in the Preamble, RIA, and publications. EPA performed inventory and air quality modeling. EPA also engaged with stakeholders, suppliers, and reviewing the literature. EPA considered cost, flexibility to manufacturers, public health, and legal requirements of the Clean Air Act. The EPA PM standard is expected to result in more than a 95% reduction in tailpipe PM from over 100 million vehicles and will bring US PM emissions closer to those that have already been established in other areas of the world such as Europe (2017), China (2020), and India (2023).

EPA accounts for relevant benefits and costs of the PM standard and is fulfilling its statutory obligation to protect human health and the environment in a reasoned, evidence-based approach, as documented in the Preamble and RIA.

EPA's justification of the PM standard is bolstered by comments and analyses by ALA, ADEQ, CARB, EDF, ICCT, MECA, NACAA, NTAA, NESCAUM and OTA, and the Wisconsin Department of Natural Resources, who comment on the need for the PM standard with respect to health benefits for all Americans and especially for low-income communities, communities of color, and people that live or work near transportation hubs and corridors and in nonattainment areas, and on the attractive benefit to cost ratio of the standard.

In response to comments from manufacturers about the challenges of integrating GPFs into vehicle designs, EPA recognizes that GPFs are not a drop-in technology and that the PM standard may require some labs to change test practices that were previously sufficient for measuring higher levels of PM. Manufacturers require lead time to adopt GPF technology across U.S. applications and make changes to testing practices and so EPA has lengthened the phase-in schedule for PM and other criteria pollutants as described in preamble Section III.D.3.ii and more generally in preamble Section III.D.1, as compared to our proposal.

The PM standard will deliver large benefits and a high benefit to cost ratio, which justify manufacturers' expending development resources. As described in RIA Chapter 3.2.6.2, typical reductions in tailpipe emissions are greater than 95% reduction in PM, greater than 98% reduction in EC (elemental carbon), and greater than 99% reduction in filter-collected PAH. New GPF technology enables such reductions under all operating conditions and temperatures. These reductions directly benefit drivers using roadways or living near roadways. Reductions total annual PM emissions resulting from the LMDV rule are shown in preamble Section VII.A and decreases in annual average PM2.5 concentrations and population-weighted average annual PM2.5 concentrations are shown in preamble Section VII.B.1. As discussed in Preamble Section V, the cost of GPF technology, which is explained in preamble Section III.D.3.viii and RIA Chapter 3.2.6.4, is justified by the benefits to public health and welfare. Similarly, for those vehicles with GVWR over 6,000 lbs, EPA finds that the final standards based on GPF technology are appropriate because they reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator has determined will be available for the model year to which such standards apply, giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology.

Stellantis and an SVM manufacturer group commented that expensive test facilities will be needed to measure PM for the standard. EPA did not propose any changes to PM test procedures because the Agency does not believe that test procedure changes are required to measure PM at the final PM standard. Current test procedures outlined in 40 CFR parts 1066 and 1065 allow robust gravimetric PM measurements well below the PM standard of 0.5 mg/mi, as demonstrated by EPA and other laboratories and described in Preamble Section III.D.3.iv-v and RIA Chapter 3.2.6.2. Although changes to Part 1065 and 1066 procedures are not required, it is important to use good engineering judgment when transitioning to measuring PM below 0.5 mg/mi. This includes consideration of filter media selection, effective removal of static charge from filter media, dilution factor, filter media flow rate, using a single filter for all phases of a test cycle, robotic weighing, and minimizing contamination from filter handling, filter screens and cassettes. EPA appreciates that changes to test practices may be needed, that PM sampling equipment may need to be installed in some cold test facilities, but EPA does not anticipate that the new PM standards will require manufacturers to build entirely new test facilities. We note that many manufacturers have submitted, and certified the validity of, PM test data below 0.5 g/mile to date. Over 20 percent of MY 2021-2024 light-duty vehicle federal PM certification test results are below 0.5 mg/mi. We recognize that test-to-test variability may be of greater concern to manufacturers for the revised standard, but based on our round robin test results we conclude that should not be a significant issue for certification. EPA has provided additional lead-time for SVMs to transition to PM lower measurements with the phase in schedules described in preamble Section III.D.1.

EPA disagrees with Stellantis' assertion that the PM standard only offers modest reductions in PM compared to gains achieved with only a market transition to electrification. Over 100 million ICE-powered vehicles are expected to be sold during the transition to more BEVs, even with new EPA standards requiring strong reductions in GHG emissions. EPA expects that even in 2055 a majority of the light- and medium-duty fleet will have internal combustion engines. An analysis by the Manufacturers of Emissions Control Association (MECA) shows that a regulatory control strategy that includes a combination of electric vehicle penetration and best available exhaust controls for PM (i.e., GPF) on the remaining ICE vehicles results in approximately double the PM2.5 reduction achievable the electrification alone, during the period from 2025 to 2060.

3) Responses to comments about technical issues of the EPA PM standard

AAI, Ford, Stellantis, Mercedes-Benz and API commented on the need for the -7°C FTP test cycle. Specifically, Ford stated it believes the benefit of the -7°C FTP PM standard is de minimis considering the effectiveness of GPF technology will be sufficiently demonstrated in the 25°C FTP and US06 test cycles. Stellantis asserted that the 25°C FTP and US06 test cycles will force GPF adoption without needing the -7°C FTP test. EPA disagrees with these assertions and CARB, ICCT, NESCAUM and OTA specifically commented on the importance of requiring all three PM test cycles (-7°C FTP, 25°C FTP, and US06). The -7°C FTP test cycle is crucial to the final PM standard because it addresses high and uncontrolled cold PM emissions from vehicle operation at cold temperatures. Tier 3 PM standards for both the FTP and US06 are only for 25°C. Absent the -7°C FTP test, vehicles would not achieve PM reductions commensurate with GPF technology across the widest range of environmental and vehicle operating conditions. As demonstrated in Preamble III.D.3.iii, some vehicles without GPFs satisfy the 0.5 mg/mile standard in the 25°C FTP and US06 cycles but exhibit dramatically higher PM emissions at -7°C (an important real-world temperature), with the same being true at other important off-cycle vehicle operating points. Without the -7°C FTP test cycle, vehicles would not be required to have low PM emissions under all operating conditions.

For many years, manufacturers have been certifying vehicles at -7°C for the FTP test cycle for NMHC and CO standards. The final PM standard requires vehicle manufacturers to measure PM in the same existing test cycle. EPA anticipates that some vehicle manufacturers will require installation of PM sampling equipment into their cold facilities, although some of the required measurement equipment, such as dilution tunnel, should already be in place. Manufacturers also have the option to use a contract lab to perform cold PM testing.

In response to the API comment that only six states have average winter temperatures that are below -7°C, EPA notes that vehicles are often started in the morning, when the temperatures are often below the average temperature of the day, and that some days are colder than the average winter temperature. -7°C is not an extreme temperature in much of the United States and has been used for CO and NMHC standards for some time.

Several commenters noted concern with increased test to test variability with a more stringent PM standard. The PM standard being finalized requires PM emissions to be at or below 0.5 mg/mi. Manufacturers typically design their vehicles to have emissions below a standard to protect for test and vehicle variability. High test-to-test variability normalized by the testing mean is not a concern for certification if the mean plus variability is low enough. For example, 0.1 mg/mi with a standard deviation of 0.1 mg/mi has high normalized variability yet provides high confidence of resulting in a measurement below 0.5 mg/mi on any given test. In conducting testing to support the feasibility of the final standard, EPA, and the labs with which we collaborated, demonstrated reduced test to test variability with good measurement practices.

CARB submitted comments supporting the technical feasibility of low PM gravimetric measurements. CARB explains that it has previously addressed the technical feasibility of gravimetric PM mass measurement at 1 mg/mi and below with a technical review presentation to the Board in October 2015. CARB concluded that the gravimetric method prescribed for the FTP driving cycle, in conjunction with appropriate laboratory practices, has a measurement precision of 0.1 mg/mi, even when measuring emission rates less than 1 mg/mi. The method can precisely measure PM emissions to determine compliance with a standard of 0.5 mg/mi. It should also be noted that such analysis was conducted on low-PM-emitting vehicles that had a higher level of vehicle test-to-test variability than what is observed in U.S. EPA’s test data for vehicles equipped with a gasoline particulate filter. As this technology is a mechanical wall-flow filtering device with a high trapping efficiency, it inherently dampens variations in PM emissions and produces more consistent results at very low PM levels, thereby reducing one element of concern regarding measurement precision at low PM levels. EPA own experience corroborates these comments and EPA agrees with these conclusions.

There should not be any special concern about designing vehicles to the -7°C FTP standard for vehicles produced by SVMs or for vehicles with high-performance engines. GPF suppliers work with SVMs and large manufacturers to design GPFs for mass produced vehicles and vehicles that are produced in small numbers. At least one SVM is already selling GPF-equipped vehicles in the United States. Large manufacturers build some vehicles with high-performance engines as well, and GPFs have been successfully applied to those applications.

Based on comments from manufacturers, EPA is providing test burden reduction by finalizing an option for manufacturers to attest to meeting the -7°C FTP PM standard for MY 2027 and MY 2028 vehicles. This option applies to vehicles at or below 6000 lb GVWR, early phase-in schedule vehicles between 6001-8500 lb GVWR, and early phase-in schedule vehicles between 8,501-14,000 lb GVWR, and provides manufacturers with extra time to integrate PM samplers into their cold test cells if they do not already have them. Manufacturers are still responsible for ensuring that vehicles comply with the -7°C FTP PM standard, and EPA may conduct testing to confirm whether vehicles meet the standard, so manufacturers must have confidence in their attestation.

A round robin test program spanning three organization and five test cells showed meeting the -7°C FTP PM standard is feasible with MY 2022 GPF technology and the test procedures described in detail in preamble Section III.D.3.iii-iv and RIA Chapter 3.2.6, with an excellent test validity rate. EPA has the same requirements on dilution factor, filter face velocity, filter sampling temperature, and filter conditioning and weighing in the -7°C FTP, as in other test cycles. As required by the CFR, sample filters must be maintained between 47 and 52°C to avoid or greatly minimize water condensation on the sample filter face and as shown in the Preamble and RIA, test to test variability was sufficiently low.

In response to the comment from the SVM manufacturer group about there being technical issues associated with measuring PM below 1 mg/mi and EPA should not require cold testing or exempt SVMs from it, EPA did not propose any changes to PM test procedures because the Agency does not believe that test procedure changes are required to measure PM at the final PM standard. Current test procedures outlined in 40 CFR parts 1066 and 1065 allow robust gravimetric PM measurements well below the PM standard of 0.5 mg/mi, as demonstrated by EPA and other laboratories and described in preamble Section III.D.3.iv-v and RIA Chapter 3.2.6.2. Although changes to Part 1066 procedures are not required, it is important to use good engineering judgment when transitioning to measuring PM below 0.5 mg/mi. This includes consideration of filter media selection, removal of static charge from filter media, dilution factor, filter media flow rate, using a single filter for all phases of a test cycle, robotic weighing, and minimizing contamination from filter handling, filter screens and cassettes. EPA is finalizing additional time for SVMs to transition to PM lower measurements with the phase in schedules described in preamble Section III.D.1.

After consideration, EPA is requiring that SVMs meet the PM standard in -7°C FTP test cycle because as explained above, the -7°C FTP is crucial to the final PM standard in that it addresses uncontrolled cold PM emissions in Tier 3, and absent the -7°C FTP test, vehicles would not achieve PM reductions commensurate with what GPF technology offers across a wide range of operating conditions. SVMs may perform -7°C FTP testing themselves or work with a contracting lab to do the testing. SVMs currently certify CO and NMHC in the same -7°C FTP test cycle and Euro 6 includes RDE solid PN standards down to -7°C.

EPA agrees that meeting the PM standard in the US06 on ICE-powered vehicles typically requires attention to both engine-out emissions and GPF designs that possess good filtration under normal conditions and high temperature, high flow conditions. Good engine controls must be used to avoid high engine-out SVOC that may contribute to PM emissions. GPFs must be used that have high filtration even without the benefit of soot loading, such as during or immediately after a GPF regeneration. However, newer GPF technology (e.g., the MY 2022 GPFs tested in round robin testing, preamble Section III.D.3.iii and RIA Chapter 3.2.6) has very high filtration even during and immediately after a GPF regeneration, and easily meets the final PM standard in the US06 as shown in preamble Section III.D.3.iii and RIA Chapter 3.2.6, for all of the test vehicles including turbocharged pickup trucks and a Class 2b truck. Even the oldest test vehicle, a 2011 F150 3.5L Ecoboost, which has high engine-out PM, uses a turbocharged downsized engine that is more likely to use enrichment, and was tested with a somewhat undersized GPF, easily met the 0.5 mg/mi standard.

AAI suggested that EPA should allow manufacturers to use US06 bag 2 in place of the full US06 test for PM testing of MDV to reduce test burden. EPA considered this suggestion but is finalizing the requirement to use the full US06, as was proposed, because only using only bag 2 of the US06 would mean that only high load highway driving would be represented, ignoring high load city driving, which all vehicles experience. The high load city driving portion of the US06 has some of the highest rates of vehicle acceleration of the US06, leading to significant passive GPF regeneration on GPF-equipped vehicles. Using the full US06 ensures good PM control even during and immediately after GPF regenerations.

The US06 test results in higher tunnel flow rates and temperatures than other cycles. If vehicles with high emissions were previously tested in that lab or if a great deal of low load operation occurred, the US06 may cause a release of stored emissions from prior use. EPA recommends that if a lab notices this in their testing, they consider running a high load conditioning test before performing a US06 test with low PM.

Regarding AAI and Mercedes-Benz' comments that the PM standard was not designed to allow GPF technology from other regions to be "dropped in" and Stellantis' comment that the PM standard requires all-new GPF systems, we appreciate that existing GPFs cannot simply be bolted onto vehicles. Applying GPFs to a vehicle is not trivial and does require development and resources. In recognition of this, EPA is finalizing a more gradual phase-in and is providing other concessions to give industry additional time for development. We judge the additional time provides manufacturers with sufficient time for GPF sizing, packaging, OBD monitoring, GPF regeneration control, and durability. Packaging GPFs into small vehicles poses challenges due to there being less space, but all manufacturers have been applying GPFs to vehicles in Europe and China for some time (approximately 100 million vehicles have already been sold with GPFs). Some large vehicles sold in the U.S. are not sold overseas so there may be fewer examples to use in the design process, but large vehicles tend to have more packaging space, which somewhat mitigates this challenge. However, in developing the feasibility of a more stringent PM standard, EPA retrofit several vehicles with MY 2022 GPFs currently in mass production in Europe. The measured PM emissions were well below 0.5 mg/mi across three test cycles, three test facilities and five test cells. Details are provided in preamble Section III.D.3.iii and RIA Chapter 3.2.6. Current MY 2022 GPFs are being used to meet current European particle number (PN) standards, but they were also more than sufficient in meeting EPA's 0.5 mg/mi PM standard.

Ferrari expressed concern about the effectiveness of their existing GPF configuration designed to meet the CARB 1 mg/mi standard in meeting the more stringent EPA 0.5 mg/mi standard considering the proposed lead time. In response to Ferrari's concern and comments from other SVMs, EPA is finalizing a criteria pollutant phase-in that provides SVMs with significantly more time, until 2032, to update vehicle GPF configurations and meet the PM standard. The round robin GPF program described in preamble Section III.D.iii and RIA Chapter 3.2.6 demonstrates that MY 2022 GPFs are able to meet the EPA 0.5 mg/mi PM standard with large compliance margins.

Various comments were submitted regarding measurement challenges. AAI, Ford, VW and Mercedes-Benz commented that uncertainty in PM measurements is too large and AAI commented that measurement challenges increase for large vehicles. As described in Preamble Section III.D.3.iii-if and RIA Chapter 3.2.6.2, EPA has shown that current test procedures outlined in 40 CFR Parts 1066 and 1065 allow robust gravimetric PM measurement well below 0.5 mg/mi across a range of vehicle sizes from passenger cars to Class 2b/3 trucks, across three organizations and five test cells. EPA also notes MECA's comment that based on over 15 years of experience with diesel emission controls, medium-duty diesel vehicles that implement DPFs will be able to meet the stringent PM requirements proposed in this rule. EPA acknowledges that minimal compliance with 40 CFR parts 1066 and 1065 does not guarantee success in measuring PM below 0.5 mg/mi and vehicle manufacturers and laboratories must still use good engineering judgement and robust measurement techniques to achieve consistent results. EPA appreciates that laboratories may have to change current practices that were sufficient for measuring PM below 3 and 6 mg/mi to reliably measure PM below 0.5 mg/mi. EPA also acknowledges that the 0.5 mg/mi standard is different from how Europe, China and India control PM emissions to a level that has driven GPFs onto vehicles, primarily with particle number (PN) standards. When any emissions standard is reduced, manufacturers must re-evaluate their current practices, and changes may have to be made. In response to these considerations, EPA is providing a more gradual phase-in, temporary relief on the criteria that trigger an IUCP, and that manufacturers may attest to meeting the -7°C FTP PM standard for MY 2027 and MY 2028 to provide manufacturers with additional time to make measurement procedure changes to achieve the ability to measure below 0.5 mg/mi. EPA has detailed the procedures used by the round robin laboratories, has met repeatedly with many manufacturers to discuss measurement practices during the rulemaking, and is willing to continue to do so to help manufacturers improve their PM measurement capability.

AAI identified several important aspects of PM measurement below 0.5 mg/mi, which along with what EPA describes in preamble Sections III.D.3.iii-iv and RIA Chapter 3.2.6.2, should be helpful to manufacturers in measuring below the 0.5 mg/mi standard. Measuring PM below 0.5 mg/mi begins with simple practices like requiring operators in PM measurement clean-rooms to use power-free gloves, avoiding clothing that sheds lint or dust, not leaning over exposed filters on workbenches, using sticky pads in clean room entranceways, wearing shoe covers to reduce dirt being tracked into the clean room, and regular clean room cleaning. Other elements may be less obvious, like grounding technicians while they handle filters, grounding work benches, etc. These practices are important not just in the PM clean room, but anywhere that filters are handled, such as when they are loaded and unloaded into PM sampling equipment.

Some important elements that EPA-manufacturer discussions have focused on include using PTFE membrane filters with PMP or similar support rings to minimize gas-phase artifact (Part 1065.170) and using sufficient static charge removal before and during filter weighing using, for example, alpha-emitter static charge removal (Part 1065.190). Discussions included improving signal-to-noise ratio by using the lower half of the allowable dilution factor range (Part 1066.110), elevating filter face velocity (FFV) to a velocity approaching the maximum allowable 140 cm/s and loading one filter per test instead of one filter per phase (Part 1066.815). Further elements of good measurement procedure include control of temperature, dewpoint, grounding, using HEPA-filtered dilution air, using an effective coarse particle separator (Part 1065.145) and good filter handing procedures (Part 1065.140/190). Laboratories may also consider using robotic auto-handling for weighing (Part 1065.190) and background correction (Part 1066.110), although the tests demonstrating the ability to measure below 0.5 mg/mile in the test program summarized in preamble Section III.D.3.iii did not use background correction and only one of three organizations used robotic auto-handling.

AAI comments that large vehicles with high exhaust flows must be tested with higher CVS flowrates (to maintain dilution factor requirements) than small vehicles with small exhaust flows. That means that tunnel contamination, filter handling contamination, and filter static charge may be magnified more for large vehicles, when converted to a mg/mi basis, than for small vehicles, due to larger vehicles using larger sample ratios. This observation applies not only to PM, but also to gaseous pollutants including NMOG, NOx and CO, when two vehicles with different exhaust flow rates must meet the same standard. LDV, LDT1-4, and MDPV had to meet the same PM standard in Tier 3, and this observation applies there as well. That is the nature of using a dilution tunnel instead of undilute (raw) tailpipe measurements. The 0.5 mg/mi PM standard now applies to light-duty vehicles and MDV, which extends this effect across a greater range of vehicle sizes than before. However, testing an MDV at EPA showed it to have PM emissions well below the 0.5 mg/mi standard, with very low variability, even without background subtraction, which is allowed by the CFR. Results and test procedures are detailed in preamble Section III.D.3.iii and RIA Chapter 3.2.6.2.3. Based on these data, we consider the 0.5 mg/mi standard to be feasible for MDV and, particularly considering the above-described sample ratio effect.

AAI comments that at the 0.5 mg/mi level, net mass on the sample filter approaches tunnel background levels. For certification purposes, this does not signify a problem so long as vehicle PM is below the 0.5 mg/mi standard. While tunnel background measurements are a useful metric to track, a tunnel background measurement is different from a vehicle measurement in a variety of ways because tunnel background measurements lack the temperature increase provided by vehicle exhaust and lack the water and hydrocarbon content of vehicle exhaust. The dry, clean gas flowing through the dilution tunnel during a background measurement may draw material from tunnel walls that was deposited during prior testing. During a vehicle test, the material on tunnel walls may be in more of an equilibrium state with the gas flowing through the tunnel. Thus, it is possible that tunnel blanks are artificially high. What really matters is the result from the vehicle test.

AAI provides data from a manufacturer that shows that when a vehicle was tested across different test cells at the manufacturer, it resulted in an average PM of 0.2853 mg/mi and two standard deviations of 0.2677 mg/mi. From the description, it isn't clear what the test cycles were, what vehicle was tested, whether it used a GPF, what GPF technology was used if the vehicle used a GPF, and what measurement procedures were followed. Thus, EPA is unable to consider what, if any, specific difficulties this example illustrates with respect to measuring GPF performance below 0.5 mg/mi. EPA has demonstrated ability to measure well below 0.5 mg/mi with low variability across multiple test cells using the procedures described in the Preamble and RIA, and is happy to continue engaging with manufacturers to work toward improved practices in measuring PM.

AAI also provides data from several round robin programs, including EPA NVFEL, at PM levels at, above, and below Tier 3 levels and points to high lab-to-lab variability. EPA suggests that data from vehicles equipped with MY 2022 or newer vehicles is used, and that the measurement procedure issues discussed above be applied. Another issue to consider is how the dilution tunnel was used before low PM testing. If vehicles with high emissions were tested, or if prolonged operation at low load was tested, running a high load cycle may help.

While recognizing that some manufacturer labs will have to make changes, these changes are reasonable, as demonstrated by that in 2023, all five test cells included in the round robin test program detailed in preamble Section III.D.3.iii and RIA Chapter 3.2.6 had no problem measuring PM to well below 0.5 mg/mi in any of the test cycles, and EPA had no problem measuring PM to well below 0.5 mg/mi using a Class 2b truck. The PM standard begins to phase in in 2027 for LDV (20% of vehicles, including BEVs), and manufacturers have until 2030 under the default phase-in schedule for LDT3-4 and MDPV, and have until 2031 under the default phase-in schedule for MDV. EPA is happy to continue to engage with manufacturer labs to share best practices and help improve PM measurement capability.

In response to API's question about whether the test-to-test repeatability demonstrated by EPA only used an aerosol generator to produce PM, the first figure in Preamble Section III.D.3.iv now shows which measurements used a vehicle and which measurements used an aerosol generator. EPA notes that only one example used an aerosol generator and the lowest bars were all from GPF-equipped vehicles.

AAI and Ford commented about allowing PM re-tests and Mercedes-Benz commented on averaging PM tests and allowing for a conformity factor. EPA already allows certification, confirmatory or in-use tests to be designated void and the test re-run if the test is determined to be invalid, e.g., the vehicle was incorrectly fueled or a loaded PM sample filter was dropped onto the floor. EPA regulations currently allow re-tests during manufacturer and EPA conducted certification and confirmatory testing if an emission data vehicle fails an emission standard, including PM. EPA does not allow re-tests for in-use testing unless the test is determined to be invalid, but in-use compliance is determined based on a statistical sample of vehicles. To reduce PM outliers, labs should use best practices described in Preamble III.D.3.iv. Labs may perform triplicate filter sampling (from the same test) and average the results. EPA is providing temporary relief on the criteria that trigger an IUCP, temporarily raising the failure rate that triggers an IUCP to 80 percent of vehicles in a test group. EPA considered laboratory PM measurement variability in developing the 0.5 mg/mi PM standard. RIA Chapter 3.2.6.2.4 quantifies test-to-test and lab-to-lab variability for two vehicles tested repeatedly across three organizations. The vehicle equipped with a MY 2022 GPF produced PM measurements well below the 0.5 mg/mi standard in all three test cycles with low variability.

AAI provided data showing more variability in repeat robot weighings of a clean blank filter as compared to a stainless-steel weight of similar mass. EPA thanks AAI for sharing these data. It is not clear to EPA which type of filter was used. PTFE membrane filters tend to have less susceptibility to organic artifact than glass fiber filters coated in PTFE. Unfortunately, there will generally be more variability in a filter than a metal weight. Labs should use best practices like using PTFE membrane filters, good static charge removal, good control of temperature and humidity, buoyancy correction, and robotic weighing to minimize variability as much as possible. AAI attributes the greater variability in filter weight to organic artifact. EPA agrees this may be part of the variability, but static charge may also play a role.

Ford commented it would like to work with EPA to determine if there is a role for limited application of PN measurements to help reduce variability and test burden. After considering alternatives to a PM mass standard, EPA decided to continue regulating based on PM mass in this rulemaking. However, EPA is willing to discuss the use of PN as a future regulatory measurement with Ford and others.

AAI recommended that EPA require all labs to adopt certain test procedure changes to support measuring PM below 0.5 mg/mi. EPA agrees that it is good practice to monitoring tunnel blanks weekly and to perform tunnel conditioning/cleaning when tunnel background becomes elevated (perhaps above 5 µg) or whenever switching from running low load for many tests or running tests at high emissions levels to running tests with GPF-equipped vehicles. At this time, however, EPA is providing laboratories with flexibility to ensure they are collecting quality data in a way that is best for that organization. If a lab has confidence that it can collect quality PM data without weekly blank tests for example (e.g., it may rely on another type of reference test), then EPA does not want to require that the lab perform weekly tunnel blanks. EPA will continue to participate in measurement procedure discussions to continue to affirm and improve best practices that are not overly burdensome and will adjust measurement requirements as needed.

In Tier 3, EPA allows but does not require tunnel background correction. EPA did not propose to make tunnel background correction mandatory and results from internal test programs and the round robin PM test program described in the Preamble and RIA indicate that tunnel background correction is not required for the 0.5 mg/mi standard being finalized. EPA will continue to participate in measurement procedure discussions and is open to adjusting requirements as needed in the future.

EPA agrees that labs should consider reducing their reference filter validity limit from 10 μg in light of the significantly lower PM limit. At this time, however, EPA is providing laboratories the flexibility as they determine what measures are needed to reliably measure PM below 0.5 mg/mi. EPA is happy to continue participating in measurement procedure discussions, including new requirements on reference filter validity limit.

EPA agrees that robotic autohandlers are one way to reduce PM measurement variability in that they reduce human handling of filters and associated issues with contamination and static charge. However, after consideration, EPA is not mandating that any labs use robotic autohandlers in this rulemaking. Two of the three labs used in the round robin testing described in the Preamble and RIA did not use robotic handling and achieved PM results that are adequate for measuring PM well below 0.5 mg/mi, including very low test-to-test variability. Human weighing of filters, if proper procedures are followed, can be perfectly satisfactory. While autohandlers can save time and reduce variability, they are costly to purchase and install, and EPA does not find it necessary to require their use to support the PM standard being finalized.

EPA agrees that in the 25°C FTP and -7°C FTP, collecting PM onto a single filter with flow weighting increases filter loading relative to sampling PM onto one filter per phase, and the higher filter loading can reduce signal to noise ratio and improve the measurement. This is discussed in preamble Section III.D.3.iv and has been an option in 40 CFR Part 1066.815. However, the largest amount of PM in an FTP is typically from the cold engine start at the beginning of Phase 1, meaning the amount of PM on the sample filter is only moderately increased by using one filter for all phases. After consideration, EPA has decided not to change test procedure requirements at this time to allow labs flexibility in their procedures.

ALA commented on the importance ensuring that critical emission controls like GPFs exhibit ongoing functionality. While not disputing the importance of ensuring ongoing functionality, VW, Stellantis, Mercedes-Benz and other commenters expressed concern that proposed GPF OBD requirements would be difficult to achieve with current sensing technology or would require additional development. In response to these comments, EPA is not finalizing the proposed GPF OBD requirements and is instead finalizing that manufacturers follow the latest CARB OBD requirements. Presently that means that manufacturers propose GPF OBD plans and CARB reviews the manufacturer plans on a case-by-case basis. Some manufacturers have already certified GPF diagnostics with CARB. Harmonizing with CARB's current requirements resolves potential conflicts of having two sets of GPF OBD requirements and addresses manufacturer concerns about the difficulty of achieving the EPA-proposed diagnostics. Further discussion is provided in preamble Sections III.D.3.vii and III.H.

An SVM manufacturer group raised concern that GPF aging and monitoring for OBD purposes is not currently fully understood. In response to this, EPA notes that GPFs have been in widespread use in other markets for some time (2017 in Europe, 2020 in China, 2023 in India) and manufacturers and suppliers already have significant experience with the technology, including GPF aging and monitoring. Also, at least one SVM already uses GPFs in the U.S. GPFs accumulate ash throughout the vehicle's life and ash improves GPF filtration, but GPFs must be sized to accommodate the accumulated ash. SVMs have until 2032 to meet the final PM standard on light-duty vehicles and MDPVs, which is more than a decade after their introduction into mass production in Europe.

EPA solicited comment on whether to revert to pre-production PM certification at the durability group level after PM control technologies have been demonstrated across a range of ICE technology and AAI was supportive of this concept. EPA thanks AAI for their input but after consideration, EPA decided that it would be appropriate to review PM certification relief if it were part of a comprehensive review of certification test burden for all criteria pollutants. Such a review in the future would appropriately consider how to select worst-case vehicles for certification testing if manufacturers demonstrate compliance based on testing vehicles from every test group for some standards and testing vehicles only based on the durability group for other standards.

4) Responses to comments about lead time and phase-in of the EPA PM standard

Commenters expressed opposing views on the phase-in of the PM standard. ALA encouraged EPA to accelerate the phase-in of the PM standard to require all new vehicles to use GPFs in MY 2027 for the health benefits that this would provide. ICCT recommended that EPA adopt an accelerated phase-in of the PM standard that EPA requested comment on (50 or 80% in 2027 and 100% in 2028 for vehicles at or below 6000 lb GVWR) because GPFs are a mature technology in widespread use in other markets. MECA commented that the PM standard should be implemented at a faster pace than proposed based on the combination of the predicted rate of electrification (BEVs count toward compliance) alongside a feasible rate of PM emission control technology implementation. MECA recommended a phase-in for vehicles at or below 6000 lb GVWR of 60/90/100% in 2027/2028/2029.

Other commenters urged EPA to adopt a slower phase-in. AAI commented that it takes time and resources to design exhaust systems that incorporate a GPF that address gaseous emissions reduction and also control PM and enable GPF regeneration. Ford and other industry commenters requested more time to apply GPF technology across all ICE models than the 40/80/100 percent phase in that was proposed. EPA appreciates that incorporating GPFs into exhaust systems is not as simple as bolting on an additional part. Vehicles must meet CO_2 standards, gaseous criteria pollutants, and the PM standard. In some applications, manufacturers may find it best to use a close-coupled catalyzed GPF. This approach can use the same number of substrates and aftertreatment cans but may be more challenging from a packaging perspective. The GPF washcoat may not warm up as quicky as it would on a TWC with lower thermal mass. In other applications, an underfloor bare GPF may work best. This requires an additional substrate but leaves all of the washcoat on TWCs and may relieve packaging challenges on some applications. Current GPF-equipped vehicles sold in Europe, China and India use a variety of configurations and EPA expects that to continue in the near term in the U.S. In recognition of these challenges, EPA is finalizing a more gradual phase-in, temporary relief on the criteria that trigger an IUCP, and an allowance to attest to meeting the -7°C FTP PM standard for MY 2027 and MY 2028 vehicles. These measures provide manufacturers with additional time for designing, manufacturing, and certifying vehicles with GPF-equipped exhaust systems, or convert more vehicles to BEVs.

An SVM small manufacturer group, AML and Ferrari commented that the proposed PM standard goes too far too soon, faster than the CARB ACC II PM standard and not providing additional lead time for SVMs. The SVM group suggested a phase-in approach consistent with Euro 7. EPA considered the SVM group's comments and in response, is finalizing a criteria pollutant phase-in schedule for SVMs, including for PM, that ends in the same place as for large manufacturers but provides SVMs with significantly more time. For example, the phase in for SVM LDV, LDT1-4 and MDPV steps from 0 to 100 percent in MY 2032 instead of the proposed 40/80/100 percent phase in for MY 2027/2028/2029 for LDV and LDT1-2. Details are provided in preamble Section III.D.1. This phase in provides SVMs with more time than the SVM small manufacturer group's characterization of Euro 7 PM phase-in and provides SVMs with ample time to apply GPFs to ICE-powered vehicles and transition some vehicles to BEVs. GPF technology is mature and has been in widespread use in other markets since 2017 and can be readily applied to SVM vehicles as well. A major GPF supplier indicated to EPA that they work with SVMs and are happy to provide GPFs that meet EPA's PM standard. Further details are provided in preamble Section III.D.3 and RIA Chapter 3.2.6.

EPA considered AAI's recommendation for an interim in-use standard for the first two model years after a test group certifies to the 0.5 mg/mi standard but ultimately decided against an interim standard because the PM standard can be met with existing MY 2022 GPF technology and manufacturers and suppliers have extensive experience in applying GPFs to vehicles in the European market since 2017, in China since 2020, and India since 2023. Application of these GPFs has gone very smoothly without major failures, recalls, deteriorating performance, or other issues. Since measuring PM below 0.5 mg/mile may require measurement procedure adjustments in some laboratories, EPA is finalizing a temporary increase in the criteria that trigger an IUCP (in-use confirmatory testing program). The temporary increase in the IUCP criteria is described in preamble Section III.G.5.ii.

5) Responses to comments about gasoline aromatics and particulate formation

We are finalizing stringent PM standards for gasoline vehicles covering a range of operating conditions, including wintertime temperatures. We expect these standards to result in widespread adoption of particulate filters (GPFs) on new light-duty vehicles by 2030 and on medium-duty vehicles by 2031.

Modlin and Detchon cite the requirements for mobile source air toxics standards issued under Section 202(l) to reflect the greatest degree of emissions reduction achievable (taking into account several factors specified in the statute) as support for more stringent PAH controls. As discussed in Section III.D.3 of the preamble, emission characterization of GPF-equipped vehicles meeting the PM standards found that filter-based PAHs were reduced by more than 99%. As such, the PM standards are expected to also reduce PAH and other toxics very well. More detailed characterization of GPF benefits is described in Chapter 3.2.6.2 of the RIA. Furthermore, air quality modeling representing the net impacts of the standards on air toxics show average net reductions in all air toxics modeled.

In light of the fact that EPA did not propose PAH standards and EPA anticipates that the PM standards will result in very effective control of PAHs, EPA finds that it would not be appropriate to finalize PAH standards in this rulemaking. However, EPA will continue to consider the need for, and appropriate means of, further reductions in PAH by continuing to investigate costs and benefits of updated standards for market gasoline that would reduce the content of heavy aromatic compounds (including PAHs) that contribute most potently to PM and PAH emissions.

Modlin and Detchon also suggest that EPA could achieve emissions reductions by requiring changes to fuel composition that displace aromatics with additional ethanol. Imposing limits on gasoline aromatics content would force refiners to reformulate their gasoline to use other high-octane components. Understanding the impact of such reformulations on overall air quality would necessarily include changes in a broad range of vehicle emissions (including refueling and evaporative processes), as well as changes in petroleum refining and increases in ethanol production and agricultural intensity. These changes may reduce the overall air quality benefits significantly. We are not aware of any analyses integrating all these pieces at this time, and such work is beyond the scope of this final rule. The CAA imposes a significantly different regulatory regime for regulating fuels under 211(c), and as a result EPA solicited comment on potential changes to fuels regulations but did not propose changes. Comments in response to EPA's request for comment on potential future fuel controls are contained in Appendix D to this document and will be further considered for a potential future rulemaking. Additional comments related to fuels issues can be found in section 19 of this document.

4.1.4 - Carbon monoxide (CO) and formaldehyde (HCHO)

Comments by Organizations

Organization: Alliance for Automotive Innovation

E. US06 CO Standards

Similar to CARB's LEV IV rule, EPA is proposing to revise the SFTP CO requirement from a composite to a stand-alone standard for Tier 4. However, unlike the CARB LEV IV rule, EPA is proposing to use the 25ºC FTP CO cap of 1.7 g/mi for LDV and 3.4 g/mi for MDV for the US06 requirement. In Table 139 in section VII of the NPRM, EPA uses the OMEGA model to estimate criteria emission impacts of the proposed standards relative to the No Action scenario, light- duty and medium-duty in tons/day. While this is an interesting mathematical exercise, what is important is whether the Proposed Rule is needed for air quality attainment. Such a drastic increase in stringency would have a big impact on engine design in a similar manner as the proposed enrichment prohibition, but this change does not have any basis in air quality attainment as noted in section 8.1.5 of the DRIA.278 [EPA-HQ-OAR-2022-0829-0701, pp. 177-178]

278 There are two primary NAAQS for CO: an 8-hour standard (9 ppm) and a 1-hour standard (35 ppm). There are currently no CO nonattainment areas; as of September 27, 2010, all CO nonattainment areas had been redesignated to attainment."

- difficulty in the high-load region of US06: There is more variability in US06 emission results associated with differences in driving at high-load. Consequently, the standard must be adjusted to account for this difference. (Even with the same vehicle speed tolerance as FTP±2mph@± 1sec, the increase in workload when running at the upper and lower tolerance limits is large. The increase in the amount of intake air also increases, and the emission impact is large). [EPA-HQ-OAR-2022-0829-0701, pp. 177-178]

- Heavy development Burden: To meet the proposed US06 CO standard, automakers would need to expand the λ=1 region. This would result in redesign to increase the heat resistance of exhaust system parts including, but not limited to air/fuel sensors, catalysts, and turbochargers. Engine changes would also likely be needed to lower combustion temperatures. [EPA-HQ-OAR-2022-0829-0701, pp. 177-178]

- Reduction in Engine Output: EPA's proposal may require limiting engine power under high loads to protect the engine. This will impact marketability, especially for vehicles needing towing capacity. [EPA-HQ-OAR-2022-0829-0701, pp. 177-178]

Furthermore, there is no need for additional reductions in CO emissions since the entire country is in attainment with National Ambient Air Quality CO standards.279 [EPA-HQ-OAR-2022-0829-0701, pp. 177-178]

279 U.S. Environmental Protection Agency, Green Book Carbon Monoxide (1971) Area Information. https://www.epa.gov/green-book/green-book-carbon-monoxide-1971-area-information. ("As of September 27, 2010, all Carbon Monoxide areas have been redesignated to maintenance.")

Auto Innovators recommends EPA align with ACC II LEV IV requirements as shown in below, which provide reductions in CO emissions, but without requiring substantial development effort, which would unnecessarily divert resources away from electrification. [EPA-HQ-OAR-2022-0829-0701, pp. 177-178]

[See original attachment for Figure 65: US06 CO Recommendation] [EPA-HQ-OAR-2022-0829-0701, pp. 177-178]

Organization: Kia Corporation

Kia Recommends EPA Align with CARB's Carbon Monoxide (CO) US06 Standard [EPA-HQ-OAR-2022-0829-0555, pp. 11-12]

Similar to CARB's LEV IV rule (in ACC II), EPA is proposing to revise the Standard Federal Testing Procedure (SFTP) US06 CO requirement from a composite to a stand-alone standard for Tier 4. However, unlike the CARB LEV IV rule, EPA is proposing that the CO cap for the US06 test cycle match the CO cap for the 25ºC FTP of 1.7 g/mi for light-duty vehicles. This change has no basis in air quality attainment as noted in section 8.1.5 of the Draft Regulatory Impact Analysis,19 as of September 27, 2010, all CO nonattainment areas had been redesignated to attainment." Kia recommends that EPA follow CARB's LEV IV rule for CO US06 that sets a standard of 9.6 g/mi cap, which delivers a meaningful reduction without substantial ICE investment. [EPA-HQ-OAR-2022-0829-0555, pp. 11-12]

19 Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles Draft Regulatory Impact Analysis (DRIA).

Organization: Lucid Group, Inc

Under section 202 of the Clean Air Act, EPA has clear authority to regulate sources of air pollutants from all mobile sources, including carbon dioxide (CO2), non- methane organic gases (NMOG) plus oxides of nitrogen (NOx) or NMOG+NOx, particulate matter (PM), carbon monoxide (CO), and formaldehyde (HCHO) from vehicle tailpipes. Lucid applauds EPA's continued efforts under this authority to improve the nation's air quality. [EPA-HQ-OAR-2022-0829-0664, p. 2]

Organization: MCS Referral & Resources (MCSRR)

In the Executive Summary at A.2.i regarding the

“Need for Continued Emissions Reductions Under 202(a) of the Clean Air Act,” EPA claims: [EPA-HQ-OAR-2022-0829-0615, pp. 1-2]

“Addressing the public health impacts of criteria pollutants (including particulate matter (PM), ozone, nitrogen oxides (NOX), and carbon monoxide (CO)) will require continued reductions in these pollutants from the transportation sector.” [EPA-HQ-OAR-2022-0829-0615, pp. 1-2]

But EPA acknowledges in section II.B.5 that: “There are currently no CO nonattainment areas; as of September 27, 2010, all CO nonattainment areas have been redesignated to attainment.” And this is despite EPA requiring since 2011 that CO monitors “be operated near roads in Core Based Statistical Areas (CBSAs) of 1 million or more persons.” [EPA-HQ-OAR-2022-0829-0615, pp. 1-2]

So given that:

1) EPA has not identified any non-attainment areas for CO in over 12 years; [EPA-HQ-OAR-2022-0829-0615, pp. 1-2]

2) ambient CO levels in all US monitoring areas average less than 10% of the EPA NAAQS 1-hour and 8-hour average limits for CO of 35 and 9 ppm, respectively; [EPA-HQ-OAR-2022-0829-0615, pp. 1-2]

3) none of the health benefits that EPA estimates will result from the adoption of this rule are based on estimated reductions in CO emissions, but only on estimated reductions in particulate matter emissions; [EPA-HQ-OAR-2022-0829-0615, pp. 1-2]

4) the EPA Administrator decided in the last CO NAAQS review in 2011, based on the same Integrated Science Assessment (ISA) on CO that EPA now cites in this proposed rule at II.C.5 as the justification for lowering current CO emission limits by more than half, that no changes were needed in either of the two primary CO standards to further protect the public from any of the health effects associated with CO emissions from any sources; it appears there are no compelling regulatory or health reasons for EPA to lower the maximum allowed CO emissions of light duty gasoline vehicles and trucks in the FTP test by more than 60%, from up to 4.2 to 1.7 g/mile, or those of heavier medium duty vehicles from 7.3 to 3.2 g/mi, while leaving the SFTP limits for CO emissions unchanged at 4.2 g/mile. [EPA-HQ-OAR-2022-0829-0615, pp. 1-2]

We note that EPA first committed to studying these lower CO limits in the 1990 revisions to the Clean Air Act. Congress at the time gave the EPA until June 1, 1997, to prepare a report on this option and until December 31, 1999 to propose a rule that would lower the CO limit to 1.7 g/mile starting in model year 2006. [EPA-HQ-OAR-2022-0829-0615, pp. 1-2]

But EPA missed these deadlines and left in place higher Phase 1 CO limits that EPA first required in model year 1996. These limited CO emissions to 3.4 g/mile at 50,000 miles and 4.2 g/mile at 100,000 miles, as shown below in Tables 3, G, and H (reprinted from the 2013 edition of 42 CFR 85 §7521.i.3.A, online at https://www.govinfo.gov/content/pkg/USCODE-2013-title42/html/USCODE-2013-title42-chap85-subchapII- partA-sec7521.htm) [EPA-HQ-OAR-2022-0829-0615, pp. 1-2]

EPA had another opportunity to lower CO emissions when it adopted Phase 2 limits for light-duty vehicles and trucks that took effect in model year 2001. But the EPA Administrator chose to keep the Phase 1 CO limits unchanged. [EPA-HQ-OAR-2022-0829-0615, pp. 1-2]

Unless EPA can now show some need to reduce CO emissions to protect public health and/or welfare, or to reduce greenhouse gases, it should not require vehicle manufacturers to lower CO emissions any further. With US monitoring stations now reporting 8-hour ambient CO averages below 1 ppm or at most 2 ppm, no further clinically relevant reductions in CO emissions are possible or needed. [EPA-HQ-OAR-2022-0829-0615, pp. 1-2]

[See original for Table 3 – Pending Emission Standards for Gasoline and Diesel Fueled Light-Duty Vehicles and Light-Duty Trucks 3,750 LBs, LVW or Less] [EPA-HQ-OAR-2022-0829-0615, pp. 1-2]

At III.C.4.ii, EPA proposes a "CO emissions cap for the −7 °C FTP" of 10.0 g/mi. But in the same section, EPA acknowledges that "Testing of a 2022 F250 7.3L in the −7 °C FTP at EPA showed average CO emissions of 2.7 g/mi CO." Although EPA concluded that this result demonstrates that a 10.0 g/mi standard is feasible for MDVs, this result also demonstrates that a separate standard for cold starts is not necessary. [EPA-HQ-OAR-2022-0829-0615, p. 3]

The test vehicle was able to meet the lower 3.4 g/mi limit proposed for other (non-cold) CO tests of MDVs, as well as the 4.3 g/mi allowed under SFTP conditions. For comparison, EPA should have reported the average CO emissions of an LDV during a similarly cold start at −7 °C. If the average CO level that LDVs emit from a cold start is already below the 4.3 g/mile that EPA allows under SFTP conditions, there is no need for a separate cold start limit of 10 g/mi. [EPA-HQ-OAR-2022-0829-0615, p. 3]

That said, if EPA decides to include a cold temperature CO emission standard in section 86.1811, it should apply for a useful life of "10 years or 120,000 miles" (like the NHMC limits in the same section), not for only "5 years or 50,000 miles." [EPA-HQ-OAR-2022-0829-0615, p. 3]

EPA Summary and Response

Summary of Carbon Monoxide Comments

EPA received a number of comments regarding the proposed carbon monoxide standards. The Alliance for Automotive Innovation (AAI), Kia and MCSRR noted that there are currently no CO non-attainment areas in the United States. AAI went on to note that some vehicles would require significant engineering changes to meet the proposed standards and that some of the changes may result in reduced engine power. AAI also commented that many vehicles demonstrate more variability in US06 emission as the result of driving at higher speed and load.

MCSRR noted that there is no need for a -7°C FTP standard that is separate from other non-cold CO standards for MDV. MCSRR also commented that if EPA decides to set a -7°C FTP MDV CO standard that is higher than the 25°C CO standard, it should apply for a useful life of 10 years or 120,000 miles, not for only 5 years or 50,000 miles.

Summary of Carbon Monoxide Responses

EPA considered submitted comments and our own analysis in setting the appropriate US06 CO standards and the environmental benefits of finalizing a standard that is lower than the Tier 3 US06 CO. We also considered the CARB US06 CO standards in the context of current vehicle performance. The environmental benefits are specifically addressed in RTC Sections 7 and 8. In response to the comments received and as the result of the technical analysis performed by EPA, EPA is finalizing US06 standards for both LDVs and MDVs 9.6 g/mi and 25 g/mi, respectively. Refer to preamble Section II.D.4 for a detailed discussion of our rationale.

After consideration, EPA disagrees with MCSRR's comment that there is no need for a -7°C FTP standard that is separate from other non-cold CO standards for MDV. Without a separate standard at -7°C, the final standard of 6.4 g/mi would apply at -7°C, and that would be significantly lower than the new standard of 10.0 g/mi for -7°C FTP MDV. While a MY 2022 F250 7.3L vehicle tested by EPA showed average CO emissions of 2.7 g/mi, other MDVs emit at higher rates and EPA has not performed a comprehensive study of the feasibility of setting the same standard at -7°C and 25C for CO. The 10.0 g/mi standard is the first -7°C FTP standard or cold test standard of any kind for MDV and our intent at this time is just to set an upper bound on what MDV may emit at this cold temperature that is common during winter months across much of the United States. Because cold CO standards have not previously been applied to MDV, we do not have certification data on cold CO emissions, which would include data from a broad range of MDV applications. Once cold CO standards are implemented for MDV, we will continue to monitor their emissions from certification testing and we will also continue monitor technologies for improving cold CO emissions in order to inform future decision making.

MCSRR commented that EPA should set an MDV -7°C FTP CO useful life of 10 years or 120,000 miles, not just 5 years or 50,000 miles. EPA is finalizing an MDV -7°C FTP CO useful life of 15 years or 150,000 miles and thus is consistent with the useful life that we have finalized for other criteria pollutants for both MDV and LDVs over 6,000 pounds GVWR. EPA is finalizing the same useful life for MDV -7°C FTP NMOG+NOX and PM. Final useful life standards for light-duty vehicles and MDV are described in 40 CFR 86.1805-17.

EPA appreciates Lucid for acknowledging EPA's CAA authority to regulate CO.

4.1.5 – Refueling incomplete spark-ignition vehicles

Comments by Organizations

Organization: Alliance for Vehicle Efficiency (AVE)

AVE supports EPA's proposal to extend On-board Refueling Vapor Recovery (ORVR) requirements to all incomplete light-duty and medium-duty vehicles. [EPA-HQ-OAR-2022-0829-0631, p. 9]

AVE supports the proposed extension of the requirements for control of refueling emissions to all incomplete spark-ignition light-duty and medium-duty vehicles for the 2030 model year. [EPA-HQ-OAR-2022-0829-0631, p. 9]

Cost-effective ORVR technology is available to control refueling emissions for all new incomplete vehicles at the proposed emission standard of 0.20 grams per gallon, supported by the EPA's draft regulatory impact analysis for this proposed rule. ORVR is an available and proven technology to significantly reduce evaporative and refueling emissions, resulting in meaningful emission reductions of volatile organic compounds that lead to the formation of ozone and secondary particulate matter (PM2.5), as well as emissions of hazardous air pollutants. [EPA-HQ-OAR-2022-0829-0631, p. 9]

With regulatory developments since ORVR technology was first introduced in 1994, primary and secondary manufacturers have gained significant experience with ORVR technology on all categories of complete gasoline vehicles, including light-, medium-, and heavy-duty vehicles. The recent 2027 heavy-duty final rule added a refueling standard (ORVR) for incomplete vehicles over 14,000 pounds Gross Vehicle Weight Rating (GVWR), leaving incomplete light- and medium-duty gasoline vehicles as the only remaining class of vehicles currently not required to meet refueling standards. [EPA-HQ-OAR-2022-0829-0631, p. 9]

AVE believes that the refueling emission control technologies used for the complete versions of light- and medium-duty vehicles are equally applicable to their corresponding incomplete versions. [EPA-HQ-OAR-2022-0829-0631, p. 9]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Refueling Emission Standards for Incomplete Vehicles

U.S. EPA's proposed standards would newly apply onboard refueling emission standards to incomplete medium-duty vehicles, which CARB supports. U.S. EPA requested comment regarding whether it would be cost-effective, feasible, and appropriate to also apply the proposed refueling emission standard to incomplete light-duty vehicles. Like U.S. EPA's assessment of incomplete medium-duty vehicles in the proposal, CARB anticipates that any future incomplete light-duty vehicle would be configurable to feasibly meet the refueling emission standard. One manufacturer already makes incomplete light-duty vehicles that have been certified in California to the refueling emission standard that U.S. EPA has proposed. 48, 49 To meet the refueling emission standard in this class of vehicle, manufacturers would be expected to use the existing design practices for controlling refueling emissions as outlined in the proposal, including optimizing fuel vapor line routing, fill pipe orientation, and position. Including incomplete light-duty vehicles in the refueling standard will help ensure that this requirement is applied evenly across all classes of vehicles that have the capability to generate refueling emissions. [EPA-HQ-OAR-2022-0829-0780, pp. 36-37]

48 General Motor's Document for Incomplete Vehicle, Applicable to the 2023 MODEL YEAR Cadillac XT5 B9Q – Funeral Coach, OR V4U – Limousine https://www.gmupfitter.com/wp-content/uploads/2022/10/IVD_2023_C1UL_85116239-XT5.pdf.

49 CARB. Executive Order A-006-2337. https://ww2.arb.ca.gov/sites/default/files/classic/msprog/nvepb/executive_orders/EO%20Web%20Files/PC - LDT-MDV/2023/0001/pc-ldt-mdv_ldt_a-6-2337 sdt–20220324.pdf.

Organization: Ingevity Corporation

Response to specific requests for comments:

14. Extension of the requirements for control of refueling emissions to incomplete SI MDVs and to other gasoline-fueled incompletes (LDV/LDT/MDPV) [EPA-HQ-OAR-2022-0829-0545, pp. 3-4]

Ingevity fully supports the proposed extension of the requirements for control of refueling emissions to incomplete SI MDVs (i.e., 8,501-14,000 lb. GVWR) for the 2030 model year (MY). The proposed emission standard is 0.20 g/gal for a certification useful life of 15yrs./150,000 miles using the provisions of 40 CFR 86 Subpart B. Control of refueling emissions from complete versions of vehicles in this proposed sub-category of HDVs was required for the 2006 MY; for MDPVs and complete vehicles of 8,501-10,000 lbs., GVWR phasing for 80% in 2005 and 100% in 2006 and in the 2018 MY for vehicles of 10,001-14,000 lbs. GVWR. We believe that the refueling emission control technologies used for the complete versions of the vehicles in these GVWR weight categories are equally applicable to their corresponding incomplete versions. [EPA-HQ-OAR-2022-0829-0545, pp. 3-4]

Technically, the current ORVR requirements do not cover "incomplete" LDVs, LDTs, and MDPVs. The EPA's NPRM (p. 29275) would extend the ORVR requirement to any or all incomplete gasoline- powered LDVs, LDTs, and MDPVs not covered by the past rulemakings. Ingevity supports this portion of the proposal and sees no issues with technical feasibility, cost, in-use effectiveness, or safety. Very similar vehicles have incorporated ORVR starting in the 1998 MY. The NPRM did not specify elements related to items such as test procedure, the refueling emission standard, certification useful life, other certification requirements and model year. It seems clear that the test procedures of Subpart B and the emission standards and other requirements for certification from Subpart S would apply. To avoid complications and the creation of inequities among the manufacturers due to the differences in their product lines, we recommend that these lighter vehicles be grouped within the certifications for their similar complete vehicles rather than providing them the option to be grouped in with incomplete MDVs and incomplete HDVs. Toward that end, EPA needs to specify the applicable model year. [EPA-HQ-OAR-2022-0829-0545, pp. 3-4]

Model Year:

We note that the NPRM proposes control for the 2030 MY, citing the need for four MY years lead time as called for in section 202(a)(3)(C) of the Clean Air Act. At this time the promulgation date for a final rule is not known. However, since the MY for heavy-duty vehicles coincides with the calendar year, we expect that a start year of MY 2028 or MY 2029 is possible and thus a revision of this mandatory start year should be considered. [EPA-HQ-OAR-2022-0829-0545, pp. 3-4]

Optional Phase-in with Other Incomplete SI HDVs:

We support providing the certifying manufacturers the flexibility of combining the sales of their incomplete SI MDVs and heavier incomplete SI HDVs for purposes of meeting the sales requirements in the alternative phase-in provided in the recently promulgated heavy-duty final rule which included an ORVR requirement for incomplete SI HDVs with a GVWR over 14,000 lbs.2 Under a provision of that rule, the certifying manufacturers can phase-in controls using the schedule of 40% for the 2026& 2027 MYs, 80% for the 2028 & 2029 MYs, and 100% for the 2030 MY in lieu of 100% in the 2027 MY.3 [EPA-HQ-OAR-2022-0829-0545, pp. 3-4]

2 US EPA, "Control of Air Pollution From New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards," 88 FR 4296, January 24, 2023.

3 Note that page 29272 of the NPRM preamble discusses the option to group incomplete SI MDVs and incomplete SI HDVs for sales purposes of meeting the alternative phase-in schedule of §86.1813-17 (b)(1)(iii). The preamble should say 2026-2030, not 2027-2030.

2. The cost, feasibility, and appropriateness of the proposed refueling emission standard for all incomplete LDVs and MDVs

Primary/Secondary Manufacturers:

We agree with EPA that any concerns of the past regarding the relative roles and responsibilities of the primary manufacturers (OEMs) and secondary manufacturers with regard to certification and completion of the fuel/emission control systems on incomplete vehicles (those involving multi-stage manufacturing) have long been resolved. Evaporative emission controls were first required on these vehicles in the 1985 MY (earlier in California) and the techniques used for these earlier evaporative emissions control, and subsequently refined over several sets of more stringent and comprehensive requirements since that time, are equally applicable for refueling emissions control through ORVR for incomplete SI MDVs.4. [EPA-HQ-OAR-2022-0829-0545, pp. 4-5]

4 US EPA, "Control of Air Pollution From New Motor Vehicles and New Motor Vehicle Engines; Evaporative Emission Regulation and Test Procedure for 1985 and Later Model Year Gasoline- Fueled Heavy-Duty Vehicles," 48 FR 1429, January 12, 1983.

Refueling Emission Families for Certification:

Incomplete SI MDVs are to be certified to the refueling emission standards using the requirements of 40 CFR §86 Subpart B. The same is true for complete SI MDVs which have been subject to the requirements since the 2018 MY. Refueling emission family language in 40 CFR §86.1821-01 requires that the certifying manufacturer use good engineering judgement for grouping vehicle models for purposes of emission testing for certification based on similar evaporative and/or refueling emission characteristics throughout their useful life. Provided that the manufacturers use good engineering judgment in the creation of families, there should be no up-front restriction on combining complete and incomplete SI MDVs in families. [EPA-HQ-OAR-2022-0829-0545, pp. 4-5]

Conversely, heavier complete and incomplete SI HDVs (>## 14,000 lbs. GVWR) are subject to the provisions of 40 CFR §1037.103 for purposes of evaporative/refueling emission certification and should not be grouped into families with complete and/or incomplete SI MDVs certified under 40 CFR§86 Subpart B. [EPA-HQ-OAR-2022-0829-0545, pp. 4-5]

Scope of Applicability:

In the preamble to the final rule, EPA should indicate that the refueling emission control requirements for incomplete SI MDVs are applicable in all 50 states. [EPA-HQ-OAR-2022-0829-0545, pp. 4-5]

Technical Feasibility and Cost:

Ingevity believes that the control of vehicle refueling emissions for incomplete SI MDVs is technically feasible. As mentioned above, ORVR has been used to control refueling emissions on all complete MDPVs and Class 2b SI HDVs since the 2006 MY and since 2018 MY for complete Class 3 SI HDVs. With appropriate lead time, the application of good engineering practice, and proper coordination with secondary manufacturers, it seems clear that ORVR can be applied to incomplete SI MDVs effectively and safely. In fact, it may well be that ORVR is already installed on many of these vehicles since both complete and incomplete SI MDVs already meet Tier 3 evaporative emission requirements and the annual SI MDV vehicle sales are in some cases not large enough to justify a multiple fuel system design. [EPA-HQ-OAR-2022-0829-0545, pp. 4-5]

EPA's system description and cost analysis as presented in the preamble to the NPRM and draft RIA are reasonable and consistent with previous analyses for similar vehicles. Note that this portion of the NPRM provides a cost estimate of $17-21 per vehicle but does not address markups. Elsewhere in the draft RIA a Retail Price Equivalent (RPE) markup of 1.5 is used for other components and component systems which if applied to ORVR would give an RPE cost range of $26-32 per vehicle. In regulatory analyses it is common to assess the cost effectiveness of control in at least the terms of $/ton per vehicle over its average life. To do so, information on vehicle operating characteristics is needed to calculate emission reductions, future fuel price, and fuel recovery credits. Using values derived from the current and a recent EPA RIA,5,6 for a 2030 model year incomplete MDV, the Net Present Value (NPV) of the fuel recovery credits for ORVR over a 30-year survival-weighted lifetime of 182,777 miles at 14.5 mpg7 is about $63 (3% discount) and $53 (7% discount). The NPV of the fuel recovery credits at both 3% and 7% exceed the projected ORVR cost, so the per vehicle cost effectiveness value in $/ton is a negative value and thus a net savings. [EPA-HQ-OAR-2022-0829-0545, pp. 4-5]

14 Information on projected gasoline costs for 2030 and later and on survival fractions by age was taken from Tables 2-47 and 2-34, respectively, of the draft RIA for this rulemaking.

14 Information on Class 2b/3 mileage accrual by age was derived using the depiction in Figure 10-4 of the EPA report "Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles – Phase 2 Regulatory Impact Analysis." August, 1016, EPA420-R-16-900..

7 The 14.5 mpg value is taken from page 8-18 of the EPA/DoT-NHTSA Joint Final RIA for the HDGHG Phase 2 rule: "Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles – Phase 2, Regulatory Impact Analysis," EPA-420-R-16-900, August 2016. This also includes an upward adjustment for the energy content of butane and pentane vapor which are the dominant species in refueling vapor to the energy content of E10 whole gasoline vapor.

Organization: MECA Clean Mobility

EPA should extend the refueling emission requirements to all incomplete SI vehicles as proposed.

EPA's regulatory framework offers the most comprehensive evaporative/refueling control program in the world for chassis certified vehicles. To meet the refueling emission limits, Onboard Refueling Vapor Recovery (ORVR) has been successfully implemented in the U.S. and Canada for over 25 years, and most recently has been implemented in China and Brazil. Within EPA's IUVP program, there have been over 4500 tests conducted on in-use vehicles equipped with ORVR with an average reduction efficiency of 98%.13 The odometer readings on a large fraction of these vehicles exceeded 100,000 miles. U.S. Tier 2 or California LEV II have reduced evaporative emissions by 90%, and U.S. Tier 3 or California LEV III are 98% effective in reducing evaporative VOC emissions. [EPA-HQ-OAR-2022-0829-0564, pp. 12-13]

13 G. Passavant, "Summary and Analysis of 2000-2015 Model Year IUVP Evaporative and Refueling Emission Data," 2017.

Consistent with EPA's proposal, MECA supports extending the refueling emission requirements to all incomplete medium-duty vehicles at a refueling emission standard of 0.20 grams hydrocarbon per gallon of liquid fuel dispensed as now applies to complete LDVs, LDTs, MDPVs, LHDGVs, and HHDGVs. Furthermore, in response to EPA's specific request to comment, MECA suggests EPA extend this requirement to include all incomplete light-duty vehicles in order to prevent any future removal of ORVR from any liquid fueled vehicles. The OEMs have twenty-five model years of experience with the design and certification of ORVR systems, which together with the EPA IUVP data mentioned above, clearly demonstrate the feasibility. MECA believes that the refueling emission control technologies used for the complete version of all vehicles are equally applicable to their corresponding incomplete vehicles. [EPA-HQ-OAR-2022-0829-0564, pp. 12-13]

Consistent with the current requirements for evaporative emission and refueling emission controls for all lighter weight vehicles, MECA supports EPA's proposal to apply a useful life of 15 years/150,000 miles to the MDV refueling emission standard, consistent with existing evaporative emission standards for these vehicles and for complete versions. Given that integrated ORVR/evaporative control system designs share hardware such as the activated carbon canister and purge valve and functions such as vapor transport and canister purge, a common requirement for evaporative and refueling emission standard useful life is logical and necessary. [EPA-HQ-OAR-2022-0829-0564, pp. 12-13]

MECA believes the implementation of ORVR is feasible and practical for primary and secondary manufacturers. OEMs and secondary manufacturers now have decades of experience in working together on measures to ensure that any actions taken by the secondary manufacturer to complete the vehicle do not violate the certificate of conformity or create in-use issues for on-vehicle fuel vapor control systems. In addition, there are now several regulatory provisions within 40 CFR §1037 which provide guidelines on how OEMs and secondary manufacturers may work together under EPA's certification programs.14 This extensive experience together with these recent regulatory provisions suggest that any concerns have been addressed and there is no need for added regulatory measures. Regarding testing for refueling emissions certification, the ORVR test procedures promulgated in 1994 are fully fit for purpose and, perhaps with minor changes or clarifications, should be applied to medium-duty gasoline vehicles using the driving cycles and SHED-test procedures currently specified in 40 CFR Part 86 Subpart B. MECA supports a compliance demonstration through a full vehicle emission testing and certification as contained in Subpart B plus continuation of the manufacturers' certification option using the compliance demonstration flexibility provided in 40 CFR §1037.103©. [EPA-HQ-OAR-2022-0829-0564, pp. 12-13]

14 40 CFR Part 1037.130, 1037.621, 1037.622.

Organization: National Association of Clean Air Agencies (NACAA)

EPA also proposes some changes related to evaporative emissions, including eliminating the exemption of MDV incomplete vehicles from onboard refueling vapor recovery requirements. NACAA supports the proposed changes and recommends that EPA also eliminate this exemption for incomplete LDVs. [EPA-HQ-OAR-2022-0829-0559, pp. 6-7]

EPA Summary and Response

Summary:

AVE believes that refueling emission control technologies used for complete vehicles are equally applicable to corresponding incomplete vehicles, and accordingly supports applying the proposed refueling standards to all incomplete spark-ignition light-duty and medium-duty vehicles starting with model year 2030.

CARB, MECA, and NACAA also support applying the proposed refueling standards to incomplete light-duty and medium-duty incomplete vehicles. CARB, MECA, and NACAA further emphasized that incomplete light-duty vehicles needed no separate treatment relative to refueling emission standards.

MECA further supported applying a useful life of 15 years or 150,000 miles for the new refueling standards to align with existing evaporative and refueling emission standards that apply for other complete light-duty and medium-duty vehicles, and applying the same SHED-based testing procedures that apply under 40 CFR part 86, subpart B. MECA also supported applying the design-based option to demonstrate compliance with emission standards from 40 CFR 1037.103©.

Ingevity fully supports the proposed extension of the requirements for control of refueling emissions to incomplete SI MDVs (i.e., 8,501-14,000 lb. GVWR) for the 2030 model year (MY), but also suggests that EPA consider applying the ORVR standards for medium-duty vehicles starting in model year 2028 or 2029 (based on the need to allow four years of lead time). Ingevity supports keeping the option of a combined phase-in for medium-duty vehicles and heavy-duty vehicles (above 14,000 pounds GVWR). Ingevity supports applying ORVR standards to incomplete light-duty program vehicles and sees no issues with technical feasibility, cost, in-use effectiveness, or safety. To avoid complications and the creation of inequities among the manufacturers due to the differences in their product lines, Ingevity recommends that these lighter vehicles be grouped within the certifications for their similar complete vehicles rather than providing them the option to be grouped in with incomplete MDVs and incomplete HDVs And accordingly specify the applicable model year. Ingevity stated that there should be no up-front restriction on combining complete and incomplete SI MDVs in families, as long as manufacturers use good engineering judgment in creating families. At the same time, Ingevity recognized that complete and incomplete SI HDV above 14,000 lbs. GVWR should not be grouped into families with MDV. Ingevity recommends that EPA indicate in the preamble to the final rule that refueling emission control requirements for incomplete SI MDVs apply in all 50 states.

Ingevity commented that EPA's system description and cost analysis is reasonable and consistent with previous analyses for similar vehicles. Ingevity noted that the cost estimated did not include markups that would allow for presenting costs as Retail Price Equivalent. Ingevity also observed that fuel savings from containing refueling vapors would lead to a cost savings from reduced fuel consumption, which would more than offset the up-front costs for an overall net savings resulting from the new standards.

Response:

EPA appreciates the broad affirmation of the proposal to adopt refueling standards for incomplete medium-duty vehicles. We are accordingly finalizing the standards as proposed, including the specifications for useful life and test procedures.

We note that the design-based certification provisions in 40 CFR 1037.103© are limited to vehicles above 14,000 pounds GVWR based on the limited facilities available to test those larger vehicles. As a result, we are not applying that certification option for the vehicles at or below 14,000 pounds GVWR that are subject to the refueling standards in this final rule.

We proposed to apply the refueling standard starting in model year 2030 to meet the four-year lead time requirement in the Clean Air Act. As we most commonly do, we proposed to apply the new standards for the first full model year following that four-year reference point. Model year 2029 may start as early as January 2, 2028. Given that this rule is finalized in spring 2024, the first full model year for setting standards is 2030. We are therefore finalizing, as proposed, the requirement to meet the new refueling standards starting with model year 2030. We are additionally finalizing, as proposed the alternative phase-in schedule based on combined implementation for vehicles above and below 14,000 pounds GVWR.

As noted in the comments, the proposed rule included a request for comment on applying refueling standards to incomplete light-duty vehicles and light-duty trucks. After more carefully reviewing of the regulations, it became clear that refueling standards have applied for those vehicles for many years. The regulatory text as adopted in the Tier 3 rulemaking stated: "Light-duty vehicles, light-duty trucks, and complete heavy-duty vehicles must meet the refueling emission standards in this paragraph (b) when measured over the procedure specified in § 86.150." (79 FR 23719, April 28, 2014) This establishes that the complete vs. incomplete vehicle distinction applies only for heavy-duty vehicles. As a result, we are clarifying the regulatory text in this final rule to describe the phase-in of the new refueling standards as applying only for incomplete heavy-duty vehicles. The Tier 3 refueling requirements for incomplete light-duty vehicles and light-duty trucks remain in place.

The provisions of 40 CFR 86.1821-01 describe how to divide vehicles into families based on the characteristics of evaporative canister and other vehicle characteristics. There is no reference to complete or incomplete vehicles, so that has not been and will not be relevant for combining vehicles into families. Since complete and incomplete vehicles of any size would presumably have the same or very similar emission control hardware and settings, those vehicles can be expected to be certified together in a single family. We modified those evaporative/refueling family provisions recently to state clearly that vehicles above and below 14,000 pounds GVWR should never be in the same family, regardless of any similarity in emission control hardware or settings (88 FR 4479, January 24, 2023). EPA did not reopen this issue in this rulemaking, and the existing requirements remain in place.

We expect all manufacturers to meet the new refueling standards and all requirements for EPA certification for vehicles sold in all 50 states, as well as the District of Columbia and the five U.S. territories named in the definition of "United States" in 40 CFR 1068.30.

EPA recognizes and appreciates the additional cost information provided by Ingevity. We have adjusted the cost discussion in RIA Chapter 3.2.7 to indicate that the tabulated values do not include a markup representative of Retail Price Equivalent values.

4.1.6 - Enrichment for power or component protection

Comments by Organizations

Organization: Ad Hoc Small OEM Group

3. COMMANDED ENRICHMENT AECD

EPA is proposing to eliminate the use of commanded enrichment as an AECD on engines used in light-duty vehicles for either power or component protection during normal operation and use. Normal operation is defined at 40 CFR 86.1803-01 to include vehicle speeds and grades of public roads, and vehicle loading and towing within manufacturer recommendations, even if the operation occurs infrequently. [EPA-HQ-OAR-2022-0829-0563, pp. 11-12]

EPA requests comment on the proposed prohibition of commanded enrichment including benefits and costs, and additional exceptions where brief rich operation should be allowed. In response, the Ad Hoc Group states as follows:

-Commanded enrichment should continue to be permitted for Small OEMs in high-performance engines [EPA-HQ-OAR-2022-0829-0563, pp. 11-12]

Small OEMs urge EPA to continue to allow commanded enrichment in high-performance Small OEM engines beyond the limited, brief permissible circumstances permitted in the NPRM based on the following considerations: [EPA-HQ-OAR-2022-0829-0563, pp. 11-12]

-Small OEM high-performance engines primarily use enrichment as a failure avoidance strategy and it is not employed during 97% of normal driving (and remember that the number of miles travelled during normal driving by Small OEM vehicles is drastically lower than the VMT by the vehicles of large volume manufacturers). We emphasize that enrichment is essential to protecting Small OEM high-performance engines. [EPA-HQ-OAR-2022-0829-0563, pp. 11-12]

-At present, there are no viable technical alternatives to enrichment for high-performance engines (i.e., alternatives that are reasonable in cost and timeframe). [EPA-HQ-OAR-2022-0829-0563, pp. 11-12]

-Enrichment allows high-performance engines to be downsized and thereby made more efficient [EPA-HQ-OAR-2022-0829-0563, pp. 11-12]

-In sum, as regards Commanded Enrichment EPA should [EPA-HQ-OAR-2022-0829-0563, pp. 11-12]

-At a minimum, allow commanded enrichment on Small OEM vehicles meeting both of the following two criteria: [EPA-HQ-OAR-2022-0829-0563, pp. 11-12]

-having a power-to-weight (mass) ratio clearly indicative of high-performance (e.g., > 200 kW/ton (based on curb weight)6, and also [EPA-HQ-OAR-2022-0829-0563, pp. 11-12]

-using high-power output engines (e.g., engines > 100 ps (pferdestärke) per liter or > 600 hp).7 [EPA-HQ-OAR-2022-0829-0563, pp. 11-12]

6 Determine a vehicle's power-to-weight ratio by dividing the engine's rated power by the vehicle's GVWR (in hp/pound). If a test group includes multiple configurations, use the vehicle with the highest power-to-weight ratio to characterize the test group

7 We also note that CARB does not have commanded enrichment rules like those proposed in the NPRM.

Organization: Alliance for Automotive Innovation

Enrichment Prohibition Outright and Using US06 CO Standards

Automakers use enrichment only as needed, and its use must be reported as an auxiliary emissions control device (AECD) during certification. EPA proposes to eliminate enrichment both outright and by setting such stringent US06 CO standards that no vehicle could use enrichment and meet the US06 CO standards even if allowed. Both changes lead to the same end – elimination of enrichment. EPA errs in stating that it is no longer needed for component protection. Under limited circumstances, enrichment is needed for component protection. The alternative is to derate the engine and reduce the vehicle’s capability, not by a small amount as asserted by EPA, but by a large amount, which would have a profound impact on consumers. [EPA-HQ-OAR-2022-0829-0701, p. 6]

EPA’s enrichment proposal effectively prohibits modern, high specific output engines. [EPA-HQ-OAR-2022-0829-0701, p. 6]

Manufacturers would need to either build a larger displacement engine that could provide the capability needed by the vehicle, or the customer could just opt for a larger engine (if available). Both cases result in higher overall GHG and criteria emissions to prevent minimal NMOG+NOx and CO emission increases in limited circumstances. [EPA-HQ-OAR-2022-0829-0701, p. 6]

I. Enrichment

EPA proposes to “eliminate commanded enrichment for ICE-powered vehicles for power and component protection.” 282 The proposed fuel enrichment restriction would apply to all Tier 4 certified gasoline spark ignition ICE vehicle applications. [EPA-HQ-OAR-2022-0829-0701, pp. 180-181]

282 NPRM at 29197. EPA asserts that during enrichment events, aftertreatment conversion efficiency drops and hydrocarbon (HC) and carbon monoxide (CO) emissions can increase by 10-fold, or greater.283

283 NPRM at 29277.

EPA claims:

Modern vehicles have sufficient power without the use of enrichment . . . The use of enrichment only has the potential to incrementally increase power . . . [and] Technologies exist that can prevent thermal damage of engine and/or exhaust system components without the use of enrichment during normal operation and use.284 [EPA-HQ-OAR-2022-0829-0701, pp. 180-181]

284 NPRM at 29277.

And,

Modern engines have also added technologies such as VVT, cylinder deactivation, turbo boost control and other technologies that effectively allow the manufacturer designed controls, when used in conjunction with electronic throttle and transmission control to operate the engine in nearly any manner they determine to be optimal for the customer and manufacturer drivability expectations and durability goals. The agency believes that these same technologies, only available in recent years, could also be used for limiting operation in areas described previously as requiring enrichment that result in substantial increases in emission levels in normal operation including high acceleration rates, high loads. The reasons for the original allowances for enrichment discussed in the SFTP FRM can easily be addressed in modern engine and transmissions by utilizing existing controls to limit or avoid operation in areas that require enrichment for any normal vehicle operation.285 [EPA-HQ-OAR-2022-0829-0701, pp. 180-181]

285 DRIA at 3-45

Automakers use enrichment only as needed, and its use must be reported as an auxiliary emissions control device (AECD) during certification. EPA errs in stating that it is no longer needed for component protection. Under limited circumstances, enrichment is needed for component protection. The alternative is to derate the engine and reduce the vehicle's capability, not by a small amount as asserted by EPA, but by a large amount. EPA's enrichment proposal effectively prohibits modern, high specific output engines. [EPA-HQ-OAR-2022-0829-0701, p. 181]

Alternatively, manufacturers would need to either build a larger displacement engine that could provide the capability needed by the vehicle, or the customer could just opt for a larger engine (if available). Both cases result in higher GHG and criteria emissions all of the time to prevent minimal NMOG + NOx emission increases in limited circumstances. [EPA-HQ-OAR-2022-0829-0701, p. 181]

1. Concerns with EPA's Enrichment Proposal

a) Necessity of Enrichment for Modern High Specific Output Engines

EPA's assertion that modern vehicle design makes enrichment unnecessary is in error. Although EPA describes several technologies that it believes can enable modern engines to operate without enrichment, it provides no further technical basis for these claims besides its general beliefs. These unsupported claims are particularly concerning given the broad range of operation that EPA proposes to define as "normal"286 during which it proposes to generally prohibit enrichment. [EPA-HQ-OAR-2022-0829-0701, p. 181]

286 NPRM at 29415. (Proposed definition of normal operation to include “any operator demand that is allowable for engine and vehicle calibrations that are available to the operator for vehicle operation within the manufacturer’s specifications fuel and load (GVWR and GCWR).

For naturally aspirated engines that are not thermally constrained, enrichment only incrementally increases maximum torque and power by about 5%. However, most naturally aspirated engines are thermally constrained and require enrichment for component protection due to their high specific output. [EPA-HQ-OAR-2022-0829-0701, p. 181]

Moreover, manufacturers have generally responded to the increasing stringency of GHG and CAFE regulations by adopting downsized and boosted engines to reduce pumping losses at part load. These improvements are achieved by operating an engine at very high specific output, and thus rely on enrichment to control exhaust temperatures and protect engine and exhaust system components from damage. Additionally, in these modern engines, enrichment is necessary to cool the combustion chamber and control abnormal combustion such as knock and pre-ignition. [EPA-HQ-OAR-2022-0829-0701, pp. 181-182]

EPA describes that the powertrain control system can be used to limit or avoid operation that requires enrichment during any normal vehicle operation. While it is true that the powertrain control system determines the operating state of an engine, it is only in response to the driver demand (accelerator pedal). If the driver floors the pedal, then the driver is demanding the maximum power output from the engine. As the exhaust heats up during this maneuver, it reaches a thermal limit due to material durability of various components, and enrichment is used to maintain the exhaust temperature at the thermal limit. The risk of knock or pre-ignition also increases under these conditions. Without enrichment, the engine control system would have to reduce mass flow through a reduction in boost and/or by closing the throttle to control the exhaust temperature to avoid damaging components. Reducing boost and/or closing the throttle reduces the power output of the engine. Knock and pre-ignition are controlled by retarding spark advance, which also decreases power output and has the additional effect of adding even more heat to the exhaust system. Due to these factors, high specific output engines without enrichment would experience 30-50% power loss when controlling exhaust temperatures. Such a large power reduction would not satisfy customer requirements, and could potentially impact safety in real-world driving situations. [EPA-HQ-OAR-2022-0829-0701, pp. 181-182]

EPA bases its claims of enrichment’s minimal impact on power and torque on the study of one large, 6.4 liter heavy-duty naturally aspirated engine.287 EPA has not provided data on any modern, downsized and boosted engines to support its contention that enrichment only incrementally increases torque / power by 5%. The projected 5% impact on power does not reflect the potential loss of power for these types of engines, which could far exceed 5%.[EPA-HQ-OAR-2022-0829-0701, p. 182]

287 DRIA at 3-47.

b) Market Concerns

The premise that “Modern vehicles have sufficient power without the use of enrichment”288 is highly subjective and ultimately decided by the customer and their increasing demand for vehicle utility. Such a broad declaration gives the impression that EPA believes that vehicle utility has reached a practical zenith or that any incremental utility can and should now be capped in order to facilitate a new, narrow emissions reduction strategy through the elimination of enrichment. This is in contrast with EPA's historical practice of setting performance-based standards that generally assume at least maintaining current levels of performance (i.e., not negatively affecting a vehicle's utility). [EPA-HQ-OAR-2022-0829-0701, pp. 182-183]

288 NPRM at 68.

New vehicle purchasers generally desire increased vehicle features, including power, not less. Power, and the enhanced utility and driving dynamics it enables, are core customer-demanded functional attributes of a vehicle and engine combination. The preference of customers for improved features transcends all price points and vehicle segments. New vehicle purchasers consistently raise the bar on what they decide to be sufficient. [EPA-HQ-OAR-2022-0829-0701, pp. 182-183]

In the past, customers who sought greater vehicle utility or higher performance did so through selection of optional engines with greater displacement. However, industry, driven in part by GHG and fuel economy regulations, has developed entire families of downsized engines that have proven capable of meeting customer demands for power while simultaneously increasing efficiency and lowering GHG emissions. This is exactly the strategy that EPA previously identified as the technological pathway to meeting increasingly stringent GHG emissions regulations while maintaining existing performance levels. [EPA-HQ-OAR-2022-0829-0701, p. 183]

Enrichment is a critical strategy that has enabled this technological shift to lower displacement engines, ensuring their safe and durable operation in transient high-power demand situations. Manufacturers use enrichment to ensure that when customers demand high power, they can do so without the risk of costly damage or interrupted performance. [EPA-HQ-OAR-2022-0829-0701, p. 183]

Customer needs for power include, but are not limited to, the ability to tow a large trailer up an occasional steep grade, to operate the vehicle with a full load of passengers and cargo, and to rapidly accelerate on a short freeway entrance ramp to safely merge into traffic. Other customers, for example those purchasing supercars, expect superior performance and racetrack i. In each case, the power requirement from the engine depends on the customer's usage, and if its "sufficient power" is inadequate to accomplish their task, then the customer may be exposed to potentially unsafe and inadequate operation and will be dissatisfied with their vehicle's utility. A sudden reduction or interruption of power in the midst of a driving maneuver (e.g., passing on a grade) could be disruptive to the driver and confusing to other drivers. In some cases, this may create an unsafe traffic condition if the vehicle suddenly loses power, forcing other drivers to take evasive actions. [EPA-HQ-OAR-2022-0829-0701, p. 183]

Customers who seek specific power levels and are dissatisfied with the reduced power of downsized engines due to prohibitions on enrichment would likely revert to seeking out higher displacement engines or shift into larger vehicle segments. Worse yet, customers may simply reject new offerings and remain in older vehicles longer, further increasing the rising average age of vehicles on the road and delaying rollouts of other technologies. Any of these outcomes would detract from achieving the agency's overall goals of reduced emissions and improved fuel economy. [EPA-HQ-OAR-2022-0829-0701, p. 183]

c) De Minimis Emissions Impact of Enrichment

Although CO emissions increase during fuel enrichment due to the physics of three-way catalyst chemistry, this operation is infrequent and only occurs when high load capability is needed. (For example, maintaining minimum safe speeds when towing up steep grades to avoid damaging components.) These events make up a relatively small portion of on-road use and are typically short in duration. [EPA-HQ-OAR-2022-0829-0701, pp. 184-185]

EPA has not provided any event and time-weighted analysis of the overall emissions impact of generally prohibiting enrichment to justify its proposal. [EPA-HQ-OAR-2022-0829-0701, pp. 184-185]

The following data in Figure 67 provides a sample for real-world driving conditions from a limited test program conducted by a member company on a set of European vehicles operating under a mix of normal driving conditions, including high-speed highway operation and occasional towing. The data, details of which will be provided by the member company under confidential submission, provides estimated cumulative duration of travel at different engine operating conditions. This sample data indicates that for the vast majority of conditions encountered in on-road use, enrichment is used infrequently and for only a short duration. This sample dataset indicates that the cumulative time in the operating zone of this particular vehicle where enrichment may occur is much less than 0.1% in total. This specific example included over 4500 instrumented vehicles and over 370,000 individual trips. While representative of European driving conditions, Auto Innovators contends that a similar pattern would likely be exhibited in the U.S. [EPA-HQ-OAR-2022-0829-0701, pp. 184-185]

[See original attachment for Figure 67: Example of limited use of enrichment in on-road operation.] [EPA-HQ-OAR-2022-0829-0701, pp. 184-185]

Also, in general, carbon monoxide emissions are no longer the concern that they once were. There are currently no areas in non-attainment with National Ambient Air Quality Standards for CO.289 This is, in part, a testament to the efficacy of modern vehicle emission control systems including when enrichment is allowed as an auxiliary emission control device. [EPA-HQ-OAR-2022-0829-0701, pp. 184-185]

289 U.S. Environmental Protection Agency, Green Book Carbon Monoxide (1971) Area Information, available at https://www.epa.gov/green-book/green-book-carbon-monoxide-1971-area-information (retrieved June 1, 2023).

2. Recommendations on Enrichment

Auto Innovators opposes the proposal to broadly eliminate enrichment and believes that EPA's proposal could reverse the holistic environmental and energy success we have achieved in customer adoption of downsized engines. [EPA-HQ-OAR-2022-0829-0701, pp. 185-186]
