123 Jeff S. Bartlett, Automakers Are Adding Electric Vehicles to Their Lineups. Here's What's Coming, Consumer Reports (Mar. 10, 2023), available at https://www.consumerreports.org/cars/hybrids-evs/why-electric-cars-may-soon-flood-the-us-market-a9006292675/.

Organization: Ceres Corporate Electric Vehicle Alliance (CEVA)

Members of the Alliance share a goal to electrify their on-road fleets and networked vehicles to reduce their carbon footprint, meet climate goals, and support the community health of their customers and employees, and thus recognize the crucial role of these standards. While the availability and diversity of commercial ZEVs in the U.S. market have improved, significant hurdles remain in securing a greater and more diverse supply of cost-competitive ZEVs to meet long-term corporate demand. The Alliance alone represents robust demand for ZEVs, with members planning to procure approximately 330,000 ZEVs as soon as 2026. Auto and truck manufacturers are also recognizing the business case for transitioning to ZEVs. Many have committed to produce only zero-emission passenger vehicles by 2035 or earlier, and several have made commitments to reach 50-67% medium- and heavy-duty ZEV sales by 2030 and 100% by 2040 or sooner. 7 Manufacturers and fleet operators rely in large part on technology-driving federal policy to close the gap between supply and demand for zero-emission commercial vehicles. Strong standards are needed to spur the availability, production volume, and variety of zero-emission cars and trucks that meet the requirements of commercial fleets (such as the need for vehicles with electronic power-takeoff or exportable power capabilities), as well as reduce harmful pollutants to the maximum extent possible. [EPA-HQ-OAR-2022-0829-0511, p. 2]

7 https://theicct.org/wp-content/uploads/2023/04/hdv-phase3-ghg-standards-benefits-apr23.pdf (p.i).

Organization: Colorado Energy Office, Colorado Department of Transportation, and Colorado Department of Public Health and Environment

Our agencies strongly support EPA's development of national air pollution and GHG emission standards that are as robust as possible to ensure strong progress nationwide on air pollution and equity. A strong national light- and medium-duty vehicle standard is important to Colorado for at least three reasons. First, air pollution from nearby states crosses into Colorado and affects public health, and the longer duration and increased stringency of the proposed criteria air pollutant standards will reduce interstate air pollution transport into Colorado. Second, Colorado is already experiencing the impacts of climate change, including increased wildfires, floods, and drought. Climate change is a global issue that is impacted by all GHG emissions regardless of geographic source, and the reductions in GHG emissions from the proposed national rule will help reduce the long-term risks of climate change in Colorado. Finally, although the proposed national GHG emissions standards are not an explicit EV sales requirement like Advanced Clean Cars and Advanced Clean Cars II, complying with the standards will effectively require vehicle manufacturers to sell a significantly greater amount of EVs. The economies of scale encouraged by the proposed rules will support the production of more affordable EVs, easing the transition to zero emission vehicles and enabling greater access to their benefits for disproportionately impacted communities. [EPA-HQ-OAR-2022-0829-0694, p. 2]

Organization: Electrification Coalition (EC)

To mitigate the impacts of climate change and to reduce national and economic security threats, the U.S. needs a solution that will decarbonize our economy, reduce dependence on oil and position the U.S. to maintain our status as a global leader in a new economy that is based on minerals. The shift to electricity as a fuel source, also called transportation electrification, is the solution to this triad of concerns. [EPA-HQ-OAR-2022-0829-0588, pp. 2-3]

For these reasons, the adoption of the strongest possible proposal would significantly limit the greenhouse gas emissions from internal combustion engine vehicles and require them to be cleaner, bringing the market for these internal combustion engine vehicles to the tipping point and thereby accelerating the adoption of EVs. The EPA forecasts that the proposed rule would lead to 67% of new sales of LD/MD vehicles being zero-emission (electric) in 2032, depending on the vehicle type. [EPA-HQ-OAR-2022-0829-0588, pp. 2-3]

Therefore, the EC supports the adoption of the strongest possible proposal, as it will accelerate the adoption of EVs in the LD/MD sector. [EPA-HQ-OAR-2022-0829-0588, pp. 2-3]

Organization: Energy Innovation

Other research from the University of California, Berkeley, Grid Lab, and Energy Innovation, 2035 2.0: Plummeting Costs and Dramatic Improvements in Batteries Can Accelerate Our Clean Transportation Future (April 2021), evaluated the technical and economic feasibility (and associated impacts and benefits) of achieving a future scenario where electric vehicles make up 100 percent of new sales of all vehicles by 2035, combined with a 90 percent clean grid (called the DRIVE Clean Scenario).[iv] Compared with the No New Policy scenario (which was pre-IRA and BIL), the total transportation sector pollutant[v] and carbon dioxide emissions reductions in the DRIVE Clean Scenario would reduce ground transportation sector CO2 emissions by 60 percent in 2035 and by 93 percent in 2050, relative to 2020 levels.9 See Figure 3. The DRIVE Clean Scenario would also avoid approximately 150,000 premature deaths and generate nearly $1.3 trillion in health and environmental savings through 2050.10 Compared to the No New Policy, the DRIVE Clean Scenario would also result in approximately $2.7 trillion in consumer savings through 2050 compared—a household savings of about $1000 per year on average over 30 years.11 [EPA-HQ-OAR-2022-0829-0561, pp. 5-6]

Organization: Energy Strategy Coalition

In addition to these financial incentives, state and international regulations are promoting greater levels of vehicle electrification. California's Advanced Clean Cars II rule will require that all new light-duty vehicles sold in the state be zero-emission vehicles by 2035.11 California's Advanced Clean Trucks regulation requires that 55% of medium-duty vehicle sales be zero-emission vehicles by 2035.12 And California's Advanced Clean Fleets regulation separately applies phased-in zero- emission vehicle requirements to 142,000 medium-duty vehicles operating in the state.13 States that have adopted one or more of these California regulations include Colorado, Massachusetts, Maryland, New Jersey, New York, Oregon, Vermont, and Washington, with more expected to follow.14 California's rules align with emerging European standards. The European Union has adopted a regulation that incentivizes zero-emission vehicles and requires 100% carbon dioxide emission reductions for both new cars and vans by 2035.15 The European standards establish intermediate emissions reduction targets for 2030 that are set at 55% for cars and 50% for vans.16 [EPA-HQ-OAR-2022-0829-0610, pp. 2-3]

Given these incentives and regulatory dynamics, some market projections anticipate EV penetration-rates comparable to the levels contemplated by the LMDV proposal. Prior to enactment of the IRA, Bloomberg New Energy Finance projected that the U.S. was on pace to reach 40 to 50 percent electric vehicle sales by 2030.17 More recent studies incorporating the effects of the IRA project that the share of electric vehicle sales is expected to increase to between 56 and 67 percent by 2032.18 [EPA-HQ-OAR-2022-0829-0610, pp. 2-3]

18 Id. (citing International Council on Clean Transportation, ‘‘Analyzing the Impact of the Inflation Reduction Act on Electric Vehicle Uptake in the US,’’ ICCT White Paper, January 2023. Available at https:// theicct.org/wp-content/uploads/2023/01/iraimpact-evs-us-jan23.pdf). As EPA notes, this study takes into effect state policies (such as the California Advanced Clean Cars II program and its adoption by Section 177 states). Id.

Organization: Environmental. and Public Health Organizations

EPA has both an opportunity and an obligation to dramatically reduce emissions of greenhouse gases (GHGs) and other pollutants from light-duty vehicles (LDVs) and medium-duty vehicles (MDVs). The Agency’s mandate to protect public health and welfare is made urgent by the ever more dire impacts of climate change, as well as the continuing harms to public health from vehicle criteria pollution. And the opportunity to significantly reduce these impacts is clear. Zero-emission vehicles (ZEVs) are not only feasible and cost-reasonable—they are rapidly penetrating the fleet, with more than 250,000 fully battery electric vehicles sold in the first quarter of 2023 alone, a 44.9% increase over the same period last year.1 In addition, numerous emission control technologies for combustion vehicles are also feasible, cost-reasonable, and already extensively deployed on the fleet, yet still have potential for greater application within the fleet of new combustion vehicles that will continue to be produced. [EPA-HQ-OAR-2022-0829-0759, p. 8]

1 Cox Automotive, Another Record Broken: Q1 Electric Vehicle Sales Surpass 250,000, as EV Market Share in the U.S. Jumps to 7.2% of Total Sales (Apr. 12, 2023), https://www.coxautoinc.com/market-insights/q1-2023-ev-sales/.

The feasibility of greater pollution control, as well as growing consumer demand for ZEVs, is demonstrated by automaker commitments to increase the number of ZEV models and by their own investments and sales targets for these vehicles. Indeed, numerous projections of the light-duty fleet show high levels of ZEVs in the coming years, with several predicting more than 50% ZEVs as a portion of light-duty vehicle sales by 2030 even in the absence of new EPA regulations, which is also consistent with automaker announcements.4 [EPA-HQ-OAR-2022-0829-0759, p. 8]

4 See, e.g., U.S. EPA, Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles; Proposed rule, 88 Fed. Reg. 29184, 29189, 29192-93 (May 5, 2023).

EPA’s analysis shows that Alternative 1 is also feasible. It relies on the same existing technology—vehicle electrification—at the core of the Proposed Standards, and the share of battery-electric vehicles (BEVs) in the new vehicle fleet projected by EPA under Alternative 1 is very similar to those under the Proposed Standards, with the share under Alternative 1 never exceeding those under the Proposed Standards by more than 3 percentage points through 2032. Id. at 29333, tbl. 99 (BEV penetration of 60% under the Proposed Standards in 2030, versus 63% under Alternative 1). While we are recommending that EPA finalize a modified version of Alternative 1 (which would yield higher levels of BEV penetration, as detailed in Section V below), EPA’s analysis at least shows that BEV levels associated with Alternative 1 are eminently feasible. [EPA-HQ-OAR-2022-0829-0759, p. 25]

According to the Alliance for Automotive Innovation, in the first quarter of 2023, there were 55 BEV models and 40 Plug-in Hybrid (PHEV) models available in the United States, representing a variety of vehicle types, including sedans, crossovers, SUVs, and light-duty trucks.102 The technology is only improving, and the number of models of plug-in electric vehicles (PEVs, which include both BEVs and PHEVs) available in the U.S. is projected to reach 197 by the end of 2025.103 Higher levels of PEV adoption are already driven by strong consumer demand and greater model choice. And as is discussed throughout these comments, the charging infrastructure, electric grid, and vehicle supply chain will be able to accommodate the projected levels of BEVs—indeed, sending a strong regulatory signal will facilitate that process. Moreover, given the flexibility in EPA's program, as well as the fact that EPA's modeling did not include any PHEVs or improvements to combustion vehicle greenhouse gas emissions (and in fact projects increasing GHG emissions from the combustion vehicle fleet, as discussed in Section VI.A), it is likely that the levels of BEVs would be lower in the real-world than EPA projected as automakers employ such technologies to comply with the final standards. That is because making even minor improvements in combustion vehicle GHG emissions—or even simply holding the average emissions of the combustion vehicle fleet constant—or manufacturing PHEVs will allow automakers to achieve compliance with relatively fewer levels of ZEVs than EPA projected. [EPA-HQ-OAR-2022-0829-0759, pp. 25-26]

Bartlett & Ben Preston, Automakers are Adding Electric Vehicles to Their Lineups. Here's What's Coming, Consumer Reports (Jan. 6, 2023),https://www.consumerreports.org/hybrids-evs/why-electric-cars-may-soon-flood-the-us-market-a9006292675/.

A. Other analyses predict high levels of ZEVs in the period of the Proposed Standards.

In the Proposal, EPA cites several sources that model the global and United States ZEV outlook over the next few decades. 88 Fed. Reg. at 29189, 29192-3.252 These models vary in their assumptions (including whether IRA funding is considered in the projections), but all point to upward momentum of the PEV market globally and in the United States. EPA appears to have considered a variety of analyses available – looking at both aggressive projections and conservative models – to understand the global transition to PEVs. The most relevant of the analyses that EPA considered are those that account for the impact of the IRA in baseline ZEV penetration levels, and each of those supports baseline ZEV sales greater than the baseline levels projected in EPA's proposed No Action scenario. For example, the 2022 Bloomberg New Energy Finance (BNEF) analysis incorporating the IRA projects baseline ZEV sales of 52% in 2030, compared to EPA's projection of 39% in 2032. Id. at 29189. And the analysis by ICCT and Energy Innovation, which also incorporated the impacts of the IRA, projects 2032 baseline ZEV sales between 17% and 28% higher than EPA's projections. Id. An additional analysis by Boston Consulting Group not cited by EPA projects similar baseline ZEV sales, anticipating 53% U.S. market share for light-duty ZEVs in 2030.253 The only analysis EPA considered that projected a baseline close to EPA's projection was IHS Markit—predicting nearly 40% ZEV sales in the U.S. by 2030—but this analysis was pre-IRA and therefore should be considered an underestimate. See 88 Fed. Reg. at 29189. These analyses justify and support strong EPA emission standards, and auto executives have signaled that their sales expectations align with baseline ZEV sales at least as high as—and most likely higher than—EPA's projections, even prior to the passage of the IRA.254 As discussed throughout these comments, we request that EPA adopt at least Alternative 1 based on strong projections of the growth of the PEV market, as well as consider additional new data that became available since the Proposal. [EPA-HQ-OAR-2022-0829-0759, pp. 100-101]

252 IHS Markit (2021) predicted nearly 40% US PEV share by 2030 (pre-IRA); BNEF found the U.S. on pace to reach 40-50% PEVs by 2030, increasing to 52% when adjusted for IRA; ICCT/Energy Innovation found BEV share to be 56% to 67% by 2032 (including IRA); IEA found OEM announcements equal about 50% ZEVs in 2030.

253 Nathan Niese et al., Electric Cars Are Finding Their Next Gear, BCG, Exhibit 1 (June 9, 2022), https://www.bcg.com/publications/2022/electric-cars-finding-next-gear. BCG's projections for 2030 include 47% market share for BEVs and 6% market share for PHEVs.

254 KPMG, 22nd Annual Global Automotive Executive Survey 2021 8 (Nov. 2021), https://assets.kpmg.com/content/dam/kpmg/xx/pdf/2021/11/global-automotive-executive-summary-2021.pdf (finding that, even before the passage of the IRA, auto executives on average expected 52% of new vehicle sales to be all-electric by 2030). See also, Michael Wayland, Auto Executives Say More Than Half of U.S. Car Sales Will Be EVs By 2030, KPMG Survey Shows, CNBC (Nov. 30, 2021), https://www.cnbc.com/2021/11/30/auto-executives-say-more-than-half-of-us-car-sales-will-be-evs-by-2030-kpmg-s urvey-shows.html.

For example, in the Proposal, EPA cites 2022 BNEF data that states that global growth of EVs is projected to reach 21 million in 2025. However, the latest BNEF EV Outlook updates that modeling, and estimates that EV sales will reach approximately 22.4 million by 2025, growing to 26.6 million sales by 2026 and reaching 44% of global sales by 2030. In the United States, EVs are expected to reach 28% of sales by 2026, which equates to over 4 million new ZEV sales, a large growth from the 980,000 new ZEVs sold in 2022.255 [EPA-HQ-OAR-2022-0829-0759, p. 101]

255 BloombergNEF, Electric Vehicle Outlook 2023: Executive Summary (2023).

Figure XV.A-1: Global near-term passenger EV sales and share of new passenger vehicle sales by market

[See original attachment for Figure XV.A-1]. [EPA-HQ-OAR-2022-0829-0759, p. 101]

B. State standards will lead to greater ZEV deployment.

In August 2022, CARB unanimously approved the ACC II standards, which, starting in model year 2026, require manufacturers to sell an increasing number of new ZEVs256 annually, culminating in 100% new ZEV sales by model year 2035. CARB submitted a waiver request for the ACC II standards in late May 2023. [EPA-HQ-OAR-2022-0829-0759, pp. 101-102]

256 Defined as Battery Electric, Plug-in Hybrid, and Fuel Cell Electric Vehicles.

While the ACC II standards cannot be enforced until the waiver is granted by EPA, six additional states257 have adopted the standards in anticipation of waiver approval. These seven states (including California) approximately 25% of the United States vehicle market.258 Further, at least five other states and the District of Columbia have announced their intention to adopt ACC II.259 Should those jurisdictions also adopt ACC II, nearly one-third of the United States vehicle market would be on a trajectory to have 100% new zero-emission vehicle sales by 2035.260 [EPA-HQ-OAR-2022-0829-0759, p. 102]

257 The states that have adopted ACCII as of the date of this comment letter are Oregon, Washington, Virginia, Massachusetts, New York, and Vermont.

258 CARB, States that Have Adopted California's Vehicle Standards under Section 177 of the Federal Clean Air Act, May 13, 2022, https://ww2.arb.ca.gov/sites/default/files/2022-05/%C2%A7177_states_05132022_NADA_sales_r2_ac.pdf

259 These states are: Rhode Island (https://dem.ri.gov/environmental-protection-bureau/air-resources/advanced-clean-cars-ii-advanced-clean-trucks), Delaware (https://news.delaware.gov/2022/03/03/delaware-to-adopt-zero-emission-vehicle-regulation/), Maryland (https://governor.maryland.gov/news/press/pages/Governor-Moore-Announces-Maryland-Adoption-of-the-Advance d-Clean-Cars-II-Rule-to-Combat-the-Effects-of-Climate-Change.aspx), New Jersey (https://nj.gov/governor/news/news/562023/approved/20230215b.shtml), and Colorado (https://cdphe.colorado.gov/coloradocleancars). Earlier this year, Washington D.C completed the public comment period on its proposal to adopt the ACC II regulations (https://doee.dc.gov/release/notice-comment-period-proposed-rulemaking-adoption-california-vehicle-emission-standards)

260 CARB, States that Have Adopted California's Vehicle Standards under Section 177 of the Federal Clean Air Act.

EPA included ACC II in a sensitivity analysis but did not include it in the central analysis, as CARB had not yet submitted the waiver request for ACC II as of the date of the Proposal. However, now that CARB has submitted the waiver request, we ask that ACC II be included in the central analysis if the waiver is granted before the Proposal is finalized. And while ACC II clearly supports the feasibility of stronger federal standards, including through changes to business-as-usual (BAU) PEV penetration, it is also clear that stronger federal standards are feasible and justified even without it. As a result, we encourage EPA to model a scenario in the final rule that does not include ACC II, which will demonstrate that the record supports the final standards even in the absence of ACC II. [EPA-HQ-OAR-2022-0829-0759, p. 102]

The addition of the ACC II sensitivity makes a significant difference in the No Action scenario, as the BAU for PEVs increases from 39% to 54% and the incremental average cost of the standards decreases from $1,164 to $164. It appears that this sensitivity does not include all of the states that have adopted ACC II or intend to adopt ACC II—specifically Virginia—implying that the BAU will increase, and the average incremental costs of the standards will decrease even further when the full range of states are included. The inclusion of the full portfolio of states that have adopted ACC II by the time of the final regulation in the central analysis will provide a more accurate picture of the state of the U.S. PEV market as well as presumed costs of the regulation. [EPA-HQ-OAR-2022-0829-0759, pp. 102-103]

The inclusion of ACC II in the central analysis is also aligned with assumptions EPA has included throughout the Proposal with respect to ACC II adoption, such as the assumption that "anticipated longer all-electric range and greater all-electric performance, partially driven by CARB's ACC II program… should result in performance more closely matching [the] proposed curve," 88 Fed. Reg. at 29254, and the alignment of the NMOG + NOx provisions with ACC II 88 Fed. Reg. at 29275. [EPA-HQ-OAR-2022-0829-0759, p. 103]

C. Private investments and commitments will lead to greater ZEV deployment.

EPA should also consider private investments and commitments that have been announced or implemented throughout the United States thus far that will further facilitate rapid growth of ZEVs. [EPA-HQ-OAR-2022-0829-0759, p. 103]

EPA states in the proposed rule that automakers, based on their public commitments, will achieve approximately 50% ZEV sales by 2030. 88 Fed. Reg. at 29296. EPA also considered additional automaker announcements to accelerate the EV market in the United States, see, e.g., 88 Fed. Reg. at 29193-94. EPA should update these estimates in the final rule, including by recognizing the $210 billion of investments in the United States to accelerate the transition to ZEVs and build up a robust, domestic supply chain – a higher investment than any other country.261 These investments will help increase the availability of ZEVs in the United States and further accelerate the transition to ZEVs that is already well underway in the market. [EPA-HQ-OAR-2022-0829-0759, p. 103]

261 Noah Gabriel, $210 Billion of Annouced Investments in Electric Vehicle Manufacturing Heading for the U.S. (January 12, 2023), https://www.atlasevhub.com/data_story/210-billion-of-announced-investments-in-electric-vehicle-manufacturing-he aded-for-the-u-s/.

Organization: Environmental Defense Fund (EDF) (1of 2)

ii. Market developments further support the feasibility and lead time reflected in EPA's proposal.

Market developments, including manufacturer plans to introduce new BEVs, concrete investments to produce these and other vehicles at volume, and future commitments for significant BEV sales are all consistent with and reinforce the conclusions of the above-described analyses and likewise support the feasibility of protective EPA standards. In fact, these market developments in many cases show manufacturers' plans to produce BEVs at even greater volumes than EPA has assumed. [EPA-HQ-OAR-2022-0829-0786, pp. 23-26]

Increasing BEV Availability and Sales Volumes. An updated report by ERM, based on announcements by major auto manufacturers, finds the number of electrified models available in the U.S. is projected to dramatically increase, reaching 197 by the end of 2025, with over 58 new models slated to launch in model years 2022-2025 (Figure 5).58 As Figure 6 shows, these vehicles will be available across all vehicle types and classes, and, as a result of IRA tax incentives, there will be five light-duty EV models available with a net cost of under $30,000 manufacturer's suggested retail price (MSRP) by the end of 2023 and 15 models available for under $40,000.59 In the United States, more than 800,000 light-duty EVs were purchased in 2022, a 65 percent increase from 2021. The first quarter of 2023 saw EV sales reach over 258,000 units, almost a 45 percent year over year increase.60 [EPA-HQ-OAR-2022-0829-0786, pp. 23-26]

58 Electric Vehicle Market Update: Manufacturer and Commercial Fleet Electrification Commitments Supporting Electric Mobility in the United States. April 2023. ERM for EDF. https://www.edf.org/sites/default/files/2023-05/Electric%20Vehicle%20Market%20Update%20April%202023.pdf (Attachment S)

Near-Term Investments Dramatically Increase Production Capacity. In addition to introducing new electric vehicles, manufacturers are investing billions of dollars to produce them at volume. As noted above, a report by WSP for EDF found over $120 billion in private EV supply ecosystem investments and 143,000 new jobs announced in the last eight years. That analysis also evaluated the production capacity of announced facilities with concrete investments. [EPA-HQ-OAR-2022-0829-0786, pp. 23-26]

As shown in the Figures below, by 2026, U.S. manufacturing facilities will be capable of producing an estimated 4.3 million new electric passenger vehicles each year, which represents about 33 percent of all new vehicles sold in 2022. And by 2026, battery manufacturing facilities will be capable of producing more than 1,000 gigawatt hours (GWh) in battery capacity, sufficient to supply up to 11.2 million new passenger vehicles each year, which represents an estimated 84 percent of new vehicle sold in 2022. Both of these levels far exceed EPA's projections for BEV deployment. [EPA-HQ-OAR-2022-0829-0786, pp. 23-26]

Manufacturer Commitments. In addition to near-term model availability and supporting production investments, vehicle manufacturers have articulated medium- to long-term commitments to even more substantially grow ZEV sales with many working toward a full ZEV fleet within the next decade. For instance, according to the recent market update from ERM, Ford expects 50 percent of its global vehicle volume, and 100 percent of its European volume, to be fully electric by 2030 with a goal of producing 2 million EVs annually by 2026; GM plans to offer a lineup of electric-only models by 2035; Honda has a goal of achieving carbon neutrality by 2050 and 100 percent ZEV sales in North America by 2040—with interim sales goals of 40 percent by 2030 and 80 percent by 2035; Volvo has committed to becoming a fully electric car company by 2030—with an interim goal of reaching 50 percent of global EV car sales and having one million EVs on the road by 2025; and Stellantis aims for 100 percent of sales in Europe and 50 percent of sales in the U.S. to be BEVs by the end of the decade,61 As EPA notes in the preamble to this proposal, virtually every major automaker is already planning on widespread electrification across global fleets. Figure 9, below, is an updated synthesis of these manufacturer commitments. [EPA-HQ-OAR-2022-0829-0786, pp. 23-26]

61 Id.

[See original attachment for Figure 9: Global Sales Goals by Manufacturers] [EPA-HQ-OAR-2022-0829-0786, pp. 23-26]

Source: ERM, EV Market Update (April 2023)

Market indicators are consistent with and strongly support protective standards. Manufacturers have (and are planning to continue to) offer new vehicles. They have invested billions of dollars to produce these vehicles at near term volumes that far exceed EPA's projections. And almost every company has articulated medium- to longer term ZEV commitments that are broadly consistent with levels in EPA's proposal. [EPA-HQ-OAR-2022-0829-0786, pp. 23-26]

iv. EDF has quantified EV sales related to the impacts of state policy, manufacturer investments and commitments, and other analyses.

As described above, many independent indicators point toward significant ZEV adoption over the next decade. As Figure 12 below shows, EDF has quantified and plotted the impacts of state action, market developments (including manufacturer investments and commitments and lithium mining supply), as well as projections from a number of different independent organizations. The analysis shows many different indicators plotted together and supports EPA's No Action (baseline) case as well as the feasibility of the proposal. Under the No Action scenario, EPA's modeling projects BEV adoption at 27% in 2027 growing to 40% by 2030. [EPA-HQ-OAR-2022-0829-0786, pp. 29-31]

A description of the methodology and sources for each of the EV sales assessments is included below and importantly, each assessment addresses the independent impacts of each metric on EV deployment and does not evaluate the combined impacts of all taken together. [EPA-HQ-OAR-2022-0829-0786, pp. 29-31]

[See original attachment for Figure 12: Indicators of Significant ZEV Adoption through 2032] [EPA-HQ-OAR-2022-0829-0786, pp. 29-31]

Source: EDF State Action

As discussed above, many states have taken action to promote ZEV adoption. Seven states71 have already adopted ACC II with five additional states72 along with the District of Columbia in the process of adopting. Additionally, many states have adopted the Advanced Clean Trucks (ACT) regulation which sets ZEV sales mandates for medium- and heavy-duty vehicles (MHDVs) including Class 2b and 3 starting with MY2024. The rule requires 5% of Class 2b and 3 sales be ZEV in MY2024 growing to 55% in 2035. Along with California, nine additional states have since adopted ACT.73 To understand the impact of state action on baseline ZEV adoption, we assumed that the 12 states and the District of Columbia adopt ACC II and the 10 states adopted ACT. [EPA-HQ-OAR-2022-0829-0786, pp. 29-31]

71 California, Oregon, Washington, Massachusetts, New York, Vermont, and Virginia

72 Maryland, Delaware, Colorado, Rhode Island, and New Jersey

73 Oregon, Washington, Massachusetts, Vermont, New York, New Jersey, and Colorado have all adopted ACT. Maryland and Colorado have both passed legislation requiring the rulemaking to take place.

To conservatively model sales in non-ACC II and non-ACT states, we used EIA's Annual Energy Outlook (AEO) 2023 ZEV sales projection. AEO2023 does not include ACC II adoption in their modeling and only minimally includes the impacts of the Inflation Reduction Act. The model uses the Congressional Budget Office's estimate for the Clean Vehicle Tax Credit (30D) which assumes roughly only 1 million ZEVs will receive a tax credit over the lifetime of the legislation. The model also does not include the impact of the additional relevant tax credits, such as the $45/kWh battery production tax credit. Given these factors, AEO2023's estimate of ZEV adoption remains a highly conservative estimate of ZEV adoption within the U.S. and might be considered the lowest bound of what is reasonable to expect in non-ACC II and non-ACT states. Nevertheless, an approach along these lines helps to isolate the impacts of ACC II in supporting nation-wide baseline levels of ZEV sales. [EPA-HQ-OAR-2022-0829-0786, pp. 29-31]

To calculate the Class 1/2a non-ACC II state ZEV sales values, we used AEO2023's LDV sales by technology type combining cars and light trucks.74 In 2025, this projects 9% of LDV sales would be ZEVs growing to 16% in 2032. For Class 2b/3, an average of AEO2023's ZEV sales projection for light commercial vehicles (Class 2b) and light medium vehicles (Class 3) was used.75,76 In 2025, we assume non-ACT states have 0.24% ZEV sales rising to 0.30% ZEV sales in 2032. [EPA-HQ-OAR-2022-0829-0786, pp. 29-31]

74 U.S. Energy Information Administration, Annual Energy Outlook 2023, Table 38. Washington, D.C. Accessed April 4, 2023. https://www.eia.gov/outlooks/aeo/supplement/excel/suptab_38.xlsx

75 Annual Energy Outlook 2023, Table 44 https://www.eia.gov/outlooks/aeo/supplement/excel/suptab_44.xlsx.

76 Annual Energy Outlook 2023, Table 49 https://www.eia.gov/outlooks/aeo/supplement/excel/suptab_49.xlsx.

ZEV sales as a result of state action along with low baseline sales in other states results in 30% ZEV sales in 2030 growing to 42% in 2035. The values are plotted above in Figure 12 with the label "ACC II/ACT + Baseline Sales." Under this scenario, Section 177 states account for 61% of the LMD ZEV sales nationwide in 2027 growing to 70% by 2035 even though they only account for 30% of vehicle sales.77 This demonstrates that even with fairly low and unrealistic ZEV sales in non-Section 177 states, a robust nationwide adoption of ZEVs will result from current state action alone. [EPA-HQ-OAR-2022-0829-0786, pp. 29-31]

77 Vehicle sales were based on MOVES3

Vehicle Manufacturer EV Commitments

Many vehicle manufacturers have made commitments to transition a significant portion of their sales to ZEVs. While many of the commitments are for a share of manufacturers' global sales, several OEMs have made U.S. specific commitments or have committed to transition their entire fleet which would mean all of their U.S. sales would be ZEV as well. Even for global commitments, manufacturers with significant U.S. sales volumes will nonetheless need to sell meaningful ZEVs to meet their commitments. Because some sales might exceed these global commitments while others fall short, we used global commitments as a reasonable proxy for U.S. sales share. Table 4 below shows OEM commitments and includes a total using 2022 manufacturer sales shares to calculate a weighted ZEV commitment. [EPA-HQ-OAR-2022-0829-0786, pp. 31-34]

[See original attachment for Table 4: Manufacturer ZEV Commitments as Share of Total Sales] [EPA-HQ-OAR-2022-0829-0786, pp. 31-34]

*Due to rounding, the sum of the market share may not equal the total

All major OEMs have set ZEV targets of at least 30% sales starting in 2030. Considering both U.S.-specific and global commitments would result in 47% of new vehicles sold in the U.S. in 2030 being ZEVs. Even unrealistically assuming only the US-specific commitments and the 100% commitments apply, at least 29% of LDV sales in 2030 would be ZEVs growing to 44% in 2035 and 48% in 2040. The 2030 value is plotted above in Figure 12. We also note that the 2035 and 2040 estimates using both approaches are perhaps significantly understated given that some manufacturers with commitments in 2030 have not made 2035 or later commitments but will nonetheless likely increase ZEV sales during that timeframe. [EPA-HQ-OAR-2022-0829-0786, pp. 31-34]

Organization: Governing for Impact and Evergreen Action (GFI)

According to EPA estimates, if the agency declines to finalize any new tailpipe emissions regulations at all — under what the agency calls its central "No Action" baseline — EV sales will nonetheless comprise approximately 39 percent of new car sales by MY 2032.59 As the EPA itself acknowledges, this may prove a conservative estimate of IRA and other non-rule impacts on EV adoption.60 For example, a synthesis of automakers' public EV commitments to date compiled by the International Energy Agency, which the EPA declined to incorporate into its projections, suggested that EVs would comprise 50 percent of new car sales by 2030 (again, even in the Proposed Rule's absence).61 Nor, in reaching its central No Action baseline, did the EPA take into account certain new state level policies, like California's, which may drive EV penetration even further.62 [EPA-HQ-OAR-2022-0829-0621, p. 8]

59 Proposed Rule at 29329, "Fleet BEV Penetration Rates, by Body Style, Under the No Action Case," Table 81. As discussed below, the EPA also conducted alternate No Action sensitivity cases.

60 Proposed Rule at 29296.

61 See Proposed Rule at 29296 ("[F]or purposes of this proposal we have not integrated manufacturer announcements directly into our modeling of the No Action baseline") (citing International Energy Agency, "Global EV Outlook 2022," p. 107, May 2022, https://iea.blob.core.windows.net/assets/e0d2081d-487d-4818-8c59-69b638969f9e/ GlobalElectricVehicleOutlook2022.pdf).

62 Proposed Rule at 29296 ("[O]ur analysis does not include the effect of state-level policies whereas projections from other sources may include those policies. We did not include these policies because many are still not in effect; however, we do anticipate that in the next decade, state level policies may play an important role in driving BEV penetration.").

Moreover, as other advocates have noted elsewhere, adoption of innovative technologies does not follow a linear trajectory, but rather "an S-shaped curve, with the adoption rate increasing more rapidly once a critical mass is reached—as we are now seeing with electric vehicles."63 As a result, now that the United States has crossed the EV "tipping point,"64 we would expect steep growth over the next several years regardless of the EPA's regulatory path. [EPA-HQ-OAR-2022-0829-0621, p. 8]

G. EPA Should Further Explain Its Choices Around Scrappage, Pass-Through, and Vehicle Sales

EPA should provide additional explanation around certain modeling choices—namely scrappage, pass-through, and sales. [EPA-HQ-OAR-2022-0829-0601, pp. 22-23]

"Scrappage" refers to the rate of which drivers discard old automobiles. OMEGA treats scrappage as exogenous, meaning that the rate of scrappage does not depend on the Proposed Rule's other effects.144 This choice is reasonable: While economic theory and evidence suggest that scrappage depends in part on the Proposed Rule's other effects (most notably the rate at which the Proposed Rule affects new vehicle prices and sales),145 this effect is very difficult to model due to data limitations, and past attempts by EPA and NHTSA to model scrappage have fared poorly.146 Moreover, the increasing movement to electric vehicles provides even more reason to treat scrappage as exogenous, as virtually no analysis on the scrappage of BEVs exists. However, the Proposed Rule provides no discussion of scrappage or EPA's choice not to model it. Particularly since EPA endogenously modeled scrappage in the 2020 Rule, the agency may wish to explain its decision not to follow this approach in the Proposed Rule and a discussion of how it may affect the results. Moreover, to the extent feasible, EPA should attempt to model scrappage in future standards. [EPA-HQ-OAR-2022-0829-0601, pp. 22-23]

144 See RIA at 9-3 to 9-5.

145 See Howard K. Gruenspecht, Differentiated Regulation: A Theory with Applications to Automobile Emissions Control (1982); Howard K. Gruenspecht, Differentiated Regulation: The Case of Auto Emissions Standards, 72 Am. Econ. Rev. 328 (1982); ENV'T PROT. AGENCY, THE EFFECTS OF NEW-VEHICLE PRICE CHANGES ON NEW- AND USED- VEHICLE MARKETS AND SCRAPPAGE 3-6 to 3-11 & 5-7 to 5-7 to 5-12 (2021).

146 Inst. for Pol'y Integrity, Comments on the Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021–2026 Passenger Cars and Light Trucks 66–71 (Oct. 26, 2018), https://policyintegrity.org/documents/Emissions_Standards_EPA_NHTSA_Comments_Oct2018.pdf.

"Pass-through" refers to the degree to which manufacturers pass on cost increases to consumers. EPA in prior tailpipe rules has assumed 100% pass-through to consumers in the vehicle market—meaning that every dollar of additional cost to the automaker is ultimately borne by the purchaser.147 EPA appears to repeat this assumption in the Proposed Rule. That approach is also reasonable given consistency with the agency's prior approach and the very limited economic evidence on vehicle pass-through. Nonetheless, that limited available evidence (from a 2010 paper) indicates that pass-through in the vehicle market may be below 100%.148 Accordingly, EPA should discuss and provide a rationale for its approach. EPA should also support further research in this area, given its potential importance. [EPA-HQ-OAR-2022-0829-0601, pp. 22-23]

147 E.g. 2020 Rule, 85 Fed. Reg. at 24,594–95.

148 Using regression analysis, Hellerstein and Villas-Boas (2010) find only partial pass through for the vehicle industry with an average pass-through rate of 38%. Rebecca Hellerstein, & Sophia B. Villas-Boas, Outsourcing and Pass-Through, 81 J. INT'L ECON. 170, 175 (2010).

Finally, with regard to sales, EPA should clarify how OMEGA treats how producers expect consumers to value fuel costs. Within the model, consumers and producers shape their preferred new vehicle mix independently,149 each informed by their unique perspectives on fuel costs: Consumers weigh their expected fuel expenses, whereas producers consider how they think consumers will weigh their expected fuel expenses. In the RIA, EPA explains that consumers are assumed to factor in fuel costs of 12,000 miles annually for 2.5 years.150 However, the OMEGA input files suggest that producers expect consumers to consider fuel costs up to 15,000 miles annually.151 Although this difference is not inherently problematic, especially if EPA posits imperfect information between consumers and producers,152 EPA should explain this difference. This might also be a minor programming error, such that EPA intended for producers to accurately peg consumer valuation of fuel costs at 12,000 miles annually. [EPA-HQ-OAR-2022-0829-0601, pp. 22-23]

149 The model then searches for solutions for a set of vehicle attributes, purchase prices, and quantities such that the sales and production shares match.

150 RIA at 4-2.

151 This information is derived from the 'sales_share_params_ice_bev_pu_b0p4_k1p0_x02031-cuv_b2p0_k1p0_x02029_nu8p0-sdn_b0p4_k1p0_x02020_nu1p0_20230228.csv' file for consumers, and the 'producer_generalized_cost-body_style_20220613.csv' file for producers, both located within the '2023-03-14-22- 42-30-ld-central-run-to2055\all_inputs' folder, downloadable from the 'Light-duty central case (zip)' section on EPA's website: https://www.epa.gov/regulations-emissions-vehicles-and-engines/optimization-model-reducing-emissions-greenhouse-gases

152 EPA, OMEGA Documentation Sec. 4.3.2 (last revised May 8, 2023), https://omega2.readthedocs.io/en/2.1.0/index.html#gl-label-producer-generalized-cost ("The producer, as an independent decision-making agent, will not have perfect information about the internal consumer decision process. Within the Producer Module, OMEGA allows the user to define the consumer decisions from the producer's perspective, which may be different from (or the same as) the representation within the Consumer Module.").

Organization: International Council on Clean Transportation (ICCT)

The United States is not alone in its commitment to transition to cleaner cars and trucks. EPA's proposal is in line with regulations in leading countries and automaker commitments. If implemented, the proposed rule would put the U.S. on track to catch up with Europe and China, which have led in the global transition to zero-emissions through 2022. Canada, the European

Union, the United Kingdom, and seven U.S. states have committed to entirely phase out the sale or registration of new internal combustion engine vehicles by 2035. EPA's proposal also aligns with announcements from auto manufacturers; Ford, General Motors, Mercedes-Benz, Audi, and others have committed to selling 100% zero-emission vehicles globally or in leading markets by 2035. With the rapid development of ZEV technologies, automakers are constantly updating their targets. In fact, ICCT reviewed EPA's compilation of automaker electric vehicle sales targets and announcements in the proposal and identified several additional announcements that had been made through 2022 beyond those in EPA's assessment, including announcements of expanded and accelerated electric vehicle targets by General Motors, Ford, Stellantis, Mercedes-Benz, Toyota, and Hyundai-Kia. These developments further reflect industry commitment to and desirability of ZEV technologies. [EPA-HQ-OAR-2022-0829-0569, pp. 3-4]

The Inflation Reduction Act (IRA) of 2022 will accelerate electric vehicle sales in the United States across all vehicle types. The $370 billion allocated to climate and clean energy investments dramatically expands tax credits and incentives to deploy more clean vehicles, including commercial vehicles, while supporting a domestic EV supply chain and charging infrastructure buildout. IRA transportation sector provisions will accelerate the shift to zero-emission vehicles by combining consumer and manufacturing policies. Consumer tax credits for new and used EVs and tax credits for commercial EVs, along with individual and commercial charging infrastructure tax credits, will increase sales. Domestic supply chain incentives and investments will boost EV manufacturing and battery production. Critical mineral mining and refining incentives will bolster industrial development. [EPA-HQ-OAR-2022-0829-0569, pp. 6-7]

An ICCT and Energy Innovation study assesses the future impact of the IRA on electrification rates for LDV sales in the United States through 2035.4 We analyze the value of the personal and commercial EV tax credits, factoring in the various supply chain, income, and price caps on new EVs, and combine this with new estimates of future light-duty EV cost declines. We find that, on average over the period 2023–2032, the IRA tax credits will reduce EV purchase costs by $3,400 to $9,050 and accelerate the timing for price parity with combustion vehicles. Using methodologies from the Energy Policy Simulator, we project how these changing costs and incentives over time will affect the LDV markets in the United States. [EPA-HQ-OAR-2022-0829-0569, pp. 6-7]

4 Slowik, P., Searle, S., Basma, H., Miller, J. Zhou, Y., Rodriguez, F., Buysse, C., Kelly, S., Minjares, R., Pierce, L. (ICCT) Orvis, R., and Baldwin, S. (Energy Innovation). (2023). Analyzing the impact of the inflation reduction act on electric vehicle uptake in the United States. https://theicct.org/publication/ira-impact-evs-us-jan23/

Figure 1 summarizes the results from the ICCT and Energy Innovation IRA study. It shows the findings of estimated new electric vehicle sales shares for different IRA scenarios depending on how certain provisions are implemented and how the value of incentives is passed on to consumers. The figure shows our modeled projection of how the IRA will accelerate electrification. By providing thousands of dollars in financial incentives, the IRA unlocks widespread consumer benefits. We find rapid projected EV uptake when considering both expected manufacturing cost reductions and the IRA incentives, as well as state policies. By 2030, we find a range of a 48%–61% projected EV sales share, increasing to 56%–67% by 2032, the final year of the IRA tax credits. [EPA-HQ-OAR-2022-0829-0569, pp. 6-7]

SEE ORIGINAL COMMENT for Figure 1. Baseline, Low, Moderate, and High projections of EV sales share for light-duty vehicles, considering ACC II adoption in only California versus increased states [EPA-HQ-OAR-2022-0829-0569, pp. 6-7]

5 ICCT and Energy Innovation. (2023). Analyzing the impact of the inflation reduction act on electric vehicle uptake in the United States. https://theicct.org/publication/ira-impact-evs-us-jan23/

Electric vehicle uptake

Figure 7 shows the historical EV sales shares from 2015 through 2022 (solid lines) and estimated future sales shares based on regulatory targets (dotted lines) for light-duty vehicles in the United States compared with other major markets. As shown, about 7% of new light-duty vehicle sales in the US. Were plug-in electric in 2022, compared to 8% in Canada, 20% in California, 23% in the United Kingdom and Europe, and 26% in China. Several jurisdictions have set a 100% ZEV target or a zero gram CO2/mile target by 23035, including California, Canada, European Union, and the United Kingdom (UK).45 The figure shows how the estimated 67% EV sales share in 2032, the last year of the proposed EPA standard, somewhat lags compared to the estimated uptake from regulations in California, Canada, Europe, and the UK. Not shown is the 46% EV sales share EPA projects for medium-duty vehicles in 2032. [EPA-HQ-OAR-2022-0829-0569, pp. 18-19]

45 European Union and UK's proposed standards do not include PHEV in ZEV definition

SEE ORIGINAL COMMENT FOR Figure 7. Historical electric vehicle sales shares (solid lines) and regulatory targets or projected ZEV shares consistent with regulatory targets (dotted lines) for light-duty vehicles in major markets [EPA-HQ-OAR-2022-0829-0569, pp. 18-19]

As discussed above and shown in Figure 7, at the state-level, California's Advanced Clean Cars II regulation will lead to 68% electric vehicle sales by 2030 and 100% by 2035. At least a dozen additional states are considering adopting California's new rules. As of May 2023, California, Massachusetts, New York, Oregon, Vermont, Virginia, and Washington have adopted ACC II. It is likely that many other states will continue to follow California's leadership and adopt the new ACC II Program to benefit from the anticipated emissions reduction and health benefits of the program.46 Many additional states currently follow the Advanced Clean Cars regulations through model year 2026; as of May 13th, 2022, 17 U.S. states have adopted all or part of California's low-emission and zero-emission vehicle regulations, and about 37% of national new light-duty vehicle sales meet California's emission standards.47 [EPA-HQ-OAR-2022-0829-0569, pp. 18-19]

A. ICE Sales Fund EV Transition

The proposed standards must reflect what is feasible for manufacturers to produce and sell to consumers and promote domestic production of cleaner technologies. The continued production of ICE vehicles, particularly light trucks (pickup trucks, sport utility vehicles, vans, and minivans), must be supported by proposed standards. The EV industry is in its infancy. On their own, EVs are not yet profitable.18 Some automakers will lose billions producing EVs and don't expect to reach profitability any time soon.19 Therefore, federal programs and regulation must work in concert to incentivize the production of EVs. While the transition is progressing, the auto industry relies on the continued production of ICE vehicles to reach profitability and fund required investments in electrification. Domestic automakers specifically rely on the sale of light trucks to fund investment into the EV transition. [EPA-HQ-OAR-2022-0829-0614, p. 8]

Organization: John Graham

The complete ignoring of mild hybrid improvements is reflected in the projected penetration of virtually zero mild hybrids in 2032.18 This is in stark opposition to what is happening in Europe, where mild hybrid market share has risen rapidly from just 0.2% in 2017 and 0.6% in 2018, to 2.2% in 2019, 7.8% in 2020, and 14.0% in 2021, with some manufacturers being far ahead of the average.19 Fiat/FCA projected in 2018 that 40% of its vehicles sold in Europe by 2022 would be MHEVs, which seemed an ambitious projection considering that Fiat sold no mild hybrid vehicles in 2019.20 However, Fiat exceeded this market share in just two years, with 42.4% of its newly registered vehicles being MHEVs by 2021. Other brands also showed rapid MHEV market share increases within a short time. These trends in Europe illustrate that mild hybrids are a cost-effective solution and that mild hybrid systems, at least P0 systems, can be implemented rapidly. [EPA-HQ-OAR-2022-0829-0585, p. 16]

18 Tables 13-65 through 13-94 in the DRIA indicate that 100% of market share is comprised of Turbo12, ATK, and BEV technologies for all cases except for Alterative 1, where 100% of market share includes 6% strong hybrids but still no mild hybrids.

I am writing today to express my opposition to the EPA's proposed rule regarding tailpipe emissions. [EPA-HQ-OAR-2022-0829-1702]

I am worried that the pace of transition outlined in this proposed rule is too quick for our economy and infrastructure to handle. [EPA-HQ-OAR-2022-0829-1702]

Under this rule, two-thirds of all light-duty vehicles sold in the United States would essentially be required to be all-electric by 2032. Considering electric vehicles only made up 6 percent of total sales in 2022, I am concerned about how such a large gap will be bridged quickly. Even if achievable, forcing the market to transition before the necessary resources and infrastructure are ready raises many concerns and challenges. [EPA-HQ-OAR-2022-0829-1702]

Also, by focusing the EPA's emissions reduction strategy on electric vehicles, this plan could ultimately leave additional reductions on the table by not encouraging the use of lower carbon fuels in the internal combustion vehicles that we currently have on the road considering these are likely to remain on the road for several more years. [EPA-HQ-OAR-2022-0829-1702]

In conclusion, the EPA should work with Congress and other stakeholders to craft a policy that balances and addresses emission reduction goals while addressing serious questions about infrastructure readiness and its impact on Americans. [EPA-HQ-OAR-2022-0829-1702]

Organization: Mercedes-Benz AG

In addition, sales of all-electric Mercedes-Benz passenger cars doubled in 2022, and electric sales continue to accelerate as we've sold more than 20% more EVs in 2023 through May than for all of 2022. [EPA-HQ-OAR-2022-0829-0623, p. 2]

Organization: Minnesota Corn Growers Association (MCGA)

Each year, sales of new vehicles displace a small fraction of the existing vehicle fleet. EPA estimates that 67% of new vehicles sales will be battery electric in 2032. The projections for battery electric vehicle adoption are based on very few—and very small—real-world data points. See generally 88 Fed. Reg. 29,187–90. Battery electric vehicles made up 5.8 percent of the new light-duty passenger vehicle market in 2022. Id. at 21,190. EPA needs these sales to increase by a factor of ten over the next 8 years. [EPA-HQ-OAR-2022-0829-0612, p. 4]

Clearly, a large number of new vehicles that burn liquid fuels will continue to be produced for many years, and those vehicles will remain on the road for many additional years. According to data from the Department of Energy's Oak Ridge National Lab,2 16% of passenger cars and 32% of light-duty trucks remain on the road for more than 20 years. If new electric vehicles are more expensive or less attractive to consumers, older liquid- fueled vehicles will remain on the road even longer. [EPA-HQ-OAR-2022-0829-0612, p. 4]

Organization: National Corn Growers Association (NCGA)

The proposed rulemaking assumes that BEVs will be the dominant technology for future emissions reductions. But relying on a single technology is a risky strategy; many factors could interfere including the supply and/or cost of critical minerals, lack of BEV recharging infrastructure, slow ramp-up of wind and solar power, poor customer acceptance of BEVs in some market segments, etc. EPA estimates that 67% of U.S. vehicles sales will be BEVs in 2032, but most major automakers predict much lower BEV sales, and the world's largest automaker predicts only 20% in 2030. For comparison, MIT predicts9 that China will achieve only 40% in 2030 despite a head start and extremely strong government interventions. EPA should not base mandatory emissions standards on unrealistic predictions of BEV sales. [EPA-HQ-OAR-2022-0829-0643, p. 4]

9 https://news.mit.edu/2021/chinas-transition-electric-vehicles-0429

It is essential for EPA to utilize life cycle analysis to create a “level playing field” which encourages speedy adoption of HEVs, PHEVs, FFVs, and other technologies (in addition to BEVs) to achieve the most rapid, affordable, robust, and practical GHG emissions reductions in a wide range of vehicle segments, while satisfying diverse customer needs and preferences. Europe is already making progress towards regulation based on life cycle analysis. 10 11 [EPA-HQ-OAR-2022-0829-0643, p. 4]

[See original comment for Table 3.15: Survival Rates for Cars and Light Trucks by Vehicle Age] [EPA-HQ-OAR-2022-0829-0581, pp. 4-5]

Based on this data, 16% of passenger cars and 32% of light-duty trucks remain on the road for more than 20 years. If new electric vehicles are more expensive or less attractive to consumers, older liquid-fueled vehicles will remain on the road even longer. [EPA-HQ-OAR-2022-0829-0581, pp. 4-5]

The proposal basically assumes that BEVs will be the dominant technology for future emissions reductions. But relying on a single technology is a risky strategy; many factors could interfere such as the supply and/or cost of critical minerals, lack of BEV recharging infrastructure, slow ramp-up of wind and solar power, poor customer acceptance of BEVs in some market segments, among others. EPA estimates that 67% of U.S. vehicles sales will be BEVs in 2032, but other projections are lower and the U.S. lags behind other countries that are not expected to reach similar levels of sales as predicted by EPA.26 EPA should not base mandatory emissions standards on unrealistic predictions of BEV sales. [EPA-HQ-OAR-2022-0829-0581, p. 12]

26 See, e.g., Nancy W. Stauffer, China's transition to electric vehicles: By 2030, 40 percent of vehicles sold in China will be electric; MIT research finds that despite benefits, the cost to consumers and to society will be substantial, MIT News, Apr. 29, 2021, https://news.mit.edu/2021/chinas-transition-electric-vehicles-0429.

Organization: National Parks Conservation Association (NPCA)

The historic passage of the Bipartisan Infrastructure Law and Inflation Reduction Act underscores the immense public investment now available for ZEVs and associated infrastructure. This public support is being further met with significant private investment from manufacturers and associated entities, while interest in EVs and ZEVs at the individual consumer level is expanding year after year. For instance, more than a quarter million battery-electric vehicles were sold in the first quarter of 2023 alone — a nearly 45% increase over the same period last year.17 Unlike past EPA efforts that may have relied on expected future improvements in technologies, EVs and ZEVs are here now and are growing as a share of the LDV and MDV market. While ZEV technology will continue to improve and evolve, a rapid transition to ZEVs is already the clear option when it comes to the on-road vehicle technology that achieves the greatest degree of emission reductions. [EPA-HQ-OAR-2022-0829-0607, p. 4]

Organization: Porsche Cars North America (PCNA)

As EPA notes in the NPRM, even with increasing sales of electric vehicles, there will be a portion of new vehicle sales that will continue to be combustion albeit at decreasing rates. Porsche believes it is important to recognize that these future combustion vehicles will include fully phased-in Tier-3 and LEV-III program requirements. As such, these vehicles will be certified to emissions levels and fleet averages that both EPA and CARB have projected to deliver significant, meaningful reductions in pollutants from new light-duty vehicles. Across the industry, fully phased-in Tier-3 and LEV- III fleets will reflect fleet average performance equivalent to Super Ultra Low Emissions Vehicle performance, commonly referred to as SULEV. Many of these new vehicle sales will replace older, higher emitting models often characterized as "gross emitters". Porsche recognizes that both LEV-IV and Tier-4 have sought to identify opportunities for further, incremental improvements in emissions control. Some of these proposals are projected by CARB and EPA to be achievable through changes in emissions control algorithms (i.e., software or calibration strategies), while others may need to rely on new emissions control hardware or other physical changes to emissions control systems. Porsche recommends that EPA carefully consider the extent to which these potential incremental gains beyond the foundational benefits of Tier-3 may consume engineering resources and drive increased costs considering the industry's general shift towards electrification. Porsche offers these comments to help inform a balanced outcome that identifies cost-effective improvements in emissions performance that will allow manufacturers to focus resources on the expansion of zero- emission electrification. [EPA-HQ-OAR-2022-0829-0637, p. 8]

Organization: Renewable Fuels Association (RFA)

IX. EPA's Proposed Rule Ignores Marketplace Realities and Underestimates Barriers to the Adoption of Battery Electric Vehicles

The challenges associated with electrifying the light- and medium-duty fleet are significant. The speed at which the Agency appears to anticipate the market and consumers will transition to electric vehicles is divorced from our assessment of reality. The proposed rule does not appear to appreciate the market obstacles associated with such a massive transition in vehicle technology, energy infrastructure, or consumer behavior. Several of the most pressing challenges are further discussed below. [EPA-HQ-OAR-2022-0829-0602, pp. 14-15]

a. Slow turnover of the vehicle fleet

Sales of new vehicles displace a small fraction of the existing vehicle fleet each year. EPA estimates that 67% of new vehicles sales will be battery electric in 2032, but clearly large numbers of new ICE vehicles that use liquid fuels will continue to be produced for many years, and those vehicles will remain on the road for many additional years. According to data from Oak Ridge National Lab, 16% of passenger cars and 32% of light- duty trucks remain on the road for more than 20 years.31 The Oak Ridge data also show that the average age of vehicles on the road is approximately 15 years. If new EVs are more expensive or less attractive to consumers, older liquid-fueled vehicles will remain on the road even longer. [EPA-HQ-OAR-2022-0829-0602, pp. 14-15]

31 Davis and Boundy, "Transportation Energy Data Book: Edition 40", Oak Ridge National Laboratory report ORNL/TM-2022/2376, February 2022; https://tedb.ornl.gov/wp-content/uploads/2022/03/TEDB_Ed_40.pdf.

Low-carbon liquid fuels in existing vehicles can achieve GHG reductions faster than new electric vehicles can displace the existing fleet. As shown in the figure below from a recent Fuels Institute report, a relatively simple change such as replacing E10 (10% ethanol) with E15 (15% ethanol) can offer greater GHG reductions than the phase-in of battery electric vehicles, because it can immediately affect a large fleet of vehicles that are already in use.32 [EPA-HQ-OAR-2022-0829-0602, pp. 14-15]

32 Fuels Institute. “Decarbonizing Combustion Vehicles: A Portfolio Approach to GHG Reductions.” June 2023.

[See original comment for Figure 21: Light- and Medum Duty Vehicle GHG Emissions Reduction Scenario (2022-2032)] [EPA-HQ-OAR-2022-0829-0602, pp. 14-15]

Organization: Senator Shelley Moore Capito et al.

The situation for infrastructure to support charging of light- and medium-duty vehicles is only slightly better, with your Agency touting the availability of 130,000 public chargers in its press release announcing its proposals.6 Setting aside their significant reliability issues and lack of broad geographical availability, even a rapid expansion of the number of operational chargers is unlikely to meet the demand for the electrification of two-thirds of the new vehicle fleet by 2032. For reference, 2022 was the worst year for US car sales in a decade with 13.7 to 13.9 million new vehicles sold due to inflation, economic uncertainty, and supply chain disruptions.7 Two--thirds of that depressed sales figure would still represent more than 9 million new vehicles per year being added to the cumulative demand on public charging infrastructure by 2032. [EPA-HQ-OAR-2022-0829-5083, pp. 2-3]

7 Wayland, Michael. Automakers are cautiously optimistic for a 2023 rebound after worst new vehicles sales in more than a decade, CNBC (Jan. 6, 2023).

In addition to pushing larger, heavier, and more expensive BEV s, domestic automakers are losing money on this transition and are passing costs on to consumers in the form of higher prices for both internal combustion engine (ICE) vehicles and BEVs.9 Ford's electric vehicle business unit is on track to lose $3 billion this year.10 GM announced it will lose money on BEVs until 2025.11 And the Chevy Bolt, cited by multiple members of the Bi den Administration as an affordable alternative is being discontinued in favor of higher-priced electric SUVs and trucks.12 Unless economies of scale and a significant reduction in the cost of presently foreign-sourced input commodities for BEV production reduce costs - the likelihood for both of which remain highly uncertain - ICE vehicle buyers will continue to subsidize purchasers of BEV s directly through taxpayer subsidies and paying fuel excise taxes into the Highway Trust Fund, as well as indirectly through increased sales prices. [EPA-HQ-OAR-2022-0829-5083, p. 4]

Organization: Steven G. Bradbury

EPA fails to consider the negative societal consequences and second-order cost effects of its proposals.

In putting forward regulatory proposals designed to force upon the American people a vast and rapid industrial transformation, EPA has an obligation to go further than just considering the direct cost effects of its proposals (which are themselves woefully under- estimated, as highlighted above); it must also consider the broader indirect economic con- sequences and negative societal costs that would follow if these rules are finalized as pro- posed. So far in these rulemakings, the Agency has either ignored or deliberately down- played these second-order effects. [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

Some of the most consequential burdens and negative ramifications of the proposed rules that EPA hides, disregards, or minimizes include the following: [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

• Increasing the purchase price of all new vehicles. Notwithstanding EPA’s gaming of the numbers, the true costs of the industrial transformation forced by the EPA’s proposed rules will be spread across the automakers’ fleets, resulting in a significant increase in the prices of all new vehicles, with greater price increases concentrated on those vehicles for which the demand is highest relative to supply. All Americans will be harmed by these price increases, but the biggest losers will be lower-income Americans who cannot afford to buy an EV or to pay more for a gas-powered vehicle at the dealership, as well as those who live in rural areas and need to drive longer distances and for whom EVs are impractical. [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

• Destroying jobs in the U.S. auto industry. The loss of popular new vehicle options and the significant price increases at the dealership will mean that fewer new vehicles will be purchased—almost certainly far fewer than EPA is predicting. This drop-off in demand will challenge the profitability of the auto industry and lead to a loss of jobs for tens of thousands of America's autoworkers, as well as a loss of jobs in the many U.S. companies that supply inputs for the production of auto- mobiles and heavy trucks.40 The United Auto Workers union has warned of the potential for job losses from the transition to EVs,41 as automakers announce more plant closures and layoffs due to the costs of electrification.42 [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

40 See Technality, "Ford Just Proved How Far Ahead Tesla Really Is: Profitability May Continue to Be a Struggle for All Legacy Automakers," May 10, 2023, https://medium.com/tech-topics/ford-just-proved-how-far-ahead-tesla-really-is-6a4d95cff519 ("Despite wanting to be a fully-electric brand by 2035, as of Q4 2022, Ford's average net margin on the Mustang Mach-E was -40.4%. Unfortunately, that's a figure that's only gotten worse since, to the point where Ford is now losing an average of $58,000 for every EV sold.").

41 See Press statement, United Auto Workers, "UAW Statement on Job Cuts at Stellantis," April 26, 2023, https://uaw.org/uaw-statement-job-cuts-stellantis.

42 See Michael Wayland, "Stellantis to indefinitely idle Jeep plant, lay off workers to cut costs for EVs," CNBC.com, December 9, 2022, https://www.cnbc.com/2022/12/09/stellantis-to-idle-jeep-plant-lay-off-workers-to-cut-costs-for-evs.html.

• Causing more deaths and serious injuries on America's highways. As new vehicle models become unaffordable or unappealing, many American families will be left driving older and older used cars, and the age of the nation's auto fleet will rise dramatically. Already, the average age of a car on the road in the United States is approaching 13 years, and many cars are on their fifth or sixth owners. The aging of the American fleet has very negative safety consequences, as NHTSA statistics show that older vehicles are much less safe than newer models in an accident.43 [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

Organization: Tesla, Inc.

Since the release of the proposed rule, figures indicate that in Q1 2023 the U.S. recorded the highest BEV sales increase (64%) ever.80 Continuing this rapid growth has led to estimates that by 2024 every third commercially newly registered car could be an electric vehicle.81 This increase is consistent with other projects of rapid BEV sales growth. Some analysts predict that by 2026 60% of new models will be BEVs and PHEVs.82 Others suggest recent forecasts, like those of IEA, still significantly underestimate the pace of electrification.83 Still other analysts project that BEVs could account for 90% of sales by 2027.84 [EPA-HQ-OAR-2022-0829-0792, p. 12]

84 Ark Invest, Sales of Gas-Powered Vehicles Could Collapse 85% In the Next Five Years (Nov. 21, 2022) available at h ttps://ark-invest.com/newsletters/issue-343/

Fourth, the agency has not included projected U.S. sales volumes, and ramp of such sales, from a number of emerging BEV-only manufacturers, including Rivian, Lucid, VinFast. Nio, and Fisker. Estimates of the combined U.S. sales from these BEV manufacturers range from almost 234,000 vehicles in 2026 to just under 340,000 in 2032. See Figure 6. Projected North American BEV-Only OEM Sales (Non-Tesla). Combined with the aforementioned severe under projections of Tesla sales, this oversight further results in the agency significantly underestimating the projected volume of BEV sales, under calculating the potential buildup of the overall credit bank available for compliance and, when correctly considered, leads to supporting increasing the stringency of the proposal. [EPA-HQ-OAR-2022-0829-0792, p. 19]

SEE ORIGINAL COMMENT FOR Figure 6. Projected North American BEV-Only OEM Sales (Non-Tesla) [EPA-HQ-OAR-2022-0829-0792, p. 19]

Organization: The Heritage Foundation (Kevin Dayaratna and Diana Furchtgott-Roth)

Light duty sales are overestimated

The study assumes that the proposed rule will decrease light duty vehicle sales by no more than 0.35% in any year (2027), and in some years may actually increase sales (2029 and 2029). (See Table 171.) These results are inconsistent with standard economics: [EPA-HQ-OAR-2022-0829-0674, pp. 13-14]

- As noted above, the rule will increase ownership costs of vehicles, resulting in fewer car purchases;

- Current EV prices, even with tax credits, are substantially above comparable gasoline-powered vehicle or hybrid vehicle prices.

- By definition, regulations reduce consumer choices, leading to less consumer activity.

- If the proposed rule were not a binding constraint on consumer choices, consumers would be purchasing the same vehicles without the rule. The Administration wants the rule to change consumer behavior, not to reinforce it.

For these and other reasons, the number of vehicles purchased under the rule will be substantially less than without the rule. [EPA-HQ-OAR-2022-0829-0674, pp. 13-14]

Organization: Transport Evolved LLC (Transportation Consultancy)

We would add:

1) Transport Evolved also favors a move away from allowing transfer of credits both from year-to-year and from automaker-to-automaker. This allows some automakers to benefit from the hard work of others, and also reduces the incentive for individual automakers to develop their own clean vehicle platforms. While some argue that it incentivises automakers to build and sell EVs, in many other markets the vast majority of automakers (including Stellantis, Ford, GM, and Honda) have fully electric offerings which are not offered for sale in the US. The choice of those automakers not to equip those vehicles for sale here should not be rewarded. [EPA-HQ-OAR-2022-0829-0453, p. 1]

2) Some vehicles (for example, the GMC Hummer EV), use substantial resources that could be used for electrifying multiple smaller vehicles and, at the same time, require substantially more energy to produce and to travel the same distance as a smaller, more efficient vehicle. As such, we would also support moves to more substantially reduce or remove the benefit within the calculation (the "medium duty multiplier") for automakers for building larger, heavier, less efficient vehicles where those vehicles are expected to substitute for a light duty passenger vehicle. [EPA-HQ-OAR-2022-0829-0453, p. 1]

Organization: U.S. Chamber of Commerce

- Vehicles sold today are on average 30% more fuel efficient than vehicles sold in 2004, helping to drive a 6% reduction in transportation sector CO2 emissions even as overall vehicle miles traveled have increased by about 10%. [EPA-HQ-OAR-2022-0829-0604, p. 1]

- Nitrogen oxide (NOx) emissions from model year 2025 vehicles will be 57% lower than vehicles sold in 2004, and 95% lower than those sold in 1994—a major contributor to the more than 20% reduction in ozone levels during that time period.

- More than 90 models of vehicles currently achieve over 40 miles per gallon in fuel efficiency.

- Availability of electric vehicle options has increased dramatically, with 150 different models expected to be available within the next few years

- Automakers have announced plans to invest at least $110 billion in domestic EV manufacturing and battery production by the end of the decade. [EPA-HQ-OAR-2022-0829-0604, p. 1]

Organization: Valero Energy Corporation

a) EPA does not adequately characterize vehicle purchase costs.

ZEVs are more expensive on average than their ICE vehicle counterparts and unaffordable for many households—in the first calendar quarter of 2023, the average price of top-selling light-duty BEV in the U.S. was about $15,000 more than the average price of top- selling ICE vehicles.161 [EPA-HQ-OAR-2022-0829-0707, pp. 33-35]

161 S&P Global, "Tracking battery-electric vehicle prices – 2023 update" at 9 (May 2023).

According to S&P Global, the ten-top selling light-vehicle models in the U.S. market during Q1 2023 were as follows162: [EPA-HQ-OAR-2022-0829-0707, pp. 33-35]

162 S&P Global, "Tracking battery-electric vehicle prices – 2023 update" at 9 (May 2023). Organization: Wisconsin Automobile and Truck Dealers Association

The EPA has lost sight of the multi-track plan to reduce multi-pollutant emissions. Substantial reductions can be accomplished through the continued development of internal combustion engines (ICE), the increased use of hybrid vehicles, plug-in hybrids, plug-in battery, hydrogen fuel cells, as well as new or immerging technologies. A genuine concern arises from consumers getting priced out of the new vehicle market. Dealers are already being notified by automobile manufacturers that products will be limited in states. CARB (California Air Resources Board) states are being notified they will receive fewer ICE vehicles and non-CARB states will receive a limited amount of EVs (electric vehicles). To further compound the problem, automobile manufacturers are going to have to reassign resources to build the number of EVs required in CARB states. That will create fewer ICE vehicles to be distributed throughout the remaining states. When demand is high and inventory is limited, prices increase. The ICE vehicles will quickly escalate to the level of current EV prices. A substantial price increase, coupled with higher interest rates will slow any transformation of consumers to cleaner vehicles. In turn, this will create a strong market for previously owned vehicles containing dated technology and higher levels of pollutants being emitted . [EPA-HQ-OAR-2022-0829-0494, p. 1]

EPA Summary and Response

Summary:

Commenters including the Alliance for Automotive Innovation (Alliance) and Renewable Fuels Association (RFA) stated that the projected EV market share is too high. RFA stated that the projections of BEV penetrations do not account for market obstacles to the transition. Commenters, including the Arizona State Legislature, stated that the projections of costs in the rule are too high, and erroneously rely on federal tax credits. Minnesota Corn Growers Association (MCGA) commented that the BEV projections in the rule are based on very few real world data points. National Corn Growers Association (NCGA), National Farmers Union (NFU), and North Dakota Farmers Union (NDFU) commented that mandatory emissions standards should not be based on unrealistic BEV sales predictions. They stated that relying on a single technology for future emissions reductions is risky because that technology could be influenced by many factors.

The Alliance for Consumers (AFC) stated that EPA failed to consider how ICE vehicle profits and EV losses interplay in the sale of EVs, and that EPA failed to address the effects of removing or replacing ICE vehicles with EVs on the ability of automakers to price EVs at current, what they perceive as, money-losing levels.

Some comments were focused on automaker announcements. AmFree, API and others stated that automaker announcements cannot be used to support the justification for the rule, and they cannot be counted on. Some commenters stated that manufacturers may revise their plans or fail to meet targets, and others stated that these statements rely on federal regulations, so relying on them in proposing the rule is circular. Others, like EDF and ICCT, commented on the fact that we missed some automaker announcements in our proposal, outlining additional announcements surrounding the planned production and sale of electric vehicles over the next five to ten years, or more. EDF also commented that market developments and manufacturer plans support the feasibility of the rule. ICCT and other commented that the IRA will result in increased EV sales across all vehicle types, as well as bolster EV manufacturing, battery production and industrial development.

AmFree, API and others commented that EPA does not indicate whether there will be additional EV offerings in affordable segments by the time the rule becomes effective, continuing on to state they doubt there will be affordable offerings. API stated that the ZEV projections in the proposal will be challenging even given investments supported by the IRA and BIL, giving examples of barriers to uptake. API stated that AEO projections are well below EPA's estimates in the proposal, and commented that EPA must explain why they are so different. On the other hand, commenters including California Attorney General's Office stated that ZEV tech is already in wide use, and that penetration in increasing quickly. CEVA commented that though availability and diversity of commercial ZEVs has improved, there are still barriers to a diverse supply of cost competitive ZEVs. CEVA also commented that strong standards are necessary and manufactures and fleet operators rely on technology driving federal regulations to help close the supply-demand gap for ZEV commercial vehicles.

American Fuel & Petrochemical Manufacturers (AFPM) commented that it is uncertain that the critical minerals needed to support the batteries for the EVs projected by this rule will be available. The also stated that they are uncertain the electric grid will be able to support the charging needs created by this rule.

AFPM commented that the timeline for this rule is unachievable and relies on a general characterization of the number of models currently available on the free market, as opposed actual number of vehicles sold, supplemented by the BIL and IRA incentives. AFPM is uncertain the consumers will purchase EVs at the rate assumed in the analysis for the proposal. They stated that the future availability of ZEVs will not be sufficient to meet ZEV adoption requirements proposed by EPA. AFPM also stated that auto manufacturers could not justify long term EV investment without federal regulations given tepid consumer demand. AFPM also commented that there is not enough charging, uncertain utility and grid capacity, and not enough domestic or allied supply of battery critical minerals.

API commented that EPA should account for EVs being less reliable than ICE vehicles due to software reliability issues, and that increasing the efficiency of ICE vehicles is promising and cost-effective.

Some commenters, including a collection of state offices and departments in Colorado (Colorado) and the Electrification Coalition (EC), commented in support of a strong, robust rule. Colorado stated that strong standards are important to progress air pollution and equity improvements. EC stated that the standards will lead to economies of scale in electrical vehicle production, which will lead to more affordable EVs and support access and benefits for disproportionality impacted communities.EC stated that the strongest possible standards will significantly limit GHG emissions and accelerate the adoption of electric vehicles. A collection of Environmental. and Public Health Organizations (EPHO) recommended EPA adopt a modified version of Alternative 1.

The Energy Strategy Coalition (ESC) commented that, given incentives and regulatory dynamics, public market projections are in line with EPA projections of BEV penetration. EPHO commented that sources that model ZEV outlook including the impact of the IRA in the baseline are most relevant to EPA projections. They also stated that there are additional studies EPA could cite that have become available since the publication of the proposal.

EPHO commented that EPA's mandate to protect public health and welfare is more urgent than ever due to climate change and stated that ZEVs are feasible and cost-reasonable, BEV and PHEV technology is improving, and PEV adoption is driven by strong consumer demand and greater model choice. They commented that the growing consumer demand for ZEVs is demonstrated by automaker commitments. EPHO also commented that there are numerous emission control technology options for ICE vehicles as well, which have potential for greater application within the fleet. EPHO noted that the flexibility of the program and the fact that EPA did not include PHEVs or improvements to ICE vehicles could lead to lower BEV projections that EPA estimated. Wisconsin Automobile and Truck Dealers Association commented that substantial emissions reductions are achievable through the application of ICE technology, hybrids, hydrogen fuel cells as well as new or emerging technology.

Some commenters focused on the availability of infrastructure, the electric grid, and the vehicle supply chain. EPHO commented that all three of these industries will be able to accommodate the projected level of BEVs, and a strong regulatory signal will only make them better. Senator Shelley Moore Capito et al. (Senator Capito) commented that it is unlikely there will be chargers to meet the demand for electrification.

EPHO commented that EPA should include ACC II in the baseline, since CARB has submitted the waiver request. They go on to state that more stringent standards than proposed are feasible and justified even without ACC II in the baseline. EPHO commented that EPA did include a sensitivity with ACC II in the baseline, though they noted that the sensitivity did not seem to include all the states who have adopted or intend to adopt ACC II by the time of the final regulation. EDF commented that even though AEO 2023 estimated low and unrealistic ZEV sales, their estimates show that robust nationwide ZEV adoption will result due to current state actions, namely those in ACC II and the section 177 states. GFI commented that the No Action baseline may be conservative because EPA did not incorporate manufacturer announcement or ACC II. They also stated that, regardless of EPA regulations, a steep growth in EV adoption is expected over the next several years because the U.S. has reached a tipping point in the EV adoption S curve. ICCT also commented that ACC II will lead to increased EV sales, focusing on California and the other states that will adopt the regulation. National Parks Conservation Association (NPCA) commented that electric vehicles are growing as a share of the LD and MD markets, and that a rapid transition to ZEVs is the clear option to achieve emission reductions.

Tesla commented that EPA did not include any newer BEV only manufacturers in sales projections, which led to a significant underestimation of projected BEV sales.

The Institute for Policy Integrity at New York University Law School (IPI) commented that EPA should give more explanation of scrappage, cost pass-through, and sales effects. They stated that the treatment of scrappage in OMEGA is reasonable, but there is no discussion in the proposal on scrappage, and that EPA should attempt to model scrappage in future standards. IPI stated that EPA should clarify how producers expect consumers to value fuel costs, explaining why consumers factor in fuel costs for 12,000 annually over 2.5 years while producer side modeling uses an annual VMT factor of 15,000 miles.

The UAW commented that the proposal must support continued production and sales of ICE vehicles. They stated that domestic automakers rely on the sale of ICE vehicles to fund investments in the transition to electrification since EVs are not profitable. Senator Capito commented that domestic automakers are passing higher costs on to consumers and that ICE vehicles buyers will continue to subsidize purchasers of BEVs through taxpayer subsidies and fuel taxes into the Highway Trust Fund, and through increased sale prices. Steven Bradbury commented that EPA fails to account for the increased purchase price of all new vehicles, which is especially harmful to lower income Americans who can’t afford the higher prices. Valero commented that ZEVs are more expensive than ICE vehicles and are unaffordable for many households.

John Graham commented that the proposal ignores improvements in mild hybrids, which are rapidly gaining market share in Europe. They stated that European trends indicate that hybrids are a cost effective solution.

Commenters in a mass comment campaign states that the pace of the transition is too fast for the economy and infrastructure to handle, and that forcing the transition before resources and infrastructure are ready is concerning. The commenters also stated that focusing on electric vehicles could lead to fewer emission reductions by not focusing on encouraging lower carbon fuels. They stated that the EPA should balance emissions reductions goals while addressing serious questions about infrastructure readiness and the impact of the rule on Americans.

MCGA, NFU, and NDFU commented that liquid fuel burning vehicles will continue to be sold for many years, and that more expensive EVs will lead to ICE vehicles staying on the road longer. RFA stated that low carbon fuels can achieve GHG reductions faster than new EVs can displace the existing fleet.

NCGA stated that EPA should use life cycle analysis in the determining this rule.

Porsche commented it is important to recognize that combustion based vehicles will include fully phased in Tier-3 and LEV-III program requirements, and that EPA should carefully consider potential incremental gains beyond Tier-3 that may consume engineering resources and drive increased costs considering the shift towards electrification.

Steven Bradbury commented that EPA does not account for the loss of jobs that will result due to reduced vehicle demand, and that EPA does not account for the safety issues that will arise due to older, less safe vehicles staying on the road longer.

The Heritage Foundation commented that the sales impacts estimates in the proposal are inconsistent with standard economics. They stated that increased ownership costs of vehicles will lead to lower sales, EV costs will be much higher than ICE vehicles, and that the regulation will reduce consumer choice. They also state that the administration wants to change consumer behavior because if the rule were not a binding constraint consumers would purchase the same vehicles without the rule. Wisconsin Automobile and Truck Dealers Association commented that there will be fewer ICE vehicles available due to this proposal, which will lead to higher prices and slow the transition to cleaner vehicles. They also commented that this will lead to increased demand for used vehicles.

Transport Evolved commented in support of moving away from credit banking and trading, as it allows some manufacturers to benefit from the hard work of other manufacturers. They also commented in support of removing the MD multiplier because it benefits manufacturers that produce larger, heavier, less efficient vehicles over smaller, more efficient vehicles.

<u>Response:</u>

Regarding comments that sales impact estimates in the proposal are inconsistent with standard economics, we do not agree. The estimates of sales impacts for this rule are based on both producer and consumer decisions, and include the impact of estimated vehicle prices. RTC Chapter 12.1 discusses producer and consumer side modeling for this rule. RIA Chapter 4.4.1

discusses how sales impacts were modeled in OMEGA using an elasticity of demand for new vehicles. The results discussed in RIA Chapter 4.4.2 estimate that there will be slightly fewer new vehicles sold due to the final rule.

We agree that the availability of electric vehicles in the market has been growing, both in the number of and models available for purchase. We also agree that PEVs are an important options for manufacturers to consider on the pathway to achieving significant emissions reductions from the light- and medium-duty vehicle market, and that these emissions reductions are important to public health and welfare. Regarding comments on the availability of electric vehicles, as well as how that may affect vehicle purchases, see Section 13 of this RTC. Regarding Tesla's comment that EPA did not include any BEV only manufacturers in determining the baseline, we note that we have updated our baseline since the proposal. Regarding comments on the baseline, or the No Action case, used in the final rule, see Section IV.B of the preamble.

Regarding comments that the rule needs to support continued production and sale of ICE vehicles, and that the availability of ZEVs in the future will not be enough to meet EPA requirements and that emissions reductions are achievable through technology other than ZEVs, we note that this rule is not a ZEV mandate and manufacturers are free to meet the standards using the mix of vehicle technologies that is best for their fleets. The main analysis for this rule assumes one possible pathway to compliance, though, as discussed in preamble IV.F and G, there are many possible pathways to compliance that utilize many different vehicle technologies, including ICE, hybrids, PHEVs and BEVs. Regarding comments that manufacturers could not justify investment in EVs without federal regulations, or that EVs are not profitable we note that manufacturers have been producing vehicles with varying degrees of powertrain electrification, including ranging from mild hybrids to full battery electric, for many years before this rule. For a discussion of consumer demand of electric vehicles, see RTC Section 13. Also, as mentioned above and discussed in RIA Chapter 2.6.4, the analysis for this rule allows for cross-subsidization as part of the producer decision making process, ensuring that producers are able to influence the pricing structure of the vehicles they produce in order to meet the standards in the manner they choose. In addition, we note that the social cost analysis for this rule accounts for costs exclusive of transfers (like fuel taxes), and shows that there are significant social benefits expected from this rule.

Regarding comments on scrappage and cost pass-through, see RTC Section 12.1. Scrappage is also discussed in RIA Chapter 4.4.2. Also, we note that we have always assumed full cost pass-through in LD vehicle regulations in our estimates of consumer impacts. Assuming otherwise might suggest lower consumer costs, therefore this assumption provides us with a conservative estimate. Regarding comments on using a different VMT for producer and consumer side fuel cost assumptions, we note that we have updated our analysis to align the assumption for producers and consumers to both assume 15,000 annual miles in fuel savings estimates. Regarding comments from IPI that we should model scrappage in future regulations, and support further research on pass-through, we note that these are topics EPA will continue to refine for possible future regulations. For more information on topics in the comment provided by IPI, refer to responses in Sections 13.2 and 13.3 of this RTC.

Regarding comments on automaker announcements surrounding electrified vehicles, we note that we have updated our discussion of these announcement in Section IV of the preamble. In addition, as noted in Section 13 of this RTC, mentioning or citing any one study, statistic or information source should not be confused with relying on that information to justify the rule. This information may be supporting information for our analysis, need for this rule, or background information. For information on the justification of this rule, see Sections III and V of the preamble. For information on the IRA and other federal actions discussed in this regulation, see Section I.A of the preamble. Regarding comments from EPHO and others on the effects of ACC II, as discussed in RTC Section 12.1.3, at the time of this final rulemaking EPA has not yet granted a waiver to California for the ACC II program, and the agency believes it would be inappropriate to prejudge the outcome of the waiver request process for program that is still under consideration by the Administrator.

Regarding comments that the timeline for this rule is unachievable, we note that the final standards for both GHGs and criteria pollutants are phased in over time. For information on the phase-ins for this final rule, see Sections III.C and D of the preamble.

Regarding comments on PEV adoption rates, projections of ZEVs in our rule, and the market share of vehicle technologies projected in the analysis for this rule, see responses in RTC Section 13 and RTC Section 12.5.3.

Comments regarding costs are addressed in RTC Sections 8 and 12.

Regarding comments on the ZEV outlook sources EPA cited in the proposal, as well as sources that EPA did not cite, see the updated discussion in RIA Chapter 4.1.

Regarding comments that EPA failed to address automaker abilities to cross-subsidize, we disagree. OMEGA incorporates cross-subsidization into producer decisions. This is discussed in RIA Chapter 2.6.4.

Regarding comments from API that EPA must explain the difference between AEO projections and EPA estimates, see RIA Chapter 8.1, which describes how we use AEO 2023 in our OMEGA analysis. In addition, RIA Chapter 8.2 discusses consistency of OMEGA results with AEO projections.

Regarding comments from API and others on advantages or disadvantages of PEVs over ICE vehicles, including conjectures that EVs are less reliable, see Section 13.2 of the RTC.

The availability of affordable vehicles is also discussed in Section 13 of the RTC. Section 13.4 of the RTC contains a discussion of the cost competitiveness of ZEVs.

Regarding comments on the availability of critical minerals, see Section 15 of this document.

Regarding comments on charging availability, see RTC Section 17.

Regarding comments on the electric grid, see RTC Section 18.

Regarding comments about lower carbon fuels, see RTC Section 19.1.

Regarding comments on the LEV-III and Tier-3 programs, see RTC Section 4.1.

Regarding comments on the adoption of the proposed, or stronger, standards, see Section 1.1 of the RTC.

Regarding comments about employment effects of this rule, see RTC Section 20.

Regarding comments on safety impacts of this proposal, see RTC Section 22.

Regarding comments life cycle analysis, see responses in RTC Section 19.2.

Regarding comments that this rule will lead to reduced fleet turnover and fuel burning vehicles staying on the road longer, we refer to Section 12.1.3 of the RTC.

Regarding comments on banking and trading and comments on the MD multiplier, see RTC Section 3.1.

14.1 - Limited vehicle choice

Comments by Organizations

Organization: Alliance for Consumers (AFC)

Alliance for Consumers, by way of its Executive Director, O.H. Skinner, files this comment to highlight the ways in which the proposed rule fails to serve the interests of everyday consumers and how EPA's proposal is procedurally and substantively deficient and should not be finalized. [EPA-HQ-OAR-2022-0829-0534, pp. 1-2]

The current EPA proposal is best understood as yet another attempt to weaponize the agency rulemaking process, and the power of the federal government, to wipe away things that everyday consumers overwhelmingly like, use, and rely upon for life's essential needs. [EPA-HQ-OAR-2022-0829-0534, pp. 1-2]

EPA is proposing to replace a majority of the cars on the market today with EVs that are currently unpopular with everyday consumers in most parts of the country and do not work within the household budgets of those who need cars to help their families thrive. And that is before considering how EPA's proposed rule is premised on speculative, wholesale changes to other parts of the economy and our national infrastructure outside the purview of EPA (e.g., the energy grid). [EPA-HQ-OAR-2022-0829-0534, pp. 1-2]

Make no mistake, this is a proposal to forcibly remove from the market a majority of the cars that everyday consumers currently buy and use. The EPA Fact Sheet for the proposal focuses throughout on electric vehicle technology as the critical aspect of the proposed rule, from how it was conceived, through how it would be complied with. See, e.g., EPA Fact Sheet, "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles," Apr. 2023, at 1 (highlighting EV technologies and support for a "rapid shift away from" "internal combustion engine (ICE) technologies"); id. at 2 (focusing on "vehicle electrification technologies" as central to proposed standards); id. at 6 (emphasizing electric vehicle costs and benefits throughout cost-benefit analysis section).1 [EPA-HQ-OAR-2022-0829-0534, pp. 1-2]

1 Fact Sheet available at https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P1017626.pdf.

And then there is the failure by EPA to consider adequately that certain automakers may be forced to limit the sale of ICE vehicles in order to meet the proposed requirements, limiting the availability of cars nationwide, driving up prices, and limiting options for consumers, especially those with families. This consequence is currently playing out with at least one automaker in response to California-led EV mandates. See Patrick George, Stellantis Is Restricting Gas-Only Car Sales In 14 U.S. States Including California And New York, TheAutopian, June 16, 2023; see also Attached Exhibits, infra. Given the stringency of the proposal, and the limited consumer appetite for expensive EVs with limited use-cases for many families (especially larger families), it is a possible aspect of the problem that automakers will be forced to limit the sale of larger, ICE vehicles to something well below the levels that would otherwise be supported by consumer demand in order to meet the requirements EPA is currently considering. Yet EPA did not adequately consider or address this reality, despite it being one that would have dramatic negative consequences for everyday consumers. [EPA-HQ-OAR-2022-0829-0534, pp. 4-5]

Organization: American Highway Users Alliance

We are skeptical that the GHG and criteria reductions estimated by EPA can be realized in the proposed rule's timeframe. [EPA-HQ-OAR-2022-0829-0696, pp. 4-5]

We noted above the substantially greater cost of EVs. With such a cost differential (even if the differential is reduced somewhat in coming years), many consumers and businesses can be expected to keep and maintain existing vehicles (average age just over 12 years) rather than pay for new, much more expensive electric vehicles. [EPA-HQ-OAR-2022-0829-0696, pp. 4-5]

Additionally, the cost of the vehicle itself is not the only consideration for a consumer in making a purchasing decision. Many businesses and hard-working families will not purchase a vehicle unless both the vehicle and fuel are cost effective and meet their needs. At this point the availability of charging stations, while increasing, seems unlikely to approach the current ubiquitous availability of fuel at gas stations within the time frame of the rule. That could result from various electricity supply and transmission issues, including the time delay and cost involved in building out more connections between the grid and charging stations.4 [EPA-HQ-OAR-2022-0829-0696, pp. 4-5]

4 A statement submitted to EPA in conjunction with EPA's May 3 hearing in the heavy-duty vehicle Phase 3 docket by ABF Freight System, a major trucking company with over 4,500 Class 8 and Class 6 vehicles, noted a wait of 2 years and counting for added utility infrastructure at a facility to support the company's current EV trucks (only 6) and anticipated EV truck purchases.

For such reasons the benefits of the proposed rule as estimated by EPA appear to be overstated, as the vehicle fleet will not turn over to EVs as quickly as EPA estimated. Further, the proposed rule will limit consumer choice and the mobility of the American public. [EPA-HQ-OAR-2022-0829-0696, pp. 4-5]

Organization: Delek US Holdings, Inc.

EPA's Proposed Rule is based on the flawed notion that vague corporate goals are sufficient to prop up the incredulously stringent standards. EPA relies, in part, on the "proliferation of announcements by automakers" to achieve increased electrification rates between 2030 and 2040," but these broad and general statements are just that - goals.5 In reality, the U.S. Department of Energy forecasts ICE-power cars will continue to dominate U.S. sales through 2050.6 And LD fleets take approximately two decades to turn over completely.7 Indeed, analysts estimate that even with ZEVs making up 25% of new sales by 2035, only 13% of vehicles on the road would be electric.8 Thus the transition to ZEVs will be, and must be, gradual—regardless of regulatory mandates— and much more gradual than EPA's anticipated growth from 4.4% to upwards of 67% in a mere nine years. EPA's proposed standards must better account for these real market conditions and, at the very least, propose more feasible and realistic emissions standards reflective of actual, practicable ZEV adoption rates. [EPA-HQ-OAR-2022-0829-0527, p. 3]

5 Proposed Rule at 29,19–92.

6 Notably, the U.S. Energy Information Administration ("EIA") predicts that the global light-duty electric vehicle fleet will grow to only 31% by 2050, indicating ICE vehicles will continue to dominate global sales through at least that time. EIA, "EIA projects global conventional vehicle fleet will peak in 2038" (Oct. 26, 2021), available at https://www.eia.gov/todayinenergy/detail.phpfiid=50096.

7 Brad Plumer et al., THE NEW YORK TIMES, Electric Cars Are Coming. How Long Until They Rule the Road?" (Mar. 10, 2021), available at https://www.nytimes.com/interactive/2021/03/10/climate/electric-vehicle-fleet-turnover.html; see also Virginia McConnel and Benjamin Leard, RESOURCES FOR THE FUTURE, "Progress and Potential for Electric Vehicles to Reduce Carbon Emissions" (Dec. 8, 2020), available at https://www.rff.org/publications/reports/potential-role-and-impact-evs-us-decarbonization-strategies/#:~:text=Passenger%20vehicle%20fleets%20take%20approximately,important%20in%20the%20following%20decades.

Organization: Matthew DiPaulo

My company produces motor oil for passenger car vehicles with proprietary formulations which exceed industry specifications, improve fuel economy, reduce emissions, and can be used in hybrid vehicles [EPA-HQ-OAR-2022-0829-1514, p. 1]

The premature rush to transition the U.S. vehicle fleet to EV's will reduce my sales.

The large-scale shift to electric vehicles, which would comprise two-thirds of all new-car sales in the U.S. by 2032 under this proposal, will hurt workers, small businesses, and consumers while doing little to help the environment. The proposed rule would lead to fewer vehicle choices for individuals and families, reducing the selection of vehicles that fit their household budgets and unique needs. [EPA-HQ-OAR-2022-0829-1514, p. 1]

Organization: Steven G. Bradbury

EPA fails to consider the negative societal consequences and second-order cost effects of its proposals.

In putting forward regulatory proposals designed to force upon the American people a vast and rapid industrial transformation, EPA has an obligation to go further than just considering the direct cost effects of its proposals (which are themselves woefully under- estimated, as highlighted above); it must also consider the broader indirect economic con- sequences and negative societal costs that would follow if these rules are finalized as pro- posed. So far in these rulemakings, the Agency has either ignored or deliberately down- played these second-order effects. [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

Some of the most consequential burdens and negative ramifications of the proposed rules that EPA hides, disregards, or minimizes include the following: [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

• Stifling consumer choice at the dealership. Many of the vehicle models most pop- ular with American families will no longer be sustainable under the EPA's proposed rules. Automobiles have long been America's favorite freedom machines. When the models of ICE vehicles Americans love the most disappear from dealerships, that will represent an enormous drop in consumer welfare (in basic happiness and well- being) for the average American family and for the U.S. economy as a whole. For many of these ICE vehicle models, there is no EV option likely to be available that could provide the same performance, utility, or recreational value at a comparable price (or at all). EPA makes no real effort to quantify this generational loss of consumer welfare. [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

Organization: Zero Emission Transportation Association (ZETA)

iii. Recent New EV Model Announcements

In 2022, the number of available EV models worldwide reached 500, up from below 450 in 2021 and more than doubling relative to 2018-2019.272 In particular, OEMs are expanding their SUV and pickup truck offerings in line with consumer demand. Consumer Reports has compiled a noncomprehensive list of at least 30 new EVs in a variety of makes and models that are expected in the U.S. by the end of 2024.273 In addition to new models from legacy automakers, there are a number of new entrants expected in 2024 including Fisker, Indi, Polestar, and VinFast. [EPA-HQ-OAR-2022-0829-0638, pp. 73-74]

272 Id. at footnote 27

273 "Hot, New Electric Cars That Are Coming Soon," Consumer Reports, (June 9, 2023) https://www.consumerreports.org/hybrids-evs/hot-new-electric-cars-are-coming-soon-a1000197429/

In the United States, there were fewer than 100 models available in 2022, but twice as many as before the pandemic.274 EV model availability has been growing quickly, at a compound annual growth rate of 30% over the 2016-2022 period. Such growth is to be expected in a nascent market with a large number of new entrants bringing innovative products to the market, and as incumbents diversify their portfolios. Even companies that had previously urged caution on EV commitments are shifting towards greater electrification. Toyota plans to release at least 10 EV models by 2026. It is also restructuring to create a unit solely dedicated to electric vehicles.275 [EPA-HQ-OAR-2022-0829-0638, pp. 73-74]

274 "Global EV Outlook 2023 Catching up with climate ambitions," IEA, (2023) https://iea.blob.core.windows.net/assets/dacf14d2-eabc-498a-8263-9f97fd5dc327/GEVO2023.pdf

275 Id. at footnote 261

In the future, the number of models can be expected to continue to increase quickly, as major carmakers expand their EV portfolios and new entrants strengthen their positions, particularly in emerging markets and developing economies.276 [EPA-HQ-OAR-2022-0829-0638, pp. 73-74]

EPA Summary and Response

Summary:

Commenters stated that this rule will lead to reduced vehicle choices for consumers. AFC stated that this rule is going to forcibly remove vehicles from the market that consumers like and rely on, replacing most ICE vehicles with unpopular, expensive EVs. Steven G. Bradbury commented that the proposal is designed to force a rapid industrial transformation and will lead to stifled choice at the dealership where American families will not be able to purchase a vehicle that fits their needs. Bradbury continues on to state that EPA does not attempt to quantify this loss in consumer welfare. ZETA commented that availability of EV models has grown very quickly, and is expected to continue to grow.

AFC also stated that the rule is premised on speculative changes to national infrastructure, like the energy grid. They commented that this rule fails to consider that automakers may be forced to limit ICE sales to meet requirements, which will increase prices and further limit options for consumers. The American Highway Users Alliance (AHUA) commented that higher prices will lead to reduced fleet turnover – consumers will keep used vehicles longer and that this means that the benefits of the rule are overstated. AHUA also stated that it is unlikely that EV charging will be available to a level as ubiquitous as the current fuel availability at gas stations. They also state that the rule, in addition to limiting consumer choice, will limit consumer mobility.

Delek commented that basing the rule on automaker announcements is flawed and that DOE forecasts indicate that ICE vehicles sales will continue to dominate vehicle sales far into the future, and that fleet turnover will take longer than EPA anticipates. They stated that the standards must better account for real market conditions and be reflective of actual, practicable, ZEV adoption rates.

Matthew DiPaulo commented that the shift to EVs under the proposal will hurt workers, small businesses and consumers while doing little to help the environment.

Response:

We do not agree that this rule will lead to reduced vehicle choice. This rule is not a ZEV mandate and allows manufacturers to meet the standards in the most effective way for their fleet, which is expected to lead to the lowest cost path for each manufacturer, yet still achieve the public health and welfare benefits associated with the reduced level of emissions set by the rule. As described in Section IV.F and G of the preamble, we demonstrate that there are multiple pathways to compliance, and that these pathways will continue to offer a wide range of mixes of technologies in the fleet for consumers to choose from, including various mixes of ICE vehicles, strong hybrid vehicles, PHEVs and BEVs. Specifically, EPA has concluded that the standards could be met by additional PHEVs and has identified several additional compliance pathways, with a wide range of BEVs, that can be achieved in the lead-time provided and at a reasonable cost. In all of these pathways, manufacturers continue to produce ICE vehicles. Indeed, as shown in RIA Chapter 8.2, EPA's central case modeling shows that over 84 percent of the on-road fleet will still use gasoline or diesel in 2032, and 58 percent will in 2055. In addition, the increased fuel economy and associated fuel savings via PEV and ICE vehicle technologies provided to consumers in the new vehicle market will also eventually be available in the used vehicle market. Overall, we expect consumers to continue to have access to a wide variety of vehicle choices under the standards. More on continued vehicle choice can be found in RTC Section 13.1. For more information on fleet turnover, see section 12.1.3 of the RTC.

Because we do not agree that this rule will lead to consumers being unable to purchase a vehicle that fits their needs, we do not agree that we should estimate a loss of welfare associated with this. In addition, as discussed in RIA 4.4, we hold performance constant in our analysis, meaning that we deter the need to estimate potential consumer welfare loss due to foregone vehicle attributes.

We do not agree that this rule will limit consumer mobility. In fact, we believe that consumer mobility will increase because of the decreased operating costs we estimate will occur due to this rule. As also discussed in Section 13 of the RTC, many consumers commented that PEVs serve the interest of many consumers. Not only will consumers be able to purchase the vehicles they need, but we estimate that operating costs are going to fall, from significant fuel savings for all vehicles and repair and maintenance savings for PEVs, as described in Sections VIII.B.3 and VII.C of the preamble and Chapter 4 of the RIA. This will make each trip relatively less expensive and, as a result, we estimate that under the "rebound effect" consumers will choose to drive more; thus the rule will actually increase mobility for consumers. See RIA chapter 4.2.1.

Regarding comments that we did not consider vehicle availability or costs in our analysis, we note that this rule uses the OMEGA model to estimate vehicles produced and sold, taking into account the estimated costs of those vehicles. In RIA Chapter 2, we discuss the OMEGA model, including the Consumer Demand module, which estimates the demand for vehicles given the estimated purchase price and other factors, the Producer Module, which estimates the producers will make given costs, policy inputs and other factors, as well as the interaction of the modules.

Regarding comments that the benefits of this rule are overstated, we refer to Section 8 of the RTC, where we discuss benefits of this rule. We disagree that this rule will lead to little environmental benefit, as described in Sections 8 and 11 of the RTC.

Regarding comments on the availability of EV charging in the future, see RTC Section 17.

For our discussion on the energy grid, including grid reliability, see RTC Section 18.

Regarding Delek's comments on basing the rule on automaker announcements, we address this issue in RTC Section 14.

Regarding the comments that the standards must be reflective of actual ZEV adoption rates, we refer to the discussion in Section 13 of the RTC.

Regarding comments about employment impacts, see Section 20 of the RTC.

For information on consumer impacts, see RTC Section 13.

For information on small business impacts, see RTC Section 25.1.

14.2 - Elasticity of demand

Comments by Organizations

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Vehicle Demand Elasticity

The vehicle demand elasticity, which represents how sensitive consumers are to changes in vehicle prices, is an important parameter in determining the costs and benefits of the proposal. The greater the elasticity (in absolute value) that is assumed, the greater new vehicle sales decline in response to price increases, potentially reducing the estimated emission benefits of the proposal. CARB agrees with U.S. EPA that the vehicle demand elasticity assumption of -0.4 is conservative, and thus overstating the effects of price increases, than other better-supported elasticity estimates would suggest. According to a recent U.S. EPA report, once interactions across new and used vehicle markets and other transportation options are accounted for in market equilibrium, the -0.4 vehicle demand elasticity could effectively result in only -0.17 and -0.04 elasticities for new and used vehicles, respectively. 80 These interactions across markets affect the new vehicle elasticity because as consumers substitute buying used vehicles in response to increased cost of new vehicles, used vehicle prices would increase, reducing the incentive to substitute away and implying a lower elasticity in market equilibrium. If the DRIA reflected these better estimates, the estimated climate and public health benefits of the proposal would be expected to be greater. [EPA-HQ-OAR-2022-0829-0780, p. 49]

XXIV. EPA’s Consideration of Sales Impacts Is Reasonable, but the Agency Should Consider Using a Sales Elasticity of Demand Lower in Magnitude for LDVs.

C. Alternative 1+ Results in the Highest BEV Sales Share of All Scenarios

Alternative 1+ results in the highest BEV sales share of all scenarios at 78% by 2032, which helps spur higher in-use BEV share by 2040 (as depicted in Figure V.C-1). The BEV sales share for Alternative 1+ is almost 10 percentage points more than what is projected to occur under EPA Alternative 1 and 13 percentage points more than what is projected to occur under the EPA Main Proposal and EPA Alternative 3 policy scenarios. [EPA-HQ-OAR-2022-0829-0759, p. 29]

SEE ORIGINAL COMMENT FOR Figure V.C-1: Comparison of BEV Adoption Rate Scenarios: Sales Share108

108 ERM, Impacts Report at 7-8.

Based on Sales Share (shown in the left side graph), in-use ZEVs will continue to increase under the Alternative 1+ scenario such that the 2040 in-use share is incrementally higher than all other scenarios analyzed. [EPA-HQ-OAR-2022-0829-0759, p. 30]

Excerpt Text:

D. Alternative 1+ Achieves the Largest Share of In-Use BEVs of All Scenarios

The graphs in Figure V.D-1 show projected shares of in-use vehicles through 2040. As shown, a policy approach implementing our recommended Alternative 1+ provides the highest in-use ZEV percentages of any scenario analyzed. Under this policy scenario, 50% of the light- and medium-duty (L/MD) vehicles on the road are expected to be BEVs by 2040.

SEE ORIGINAL COMMENT FOR Figure V.D-1: Comparison of BEV Adoption Rate Scenarios: In-Use Share109 [EPA-HQ-OAR-2022-0829-0759, p. 30]

109 Id. at 7-8.

In this section, we turn to EPA's consideration of sales impacts. While we support EPA's proposal to use a sales elasticity of demand of zero for MDVs, we recommend that it use a sales elasticity of demand lower than –0.4 for LDVs. [EPA-HQ-OAR-2022-0829-0759, p. 183]

A. EPA should consider using a sales elasticity of demand lower in magnitude than –0.4 for LDVs.

EPA continues to use the new vehicle demand elasticity of –0.4 for its modeling of LDV sales impacts, based on the Agency's final 2021 rule and a 2021 EPA peer reviewed report on this topic. 88 Fed. Reg. at 29,370.597 Recent research supports a sales elasticity value of –0.4, or one even lower in absolute value, as EPA suggests. See 88 Fed. Reg. at 29370 (noting that " –0.4 appears to be the largest estimate (in absolute value) for a long-run new vehicle demand elasticity in recent studies," and that "EPA's report examining the relationship between new and used vehicle markets shows that, for plausible values reflecting that interaction, the new vehicle demand elasticity varies from –0.15 to –0.4"); see also 83 Fed. Reg. at 43075 (based on the available research, the 2020 Rule NPRM conducted a data analysis and projected an elasticity in the range of –0.2 to –0.3.)598 [EPA-HQ-OAR-2022-0829-0759, p. 183]

597 Citing EPA, The Effects of New-Vehicle Price Changes on New- and Used-Vehicle Markets and Scrappage, EPA–420–R–21–019 (2021), https://cfpub.epa.gov/si/si_public_record_Report.cfm?dirEntryId=352754&Lab=OTAQ.

598 This number was actually incorrectly calculated and too high due to a spreadsheet error identified in a Comment to the 2018 NPRM. It should be -0.07. See J.H. Stock et al., Comments on Notice of Proposed Rulemaking for The Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021–2026 Passenger Cars and Light Trucks, EPA-HQ-OAR-2018-0283-6220, at 6–8 (Oct. 26, 2018). See also Brief of Amici Curiae Economists in Support of Coordinating Petitioners, Competitive Enterprise Institute v. NHTSA, D.C. Cir. No. 20-1145, at 26 (filed Jan. 21, 2021) (hereinafter "Amicus Brief of Economists").

Using a price elasticity of demand that is lower in absolute value could provide a more realistic picture of the sales impacts of LDV GHG regulations, and EPA should consider whether a value lower in magnitude than –0.4 is appropriate here. The price elasticity of demand for new vehicles is a critical factor to consider in setting LDV regulations because without this input EPA could not quantify the rule's effect on vehicle purchases. Changes in demand for new vehicles can have an impact on jobs, emissions, safety, and other factors relevant to the net benefits of revised standards. [EPA-HQ-OAR-2022-0829-0759, pp. 183-184]

Vehicles have different price elasticities depending on the timeframe considered, and sales of automobiles tend to be less sensitive to price fluctuations, especially in the long run.599 This is because in most areas of the United States vehicles are essential goods.600 EPA's Science Advisory Board explained that while "a consumer can easily hold on to their existing vehicle a bit longer[,] . . . an old vehicle will not be functional forever, and thus the long-run price elasticity for new vehicles is likely to be smaller [in magnitude] than the short-run elasticity."601 Therefore, it is common to distinguish between short-run elasticity values (sales effects that take place within one year of a price change)602 and long-run elasticity values (sales effects beginning approximately five years into the future).603 Thus, the 2012 Final Rule explained, while short-run elasticity may apply very briefly at the start of a program, "over time, a long-run elasticity may better reflect behavior." 77 Fed. Reg. at 63102 n.1300. Similarly, in the 2016 Midterm Evaluation Proposed Determination, EPA explained that "short run elasticity estimate[s] . . . may not be appropriate for standards that apply several years into the future."604 [EPA-HQ-OAR-2022-0829-0759, p. 184]

599 Howard, P. & M. Sarinksy, Turbocharged: How One Revision in the SAFE Rule Economic Analysis Obscures Billions of Dollars in Social Harms, N.Y.U. Inst. for Policy Integrity, at 3 (Nov. 2020), https://policyintegrity.org/files/publications/Turbocharged_How_One_Revision_in_the_SAFE_Rule_Economic_An alysis_Obscures.pdf ("Because automobiles are essential goods in most areas of the United States (and lack any comparable substitute), both economic theory and observed behavior finds that vehicle sales are relatively inelastic—meaning that price fluctuations produce just modest changes in vehicle sales").

600 See, e.g., Anderson P.L. et al., Price Elasticity of Demand (1997), https://scholar.harvard.edu/files/alada/files/price_elasticity_of_demand_handout.pdf.

601 EPA, Science Advisory Board (SAB) Consideration of the Scientific and Technical Basis of the EPA's Proposed Rule titled The Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021-2026 Passenger Cars and Light Trucks, EPA-HQ-OAR-2018-0283-7659, at 22 (Feb. 27, 2020).

602 See Pindyck, R.S. & D.L. Rubinfeld, Microeconomics (8th ed.), at 39 (1989) (describing short-run elasticity as measuring "one year or less").

603 See Klier, T. & J. Linn, The Effect of Vehicle Fuel Economy Standards on Technology Adoption, Resources for the Future Discussion Paper, at 3, 6 (Rev'd 2015), https://media.rff.org/archive/files/document/file/RFF-DP-13-40-REV2.pdf (noting that long-run impacts measure across engine design cycles, and that "models contain redesigned engines about once every five years in the United States"); see also Amicus Brief of Economists at 20 (noting that "long-run" concerns sales effects that begin approximately five to ten years into the future).

604 EPA, Proposed Determination on the Appropriateness of the Model Year 2022-2025 Light-Duty Vehicle Greenhouse Gas Emissions Standards under the Midterm Evaluation, EPA-HQ-OAR-2018-0283-7640, at A-40 (Nov. 2016). See also NHTSA CAFE Model Peer Review, at B-35 (rev. July 2019) (advising EPA and NHTSA that the long-run price elasticity of demand provides the "proper focus" for analyzing the 2020 Final Rule's impacts).

Because analyses of LDV GHG emissions standards project sales many years into the future, the long-run price elasticity is the relevant value to apply to the analysis. And because vehicle sales are less elastic in the long run, the price elasticity of demand for vehicles is substantively lower in magnitude in the long run than in the short run. [EPA-HQ-OAR-2022-0829-0759, pp. 184-185]

The chart below provides a comprehensive review of current and historical long-run and short-run elasticity estimates.605 The median elasticity of the studies published since 2000 (including an outlier estimate) is approximately –0.35, with a mean of –0.4, and those numbers decrease when looking only at studies published since 2010.606 The most recent reliable studies, such as Leard (2021) and Stock et al. (2018), would support values even lower in magnitude than –0.4. [EPA-HQ-OAR-2022-0829-0759, p. 185]

605 This review included the sources cited by the agencies in the 2020 Final Rule, 85 Fed. Reg. 24174 (June 29, 2020), as well as other relevant sources (in particular those in National Research Council, Cost,

Effectiveness, and Deployment of Fuel Economy Technologies for Light-Duty Vehicles (June 2015), and previous EPA rules) and more recent studies.

606 These values are consistent with a review done by several economists and detailed in an amicus brief filed in the litigation over the 2020 Final Rule. That review considered what the economists viewed as the four most relevant, distinct estimates of long-run elasticity based on original data analysis since 2000, and found a long-run price elasticity of demand for vehicles subject to the Proposal of between -0.03 and -0.61. See Amicus Brief of Economists at 25-26.

* McAlinden et al. (2016) conducted both a literature review, represented at the top of this table, and separately produced its own elasticity estimates, shown here.

** Inconsistent estimates: Nerlove (1957) as long-run elasticity is higher than short-run elasticity; Evans (1969) as elasticities are extreme outliers with long-run elasticity that is elastic contrary to intuition in the literature; and Berry et al. (2004) as estimate was suggested by General Motors staff despite “impl[ying] a large (in absolute value) own-price semi-elasticity of demand equal to −10.56” and conducted sensitivity analysis using –0.2 and –0.4 (the latter producing more realistic own-price semi-elasticity) (Leard (2021)).610[EPA-HQ-OAR-2022-0829-0759, p. 187]

610 Benjamin Leard, Estimating Consumer Substitution Between New and Used Passenger Vehicles, Resources for the Future 12 (rev. Aug. 2021), https://media.rff.org/documents/WP_19-01_rev_2021.pdf.

B. EPA is correct to use a sales elasticity of zero for MDVs.

For MDV sales impacts, EPA’s Proposal assumes an elasticity of zero, reasoning that MDVs largely serve commercial applications and that business owners are less sensitive to changes in vehicle price. 88 Fed. Reg. at 29372. As EPA explains, “as long as the characteristics of the vehicle do not change, commercial buyers will still purchase the vehicle that fits their needs,” even with a change in price. Id. We agree with EPA that, for this reason, the literature examining LDV sales elasticity does not directly translate to MDV sales elasticity, and that factors such as the importance of fuel efficiency, warranty considerations, maintenance cost, and replacement parts could be more relevant to commercial vehicle purchasers than changes in vehicle price. DRIA at 4-43. [EPA-HQ-OAR-2022-0829-0759, p. 187]

Attributes of MD ZEVs also could help to mitigate vehicle sales impacts, particularly for commercial applications. For example, as with commercial HDVs, educating commercial MDV purchasers regarding the benefits of ZEV ownership such as reduced operating and maintenance costs can be especially effective in mitigating possible sales impacts, 88 Fed. Reg. at 26068,611 as TCO has long been a key consideration for commercial vehicle owners and operators.612 The availability of data analytics tools for commercial fleets also makes it easier for commercial purchasers to understand and evaluate the TCO.613 Medium-duty ZEVs largely have reached TCO parity with their conventional counterparts, or will in the very near future and by the time period covered by the Proposed Rule.614 For commercial HDVs, EPA has projected little to no sales impacts as a result of its newly proposed GHG standards, which are likely to be complied with through increased ZEV penetration,615 and EPA is correct to do the same for MDVs. [EPA-HQ-OAR-2022-0829-0759, p. 188]

Kolman, The True Costs of a Truck Purchase, Fleet Maintenance (June 9, 2015) (explaining the use of telematics software in analyzing TCO, and noting that "OEM dealer sales representatives are trained on effectively calculating TCO costs and on assisting truck buyers [to] evaluate and assess planned operation of their trucks.").

614 Saxena et al., Electrification Cost Evaluation, at 26 ("While the economics vary based on several factors, the TCO of most MY 2027 and MY 2030 class 2b–3 BEV types is lower than the TCO of comparable ICEVs, largely due to BEVs' lower maintenance and energy costs. Across the vehicle types and three scenarios of electrification considered in this report, the TCO of BEVs averages $0.334 per mile (ranging from $0.291 per mile to $0.39 per mile), while the TCO of ICEVs averages $0.428 per mile (ranging from $0.336 per mile to $0.574 per mile)."); Ari Kahn, et al., The Inflation Reduction Act Will Help Electrify Heavy-Duty Trucking, RMI (Aug. 25, 2022), https://rmi.org/inflation-reduction-act-will-help-electrify-heavy-duty-trucking/ (finding that the IRA will result in the TCO of electric trucks falling below the TCO of comparable diesel trucks about five years faster than without the IRA).

615 EPA, Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles: Phase 3, Draft Regulatory Impact Analysis (Apr. 2023), at 414.

Organization: American Honda Motor Co., Inc.

It is critical that the impact of a potentially significantly higher new vehicle transaction price on total sales be accounted for by the agency. Unfortunately, the agency's analysis is extremely limited, as their sensitivity cases are independently analyzed and omit the possibility of IRA being weakened. Honda attempted to quantify the impact that a "stacking" of uncertainties would have on average new vehicle price. We examined average new vehicle price from OMEGA 2.0

under EPA's proposal (shown in light blue in Figure 6, below), as well as the resulting increase in price that would occur under two additional stacked scenarios: (1) elimination of IRA incentives, and (2) EPA's high battery cost assumptions. As shown in Figure 6, the cumulative impact of these two uncertainties could increase the average new vehicle price by more than $8,600 (a 25% increase) in 2030, relative to the agency's proposal. [EPA-HQ-OAR-2022-0829-0652, pp. 26-28]

Qualitatively, one would assume that such a significant increase in price would have a noticeable quelling effect on new vehicle sales. Strangely, the agency's OMEGA output files show very little impact on overall sales, despite the significant price increase. The agency's modeled sales impacts show a long run demand elasticity of just -0.21, notably different than values cited in EPA's Draft RIA as well as by other industry experts.46 47 As shown in Table 3 below, the implication of a different demand elasticity has a significant impact on the magnitude of overall new vehicle sales. If actual demand elasticities are closer to -0.40 (EPA estimate) or -0.61 (CAR estimate), loss of sales due to a 25% price increase would be between 1.5 million and 2.3 million new vehicle sales annually. One can speculate on the potential impact that such a loss of sales would have both on the industry and the economy, as well as the impact on consumer choice, vehicle affordability and equity. [EPA-HQ-OAR-2022-0829-0652, pp. 26-28]

Available online at https://www.cargroup.org/wp-content/uploads/2017/02/The-Potential-Effects-of-the-2017_2025-EPANHTSA-GHGFuel-Economy-Mandates-on- the-US-Economy.pdf

Organization: National Automobile Dealers Association (NADA)

Based on OEM fleet electrification investment and production plan announcements and federal subsidies in the Infrastructure Investment and Jobs Act (IIJA) and the IRA, EPA contends that EV technologies have advanced to such a degree that EVs now "are a feasible way to greatly reduce emissions" and can be used "as an emissions control technology to comply with" the proposed standards.15 EPA projects that, although "[t]he proposed standards are performance-based and do not mandate any specific technology...or any vehicle type[,]" new light-duty EV sales will increase from 36 percent in MY 2027 to 67 percent in MY 2032.16 EPA also projects new medium-duty EV sales ranging from 17 percent in MY 2027 to 46 percent in MY 2032.17 [EPA-HQ-OAR-2022-0829-0656, pp. 3-4]

15 88 Fed. Reg. at 29194, 29284, 29341-44.

16 88 Fed. Reg. at 29329.

17 88 Fed. Reg. at 29331.

EPA also projects that its proposed standards will cause new light-duty vehicle sales to decrease a small amount during the first two years, increase a small amount in the next two years, and then decrease by a small amount in the final two years.18 EPA projects no change in new medium-duty vehicle sales as a result of its proposed standards based on an assumption that, because commercial buyers "are less sensitive to changes in vehicle prices than personal vehicle owners[,]" they will not "change purchase decisions if the price of the vehicle changes" and "will still purchase the vehicle that fts their needs."19 [EPA-HQ-OAR-2022-0829-0656, pp. 3-4]

18 88 Fed. Reg. at 29370.

19 88 Fed. Reg. at 29371.

5. EPA's Sales Projections Are Inaccurate.

In discussing its sales response model, EPA states that it used "a demand elasticity of -0.4 for [light-duty] vehicles based on an EPA peer reviewed report (U.S. EPA 2021)."51 EPA assumes that a one percent increase in the average price of new vehicles produces a 0.4 percent decrease in new light-duty vehicle sales. EPA then concludes that its proposed standards would result in only a small change in total new light-duty vehicle sales, which equate to -0.35 percent in 2027, -0.13 percent in 2028, 0.07 percent in 2029, 0.05 percent in 2030, -0.15 percent in 2031, and -0.29 percent in 2032.52 NADA takes issue with EPA's -0.4 percent demand elasticity assumption and the accuracy of its light-duty sales impact projections. Curiously, EPA's demand elasticity response for light-duty vehicles is significantly smaller than the -1.0 elasticity of demand NHTSA used in its most recent fuel economy mandates, and thus implies much smaller price-related impacts on new vehicle sales. [EPA-HQ-OAR-2022-0829-0656, pp. 10-11]

51 88 Fed. Reg. at 29370-71.

52 Id.

As depicted in the table below [See original attachment for table of sales projections] , NADA's sales projections differ significantly from EPA's sales projections and show sales declines in all six years covered by EPA's proposal.53 [EPA-HQ-OAR-2022-0829-0656, pp. 10-11]

53 NADA calculates forecasted price increases using the average year-over-year increase in new vehicle transaction prices from 2016–April 2023 YTD. During this period, new vehicle prices increased annually, on average, by 4.62 percent. Note that because price increases in 2020-2021 and 2021-2022 were abnormally high due to circumstances related to the COVID-19 pandemic and the semiconductor microchip shortage, NADA assumes an annual new vehicle transaction price increase of only 2% for 2024–2032.

54 See DRIA Table 13-45. p. 13-25.

NADA believes EPA's sales impacts are significantly understated based on its use of demand elasticity of -0.4 and asserts that the -1.0 used by NHTSA is a more appropriate elasticity of demand. Nevertheless, based on EPA's assumed demand elasticity of -0.4 percent, the proposal's projected regulatory costs, and reasonable assumptions about increased new light- duty vehicle prices, NADA's analysis suggests that the price increases associated with EPA's proposed standards (and regulatory alternatives) will result in much more significant negative sales impacts. For example, in 2027 EPA projects a sales decline of just 0.35%. After accounting for the additional conservatively forecast market-based price increases, and using EPA's own demand elasticity metric, NADA estimates a new light-duty sales decline of 1.3%, nearly four times greater than EPA's estimate. Sales impacts in subsequent years are understated as well. [EPA-HQ-OAR-2022-0829-0656, pp. 11-12]

EPA did not disclose the baseline pricing data, historical or forecast, on which it relied to calculate its sales projections. Consequently, NADA is unable to fully assess whether EPA's projections are premised on data from outside the regulatory impact period. NADA urges EPA to clarify (and rationalize) how it computed average baseline new vehicle transaction prices, and how it derived its sales impact forecast due to the proposal's increased regulatory costs. [EPA-HQ-OAR-2022-0829-0656, pp. 11-12]

NADA also questions EPA's assumption and use of a demand elasticity of zero when modeling the medium-duty vehicle sales impacts of its proposal. Goods with a demand elasticity of zero are referred to as "necessity goods" for which no reasonable substitute is available. Assuming commercial customers need medium-duty vehicles to run their businesses, they are unlikely to purchase new vehicles if unaffordable or if they fail to meet their business use case needs. [EPA-HQ-OAR-2022-0829-0656, pp. 11-12]

As discussed above and elsewhere, new medium-duty vehicles are not "necessity goods" in that prospective purchasers have several alternative options. For example, prospective commercial medium-duty customers almost always have the option to keep existing vehicles on the road longer than they might otherwise with enhanced maintenance and repair strategies that may even include engine and/or vehicle re-building. Alternatively, they may meet their needs with used vehicles, often at costs significantly lower than that of new medium-duty vehicles subject to EPA's proposed standards. Consequently, NADA urges EPA to use at least a -1.0 elasticity of demand when calculating the impact of its proposed standards on new medium-duty sales. [EPA-HQ-OAR-2022-0829-0656, pp. 11-12]

EPA Summary and Response

Summary:

Comments from CARB stated that the elasticity EPA used in the proposal is conservative, and better, smaller estimates would likely lead to greater estimated climate and public health benefits. Comments from the Environmental and Public Health Organizations stated that, though the consideration of sales impacts in the proposal is reasonable, EPA should consider using smaller elasticity of demand for light duty vehicles, though they agree with the medium duty elasticity of demand of zero used in the proposal. They state that the analysis for this rule supports a long run elasticity, and therefore a smaller elasticity is more relevant.

Honda commented that the long run sales elasticity in the modeled sales impacts is noticeably different than the -0.4 value cited in the proposal, and if demand elasticities are actually closer to that -0.4 level, vehicle sales impacts will be much larger than EPA estimates.

NADA commented that sales impacts in the proposal are understated, the elasticity used in the proposal is too small, and EPA should use an elasticity of -1, like NHTSA used in their recent rules, rather than -0.4 values EPA uses.

NADA commented that the elasticity of demand of zero used for MD vehicles is questionable because MD vehicles are not "necessity goods" and the EPA should also use an elasticity of demand of -1 for MD vehicles. NADA points out that MD customers have the option to keep existing vehicles on the road longer rather than purchase a new vehicle, or may purchase a used vehicle instead of a new one.

Honda commented that the impact of higher purchase prices must be accounted for in the total sales estimates for this rule. They also stated that the sensitivity cases analyzed by EPA are independent and make the analysis extremely limited, and the EPA does not include the possibility of the IRA being weakened.

NADA commented that EPA did not disclose the baseline pricing data that was relied on to calculate sales projections, and the EPA should clarify and rationalize how average baseline new vehicle transaction prices were estimated. They also commented that EPA should clarify how sales impacts of increased costs were forecast.

Response:

We agree with CARB that the elasticity measurement use in our modeling is conservative, and smaller estimates would lead to greater estimated benefits. Regarding comments that EPA should use a different elasticity of demand for LD vehicles, we point to our discussion in RIA Chapter 4.4, where we note the reasons for using an elasticity of demand smaller than -1, as well as why we chose -0.4 as opposed to something smaller. We note that commenters who disagreed with EPA's choice of elasticities used in the analysis did not provide additional data to support these views. EPA believes that our choice of vehicles sales elasticities remains appropriate as it is based on the best available science in the record, as discussed further in RIA Chapter 4.4.

Regarding the comment that MD vehicles are not "necessity goods", we note that necessity goods are generally goods that are inelastic with respect to income, not with respect to price, for example tobacco, and medications. Goods with a demand elasticity of 0, or perfectly inelastic demand, are those whose purchase quantity doesn't change with respect to their own price. Some of these are necessities (like food or water), but others are things that will remain in demand even if the price changes.

Commercial vehicle owners purchase vehicles based on the needs of their business, and we expect them to be less sensitive to changes in vehicle price than personal vehicle owners. As such, we generally expect that purchasers will purchase the MDV that meets their needs. In the short run, it is theoretically possible increased upfront costs may lead to short run sales impacts not modeled here. Short run impacts may include purchasers opting to keep their vehicles on the road longer, or to buy a used vehicle. With respect to purchasers who decide to keep their vehicles on the road longer, we note that this will likely increase the cost of maintenance and may impact the cost of operating the vehicle. As pointed out by other commenters, operating cost, including maintenance costs and fuel efficiency, are strong motivators in the purchase decisions of MDV purchasers. Thus, and as we further explain based on our review of past studies relating to pre-buy and low-buy in preamble VIII.H.2, we expect any possible pre- or low-buy that may occur in the medium-duty segment as a result of this rule would be small and short lived.

Further, these short term impacts will likely even out in the long run. The elasticities in our analysis are long-run elasticities and reflect long-run changes in the market. In the long run, for example, even if a purchaser decides to keep a used MDV for a longer period of time, that used vehicle will eventually be replaced with something that costs less to maintain and operate. This rule is estimated to lead to decreased operating costs for both ICE and PEV vehicles. In addition, assuming the market served by the MDV purchasers does not grow or shrink, one MDV purchaser buying a used vehicle will mean another MDV purchaser buying a new vehicle due to the finite number of used vehicles that will meet the needs of the individual MDV purchaser available in the market.484 .

Regarding comments that the impact of increased purchase price must be accounted for in our analysis, as well as that estimated elasticity of demand is not -0.4 as EPA assumes, we note that the OMEGA model used to estimate impacts from the rule includes the estimated purchase price of the vehicles, and therefore we do not agree that purchase price was not accounted for in the sales estimates. In addition, regarding comments that the modeled sales results show an impact much different than the -0.4 percent elasticity, as discussed in Chapter 4 of the RIA, the elasticity of demand is one input into the estimate of consumer demand for vehicles in OMEGA and the estimate of a change in final new vehicle sales as a function of the change in final new vehicle price (or cost) will not return a value of -0.4. Regarding comments that EPA should use a sales elasticity of -1.0, as NHTSA has used, we note that in the most recent CAFE standards proposed in July 2023, NHTSA uses a sales elasticity of -0.4.485 For more information on how the elasticity of demand is implemented in the analysis of this rule, see Chapter 4.4 of the RIA.

Regarding comments that the sensitivity cases estimated by EPA are independent and the uncertainties addressed by them cannot be 'stacked', we note that this is not the purpose of the sensitivities we analyze. The sensitives published in the final rule are meant to further explore the assumptions made in support of the analysis of our standards and help assess key areas of uncertainty in both underlying data and modeling assumptions. For example, in this final rule, we assess sensitivities about consumer adoption, battery costs, and credit trading. For more information on the sensitives estimated for the final rule, see preamble Sections IV.E, F, G and H.

Regarding comments that EPA does not include an analysis of the possibility of the IRA being weakened, the agency follows OMB Circular A-4, which encourages federal agencies to consider likely paths of future government programs and policies, as well as ground assumptions of the future in sound theories and empirical evidence about current conditions and ongoing and anticipated future trends.[486] Based on current evidence, we continue to support the inclusion of IRA provisions in our modeling assessments. For information on how we include the IRA in modeling for this final rule, see RIA Chapter 2.6.8.

We do not agree that baseline pricing data or how we analyze sales impacts was not disclosed. The base year pricing data used for this analysis was assembled from publicly available MSRP value, and is reported for each vehicle in OMEGA's vehicles.csv input file (in the "msrp_dollars" data column). EPA recognizes that these values do not reflect manufacturer purchase incentives or other adjustments that determine overall transaction prices, but EPA has concluded that MSRP values are appropriate for this analysis because it is a reasonable proxy for the price of the vehicle and because of its consistent availability across all manufacturers. More

[484] Another possibility is increasing the market served by other vehicles in the fleet, which increases the wear, and therefore the maintenance and repair costs, for those other vehicles. This may also lead to the vehicles needing to be replaced sooner than they otherwise would have been.

information on base year vehicle prices and sales impacts estimates can be found in public documentation for the OMEGA model found in the docket, or through exploration of the OMEGA model itself. Chapter 4.4 of the RIA contains information on how sales impacts were modeled and RTC Section 12 contains responses to comments on the OMEGA model.

14.3 - Energy efficiency gap

<u>Comments by Organizations</u>

Organization: Institute for Policy Integrity at New York University School of Law

III. EPA Should More Robustly Affirm That Standards Help Correct Market Failures That Prevent Consumers From Achieving Valuable Fuel Savings

The "energy efficiency gap" refers to the effect of a suite of market failures that together "lead[] to a slower diffusion of energy-efficient products than would be expected" if consumers maximized their net investment returns.153 EPA correctly recognizes the presence of the energy efficiency gap in the Proposed Rule.154 Accordingly, the Proposed Rule properly counts the full value of energy savings as a benefit, just as it and other agencies have done in prior tailpipe and appliance-efficiency regulations.155 [EPA-HQ-OAR-2022-0829-0601, pp. 23-25]

153 Kenneth Gillingham & Karen Palmer, Bridging the Energy Efficiency Gap: Policy Insights from Economic Theory and Empirical Evidence, 26 J. Econ. Perspectives 3, 19 (2014); see also Proposed Rule, 88 Fed. Reg. at 29,397; RIA at 4-38.

154 Proposed Rule, 88 Fed. Reg. at 29,397; RIA at 4-38 to 4-41.

155 See BETHANY DAVIS NOLL ET AL., INST. FOR POLICY INTEGRITY, SHORTCHANGED 21–29 (2020), https://policyintegrity.org/files/publications/Clean_Car_Standards_Rollback_and_Fuel_Savings_Report.pdf.

Despite this consistent practice and the widespread evidence of the energy efficiency gap, certain challengers to the 2021 Rule have disputed the validity of this gap in the ongoing litigation. They have argued that consumers avoid purchasing fuel-efficient vehicles because they prioritize other vehicle attributes that these challengers allege are adversely affected by fuel efficiency, not because of the existence of market failures as is suggested by much of the economic literature.156 While their argument lacks merit,157 its existence counsels EPA to thoroughly document the energy efficiency gap. [EPA-HQ-OAR-2022-0829-0601, pp. 23-25]

156 See Brief for Private Petitioners at 65–68, Texas v. EPA (D.C. Cir. filed Nov. 3, 2022). This account echoes reasoning that EPA flirted with (but ultimately declined to adopt) in the 2020 Rule. In that rule—as a sensitivity analysis only—EPA subtracted 42 months of fuel savings per consumer to approximate the alleged loss of welfare from other vehicle attributes. 85 Fed. Reg. 24,174, 24,701–02 (Apr. 30, 2020).

157 See, e.g., Gloria Helfand et al., Searching for Hidden Costs: A Technology-Based Approach to the Energy Efficiency Gap in Light-Duty Vehicles, 98 ENERGY POL'Y 590, 605 (2016) ("We find scant systematic evidence of hidden costs for the primary technologies expected to be used to meet EPA and DOT standards."); Hsing-Hsiang Huang et al., Re-searching for Hidden Costs: Evidence from the Adoption of Fuel-Saving Technologies in Light- Duty Vehicles, 65 TRANSP. RESEARCH PART D: TRANSP. & ENV'T 194, 194 (2018) ("[A]utomakers have typically been able to implement fuel-saving technologies without harm to vehicle operational characteristics.").

Yet EPA provides less analysis of this issue than it did in the 2021 Rule. EPA can bolster its discussion of the energy efficiency gap in three key ways. First, EPA should fully adopt its justification for the energy efficiency gap from the 2021 Rule. Second, EPA should expand upon that justification by offering additional explanations that it omitted in 2021. And third, EPA should affirm the continued relevance of the energy efficiency gap with respect to electric vehicles, and delete language that could be read to question the gap's continued relevance. [EPA-HQ-OAR-2022-0829-0601, pp. 23-25]

A. At a Minimum, EPA Should Fully Adopt Its Justification for the Energy Efficiency Gap That It Provided in the 2021 Rule

Although EPA offers support for the existence of the energy efficiency gap in the Proposed Rule and RIA, it offers less evidence now than it did in the 2021 Rule.158 The agency should fully adopt its 2021 explanation of the energy efficiency gap to avoid any confusion as to whether it continues to support the explanation it previously provided. [EPA-HQ-OAR-2022-0829-0601, pp. 23-25]

158 See Proposed Rule, 88 Fed. Reg. at 29,397; RIA at 4-38 to 4-41.

For instance, EPA's regulatory impact analysis for the 2021 Rule (2021 RIA) provided significantly more explanations for the market failures that cause the energy efficiency gap and numerous additional supporting citations.159 The current RIA omits several key market failures that the agency recognized previously, including consumer prioritization of attributes that convey status, consumer use of simplified decision rules, and consumer "satisficing" on fuel economy rather than optimization.160 [EPA-HQ-OAR-2022-0829-0601, pp. 23-25]

159 2021 RIA at 8-4 to 8-6.

160 Id. at 8-4 (providing all three rationales).

The 2021 RIA also described research identifying problematic assumptions underlying a few studies showing an efficiency-performance tradeoff,161 and clearly explained that, if producers did reduce vehicle performance to comply with fuel-efficiency standards (contrary to the best available evidence), then EPA's estimate of compliance costs would be too high because that estimate assumes that producers retain all performance features.162 While EPA briefly alludes to this research now, it does not offer nearly as detailed a defense for its conclusion that "the presence of fuel-saving technologies do not lead to adverse effects on other vehicle attributes."163 Similarly, EPA nods at the constant-performance modeling assumption without explaining how compliance costs would need to be revised downward without it.164 [EPA-HQ-OAR-2022-0829-0601, pp. 23-25]

161 Id. at 8-2 to 8-3.

162 Id. at 8-3.

163 RIA at 4-38.

164 See id. at 4-40.

To avoid any potential confusion over whether EPA still supports the justifications for the energy efficiency gap that it provided in 2021, EPA should fully readopt its previous explanation. EPA can do this through one of two ways: either by expressly incorporating by reference its full 2021 explanation or by inserting the explanations that it provided in 2021 but omits now. [EPA-HQ-OAR-2022-0829-0601, pp. 23-25]

B. EPA Should Provide Additional Justifications for the Energy Efficiency Gap in Addition to Those It Provided in the 2021 Rule

While EPA provided considerable support for the energy efficiency gap in the 2021 Rule and 2021 RIA (much of which it restates in this proposal), it could have gone further then. In fact, economic literature offers numerous additional explanations for the energy efficiency gap. Additionally, these further justifications support EPA's correct choice not to devalue consumer fuel savings due to any alleged efficiency-performance tradeoff. EPA should now adopt these additional arguments supporting its treatment of fuel savings, particularly in light of the litigation over this aspect of the 2021 Rule. Similarly, EPA should state (even more clearly than it did in 2021) that its model's constant-performance assumption obviates the need to estimate any potential lost consumer welfare. [EPA-HQ-OAR-2022-0829-0601, pp. 23-25]

1. EPA Should Discuss Additional Contributing Market Failures

EPA should describe additional market failures that contribute to the energy efficiency gap. These include dealership incentives, biases, and information asymmetries; institutional myopia; and manufacturer market power. As discussed below, most or all of these market failures apply similarly to electric vehicles as they do to ICE vehicles. [EPA-HQ-OAR-2022-0829-0601, pp. 25-27]

i. Dealership incentives, biases, and information asymmetries

Salespeople's incentives and biases may cause informational asymmetries that prevent consumers from optimizing fuel efficiency.165 Studies show that dealers and salespeople often believe that electric vehicles and other efficient cars have lower profits for dealers than gas-powered cars,166 for various reasons.167 Consumers (and researchers posing as consumers) have often complained of poor dealership experiences when trying to purchase electric vehicles, citing salespeople's limited knowledge; misinformation and dishonesty about vehicle cost, range, and other attributes; inconsistent enthusiasm for electric vehicles; lack of inventory for more efficient and electric vehicles; poor timeliness for completing paperwork and vehicle delivery; limited promotional materials on energy efficiency; and inability to facilitate consumers' cost comparisons of electric versus gas vehicles.168 Some dealerships have admitted that poor sales training is a major barrier to electric vehicle sales.169 [EPA-HQ-OAR-2022-0829-0601, pp. 25-27]

165 See Fred Lambert, After Losing Dealers over Its Electric Move, Cadillac Is Now Gaining New Ones, ELECTREK, Sept. 23, 2021 (reporting that one-fifth of U.S. Cadillac dealers exited from the brand in 2020 rather than commit to selling electric vehicles).

166 Cox Automotive, Evolution of Mobility: The Path to Electric Vehicle Adoption 23 (2019), https://perma.cc/UV7N-42BE (reporting that 54% of surveyed dealers say there is a lower ROI for sales of EVs compared to gas); Eric Cahill et al., New Car Dealers and Retail Innovation in California's Plug-In Electric Vehicle Market (U.C. Davis Inst. Of Transp. Stud., Working Paper UCD-ITS-WP-14-04, 2014), https://perma.cc/DJ7T- SGXT (citing real or perceived profitability concerns, especially for compact or midsized vehicles).

167 Cahill et al., supra note 166, at 10 ("[A]s a category, PEVs may not represent a compelling investment to many dealers."); id. at 9–10 (noting that dealers have the false perception that PEVs entail longer transaction times and lower profits, when in fact dealers make more than average on PEVs in gross profits).

168 Id.; EPA, Draft Technical Assessment Report: Midterm Evaluation of Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards for Model Years 2022–2025 at 3-14 (2016) at 6-15; Cox Automotive, supra note 166; Gerardo Zarazua de Rubens et al., Dismissive and Deceptive Car Dealerships Create Barriers to Electric Vehicle Adoption at the Point of Sale, 3 NATURE ENERGY 501 (2018); Lindsay Matthews et al., Do We Have a Car for You? Encouraging the Uptake of Electric Vehicles at Point of Sale, 100 ENERGY POL'Y 79 (2017); Zoe Long et al., Consumers Continue to Be Confused About Electric Vehicles: Comparing Awareness Among Canadian New Car Buyers in 2013 and 2017, 14 ENV'T RES. LTRS. 114036 (2019).

169 Cox Automotive, supra note 166, at 30 (citing lack of OEM support).

ii. Institutional myopia and inattention, including short-termism

Though EPA refers to myopia in both the 2021 RIA170 and (more briefly) in the current RIA,171 this applies to both individual and institutional consumers. In particular, economists find that corporate managers can exhibit similar kinds of inattention as individual consumers and so fail to implement energy efficiency initiatives despite positive paybacks.172 Businesses may also face a kind of myopia called short-termism, in which corporate employees have an incentive to favor short-term profits over long-term investments if, for example, their compensation or career prospects are tied to near-term earnings (or if they must meet a particular budget in a given year).173 Employees with such incentives may have reason to purchase cheaper, less efficient vehicles.174 Studies suggest that short-termism can affect managers' choices about energy efficiency specifically,175 and about environmental sustainability broadly.176 [EPA-HQ-OAR-2022-0829-0601, pp. 25-27]

170 2021 RIA at 8-4.

171 RIA at 4-39 (discussing "a lack of foresight [and] an aversion to short term losses relative to longer term gains").

172 See Suresh Muthulingam et al., Energy Efficiency in Small and Medium-Sized Manufacturing Firms, 15 MFG. & SERV. OPERATIONS MGMT. 596, 612 (2013) (finding that manager inattention contributed to the non-adoption of energy efficiency initiatives, since initiatives that appear lower on a list of efficiency recommendations, and initiatives that require more managerial attention, are less likely to be adopted).

173 A similar dynamic could exist in government, and so affect local, state, and federal government fleet purchases, if officials are rewarded for short-term cost savings rather than long-term fiscal health.

174 This incentive could be muted by a firm's accounting practices if costs and expenses are amortized over time.

175 See Stephen J. DeCanio, Barriers Within Firms to Energy-Efficient Investments, 21 ENERGY POL'Y 906, 907–08 (1993); Suresh Muthulingam et al., Adoption of Profitable Energy Efficiency Related Process Improvements in Small and Medium Sized Enterprises 1, 7 (Working Paper, 2008) (finding that managers fail to implement energy efficiency improvements with short payback periods for several reasons, including myopia and a stronger focus on upfront costs than on net benefits, attributed partially to short-termism).

176 See Yujing Gong & Kung-Cheng Ho, Corporate Social Responsibility and Managerial Short-Termism, ASIA- PACIFIC J. ACCT. & ECON. (2018).

This market failure should remain prominent as electric vehicles become more widely available, due to the fact that electric vehicles frequently have higher purchasing prices but provide operating-cost savings over time. The limited price salience of electricity, including the use of automatic bill-pay, means that many consumers (including corporate consumers) will not properly factor in long-term operating cost savings. [EPA-HQ-OAR-2022-0829-0601, pp. 25-27]

iii. Manufacturer market power

Though EPA mentions in both the 2021 RIA and the current RIA that strategic marketing choices by manufacturers can result in inefficient under-supply of fuel economy to some consumer segments,177 EPA does not fully connect this inefficient pattern to market power. Because of the limited competition in at least some segments of the vehicle market, manufacturers may be able to act strategically when pricing vehicles and when producing vehicles with combinations of different fuel economy and other vehicle features to push consumers toward purchases that lead to higher manufacturer profits at the expense of optimal fuel economy.178 There is a relatively small number of firms producing several types of vehicles and engines.179 This market failure therefore could influence purchases by all consumer groups and across several vehicle classifications, including electric vehicles. [EPA-HQ-OAR-2022-0829-0601, pp. 25-27]

177 2021 RIA at 8-5; id. at 4-39 to -40.

178 See generally Carolyn Fischer, Res. for the Future, Imperfect Competition, Consumer Behavior, and the Provision of Fuel Efficiency in Light-Duty Vehicles (2010), https://www.rff.org/documents/1472/RFF-DP-10-60.pdf.

179 See id. at 3 (explaining that "the largest four firms accounted for 75.5 percent of the value of shipments in the automobile market and 95.7 percent of the light-duty and utility vehicle market"); Nat'l Acad. of Scis., Assessment of Technologies for Improving Light-Duty Vehicle Fuel Economy—2025–2035 at 11-356 (2021) (citing that the top ten firms accounted for 90% of light-duty sales in 2018); see also Winston Harrington & Alan Krupnick, Res. for the Future, Improving Fuel Economy in Heavy-Duty Vehicles (2012), https://media.rff.org/documents/RFF-DP-12- 02.pdf (explaining that the heavy-duty trucking industry "is dominated by a small number of large manufacturers" and is even smaller than it would seem at first glance because of "affiliations, partnerships, and outright ownership of one company by another").

2. EPA Should More Clearly State That Its Model's Constant- Performance Assumption Obviates the Need to Estimate Lost Consumer Welfare

As in prior rules, EPA assumes when modeling the Proposed Rule that manufacturers will incur any additional costs necessary to hold vehicle performance constant. While EPA highlighted this fact in the 2021 RIA,180 it should strongly conclude that the constant-performance assumption built into OMEGA obviates the need to estimate any potential lost consumer welfare from forgone attributes. The reason for this is straightforward: Because EPA already models the costs of maintaining vehicle performance, any alleged reductions in vehicle performance resulting from the Proposed Rule would be offset by a reduction in compliance cost relative to EPA's projection. In effect, therefore, EPA's analysis already accounts for the cost of any possible efficiency-performance tradeoffs through its projection of compliance costs. [EPA-HQ-OAR-2022-0829-0601, pp. 25-27]

180 2021 RIA at 8-3.

Thus, while EPA sensibly concludes that "the presence of fuel-saving technologies do not lead to adverse effects on other vehicle attributes,"181 it should more forcefully assert that this conclusion does not increase its estimate of net benefits. [EPA-HQ-OAR-2022-0829-0601, pp. 27-29]

181 RIA at 4-38; see also Davis Noll et al., supra note 155, at 32–33 (discussing how “many fuel economy technologies actually improve various performance attributes”).

C. EPA Should Reaffirm the Continued Relevance of the Energy Efficiency Gap, Particularly With Respect to Electric Vehicles, and Remove Confusing Language that Could Be Read to Suggest the Opposite

While EPA supports the energy efficiency gap in the Proposed Rule and RIA, it also makes some confusing statements that could be read to suggest that the gap may be inapplicable to electric vehicles,182 that it has become very small for ICE vehicles,183 or even to question the energy efficiency gap’s existence.184 If EPA does not intend these suggestions and instead means only that a narrow subset of market failures are becoming less impactful, it should clarify its confusing statements. Insofar as EPA intends to suggest that the energy efficiency gap may not apply to electric vehicles, it should rethink these claims. For the reasons explained below, EPA should strongly reaffirm the continued existence and relevance of the energy efficiency gap. [EPA-HQ-OAR-2022-0829-0601, pp. 27-29]

182 Proposed Rule, 88 Fed. Reg. at 29,397 (stating that “it becomes less and less of an issue with the growing share of electric vehicles in the market, and changes in vehicle attributes due to the new technology are clearer”); RIA at 4-40 (similar).

183 Proposed Rule, 88 Fed. Reg. at 29,397 (“[T]here may still exist a slight gap in ICE vehicle purchases due to this uncertainty ”); RIA at 4-40 (“[T]he availability of more fuel efficient vehicles has increased steadily over time, thus narrowing or closing the energy efficiency gap [A] slight gap in ICE vehicle purchases may still exist due to uncertainty surrounding new fuel savings technologies ”).

184 Proposed Rule, 88 Fed. Reg. at 29,397 (describing “uncertainty surrounding the existence or reason behind the energy efficiency gap”). EPA also states that the energy efficiency gap “may still exist,” implying that it may not. Id.; RIA at 4-38, 4-40.

EPA’s problematic statements reference the “invisibility” explanation for the energy efficiency gap—i.e., that “the mainstream consumer would [not] know about” certain fuel-efficient technologies when selecting between vehicles.185 The agency seems to hypothesize that this explanation does not apply to electric vehicles, whose fuel efficiency is more salient.186 However, consumer salience effects should also apply strongly to electric vehicles since consumers often pay their electricity bills automatically (and with a time delay) and therefore may not be aware of how much they can save on fuel costs.187 And, as EPA acknowledges, the energy efficiency gap is caused by a variety of market failures.188 Many of these market failures would not be cured by increased visibility; rather, electric vehicles may exacerbate some market failures that contribute to the energy efficiency gap. For instance, network externalities apply especially strongly to electric vehicles as consumers may be reluctant to purchase electric vehicles until adequate charging and maintenance infrastructure is available. A study finding that homeowners—who have greater incentive to invest in charging infrastructure than more transient home renters189—purchase electric vehicles at a far higher rate supports this hypothesis.190 And as discussed above, research on dealership biases, incentives, and information asymmetries often pertains to electric vehicles.191 [EPA-HQ-OAR-2022-0829-0601, pp. 27-29]

185 Proposed Rule, 88 Fed. Reg. at 29,397; see also RIA at 4-40.

186 Id. at 29,397; RIA at 4-39.

187 Laura Abrardi, Behavioral Barriers and the Energy Efficiency Gap: A Survey of the Literature, 46 J. INDUS. & BUS. ECON. 25 (2019).

188 RIA at 4-39 to -40 ("In fact, the gap likely exists due to a combination of consumer- and producer-side characteristics.").

189 Numerous studies point to a homeowner-tenant agency problem, also known as the split incentives, in residential rental markets whereby landlords fail to sufficiently invest in energy efficiency because their tenants (rather than the landlords themselves) will realize the monetary savings. See, e.g., Jesse Melvin, The Split Incentives Energy Efficiency Problem: Evidence of Underinvestment by Landlords, 115 ENERGY POLICY 342 (2018).

190 Lucas W. Davis, Evidence of a Homeowner-Renter Gap for Electric Vehicles, 26 APP. ECON. LTRS. 927 (2019) (recognizing evidence that "automatic billing increases residential electricity consumption by 4–6%")

191 See supra notes 165–169 and accompanying text.

On the producer side, too, market failures that contribute to the energy efficiency gap apply strongly to electric vehicles.192 For instance, the first-mover disadvantage may be especially prominent for electric vehicles because early movers for electric vehicles must pay to educate consumers about their product.193 Indeed, in the same paragraph where EPA appears to suggest that the energy efficiency gap "becomes less of an issue with the increasing prevalence of BEVs in the market," EPA also states that "the share of [plug-in electric vehicles] in the marketplace is, at least partially, constrained due to the lack of offerings."194 [EPA-HQ-OAR-2022-0829-0601, pp. 27-29]

192 See RIA at 4-40.

193 Todd D. Gerarden et al., Assessing the Energy-Efficiency Gap, 55 J. ECON. LIT. 1486, 1492–93 (2017).

194 RIA at 4-40.

Because many of the justifications for the energy efficiency gap apply to electric vehicles, it is implausible to suggest that this phenomenon will dissipate as electric vehicles become more prevalent. In fact, the Department of Energy has consistently recognized evidence that "consumers undervalue future energy savings" from more efficient electrified appliances, including because of "excessive focus on the short term."195 Likewise, numerous economic studies confirm that the energy efficiency gap applies to electrical appliances.196 [EPA-HQ-OAR-2022-0829-0601, pp. 27-29]

195 Energy Conservation Program: Energy Conservation Standards for Room Air Conditioners, 88 Fed. Reg. 34,298, 34,352 (May 26, 2023).

196 E.g. Gerarden et al., supra note 193, at 1515; Francois Cohen et al., Consumer Myopia, Imperfect Competition and the Energy Efficiency Gap: Evidence from the UK Refrigerator Market, 93 EUR. ECON. REV. 1 (2017); Shigeru Matsumoto, Consumer Valuation of Energy-Saving Features of Residential Air Conditioners With Hedonic and Choice Models, 55 EMPIRICAL ECON. 1779 (2018); Jiaxing Wang et al., Determinations of Household Energy Efficiency Investment: Analysis of Refrigerator Purchasing Behavior, 13 INT'L J. ECON. POL'Y STUDS. 389 (2018).

Regarding ICE vehicles, EPA does not cite any evidence that would justify this seeming break from its prior analyses regarding the significance of the energy efficiency gap.197 To the contrary, most or all of the theoretical explanations for the energy efficiency gap still hold. EPA should therefore delete these unsubstantiated and stray statements regarding the energy efficiency gap and ICE vehicles, or at least provide a balanced literature review. [EPA-HQ-OAR-2022-0829-0601, pp. 27-29]

197 See RIA at 4-40.

Organization: National Automobile Dealers Association (NADA)

1. EPA's Use of a Cost-of-Ownership Payback Analysis Is Flawed and Problematic.

EPA correctly acknowledges that under its proposed standards "the average purchase price of vehicles is estimated to be higher," which it attributes to an anticipated larger share of EVs in the market. However, its assertion that lower EV operating costs and IRA purchase incentives will offset these higher up-front costs is unsound.34 As NADA has explained previously, for most prospective new vehicle purchasers, using a total cost of ownership (TCO) "payback" cost/benefit analysis is flawed and problematic for several reasons. [EPA-HQ-OAR-2022-0829-0656, pp. 7-8]

34 88 Fed. Reg. at 29201, 29328-29, 29344, 29364.

First, consumers shopping for vehicles with better fuel economy35 must be willing and able to pay for it. As noted above, 67 percent of Americans presently cannot afford any new vehicle. And of the 33 percent who can, high interest rates are driving many of them out of the market. NADA takes issue with EPA's projections that its proposal will result in only a small change in total new light-duty vehicle sales and no change in new medium-duty vehicle sales. NADA's projections differ significantly, showing vehicle sales declines corresponding with the higher vehicle costs attributable to EPA's proposed standards. [EPA-HQ-OAR-2022-0829-0656, pp. 7-8]

35 For at least two practical reasons, improved fuel economy performance is a surrogate for better emissions performance. First, strategies for improving a vehicle's fuel economy often result in improved emissions performance, especially with respect to GHGs. Second, while some prospective purchasers seek and are willing to pay for improved fuel economy performance, few seek and are willing to pay for improved emissions performance.

Second, consumer demand for fuel efficiency fluctuates with fuel prices. Prospective purchasers form expectations of the net present value of future fuel savings that are related, but not closely related, to a standardized financial calculation.36 During dramatic upward fuel price swings followed by heavy media coverage, consumers place a large value on fuel economy, as revealed by shifts in demand to more fuel-efficient segments of the market. But during slow and steady increases in the price of liquid fuels with little or no media attention, consumer demand reveals a diminished value for fuel economy. [EPA-HQ-OAR-2022-0829-0656, pp. 7-8]

36 See Exhibit B, Walton & Drake, Willingness to Pay for MY 2025 Fuel Economy Mandates: Government Estimates v. Economic Reality, February 2012.

Third, a consumer's willingness to purchase improved fuel economy must be viewed in the context of other vehicle attributes. When assessing the value of fuel economy improvements to prospective purchasers, the financial benefits of future fuel savings cannot be separated from the utility lost by necessary reductions to other vehicle qualities and performance. A study released earlier this year examined the tradeoff between fuel economy and vehicle performance in connection with NHTSA's most recent round of fuel economy mandates.37 It found evidence that consumers and OEMs undervalued fuel economy compared to the predictions of a rational-choice model. However, it also found that fuel economy mandates resulted in foregone performance, upon which consumers placed a value approximately equal to that of any fuel-savings benefits resulting from the standards. And it found that models attempting to assess the new vehicle buying public's willingness to purchase fuel economy, without controlling for performance tradeoffs, likely suffered from omitted variables bias. [EPA-HQ-OAR-2022-0829-0656, p. 8]

37 Leard, Linn, Zhou; How Much Do Consumers Value Fuel Economy and Performance? Evidence from Technology Adoption, The Review of Economics and Statistics (2023); 105(1), 158-74.

EPA assumes that consumers value any fuel savings associated with new vehicle purchases over a 30-month period (at most) but suggests erroneously that there is no consensus regarding how consumers value fuel efficiency. EPA also made no real attempt to assess how new light-duty vehicle consumers actually value emissions reduction/fuel economy technology when making purchase decisions.38 Instead, EPA made reference to a so-called "energy efficiency gap" and asserted that the issue will become less relevant as the share of EVs in the market increases.39 But the aforementioned study suggests that the proper approach for setting fuel economy mandates designed to maximize the achievement of regulatory objectives is to control for consumer willingness to purchase changes in both a vehicle's performance and fuel economy. EPA's failure to do so undermines its ability to set emissions reduction mandates premised on realistic and accurate conclusions. [EPA-HQ-OAR-2022-0829-0656, p. 8]

39 88 Fed. Reg. at 29397.

EPA Summary and Response

Summary:

The Institute for Policy Integrity at New York University School of Law (IPI) commented on EPA's energy efficiency gap discussion, stating that there is less analysis in this rule than provided in previous rules, and suggesting that EPA affirm the continued relevance of this topic to EV technology. IPI stated that EPA should offer more detail on how the presence of fuel saving technology does not lead to adverse effects on other vehicle attributes, or how compliance costs would have to be revised downward without the inclusion of this constant performance assumption. They stated that EPA should clearly state that the presence of fuel saving technology not leading to adverse effects on other attributes does not increase the estimate of net benefits because any possible efficiency-performance tradeoffs are accounted for in the projection of compliance costs, and therefore obviates the need to estimate potential lost consumer welfare from foregone attributes.

IPI also outlined additional market failure factors contribute to the energy efficiency gap, including dealership incentives, biases and information asymmetries, institutional myopia, and manufacturer market power. They commented that dealership incentive, biases and information asymmetries are clear in reports from consumers, or researcher posing as consumers, who complain about poor experiences when trying to purchase and electric vehicles at the dealership. They commented that, in addition to consumer myopia, we should discuss institutional myopia, where businesses may have an incentive to favor short-term profits over long-term investments. IPI stated that there is limited competition in some vehicle market segments, leading manufacturers with market power to implement strategic choices in pricing and vehicle attribute offerings, which can influence purchase choice across several vehicle classifications including EVs.

NADA commented that EPA's assumption that lower operating costs and purchase incentives will offset higher upfront costs is unsound. NADA commented that EPA's use of a cost-of-ownership payback analysis is flawed and problematic for three reasons: 1) people must still be willing to pay for any improvements to fuel economy and with the high prices and interest rates today, many consumers cannot afford new vehicles; 2) demand for fuel economy tracks fuel prices and the media attention surrounding those prices; and, 3) prospective purchasers weigh future fuel savings against reductions in other vehicle qualities and performance. NADA references a recent study finding that there is a tradeoff between fuel economy and vehicle performance. NADA also commented that EPA's assessment that there is not a consensus on how consumers value fuel efficiency is "erroneous", and that EPA did not attempt to assess this value. The commenter stated that failing to control for consumer willingness to purchase changes in both vehicle performance as well as fuel economy undermines the conclusions reached in the analysis of the rule.

Response:

As seen in Section VIII.K.1 of the preamble, and RIA Chapter 4.4, we have updated the discussion of the energy efficiency gap to be clearer on its continued relevance, including that the energy efficiency gap discussion applies to both ICE technology and other fuel saving technology, including PEVs. In the preamble discussion, we clearly refer to previous EPA light-duty vehicle regulations and the included, extensive, discussions included in them. In addition, we have added language indicating that some hypotheses presented as likely reasons for the existence of the energy efficiency gap, including myopia and asymmetric information, could apply to both consumers, producers, and dealerships.

Regarding NADA's comments about consumer demand for fuel economy, EPA agrees that fuel economy is an important purchasing criteria for many consumers, and consumers buy what they can afford. EPA agrees that affordability is an important consideration in vehicle purchases and ownership. We do, however, note that affordability is only one criterion among many that influences consumers' vehicle choice, new or used. We address consumer demand and affordability comments further in Chapter 13 of this RTC. In addition, though NADA asserts that the there is consensus in the literature regarding consumer valuation of fuel efficiency, they only point to one paper on the subject. However, as discussed in RIA Chapter 4.4, there is a much broader range of literature. The paper the commenter points to indicates that there is a tradeoff between fuel economy and vehicle performance. However, as also discussed in that RIA chapter, we provide evidence that this tradeoff may not actually be happening. That is to say, we do not observe that vehicles with higher fuel economy and lower GHG emissions are otherwise worse performing vehicles. In some cases, GHG emissions performance and fuel efficiency are improving alongside other aspects of vehicle performance. Regarding NADA's comments disagreeing with the sales impacts estimates of this rule, see RTC Section 14, as well as RIA Chapter 4.4.

Regarding comments about accounting for performance, we note we model constant performance, which obviates the need to estimate potential lost consumer welfare from foregone attributes. Regarding comments about fuel economy being accounted for in our modeling, we note that fuel economy is included through the inclusion of 2.5 years of fuel savings in the consumer decision making modeling. These are discussed in Chapter 4.4 of the RIA.

Regarding NADA's comments regarding sales, we acknowledge NADA's statement that their estimates differ from EPA's, and we acknowledge that NADA attributes their estimates to "higher vehicle costs attributable to EPA's proposed standards." In response, we note that while EPA's estimates of vehicle technology costs (See RIA Chapter 9) may indeed translate into higher upfront purchase costs for consumers, we also estimate that such upfront purchase costs would be more than offset over time with operating cost savings (See RIA Chapter 4). We also note the considerable benefits that the IRA tax credits provide to purchasers of new PEVs. In addition, we note that NADA is unclear on how it estimates these sales impacts, however EPA's OMEGA model estimates sales impacts using an interaction between consumer purchase decisions and producer production decisions as described in RIA Chapter 4.4. We also note that, as discussed in RIA Chapter 2.6 and shown in RIA Chapter 4.3, cost estimates have been updated from the proposal, and therefore, the final sales impacts for this rule have as well. These final sales impacts show minor decreases in sales across MYs 2027 – 2032 and are shown in Chapter 4.4.2 of the RIA.

15 - PEV supply chain, critical minerals, and mineral security

15.1 - General

Comments by Organizations

Organization: 25x'25 Alliance, et al.

First, there are no established supply chains capable of supplying the raw materials to manufacture the millions of vehicles needed—just over the next decade—to supply the projected market. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

Organization: Alliance for Automotive Innovation

Beyond BEV affordability, success of this regulation will be determined by factors outside of the vehicle; the U.S. is sorely behind in this effort (despite over the $150 billion of private sector investment thus far) and the NPRM does little to address these factors. Current charging and fueling infrastructure is inadequate (particularly residential charging), the grid resources are at least 5 to 10 years away (without even factoring in the additional demand for grid resources from the heavy-duty vehicle sector facing similar concerns in a concurrent EPA rulemaking6), and battery critical minerals (except lithium), which primarily determine the affordability and availability of EVs, are minimally addressed in the NPRM. [EPA-HQ-OAR-2022-0829-0701, pp. 4-5]

6 U.S. Environmental Protection Agency, Proposed Rule: Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3 (for Model Years 2027-2032), 88 Fed. Reg. 25,926 (Ap. 27, 2023). Hereinafter "EPA HD GHG NPRM)."

No requirements to support required EVs or the drivers that must buy them [EPA-HQ-OAR-2022-0829-0701, p. 5]

The NPRM and all the requirements set forth to date focus solely on the sale of BEVs. They propose no requirements to ensure that infrastructure will be available at homes, businesses, public event venues, highway corridors, transportation hubs, or other public locations. They contain no requirements to provide hydrogen or hydrogen fueling stations, or for utilities to quickly bring reasonably priced high-power charging (5-20 megawats (MW)) to highway service plazas, fleet locations, city centers, or transportation hubs. They do not address the need for battery critical minerals to power everything from light-, medium-, and heavy-duty vehicles, energy storage systems (ESS), lawn and garden equipment, laptops, cell phones, forklitis, and airport services—not just in the United States, but around the world. [EPA-HQ-OAR-2022-0829-0701, p. 5]

To support the vehicle requirements proposed, all these changes are necessary in under 10 years. For perspective, 10 years is the time required to obtain the necessary permits for a mine in the United States. Once permitted, another ten years could elapse before the mine produces at capacity. Ten years is also close to the time required to bring 20 MWs of power to a single location in the United States. Consequently, to the extent we need critical minerals and high-power charging, we must start today. Yet, there is no plan to do so. There is no roadmap to developing these essential pieces necessary for the transformation. Nor is there a commitment from EPA for ongoing monitoring of these factors as the EV market develops over the duration of EPA's proposed standards. [EPA-HQ-OAR-2022-0829-0701, p. 5]

D. Benchmark Minerals Intelligence - U.S. Electric Vehicle Feasibility Study for Auto Innovators

Achieving the EV market share EPA projects in support of its proposed light-duty GHG and criteria pollutant standards will require massive investments in the EV supply chain from cell manufacturing upstream to active material manufacturing, mineral processing, and mineral extraction. In assessing this nascent supply chain, EPA limits itself to only light-duty vehicle cell demand and the potential for the U.S. to satisfy its lithium needs. Its assessment is also limited to only battery electric vehicles, ignoring PHEVs as both a technology option and their impact on EV supply chains. EPA's analysis falls short of what is needed to justify such a transformational rule on an abbreviated timeline relative to the 40-50% EV market share in 2030 that automakers already feel is an aspirational target. [EPA-HQ-OAR-2022-0829-0701, p. 33]

A more robust analysis of the EV supply chain would include: [EPA-HQ-OAR-2022-0829-0701, p. 33]

- U.S. and global Li-ion battery demand across multiple transportation sector segments (e.g., including medium- and heavy-duty vehicles) and other product sectors (e.g., portable devices and stationary energy storage systems). [EPA-HQ-OAR-2022-0829-0701, p. 33]

- Analysis of nickel, cobalt, and graphite supplies and processing in addition to lithium. [EPA-HQ-OAR-2022-0829-0701, p. 33]

- An assessment of U.S. light-duty vehicle automakers' ability to access the necessary manufacturing capacity and raw and processed material supplies both in general, and in the context of IRA 30D-compliant materials that are presumed to be available to eligible taxpayers. [EPA-HQ-OAR-2022-0829-0701, p. 33]

All of these analyses would be done in a manner that includes the time necessary to permit, construct, and start operation of new manufacturing (cell and active materials), chemical processing, and mineral extraction facilities, including their ramp-up to nameplate capacity, and level of risk given their current phase of investment, construction, and other considerations. This level of assessment is particularly important given the timeline that EPA proposes for regulations that, once finalized, cover a timeframe that is two to seven model years away. [EPA-HQ-OAR-2022-0829-0701, p. 33]

Given the broad scale of analysis and level of expertise needed for a more robust assessment, Auto Innovators engaged Benchmark Minerals Intelligence (BMI) to develop a study of U.S. EV feasibility. Benchmark Minerals Intelligence is a well-known, respected consultant in the area of Li-ion battery supply chains from the materials extraction to cell production stage. [EPA-HQ-OAR-2022-0829-0701, pp. 33-34]

The resultant work product, a U.S. Electric Vehicle Feasibility Study37 (the "BMI Study," attached to these comments) addresses many of the shortcomings of EPA's efforts. The BMI Study presents the results of two scenarios – a base case defined as BMI's view of "the most likely demand scenario," and a policy case that assumes 50% U.S. light-duty EV market share (including PHEVs) in 203038 and 100% U.S. light-duty vehicle EV market share by 2035.39,40 The study also examines a "supply constrained" scenario to assess the potential limits of IRA-compliant materials. [EPA-HQ-OAR-2022-0829-0701, pp. 33-34]

37 Benchmark Minerals Intelligence (Q1, 2023), U.S. Electric Vehicle Feasibility Study for Alliance for Automotive Innovation. Hereinafter "BMI Study."

38 I.e., consistent with the Executive Order 14037 and The U.S. National Blueprint for Transportation Decarbonization.

39 BMI Study at 3.

40 The BMI Study explores risks to U.S. light-duty vehicle policy objectives in isolation from the additional U.S. heavy-duty vehicle electrification objectives. (BMI Study at 25.) Auto Innovators believes that inclusion of those heavy-duty vehicle objectives would further increase the overall level of risk described in the BMI Study.

The BMI Study attempts to answer two core questions: (1) What is the feasibility of achieving the two demand scenarios with global supply chains; and (2) What is the feasibility of achieving these two scenarios in a manner that is compliant with the IRA 30D sourcing requirements? BMI assesses these scenarios in the context of a growing global, multi-sector demand for Li-ion batteries. The BMI Study spans the supply chain from raw material extraction and processing (including lithium, nickel, cobalt, and graphite) to active electrode material manufacturing to cell manufacturing. [EPA-HQ-OAR-2022-0829-0701, pp. 33-34]

1. Comparing the BMI Study's Li-Ion Battery Demand to EPA's Projections

As shown in Figures 5 and 6, EPA's proposal exceeds both of the scenarios studied by BMI. In 2032, the EPA-projected Li-ion battery cell demand to meet its proposed standards is nearly double that of the BMI Study's base case. EPA's projected demand is 21% higher in 2032 than that studied by BMI in its policy case. To the extent that the BMI study expresses concerns with the Li-ion battery supply chain, such concerns would only become greater given EPA's projected battery demand. Similarly, BMI's assessment of needed investments would also be expected to increase under a scenario aligned to that of EPA's. Where the BMI Study finds adequate capacity under its scenarios, additional work would be required to assess if supply is adequate under the higher EPA-projected demand. [EPA-HQ-OAR-2022-0829-0701, pp. 34-35]

[See original comment for Figure 5: EPA-projected Li-ion battery demand (GWh) vs. BMI Study base case projections.41] [EPA-HQ-OAR-2022-0829-0701, pp. 34-35]

[See original comment for Figure 6: EPA-projected Li-ion battery demand (GWh) vs. BMI Study policy case projections.42] [EPA-HQ-OAR-2022-0829-0701, pp. 34-35]

42 Id.

2. Results

BMI summarizes U.S. battery supply chain risks in its base case (i.e., demand much lower than EPA's projections) across the Li-ion battery value chains as shown in Figure 7. The first row of data presents the absolute gap between base case demand and supply from the U.S. plus 50% of supply from free trade agreement countries (i.e., an approximation of potentially IRA 30D- compliant supply). The second row shows the relative (percentage) gap to the U.S. / 50% FTA supply. The final row of data responds to the broader question of the risk associated with meeting even base case demand through global supplies. [EPA-HQ-OAR-2022-0829-0701, p. 36]

BMI's assessment suggests that it is unlikely that U.S. and free trade agreement country supply chains will fully satisfy IRA 30D sourcing requirements with most of the supply chain at high risk, including cobalt, nickel, graphite, and anode active material supply. There is some risk to meeting base case demand (about half of EPA's projected demand) even with global supply chains. It is also worthwhile to note that the only raw material that EPA analyzed, lithium, is the only raw material not considered by BMI as a medium or high risk. [EPA-HQ-OAR-2022-0829-0701, p. 36]

[See original comment for Figure 7: Benchmark Minerals Intelligence of U.S. battery value chain supply risks in its base (current OEM plans) case.] [EPA-HQ-OAR-2022-0829-0701, p. 36]

Other take-aways from the BMI Study include: [EPA-HQ-OAR-2022-0829-0701, pp. 37-38]

- "Chinese suppliers dominate many of the constituent stages of the LiB supply chain, currently engaged in >50% of global capacity, a fact that potentially circumscribes IRA-compliant sourcing options for U.S. cell makers and OEMs."43 [EPA-HQ-OAR-2022-0829-0701, pp. 37-38]

- "Resulting from the extreme concentration of anode value chain manufacturing in China [EPA-HQ-OAR-2022-0829-0701, pp. 37-38]

– measuring >60% global capacity from mine to anode – removal of compliant Chinese supply will restrict the application of Clean Vehicle Credits under Section 30D beyond 2025.

This represents the most critical bottleneck for U.S. battery supply."44 [EPA-HQ-OAR-2022-0829-0701, pp. 37-38]

- "As a consequence of the availability of compliant anode active materials, the "supply constrained" scenario demonstrates U.S. battery cell manufacturing and ZEV objectives are potentially limited to 15% passenger EV penetration by 2030 vs. a policy driven target of 50% for the same year."45 [EPA-HQ-OAR-2022-0829-0701, pp. 37-38]

- "Immediate action is necessary due to the inelastic supply response from elements of the upstream, with lead times for new critical mineral supply extending 5 – 15-years in many jurisdictions while adhering to minimum Western ESG standards." 46 [EPA-HQ-OAR-2022-0829-0701, pp. 37-38]

- ". . . [Anode active material] stands out as a section of the supply chain where deficits could prove more resilient, even in the face of IRA incentives." [EPA-HQ-OAR-2022-0829-0701, pp. 37-38]

- According to BMI, IRA 30D-compliant cathode active material is also at risk without significant immediate investments in the U.S. and/or free trade agreement countries. "Security of supply via 50% FTA volumes offers some near-term respite for U.S. procurement . . . Expanding to the 'policy driven' demand scenario, additional FTA supply would only support the U.S. market until 2025 before falling short, requiring sustained IRA-compliant capital investment and proactive purchasing strategies."47 [EPA-HQ-OAR-2022-0829-0701, pp. 37-38]

- "Scale imports of Chinese [active anode material] will likely be necessary in the near- and medium-term, limiting the application or IRA-derived tax credits from Section 30D. [A]node battery components face sustained structural shortages of units under both the 'base case' and 'policy driven' demand scenarios throughout the modelling period. There is a 74% supply/demand shortfall in 2032 under the high case 'policy driven' despite relying on 50% FTA material deliveries."48 [EPA-HQ-OAR-2022-0829-0701, pp. 37-38]

43 BMI Study at 2. (Emphasis added.)

44 BMI Study at 2. (Emphasis added.)

45 BMI Study at 2. (Emphasis added.)

46 BMI Study at 2.

47 BMI Study at 6.

48 BMI Study at 8.

- Regarding lithium, "Competing requirements from Europe and first-mover advantages from Chinese capital has already secured significant volumes of FTA materials, potentially limiting the availability of unallocated IRA-compliant lithium chemicals for North America."49 "While evidence is growing for direct OEM procurement strategies. there is development risk associated with new capacity."50 [EPA-HQ-OAR-2022-0829-0701, p. 38]

- Regarding nickel, "The USA is limited as it currently produces zero domestic nickel sulphate needed to sustain the growth of its battery value chain; the USA is entirely reliant on imports . . . [S]ourcing primarily from Canada and Australia presents challenges due to allocated volumes in legacy markets. The U.S. nickel sulphate balance is forecast to remain in structural negative balance into the next decade.” [EPA-HQ-OAR-2022-0829-0701, p. 38]

- “[T]he absolute volume of cobalt required to sustain the U.S. growth remains on an upward trajectory . . . [D]omestic and FTA sourcing yields limited compliant volumes . .. [W]ithout immediate capital allocation, there are sustained challenges for alternative sourcing to incumbent Chinese cobalt refining.” [EPA-HQ-OAR-2022-0829-0701, p. 38]

- “U.S. domestic occurrence and output of natural flake graphite is extremely limited . . . Additionally, the availability of IRA-compliant FTA sources are also restricted . . . In the near-term fundamental supply will need to originate from China to meet U.S. base case demand through 2025 . . . [A]lmost 100% of spherical graphite (SPG) processing [is] currently controlled by the FEOC nation . . . IRA credits offer major incentives for SPG processing capacity localised in domestic or FTA regions, although the challenge remains to connect the upstream feedstock in sufficient volumes to maintain utilisation, especially given the extended lead times . . . Despite the encouragement from IRA credits, a strong business case needs to be defined for greenfield production.”51 [EPA-HQ-OAR-2022-0829-0701, p. 38]

- “Common to the critical minerals theme, the structural shortfall of domestic and FTA synthetic graphite output is forecast to be sustained throughout the forecast period, creating a high reliance of imported volumes. While the U.S. is responsible for petroleum coke processing, the value-add graphitization is predominantly associated with China due to the incredible energy requirements for the process (requiring sustained temperatures of 2800-3000°C) . . . The concentration of manufacturing in China therefore presents the most substantial IRA bottleneck in the expansion of U.S. ZEV penetration across the entire battery value chain . . . [O]utsized capital is required in expanding greenfield production capabilities.”52 [EPA-HQ-OAR-2022-0829-0701, pp. 38-39]

- “Expanding the U.S. battery value chain is a critical assignment to draw resilience and competitiveness against the currently established Asian-centric output and optimize the Western transition to a low-carbon economy . . . [M]aping the capacity plans against the operational reality will be challenging without sufficient maturity of [IRA] compliant supply chains from the upstream critical minerals . . . [E]xploring the ‘policy driven’ demand scenario, the U.S. market remains exposed to foreign imports (predominantly from China) to meet domestic EV penetration objectives . . . [E]vidence demonstrates structural shortialls of the entire battery suite, originating from the diffierential lead times to established greenfield, qualified battery-purity material supply.”53 [EPA-HQ-OAR-2022-0829-0701, pp. 38-39]

- “The cumulative global battery industry is forecast to top 1TWh during 2023, swelling to approximately 3.6TWh by 2030 and to 7.8TWh by 2040. The evolution will place major pressure on critical minerals supply. Alignment to U.S. EV penetration objectives under the “policy driven” scenario generates significantly greater global lithium-ion battery demand by 2040 (19% higher in GWh-equivalent terms), with a corollary requirement for additional raw materials.”54 [EPA-HQ-OAR-2022-0829-0701, pp. 38-39]

- “Based on BMI’s current view of existing and planned AAM capacity, Chinese supply could account for almost 90% of the global total by 2030.”55 [EPA-HQ-OAR-2022-0829-0701, pp. 38-39]

3. Recommendation

Based on the results of the BMI Study, Auto Innovators recommends that EPA expand its analysis to critical minerals beyond lithium, that EPA consider cathode and anode active material manufacturing in addition to cell manufacturing, and that EPA reconsider its overly optimistic assumptions for the number of vehicles that will qualify for IRA 30D and 45X incentives. [EPA-HQ-OAR-2022-0829-0701, p. 39]

E. Additional Comments on Critical Minerals

1. Availability

Plug-in electric vehicles (PEVs), which include fully electric and plug-in hybrids, heavily rely on certain critical minerals, such as lithium, cobalt, nickel, and graphite, as well as rare earth elements. Meeting the increasing demand for these minerals raises concerns about responsible sourcing, environmental impacts, and geopolitical challenges. Ensuring a sustainable and ethical supply chain for critical minerals is crucial. [EPA-HQ-OAR-2022-0829-0701, pp. 40-41]

Demand for lithium-ion batteries in North America is forecast to increase nearly six times between 2022 and 2030, according to Benchmark Minerals Intelligence (BMI).56 BMI forecasts lack of upstream mining and midstream processing and cathode/anode production capacity to supply the new battery factories with the necessary battery materials.57 According to BMI, more than 300 new mines will need to be built over the next decade to satisfy critical mineral demand (Figure 8).58 [EPA-HQ-OAR-2022-0829-0701, pp. 40-41]

56 BMI Study at 23.

58 Benchmark Source, More than 300 new mines required to meet battery demand by 2035 (Sep. 6, 2022). Available at https://source.benchmarkminerals.com/article/more-than-300-new-mines-required-to-meet-battery- demand-by-2035. (Retrieved Jun. 30, 2023.)

[See original comment for Figure 8: Benchmark Minerals Intelligence infographic on mines needed to support demand for critical minerals] [EPA-HQ-OAR-2022-0829-0701, pp. 40-41]

Additionally, recycling will not be able to satisfy society's rising demand in the near term. The current small EV market share coupled with EV batteries' long lifespan (on average between 10- 20 years59) suggests that society will not likely be able to meet the rising demand for critical minerals through recycling. [EPA-HQ-OAR-2022-0829-0701, p. 42]

59 Moscaritolo, A. (2022, June 29). EV Batteries 101: Degradation, Lifespan, Warranties, and More. PCMAG. https://www.pcmag.com/news/ev-batteries-101-degradation-lifespan-warranties-and-more

EPA assumed a normal and predictable behavior of the critical minerals market that is instead experiencing exponential growth; EPA expects that growth to continue to develop smoothly. EPA took only a snapshot in time and smoothly forecasted out in what is expected to be a very unstable market as it continues to develop, without consideration of outside impacts. [EPA-HQ-OAR-2022-0829-0701, p. 42]

EPA has also stated that the potential for cost reductions of battery packs is supported by the EPA observation that analysts largely expect the price of lithium to stabilize at or near its historical low levels by the mid-2020s. Despite diverse geographic lithium development around the world, the role of China in the chemical conversion phase of manufacturing represents 61% global output in 2023 as the nation manufactures and sells large quantities of lithium hydroxide and lithium carbonate.60 Chinese lithium chemical company ownership is “forecast to maintain elevated levels around 70% by 2030, placing potentially challenging procurement conditions as determined by the final IRA definitions for ‘Foreign Entity of Concern.’”61 [EPA-HQ-OAR-2022-0829-0701, p. 42]

60 BMI Study at 41.

61 BMI Study at 21.

In the EPA analysis, the agency highlighted lithium availability and did not bother to look in depth at the other three critical materials needed for EVs. It just assumed that lithium was the bottleneck and biggest concern. Despite EPA’s belief that lithium supplies are adequate, there is growing concern with global supplies given planned EV production. Reuters highlights such concerns in a recent article covering the June 2023 Fastmarkets Lithium and Battery Raw Materials conference.62 [EPA-HQ-OAR-2022-0829-0701, pp. 42-43]

62 Ernest Scheyder, “Lithium producers warn global supplies may not meet electric vehicle demand,” Reuters (Jun. 22, 2023). Available at htps://www.reuters.com/markets/commodities/lithium-producers-warn-global-supplies-may-not-meet-electric-vehicle-demand-2023-06-22/. Retrieved June 26, 2023.

There were 45 lithium mines operating in the world last year, with 11 expected to open this year and seven next year, according to Fastmarkets. That pace is far below what consultants say is needed to ensure adequate global supply . . . Those growth projections assume a best-case-scenario, even as mining companies face difficulty hiring technical talent, rising costs and delay times for crucial equipment. [EPA-HQ-OAR-2022-0829-0701, pp. 42-43]

EPA acknowledged that there is a lack of diverse supply of graphite, describing that U.S. deposits of natural graphite exist, but graphite has not been produced in the U.S. since the 1950s. In addition, significant known resources are largely undeveloped.63 [EPA-HQ-OAR-2022-0829-0701, pp. 42-43]

63 NPRM at 389.

The U.S. does not produce any natural graphite; therefore, it must rely solely on imports to satisfy domestic demand. Nearly 60% of the world’s mined production last year came from China, making it a dominant player in every stage of the graphite supply chain. Almost all graphite processing today also takes place in China because of the ready availability of graphite supplies, weak environmental standards, and low costs.64 [EPA-HQ-OAR-2022-0829-0701, p. 43]

64 Adams, A. (2023). Report: A Global Race to the Top for Critical Minerals. SAFE. htps://secureenergy.org/a-global- race-to-the-top/

According to BMI, the liake graphite feedstock required for all uses in 2021 was just 1 million tons65. BMI estimates the graphite market is nearing an immediate deficit, with the supply shortfall growing to 8Mt by 2040. To fill this gap, the mining industry would need to produce nearly 8x as much graphite as it does currently over the next 18 years.66 [EPA-HQ-OAR-2022-0829-0701, p. 43]

65 (2022, July 22). Graphite deficit starting this year, as demand for EV battery anode ingredient exceeds supply. Mining.com. Retrieved June 10, 2023, from htps://www.mining.com/web/graphite-deficit-starting-this-year-as- demand-for-ev-battery-anode-ingredient-exceeds-supply/#:~:text=According%20to%20Benchmark%20Mineral%20Intelligence%20%28BMI%29%2C%20the%20flake, uses%20in%202021%2C%20was%20just%201%20million%20tonnes.

2. Country of Origin

China dominates minerals processing, processing anywhere from 60 to 100% of all the minerals needed for batteries and electric motors.67 Moreover, China has strategically invested in mineral deposits around the world. For example, Chinese-owned interests have developed vested partnerships in most of the world's lithium deposits, despite only having 8% of global lithium reserves. Chinese companies also control 15 of the 19 cobalt-producing mines in the Democratic Republic of the Congo (DRC).68 China's dominance in cobalt mine ownership allows it to have a major influence over the majority of the cobalt supply, despite having negligible resources of their own. Diversifying the critical mineral supply chains in this environment and competing on cost will be incredibly difficult. [EPA-HQ-OAR-2022-0829-0701, pp. 43-45]

67 Adams, A. (2023). Report: A Global Race to the Top for Critical Minerals. SAFE. htps://secureenergy.org/a-global- race-to-the-top/

68 Adams, A. (2023). Report: A Global Race to the Top for Critical Minerals. SAFE. htps://secureenergy.org/a-global- race-to-the-top/

The world's reliance on China for more than 80% of processing of minerals leaves all global automakers vulnerable to political pressure from China (Figure 9), which has a history of leveraging supply chains influences in times of conflict. Mines and related processing in the U.S. are undeveloped, and new permitting can take as long as ten years, yet EPA's proposed requirements for 67% BEVs by 2032 are less than eight model years away. [EPA-HQ-OAR-2022-0829-0701, pp. 43-45]

Figure 9: Key Mineral Reserves, Mine Production and Processing, 2022 [EPA-HQ-OAR-2022-0829-0701, pp. 43-45]

Source: Adams, A. (2023). Report: A Global Race to the Top for Critical Minerals. SAFE. htps://secureenergy.org/a-global-race-to-the-top/ [EPA-HQ-OAR-2022-0829-0701, pp. 43-45]

"Two-thirds of forecasted lithium chemical production in 2030 will be owned by Chinese companies, despite just half of production taking place in the country in the same year, according to Benchmark's Lithium Forecast. Second to China is the U.S., with companies from the country forecast to own 17% of lithium chemical production at the end of the decade.” 69 The lithium supply will need to double again to reach two million tons of lithium carbonate equivalent demand as soon as 2027, BMI forecasts.70 Annual growth in lithium supply will ease in 2024 to 27%, fading to single figures by 2028.71 This is before prolonged market deficit sets in from 2029 until at least 2040, according to Benchmark’s base forecast.72 [EPA-HQ-OAR-2022-0829-0701, pp. 43-45]

3. Mining/Processing

Not only does China possess an advantage for every critical mineral required for EVs, but as shown in Figure 10, it also dominates critical minerals mining, processing, active material and other component production, and battery cell production. While U.S. officials have begun negotiating agreements with other countries to expand access to important needed minerals, it remains unclear which of these partnerships will succeed, or if they will be able to generate anything close to the supply of minerals and components auto manufacturers are projected to need. [EPA-HQ-OAR-2022-0829-0701, pp. 45-46]

Mining is subject to supply/demand economics. If material prices drop, U.S. mines will not be built. For example, a U.S. cobalt mine was permitted, but stopped construction claiming the minimum price of cobalt needs to be $25 per pound to continue construction.73 Such events have implications for both the availability of U.S. / FTA supplies of critical minerals and the global prices of critical minerals. [EPA-HQ-OAR-2022-0829-0701, pp. 45-46]

73 E&E News: Biden is scrambling for minerals. This U.S. cobalt mine just closed. (2023, May 12). https://subscriber.politicopro.com/article/eenews/2023/05/12/biden-is-scrambling-for-minerals-this-u-s-cobalt- mine-just-closed-00096440

EPA acknowledges that about 72% of U.S. cobalt consumption is imported,74 with nearly 70% of cobalt originating from the Democratic Republic of Congo, some significant production in Russia and Australia, and about 20% in the rest of the world.75 [EPA-HQ-OAR-2022-0829-0701, pp. 45-46]

74 NPRM at 29314.

75 NPRM at 29314.

Figure 10: China's Percent of Supply Across the Lithium Ion Battery Value Chain, 202276 [EPA-HQ-OAR-2022-0829-0701, pp. 45-46]

76 Benchmark Minerals Intelligence Q4 2022 Review at 41.

Because China controls all spherical graphite processing, the U.S. is completely dependent on its battery-grade graphite from China. This is why the U.S. government has included graphite among the 35 minerals that it deems critical to its national security and economy. A White House report on critical supply chains showed that graphite demand for clean energy applications will require 25 times more graphite by 2040 than was produced worldwide in 2020. [EPA-HQ-OAR-2022-0829-0701, pp. 46-47]

The Inflation Reduction Act requires 50% (and 100% by 2029) of the battery components to be manufactured in North America to qualify for a portion of the 30D tax credit. However, in 2030, BMI forecasts North America will only be able to domestically fulfill 3.5% and 3.4% of its domestic cathode and anode demands, respectiully (see Figure 11).77 [EPA-HQ-OAR-2022-0829-0701, pp. 46-47]

77 Benchmark Minerals Intelligence (2022, November 17). Can North America build a battery supply chain? Benchmarkminerals.com. Retrieved June 10, 2023, from htps://source.benchmarkminerals.com/article/can-north- america-build-a-battery-supply-chain.

Figure 11: Global Battery Component Supply by Source [EPA-HQ-OAR-2022-0829-0701, pp. 46-47]

While there are five cathode facilities between the U.S. (4) and Canada (1), they are not at commercial scale yet. Even with additional facilities set to come online through the decade, North America's cathode production deficit is forecast to increase 3.5 times between now and 2030.78 [EPA-HQ-OAR-2022-0829-0701, pp. 46-47]

78 "Can North America Build A Battery Supply Chain?," Benchmark Minerals Intelligence, 11/17/22

Currently, China produces approximately 78% of the world's cathodes and 91% of the world's anodes.79 China will remain the largest producing country for cathode active materials from today until 2040.80 BMI expects Chinese production to comprise 71% of the globally produced cathode material – almost seven times the amount of the world's second largest producer, South Korea. 81 [EPA-HQ-OAR-2022-0829-0701, pp. 46-47]

81 Benchmark Minerals, Report, Q1 2023

A detailed analysis of global supply chains is required. In the case of lithium, for example, agencies need to consider the price of electricity where the lithium is mined, where the lithium is processed, where the lithium is used in cathode production, where the battery cells are made, and where battery packs are assembled. Electricity prices vary significantly around the world, However, EPA projects 100% of battery cells will be produced in the U.S. by 2027 and growing critical mineral production. As more of the lithium-ion battery supply chain develops in the U.S., the analysis of U.S. electricity prices on battery costs will be more straightforward. [EPA-HQ-OAR-2022-0829-0701, pp. 60-61]

G. Battery Manufacturing Capacity

Despite announced investments in the U.S. and E.U. battery manufacturing capacity, China is poised to maintain its market dominance throughout the decade. By 2032, China is expected to continue to control the battery market with more than 4,800 GWh of annual battery production capacity— approximately 67% of all forecasted battery cell manufacturing capability. Elon Musk estimates a needed global battery capacity of 300 terawatt-hour by 2050.124 [EPA-HQ-OAR-2022-0829-0701, pp. 67-68]

124 How Can the World Meet Elon Musk's 300 TWh Battery Capacity Target?, BENCHMARK SOURCE (Nov. 16, 2022), htps://source.benchmarkminerals.com/article/how-can-the-world-meet-elon-musks-300-twh-batery-capacity- target.

EPA states that a recent forecast by the Department of Energy, illustrates the rapid recent growth in new plant announcements, estimating that announcements for North America to date will enable an estimated 838 GWh of annual capacity by 2025, 896 GWh by 2027, and 998 GWh by 2030, the vast majority of which is cell manufacturing capacity, enough to supply from 10 to 13 million BEVs per year.125 [EPA-HQ-OAR-2022-0829-0701, pp. 67-68]

BMI provides somewhat lower estimates for anticipated battery cell manufacturing capacity in North America, reaching 890 GWh of operating, highly probable, probable, and possible production by 2032 (Figure 20).126 BMI also notes that about 70% of the capacity will be owned by companies based outside of the U.S. [EPA-HQ-OAR-2022-0829-0701, pp. 67-68]

125 NPRM at 29317.

126 BMI Study at 47.

Figure 20: Benchmark Mineral Intelligence assessment of N. American battery cell manufacturing capacity, 2020-2032, and country of ownership. [EPA-HQ-OAR-2022-0829-0701, pp. 67-68]

While these projections and announcements demonstrate progress in expanding battery manufacturing capacity outside of China, it is important to acknowledge the time required to realize these goals. The time between announcements and a plant being at full capacity can take several years. Moreover, the auto industry faces the challenge of meeting the growing demand for batteries while balancing the complexities of establishing and scaling up manufacturing operations, which includes building a skilled workforce and securing an adequate supply chain stretching back to the raw critical minerals. [EPA-HQ-OAR-2022-0829-0701, pp. 68-69]

The battery manufacturing landscape is witnessing significant developments, with China maintaining its stronghold as the dominant player in the market. While the U.S. is making strides to expand its battery production capacity, the scale and pace of China's investments and advancements in this sector continue to position it as the frontrunner. As the demand for electric vehicles and energy storage solutions continues to grow, the need for a substantial global battery capacity becomes increasingly apparent. Scaling up North American battery manufacturing is a complex endeavor that requires significant time and effort. Simply put, China has a 10–15-year head start. Establishing a robust and competitive battery manufacturing ecosystem involves various challenges as described above. It is crucial to acknowledge that scaling up production capacity cannot happen overnight. It requires a long-term commitment and sustained support and investment from governments, industry, and other stakeholders. [EPA-HQ-OAR-2022-0829-0701, pp. 68-69]

One of the complicated factors that the agency needs to analyze is the current and projected global shortage (2027-2030) of electrical steel. This type of steel is comprised of ultra-thin sheets that transfer electricity into mechanical power. For use in an EV's electric motor, a higher-grade electrical steel is required that entails stamping and stacking steel into precise shapes that may be less than a millimeter thick. The U.S. has very limited production capability for electrical steel and has imposed tariffis on the supplies from South Korea, Japan and China. The cost-reduction factors that the agency is using for electric motors need to be modified, as they ignore the current and likely costs of electric motors. [EPA-HQ-OAR-2022-0829-0701, pp. 69-70]

2. Daniel Sims. Electrical Steel Supply and Demand Could Impact EV Prices Later This Decade. Techspot.com. March 28, 2023. [EPA-HQ-OAR-2022-0829-0701, pp. 69-70]

R&D efforts are looking into new alternatives that can reduce or eliminate the use of rare earths while maintaining the effciency advantages of permanent magnet synchronous motors. Some alternatives require expanded use of liners that depend on the ultra-thin electrical steel, but the cost premium for electrical steel is signiffcant and global shortages are projected in the 2027-2030 timeframe. It is possible that some innovations in motor design will penetrate luxury/premium models prior to 2032, but most of the 2032 light-duty fleet is likely to retain use of rare earth magnets. [EPA-HQ-OAR-2022-0829-0701, pp. 70-71]

While the U.S. is poised to increase domestic manufacturing and processing of battery components and critical minerals, we are currently heavily reliant on other nations. This transition will take time, and that will have a role to play in vehicle eligibility for the 30D tax credit. Figure 24 shows the portion of battery manufacturing and critical mineral processing that takes place in China (a foreign entity of concern), the U.S., FTA countries, major U.S. allies, and other countries that don't fit into the previous categories (e.g., Democratic Republic of Congo). The dearth of U.S. mining, processing, component production, and cell production is noticeable, as is the dominance of China in all these areas. [EPA-HQ-OAR-2022-0829-0701, pp. 74-75]

1. Soil and Water Contamination from the Mining and Processing of Rare Earths

Rare earths (especially neodymium and dysprosium) are standard materials used in the electric motors of BEVs. There is much effort underway to make electric motors with fewer rare earths or none at all, but most EVs produced in the 2027-2032 time frame will use rare earths. [EPA-HQ-OAR-2022-0829-0701, pp. 280-281]

The mining and processing of rare earths is environmentally challenging and, if not done properly, wastes can lead to damaging soil and water contamination near the mine and/or processing facility. The process of extracting rare earths entails open pits, which leave a large ecological footprint. The dust at the mine can be radioactive because thorium is often found with rare earths. [EPA-HQ-OAR-2022-0829-0701, pp. 280-281]

Until 1984, the United States accounted for most of the world's supply of rare earths. The Mountain Pass mine in California, located in the Mojave Desert near the Nevada line, was the single largest source of U.S. production. The mine closed in 2002, partly because it could not earn a profit in competition with low-cost mines in China, and in part because of radioactive wastewater leaks that triggered community and regulatory at concerns and took more than a decade to clean up. China has also experienced environmental pollution from rare earth mining, and has cracked down on illegal rare earth mining, which circumvents the country's export quotas and is difficult to regulate for environmental protection. [EPA-HQ-OAR-2022-0829-0701, pp. 280-281]

The Mountain Pass mine was revived in 2012 under new ownership but the owner declared bankruptcy in 2015 in the face of low prices, debt, and a flood of low-cost material from China. Another owner, Mountain Pass (MP) Materials, has gradually expanded output at the mine from 2018 to 2020 and announced plans for a processing facility. (The company until now has been using a processing facility in China). In late 2020 the Department of Defense announced a $35 million award to help finance a processing facility. A new plant in Fort Worth, Texas, will begin processing and magnet production in 2024. General Motors has made a commitment to source its rare earths from Mountain Pass. [EPA-HQ-OAR-2022-0829-0701, pp. 280-281]

An alternative to open-pit mining of rare earths is vacuuming them from the ocean floor. The technology for ocean mining does not require the blasting and digging operations that occur at open-pit land mines. However, the United Nations International Seabed Authority has not been able to develop standards and permit procedures that satisfy the environmental concerns of member countries. Thus, ocean mining of rare earths (and other materials used in EVs such as cobalt and nickel) will not happen on a large scale in the foreseeable future. [EPA-HQ-OAR-2022-0829-0701, pp. 280-281]

2. Depletion of Scarce Water Supplies from Lithium Mining in the Deserts of Chile

Lithium is a critical mineral used in all variants of the lithium ion battery, and thus will likely be used in most EVs sold in the U.S. from 2027 to 2032. The largest lithium deposits in the world are in a remote region of South America, Atacama, near the borders of Chile, Bolivia, and Argentina ("the Lithium Triangle"). As recently as 2014, Chile was the number one miner of lithium, and much of Chile's lithium was processed in Chile and then exported to North America. However, environmental concerns about ecological harm to water-stressed communities in Chile have slowed the expansion of lithium mining in Chile. [EPA-HQ-OAR-2022-0829-0701, pp. 282-283]

Beginning in 2015, Chile's national government and major companies announced plans to expand lithium mining. Those plans triggered well-organized, intense opposition from indigenous groups as well as local and international environmental groups. The reasons for opposition were variable, but the most common concern was about consumption of scarce water resources. The Atacama region is one of the driest places in the world: meaningful rainfall of about 1.5 inches occurs only once per century on average. Despite the dry conditions, the region is home to protected wetlands, extraordinary wildlife, and unique microorganisms. [EPA-HQ-OAR-2022-0829-0701, pp. 282-283]

Lithium mining in Chile entails withdrawing high volumes of liquid brine that are evaporated in the dry desert air to create a precursor to the desired lithium material. The brine is not potable water, but the withdrawals have been associated with measurable changes to regional hydrology and increases in local temperatures, which mean lithium mining is one of the major stressors leading to local environmental degradation. Environmental concerns were first expressed by leaders of indigenous groups. They reported anecdotal evidence of diminished productivity of desert farms near lithium mining sites. They also reported harm to desert and wetlands wildlife. Recently published scientific evidence revealed a 10% decline in flamingo populations near brine operations in Chile. Insofar as the anecdotal reports reflect a pattern of ecological disruption, the pattern may not be due entirely to lithium mining, as climate change itself can have similar disruptive effects. [EPA-HQ-OAR-2022-0829-0701, pp. 282-283]

Lithium mining has become so controversial in Chile that the new leftist government has pledged stricter environmental controls and control of all lithium mining by a state-owned enterprise. Since 2015, Australia has surpassed Chile as the number one lithium miner in the world. [EPA-HQ-OAR-2022-0829-0701, pp. 282-283]

3. Environmental Concerns about Hard-Rock Mining of Lithium and Other Materials

Although hard-rock mining of lithium is growing more rapidly than lithium production from brine operations, hard-rock mining is not necessarily preferable from an environmental perspective. Lifecycle studies have compared hard rock mining to brine operations. They find that hard-rock mining is more energy intensive, generates more CO_2 emissions, uses more freshwater supplies, generates more waste material, and creates more local dust and noise in nearby communities than brine operations. The ecological concerns about hard rock mining help explain why recent proposals for new hard rock lithium mines have been cancelled or delayed in Serbia, Portugal, and North Carolina. [EPA-HQ-OAR-2022-0829-0701, pp. 283-284]

Sources: [EPA-HQ-OAR-2022-0829-0701, pp. 283-284]

Organization: American Coalition for Ethanol (ACE)

It must also be pointed out that the proposal will not make the U.S. more energy secure. In fact, the opposite is true. The lithium, nickel, copper, cobalt and other critical minerals necessary to make batteries and electric vehicles in the ambitious timeframe set forth by the Agency are not found in sufficient quantities in the U.S. Instead, these precious minerals must be mined and imported from countries such as China, Russia, and the Congo. EPA's aggressive timeline will only serve to increase U.S. reliance on foreign supplies of minerals for BEVs. [EPA-HQ-OAR-2022-0829-0613, pp. 2-3]

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

Moreover, EPA's feasibility analysis fails to meaningfully confront multiple serious obstacles to the widespread adoption of electric vehicles on which its proposed rule depends. Increased production of electric vehicles is constrained by the supply of certain minerals critical to manufacturing batteries. That supply is sharply limited; mining and processing operations are nowhere near the levels needed to support the expansion of electric vehicles EPA's proposed rule would require. The supply chain is subject to serious disruptions, as other fed- eral agencies have underscored. For example, nearly all existing supply of several critical minerals is controlled by a small number of foreign and unfriendly nations. The insufficiency of these essential inputs will only become more acute as worldwide demand for them increases. And developing new operations would be a decades-long process that extends far beyond the compliance period for the proposed rule. On average, it takes 16 years to move mining projects from discovery to first production, and another ten to begin producing at max- imum capacity. EPA barely addresses this problem in its proposed rule and offers no plausible solution. [EPA-HQ-OAR-2022-0829-0683, p. 4]

EPA's Analysis Fails To Confront Multiple Specific Obstacles To The Level Of Widespread Electric-Vehicle Adoption Its Proposed Rule Requires

EPA's projection of future electric-vehicle adoption is not only flawed on its own terms, but it also fails meaningfully to address several chokepoints that could severely constrain future production and utilization of electric vehicles. [EPA-HQ-OAR-2022-0829-0683, p. 31]

a. The Supply Chain For Critical Minerals Is Vulnerable To Disruption And Price Volatility

Electric-vehicle technology, and particularly production of batteries, is vi- tally dependent on certain minerals—including lithium, nickel, copper, cobalt, graphite, and manganese. See IEA, Global Supply Chains of EV Batteries, at 21 (July 2022) ("Global Supply Chains"). Because "[a] typical electric car requires six times the mineral inputs of a conventional car," manufacturers would need a steady, reliable supply of those minerals, much larger than they require today, to increase production of electric vehicles to the levels necessary to comply with the proposed standards. Role of Critical Minerals at 5. But by all available evi- dence, manufacturers will face substantial—possibly insurmountable—chal- lenges in obtaining the necessary quantities of those essential inputs. [EPA-HQ-OAR-2022-0829-0683, p. 31]

Both the production (mining) and processing (refining) of minerals critical to production of electric-vehicle batteries are highly concentrated among a small group of countries—and the

United States is not one of them. According to the Department of Energy, "[a]lmost all production of raw materials for lith- ium ion batteries, apart from some lithium extraction and refinement, occurs abroad today," and the United States "currently has virtually no domestic pro- cessing capacity." Building Resilient Supply Chains, Revitalizing American Manu- facturing, and Fostering Broad-Based Growth, The White House, at 93–94 (June 2021) ("White House Report"). For example, more than 80 percent of all lith- ium is sourced from Australia, Chile, and China; 80 percent of natural graphite is sourced from China; more than 70 percent of cobalt is sourced from the Dem- ocratic Republic of Congo; about half of copper is sourced from Chile, Peru, and China; and more than half of nickel is sourced from Indonesia, the Philip- pines, and Russia—with Russia being the world's largest producer of the "Class 1" grade needed for batteries. See Global Supply Chains at 22, 29; Role of Critical Minerals at 30. And the "project pipelines" for these minerals indicate that, "in most cases, the geographic concentration of production is unlikely to change in the near term." Role of Critical Minerals at 121. [EPA-HQ-OAR-2022-0829-0683, pp. 31-32]

Concentration levels are "even higher for processing operations, where China has a strong presence across the board." Role of Critical Minerals at 12. The Department of Defense reports that, "[e]ven in cases where other countries conduct the initial beneficiation of a strategic and critical material, China dom- inates the processing of strategic and critical minerals, giving it de facto control over the flow of material through the supply chain." White House Report at 165. China refines almost 60 percent of lithium, over 50 percent of graphite, 72 percent of cobalt, 40 percent of copper, around 35 percent of nickel, and 90 percent of manganese. See Global Supply Chains at 2,23; Role of Critical Minerals at 31–32; White House Report at 103. It also produces three-quarters of all lith- ium-ion batteries. See Global Supply Chains at 2. [EPA-HQ-OAR-2022-0829-0683, pp. 31-32]

This lack of supplier diversity greatly increases supply-chain risk. As de- tailed below, disruptions in even a single country can create supply bottlenecks; the limited number of countries producing and processing minerals may not be able to meet rapidly increasing demand; and, according to the federal govern- ment, scholars, and industry observers, the dominance of potentially uncoop- erative or hostile countries in every segment of the market threatens U.S. en- ergy security. Under these challenging and unpredictable circumstances, a widespread shift to electric vehicles in less than a decade is plainly infeasible. [EPA-HQ-OAR-2022-0829-0683, pp. 31-32]

Supply-Chain Disruption. Because the production of these critical minerals depends on one country or a few countries, "a large portion of global supply is subject to single point disruption risk." White House Report at 175–76. If a major producing country suffers a natural disaster, imposes new trade re- strictions, faces political or social unrest, or becomes involved in geopolitical conflict, the stream of minerals entering the market could dramatically slow. See Role of Critical Minerals at 32 ("supply chains can quickly be affected by reg- ulatory changes, trade restrictions or political instability in a small number of countries"); id. at 129 ("Under these circumstances, physical disruptions (e.g. earthquakes, tsunamis and flooding) or regulatory and geopolitical events in major producing countries can have large impacts on the availability of miner- als, and in turn on prices."). [EPA-HQ-OAR-2022-0829-0683, p. 32]

These concerns are not hypothetical. Independent and governmental re- ports—many of which EPA relies on in support of the proposed rule— document instances in which each of these disruptions have occurred. Natural disasters, for example, have “become one of the most frequent causes of min- eral supply disruption.” Role of Critical Minerals at 12, 129. Mining operations are also vulnerable to high water-stress levels, extreme heat, and flooding. Id. Over half of today’s lithium and 80 percent of Chile’s copper is produced in areas with high water-stress levels. Id. at 131. In 2019, “the worst drought in more than 60 years severely affected some operations” in Chile, and that na- tion’s “largest underground copper mine” had to implement water rationing. Id. “[S]imilar events hav[e] occurred in Australia, Zambia and others.” Id. [EPA-HQ-OAR-2022-0829-0683, pp. 32-33]

The federal government has expressed concern that the increased tendency of countries to engage in “unfair foreign trade practices” presents “[a]nother risk to critical material supply chains.” White House Report at 183–84. The International Energy Agency offered a similar assessment, explaining that “[r]ecent events, such as Indonesia’s ban on nickel ore export and China’s ex- port ban on [rare earth elements],” show that “regulatory and geopolitical events in major producing countries can have large impacts on the availability of minerals.” Role of Critical Minerals at 129. Moreover, news outlets have re- ported that “Chile, a major producer of lithium, has proposed nationalizing its lithium industry to better control how the resources are developed and de- ployed, as have Bolivia and Mexico.” Ana Swanson, The U.S. Needs Minerals for Electric Cars. Everyone Else Wants Them Too., N.Y. Times (May 21, 2023), https://tinyurl.com/2p8txa2h (“Minerals for Electric Cars”). And, according to the Department of Defense, China has continuously engaged in “dumping”— i.e., exporting products at low prices in the short term to drive competing pro- viders out of business and secure long-term dominance. White House Report at 184. [EPA-HQ-OAR-2022-0829-0683, pp. 32-33]

Legal, legislative, and grassroots scrutiny of the environmental and social issues surrounding the production of critical minerals also threatens supply chains. See Role of Critical Minerals at 12. “Grassroots protests and lawsuits against lithium mining are on the rise . . . amid rising concern about the socio- environmental impacts and increasingly tense geopolitics around supply.” Nina Lakhani, Revealed: How US Transition to Electric Cars Threatens Environmen-tal Havoc, Guardian (Jan. 24, 2023), https://tinyurl.com/995uawn8. Reporters have noted that, “[i]n Chile and Argentina, the world’s second- and fourth- largest lithium producers respectively, broken promises by corporations, water scarcity, land contamination and the lack of informed consent from Indigenous groups has fueled resistance and social conflicts.” Id. And, according to the Bureau of International Labor Affairs, cobalt mining operations in the Demo- cratic Republic of Congo have been under the spotlight for their use of child labor. See Exposing Exploitation in Global Supply Chains, Bureau of Int’l Lab. Affs., https://www.dol.gov/agencies/ilab/reports/child-labor/list-of- goods/supply-chains/lithium-ion-batteries. These types of events have the po- tential to depress output. Labor strikes are already a leading cause of mineral supply disruption, see Role of Critical Minerals at 129, and major protests and legal challenges “could serve as a hard brake” on production, Bentley Allan et al., Friendshoring Critical Minerals: What Could the U.S. and Its Partners Produce, Carnegie Endowment for Int’l Peace (May 3, 2023) (“Friendshoring Critical Min-erals”). Public opinion in the United States, too, “could turn sharply against any material imports associated with human rights violations or corruption,” which could require manufacturers “to identify other sources for input materials.” White House Report at 122. [EPA-HQ-OAR-2022-0829-0683, pp. 33-34]

Other forms of internal conflict can affect operations within major produc- ing countries. In the 1970s, for example, the supply of cobalt "was disrupted due to an uprising in the region." Alexandra Leader et al., The Effect of Critical Material Prices on the Competitiveness of Clean Energy Technologies, Materials for Renewable and Sustainable Energy, at 2 (2019) ("The Effect of Critical Material Prices"). "The market saw price increases of over 500%, causing severe inter- ruptions for the downstream cobalt users, such as General Electric." Id. The majority of cobalt continues to come from that region, and "such a concen- trated supply in a provenly unstable region leaves concern over the potential for another major supply disruption." Id. [EPA-HQ-OAR-2022-0829-0683, p. 34]

Geopolitical conflict could also rapidly shift the supply landscape. See White House Report at 175. The war in Ukraine, for example, has affected the availability and cost of nickel, showing "just how quickly events can change." McKinsey & Co., Could Supply-Chain Issues Derail the Energy Transition (Dec. 5, 2022) ("Supply-Chain Issues"); see also Emily Pickrell, Russia-Ukraine War Helps Drive Nickel Prices, EV Headaches, Forbes (Mar. 31, 2022), https://tinyurl.com/2p95mwfx; Global Supply Chains at 15–16. Likewise, the "military coup in Myanmar has raised concerns over supply disruption of heavy [rare earth elements], fueling a surge in prices." Role of Critical Minerals at 129. [EPA-HQ-OAR-2022-0829-0683, p. 34]

Rapidly Increasing Demand. Beyond potential supply disruptions, the world's facilities for mining and processing critical minerals will face immense challenges in meeting the increased demand required by the proposed rule. Shortages could delay electric-vehicle production—of vital importance to the proposed rule's timelines—and at a minimum will contribute to price volatility. [EPA-HQ-OAR-2022-0829-0683, pp. 34-36]

Imbalances between supply and demand have already resulted in skyrock- eting prices for critical minerals. Between the beginning of 2021 and May 2022, nickel prices "reach[ed] levels not seen for almost a decade," cobalt prices more than doubled, and lithium prices increased more than sevenfold. Global Supply Chains at 15. By September 2022, prices for lithium rose even more, ranging from 800 to 1,000 percent higher than they were in the beginning of 2021. Thea Riofrancos et al., Achieving Zero Emissions with More Mobility and Less Mining, Univ. of Cal., Davis, at 16–17 (Jan. 2023) ("Achieving Zero Emissions"). [EPA-HQ-OAR-2022-0829-0683, pp. 34-36]

These problems are likely to increase. The Department of Energy reports that "[g]lobal demand for critical materials is expected to increase by 400-600% over the next several decades" and that "[f]or certain materials, such as lithium and graphite used in electric-vehicle batteries, demand is expected to increase by as much as 4,000%." Biden-Harris Administration Launches $675 Million Bipar- tisan Infrastructure Law Program to Expand Domestic Critical Materials Supply Chains, Dep't of Energy (Aug. 9, 2022), https://www.energy.gov/arti- cles/biden-harris-administration-launches-675-million-bipartisan-infrastruc- ture-law-program. The International Energy Agency similarly reports that "[t]he exceptional rise in demand for batteries is now outstripping supply" and projects that mineral supply chains "will have to expand ten-fold to meet gov- ernment EV ambitions." Global Supply Chains at 3, 18. To avert inevitable bottlenecks, operations must "dramatically scale up." Id. at 46. Even under existing standards, at a minimum, "dozens of mining projects will have to enter the market and reach capacity on schedule and tens of new mineral processing and precursor plants will have to be commissioned." Id. at 59. Even that may be insufficient to meet demand. See Supply-Chain

Issues ("Minerals supply from open mines and those with a high probability of opening may be able to partly meet this growth. However, the supply falls short of reaching all demand, and harder measures . . . may be required."); Achieving Zero Emissions at 16 ("Despite ongoing discoveries, most forecasters predict a near- to medium-term gap be- tween market supplies and demand, resulting in a supply crunch in the next 5 to 10 years."). [EPA-HQ-OAR-2022-0829-0683, pp. 34-36]

"If history is any guide," attempts to ramp up production will be beset with "considerable time lags." Role of Critical Minerals at 117. It takes "on average over 16 years to move mining projects from discovery to first production." Id. at 12. And even once operational, "mines often require around ten years before they reach nameplate production capacity." Global supply Chains at 52. It is typ- ical for "[m]arket tightness" to "appear much more quickly than new projects." Role of Critical Minerals at 122; see also id. at 12 ("These long lead times raise questions about the ability of suppliers to ramp up output if demand were to pick up rapidly."). [EPA-HQ-OAR-2022-0829-0683, pp. 34-36]

These high lag times may be exacerbated by declining mineral quality. Some mining operations, such as those for copper, have "already peaked" or are "expected to peak in the early 2020s due to declining ore quality and reserve exhaustion." Role of Critical Minerals at 136. As a result, "developing new pro- jects has become challenging," and producers will need to offset cost escalations with "technology innovation." Id. at 137. Similarly, most of the production growth in nickel over the coming years will come from regions with large amounts of "Class 2" resources, which cannot be used for batteries without undergoing high-pressure acid leaching. Id. at 146. That process brings "several challenges," including projects that "tend to take four to five years to ramp up to 80% capacity" and have "track records of large cost overruns and delays." Id. [EPA-HQ-OAR-2022-0829-0683, pp. 34-36]

Moreover, even when raw material can be mined, major strains may arise at later points in the supply chain—such as processing. See Role of Critical Min- erals at 142. With respect to lithium, for example, "[o]nly a handful of compa- nies can produce high-quality, high-purity lithium chemical products," and "[w]hile several planned expansion projects are in the pipeline, there is a ques- tion mark over how rapidly their capacity can come online to keep up with demand growth." Id. [EPA-HQ-OAR-2022-0829-0683, pp. 34-36]

The market's inability to respond quickly to increases in demand will likely lead to high prices. The Department of Energy concludes that it is "reasonable to anticipate future spikes in prices as demand increases and supply might, at least temporarily, struggle to catch up." White House Report at 122. Others explain that "[h]igh demand, coupled with criticality, promotes the risk of ex- treme price spikes or even material unavailability in the event of a disruption in the supply chain." The Effect of Critical Material Prices at 2. And because raw materials now account for the majority of battery costs, "higher mineral prices could have a significant effect on achieving industry cost targets," Role of Critical Minerals at 107, which in turn could "lead to lower demand for, and adoption of, clean energy technologies," The Effect of Critical Material Prices at 3. [EPA-HQ-OAR-2022-0829-0683, pp. 36-37]

Energy Security. Researchers and news outlets report that the urgent need for more materials is already "stoking geopolitical tensions" and causing "a wave of resource nationalism that could intensify" as countries around the world compete for access. Achieving Zero Emissions at 11; Minerals for Electric Cars. According to the Department of Energy, American companies in partic- ular are at heightened risk because many key minerals come from countries “that are geopolitical competitors of the United States” that may block access to dominant segments of the supply chain. White House Report at 122, 138. The agency advises that China has already “shown a willingness to restrict ac- cess to resources,” such as rare earth elements, and could easily curb exports of cobalt, nickel, lithium, graphite, or other battery components next. Id. at 122. For that reason, the agency warns that “it is reasonable to expect that China could restrict exports of any or all of the battery supply chain materials it pro- duces, due to trade tensions with the United States or a simple prioritization of domestic customers for its battery materials.” Id. In addition, the agency raises the “related concern” that China could also sell American manufacturers “sub- standard or less advanced material” to gain a competitive advantage. Id. U.S. companies have already indicated “that they were supplied ‘previous genera- tion’ material as China’s cathode producers reserve their most recent, and best, material for their larger volume Chinese cell making clients.” Id. [EPA-HQ-OAR-2022-0829-0683, p. 37]

The current Administration has concluded that there is a need to build a more secure international supply chain that is less concentrated on China, but its strategy so far has been criticized as “a bit incoherent and not necessarily sufficient to achieve that goal.” Minerals for Electric Cars. A recent report by Johns Hopkins University explains that, even if the United States can relocate supply chains to countries with shared interests and values, those countries do not have enough supply to meet demand. See Friendshoring Critical Minerals at 6. Given the amount of critical minerals that will be needed for solar, wind, and electric-vehicle battery supply chains by 2030, the study concluded that “[e]ven aggressive growth in the mining sector would leave democratic coun- tries drastically short on critical minerals supply.” Id. “[I]ncreasing production to achieve clean energy targets for 2030 would require unprecedented action,” and as a result, “excluding China from supply [of] critical minerals is simply not possible in the short term.” Id. [EPA-HQ-OAR-2022-0829-0683, p. 37]

Despite all of these problems, EPA asserts that critical minerals will not pose an obstacle for compliance. Its explanation, however, comes up short. [EPA-HQ-OAR-2022-0829-0683, p. 38]

EPA principally argues that it accounted for the supply problems associated with critical minerals by assuming an upper limit on the amount of lithium-ion batteries that will be available each year for electric vehicles. 88 Fed. Reg. at 29,323; Draft RIA at 3-22. But that assumption rests on an incomplete and un- reliable analysis. [EPA-HQ-OAR-2022-0829-0683, p. 38]

In setting its assumed upper limit on lithium-ion-battery availability, EPA analyzed only one critical mineral: lithium. 88 Fed. Reg. at 29,323; Draft RIA at 3-22. But as discussed above, lithium is only one of the critical minerals needed for manufacturing batteries, and the availability of each turns on cir- cumstances unique to the location of its production and processing. EPA acknowledges that other minerals, such as “cobalt, nickel, and manganese[,] are important.” Draft RIA at 3-23. EPA attempts to justify its failure to consider critical minerals other than lithium with the blithe assurance that “opportunity will exist” to reduce or eliminate other minerals’ use in battery chemistries in the future. Id. But EPA offers no analysis of key questions that response raises—such as when those “opportunit[ies]” for replacing other minerals would arise, the availability of the alternatives that would serve as replace- ments, whether new plants or production processes would be necessary, and the lead time required to implement the changes. To assess accurately how the supply and demand problems associated with critical minerals will impact com- pliance, the agency must address each of the minerals that it expects manufac- turers to obtain. It has not done so. Instead, EPA brushes the issue away with the unfounded hope that new battery technologies might one day render these minerals less essential. But they are essential now, a reality that EPA cannot ignore. [EPA-HQ-OAR-2022-0829-0683, p. 38]

Moreover, even as to lithium, the agency's analysis focuses solely on whether global production could accommodate growing domestic demand. Draft RIA at 3-23. The agency does not appear to have considered any of the potential disruptions discussed above that could render aggregate global supply of minerals inadequate or unavailable for producing batteries for vehicles to be sold domestically, or how price volatility might affect electric-vehicle penetra- tion rates. Id. Moreover, as EPA acknowledges, the data it used to forecast sup- ply and demand do not reach beyond model year 2027—the start of the compliance period for the proposed rule. See id. at 3-25. Instead, EPA recog- nizes that projections that far out become prohibitively difficult. See id. ("Past 2027, estimates of 'excess' lithium as a difference between [rest-of-world] de- mand and a current accounting of global supply become less informative, be- cause a demand response is not built into the supply data. Therefore, uncer- tainty about the supply-demand balance . . . increases rapidly as the time hori- zon increases."). That admitted uncertainty is more reason for caution, not an excuse to regulate in the absence of adequate information. [EPA-HQ-OAR-2022-0829-0683, pp. 38-39]

PA also asserts that "widespread automotive electrification in the U.S. will not lead to a critical long-term dependence on foreign imports of minerals or components," and that "increased demand for these products will [not] be- come a vulnerability to national security." 88 Fed. Reg. at 29,313. EPA offers two justifications for that "assessment": (1) with funding and motivation, com- panies can develop a domestic supply chain; and (2) disruptions caused by sup- ply bottlenecks and volatile prices will not be significant. Neither justification withstands scrutiny. [EPA-HQ-OAR-2022-0829-0683, pp. 39-40]

As to EPA's first justification—that an adequate domestic supply chain can be developed—doing so by the time the proposed rule would take effect is vir- tually impossible. Although the United States has some (small) reserves in this area, mining operations for most minerals are limited or nonexistent. See Global Supply Chains at 28. There is no domestic production of graphite or manganese. See White House Report at 105. And there is only one active domestic mine for each of lithium, cobalt, and nickel—none of which is capable of sourcing enough material even to scratch the surface of projected U.S. demand. The lith- ium mine's annual output is enough for only 80,000 vehicles—less than the number of electric cars that a single manufacturer (Tesla) sold in the first quar- ter of 2022. See Lithium Mining in North America, Inst. for Energy R'sch (Sept. 21, 2022), https://tinyurl.com/2p89vrkv; Dustin Hawley, What Percent of US Car Sales Are Electric?, J.D. Power (Apr. 3, 2023), https://ti- nyurl.com/w6vn9rc5. The cobalt mine has not reached full production, and even when it does, the company expects to produce enough material for only "several hundred thousand electric cars." Kirk Siegler, In Idaho, America's First, and Only, Cobalt Mine in Decades Is Opening, OPB (Oct. 8, 2022), https://ti- nyurl.com/3v929nd3. And the nickel mine is set to shut down in 2025, mean- ing that it will not even be in operation by the time the proposed standards take effect. See White House Report at 99. [EPA-HQ-OAR-2022-0829-0683, pp. 39-40]

Because the baseline for domestic mineral production is close to zero, new mining operations are necessary. But although various projects have been an- nounced or are under development, whether and when they might begin oper- ations remains uncertain. In the United States, as elsewhere, establishing a min- ing operation is “an extremely lengthy process.” White House Report at 158. According to the Department of Defense, a “reasonable industry benchmark for the development . . . is not less than ten years” and can sometimes take over thirty years. Id. And that is before factoring in the time needed to obtain the necessary permits, which itself can take “years, if not decades,” even account- ing for the federal government’s efforts to “streamline” the process. Minerals for Electric Cars. Moreover, it is reportedly “quite common for most companies to fail to reach the end of this development process, simply due to the long project development time without cash flows to offset expenses and the technical chal- lenges associated with large, complex project financing for materials produc- tion.” White House Report at 158. For example, during the “peak of industry and market interest in the rare earth sector in early 2011,” the “Advanced Rare- Earths Project Index” tracked 275 projects that were under development by 180 publicly traded companies in 30 different countries. Id. By 2021, only two had entered full-scale production, with two others still in pilot-plant production and the rest having failed—representing a “combined success rate of 1.5 percent” over a decade. Id. Thus, even if EPA is right that minerals could be produced in the United States, that companies have a competitive interest in developing these operations, and that the federal government is providing helpful re- sources, there is little chance that enough mines will be up and running in time to supply manufacturers with minerals they need for any year in the proposed rule’s compliance period. [EPA-HQ-OAR-2022-0829-0683, pp. 39-40]

As to EPA’s second justification—speculation that supply disruptions and fluctuating prices will not have a material effect on the electric-vehicle industry—that conjecture is unfounded and implausible. See 88 Fed. Reg. at 29,323. Contrary to the agency’s contention, supply disruptions and fluctuating prices of critical minerals will “constrain[] the ability to travel” if manufacturers can- not offer enough vehicles for their consumer base or must raise prices beyond what many consumers can afford. Id. And even if the agency is right that manufacturers have thus far been able to avoid short-term price fluctuations by entering long-term contracts, EPA cites nothing to demonstrate that those arrangements will continue to be offered as the demand for a limited supply of critical minerals skyrockets over the coming years. EPA also cites nothing to demonstrate that substitutes will be readily available and affordable when the primary critical mineral is not. [EPA-HQ-OAR-2022-0829-0683, p. 41]

In sum, the vulnerable and volatile supply chain for critical minerals is a challenge that cannot be overcome in a matter of a few years. Rather than thrusting manufacturers into a sea of risk and uncertainty, EPA should wait until the global market stabilizes or the domestic market develops before effec- tively mandating a widespread shift to electric vehicles.4 [EPA-HQ-OAR-2022-0829-0683, p. 41]

4 Supply-chain problems are also likely to affect the manufacture of fuel-cell vehicles. Fuel-cell vehicles “rely on a platinum catalyst, which is a major downside to this technology, as platinum group elements are expensive and deposits concentrated enough for economic mining are rare.” The Effect of Critical Material Prices at 3. “According to the United States Geological Survey, platinum group elements are among the rarest elements on earth and are found in earth crust in concentrations of around 0.5 parts per billion.” Id. at 4. And just like the materials needed for batteries, production of platinum group elements is highly concentrated in South Africa, “accounting for 72% in 2017.” Id.

Organization: American Fuel & Petrochemical Manufacturers

EPA's proposal also ignores the national security implications of its proposed electric vehicle mandate. The proposal would trade our energy security for energy dependence on countries like China. Currently, China controls the vast majority the EV battery supply chain and most of the related critical mineral mining and processing. Contrast that with the fact that 85 percent of the crude that ran through U.S. refineries last year was sourced from North America. Forcing Americans to buy EVs makes us less secure, not more. [EPA-HQ-OAR-2022-0829-0733, p. 2]

The Proposed Rule requires increased reliance on imported critical minerals and metals for battery production and grid expansion that could have serious negative consequences for our energy and national security. The supply chain for key minerals needed to produce electric vehicle batteries is not assured and will require dramatic increases to meet expected demand. The extraction and processing of battery critical minerals is concentrated in politically unstable or unfriendly nations. Domestic copper and aluminum smelting capacity is insufficient to meet grid expansion needs, and new mines can take over a decade to increase domestic supply. The deployment timeline necessary to develop new resources for batteries and the grid is impracticable and presents unnecessary risks to our energy and economic security. In contrast, domestically consumed liquid fuels sourced from petroleum and bio feedstocks are largely sourced in North America, and the U.S. benefits from its position as a net exporter of petroleum and refined product exports. [EPA-HQ-OAR-2022-0829-0733, p. 3]

I. EPA's Proposal Does Not Comprehensively Address Cross-Cutting Issues

EPA's desire to remake the automotive sector creates significant energy and national security concerns and stresses an aging electrical grid subject to increasing demand. In glossing over these issues, EPA fails to adequately consider the mineral, metal, electricity generation, transmission, distribution, and charging infrastructure requirements necessary for the Proposed Rule to be feasible. This is alarming and undermines our energy security. We lack the supply of domestically sourced minerals and metals needed to build batteries and transmission lines and, contrary to the legislative intent of U.S. laws such as the Bipartisan Infrastructure Law ("BIL") and Inflation Reduction Act ("IRA"), we will have to rely on foreign countries to fulfill the Proposed Rule's mandate. [EPA-HQ-OAR-2022-0829-0733, p. 4]

Even if we could import vast quantities of mineral resources, EPA's electrification mandate is unobtainable. We face a limited supply of copper, which is a critical mineral needed to build out the transmission grid to supply electricity to charging stations. We also do not have near the vehicle charging infrastructure necessary to power the mandated number of ZEVs. Rather than conducting a clear-eyed assessment of these challenges, EPA erroneously assumes that all the necessary conditions to enable its proposal will happen on its aggressive timeline. This conclusion dismisses or outright ignores a multitude of evidence to the contrary. [EPA-HQ-OAR-2022-0829-0733, p. 4]

A. The Proposal Compromises Energy and National Security

1. Inadequate Minerals for Batteries Will Make Original Equipment Manufacturers ("OEMs") Dependent on Foreign Suppliers and Make it Difficult to Supply Electric Vehicles Required by this Proposal

The Russian invasion of Ukraine highlights the importance of assessing, planning, and mitigating risks to energy supplies. As we have seen with Europe, a strategy of supply diversification (e.g., increasing imports from a diverse pool of suppliers) is an important way to mitigate global supply disruptions.3 The key tenet of risk mitigation is not about removing the likelihood of a risk but about reducing its impact to an acceptable level—the primary justification for the U.S. holding a Strategic Petroleum Reserve. The U.S. similarly holds a national defense commodity-based stockpile meant to decrease or prevent "dependence upon foreign and single points of supply for strategic and critical materials needed in times of national emergency."4 Exposing U.S. mobility to the risk of critical mineral supply availability raises an essential energy security question: How best does the U.S. trade risks it can mitigate for risks it cannot? But EPA fails to address this question in its Proposal. Rather, EPA largely limits its analysis to energy security impacts resulting from decreased fuel consumption and ignores the riskier implications of mandating reliance on an unstable, foreign-dominated supply chain, as evidenced by China's announcement this week that it is limiting exports of two rare earth minerals.5 [EPA-HQ-OAR-2022-0829-0733, pp. 4-5]

5 See, e.g., Proposed Rule at 29,345, 29,388–90; Archie Hunter & Alfred Cang, China Restricts Export of Chipmaking Metals in Clash with US, July 3, 2023. Bloomberg. Available at China to Restrict Exports of Metals Critical to Chip Production - Bloomberg.

The supply chain necessary to support new technologies contemplated by the Proposed Rule is far from assured and is likely to increase dependence on critical minerals from foreign sources. Reliance on a limited number of technologies (e.g., ZEVs) on the timeline required by the Proposed Rule will result in a non-resilient transportation sector that is vulnerable to unexpected disruptions and cost increases. For instance, both the federal government and the private sector recognized critical minerals are essential to the future of ZEVs.6 Unstable critical mineral supply chains could disrupt this future. ZEVs, as compared to ICEVs, have a much greater reliance on several critical minerals, as seen in Figure 1 below. There are six minerals critical to the production of ZEVs: cobalt, copper, graphite, lithium, manganese, and nickel.7 [EPA-HQ-OAR-2022-0829-0733, p. 5]

6 Note that the term "zero emissions vehicle" ("ZEVs"), and even near-ZEVs as used by EPA, is a misnomer. ZEVs are not actually zero emission when accounting for the vehicle lifecycle, including GHG and criteria pollutant emissions associated with electricity generation required for charging certain ZEVs and production of the ZEV vehicle and battery. We recognize that in the Proposed Rule, EPA uses "ZEV" to refer only to those vehicles with a specific meaning under California's EV program, but for ease of review, "ZEVs" is used throughout these comments and encompasses all of the EV technologies, including plug in electric vehicles ("PEVs") such as plug-in hybrid electric vehicles ("PHEVs") and battery electric vehicles ("BEVs").

7 INTERNATIONAL ENERGY ADMINISTRATION, "The Role of Critical Minerals in Clean Energy Transitions," (revised March 2022) available at https://www.iea.org/reports/the-role-of-critical-minerals-in-clean-energy- transitions. [hereinafter IEA Report 2022].

8 TURNER, MASON & COMPANY. “Evaluation of EPA’s Assumptions and Analyses Used in Their Proposed Rule for Multi-Pollutant Emissions Standards” (June 7, 2023) (Research funded by AFPM and available upon request) [hereinafter “Turner Mason Report”].

Critical mineral supply, especially those essential to the manufacturing of a lithium-ion (Li-ion) battery, is dominated by three lithium producing countries as summarized in Figure 2 below. Of the foreign nations that produce cobalt, molybdenum, and other minerals needed to produce ZEVs, China has disproportionate influence. While 70 percent of global cobalt production comes from the Democratic Republic of Congo,9 most of those mines are owned/operated by China, and more than 60 percent of cobalt processing is in China. Moreover, 67 percent of the world’s graphite is also produced in China.10 The U.S. imports most of its manganese from Gabon, a less politically stable country, providing 65 percent of the United States’ supply.11 [EPA-HQ-OAR-2022-0829-0733, p. 6]

SEE ORIGINAL COMMENT FOR China Dominates Processing of Critical Energy Transition Minerals. Figure 2: U.S. lack of critical mineral extraction or processing capacity 12 [EPA-HQ-OAR-2022-0829-0733, p. 6]

12 Turner Mason Report.

Expected supply from existing mines and projects under construction is estimated to meet only half of projected world demand for lithium and cobalt.”13 [EPA-HQ-OAR-2022-0829-0733, p. 6]

13 Axios Generate, The supply crunch that could slow the climate fight, (May 5, 2021).

In contrast to oil, which has a lower global market concentration than the critical minerals required for ZEVs, Figure 3 shows that most critical materials for ZEVs are concentrated in less politically stable countries. Other than lithium production which is dominated by Australia (52 percent), all other critical ZEV minerals have a political stability index less than oil. As demand for these commodities grows, the market concentration (and ability to exert power over pricing) swings toward producers in less politically stable countries. If producer countries have market power, they have the potential to impact not only price, but the ability for consumer countries to influence other issues, such as sanctity of commercial contracts, labor and/or/human rights, and environmental standards in the producing jurisdictions. The significance of this issue is compounded by the fact that multiple critical minerals are needed for ZEV production, so a disruption in the supply of a single mineral can disable the entire supply chain. The operation of ICEVs, to the contrary, relies on a single natural resource for which there is an abundant domestic supply. [EPA-HQ-OAR-2022-0829-0733, pp. 7-8]

SEE ORIGINAL COMMENT FOR Resource Extraction Locations Are Concentrated in Risky Jurisdictions. Figure 3: U.S. risk exposure to critical energy resources 14 [EPA-HQ-OAR-2022-0829-0733, pp. 7-8]

14 Turner Mason Report.

The supply chain necessary to support new technologies contemplated by the Proposed Rule is far from assured and is likely to increase dependence on critical minerals from foreign sources.15 In the event of supply disruption or pricing volatility related to geopolitical pressures, the U.S. is highly exposed as it heavily relies on imports to satisfy domestic demand in each of these critical minerals.16 Figure 4 puts this import dependence in perspective. By 2032 the Proposed Rule would raise import dependence to 100 percent of U.S. demand for most minerals, and more than 50 percent for nickel and copper. Except for copper, the U.S. does not mine significant quantities of these critical minerals. And, despite the U.S. having substantial domestic copper mining, it still relies on imports to meet 45 percent of U.S. demand. [EPA-HQ-OAR-2022-0829-0733, pp. 7-8]

15 See, e.g., Shelley Challis, POST REGISTER, "Jervois shuts down Idaho Cobalt mine" (Apr. 7, 2023), available at https://www.postregister.com/messenger/news/jervois-shuts-down-idaho-cobalt-mine/article_efd97f32-d015-11ed-9424-bfb28220210c.html (describing suspension of construction at Idaho Cobalt Operations due to, in part, low cobalt prices).

16 China announced it will restrict the export of two metals (gallium and germanium) used in EV production. While these metals are not particularly rare, China could limit export of processed key EV battery minerals to maintain its supply chain dominance. See Archie Hunter & Alfred Cang, China Restricts Export of Chipmaking Metals in Clash with US, July 3, 2023. Bloomberg, available at https://www.bloomberg.com/news/articles/2023-07-03/china-to-restrict-exports-of-metals-critical-to-chip-production.

SEE ORIGINAL COMMENT FOR EPA Proposal Essentially Increases Import Reliance of Most Critical Minerals to 100% Figure 4: U.S. import reliance of several critical minerals 17 [EPA-HQ-OAR-2022-0829-0733, pp. 7-8]

17 Turner Mason Report.

China's dominance does not stop at critical mineral extraction and processing. China produces 75 percent of all Li-ion batteries and houses the production capacity for 70 percent of cathodes and 85 percent of anodes (both key battery components).18 Conversely, the United States plays a very small role in the global electric vehicle ("EV") supply chain, with only 7 percent of battery production capacity.19 [EPA-HQ-OAR-2022-0829-0733, pp. 9-10]

18 International Energy Agency, "Global Supply Chains of EV Batteries," (July 2022), https://iea.blob.core.windows.net/assets/961cfc6c-6a8c-42bb-a3ef-57f3657b7aca/GlobalSupplyChainsofEVBatteries.pdf.

19 See id. Regardless of recent funding awarded by the Department of Energy to construct three battery plants, the domestic supply of these critical minerals remains unchanged and, once these manufacturing facilities are permitted, constructed, and operable, they will rely heavily on foreign-sourced materials to maximize capacity and output, if even possible.

This new demand for foreign-sourced materials will upset the decades of progress theU.S. made in energy security, where we are currently a net exporter of crude and refined petroleum products combined, and it will undermine the domestic security provided by our refining industry. Sourcing critical minerals and building a secure, North American supply chain for

ZEVs is not guaranteed as foreign production and processing of critical minerals have an established, large market share and competitive advantage today. Because passenger vehicles have domestic manufacturing and sourcing requirements in the IRA to be eligible for the clean vehicle tax credit, compliance will be challenging.20 Yet the proposal assumes, without basis, that virtually all batteries will qualify for the full tax credits and will achieve cost parity despite a significant increase in demand. In making this assumption, EPA ignores the obvious benefits of a multi-technology approach that would reduce the risks associated with a ZEV-focused approach. For example, Toyota recently noted in a memo to its dealers that “the amount of raw materials in one long- range battery electric vehicle could instead be used to make 6 plug-in hybrid electric vehicles or 90 hybrid electric vehicles . . . the overall carbon reduction of those 90 hybrids over their lifetimes is 37 times as much as a single battery electric vehicle.”21 [EPA-HQ-OAR-2022-0829-0733, pp. 9-10]

20 IRA, Section 45W(c) (The IRA requires 50% of the value of battery components to be produced or assembled in North America to qualify for a $3,750 credit and 40% of the value of critical minerals sourced from the United States or a free trade partner also for a $3,750 credit).

B. The United States Lacks Copper and Aluminum Production Required for Grid Expansion

Beyond the ZEV itself, electricity networks need a large amount of copper and aluminum.23 The need for grid expansion that would result from this rapid increase in electricity demand underpins a doubling of annual demand for copper and aluminum.24 Most supply of these materials will come from overseas, as the United States lacks current production capacity or the ability to increase such capacity in time to meet the demands of the Proposed Rule. [EPA-HQ-OAR-2022-0829-0733, pp. 11-12]

23 IEA Report 2022.

24 Id.

The United States does not supply much of the world’s aluminum. Instead, China, Russia, and India lead global production with an estimated 45 million metric tons per year. China possesses more than half of the entire world’s aluminum smelting capacity and produces by far the most aluminum of any country at over 36 million tons per year.25 The United States, by contrast, produces approximately 1 million tons per year. Similarly, countries supplying the most copper are Chile, Peru, China, and the Democratic Republic of the Congo. These countries supply ten times the amount produced domestically. [EPA-HQ-OAR-2022-0829-0733, pp. 11-12]

25 Andy Home, “Global aluminum production pendulum swings back to China” (June 21, 2022) available at https://www.mining.com/web/column-global-aluminum-production-pendulum-swings-back-to-china/.

Experts predict our demand for these materials will rise dramatically, but we lack the ability to source them domestically. The latest data concludes sourcing copper for electric infrastructure (e.g., charging stations and storage) needed to accommodate increased electrical demand will be challenging.26 Copper demand is expected to rise by 53 percent, while supply is expected to rise by only 16 percent.27 U.S. import dependency for copper has grown from 10 percent in 1995 to

40 percent in 2020, with projections of copper import dependency reaching between 55 percent and 67 percent between 2020 and 2040.28 Other estimates predict that by 2030 supply from existing mines and projects under construction is estimated to meet only 80 percent of copper needs by 203029—not considering the anticipated increase in ZEV production anticipated by EPA's Proposed Rule. [EPA-HQ-OAR-2022-0829-0733, pp. 11-12]

29 IEA Report 2022.

Establishing new mines, particularly in the United States, is not a near-term solution. Permitting and authorizing new domestic mining and smelting capacity requires a substantial amount of time and government support. According to the National Mining Association, it can take up to 10 years to obtain a permit to commence mining operations in the U.S., while permitting takes two years in Canada and Australia.30 "[U]nless the permitting process can be improved, U.S. mining developments will continue to take longer to come online and carry more financial risks compared with the rest of the world, China's domination of battery manufacturing and critical minerals production will continue for a longer period, and the U.S. will find it increasingly difficult to acquire the metals and minerals it needs for its long-term clean-energy goals."31 Despite this Rule's unlawful push to transition to EVs, the Bureau of Land Management placed a 20-year moratorium on mining rare earth minerals, such as copper, nickel, and cobalt, from almost a quarter of a million acres of Minnesota, effectively killing the proposed Twin Metals copper-nickel mine project.32 [EPA-HQ-OAR-2022-0829-0733, p. 12]

32 88 Fed. Reg. 6308 (Jan. 31, 2023).

Globally, regulatory approval for new copper mines is at its lowest level in a decade.33 As a case in point, the Resolution copper deposit in Arizona was discovered in 1995. This world-class resource has been trying to acquire the necessary regulatory approvals for over 27 years. As recently as May 19, 2023, the U.S. Forest Service told a federal court it was suspending approval of a land swap between the project (owned by Rio Tinto and BHP) and several Native American groups.34 The land swap was approved by the U.S. Congress in 2014, but the completed environmental report was blocked in March 2021. Other copper mining projects in Alaska and Minnesota have been halted by this administration, resulting in increased import dependence.35 [EPA-HQ-OAR-2022-0829-0733, p. 12]

2. Required battery production is not feasible within the Proposal’s time frame.

EPA severely overestimates the availability of minerals and the mining/processing infrastructure and capabilities in the U.S.54 EPA’s position in the DRIA that “PEV production in the U.S. need not be heavily reliant on foreign manufacture of battery cells or packs as PEV penetration increases and domestic mineral and cell production comes online” is unfounded.55 [EPA-HQ-OAR-2022-0829-0733, pp. 16-17]

54 AAI Comments at iv.

55 DRIA at 3-20.

The development of natural resources projects, like critical mineral mining and processing, can easily require more than a decade. Increasing supply is not merely a matter of increasing current production. “The ability for the miners to quickly ramp up production of key ores is limited by regulatory hurdles and capital investment.” Globally, it takes on average more than 16 years to move mining projects from first discovery to production.56 The ability to quickly scale minerals production is further affected by ore quality, which in recent years has been declining, and thus requires more material to be mined, more resources such as water in stressed areas for processing, and ultimately greater environmental impacts. Even with the requisite authorizations in hand, mine development and production can take years. For an open pit mine, it takes about 7 to 8 years from discovery to first ore; for a subsurface mine, the time frame is more like 10 to 12 years. [EPA-HQ-OAR-2022-0829-0733, pp. 16-17]

56 IEA Report 2022.

Extracting critical minerals is challenging because most critical mineral ores exist in relatively low concentrations and the quality of the ore grade is declining. For example, the average ore grade for copper discoveries decreased in excess of 25 percent during the last 15 years. In that same period, total energy consumption increased at a higher rate (46 percent) than production (30 percent). Extraction (i.e., mining and processing) of metal content from lower- grade ores requires removing more overburden to access the ore body, which requires more energy, exerting upward pressure on production costs, greenhouse gas and criteria pollutant emissions, and waste volumes. And once the raw material is mined, it must be qualified. This is not a mine-to-producer scenario. It is a specialty chemical that must be tested at different stages for safety, consistency of product output, and performance before it can be qualified for use in battery/ZEV manufacturing. Substantial lead time is needed to qualify battery-grade materials as they go through a very rigorous, staged approach. Careful attention to putting up projects on the scale of raw material resource extraction and gigafactories requires time, careful consideration, and intensive safety precautions. Accelerating the buildup of a domestic battery value chain should not overstep aspects of safe project development. [EPA-HQ-OAR-2022-0829-0733, p. 17]

The required critical minerals are not available at scale today. Mining capacity cannot be increased as quickly as required to meet the production rate required under the Proposed Rule, and at-scale recycling capabilities to remove these materials will not be available soon. EPA's willingness to assume that global supply shortages of critical minerals will resolve themselves without specific analysis of how that problem will be addressed is another example of EPA ignoring an issue of central relevance to this rulemaking. EPA neglects to appreciate these limitations, rendering its Proposed Rule arbitrary and factually unsupported. [EPA-HQ-OAR-2022-0829-0733, p. 17]

EPA notes that many OEMs and battery manufacturers announced plans to build gigafactories in North America due to government incentives like the IRA. But these are extraordinarily complex projects that will take many years to materialize if they progress to the point of battery production. In the DRIA, EPA states that, based on construction announcements by major automakers, "the U.S. will have more than 800 GWh of cell or battery manufacturing capacity by 2025, and ~1000 GWh by 2030, enough to supply from 10 to 13 million BEVs per year."130 By contrast, Wood Mackenzie projects U.S. capacity of less than half that level, at 422 GWh/ year in 2030,131 because many projects have failed to materialize or are delayed as market and other conditions change. [EPA-HQ-OAR-2022-0829-0733, p. 30]

130 DRIA at 3-20.

131 Wood Mackenzie, "The EPA plans to rev up US EV sales," (Apr. 14, 2023), available at https://www.woodmac.com/news/opinion/the-epa-plans-to-rev-up-us-ev-sales/.

Regardless of the purported capacity, it is unlikely these factories will operate beyond 50 percent capacity for years. Mature battery factories today rarely operate above 80 percent utilization rates. For example, in 2022, there was 1,036 GWh of global battery production capacity, but only 450 GWh of actual production. While there was approximately 7TWh of forecast battery capacity planned as of September 2022, Benchmark Minerals Intelligence (BMI) forecast total global supply of Li-ion batteries to reach only 4.5 TWh by 2031 or a 64 percent utilization rate.132 This step in the value chain could potentially create a critical bottleneck, in stark contrast to EPA's assumed 998 GWh capacity by 2030. Given the disparity in forecasts from different reputable sources, EPA's technology feasibility assessment should factor in sensitivity cases and acknowledge potential disruptions in the supply chain. Including such sensitivity cases is fully justified given EPA's experience in projecting available volumes of cellulosic biofuel for purposes of the RFS. EPA consistently overestimated production of liquid cellulosic biofuel from Cellulosic Biofuel Production 2010–2013 (RINs). [EPA-HQ-OAR-2022-0829-0733, p. 30]

132 BENCHMARK SOURCE, "Ambition versus reality: why battery production capacity does not equal supply" (Sept. 2, 2022) at Charts 5, 6, available at https://source.benchmarkminerals.com/article/ambition-versus- reality-why-battery-production-capacity-does-not-equal-supply.

EPA requests comment on their approach to determining charging time, as set forth in the DRIA, Chapter 4.155 EPA's analysis is contingent on unsupported assumptions regarding (1) U.S. consumers' adoption of and ability to purchase more expensive ZEVs (see Sections IV.B.2 and IV.E.2.ii); (2) the type of ZEV purchased (used ZEVs or PHEVs compatible with slower charging units or new ZEVs that can use DCFC) (Section IV,B.2 addresses charging times); (3) the availability of critical minerals and metals to expand the supply of reliable and renewable electricity (see Section I.B); and (4) the availability of reliable and affordable charging for all users (see Sections IV.B.4). Given the flaws in EPA's methodology that omits significant data sources and other factors and makes unsupported assumptions, EPA should revise its analysis concerning charging time and continue with promulgating a final rule for future emissions standards, that accounts for the reality of today's automotive market and not the public pronouncements of the automotive industry, a single state or group of states, or other unsupported estimates of future market growth. [EPA-HQ-OAR-2022-0829-0733, pp. 33-34]

155 88 Fed. Reg. at 29,367.

4. EPA ignores the lack of reliable ZEV charging

The Proposal's success is partially contingent on the availability of "equitable, affordable charging."169 Currently, ZEV charging is most available in metropolitan areas, with less investment occurring outside urban areas.170 EPA's evaluation of the sourcing of critical minerals and building a secure supply chain for ZEVs does not consider how challenging it will be to meet the demand for copper needed for electric infrastructure (e.g., charging stations and storage) to accommodate increased electrical demand.171 The Proposed Rule fails to even consider that copper demand is expected to rise by 53 percent when supply is expected to rise by only 16 percent by 2040.172 Indeed, by 2030, the expected supply from existing mines and projects under construction is estimated to meet only 80 percent of copper needs by 2030173—not considering the anticipated increase in ZEV production anticipated by EPA's Proposed Rule. Domestic production of critical minerals required for battery production is insufficient to meet the projected demands. According to a review of multiple sources, there is a six-fold demand growth expectation by 2030 and approximately 15 times by 2040. This growth rate outpaces the market's ability to supply such minerals. [EPA-HQ-OAR-2022-0829-0733, pp. 36-37]

173 IEA Report 2022.

5. The Proposed Rule Incorrectly Assumes that a Secure Supply Chain Will Exist for ZEV Technologies.

a. The Proposed Rule Does Not Properly Account for the Reliance on Foreign Markets for Critical Minerals.

In the DRIA, EPA states "according to analyses by Department of Energy's Li-Bridge, no shortage of cathode active material or lithium chemical supply is seen globally through 2035 under current projections of global demand." But there are many sources that contradict this point. Looking forward toward 2030, based on current and anticipated global production plans, a global supply shortfall is likely to begin toward end of the decade if planned mining and brine projects do not deliver as expected. Some critical minerals could face shortages as early as next year.178 The options for mitigating supply chain risks are increasingly limited. At current production rates, the world exhausts the minable reserves of copper, cobalt, and nickel in the 2030s. This timeline accelerates significantly with the greater production needed for EPA's envisioned energy transition. EPA's cherrypicked data on mineral availability is another example of EPA's failure to address a major aspect of the proposal, in this case obscuring real world obstacles to the Proposed Rule. [EPA-HQ-OAR-2022-0829-0733, p. 38]

178 Lilly Lee, ENERGY INTELLIGENCE, Mining the Gap to a Net-Zero Future (May 15, 2023) available at https://www.energyintel.com/00000188-1e5f-d806-ad9f-5edfeb1d0000?utm_campaign=website&utm_source=sendgrid.com&utm_medium=email.

b. The Proposed Rule Over-Estimates the Ability for the U.S. to Source Materials and Fabricate Batteries Domestically.

The Proposed Rule fails to fully account for the challenges associated with creating and sustaining a viable domestic supply chain that can deliver production-ready batteries necessary to meet the Rule's assumed pace of electrification. Notably, the Rule does not carefully consider the impediments to a viable domestic supply chain because of mineral availability, mineral processing and manufacturing, and overall costs (see Section I.A.1 and Figures 2, 3, and 4). [EPA-HQ-OAR-2022-0829-0733, p. 38]

EPA's DRIA severely overestimates both the availability of minerals and mining/processing infrastructure and capabilities in the U.S., assuming PEV production will not be dependent on foreign manufacture of battery cells.179 In April, the United States' first and only cobalt plant decided to halt construction at the Idaho Cobalt Operations mine due to low cobalt prices, inflation, and the mine's remote location despite Jervois's beneficial support from federal grants—including a not-yet-approved $15 million award from the U.S. Department of Defense—for additional drilling and to pay for studies to assess the possibility of constructing a cobalt refinery in the U.S. 180 Given the Agency's lack of expertise in this area, it is not surprising EPA neglects to properly analyze mineral availability and mining processing capabilities. [EPA-HQ-OAR-2022-0829-0733, p. 38]

Though EPA mentions that OEMs are taking steps to secure domestically sourced minerals and related commodities to supply production for these plants, the OEM's recent comments express grave concern regarding the availability of critical minerals needed to produce batteries,181 Moreover, many of those offtake agreements referred to EPA are with projects yet to be permitted, built, or commercialized at scale.182 OEMs, cathode or anode producers, and battery manufacturers are internally assessing their raw material offtake agreements and expect that some projects will not materialize to fruition. ZEVs are projected to represent approximately 90 percent of lithium demand by 2030, so, contrary to the assumption in the DRIA, switching chemistries for other uses will not reduce the burden or price on lithium. [EPA-HQ-OAR-2022-0829-0733, p. 39]

179 DRIA at 3-20.

180 See, e.g., Shelley Challis, POST REGISTER, "Jervois shuts down Idaho Cobalt mine" (Apr. 7, 2023), available at https://www.postregister.com/messenger/news/jervois-shuts-down-idaho-cobalt-mine/article_efd97f32-d015-11ed-9424-bfb28220210c.html.

181 AAI Comments at iv-v.

182 See, e.g., Shelley Challis, Post Register, "Jervois shuts down Idaho Cobalt mine" (Apr. 7, 2023), available at https://www.postregister.com/messenger/news/jervois-shuts-down-idaho-cobalt-mine/article_efd97f32-d015-11ed-9424-bfb28220210c.html (describing Jervois's decision to halt construction at the Idaho Cobalt Operations mine due to low cobalt prices, inflation, and the mine's remote location despite Jervois's beneficial support from federal grants—including a not-yet-approved $15 million award from the U.S. Department of Defense—for additional drilling and to pay for studies to assess the possibility of constructing a cobalt refinery in the U.S.)

Considering the above, the Proposed Rule creates a multi-year—and perhaps insurmountable—dependence on foreign mineral production and this, coupled with domestic limitations in battery manufacturing capabilities, will make it impossible to sustain the viable domestic supply chain that EPA envisions. While EPA acknowledges that "much of the supply chain supporting the manufacture of ZEVs is located outside of the U.S.,"183 it arbitrarily underplays this dependency by claiming that "more than half of battery cells and 84 percent of assembled packs in PEVs sold in the U.S. from 2010 to 2021 were produced in the U.S." Battery cell production, however, is just a piece of the value chain, and it cannot grow absent a stable supply of refined critical minerals and precursors. Even assuming critical minerals are available, a viable supply chain requires sufficient capacity of midstream refining operations prior to battery cell production. Such capacity does not exist. For instance, BMI foresees a 77 percent deficit in domestic available cathode active material to meet 2035 demands in North America (N.A.). And this estimate was done prior to the EPA Proposal. [EPA-HQ-OAR-2022-0829-0733, p. 39]

183 DRIA at 3-20.

While Congress and the Administration have taken steps to accelerate the supply chain, their efforts are insufficient to fully support the rate of production required by the Proposal. For example, U.S. supply of battery anode material is supported by the IRA and BIL, but the production of raw materials supply that feeds the production of battery anode material is not supported. Currently, Chinese battery firms are the most advanced and the majority of raw material mining and processing goes through Chinese entities. See Section I.A. and Figure 2. Thus, it will be difficult for many OEMs to meet the requirements for IRA credits in the near term. Without a domestic solution to this value chain, reliance on imports will only add to cost to the battery pack.184 [EPA-HQ-OAR-2022-0829-0733, pp. 39-40]

184 Benchmark Minerals Intelligence, BMI (see Chart 2, 3 & 4).

Ignoring these potential supply chain shortfalls leads to further deficiencies in EPA's analysis. Indeed, limited supplies and constrained supply chains risk production downtime and inventory backlogs—and this is just for production of the ZEVs.185 The Daimler Truck Group ("Daimler"), for example, has been and is likely to continue to be "acutely affected by an ongoing global shortage of semiconductors, which must be purchased on the global market."186 And with the "rapidly rising demand for certain new technologies, such as electrified powertrains," Daimler anticipates higher product costs, supply bottlenecks, and "long-term increases in demand for battery cells, semiconductors, and certain critical materials, such as lithium." Taken together, Daimler anticipates these supply chain concerns would limit its "ability to meet demand for its current generation of vehicles (including its vehicles with conventional combustion engines) or commercialize its new [ZEVs] profitably (or at all)."187 Daimler, of course, is not alone in these conclusions and yet EPA's Proposed Rule appears to reject outright any realistic assessment of future supply chains. [EPA-HQ-OAR-2022-0829-0733, p. 40]

185 See Daimler Truck Group, Annual Report 2022, 141 available at https://www.daimlertruck.com/fileadmin/user_upload/documents/investors/reports/annual-reports/2022/daimler-truck-ir-annual-report-2022-incl-combined-management-report-dth-ag.pdf (describing Daimler Truck Group's reliance on certain commodities, like steel, copper, and precious metals that are usually sourced from individual suppliers, meaning that a single supplier's inability to fulfill delivery obligations can have detrimental effects for an entire production line).

186 Id.

187 Id.

The mining sector will also need to grow significantly to meet ZEV demand as anticipated, and required, by the Proposed Rule. Mining is an energy- and environmental resource-intensive activity. Critical minerals for electric batteries such as lithium and copper are particularly vulnerable to water stress given their high-water usage.208 And more than 50 percent of today's lithium and copper production is concentrated in areas with high water stress levels. Several major producing regions such as Australia, China, and Africa are also subject to extreme heat or flooding, which pose greater challenges in ensuring reliable and sustainable supplies. Strong focus on environmental best practices in this sector are needed to safeguard natural lands, biodiversity, and sustainable water use. Similarly, focus on ethical best practices is needed to protect indigenous peoples' rights, and to provide better child labor protections. These challenges call for sustainable and socially responsible producers to lead the industry. The accelerated ZEV technology penetration rate required under the EPA's proposal poses significant challenges for the timely and widespread implementation of best practices to be developed, implemented, and ensure oversight mechanisms are working.209 [EPA-HQ-OAR-2022-0829-0733, pp. 45-46]

208 See EIA 2022 Report.

209 For example, the United Nations Environment Programme is advising the Global Investor Commission on Mining 2030 to identify best practice standards for responsible mining. See Mining 2030 at https://mining2030.org/new-global-commission-launched-to-raise-mining-sustainability-standards-by-2030/.

In addition, activities associated with mining produce GHG emissions, particulate matter emissions, nitrogen oxide emissions, and other air pollutant emissions from mining equipment. As shown in Figure 8, mining and processing several minerals and metals used for ZEV production are carbon intensive. [EPA-HQ-OAR-2022-0829-0733, pp. 45-46]

SEE ORIGINAL COMMENT FOR Average GHG emissions intensity for production of selected commodities. Figure 8: 210 [EPA-HQ-OAR-2022-0829-0733, pp. 45-46]

210 IEA Report 2022 at 17.

Source: INTERNATIONAL ENERGY ADMINISTRATION [EPA-HQ-OAR-2022-0829-0733, pp. 45-46]

The process for extracting and processing critical minerals can be responsible for approximately 20 percent of the lifecycle GHG emissions from battery production.211 EPA failed to weigh any of these consequences appropriately in the Proposed Rule. [EPA-HQ-OAR-2022-0829-0733, pp. 45-46]

211 H.C. Kim, et al., ENVIRONMENTAL SCIENCE AND TECHNOLOGY (Vol. 50) “Cradle-to-Gate Emissions from a Commercial Electric Vehicle Li-Ion Battery: A Comparative Analysis,” (2016), pp. 7715–22.

EPA’s reliance on an ICCT study to justify its estimate of falling battery costs is misplaced. ICCT ignored literature that PHEVs depreciate with certain models and makes losing greater value than others, like Tesla, especially those with long-range features. A May 2023 CBS article highlighted a statement from Kelley Blue Book, an automotive research company, that PHEVs generally depreciate faster than ICEVs.228 Kelley Blue Book said that three-year-old PEVs hold 63 percent of their value compared to 66 percent for ICEVs.229 Additionally, ICCT’s battery cost curve does not account for the potential of rising PEV-related metal prices which can cause the price of battery packs to increase, as seen in 2022 and 2023. If ICCT's estimates of PEV battery pack costs were revised to be higher, PEVs are likely to be priced at a substantial premium compared to ICEVs. [EPA-HQ-OAR-2022-0829-0733, pp. 49-50]

229 Id.

Moreover, the minerals used for EV batteries are also essential to many components of a lower-carbon energy system beyond EV batteries, such as solar photovoltaic cells, wind turbines, and hydrogen electrolyzers. In addition, these minerals have multiple traditional uses, such as military defense systems, aerospace, mobile phones, computers, fiber-optic cables, semi-conductors, medical applications, and even bank notes. Without substantial increases in new mining capacity (or massive shifts toward recycling), competition for these minerals will materially stiffen with increased electrification and the shift in underlying grid energy mix. An acceleration in demand for these key minerals could result in price volatility stemming from supply disruptions and/or geopolitical pressures. By contrast, the U.S. is much less reliant on foreign sources of petroleum energy sources. In fact, the U.S. has been a net exporter of gasoline and diesel since late 2009. And much of our petroleum imports come from friendly countries such as Canada. [EPA-HQ-OAR-2022-0829-0733, pp. 50-51]

Organization: American Highway Users Alliance

More specifically, EPA’s proposal in this docket appears to be premised on huge and rapid growth in the portion of light-duty and medium-duty vehicles that are electric powered (EVs) as well as on rapid transformation of the marketplace in a number of related areas that are not the subject of the proposed regulation. EPA seems to have made favorable assumptions on many issues bearing on the feasibility of the proposal, including as to the issues set forth below. The Highway Users, on the other hand, drawing on the expertise of its members, questions that, within the MY 2027 – 2032 timeframe of the proposed rule, all or most of the following will occur, that -- [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

[,,,]

• there will be an adequate supply of rare earth and other critical minerals, and the ability to process them, with those minerals being so essential to the manufacture of EVs and batteries, [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

- with a large portion of such minerals being sourced and/or processed overseas, including in China and Africa, whether the national interest in sourcing and processing such minerals in the United States can be met, and [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

Access to Critical Minerals

As EPA well knows, EVs, whether light-duty, medium-duty, or heavy-duty, require use of rare earth and other critical minerals for manufacture of batteries and to reduce the weight of EV parts other than the batteries. These minerals, such as lithium, cobalt, graphite, and nickel, currently are sourced in and must be transported from places such as China and Africa. Increasing reliance on EVs both for light/medium-duty vehicles and heavy-duty vehicles means that important industries and the nation would become increasingly reliant on components and very long-distance transportation from China, Africa and elsewhere, weakening national security and increasing trade deficits. These are reasons to do less, not more, to accelerate EV use until U.S. sources of these materials can be identified and developed. [EPA-HQ-OAR-2022-0829-0696, p. 6]

And the need for U.S. sourced minerals and processing will be major. There are reports that, globally, over 300 new, additional mines will be needed to meet raw materials needs for batteries and energy storage by 2035.7 Yet, the overall proposal by EPA does not appear to seek to do anything to accelerate or facilitate the ability to acquire and process these scarce metals in the United States, where mining would be subject to greater environmental protection. At least to that extent the vehicle emissions reduction NPRMs appear to underweight adverse environmental and social impact of less regulated mining (though outside the U.S.), emissions from very long-distance transportation of important supplies, and perhaps other aspects of EV manufacture and deployment. [EPA-HQ-OAR-2022-0829-0696, p. 6]

7 Benchmark Minerals Intelligence, September 6, 2022, “More than 300 new mines required to meet battery demand by 2035”, https://source.benchmarkminerals.com/article/more-than-300-new-mines-required-to-meet-battery-demand-by-2035

Organization: American Petroleum Institute (API)

EPA notes in the proposal various partnerships and plans to build battery manufacturing plants in the U.S., taking advantage of incentives such as the IRA, one must view these as highly complex projects – in addition to siting and construction, it will take time for these new battery manufacturing facilities to be up and running to ramp up to full production. Further, there is the probability that not all announced projects will materialize. [EPA-HQ-OAR-2022-0829-0641, p. 15]

f. Critical Minerals, Energy Security, BEV Supply Chains, Feasibility and Modeling.

i. Critical minerals.

Reliance on a limited number of technologies (e.g., ZEVs) on the timeline required by the proposed rule will likely result in a non-resilient transport sector that is vulnerable to unexpected disruptions. Both the federal government and the private sector have recognized that critical minerals are essential to the future of ZEV technology, and likewise, that unstable critical mineral supply chains could disrupt this future. [EPA-HQ-OAR-2022-0829-0641, pp. 20-21]

BEV battery supply chains, including critical minerals and precursors are controlled by a small number of countries, some with unsustainable environmental and human rights practices, and geopolitical concerns. The mining sector will need to grow exponentially to meet demand, and mining is an energy- and environmental-intensive activity. The accelerated BEV technology penetration rate required under EPA's proposal poses significant challenges for best practices to be widely and fully deployed in the timeframe anticipated by the proposed rule. [EPA-HQ-OAR-2022-0829-0641, pp. 20-21]

Regarding the availability of critical minerals, especially those essential to the manufacturing of a Li-ion battery, the supply is dominated by three lithium producing countries — Australia, Chile and China, which account for nearly 90 percent of the global market.65 While 70% of global cobalt production comes from the Democratic Republic of Congo,66 most of the mines are owned/operated by China and more than 60 percent of cobalt processing is located in China. China produces 67 percent of the world's graphite.67 The U.S. imports most of its manganese from Gabon, a less geopolitically stable country, providing 65 percent of the United States' supply.68 Electricity networks need a large amount of copper and aluminum. The need for grid expansion that would result from this rapid increase in electricity demand underpins a doubling of annual demand for copper and aluminum.69 China possesses over half of the entire world's aluminum smelting capacity. [EPA-HQ-OAR-2022-0829-0641, pp. 20-21]

69 "The Role of Critical Minerals in Clean Energy Transitions", International Energy Agency World Energy Outlook Special Report. May 2021. https://iea.blob.core.windows.net/assets/?d2a83b-8c30-4e9d-980a- 52b6d9a86fdc/TheRoleofCriticalMineralsinCleanEnergyTransitions.pdf.

There are sources that indicate a shortage of critical minerals as well as volatility in critical mineral prices. U.S. energy security would also undergo a dramatic paradigm shift if vehicle technologies were shifted from ICEVs to ZEVs in the exponential rate that the proposal contemplates. Domestic production of critical minerals required for battery production is insufficient to meet the projected demands. Although Congress and the Administration have taken significant steps to accelerate this activity by funding, facilitating, and promoting the rapid growth of U.S. supply chains for these products through the IRA, BIL, and numerous Executive Branch initiatives, more will still be needed given the proposed increase in demand. Further, EPA failed to consider all the complexities, such as federal permitting, National Environmental Protection Act reviews, and the supply chains for these critical materials in their technology feasibility assessment. API requests that EPA include a thorough evaluation of the full supply chains for each critical mineral/material in their final proposal and their implications on energy security, factoring in sensitivity cases and acknowledging potential disruptions in the supply chain. Please see Appendix A for more discussion regarding our concerns on critical minerals. [EPA-HQ-OAR-2022-0829-0641, pp. 20-21]

Mineral security and energy security, defined as "the uninterrupted availability of energy sources at affordable prices"71 are essentially interchangeable concepts because the proposed rule will require affordable supplies of critical minerals, that while available within the U.S., are largely inaccessible due to permitting challenges.72 [EPA-HQ-OAR-2022-0829-0641, pp. 21-22]

71 88 Fed. Reg. 29,388 (May 5, 2023).

72 The Martec Group, "Electric vehicle growth in the U.S.: A look Into the EV Battery Supply Chain", March 2022, https://martecgroup.com/electric-vehicle-battery-supply-chain/.

According to the Congressional Research Service,73 the U.S. has a heavy dependence on imported critical minerals and for the five critical minerals used in battery production there is a "higher potential" for disruptions to the supply chain. In addition to domestic reserves of critical minerals where it may not even be economical to produce,74 there is a lack of liquidity75 in global markets that are highly concentrated. Markets for critical minerals are "small, thin, and opaque"76 and inefficient which is crippling to development and advancement of critical minerals. [EPA-HQ-OAR-2022-0829-0641, pp. 21-22]

73 Tracy, B. S. (2022). "Critical Minerals in Electric Vehicle Batteries" (CRS Report No. R47227). https://crsreports.congress.gov/product/pdf/R/R47227.

74 Ibid.

75 Hendrix, C. December 2022. "Markets for Critical Minerals Are Too Prone to Failure." Barron's. https://www.barrons.com/articles/markets-critical-minerals-lithium-cobalt-copper-51671227168.

76 Ibid.

U.S. energy security would also undergo a dramatic paradigm shift if vehicle technologies were shifted from ICEVs to ZEVs in the exponential rate that the proposal would likely entail. The U.S. would move from being energy secure to being dependent largely upon foreign sources for the minerals needed to make ZEV technologies such as batteries. [EPA-HQ-OAR-2022-0829-0641, pp. 21-22]

iii. BEV Supply Chains.

Given the market and domestic resource challenges identified above, the EPA has failed to properly address effects on energy security of the U.S. The proposed rule would make the U.S. more reliant on imported critical minerals that are subject to supply disruptions and market concentrations. As EPA mentions, disruptions in petroleum supply chains and critical mineral supply chains are not perfectly comparable; however, similarities should not be ignored. [EPA-HQ-OAR-2022-0829-0641, pp. 21-22]

i. Additional Concerns.

EPA must address several aspects of their analysis of vulnerabilities associated with critical minerals as outlined in Appendix A and related to cost, modeling, and assumptions as outlined in Appendix B. [EPA-HQ-OAR-2022-0829-0641, p. 34]

Appendix A:

Critical Minerals Assessment

There are hurdles to address in order to support the scale-up adoption of BEV. These hurdles include impacts on supply chains, energy resilience and the environment. Consideration to both the hurdles and mitigation measures should be given to inform responsible and effective implementation of vehicle standards. [EPA-HQ-OAR-2022-0829-0641, p. 36]

Reliance on a limited number of technologies (e.g., BEVs) on the timeline required by the proposed rule will likely result in a non-resilient transport sector that is vulnerable to unexpected disruptions. Both the federal government and the private sector have recognized that critical minerals are essential to the future of BEVs, and likewise, that unstable critical mineral supply chains could disrupt this future. A BEV passenger car requires six times85 more minerals than a conventional gasoline car. A PHEV requires just one-sixth the critical minerals compared to a BEV, making it a more achievable bridge while the industry scales.86 We understand that EPA's current analysis does not include PHEV in their technology penetration rates, and that EPA plans to incorporate these technologies in the final rule. API recommends the critical minerals section of the rule be revisited considering PHEV in the assumptions and analysis. Additionally, EPA needs to explain why more of the total electrical vehicle miles travelled (VMT) could not be satisfied by PHEV, which would allow supply chains to better accommodate the demand for critical minerals and hence lower potential global environmental risk. [EPA-HQ-OAR-2022-0829-0641, p. 36]

I. Mineral availability and mining.

BEV battery supply chains, including critical minerals and precursors are controlled by a small number of countries, some with unsustainable environmental and human rights practices, and geopolitical concerns. The mining sector would need to grow exponentially to meet the proposed rule's demands. According to a forecast by BMI, at least 384 combined new mines for graphite, lithium, nickel, and cobalt are required to meet the global demand by 2035.87 These numbers highlighted by the BMI report were derived prior to EPA releasing the new rule proposals, which will significantly increase the need for new mines. [EPA-HQ-OAR-2022-0829-0641, pp. 36-37]

87 More than 300 new mines required to meet battery demand by 2035: https://source.benchmarkminerals.com/article/more-than-300-new-mines-required-to-meet-battery-demand-by- 2035.

Mining is an energy- and environmental-intensive activity. Critical minerals for electric batteries such as lithium and copper are particularly vulnerable to water stress given their high-water requirements.88 Over 50 percent of today's lithium and copper production is concentrated in areas with high water stress levels. Activities associated with mining produce GHG emissions, as well as particulate matter emissions, nitrogen oxide emissions, and other air pollutant emissions from mining equipment. A strong focus on environmental and ethical best practices in this sector are needed to safeguard natural lands, biodiversity, sustainable water use, indigenous peoples' rights, and labor protections.89 [EPA-HQ-OAR-2022-0829-0641, pp. 36-37]

II. Supply chain resilience.

Looking forward toward 2030, based on current and anticipated global production plans, a global supply shortfall is likely to begin toward the end of the decade. If planned mining projects do not deliver as expected, some critical minerals could face shortages as early as next year.94 Globally, it takes on average over 16 years to move mining projects from first discovery to production.95 The ability to quickly scale minerals production is further affected by ore quality, which in recent years has been declining and thus requires more material to be mined, more resources such as water in stressed areas for processing, and ultimately greater environmental impacts. [EPA-HQ-OAR-2022-0829-0641, pp. 37-38]

94 L. Lee, Energy Intelligence "Mining the Gap to a Net-Zero Future," May 15, 2023. https://www.energyintel.com/00000188-1e5f-d806-ad9f-5edfeb1d0000?utm_campaign=website&utm_source=sendgrid.com&utm_medium=email.

https://iea.blob.core.windows.net/assets/?d2a83b-8c30-4e9d-980a-52b6d9a86fdc/TheRoleofCriticalMineralsinCleanEnergyTransitions.pdf.

EPA also fails to consider the value chain before the battery cell production. The domestic supply chain is in its early stages and to meet the proposed goals, automakers and battery manufacturers will still need to rely on foreign sources of critical materials and precursors. For instance, BMI foresees a 77 percent deficit in domestic available cathode active material to meet 2035 demands in North America. This estimate was done prior to the proposal. This step in the value chain will require import/export until it is further built out, which will add to cost to the battery pack.96 Although Congress and the Administration have taken significant steps to accelerate this activity by funding, facilitating, and promoting the rapid growth of U.S. supply chains for these products through the IRA, BIL, and numerous Executive Branch initiatives, more will still be needed given the increase in demand. [EPA-HQ-OAR-2022-0829-0641, pp. 37-38]

96 Benchmark Minerals Intelligence, BMI (see Charts 2, 3 & 4): https://source.benchmarkminerals.com/article/ambition-versus-reality-why-battery-production-capacity-does-not- equal-supply.

For any one of these minerals, this regulation, taken to its logical end, puts the U.S into a situation resembling the oil embargoes of the 1970s, where foreign actors control majorities of the critical raw material supplies used in the manufacture of fuels, battery, and motor components designed to provide transportation mobility services for the U.S. consumer. Compared with fossil fuel supply, the supply chains for clean energy technologies can be even more complex (and in many instances, less transparent).97, 98 [EPA-HQ-OAR-2022-0829-0641, pp. 37-38]

97 International Energy Agency. "The Role of Critical Minerals in Clean Energy Transitions", International Energy Agency World Energy Outlook Special Report. https://iea.blob.core.windows.net/assets/?d2a83b-8c30-4e9d-980a- 52b6d9a86fdc/TheRoleofCriticalMineralsinCleanEnergyTransitions.pdf.

98 SAFE. "The Commanding Heights of Global Transportation," https://secureenergy.org/wp-content/uploads/2020/09/The-Commanding-Heights-of-Global-Transportation.pdf.

EPA failed to consider all the hurdles and complexities such as federal permitting, National Environmental Policy Act reviews, and the supply chains for these critical materials in their technology feasibility assessment. API requests EPA include a thorough evaluation of the full supply chains for each critical mineral/material in their final proposal and their implications on energy security. [EPA-HQ-OAR-2022-0829-0641, pp. 37-38]

III. Operational ineffciency of battery production facilities.

While many OEMs and battery manufacturers have announced plans to build gigafactories in North America, taking advantage of incentives such as the IRA, one must view these as highly complex projects. It should also be noted that it will take time for these new battery manufacturing facilities to ramp up to full production. Capacity gives a reflection of what a plant could potentially produce; capacity reflects ambition. EPA notes in the DRIA that "the Department of Energy estimates that recent plant announcements for North America to date could enable an estimated 838 GWh of capacity by 2025, 896 GWh by 2027, and 998 GWh by 2030, the vast majority of which is cell manufacturing capacity." This assumes battery manufacturing capacity at initial opening or at mature stage at 100% scale. This is not accurate.

In their early years, battery factories will likely operate at approximately 50 percent production capacity. Mature battery factories today rarely operate above 80 percent utilization rates.99 The EPA projects a ten-fold increase in North American battery manufacturing capacity in just eight years, from 90 gigawatt hours per year in 2022, to 998 GWh/year in 2030, with the great majority of that sited in the U.S. Wood Mackenzie projects U.S. capacity of less than half that level, at 422 GWh/ year in 2030.100 Given the disparity in forecasts from different reputable sources, EPA's technology feasibility assessment should factor sensitivity cases and acknowledge potential disruptions in the supply chain. [EPA-HQ-OAR-2022-0829-0641, pp. 38-39]

IV. Raw materials are specialty chemicals, not commodities.

To meet the ambitions that OEMs have set forth in terms of percentage of BEV entering the market, they must secure adequate amounts of raw materials. With the projected supply and demand gap that many analysts foresee, as mentioned earlier, pricing of critical minerals could remain volatile as we have seen through the early 2020s. There are varying views by different analysts on the direction of critical mineral pricing scenarios. Morgan Stanley estimates BEV manufacturers will need to increase prices by 25 percent to account for rising battery prices.101 Battery raw materials are not commodities, they are classified as specialty chemicals, and pricing should be analyzed as such as they will not follow traditional commodity pricing structures, especially given where these supplies are geographically concentrated in areas with geopolitical instabilities. [EPA-HQ-OAR-2022-0829-0641, p. 39]

101 Thornhill, J. "Morgan Stanley Flags EV Demand Destruction as Lithium Soars," see Chart 7. Bloomberg. March 24, 2022. https://www.bloomberg.com/news/articles/2022-03-25/morgan-stanley-flags-ev-demand-destruction-as- lithium-soars#xj4y7vzkg.

Battery Raw Materials

Global demand for critical raw materials has been increasing with the increase in demand for automotive batteries as shown in Table 1. The key raw materials of interest for batteries are lithium, nickel, cobalt, and graphite. The production of these materials has increased by 18% to 251% over the last 10 years.119 [EPA-HQ-OAR-2022-0829-0641, pp. 46-47]

119 USGS Global material production sourced in May 2023.

Table 1 [EPA-HQ-OAR-2022-0829-0641, pp. 46-47]

Raw Material (1000 tons)	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022	% Increase
Lithium	37	35	36	32.5	35	43	96	87.1	83.2	107	130	251%
Graphite	1100	1190	1170	1190	1200	1200	930	1100	1100	1130	1300	18%

Nickel	2100	2490	2400	2530	2250	2100	2300	2610	2500	2730	3300	57%
Cobalt	110	120	112	124	123	110	140	144	140	165	190	73%

[EPA-HQ-OAR-2022-0829-0641, pp. 46-47]

If we assume that the global production of electric light-duty vehicles grows to ~50% by 2032 and that technological improvements will be made in battery cell chemistry consistent with known publicly available technology announcements, the demand for these critical raw materials will continue to increase by 47% to 438% by 2032.120 The output of this analysis is that there will be significant pressure on the mining industry to develop and process the raw materials to meet automotive battery demand. [EPA-HQ-OAR-2022-0829-0641, pp. 46-47]

120 Martec Group study on raw material demand from light-duty vehicles – 2022.

[See original for graph titled "Figure 4 – Global Raw Material Demand from Light-Duty Vehicles"] [EPA-HQ-OAR-2022-0829-0641, pp. 46-47]

In Figure 4 above, the increase in global production of raw materials for just light-duty vehicles is calculated based on the assumed global demand of 50% BEVs by 2032. The global average kWh per vehicle is assumed to be 71kWh and battery chemistry is expected to be ~30% LFP and 70% NMC battery types. This analysis then calculates the amount of raw material per kWh based on these inputs.121 [EPA-HQ-OAR-2022-0829-0641, pp. 46-47]

121 https://www.nature.com/articles/s43246-020-00095-x#Sec16 Supplementary Table 23.

What the outputs show is that lithium will need to increase the amount of mined material by more than 4 times in the next 10 years to keep up with just global light-duty automotive demand. Graphite is also expected to need ~3 times the amount currently produced globally. Nickel seems to be a low number at only a 50% increase from the 2022 production level however, nickel is already consumed in large quantities for other applications. This 50% increase represents ~1.6M tons of nickel while the 400% increase in lithium is only 400k tones. [EPA-HQ-OAR-2022-0829-0641, pp. 46-47]

The agency must consider the global demand for these raw materials in the final regulatory impact assessment and the associated increase in costs to develop supply for these raw materials that are more in line with market forces rather than assuming the cost of these raw materials will decrease with increasing production as stated in the DRIA.122 [EPA-HQ-OAR-2022-0829-0641, pp. 46-47]

122 Draft Regulatory Impact Analysis EPA-420-D-23-003 April 2023, Figure 2-24.

Organization: Arizona State Legislature

10. The proposed rule makes erroneous estimates about energy security and critical mineral availability. The proposed rule will force American dependence on China and impose a high cost for energy security, not a benefit as EPA calculates. [EPA-HQ-OAR-2022-0829-0537, p. 3]

X. The proposed rule is arbitrary and capricious because of erroneous estimates about energy security and critical mineral availability.

EPA calculates a $4.4 billion benefit from energy security resulting from the proposed rule. 88 Fed. Reg. 29,362. In EPA's view, "widespread automotive electrification in the U.S. will not lead to a critical long-term dependence on foreign imports of minerals or components, nor that increased demand for these products will become a vulnerability to national security." Id. at 29,313. EPA believes that existing foreign production is adequate simply because of other countries' investment in supply chains, and the Bipartisan Infrastructure Law and Inflation Reduction Act combined with market forces will cause American companies to develop their own supply chains. Id. EPA also reasons that minerals imported into the United States can be reclaimed and thus increase America's supply of those minerals. Id. [EPA-HQ-OAR-2022-0829-0537, p. 30]

EPA's own statistics show that foreign production of critical minerals presents an energy security problem. According to EPA [EPA-HQ-OAR-2022-0829-0537, pp. 30-31]:

As shown in Figure 28, in 2019 about 50 percent of global nickel production occurred in Indonesia, Philippines, and Russia, with the rest distributed around the world. Nearly 70 percent of cobalt originated from the Democratic Republic of Congo, with some significant production in Russia and Australia, and about 20 percent in the rest of the world. More than 60 percent of graphite production occurred in China, with significant contribution from Mozambique and Brazil for another 20 percent. About half of lithium was mined in Australia, with Chile accounting for another 20 percent, and China about 10 percent. [EPA-HQ-OAR-2022-0829-0537, pp. 30-31]

According to the Administration's 100-day review under E.O. 14017, of the major actors in mineral refining, 60 percent of lithium refining occurred in China, with 30 percent in Chile, and 10 percent in Argentina. 72 percent of cobalt refining occurred in China, with another 17 percent distributed among Finland, Canada, and Norway. 21 percent of Class 1 nickel refining occurred in Russia, with 16 percent in China, 15 percent in Japan, and 13 percent in Canada. Similar conclusions were reached in an analysis by the International Energy Agency, shown in Figure 29. [EPA-HQ-OAR-2022-0829-0537, pp. 30-31]

Id. at 29,314.

Indeed, the United States imports most of the minerals needed for the current electric vehicle production demand, with a net import reliance of 100% for manganese, 100% for graphite, 76% for cobalt, 48% for nickel, and more than 25% for lithium.60 As the EPA recognizes, "Currently, the United States is lagging behind much of the rest of the world in critical mineral production." 88 Fed. Reg. 29,315. [EPA-HQ-OAR-2022-0829-0537, pp. 30-31]

60 Congressional Research Service, Critical Minerals in Electric Vehicle Batteries, Aug. 29, 2022, 9, available at https://crsreports.congress.gov/product/pdf/R/R47227.

EPA's electric vehicle mandate will surge demand for critical minerals that the United States will have to import. According to the International Energy Agency, in the "global energy transition like the one President Biden envisions, demand for key minerals such as lithium, graphite, nickel and rare-earth metals would explode, rising by 4,200%, 2,500%, 1,900% and 700%, respectively, by 2040."61 The American Transportation Research Institute estimates that replacing the existing American vehicle fleet with electric cars will require 6.3 to 34.9 years of current global production of critical minerals and 8.4 to 64.4 percent of global reserves, depending on the material.62 EPA does not account for the greenhouse gas emissions resulting from this dramatically expanded mining production. [EPA-HQ-OAR-2022-0829-0537, p. 31]

62 American Transportation Research Institute, supra note 55, at 2.

EPA's electric vehicle mandate will force American dependence on China. In 2019, China accounted for 80% of the world's total production of raw materials for electric batteries.63 China's reach extends around the world. In the Democratic Republic of the Congo, for example, 15 of 19 cobalt-producing mines are owned or financed by Chinese companies.64 China also refines 95% of the world's cobalt supply.65 China controls 65% of the global lithium processing and refining capacity and is securing deals to extract lithium from mines in Latin America.66 [EPA-HQ-OAR-2022-0829-0537, p. 31]

69 Id.

In the proposed rule, EPA identifies domestic production efforts for only one mineral, lithium. 88 Fed. Reg. 29,321. The global supply of lithium needs to increase by 42 times by 2040 or 2050 to meet demand for electric vehicles.70 But "getting approval for [new mines] can still take years, if not decades."71 And the Biden Administration admits it does not even know where all critical minerals may exist: "The United States' non-fuel mineral resources are significantly under-mapped relative to those of other developed nations; only 12 percent of U.S. territory has modern high-resolution geophysical surveys of the subsurface, and only 35 percent is covered by detailed geologic mapping of the surface and near-surface."72 The Alaska governor noted that the White House's 250-page report on critical minerals mentions Australia 60 times, Canada 32 times, but Alaska only once, in a footnote.73 [EPA-HQ-OAR-2022-0829-0537, pp. 31-32]

70 Ana Swanson, The U.S. Needs Minerals for Electric Cars. Everyone Else Wants Them Too., The New York Times, May 21, 2023, available at https://www.nytimes.com/2023/05/21/business/economy/minerals-electric-cars- batteries.html.

73 Carrie Sheffield, Hypocrite Biden blocks mineral mining his clean-energy goals require, New York Post, Mar. 22, 2023, available at https://nypost.com/2023/03/22/biden-blocks-mineral-mining-his-clean-energy-goals-require/.

Under the apparent strategy of "if you subsidize it, they will come," EPA brushes off these inconvenient facts by focusing on the public and private focus on manufacturing electric batteries in the United States. 88 Fed. Reg. 29,318-319. But even if America builds all of the manufacturing capacity needed to supply EPA's forced electric vehicle demand, manufacturing still requires critical minerals that China has and America does not. Other than recycling critical minerals from old batteries, EPA proposes no solutions to this grave energy security problem. [EPA-HQ-OAR-2022-0829-0537, p. 32]

Organization: BMW of North America, LLC (BMW NA)

BMW NA, together with the Alliance of Automotive Innovators, has already agreed with Biden Administrations' stated goal of reaching 40-50% sales of electric vehicles within the market by 2030. Achieving this goal will only be possible if the framework conditions allow the market to develop - i.e. charging infrastructure, availability of critical raw materials and the overall cost situation for xEVs. [EPA-HQ-OAR-2022-0829-0677, p. 2]

At this time, BMW NA does not believe that the necessary framework conditions, especially infrastructure, are advancing as necessary to achieve the targets set forth in the Proposed Rule. Therefore, we share the concerns expressed by the Alliance of Automotive Innovators that these targets cannot be met without massive and coordinated efforts of the auto industry, energy providers, mineral suppliers and the government. [EPA-HQ-OAR-2022-0829-0677, p. 2]

Further, there are an insufficient number of mining operations available from which to source critical minerals. Benchmark Minerals3 identifies the need for at least 300 additional mining operations to be developed worldwide - within the next 10 years. The creation and production from those mines cannot reasonably be accomplished within that timeframe, - as the usual development time for new mine operations is at least 10 years. - This is a significant challenge, which needs to be solved. [EPA-HQ-OAR-2022-0829-0677, p. 2]

3 https://source.benchma rkmineraIs.com/article/more-than-300-new-mInes-requ ired-to-meet-battery-demand-by-2035

Without the availability of adequate mining operations, the scarcity of available critical minerals can only be managed to a small extent by improved battery technology. The undersupply of minerals and associated high costs to acquire will mean that price parity between ICE and xEV will not be achieved in enough time to support the GHG targets. The scarcity and availability of critical materials are a material and decisive factor, as they represent approximately 70% of the total cost to manufacture a battery. [EPA-HQ-OAR-2022-0829-0677, p. 2]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Beyond savings to individual consumers, the proposed standards, to the extent manufacturers use ZEVs to comply, present economic growth opportunities for many sectors in the United States, especially auto manufacturing, electricity generation, and upstream ZEV supply chains as consumers direct more spending to ZEV technology and electricity for transportation fuel. Many manufacturers are already domestically producing ZEVs, providing tangible employment opportunities nationwide. 128 Provisions in the Inflation Reduction Act to support domestic production and materials sourcing will further shore up these benefits. [EPA-HQ-OAR-2022-0829-0780, pp. 65-66]

Even in the short time since U.S. EPA released its proposal, manufacturers have announced new investments in vehicle and battery manufacturing and assembly that will strengthen and expand the ZEV industry across the U.S. For example, Toyota announced that it will assemble its new battery electric sport utility vehicle at its Kentucky facility using batteries from a new battery plant in North Carolina. 129 General Motors and Samsung SDI are investing more than $3 billion to build a battery plan in Indiana, providing local jobs. 130 Hyundai Motor Group and LG Energy Solution announced that they will build a $4.3 billion electric battery plant in Georgia. 131 These are just a few examples of the tremendous economic opportunity this expanding industry can provide to support local jobs and build a resilient supply chain for ZEVs. [EPA-HQ-OAR-2022-0829-0780, pp. 65-66]

D. Sales of Zero-Emission Vehicles Are Projected to Continue Growing at a Dramatic Rate

Zero-emission-vehicle technologies107 are the most effective tailpipe emission control technologies available to date, and demand for zero-emission vehicles specifically has exploded in recent years. In response to this demand, significant public and private investments across the country continue to be made to build sufficient charging infrastructure and develop the domestic battery supply chain, and these investments are projected to keep pace with the dramatic growth of the zero-emission vehicle market. There is every reason to expect this growth to continue. [EPA-HQ-OAR-2022-0829-0746, p. 18]

107 The term “zero-emission-vehicle technologies” includes batteries with on-board chargers and hydrogen stored in a fuel cell stack that transforms chemical energy into electrical energy to propel a vehicle.

Recent congressional actions demonstrate the federal commitment to substantial electrification of the transportation sector. In 2021, Congress passed the Bipartisan Infrastructure Law, which allocates $7.5 billion to building out a national network of electric vehicle chargers, $7 billion to ensure domestic manufacturers have the critical minerals and other components necessary to make electric vehicle batteries, and $10 billion for clean transit and school buses.110 In 2022, Congress passed the CHIPS and Science Act, which invests $52.7 billion in America’s manufacturing capacity for the semiconductors used in electric vehicles and chargers.111 Later in 2022, Congress passed the Inflation Reduction Act, which provides $7,500 to buyers of new electric vehicles and $4,000 to purchasers of pre-owned electric vehicles.112 Additionally, the Inflation Reduction Act provides billions of dollars to support vehicle manufacturers’ expansion of their domestic production of clean vehicles,113 and billions to support battery production in the United States and mining and processing of critical minerals needed for battery cells and electric motors.114 The Inflation Reduction Act also allocates billions to upgrade the nation’s power grid in order to help address the new surge in grid demand from electric vehicles.115 [EPA-HQ-OAR-2022-0829-0746, pp. 18-19]

3. Significant Investments Are Being Made to Build Out and Reinforce the Domestic Battery Supply Chain

The federal and state governments, manufacturers, and others in the private sector are investing billions to develop the domestic battery supply chain in order to meet the increased demand for zero-emission vehicles. [EPA-HQ-OAR-2022-0829-0746, pp. 25-27]

Congress and the Biden Administration have taken significant steps to accelerate the growth of the domestic battery supply chain, which consists of (1) the production of raw minerals from mining and recycling operations and (2) battery component and battery manufacturing. Specifically, the Bipartisan Infrastructure Law provides $7.9 billion for battery manufacturing, battery recycling, and critical minerals production.156 The Inflation Reduction Act’s Advanced Manufacturing Production Credit may provide manufacturers $136 billion or more, and the

Advanced Energy Project Credit may provide manufacturers at least another $6.2 billion. 88 Fed. Reg. at 29,318. [EPA-HQ-OAR-2022-0829-0746, pp. 25-27]

156 Congressional Research Service, Energy and Minerals Provision in the Infrastructure Investment and Jobs Act (P.L. 117-58) (Mar. 31, 2023), available at https://crsreports.congress.gov/product/pdf/R/R47034.

These federal funds are successfully encouraging large-scale investments in domestic production of critical minerals and battery manufacturing. For example, recipients of $2.8 billion of the Bipartisan Infrastructure Law funding matched the federal investment, leveraging this portion of the funding to a total of $9 billion to expand domestic production of critical minerals and manufacturing of batteries for electric vehicles.157 This investment supports 21 new or upgraded facilities that produce battery materials, recycle batteries, or manufacture batteries.158 Additionally, by the end of March 2023, the Inflation Reduction Act had already spurred over $45 billion in announced investments across the domestic battery supply chain,159 including LG Energy Solution's $5.5 billion investment to build a new battery factory in Arizona160 and Ford's $3.5 billion investment to build a battery factory in Michigan.161 And more investments in battery plants continue to be announced.162 [EPA-HQ-OAR-2022-0829-0746, pp. 25-27]

These federal funds are complemented by state and local government investments in the domestic battery supply chain. For example, California offers $25 million in grant funds for projects that will promote in-state battery manufacturing for zero-emission vehicles.163 And New York has invested more than $50 million to support the creation of Battery-NY, a technology development, manufacturing, and commercialization center in upstate New York.164 [EPA-HQ-OAR-2022-0829-0746, pp. 25-27]

By the end of May 2023, over $100 billion of investments had been announced to build or expand over 160 domestic facilities to extract and refine critical minerals and manufacture batteries.165 “In total, domestic [electric vehicle] battery manufacturing capacity will increase by almost 20-fold between 2021 and 2030.”166 Especially given the growing trend toward domestic battery production,167 there is every reason to believe that these investments will build a resilient domestic battery supply chain. See 88 Fed. Reg. at 29,313 (“EPA has confidence that these efforts are effectively addressing supply chain concerns.”). [EPA-HQ-OAR-2022-0829-0746, pp. 25-27]

This trend toward domestic production has grown over time, with 70% of battery cells and 87% of battery packs produced in the U.S. in 2020.”).

Organization: Center for American Progress (CAP)

Battery manufacturing is expected to increase even faster, with the U.S. expected to have battery manufacturing capabilities to support the production of approximately 11.2 million EVs per year by 2026. This equates to 84 percent of U.S. new vehicle sales in 2022. DOE estimates that by 2030 North American battery manufacturing capacity will be able to supply up to 13 million EVs per year.19 It is critical that EPA’s final rule accurately account for domestic EV and battery manufacturing capability as supply is expected to remain the limiting factor in EV adoption. RMI finds that battery supply may just be able to keep up with demand as demand for passenger EVs alone could exceed 1,000 GWh/year by 2030.20 Survey data from Consumer Reports finds that demand for EVs has increased 350 percent since 2020, with 45 interested buyers for every EV produced in the United States.21 [EPA-HQ-OAR-2022-0829-0658, pp. 4-5]

Organization: Charles Forsberg

Converting transportation to batteries is unaffordable because the batteries are made of non-earth abundant expensive materials and all-electric battery vehicles imply large increases in electricity costs for everyone. These two effects add trillions of dollars of cost to the EPA strategy. The primary economic cost drivers were not addressed by EPA. [EPA-HQ-OAR-2022-0829-0738, pp. 1-2]

• Earth-abundant materials. Internal combustion engine (ICE) light vehicles are inexpensive because they are made of earth abundant materials: iron, aluminum, plastic (carbon and hydrogen) and sand (glass). In contrast, all-electric vehicles are made of non-earth-abundant materials. The average battery electric vehicle (Mechanical Engineering April/May 2023) has: Copper: 53.2 kg, Lithium: 8.9 kg, Nickel: 39.9 kg, Manganese: 24.5 kg, Cobalt: 13.3 kg, Graphite: 66.3 kg, Zinc 0/1 kg and Rare Earths: 0.5 ks. Non-earth-abundant materials are expensive because they are uncommon and the ore grades are low. For example, one must process almost a 100 times as much ore to recover a pound of nickel versus a pound of iron. Technology advances do not fix the problem that these elements are expensive on planet earth. The costs of these materials will increase as will the cost of all-electric vehicles as global production increases. If our ultimate goals include moving 8 to 10 billion people into the middle class, that goal can only be done using primarily affordable earth abundant elements (see discussion in paper). Such futures may allow the use of hybrid or plug-in hybrid vehicles with much lower quantities of non-earth-abundant materials. [EPA-HQ-OAR-2022-0829-0738, pp. 1-2]

This is not a new observation. It has been well understood since the studies of Goellar and Weinberg ("The age of substitutability", Science 1976;191:4228. doi: 10.1126/science.191.4228.683) that a global middle-class standard of living requires that the civilization be built out of earth-abundant materials. [EPA-HQ-OAR-2022-0829-0738, pp. 1-2]

Separate from the costs, fast scale up of the mining of non-abundant elements is not credible. The International Energy Agency projects that the world will need to increase lithium production by 40 and nickel production 20. On the average it takes 16 years to open a new mine on earth-versus a couple of years to build a battery factory. It will take decades, assuming cost is no concern, to scale up production of these non-abundant elements. In this context, the federal government in the last two years has blocked opening nickel mines in Minnesota and copper mines in Alaska-a clear statement that the federal government will not tolerate mining at scale and that the U.S. is betting on China, Russian (Siberia) and third-world countries to supply the necessary materials. Unlike oil and natural gas, each of these less-abundant elements are found only in a few countries. As a starting point, the EPA strategy requires a reversal of current U.S. policies with Russia and China for access to some of these less-abundant elements. Simultaneously, Indonesia and other countries are enacting laws prohibiting export of these raw materials to force conversion of ore to nickel and more value-added products in their own countries. Ultimately, the battery production will move to the countries that control the required non-abundant raw materials. [EPA-HQ-OAR-2022-0829-0738, p. 2]

It is possible that new battery chemistries may enable battery systems made of only earth-abundant materials-but those do not exist today and may or may not be possible to economically construct. One can't tolerate batteries with large quantities of copper, nickel or lithium. As a side note, the numbers from the U.S. Energy Information Agency show the total installed cost of utility batteries has leveled off-in contrast to the belief in the EPA rule making that costs will continue to go down for batteries based on academic studies. The economics of scale and learning curves end when the raw materials in the manufactured product are a significant fraction of the final costs-as we are now beginning to see with battery packs. The bad news is just starting on the mining front and costs of these less-abundant elements. [EPA-HQ-OAR-2022-0829-0738, p. 2]

Recommended action for EPA. Evaluate cost of non-abundant materials required for your scenarios that accounts for (1) increased European, Chinese and Indian demand, (2) the time it takes to build real mines for copper, nickel and lithium, and (3) how to obtain the resources that are mostly in the wrong political locations. This should include analysis by the U.S. State Department on the national security implications and required changes in U.S. foreign policy. If EPA assumes significant domestic supplies, the proposed regulatory changes should simultaneously include changes in mining regulations to fast track mining permits, limit grounds for denial of permits and limit local objections to such mines. This scale of mining requires a government willing to quickly move people if in the way. Hand waving does not work when proposing an increase in hard-rock mining beyond anything seen in human history. The likely outcome of a credible analysis will be abandonment of the current regulatory strategies. [EPA-HQ-OAR-2022-0829-0738, p. 2]

Organization: Chevron

Stakeholders have expressed concern about the supply and availability of critical minerals and supply chains for battery manufacturing, many of which are sourced from China. EPA should quantitatively assess the impact this regulation will have on the nation/worldwide demand of lithium and other rare earth metals, and the emissions that will be produced as a result of mining and shipping these materials. EPA should consider environmental impacts from mining of semi-precious metals and potential mitigations. The proposal does not address the potential hazards, construction, noise, or other impacts and potential mitigations for these impacts. [EPA-HQ-OAR-2022-0829-0553, p. 6]

Organization: Clean Fuels Development Coalition et al.

III. The Proposed Rule is Not Feasible for Other Reasons.

[…] Even if consumers did want to purchase these electric vehicles in the volumes EPA projects, the proposal fails to confront several barriers to its rapid electrification plans, including limits on the supply of minerals necessary to manufacture batteries, inadequate charging infrastructure and electrical supplies, and the complex interactions between this rule and other proposed rules all of which will further hinder this development. In light of these many barriers, it is unreasonable for the agency to conclude that compliance with its proposed emission standards is feasible. [EPA-HQ-OAR-2022-0829-0712, pp. 25-26]

D. There is not enough international mining and manufacturing capacity for the global electric vehicle push.

The proposal also systematically neglects the fact that there are simply not enough minerals, particularly lithium, available to sustain global electric vehicle growth. The U.C. Davis Climate + Community Project explains that the "primary driver of lithium demand—and new lithium mines—is EVs. Global EV sales for 2022 are estimated to reach 10.6 million, a 60 percent increase from 2021 (and a 333 percent increase from 2020) that has been driven largely by China and Europe." Thea Riofrancos et al., Achieving Zero Emissions with More Mobility and Less Mining, U.C. Davis Climate + Community Project (Jan. 2023), https://subscriber.politicopro.com/eenews/f/eenews/?id=00000185-e562-de44-a7bf-ed7751a00000. In 2021, global lithium production was estimated at just over 100,000 metric tons and consumption at 93,000 metric tons. Id. But "cumulative global lithium demand" could reach "30.3 million metric tons in 2050" and "exhaust[ ] currently existing reserves by 2045." Id. Replacing "the ICE vehicles on the road with EVs on a 1:1 basis is infeasible." Id. [EPA-HQ-OAR-2022-0829-0712, pp. 29-30]

As Gill Pratt, chief executive of the Toyota Research Institute, told reporters "[I]t's going to take decades for battery material mines, renewable power generation, transmission lines and seasonal energy-storage facilities to scale up." Daniel Leussink, Not enough resources for EVs to be only cleaner car option, Toyota says, Reuters (May 18, 2023), https://www.reuters.com/business/autos-transportation/not- enough-resources-evs-be-only-cleaner-car-option-toyota-says-2023-05-18/. This is an insuperable obstacle to EPA's proposal. [EPA-HQ-OAR-2022-0829-0712, pp. 29-30]

C. The proposed rule also gets energy security costs backwards— electric vehicles are worse for energy security, not better.

The proposed rule also gets energy security costs backwards—electric vehicles are worse for energy security, not better. See Table 6, 88 Fed. Reg. 29,200.18 In the present day, China dominates critical mineral supply chains. China controls nearly two-thirds of all lithium, four-fifths of the refined cobalt market, and nearly all processed natural graphite. The United States has nearly no control of critical mineral supply chains and produces less than a tenth of the world's battery cells, while China is the world's leading producer. China controls much of the extraction of these materials and has 90 percent of the world's rare earth element processing capacity, cornering the market for the core minerals of electric car batteries, and dominating battery and renewable supply chains. See C. Boyden Gray, American Energy, Chinese Ambition, and Climate Realism, 5 American Affairs Journal (Winter 2021), https://americanaffairsjournal.org/2021/11/american-energy-chinese-ambition-and- climate-realism/. EPA acknowledges that there are very few domestic battery manufacturing plants, but assumes, without justification, that American manufacturers will increase production to a point sufficient to eliminate the energy security costs flowing from this massive transition. [EPA-HQ-OAR-2022-0829-0712, pp. 35-36]

18 This also ignores that the United States is a net exporter of oil. "The United States is the largest producer of oil, responsible for nearly a fifth of the world's oil production. Thanks to the hydraulic fracturing revolution, the United States is a net exporter of oil. China, on the other hand, is the world's largest net importer of oil. China has few oil reserves, and its dwindling domestic supplies come from legacy fields

that require expensive enhanced-recovery methods. China's demand for oil is also rapidly increasing. This explains China's long-term bet on powering transportation with electricity: China can use its abundant coal reserves, hydropower, and growing nuclear capabilities to power battery-electric cars, vans, and trucks." C. Boyden Gray, American Energy, Chinese Ambition, and Climate Realism, 5 American Affairs Journal (Winter 2021), https://americanaffairsjour- nal.org/2021/11/american-energy-chinese-ambition-and-climate-realism/. "First, policies that restrict the domestic supply of oil and gas and mandate renewable and electric car deployment will reduce U.S. geopolitical power. The United States is the world's largest producer of oil and gas. It is a net loser from unilateral restrictions on domestic hydro-carbons, while Russia, Saudi Arabia, and Iran have the most to gain, as a decline in U.S. supply increases their power to set cartel prices. China, on the other hand, is the largest net importer of oil and gas, but the dominant producer of 'green' substitutes like solar panels, battery cells, and critical minerals. 'Greening' the U.S. economy at the scale envisioned by the Biden administration would damage U.S. growth while jeopardizing U.S. national security and even global stability. It would empower antagonistic regimes like Russia, Saudi Arabia, and Iran, while reducing U.S. leverage with China." Id.

Organization: Countymark

In April 2023, the Environmental Protection Agency (EPA) proposed new emissions standards for passenger vehicles and trucks that are significantly more stringent than previous rules. The new proposed standards would require automakers to meet a tailpipe emissions average of 82 grams of CO2/mile across a company's production by model year (MY) 2032. Your agency estimated this new regulation would result in electric vehicles (EVs) accounting for 67 percent of recent light-duty vehicle sales and 46 percent of new medium-duty vehicle sales in less than ten years. Countrymark believes that this proposal significantly increases costs for American families, undermines American energy security, and falls short of estimated environmental benefits. [EPA-HQ-OAR-2022-0829-0665, p. 1]

Mandating the US's adoption of electric vehicles (EVs) has geopolitical implications that make the country more reliant on its competitors. The US achieved historic levels of energy security by becoming a net exporter of petroleum and products in 2020. However, forcing EV adoption would reduce reliance on American petroleum and increase dependence on batteries, primarily produced in China, which controls 90% of battery anode production. The US is a global leader in exporting refined petroleum products, and its refineries heavily rely on American-sourced crude oil. Implementing a policy that promotes EVs would exclude affordable vehicles running on US-made liquid fuels, leading to the offshore relocation of millions of jobs supported by the petroleum industry. Furthermore, America's geopolitical rivals, particularly China, dominate the supply chain for crucial minerals used in EVs. China controls Africa's major lithium mining projects and 80% of refining operations. Within two years, they are expected to control half of the world's cobalt production. In summary, mandating EV adoption in the US would increase reliance on competitors for battery production, disqualify vehicles running on US-made liquid fuels, and place the supply chain for essential EV minerals under the control of geopolitical rivals like China. [EPA-HQ-OAR-2022-0829-0665, p. 2]

Organization: Dana Incorporated

Dana also proposes that EPA expand its consideration of sourcing issues related to ePropulsion systems in assessing the cost, environmental impact, and feasibility of the proposed rules. Much of the analysis in the NPRM focuses on sourcing of batteries and battery materials, which has also been the focus of federal incentives. During the ZEV transition period, however, sustainable sourcing of magnets, copper, aluminum, and electrical steel materials and local processing for ePropulsion systems will be a major challenge for automakers and component suppliers. [EPA-HQ-OAR-2022-0829-0538, pp. 2-3]

Studies by the U.S. International Trade Commission and other groups have highlighted U.S. dependence on imports of NdFeB magnets and rare earths, for example, and a S&P Global study found that demand for copper will strain global supplies due to efforts to achieve net-zero carbon emissions. A group of nine large trade associations recently wrote to President Biden expressing concern about maintaining a sustainable supply of electrical steel in light of rising demand. [EPA-HQ-OAR-2022-0829-0538, pp. 2-3]

These trends will prove a major challenge, at least during the early years of the ZEV transition. Dana proposes that EPA consider ways to incentivize the use of sustainable sources of such key materials and local processing for ePropulsion systems, similar to battery incentives available during the transition period. [EPA-HQ-OAR-2022-0829-0538, pp. 2-3]

Organization: Darius, Matthew DiPaulo

The EPA's proposal boosts an electric vehicle supply chain dominated by China, which powers its manufacturing-base through coal-fired power plants and mines minerals for EV batteries with the use of environmental practices that we would never approve of in the United States. Emissions coming out of tailpipe matter, but so do the lifecycle emissions of building a car, constructing and charging a battery, and retiring vehicles. [EPA-HQ-OAR-2022-0829-0519, p. 1]

Organization: Delek US Holdings, Inc.

Most illustrative of the future foreign reliance resulting from EPA's Proposed Rule is the lithium-ion battery supply chain controlled nearly entirely by China. China controls each step of battery production and, by 2030, is anticipated to "make more than twice as many batteries as every other county combined."13 This is because China controls 41% of the world's cobalt, 28% of the world's lithium, and 78% of the world's graphite; China also refines 95% of manganese, 74% of cobalt, 70% of graphite, 67% of lithium, and 63% of nickel.14 And even if the U.S. had sufficient resources to extract and refine independent of foreign sources, a refinery takes two to five years just to build—not accounting for the time necessary for permitting, construction, and operations, including waste disposal.15 Beyond the raw materials, China also makes the battery components—73% of NMC cathodes and 99% of LFP cathodes—compared to 1% made domestically.16 Indeed, "[e]xperts say it is next to impossible for any other country to become self-reliant in the battery supply chain, no matter if it has cheaper labor or finds other global partners. Companies anywhere in the world will look to form partnerships with Chinese manufacturers to enter or expand in the industry."17 EPA's reliance on federal funding and tax incentives—such as those under the BIL and IRA—to conclude a domestic supply chain is forthcoming is, therefore, misplaced. Regardless of these funding sources, domestic manufacturing alone is unable to meet the production goals EPA is requiring. [EPA-HQ-OAR-2022-0829-0527, p. 4]

13 Agnes Chang and Keith Bradsher, NY TIMES, "Can the World Make an Electric Car Battery Without China?" (May 17, 2023), available at https://www.nytimes.com/interactive/2023/05/16/business/china-ev-battery.html.

16 Id.

17 Id.

Although EPA has acknowledged that a "transition period must take place in which a robust supply chain develops to support production of [critical minerals]," the limited time afforded under the Proposed Rule is simply insufficient to build this supply chain.18 [EPA-HQ-OAR-2022-0829-0527, p. 4]

18 Proposed Rule at 29,313.

And as discussed above, EPA hardly pays any mind to the volatile pricing of critical minerals and how that can greatly affect battery costs. The price of lithium, for example, has consistently risen in recent years. Between January 2021 and March 2022, the cost of lithium increased by 738% and continues to rise today.36 Despite these very public findings, EPA asserts that these costs are an uncertainty and that EPA plans to "continue updating [its] estimates of battery cost for current and future years."37 Rather, future lithium-ion battery production will be heavily subsidized if the BIL and IRA remain in place, which likely serves as an impediment to actually reducing the cost of the battery. [EPA-HQ-OAR-2022-0829-0527, pp. 7-8]

36 See CANADA ENERGY REGULATOR, Market Snapshot: Critical Minerals are Key to the Global Transition (Jan. 18, 2023), available here. (Link: https://www.cer-rec.gc.ca/en/data-analysis/energy-markets/market-snapshots/2023/market-snapshot-critical-minerals-key-global-energy-transition.html)

37 Proposed Rule at 29,301 (recognizing the "global average price for lithium-ion battery packs (volume-weighted across the passenger, commercial, bus, and stationary markets) climbed by about 7 percent in 2022"). Notably, this is in contrast to EPA's conclusion just a few weeks prior. Proposed Rule at 25,930 ("the cost to manufacture lithium-ion batteries (the single most expensive component of a BEV) has dropped significantly in the past eight years, and that cost is projected to continue to fall during this decade, all while the performance of the batteries (in terms of energy density) improves.").

Organization: Departments of Transportation of Idaho, Montana, North Dakota, South Dakota and Wyoming

Another issue is the dependence of EVs and their batteries on rare earth and other minerals that are largely sourced from and processed in China and other overseas locations. It raises implications for economic security and national security when a sector as important as car, truck and battery manufacturing becomes more dependent on foreign suppliers. [EPA-HQ-OAR-2022-0829-0525, p. 2]

Organization: Electric Drive Transportation Association (EDTA)

Across the private sector, vehicle manufacturers, materials and components suppliers, utilities, charging companies and other organizations are making investments in the EV supply chain that parallel these critical essential policy drivers. [EPA-HQ-OAR-2022-0829-0589, p. 1]

In the United States, the EV ecosystem is growing. 3.8 million plug-in electric vehicles have been sold since 2010. There are 87 plug-in electric models available today – and automakers have announced an additional 58 models to be rolled out by 2027. [EPA-HQ-OAR-2022-0829-0589, p. 1]

The U.S. supply chain is expanding too. According to a study conducted by Atlas Public Policy, more than $210 billion in EV manufacturing and battery investment has been announced in the U.S. since 2021. [EPA-HQ-OAR-2022-0829-0589, p. 2]

This rapid growth is speeding the transition to e-mobility but there is much public and private sector work to do to achieve a fully built-out system, as envisioned by the proposed rule. As the EPA develops a regulatory framework for 2027 -2032, it is important that the final rule recognizes these remaining policy and market variables. [EPA-HQ-OAR-2022-0829-0589, p. 2]

The electric drive industry is working rapidly to build a diverse and increasingly domestic value chain and grow the consumer base with expanding product offerings. This year, manufacturers are making investments in products and commitments to suppliers for 2027 vehicles. However, the eligibility of the vehicles for federal tax incentives is contingent on future determinations of eligible trade partners and disqualifying content. Meanwhile, a global race to secure materials creates pricing volatility throughout the supply chain. [EPA-HQ-OAR-2022-0829-0589, p. 2]

Organization: Elizabeth Boynton

Also, the EPA is to be concerned about the environment as a whole, not just the air quality. As that is the case, EPA needs to realize that encouraging the manufacture, purchase and use of EVs is not actually that great for the environment. You’re just cleaning the air from gas exhaust pollution by encouraging environmental destruction in the mining of rare earth minerals and creation of electricity to charge the EV batteries. [EPA-HQ-OAR-2022-0829-0568, p. 1]

And finally, one of the very biggest concerns about this is China. It is extremely short sighted and irresponsible to make this proposed rule without seriously considering and discussing China’s choke hold on the US, and indeed the world, over the rare earth minerals that are required to make EV batteries, the increased US demand of which is the logical conclusion of this proposed rule. According to a January 18, 2023 Elements article entitled “Visualizing China’s Dominance in Battery Manufacturing (2022-2027P)”, “Regardless of the growth in North America and Europe, China’s dominance is unmatched. Battery manufacturing is just one piece of the puzzle, albeit a major one. Most of the parts and metals that make up a battery—like battery-grade lithium, electrolytes, separators, cathodes, and anodes—are primarily made in China.” This same article projects a 10-fold increase in battery production in the US, but even so, China is still projected to make 69% of the world’s EV batteries in 2027. The ONLY rare earth minerals mine in the US still sells its concentrate to China for refining into usable materials. (December 14, 2022 Politico article, “China Dominates the Rare Earths Market. This U.S. Mine Is Trying to Change That”) [EPA-HQ-OAR-2022-0829-0568, pp. 1-3]

As the US industry struggles to try to catch up and provide a viable US-based rare earth minerals refining structure for our already great demand, including alloys used in our fighter jets and missiles not to mention phones and other electronics, why accelerate the burden now and further overwhelm them unnecessarily by artificially increasing demand for EVs and their batteries? [EPA-HQ-OAR-2022-0829-0568, pp. 1-3]

And, in the process, make us even more reliant on a country that just a year ago, Army Lt. Gen. Scott D. Berrier testified before the Senate Armed Services Committee remains a pacing threat and a major security challenge to the United States and its allies (US Department of Defense, Top Intelligence Chiefs Testify on Global Threats, May 10, 2022). [EPA-HQ-OAR-2022-0829-0568, pp. 1-3]

Indeed, China has proven itself to have no qualms using its rare earth minerals advantage against us. The most recent example I found was a Wall Street Journal article on July 3, 2023 titled “China Restricts Exports of Two Minerals Used in High-Performance Chips. Industry executives see export ban on gallium and germanium as retaliation over chip curbs by U.S. and others” From another Wall Street Journal article on June 22, 2023, “…It [China] accounts for 66% of lithium-ion cells, used in electric-vehicle batteries.” The article recounts how China has been aggressive with other countries as well, “Indeed, Beijing once blocked Japan’s access to rare earth elements during a 2010 dispute over Tokyo’s detention of a Chinese fishing trawler captain. Then in 2019, China threatened to include certain products using rare earths in Beijing’s technology-export restrictions, a response to the Trump administration’s pressure on telecom giant Huawei.” [EPA-HQ-OAR-2022-0829-0568, pp. 1-3]

And it isn’t just the supply of rare earth minerals they exploit to injure us with. In a March 9, 2020 Washington Examiner article, at the beginning of the Covid outbreak, “[Marco Rubio] said that the Chinese Communist Party published a thinly veiled threat in its newspaper to cut off the U.S. from many drugs needed by Americans in response to criticisms about China’s handling of the coronavirus. Rubio explained that many generic drugs the public depends on are produced in China.” This was also covered in a March 13, 2020 UK Independent story. [EPA-HQ-OAR-2022-0829-0568, pp. 1-3]

Additionally, in the Politico article cited above, Defense Secretary Lloyd Austin is quoted as saying that summer, “We’ve seen an alarming increase in the number of unsafe aerial intercepts and confrontations at sea by PLA aircraft and vessels. This should worry us all.” [EPA-HQ-OAR-2022-0829-0568, pp. 1-3]

I vehemently oppose this rule for all of the above reasons, but most strenuously because by so shackling the gas-powered vehicle industry, this proposed rule will ultimately make us more reliant on a country that is antagonistic to the US in so many ways by leaving Americans with few vehicle options but EVs. Granted, the US infrastructure for obtaining and refining rare earth minerals has begun, but it is just starting. This proposed rule recklessly runs ahead of industry and American demand of EVs, proceeding to the detriment and endangerment of US security, economic stability, and the welfare of millions of working class and financially struggling American citizens. [EPA-HQ-OAR-2022-0829-0711, p. 4]

Organization: Environmental. and Public Health Organizations

XVIII. EPA Appropriately Concludes that Critical Minerals and the Battery Supply Chain Will Be Sufficient for the Levels of BEVs Projected in the Proposal, and More Reasonable Battery-Related Modeling Assumptions Would Demonstrate the Feasibility of Even Higher Levels of BEVs. [EPA-HQ-OAR-2022-0829-0759, p. 131]

In this section, we explore how critical mineral and battery supply chain issues should not act as constraints on strong final standards, including Alternative 1 with a steeper increase in stringency after 2030. As EPA's analysis demonstrates, there will be sufficient materials and battery supply chain production to electrify light- and medium-duty vehicles consistent with the levels EPA projects for the Proposal, and for more stringent alternatives. In this section, we provide additional analysis that supports this conclusion. [EPA-HQ-OAR-2022-0829-0759, p. 131]

In addition, alternative battery-related modeling inputs would increase the feasibility and benefits of PEVs. Below, we highlight modeling inputs that we believe led EPA to overestimate battery capacity requirements for electric vehicles. We provide support for alternative input values including new technologies, specific energy, and battery design, all of which will have direct implications for cost modeling and mineral demand (underscoring EPA's conclusion that there is sufficient mineral supply to meet electric vehicle demand). [EPA-HQ-OAR-2022-0829-0759, p. 131]

As EPA notes, "with any emerging technology, a transition period must take place in which a robust supply chain develops to support production." 88 Fed. Reg. at 29313. Indeed, this is not the first time that the automotive industry has confronted critical mineral supply chain issues, and the industry has proven that it can rise to such challenges. For example, metal supply chain concerns arose during the move toward catalytic converters, and equipping all new vehicles with catalytic converters was seen at the time as a challenging "awesome prospect."356 At the time, "[c]atalyst companies were concerned about their ability to obtain adequate supplies of noble metals if they would be used extensively in automotive catalytic converters."357 Contemporaneous considerations of the "primary technical barriers" to catalytic converter adoption included "reducing the amount of precious metals used in each converter to a point where aggregate demand can be supplied without exhausting world reserves in the near future."358 The only significant reserves of the necessary platinum group metals were located in the Republic of South Africa and the former USSR, "neither of which [could] be considered secure sources of supply."359 Despite these concerns—which sound very similar to some of the rhetoric surrounding the battery minerals conversation—the automotive industry succeeded in incorporating catalytic converters in all U.S. vehicles. As detailed below, the industry can rise to the challenge again today. [EPA-HQ-OAR-2022-0829-0759, pp. 131-132]

A. There will be enough materials and battery supply chain production to electrify transportation.

We agree with EPA's conclusion that vehicle electrification, including the electrification of the heavy-, medium-, and light-duty fleets, will not lead to energy security risks but will instead provide the potential for a low-impact and domestic energy supply.360 This section provides comments on the assessment of battery critical materials and battery production. [EPA-HQ-OAR-2022-0829-0759, p. 132]

360 88 Fed. Reg. at 29313.

The lithium-ion batteries used to power PEVs include the following materials deemed critical by the United States Geological Survey: lithium, nickel, manganese, cobalt, graphite, and aluminum.361 Of these materials, lithium is the only one that does not have a substitute currently on the market. Nickel and cobalt are in the cathodes nickel-manganese-cobalt (NMC) and nickel-cobalt-aluminum (NCA). These are not the constraining materials because they are now substituted in a growing portion of PEVs with the lithium-iron-phosphate (LFP) cathode.362 Graphite can also be substituted; synthetic graphite is a direct substitution for mined graphite,363 and research has also demonstrated the use of silicon mixed with or to replace graphite as the anode.364 [EPA-HQ-OAR-2022-0829-0759, p. 132]

361 U.S. Geological Survey, United States Geological Survey Releases List of 2022 Critical Minerals (2022), https://www.usgs.gov/news/national-news-release/us-geological-survey-releases-2022-list-critical-minerals.

363 Jinrui Zhang, Chao Liang, and Jennifer B. Dunn, Graphite Flows in the U.S.: Insights into a Key Ingredient of Energy Transition, See 3402–3414, Environ. Sci. and Tech. (2023), https://pubs.acs.org/doi/10.1021/acs.est.2c08655.

364 Xiuxia Zuo, Jin Zhu, Peter Müller-Buschbaum, Ya-Jun Cheng, Silicon based lithium-ion battery anodes: A chronicle perspective review, See 2211–2855, Nano Energy, (2017), http://dx.doi.org/10.1016/j.nanoen.2016.11.013.

Lithium is vital to manufacturing lithium-ion batteries, which are currently the only type of PEV battery used in all PEVs purchased in the U.S. Therefore, the analysis correctly points to lithium as the constraining material for lithium-ion batteries. Yet, this is a slightly conservative estimation for future constraints because alternative battery types are beginning to be marketed globally. For example, sodium-ion batteries have recently been recognized as a potential lithium-ion battery substitute365 as Chinese automakers unveil their new technology.366 This type of innovation is likely to reduce lithium demand globally and is further discussed in the next section. [EPA-HQ-OAR-2022-0829-0759, p. 132]

365 Petrova, Here’s why sodium-ion batteries are shaping up to be a big technology breakthrough (2023), https://www.cnbc.com/2023/05/10/sodium-ion-batteries-shaping-up-to-be-big-technology-breakthrough.html.

366 Jiri Opletal, CATL’s sodium-ion batteries will debut in Chery Auto EVs, Car News China (2023), https://carnewschina.com/2023/04/16/catls-sodium-ion-batteries-will-debut-in-chery-auto-evs/.

Furthermore, we know that advocating for increased deployment of ZEVs within the light- and medium-duty fleet, which is an essential step to reducing fossil fuel emissions and addressing the climate crisis, will potentially include mining projects that impact environmental justice communities and, in particular, indigenous communities. PEVs also eliminate tailpipe emissions of harmful air pollutants that cause asthma and respiratory diseases, especially among Black, Indigenous, and other communities of color. However, without adequate protections for workers, communities, and environments near mining and processing sites, we risk replicating the harms of fossil fuel extraction. Besides the details below that discuss opportunities for PEV batteries that will not rely on lithium, there are measures that EPA can and should take to address the potential mining impacts. For example, EPA and the Administration can take action to build a robust circular economy to reduce the need for virgin material extraction and increase the supply of more responsibly sourced materials. [EPA-HQ-OAR-2022-0829-0759, p. 133]

EPA points to findings by several sources that concur with its assessment that material and production will be sufficient to meet electric vehicle uptake in the LDV, MDV, and HDV sectors. See 88 Fed. Reg. at 29312-23; DRIA Chs. 3.1.3.2., 3.1.3.3. Increased demand for minerals, as well as government investments, will continue to spur these developments. The 2023 BNEF Electric Vehicle Outlook demonstrates these effects on the continued expansion of the supply chain.367 In addition, academic sources have demonstrated that there are enough reserves and recycled content such that demand for lithium will barely exceed a quarter of the available reserve by 2050 and about half by 2100.368 [EPA-HQ-OAR-2022-0829-0759, p. 133]

1. Federal investments have spurred private investments in domestic supply.

Actions taken by the federal government have increased private investment in U.S. battery production. The impact of the BIL and the IRA on U.S.-based PEV manufacturing, repurposing, and recycling growth demonstrates the influence U.S. policy has on rapidly growing a domestically-produced supply. Within six months of the IRA’s passage, automakers and battery manufacturers had announced a total of roughly $52 billion of planned investment in North America’s PEV supply chain, with over 70% of those investments going toward battery supply chains and recycling.369 [EPA-HQ-OAR-2022-0829-0759, p. 133]

369 Cory Cantor, US Climate Law Fuels $52 Billion in New EV Investments, p 1, BloombergNEF, Mar. 13, 2023. Subscription required.

2. Recycled content can provide additional domestic mineral supply.

The current oil-dependent transportation system not only impacts the climate and the health of the U.S. population, it also requires continual drilling, production, and importing of fuel. This is in stark contrast to the use of materials needed for electrified transportation, which can be continually recycled to produce the next generation of more efficient vehicles. This results in the continued growth of U.S. material stock even when initially relying on imported minerals. As the Proposal states, in 2050, 25 to 50% of lithium demand from electric vehicles can be met with recycled content. 88 Fed. Reg. at 29323-24.370 Recycled content availability has been highly studied and documented in academic studies beyond the two listed in the Proposal (Sun et al., 2022; Ziemann et al., 2018), including in findings by Xu et al.371 and Dunn et al.372 Xu et al. demonstrates that the material demand that could be met by retiring and recycled supply is highly impacted by innovation and advancing energy density. As batteries become more advanced and energy-dense, either through innovation of chemistries used (e.g., the progress made in NMC) or through different chemistries (e.g., lithium-sulfur or lithium-air batteries), the mineral demand decreases to meet the same energy storage needs. This means that a high percentage of material demand can be met with the retiring supply of less material-efficient and lower density batteries. This is demonstrated in Figure XVIII.A-1 below; the more energy dense batteries (Li-S/Air) have higher recycled content for lithium, cobalt, and nickel in 2040-2050 (green bar).373 [EPA-HQ-OAR-2022-0829-0759, pp. 133-134]

370 The Proposal cites Sun et al., Surging lithium price will not impede the electric vehicle boom, Joule, doi:10.1016/j.joule.2022.06.028, https://dx.doi.org/10.1016/j.joule.2022.06.028, and. Ziemann et al., Modeling the potential impact of lithium recycling from EV batteries on lithium demand: a dynamic MFA approach, Resour.Conserv. Recycl. 133, 76–85. https://doi.org/10.1016/j.resconrec.

Figure XVIII.A-1: Closed-loop recycling potential of battery materials in a STEP scenario.

[See original comment for Figure XVII.A-1]. [EPA-HQ-OAR-2022-0829-0759, p. 135]

(Source: Xu et al.)

Dunn et al.374 demonstrate that the choice of cathode materials can also highly increase potential circularity. Figure XVIII.A-2 below shows that a future with high lithium-iron-phosphate (LFP) market concentration, labeled as C6 in the legend, can significantly increase the amount of lithium, cobalt, manganese, and nickel demand met with recycled content, compared to a business-as-usual cathode market share, labeled as C1 in the legend. [EPA-HQ-OAR-2022-0829-0759, p. 135]

Source: Dunn et al.

The recycled content also varies based on the collection rate and the material recovery rate. There is potential for high material recovery due to the 95% recovery rate of lithium, nickel, cobalt, and manganese by commercial-scale hydrometallurgical recyclers in the U.S., such as Lithion, Redwood Materials, Licycle, and Cirba Solutions. In addition, direct cathode recycling, which can recover a cathode without breaking it down into separate materials, is under development by several startups as well as the National Lab research group, ReCell. As shown in Table XVIII.A-1 below, direct recycling currently has a recovery rate of 40% for lithium. But increasing the lithium recovery rate is a priority area for ongoing research.375 The Argonne National Laboratory model, BattPac, lists the following recovery rates shown in Table XVIII.A-1.376 [EPA-HQ-OAR-2022-0829-0759, p. 136]

375 See generally Kendall, A., Slattery, M., Dunn, J., Lithium-ion car battery recycling advisory group report, (Mar. 16, 2022), https://calepa.ca.gov/lithium-ion-car-battery-recycling-advisory-group/.

3. EPA appropriately concludes that there will be sufficient lithium for the Proposed Standards, and supporting analysis also indicates likelihood of IRA-qualifying sources.

As discussed above, the current primary constraining material for PEVs is lithium. EPA points to a variety of sources to support its assumptions regarding lithium availability for U.S. PEV demand. See 88 Fed. Reg. at 29312-23; DRIA Chs. 3.1.3.2, 3.1.3.3. [EPA-HQ-OAR-2022-0829-0759, p. 139]

Recent analysis by Benchmark Mineral Intelligence (BMI) on future lithium supply supports EPA's findings.378 BMI compiled a list of all currently known lithium mining projects, including those already in operation as well as those in development, totaling 330 projects globally as of December 2022. Of those, 153 are already producing lithium or have public, identified supply projections. BMI took those supply projections and assigned them probabilities—e.g., currently producing mines were weighted at 100%, while projects that have secured a significant proportion of their funding and completed certain feasibility milestones necessary for production within the next 5 years were considered "probable" and weighted at 50%. Supply from the other 177 lithium mining projects (which do not yet have supply projections) were all counted as 0. [EPA-HQ-OAR-2022-0829-0759, p. 139]

378 BMI, Lithium Mining Projects – Supply Projections, June 2023 (slide deck); BMI, Lithium Mine Projects (06.30.2023) (Excel spreadsheet), both attached to this comment letter.

BMI then compared these projections to the projected lithium demand through 2032, using forecast global demand (including for non-battery applications), as well as demand based on EPA's proposed light-, medium-, and heavy-duty vehicle emission standards. Based just on the

153 included projects, BMI's weighted projections show sufficient lithium for the EPA's Proposed Standards (on top of forecast demand for the rest of the world) through 2028 as shown below in Figure XVIII.A-3. When the 18 U.S. projects with supply projections (out of 48 total U.S. projects) are weighted at 100%, lithium supply is sufficient for the Proposed Standards through 2030. And when the 153 included projects are weighted at 100%, global supply greatly exceeds demand through 2032. [EPA-HQ-OAR-2022-0829-0759, p. 139]

SEE ORIGINAL COMMENT FOR Figure XVIII.A-3: Global Lithium Supply Based with U.S. and Global Demand [EPA-HQ-OAR-2022-0829-0759, p. 140]

Given that BMI's projections exclude 177 projects that have been announced but do not yet have supply projections, even a 100% weighting for the 153 projects that are operating or have supply projections is a conservative approach. It does not include any supply growth outside of the 153 projects identified as of December 2022, not even from the other 177 identified projects, despite increasing global demand and strong U.S. tax incentives. Moreover, it would be reasonable and expected that even BMI's supply projections would continue to increase as the identified projects get further along in the development process and market forces continue to act. [EPA-HQ-OAR-2022-0829-0759, p. 140]

In addition, BMI's analysis indicates that there will be sufficient supply for U.S. demand even after considering competing lithium battery demand from China and Europe and global non-lithium battery demand as shown below in Figure XVIII.A-4. [EPA-HQ-OAR-2022-0829-0759, p. 140]

SEE ORIGINAL COMMENT FOR Figure XVIII.A-4: Remaining Global Lithium Supply with U.S. Demand [EPA-HQ-OAR-2022-0829-0759, p. 141]

BMI also broke down the supply from the 153 included projects by country, and then grouped those countries into categories based on U.S. trade-agreement status, consistent with the terms in the IRA. This projection shown in Figure XVIII.A-5 below makes clear that there is ample lithium supply from sources that satisfy the IRA § 30D Clean Vehicles Tax Credit requirements—specifically, domestic sources, as well as countries that have free trade agreements with the U.S. ("FTA countries"). This supports EPA's modeling assumption of an average tax credit of $6,000 per electric vehicle (out of a maximum allowable credit of $7,500), as lithium from these sources would qualify a vehicle for the tax credit, provided other conditions are met (e.g., vehicle assembly in North America, purchaser income limits). [EPA-HQ-OAR-2022-0829-0759, p. 141]

SEE ORIGINAL COMMENT FOR Figure XVIII.A-5: U.S. Lithium Supply and Free Trade Agreement Country Supply with U.S. Demand [EPA-HQ-OAR-2022-0829-0759, p. 142]

Slides of BMI's analysis, as well as their full list of lithium supply projects, are attached to these comments. [EPA-HQ-OAR-2022-0829-0759, p. 142]

Finally, as has been noted elsewhere in these comments, there are alternative battery chemistries that do not use lithium (including sodium-ion batteries), and thus may end up lowering lithium demand in the future. In addition, in light of the points made in Section XVIII.B, below, we believe EPA's analysis of future lithium demand—and thus future lithium supply sufficiency—is conservative. [EPA-HQ-OAR-2022-0829-0759, p. 142]

Minerals are “an input to the construction” of vehicles and their infrastructure rather than “a fuel that is combusted on an ongoing basis,” meaning that “the near term risk is not one of ‘traditional’ energy security (short-term supply constraints or high prices).”659 Critical minerals do not pose energy security concerns because, “unlike reliance on oil (where the resource is consumed with each trip) EVs consume locally produced electricity with each trip and additional lithium is only required when the battery is replaced or a new vehicle is purchased.”660 An event squeezing or shutting off the supply of oil would have “an almost immediate deleterious effect on transportation,” but a squeeze in critical mineral supply would allow “batteries in existence [to] continue to function,” and “there [would] not be a fundamental disruption of the transportation sector.”661 Increases in oil prices and decreases in supply impact all drivers, and easing this dependence through electrification would shield drivers from daily price volatility. Moreover, whereas “fuel is burnt once,” EV battery materials “can be reused and recovered in a circular loop to produce new batteries.”662 Recyclers such as Redwood Materials and Li-Cycle can recover up to 95% of the minerals from old batteries at commercial scale today.663 [EPA-HQ-OAR-2022-0829-0759, p. 200]

Finally, combustion vehicles will remain in production and operation for many years, diversifying the one-time and ongoing inputs needed for vehicles and allowing the U.S. battery supply chain time to stabilize through increased domestic mining and production, advances in battery design and recycling, and cooperation with allies over the next decade. [EPA-HQ-OAR-2022-0829-0759, p. 200]

XVIII. EPA Appropriately Concludes that Critical Minerals and the Battery Supply Chain Will Be Sufficient for the Levels of BEVs Projected in the Proposal, and More Reasonable Battery-Related Modeling Assumptions Would Demonstrate the Feasibility of Even Higher Levels of BEVs. [EPA-HQ-OAR-2022-0829-0759, p. 200]

Organization: Environmental Defense Fund (EDF) (1of 2)

Vehicle Manufacturer EV Commitments

Many vehicle manufacturers have made commitments to transition a significant portion of their sales to ZEVs. While many of the commitments are for a share of manufacturers’ global sales, several OEMs have made U.S. specific commitments or have committed to transition their entire fleet which would mean all of their U.S. sales would be ZEV as well. Even for global commitments, manufacturers with significant U.S. sales volumes will nonetheless need to sell meaningful ZEVs to meet their commitments. Because some sales might exceed these global commitments while others fall short, we used global commitments as a reasonable proxy for U.S. sales share. Table 4 below shows OEM commitments and includes a total using 2022 manufacturer sales shares to calculate a weighted ZEV commitment. [EPA-HQ-OAR-2022-0829-0786, pp. 31-34]

[See original attachment for Table 4: Manufacturer ZEV Commitments as Share of Total Sales] [EPA-HQ-OAR-2022-0829-0786, pp. 31-34]

*Due to rounding, the sum of the market share may not equal the total [EPA-HQ-OAR-2022-0829-0786, pp. 31-34]

All major OEMs have set ZEV targets of at least 30% sales starting in 2030. Considering both U.S.-specific and global commitments would result in 47% of new vehicles sold in the U.S. in 2030 being ZEVs. Even unrealistically assuming only the US-specific commitments and the 100% commitments apply, at least 29% of LDV sales in 2030 would be ZEVs growing to 44% in 2035 and 48% in 2040. The 2030 value is plotted above in Figure 12. We also note that the 2035 and 2040 estimates using both approaches are perhaps significantly understated given that some manufacturers with commitments in 2030 have not made 2035 or later commitments but will nonetheless likely increase ZEV sales during that timeframe. [EPA-HQ-OAR-2022-0829-0786, pp. 31-34]

EV Manufacturing Investment Announcements

As discussed above, in their March 2023 report, WSP analyzed investment announcements for domestic EV manufacturing. Their analysis found that announced investments amount to the production of 4.4 million EVs per year by 2026 in the U.S.99 This equals roughly a third (31%) of all LDVs sold in the U.S. last year. Vehicle manufacturers have already committed to manufacturing these vehicles and it provides a lower bound for what might be expected as more manufacturers make EV investment announcements, and the industry continues to grow. [EPA-HQ-OAR-2022-0829-0786, pp. 34-35]

99 U.S. Electric Vehicle Manufacturing Investments and Jobs, Characterizing the Impacts of the Inflation Reduction Act after 6 Months, WSP for EDF, (March 2023). https://blogs.edf.org/climate411/files/2023/03/State-Electric- Vehicle-Policy-Landscape.pdf.

Over the past ten years, between 60% and 70% of the LDVs sold in the U.S. were domestically manufactured with imports accounting for the remaining 30% to 40%.100,101 It is reasonable to expect that not all EVs purchased in the U.S. will be domestically produced. To scale the vehicles, we have assumed that the proportion of EVs within the pool of domestically produced vehicles will be the same as those imported. [EPA-HQ-OAR-2022-0829-0786, pp. 34-35]

100 Board of Governors of the Federal Reserve System. Industrial Production and Capacity Utilization– G.17 Table 3. Originally from Ward's Communications, Chrysler, and GM. 16 Nov 2022. https://www.federalreserve.gov/releases/g17/current/table3.htm.

101 Bureau of Economic Analysis. Motor Vehicle Unit Retail Sales, Table 6. 2023, https://apps.bea.gov/national/xls/gap_hist.xlsx

If the U.S. imported 35% of its vehicles, the average of the last ten years, the EV manufacturing investments have been made already account for 48% of domestically made vehicles sold in the U.S. If the trend of more domestically produced EVs continues and only 20% of sales are imports, the U.S. produced 4.4 million EVs would result in 39% of LDV sales being EVs. [EPA-HQ-OAR-2022-0829-0786, pp. 34-35]

For this analysis, we chose an assumption of 80% domestically produced EVs. While this number is higher than the current share of domestic production, it is in line with the recent trend of onshoring EV manufacturing.102 There are significant incentives and funding opportunities to make domestically producing EVs more attractive to manufacturers. [EPA-HQ-OAR-2022-0829-0786, pp. 34-35]

102 David Gohlke, Zhou, Yan, Wu, Xinyi, and Courtney, Calista. 2022. "Assessment of Light-Duty Plug-in Electric Vehicles in the United States, 2010 – 2021". United States. https://doi.org/10.2172/1898424. https://www.osti.gov/servlets/purl/1898424. (Attachment Z)

Manufacturers only make announcements for facilities a few years in advance of production. As such, this gives a glimpse into the near future but should the general trend in announcements continue, tremendous growth would be expected for domestic EV manufacturing. To that end, WSP's analysis is current only through March of 2023. Since that time, manufacturers have announced billions of dollars in additional investment and production capacity, which reinforces the likelihood that these trends will continue to grow and accelerate over time. [EPA-HQ-OAR-2022-0829-0786, pp. 34-35]

EV Battery Manufacturing Investment Announcements

WSP also published analysis assessing the annual capacity of lithium-ion batteries that will be produced in the U.S. based on announced investments.103 Their analysis found 37 battery and component manufacturing and recycling announcements totaling nearly $80 billion in investment and over 1,000 GWh/year of capacity by 2027. Such a large investment into the EV battery industry demonstrates a significant shift towards EV adoption and the existing market expectation that EVs will be a dominant powertrain within the decade. [EPA-HQ-OAR-2022-0829-0786, p. 35]

103 U.S. Electric Vehicle Manufacturing Investments and Jobs, Characterizing the Impacts of the Inflation Reduction Act after 6 Months, WSP for EDF, (March 2023). https://blogs.edf.org/climate411/files/2023/03/State-Electric- Vehicle-Policy-Landscape.pdf (Attachment E).

To get a sense of the scale of the battery investments, WSP calculated the number of LD EVs those batteries could support. They assumed an average LDV battery is 89 kWh, which would mean by 2027, the U.S. will be producing enough batteries to supply 84% of all domestic LDV sales if all of these batteries went exclusively to LDVs. However, it is likely there will be other demands for those batteries. The exact split between LD and HD demand for batteries will depend on how fast different vehicle classes electrify and the market demand for battery sizes. EDF used current energy consumption as a proxy for relative demand for batteries between LD and HD vehicles. According to MOVES3, in 2022, LDVs consumed 72% of the on-road energy. To calculate a more conservative value, EDF assumed that only two-thirds of batteries would go to LDVs. In this case, 56% of LDV sales could be outfitted with domestically supplied batteries that manufacturers have already invested in producing by 2027. As with manufacturing investments, additional investments have been made since WSP published its report and accordingly, these investments could only be expected to grow. [EPA-HQ-OAR-2022-0829-0786, p. 35]

Lithium Mining Announcements

Announcements of domestic lithium mines have also increased recently. Using a Benchmark Mineral Intelligence (BMI) database of proposed lithium mines and production amounts by year, EDF assessed how lithium production would translate to vehicles.104 [EPA-HQ-OAR-2022-0829-0786, pp. 36-37]

104 Benchmark Mineral Intelligence, Lithium Mine Projects (06.30.2023) (Excel spreadsheet), attached to comments submitted by Center for Biological Diversity, et al. Mining projects are current as of December 2022.

Forty-eight mines have been announced in the U.S. and are at some stage of development. Though only one is currently in operation, companies have claimed that many will start producing lithium in the next few years. Of the 48 mines, BMI has projections of potential production for 18 mines with 1 mine in operation, 7 “probable” mines and 11 considered “possible” mines.105 To understand anticipated lithium production within the U.S., we used this information from BMI to develop two scenarios. [EPA-HQ-OAR-2022-0829-0786, pp. 36-37]

105 BMI defines a “probable mine” as a project having secured a significant portion of its funding, and completed certain feasibility milestones necessary for production within the next five years. BMI defines a “possible mine” as a project in the early stages of development with only a small portion of financing secured.

Scenario A: Only production from the 18 mines with announced anticipated production were included and they were weighted based on how far along in the development process the mine is consistent with BMI’s weighting system. “Possible” mines were only weighed at 40%, “probable” mines were weighed at 50%, and mines in operation were weighed at 100%. This scenario does not include the other 30 announced mines that BMI identified. This provides a conservative estimate of U.S. lithium production. Under this scenario, domestic lithium production would supply enough material to outfit 25% of annual LDV sales with battery packs in 2035. [EPA-HQ-OAR-2022-0829-0786, pp. 36-37]

Scenario B: Production from the 18 mines described above was included and weighed at 100%. This assumes that all of the 18 mines will reach the projected production on the anticipated timeline but still does not include the other 30 announced mines that are at the beginning stages of production. Since only one-third of the announced lithium projects are included in this scenario, it remains a conservative estimate of domestic lithium production based on current announcements. Under this scenario, domestic lithium production would supply enough material to outfit 55% of annual LDV sales with battery packs in 2035. [EPA-HQ-OAR-2022-0829-0786, pp. 36-37]

EDF converted the tons of lithium production into an equivalent number of LDVs. We used BMI's projection for kg of lithium per kWh of battery for an average battery chemistry. This value falls over time as batteries are assumed to become more efficient from 0.66 to 0.56 kg LCE/kWh of battery. We assumed 89 kWh per EV to get the number of LDVs. [EPA-HQ-OAR-2022-0829-0786, pp. 36-37]

Since the IRA's Commercial Clean Vehicle Credit does not contain the same domestic source requirements for battery critical minerals that the Clean Vehicle Credit does, it is likely that domestically produced lithium will go to LDVs rather than HDVs at least through the end of the IRA credit in 2032. In this analysis, we assume none of the U.S. produced lithium goes to HDVs. [EPA-HQ-OAR-2022-0829-0786, pp. 36-37]

We plotted the results from Scenario B above as a possible representation of future U.S. lithium production from announced projects. As described more fully below, this does not fully account for all U.S. projects nor does it account for projects in countries with which the U.S. has a free trade agreement. This also does not reflect EDF's view on any particular project. Instead, based on publicly available information, it provides an indication of the degree to which U.S. lithium supply may support future EV production based solely on current announcements. [EPA-HQ-OAR-2022-0829-0786, pp. 36-37]

VI. The supply chain for electric vehicle batteries and critical minerals is capable of safely and equitably meeting the demands of strong standards. [EPA-HQ-OAR-2022-0829-0786, pp. 60-61]

The current and projected critical minerals supply chain for EV batteries is capable of meeting the demands of strong standards. It is vital that any increase in minerals mining and processing be undertaken in a safe and equitable way that does not increase pollution burdens on underserved communities, which have historically faced disproportionate harms from these processes. Any projects undertaken must be carried out in a way that affirmatively prioritizes the needs of these communities. [EPA-HQ-OAR-2022-0829-0786, pp. 60-61]

Domestic production of batteries and battery components is growing rapidly to meet the rising needs of the EV industry. Analysis by EDF and WSP found that there has been over $79.7 billion in investment in U.S. battery and battery component production announced within the past 8 years, resulting in almost 70,000 new jobs.164 In 2026, these already announced investments will be capable of producing batteries sufficient to supply the equivalent of 11.2 million new passenger vehicles per year.165 [EPA-HQ-OAR-2022-0829-0786, pp. 60-61]

164 U.S. Electric Vehicle Manufacturing Investments and Jobs, Characterizing the Impacts of the Inflation Reduction Act after 6 Months, WSP for EDF, (March 2023). https://blogs.edf.org/climate411/files/2023/03/State-Electric- Vehicle-Policy-Landscape.pdf. (Attachment E)

165 Id.

Much of this investment has occurred within the last year as a result of the IRA's incentives for domestic battery production, which will continue to spur production growth and reduce battery costs throughout the timeframe of this rule.166 The Advanced Manufacturing Production credit, for instance, provides up to $45 per kilowatt-hour for the production of battery cells and modules as well as up to 10% of the cost of critical minerals through 2032.167 Additionally, the IRA's amendments to the Clean Vehicle Credit includes provisions requiring that qualifying vehicles source an increasing percentage of their critical minerals and battery components domestically, which will further incentivize increased domestic production capacity.168 [EPA-HQ-OAR-2022-0829-0786, pp. 60-61]

166 Id.

168 Inflation Reduction Act of 2022, P.L. 117-1698 ,136 Stat. 1956-57 (2022).

The extraction, processing, and recycling of the critical minerals necessary to support rapid ZEV proliferation is also ramping up and supports the feasibility of protective emission standards. [EPA-HQ-OAR-2022-0829-0786, pp. 61-62]

EDF has conducted a review of announced investments in the critical minerals supply chain, including new investments and expansion of existing capacities in raw minerals extraction (mining), materials separation and processing, and recycling efforts—in both the U.S. and free-trade-agreement countries - based on publicly available information from company websites and announcements issued by investors, government agencies, and news media on the operators, materials, locations, annual capacities, and timelines of the projects.169 The compilation of projects includes the scale and date of any announced investments in the projects, including OEM investments, as well as the details of partnership agreements. We have also compiled information on specific funding levels secured under the BIL. [EPA-HQ-OAR-2022-0829-0786, pp. 61-62]

169 The compilation is attached to this comment as an Excel file titled "Domestic Critical Minerals Projects." We are expanding the review to include countries with which the U.S. has free trade agreements. (Attachment W)

The numerous projects and partnerships identified demonstrate a growing effort—that is supported by the BIL and the IRA—to develop a secure supply of critical minerals. In October 2022, the White House announced $2.8 billion in funding under the BIL for projects to support "new, retrofitted, and expanded commercial-scale domestic facilities to produce battery materials, processing, and battery recycling and manufacturing demonstrations."170 The funding is the first phase of a total $7 billion investment by the federal government to develop domestic supply chains for electric vehicle battery production.171 According to project announcements, these investments in critical minerals projects have been spurred on by downstream consumer tax benefits under the IRA.172 [EPA-HQ-OAR-2022-0829-0786, pp. 61-62]

170 U.S. DOE Office of Manufacturing and Energy Supply Chain Bipartisan Infrastructure Law: Battery Materials Processing and Battery Manufacturing Recycling Selections, available at: https://www.energy.gov/mesc/bipartisan- infrastructure-law-battery-materials-processing-and-battery-manufacturing-recycling.

171 U.S. DOE, October 19, 2022 Biden-Harris Administration Awards $2.8 Billion to Supercharge U.S. Manufacturing of Batteries for Electric Vehicles and Electric Grid, https://www.energy.gov/articles/biden-harris- administration-awards-28-billion-supercharge-us-manufacturing-batteries.

172 E.g., General Motors announced that, "[m]aterial sourced from Lithium Americas [Thacker Pass mine in Nevada] will help support EV eligibility for consumer incentives under the U.S. clean energy tax

> credits." Ford noted, in its announcement of a long-term agreement with Nemaska Lithium, that its lithium hydroxide should help qualify Ford vehicles for consumer tax benefits under the IRA. And Livent Corporation, in its announcement of the expansion of its largest lithium hydroxide production site in the U.S. said that its, "leading footprint in North America positions the company to take advantage of long-term growth opportunities and downstream incentives from the recently enacted Inflation Reduction Act (IRA), which encourages use of lithium produced or processed in North America."

In all, our review identified 74 domestic mining, processing, and recycling projects and an additional 30+ projects and agreements in countries with which the United States has a free trade agreement. Investment levels are not known for all projects but announced domestic investments total over $25 billion, including $1 billion funded under the BIL and $2.7 billion funded by automakers. Known investments in free-trade-agreement countries total over $800 million. [EPA-HQ-OAR-2022-0829-0786, p. 62]

Because less than half of the projects we identified included a projected investment amount, we can assume that the actual total investment in mining, processing, and recycling projects in the U.S. and in free-trade-agreement countries is far higher than these publicly announced figures reflect. [EPA-HQ-OAR-2022-0829-0786, p. 62]

Organization: Ford Motor Company

Ford is enthusiastic and optimistic about the ICE-to-ZEV transition, and we are already delivering electrified light- and medium-duty EVs at scale. While we remain optimistic, we are also mindful of the considerable challenges and uncertainties that lie ahead. The pace of electrification has been and may continue to be limited by many factors and forces, many of which are outside the control of vehicle manufacturers. These include the availability of critical minerals for battery manufacturing, the need to allocate finite resources between EV programs and efforts toward incremental reductions in emissions from ICE vehicles, consumer demand especially as we proceed beyond early-adopters to the majority of new vehicle purchasers, economic turbulence, geopolitical events, and, of course, electric vehicle charging infrastructure. [EPA-HQ-OAR-2022-0829-0605, pp. 2-3]

Critical minerals are essential for EV manufacturing, but demand may outstrip supply during portions of 2027 – 2032. Automakers are taking extraordinary steps to vertically integrate with their battery supply chains in order to secure supply and control costs, but in this highly dynamic market and in light of unprecedented demand from lithium-ion battery manufacturers worldwide, it is unclear whether critical minerals will be available at a price that makes the EVs sufficiently competitive in the US market to achieve the EV adoption rates needed to meet EPA's proposed standards. The production tax credit available under section 45X of the tax code provides some amount of certainty, but not enough to achieve a high-level of confidence. [EPA-HQ-OAR-2022-0829-0605, p. 7]

Organization: Fred Reitman

Leads to child labor. The metals needed for the EV batteries including lithium and cobalt are mined in third world countries particularly the Congo by child labor under deplorable conditions. This is what takes place so that people in the United States, western Europe and other countries can feel good about limiting so-called climate change. Should this proposal become a final rule it would only lead to more child labor as it would open a growing market for these batteries in the U.S. [EPA-HQ-OAR-2022-0829-0432, p. 2]

Organization: HF Sinclair Corporation

And it will have profound impacts on national security by forcing the American automotive industry to depend on critical minerals from foreign suppliers, with geopolitical challenges—most notably, China—rather than a domestically-abundant and secure resource. These issues go well beyond EPA's expertise, and the Agency is not positioned to fully grapple with the consequences that such a rapid push for PEV will have across the nation. As a result, EPA can only proceed with the Proposed Rule if Congress bestowed upon EPA clear authorization to do so. But Congress did not. [EPA-HQ-OAR-2022-0829-0579, p. 4]

d. EPA's Assumed Supply Chain is no Assured and will Increase Dependence on Foreign Sources

Today, the U.S. is virtually independent48 as a net exporter of petroleum. The U.S. has worked for decades to progress this energy security, which is especially pronounced for transportation fuels (i.e., petroleum- and ethanol-based liquid fuel products) for ICE-powered vehicles. Although EPA conducts an analysis regarding the Proposed Rule's effect on domestic "energy security," EPA limits itself to drawing broad conclusions regarding future projections for exports, imports, and consumption of crude oil and refined petroleum products—as well as relying on inflated support from potential funding mechanisms of the BIL and IRA. But this ignores the current state of the supply chain of critical materials necessary for battery and PEV production at large: "Given the current state of the global supply chain for these raw materials and the requirements to bring additional supply to market, it is likely that the mandated goals are unachievable even over several decades."49 [EPA-HQ-OAR-2022-0829-0579, pp. 12-13]

48 While "energy independence" has varying definitions, we are using the term consistent with EPA's use in the Proposed Rule—"[t]he goal of U.S. energy independence is the elimination of all U.S. imports of petroleum and other foreign sources of energy, but more broadly it is the elimination of U.S. sensitivity to the variations in the price and supply of foreign sources of energy"). Proposed Rule at 26,077.

49 CEA Study at 9.

Most illustrative of the future foreign reliance resulting from EPA's Proposed Rule is the lithium-ion battery supply chain controlled nearly entirely by China. China controls each step of battery production and, by 2030, is anticipated to "make more than twice as many batteries as every other county combined."50 This is because China controls 41% of the world's cobalt, 28% of the world's lithium, and 78% of the world's graphite; China also refines 95% of manganese, 74% of cobalt, 70% of graphite, 67% of lithium, and 63% of nickel.51 And even if the U.S. had sufficient resources to extract and refine independent of foreign sources, a refinery takes two to five years to build—not accounting for the time necessary for permitting, construction, and operations, including waste disposal.52 Beyond the raw materials, China also makes the battery components—73% of NMC cathodes and 99% of LFP cathodes—compared to 1% made domestically.53 Indeed, "[e]xperts say it is next to impossible for any other country to become self-reliant in the battery supply chain, no matter if it has cheaper labor or finds other global partners. Companies anywhere in the world will look to form partnerships with Chinese manufacturers to enter or expand in the industry."54 [EPA-HQ-OAR-2022-0829-0579, pp. 12-13]

50 Agnes Chang and Keith Bradsher, NY TIMES, "Can the World Make an Electric Car Battery Without China?" (May 17, 2023) available at https://www.nytimes.com/interactive/2023/05/16/business/china-ev-battery.html.

Looking at the lithium alone, the "U.S. Geological Survey estimates that in 2022, there was approximately 130,000 tons of lithium mined globally" and that the "quantity of lithium mined would be able to produce just under 14 million EV batteries," not accounting for "the lithium used in other products, including laptop batteries, phones, residential power packs, and utility scale storage."55 But under proposed PEV mandates, the global annual light-duty vehicle sales of over 66 million and a global fleet of over 1.3 billion vehicle alone illustrate the difficulty with practically achieving EPA's proposed mandates.56 [EPA-HQ-OAR-2022-0829-0579, pp. 12-13]

55 CEA Study at 9.

56 Id.

The volatile and increasing costs for these materials further threaten a secure and stable supply chain capable of meeting EPA's proposed demands. Indeed, EPA ignores the fact that copper demand is expected to increase by 53% while supply is expected to increase by 16%--the global copper demand will outstrip supply of copper by just 2026.57 Similarly, the price of lithium has consistently risen in recent years. Between January 2021 and March 2022, the cost of lithium increased by 738% and continues to rise today.58 Despite these very public findings, EPA asserts that these costs are an uncertainty and that EPA plans to "continue updating [its] estimates of battery cost for current and future years."59 [EPA-HQ-OAR-2022-0829-0579, pp. 13-14]

57 Id.

58 See CANADA ENERGY REGULATOR, Market Snapshot: Critical Minerals are Key to the Global Transition (Jan. 18, 2023), available here.

59 Proposed Rule at 29,301 (recognizing the "global average price for lithium-ion battery packs (volume-weighted across the passenger, commercial, bus, and stationary markets) climbed by about 7 percent in 2022"). Notably, this is in contrast to EPA's conclusion just a few weeks prior. Proposed Rule at 25,930 ("the cost to manufacture lithium-ion batteries (the single most expensive component of a BEV) has dropped significantly in the past eight years, and that cost is projected to continue to fall during this decade, all while the performance of the batteries (in terms of energy density) improves.").

Instead of comprehensively analyzing these supply chain concerns, though, EPA relies heavily on federal funding and tax incentives—such as those under the BIL and IRA—to merely conclude a domestic supply chain is forthcoming.60 This incomplete analysis fatal to the Proposed Rule. Regardless of these funding sources, domestic manufacturing alone is unable to meet the production goals EPA is requiring right now and this threatens domestic energy security. [EPA-HQ-OAR-2022-0829-0579, pp. 13-14]

60 See, e.g., DRIA at 2-86–87; Proposed Rule at 29,328.

Finally, although EPA has acknowledged that a “transition period must take place in which a robust supply chain develops to support production of [critical minerals],” the limited time afforded under the Proposed Rule is simply insufficient to build this supply chain.61

61 Proposed Rule at 29,313.

Organization: Hyundai America Technical Center, Inc. (HATCI)

HMG also has supply chain concerns, as major parts suppliers related to ICEs are also accelerating their conversion to ZEVs and likewise may not be able to meet the sudden increased demand required to comply with the Proposed Rule. [EPA-HQ-OAR-2022-0829-0554, p. 2]

The NPRM Does Not Fully Capture True Costs of the Proposed Alternative.

The Proposed Alternative’s stated cost assumptions exclude important considerations. Currently, the NPRM estimates the average upfront per-vehicle cost to the automaker to be $1200 in MY 2032. The NPRM also estimates that by MY 2032, consumers who purchase a BEV instead of an ICE vehicle will save between $400 and $4,000 at the time of purchase.23 This is predicated on significant assumed reductions in battery pack pricing, which is far from guaranteed given uncertainties in mineral availability, ability to meet IRA mineral sourcing requirements, manufacturing and supply chain limitations, and required improvements in battery energy density. [EPA-HQ-OAR-2022-0829-0599, pp. 6-7]

23 EPA NPRM, Draft Regulatory Impact Analysis, “Table 4-8: Estimated average savings over the first 8 years of vehicle life when MY 2032 BEV purchased instead of ICE (2020 dollars)”

Organization: Illinois Corn Growers Association

Enormous advances have been made in electric vehicle technology in the last two decades and there is strong auto industry commitment to eventually replace internal combustion engine powered vehicles with electric ones. There are, however, still technological and economic challenges in creating products that meet consumer expectations. In addition, there are many things that must happen to support electric vehicles, many of which are outside the control of automakers. [EPA-HQ-OAR-2022-0829-0756, p. 3]

These include: [EPA-HQ-OAR-2022-0829-0756, p. 3]

[…]

-Securing enough raw materials to build the large batery packs needed to give electric vehicles the range consumers demand. [EPA-HQ-OAR-2022-0829-0756, p. 3]

-Upgrading the nation’s roads, bridges and parking structures to ensure they can absorb the extra weight of inherently heavier electric vehicles. [EPA-HQ-OAR-2022-0829-0756, p. 3]

Thus, even if in the next eight years automakers, suppliers and retailers can retool their businesses to supply an estimated 7.5 million new vehicles in 2032 and beyond, it is far from assured that: [EPA-HQ-OAR-2022-0829-0756, p. 3]

[…]

-The mines can extract enough raw materials to build the bateries necessary to build these vehicles, especially since it is expected that electric utilities will be buying huge bateries made of the same materials to deal with the intermit nature of wind and solar energy. [EPA-HQ-OAR-2022-0829-0756, p. 3]

Organization: Illinois Farm Bureau (IFB)

-“If thought through, individuals would realize that EVs are not environmentally efficient nor cost-effective. The mining of resources for batteries is not environmentally friendly.” [EPA-HQ-OAR-2022-0829-0532, pp. 1-2]

Organization: Institute for Policy Integrity at New York University School of Law

D. EPA Provides Rigorous Analysis of Mineral and Energy Security and Could Provide Further Support and Analysis

In the context of the Proposed Rule, mineral security refers to the uninterrupted availability at affordable prices of minerals needed to produce vehicles. Relatedly, energy security refers to the uninterrupted availability at affordable prices of gas and electricity needed to drive vehicles.100 While EPA conducts an extensive analysis of both mineral security and energy security, additional analysis would further support its findings. [EPA-HQ-OAR-2022-0829-0601, pp. 16-17]

100 In the RIA, EPA sometimes uses the term “electricity security” when referencing electricity specifically.

On mineral security, EPA concludes that increased penetration of electric vehicles resulting from the Proposed Rule will “not lead to a critical long-term dependence on foreign imports of minerals or components, nor that increased demand for these products will become a vulnerability to national security.”101 This is mainly attributable to two basic reasons. First, EPA explains that there is already substantial domestic capacity to produce critical minerals, which is likely to increase in the future due to recent policies.102 Second, EPA explains that because vehicles are durable goods that can last many years, supply disruptions of critical minerals have limited impacts because consumers can normally delay vehicle purchases.103 [EPA-HQ-OAR-2022-0829-0601, pp. 16-17]

101 Proposed Rule, 88 Fed. Reg. at 29,313.

102 Id. at 29,313–23; RIA at 3-19 to 3-29.

103 Proposed Rule, 88 Fed. Reg. at 29,323;

EPA can provide additional context for the first point. Specifically, EPA should highlight that ICE vehicles may be susceptible to similar risks as BEVs from supply shocks due to our reliance on foreign vehicles and vehicle parts. From 2017 to 2021, just 69% of U.S. consumer passenger vehicles and 84% of commercial vehicles were produced domestically.104 Moreover, an estimated one-fourth of the 15,000 to 30,000 parts making up an ICE vehicle are sourced globally as of 2011.105 In fact, ICE vehicles have far more parts and moving parts than electric vehicles.106 Thus, shortages of key inputs can cause production delays and shortages, with supply-chain shortages resulting from the 2011 Tohoku earthquake and tsunami107 and the COVID-19 pandemic.108 Moreover, like the rare earth metals in BEV batteries, there are also supply-chain risks for metal inputs into ICE vehicles.109 These various risks put EPA's analysis of mineral security into context, highlighting the mineral and supply security risks of continuing to rely on ICE vehicles under the No Action scenario. [EPA-HQ-OAR-2022-0829-0601, pp. 16-17]

Battery mineral resources and production capacity are sufficient to meet the standards. There are enough mineral resources available to support a global transition to EVs and there are substantial ongoing investments in new projects along the mineral supply chain in the U.S. and in friendly countries. Significant and growing battery recycling capacity, along with battery technology diversification and improving EV efficiency, will reduce pressure on EV mineral demand. Domestic battery production capacity is quickly ramping up, already increasing by more than one-third since the IRA was passed. With major announced public, private, and utility investment in chargers, the infrastructure is also being built to meet the BEV expansion projected by EPA. [EPA-HQ-OAR-2022-0829-0569, p. 3]

There is evidence that it should be possible to quickly scale up investments into mining and battery production with careful planning and investment. EPA's proposal lays out the much needed roadmap for the mineral mining, refining, and battery production supply chain to plan and invest around. There are more than enough minerals available for a global transition to EVs, and the amount of raw material reserves domestically and in friendly countries greatly exceeds what is needed to meet EPA's proposal.21 With the IRA's Advanced Manufacturing Production Tax Credit and the domestic content provisions in the Clean Vehicle Tax Credit, the U.S. directly incentivizes mining, recycling, and battery production on U.S. soil, and further supports establishing resilient material supply chains from friendly countries. The manufacturing subsidy of $45/kWh cuts about one third of total battery costs (global average of $151 in 2022), making battery production in the U.S. even cheaper than in China.22 This support showed an immediate effect. In response to the IRA, we saw a significant uptick by more than one-third in announced plans for battery production facilities, catching up with Europe.23 Longer-term forecasts now indicate U.S. battery production capacity at 1 TWh by 2030, approaching forecasted battery demand of 1.2 TWh taking the proposed EPA standards into account.24 A mapping compilation of U.S. EV supply chain investment from December 2022 shows that there are several dozen investments in minerals, battery production, recycling, and other electric vehicle facilities across the country.25 A separate study by the U.S. Department of Energy compiled U.S. battery supply chain announcements and found over $100 billion announced as of May 2023 with over 160 new or expanded minerals, materials processing, and manufacturing facilities, and over 70,000 new jobs.26 Specific recent examples from June 2023 include a $9.2 billion federal loan to Ford to greatly expand U.S. electric vehicle and battery production, and Hyundai's announcement to increase its EV investments to $28 billion while reducing China operations.27 [EPA-HQ-OAR-2022-0829-0569, pp. 9-10]

B. Uncertain EV Job Quality

Federal policy must ensure EV jobs are as good as or better than ICE jobs. Compliance with GHG emissions standards can never justify the offshoring of jobs, the slashing of wages, or the busting of unions. [EPA-HQ-OAR-2022-0829-0614, p. 6]

Unless and until we build a comprehensive domestic EV supply chain, the transition to EVs will risk trading dependency on fossil fuels for dependency on imported EVs, batteries, fuel cells, and materials, all while hollowing out quality union jobs in the process. Uncertainty around the build-out of the domestic EV supply chain is not recognized by the EPA and therefore does not play a significant role in altering the proposed standards' increased adoption of ZEVs.12 The

EPA must craft its standards to hold manufacturers accountable to both environmental and labor concerns. [EPA-HQ-OAR-2022-0829-0614, p. 6]

12 For example, the EPA cites to 13 announced domestic battery plants, but does not indicate how many are operational or ready to help achieve compliance with the standards. See supra note 29317.

Organization: Jeremy Michalek et al.

Global commodity supply disruptions raise prices but don't necessarily make materials impossible to acquire. Global commodity supply disruptions of either oil or critical battery materials may raise prices on the world market, but are unlikely to cut off the supply entirely. We find that a large portion of lithium, cobalt, nickel and manganese is used in products other than electric vehicle battery cathodes (Figures 2 and 3). In the event of a supply disruption, higher prices would be expected to shift demand for these materials among product applications in the short- run to medium-run. Over the long-term, the price jump will affect the U.S. economy regardless of how much supply of critical materials originates from the U.S. or its allies. However, price increases will induce product innovation and redesign, such as shifts in electric vehicle battery chemistry, which will counteract the price increases. And, applications with sufficient willingness to pay for higher price materials and products may continue to have access to materials. How particular material supply disruptions may affect individual automakers and whether they experience shortages in the short- run depends on a number of factors, including the specifics of contracts in their supply chains. However, because material markets, battery manufacturers, and automakers tend to respond to disruptions, and the proposed policy includes a number of flexibil- ities such as credit borrowing, supply disruptions may result in increased production costs but not necessarily an inability to produce EVs as a compliance pathway for the proposed GHG regulations. [EPA-HQ-OAR-2022-0829-0706, p. 2]

Recommendation: EPA could consider using a sensitivity analysis with higher ma- terial prices as an alternative to using a GWh constraint to represent the effect of potential critical material supply disruptions. [EPA-HQ-OAR-2022-0829-0706, p. 2]

The supply vulnerability for battery materials is fundamentally different from supply vulnerability for fuels. As discussed in the proposed rule, sensitivity of the U.S. economy to a supply disruption of critical battery materials is fundamen- tally different from sensitivity of the U.S. economy to a supply disruption of oil. When oil supply is disrupted, such as in the 1970s OPEC embargo that triggered the origi- nal CAFE standards, everyone in the economy is immediately affected as travel costs increase and fuel shortages reduce availability. In contrast, when critical battery mate- rials are disrupted, economic sectors that produce batteries and vehicles may be quickly disrupted, but ordinary consumers and businesses can continue operations with existing vehicles, delay purchase of new vehicles, and delay scrappage of used vehicles, buying time for responses to disruptions to come online (such as new geopolitical agreements, shifts in the mix of EVs that have battery chemistries with lower use of the critical material affected, shifts in supply paths currently used for other products, new mines, refining facilities, cathode production operations, and increased production from exist- ing facilities). Thus, while supply disruption vulnerabilities for EVs remain critically important, their impact may be far more limited than that of oil (though potentially with important second order effects). [EPA-HQ-OAR-2022-0829-0706, pp. 2-3]

Current battery material supply chains are dependent upon locations in China in processing and refining, but these supply chain stages are movable. The proposed rule finds that “widespread automotive electrification in the U.S. will not lead to a critical long-term dependence on foreign imports of minerals or components, nor that increased demand for these products will become a vulnerability to national security,” in part because the Inflation Reduction Act (IRA) incentivizes battery supply chains to shift toward the United States. We analyzed battery material supply chains based on the most recent production and trade data available and found that current supply chains are dependent on locations in China, primarily in the materials refining and battery production phases, rather than in mining (Figure 1). However, unlike raw material deposits, materials refining and battery production operations can potentially be shifted to other countries over the period of transition to electric vehicles. [EPA-HQ-OAR-2022-0829-0706, p. 3]

Material supply vulnerabilities depend on battery chemistry. Key lithium- ion battery chemistries used in electric vehicles include (1) nickel manganese cobalt (NMC) and (2) lithium iron phosphate (LFP). Of these, NMC has more potential dis- ruption pathways because it requires Li, Ni, Co and Mn, whereas LFP requires only Li (Figures 2 and 3). Today, a larger percentage of LFP cathodes than NMC cathods pass through China, largely because of its dominance in LFP cathode production (Fig- ure 2). However, the patents associated with LFP cathode production expired in 2022, opening up opportunities to open new LFP cathode production facilities worldwide (Alamalhodaei, 2021). With either chemistry, reducing disruption vulnerabilities re- quires a whole-supply-chain approach that considers how multiple stages of the supply chain interact. In the event of extended supply disruptions of Ni, Co or Mn, a shift of battery chemistry toward LFP could be one pathway to responding to a disruption. [EPA-HQ-OAR-2022-0829-0706, p. 3]

Overall, the U.S. economy’s vulnerability to supply disruption could potentially be much lower for electric vehicle batteries than for oil, given (1) the more limited number of economic sectors directly impacted, (2) longer time periods for the economy to respond to disruptions, (3) potential for circular economy strageties, such as recycling and material extraction from waste streams, and (4) a shift in supply chain diversification encouraged by policies like the IRA. We recommend that supply chain vulnerability is not a reason to avoid transitioning to electric vehicles, but it is important that the U.S. simultaneously pursue strategies to reduce supply chain vulnerabilities as the transition to electric vehicles occurs. [EPA-HQ-OAR-2022-0829-0706, p. 3]

Organization: Job Creators Network Foundation (JCNF)

EPA’s Proposed Rule Is Not Feasible [EPA-HQ-OAR-2022-0829-0709, pp. 2-3]

In addition to being illegal, the proposal is not technically feasible. Daniel Yergin, one of the world's leading energy experts, highlights how electric cars have 2.5 times more copper in them than regular vehicles.6 He cites the International Monetary Fund's warning that such environmental policies will "spur unprecedented demand for some of the most crucial metals," with price increases that "could derail or delay the energy transition itself.”7 [EPA-HQ-OAR-2022-0829-0709, pp. 2-3]

6 Daniel Yergin, "'Net Zero' Will Mean a Mining Boom," (Link: https://www.wsj.com/articles/net-zero-will-mean-a-mining-boom-electric-cars-minerals-oil-fossil-fuels-climate-change-policy-cb8d5137) Wall Street Journal (April 12, 2023).

EPA's Proposed Rule Would Weaken America's Energy Security and Harm the Environment

Nearly half of the world's copper and 60% of lithium needed for electric cars' lithium-ion batteries are processed in China.8 Instead of using our rich oil and natural gas resources, this proposed rule would mean that America would now rely on China for its energy needs. [EPA-HQ-OAR-2022-0829-0709, p. 3]

8 Iea, "Clean energy supply chains vulnerabilities," (Link: https://www.iea.org/reports/energy-technology-perspectives-2023/clean-energy-supply-chains-vulnerabilities) Energy Technology Perspectives 2023 (Jan. 2023).

Moreover, EPA's proposed emissions regulations would hurt the environment, since mining the lithium and cobalt used in batteries is energy intensive. And what will be done with these car batteries after they have been used? Will they make up the landfills of tomorrow? [EPA-HQ-OAR-2022-0829-0709, p. 3]

Finally, there are significant concerns regarding the use of child labor to cultivate these needed minerals. Seventy percent of cobalt needed for lithium-ion batteries comes from the Democratic Republic of the Congo,9 where children hand dig in crowded, primitive mines to try to service the West's insatiable demand.10 [EPA-HQ-OAR-2022-0829-0709, p. 3]

Organization: John Graham

The most potent barriers are not physical, geological, technical, or financial; they are environmental, political, and sociological, as most communities in the world have no interest in serving as hosts to large mining operations and processing plants with large waste streams. In the last several years alone, promising proposals for large new lithium mines have been cancelled or delayed indefinitely in Serbia, Portugal, Oregon, North Carolina, Mexico, and Chile (see below for details). Since it takes 7 to 15 years to launch large new lithium mines, hybrids will be needed for the transitionary period. [EPA-HQ-OAR-2022-0829-0585, pp. 9-10]

The major reason to expect shortages of raw materials in the 2029-2035 period is that miners and processers require a "social license" to operate. Owners of mines and processing facilities require permits to operate because such operations are ecologically disruptive (at least temporarily), controversial to nearby residents, farmers, ranchers, businesses, schools, and tourists, and heavily regulated (e.g., due to their waste streams and threats to water and air quality). Local public opposition to new mines and processing facilities is often substantial, which explains why many geologically promising proposed projects never come to fruition.33 [EPA-HQ-OAR-2022-0829-0585, p. 22]

33 John D. Graham, John A Rupp, Eva Brungard. Lithium in the Green Energy Transition: The Quest for both Sustainability and Security. Sustainability. 13(20). 2021. 0.3390/su132011274.

A different problem for mining companies is that many geologically promising sites are in countries with unstable regimes or stable leftist regimes that want commercial control in the hands of state-owned enterprises and pro-government royalty policies. The state-owned approach to mining has failed for many years in Bolivia, yet Chile and Mexico are now moving in that direction. Leftist governance approaches discourage foreign investors from allocating start-up capital for mining projects, and miners are often unable to muster the necessary capital from sources inside the host country. Thus, one cannot imagine a global industry that departs more sharply from a free-market situation than the global materials sector supporting BEVs. [EPA-HQ-OAR-2022-0829-0585, pp. 22-23]

While the challenge of obtaining capital is less severe than the challenge of obtaining the social license to operate, the capital challenge for miners is not trivial; indeed, it is much more difficult than the challenge of obtaining capital for plants that make lithium ion batteries or assemble electric vehicles. A recent survey of capital announcements through 2022 found that $105.0 billion was allocated for electric vehicle assembly operations, $45.3 billion for battery manufacturing, yet only $15.7 billion was allocated for the battery materials sector. To meet the six-fold growth in global demand for battery materials, the capital in the mining sector needs to be roughly equal to the allocations provided to the battery sector.34 This is why mining specialists know that materials shortages are likely in the medium term. [EPA-HQ-OAR-2022-0829-0585, pp. 22-23]

34 Matt Fernley. Battery Materials Review: 2022 Yearbook. February 2023, 21.

Recent US Federal Efforts to Promote Mining. The Biden administration has invoked the Defense Production Act, identified critical minerals, and provided technical guidance to developers on how to access them in the United States. Congress, in the Inflation Reduction Act of 2022, also applied a new manufacturing tax credit to mining operations, which will ease somewhat the capital requirements facing a developer. DOE was also awarded roughly $7 billion in grant authority to stimulate the U.S. supply chain for electric vehicles. However, virtually none of the DOE grants have been allocated to mining projects; some have supported mine processing facilities but most of the grants have been awarded to recyclers, component producers, and battery cell/pack producers. [EPA-HQ-OAR-2022-0829-0585, p. 23]

Explanations for Recent Price Volatility. An understanding of global supply and demand helps explain why raw material prices for EVs surged in 2021-2022, collapsed in early 2023, and began to recover in mid-2023.35 Most of the action has been on the demand side because, except for output from existing mines, the global supply of raw materials does not change rapidly.36 Specifically, the unexpected shortages in raw materials in 2021 – 2022, which led to extreme price volatility for some materials, were not caused by an unexpected loss of supply. They were caused by a rapid resurgence in demand for BEVs as China’s economy recovered more quickly from the pandemic than expected.37 [EPA-HQ-OAR-2022-0829-0585, p. 23]

35 Matt Fernley. Why I Think Lithium Prices Will Bounce. Kitco.com. April 3, 2023.

36 US Geological Service. Mineral Commodity Summaries. 2022, 100 (lithium).

37 https://internationalbanker.com/brokerage/why-are-lithium-prices-collapsing/#:~:text=The%20surge%20in%20demand%20for%20lithium%20batteries%20amidst,rally%20observed%20throughout%202021%20and%20much%20of%202022.

The collapse of raw material prices in early 2023 reflected both demand and supply factors: demand growth for BEVs in China moderated as subsidies for BEVs ended while output from existing mines in Australia and Chile surged in response to the 2021-2022 price surge. Materials prices showed signs of recovery in the second quarter of 2023 as BEV demand in China resumed its strong growth rate.38 [EPA-HQ-OAR-2022-0829-0585, p. 23]

38 Eric Onstad, Siyi Liu, Mai Nguyen. Lithium Prices Bounce After Big Plunge But Surpluses Loom. Reuters.com. May 2, 2023.

Flaws in the NPRM Analysis of Materials Shortages. In the NPRM EPA (and some private forecasters) misanalyze the challenge by treating material shortages as only a near-term problem (pre-2026) that will disappear as the global supply response occurs.39 The DRIA states (page 2-50) that battery costs after 2026 "are expected to resume their decline as mineral supply and demand balance out." EPA explains further: "For the years 2022 through 2025, we suspended use of the learning factor, to reflect consensus views that elevated mineral prices are likely to cause battery costs to remain flat for a time." (2-49) Even though EPA finds that battery prices "are poised to remain somewhat elevated until about 2025 to 2026" and despite forecasting battery material demand will explode after 2025, somehow EPA finds that battery costs after 2026 "are expected to resume their decline as mineral supply and demand balance out" (2-50). [EPA-HQ-OAR-2022-0829-0585, pp. 23-24]

39 Wood Mackenzie Q3 2022 (Wood Mackenzie 2022) and EDF/ERM (MacIntosh, Tolomiczenko and Van Horn 2022). Reports referenced in DRIA, page 2-50.

The more likely scenario is virtually the opposite of what EPA predicts: adjusted output from existing mines will address short-term shortages (with less than 1 year of lag) but medium-run shortages are likely because it is so difficult – and takes so long -- to launch new mines. Mining specialist Matt Fernley explains: “Even in the hard rock (areas), the most commodity-like of all the lithium products, it’s proven exceedingly complex to get new assets into production, and even to add Brownfield capacity.”40 The new mines that start are often delayed many years compared to plan, and/or confront challenges in continuing to operate or expand due to local concerns.41 Moreover, some new mines – despite their promise – cannot produce the battery-grade material that is required for BEVs.42 The real mineral-shortages challenge is the medium run (2029-2035), after output from existing mines is exhausted but before numerous new mines are launched and before the impact of a new recycling industry kicks in.43,44 In the long run (post-2035), there is no reason to expect chronic materials shortages unless miners simply cannot obtain permits to operate – a distinct possibility given the extensive environmental harm of many mining operations – and/or the recycling industry confronts insurmountable challenges or doesn’t yet have enough scrapped BEVs to provide large amounts of materials. [EPA-HQ-OAR-2022-0829-0585, pp. 23-24]

43 Eric Onstad, Siyi Liu, Mai Nguyen. Lithium Prices Bounce After Big Plunge But Surpluses Loom. Reuters.com. May 2, 2023.

44 Joe Miller, Peter Campbell, Patrick McGee. Musk Joins Rivals in Warning of Supply Disruption Threat to EV Rollout. Financial Times. May 14-15, 2022, 8.

Where will materials prices settle in the long run? No one knows for sure, but a good guess is at the marginal cost of global production. The new mines that are added typically have much higher costs of production than the existing mines. [EPA-HQ-OAR-2022-0829-0585, p. 24]

However, it is possible that new modes of production (e.g., direct lithium extraction from brines) will shift the cost curve downward. On the other hand, the increasing demands for environmental, social, and governance improvements at new mines will only increase marginal costs of operation (as certain mines and suppliers are judged unacceptable). From the standpoint of long-run marginal costs, there is no valid reason to expect the steady decline in materials costs that EPA is projecting from 2026 to 2035.45 [EPA-HQ-OAR-2022-0829-0585, p. 24]

45 Matt Fernley. Battery Materials Review: 2022 Yearbook. February 2023, 7-9.

The previous section described the global markets for EV materials generally, often using lithium as the prototypical example. EPA studied only lithium, but here we review the distinctive challenges with cobalt, nickel, and neodymium as well as lithium. We urge EPA to go beyond lithium and create global supply-demand analyses for each important material. [EPA-HQ-OAR-2022-0829-0585, pp. 24-25]

Cobalt

The cathode in the lithium-ion battery requires a transition metal as a stabilizer for the chemical structure. Cobalt, though it is relatively expensive, has ideal properties: thermal stability, which reduces safety risks, and high energy density, which facilitates long driving range. The International Energy Agency estimates that 17 new cobalt mines will be needed by 2030 to meet global demand for cobalt induced by the global electric vehicle industry. [EPA-HQ-OAR-2022-0829-0585, pp. 24-25]

Most global reserves and current cobalt production are in a single country: the Democratic Republic of Congo (DRC). Labor is so cheap in DRC that it is difficult for new mines around the world to compete with cobalt from the DRC. [EPA-HQ-OAR-2022-0829-0585, pp. 24-25]

Since 97% of the mined cobalt comes as a byproduct of mined copper or nickel, the global supplies of cobalt are highly inelastic with respect to the price of cobalt. Even if cobalt prices rise substantially between now and 2030, the supplies of cobalt will not respond proportionately unless copper and nickel prices happen to rise at the same time. [EPA-HQ-OAR-2022-0829-0585, pp. 24-25]

There are three other complications with the global cobalt market that are causing global automakers to look for alternatives to cobalt. Chinese corporations have bought up a substantial share of the low-cost cobalt mines in DRC and the central government of China has fostered a working relationship with the DRC leadership. From a western perspective, the government of DRC seems unstable and unreliable, and there is a history of corruption in the DRC's mining sector. Finally, international rights groups have exposed human-rights abuses in the DRC mines, including use of child labor and both worker and community exposures to hazardous materials. It is these human-rights problems in DRC that motivated the OECD to develop responsible-sourcing guidelines. At a minimum, those guidelines expect automakers and their suppliers to know where their cobalt supplies come from and whether those mines engage in responsible practices. Several global automakers, including Tesla and GM, have pledged to go cobalt free as soon as possible. [EPA-HQ-OAR-2022-0829-0585, p. 25]

The United States does not have any operational cobalt mines. A sustained effort in Utah, supported by the US Department of Defense, led to the partial construction of a new cobalt mine. The developer suspended completion of construction in March 2023 due to inflationary cost pressures and low cobalt prices. The developer also cited the need for an affordable US cobalt refiner to assist in the commercial viability of the mine.46 [EPA-HQ-OAR-2022-0829-0585, p. 25]

46 https://www.kitco.com/news/2023-03-28/Jervois-suspends-final-construction-at-Idaho-Cobalt-Operations-due-to- low-cobalt-prices-and-inflationary-pressures.html.

The most promising substitute for cobalt is nickel because nickel has high energy density. However, nickel-rich cathode materials tend to suffer from rapid capacity fade and impedance rise due to deleterious reactions between the nickel atoms on the surface of the cathode and the cell's electrolyte. R&D projects found that a blend of nickel, manganese and aluminum can counteract the negative aspects of nickel-rich cathodes.47 Due to the growing use of nickel in cathodes, the International Energy Agency estimates that 60 new nickel mines around the world will be needed by 2030 to meet the demand induced by the electric-vehicle transition. [EPA-HQ-OAR-2022-0829-0585, pp. 25-27]

The global nickel industry is much larger than the cobalt industry, as 65% of the refined nickel in the world is used in stainless steel production.48 A higher grade of nickel is required for use in the cathodes of lithium-ion batteries. Even with rapid growth of nickel use for electric vehicles, batteries will account for a minority of refined nickel consumption, but cathode makers need access to refiners that can deliver the high-grade (Class I) nickel. [EPA-HQ-OAR-2022-0829-0585, pp. 25-27]

47 https://www.energy.gov/eere/vehicles/articles/reducing-reliance-cobalt-lithium-ion-batteries.

48 https://www.usgs.gov/centers/national-minerals-information-center/nickel-statistics-and-information.

Global reserves of nickel are plentiful and accessible. The mining and processing of nickel, however, presents their own challenges. Four countries (Indonesia, Philippines, Russia, and New Caledonia) account for about 67% of refined nickel production.49 [EPA-HQ-OAR-2022-0829-0585, pp. 25-27]

49 https://pubs.usgs.gov/periodicals/mcs2022/mcs2022-nickel.pdf.

Indonesia is by far the largest nickel producer, and it has the largest amount of global reserves, but it has export quotas on unprocessed nickel to boost the commercial fortunes of its own nickel processing industry. Europe won a World Trade Organization ruling against Indonesia's export quotas, but the government of Indonesia is not likely to repeal them.50 Indonesia also uses export quotas to attract foreign investment in cathode plants, battery plants, and electric-vehicle assembly plants. China has already responded with $30 billion for Indonesia's refining capabilities, but it remains to be seen whether Indonesia can build out the entire supply chain for electric vehicles.51 Historically, the government of Indonesia has been suspicious of multi- national corporations based in the West, so it may not be the best place for Western companies to place their bets. Ford Motor Company decided otherwise, and recently signed a $4.5 billion nickel deal with Indonesian officials.52 [EPA-HQ-OAR-2022-0829-0585, pp. 25-27]

50 https://thediplomat.com/2022/12/indonesia-to-appeal-wto-ruling-on-nickel-export-ban/.

52 https://www.verdict.co.uk/ford-signs-4-5bn-deal-for-new-nickel-plant-in-indonesia/:~:text=US%20motor%20company,%20Ford,%20has%20signed%20a%20$4.5bn,to%20build%20a%20ni ckel%20processing%20plant%20in%20Indonesia.

China has turned to the Philippines as an alternative supplier of nickel, but environmental concerns have restrained the country's growth of nickel production. The government of the Philippines ordered a shutdown of half of the country's nickel mines because they were contributing to water pollution and other environment damages.53 [EPA-HQ-OAR-2022-0829-0585, pp. 25-27]

53 https://www.nytimes.com/2017/04/27/world/asia/philippines-mining-environment.html#:~:text=In%20February%2C%20Gina%20Lopez%2C%20the%20acting%20secretary%20of,field s%20and%20watersheds%20stained%20red%20with%20nickel%20laterite.

Russia's invasion of the Ukraine has only underscored the liabilities of depending on Russia for nickel. Nonetheless, Russia remains a significant nickel supplier of the US and Europe.54 [EPA-HQ-OAR-2022-0829-0585, pp. 25-27]

54 https://www.reuters.com/markets/europe/exclusive-eu-us-step-up-russian-aluminium-nickel-imports-since- ukraine-war-2022-09-06/.

Tesla is trying to develop New Caledonia as a regular supplier of nickel, but mining on the island has a controversial history. There has been exploitation of indigenous people and unmanaged ecological destruction.55 [EPA-HQ-OAR-2022-0829-0585, pp. 25-27]

55 https://www.nytimes.com/2021/12/30/world/asia/tesla-batteries-nickel-new-caledonia.html.

The United States has only one active nickel mine, the Eagle Point mine in Michigan. It is nearing the end of its useful life, but there was once hope that two new nickel mines in Minnesota would take its place. However, both of those mining projects are tied up in regulatory and judicial hurdles, which means they will not be producing nickel anytime soon.

The most promising paths for the United States might be new mines in Canada, Norway, and Australia. However, other countries, including China, are also talking to miners in those countries. [EPA-HQ-OAR-2022-0829-0585, pp. 25-27]

Global demand for neodymium, one of the rare earths, is projected to grow five-fold by 2030, as it is crucial for two aspects of the clean-energy transition: electric motors and wind turbines. Finding reliable suppliers of neodymium is a major challenge for automakers and their suppliers. [EPA-HQ-OAR-2022-0829-0585, pp. 27-28]

In the 1980s, low-cost mines in China caused other rare-earth mines to close, including the Mountain Pass mine in California near the Mojave Desert on the Nevada line. In less than a decade, China captured 95% of global rare-earth production. China's competitive advantages are low-cost labor in Inner Mongolia, lack of strict environmental controls, and state support of rare-earth producers. China's largest mine produces rare earths as a byproduct of iron ore mining. [EPA-HQ-OAR-2022-0829-0585, pp. 27-28]

Due to a fishing dispute with Japan in the South China Sea, China in 2011 instituted export quotas on rare earths, leading to a temporary surge in neodymium prices from $19 per kilogram to $500 per kilogram. Japan, Europe, and the US won a WTO lawsuit against China, which claimed, without success, that its export controls were designed only to promote sustainable development and reduce the environmental damages of mining. By the time the case worked its way through the WTO appeals process, China had removed its export controls and the prices of neodymium tapered. [EPA-HQ-OAR-2022-0829-0585, pp. 27-28]

Despite this hard evidence that China is willing to use rare-earths dominance as a geopolitical weapon, Japan, Europe, and the United States have not come close to self-sufficiency in the mining and processing of neodymium. The most recent data show China responsible for 69% of rare-earth mining, 85% of rare-earth processing and 92% of rare-earth magnet production.56 [EPA-HQ-OAR-2022-0829-0585, pp. 27-28]

56 https://www.politico.com/news/magazine/2022/12/14/rare-earth-mines-00071102.

The United States, with Department of Defense subsidies, has stimulated a restart of the Mountain Pass mine, giving priority to neodymium and other rear earths needed for military applications. A new processing and separation plant is also under construction in Fort Worth, Texas. Production of rare earth magnets is scheduled to begin in 2025. But, even if all goes as planned, the United States will account for a small share of neodymium mining and processing in 2030. [EPA-HQ-OAR-2022-0829-0585, pp. 27-28]

If automakers and their suppliers do not want to be dependent on China and cannot access enough supply from Mountain Pass, where should they go? The reserves data suggest that the next most promising countries are Vietnam (with half the reserves that China has), Brazil, India, Australia, and Greenland.57 Some of those countries would likely require foreign investment to launch new mines and processing facilities. [EPA-HQ-OAR-2022-0829-0585, pp. 27-28]

In 2021, global lithium production exceeded 100,000 tons of lithium-carbonate-equivalent (LCE) for the first time in history. To satisfy the global demand forecasts for electric vehicles (which are dominated by China, Europe, and North America), lithium production will need to grow three-fold by 2025 and six-fold by 2030.58 If lithium is also required for grid-scale energy storage of electricity from wind and solar, the global demand for lithium could increase 20-fold by 2030.59 While existing mines are expected to double their production in the next few years, most of the growth in production must come from new mines. [EPA-HQ-OAR-2022-0829-0585, p. 28]

58 Govind Bhutada. This Chart Shows Which Countries Produce the Most Lithium. Wef.com. January 5, 2023.

59 Stephen Wilmot. Battery Metals Rush is Just Starting. December 3, 2021, B12.

There are vast quantities of lithium around the world and on the ocean floor, but several mines in four countries (Australia, Chile, Argentina, and China) accounted for almost 98% of global production in 2020-2021.60 Australia has had the most success expanding production at hard-rock mines, largely for export to China, as Chinese companies possess ownership stakes in large Australian mines. [EPA-HQ-OAR-2022-0829-0585, pp. 28-30]

60 USGS. Mineral Commodities Summaries. 2022, 100 (lithium).

Chile was once (2014) the #1 lithium global producer, based on brine operations in the Atacama desert. To years of royalty increases (2017-2019) hurt Chile's competitiveness. Chile's brine operations also become controversial in Chile due to ecosystem disruption in desert areas, overdraws of brine by developers, and protests from indigenous populations.61 The new leftist government in Chile started by cancelling contracts for some new mines in the Atacama desert. A Chilean appeals court also suspended a new mining contract following objections from the local Chilean governor.62 The Chilean government later proposed a new governance arrangement where all lithium mining will be supervised by a state-owned enterprise. Investors in Chile's mining operations were appalled to learn of this new governance arrangement.62 [EPA-HQ-OAR-2022-0829-0585, pp. 28-30]

Argentina has a promising lithium sector governed primarily by mining-friendly provincial leaders that have kept royalty rates relatively low.64 But, the industry starts from a small base. As it grows, it will likely confront opposition from indigenous groups and environmentalists like Chile has experienced.65,66 [EPA-HQ-OAR-2022-0829-0585, pp. 28-30]

64 Harry Dempsey, Edward White. Chile's Move to Control Lithium Alarms Industry. Financial Times. May 2, 2023.

66 Natalie Alcobo. A Race for Lithium is Sparking Fears of Water Shortages in Northern Argentina. Climatechangenews.com. October 26, 2022.

The efforts of other countries to launch lithium mining and processing have encountered numerous obstacles. Here is a summary of reasons why other countries have not been highly successful to date. [EPA-HQ-OAR-2022-0829-0585, pp. 28-30]

1. Bolivia. Although Bolivia has enormous lithium reserves and has been striving to launch lithium mines for more than a decade, no mining has yet occurred. Bolivia's state-owned corporation controls lithium mining and has had difficulty attracting foreign capital and expertise.67 [EPA-HQ-OAR-2022-0829-0585, pp. 28-30]

2. Mexico. The leftist government upset almost a decade of work at a potential large mining site when it proposed to nationalize energy assets such as lithium.68 The prospects of foreign investment are now uncertain.69 [EPA-HQ-OAR-2022-0829-0585, pp. 28-30]

3. Brazil. The impoverished Jequitinhonha Valley is home to 85% of Brazil's large lithium reserves. A large new hard-rock mine is scheduled to begin production in 2024, but nearby residents are already expressing concerns about noise, dust, and water consumption from early-stage pilot activities.70 [EPA-HQ-OAR-2022-0829-0585, pp. 28-30]

4. Africa. Several African countries (Namibia, Zimbabwe, and the Democratic Republic of Congo) are exploring the promise of lithium development projects with financial assistance from foreign investors, including Chinese companies. Obstacles to progress include concerns about corruption, legal battles over ownership of lithium deposits, capricious politics, lack of electric power to support local processing, and the absence of adequate roads and port infrastructure.71 [EPA-HQ-OAR-2022-0829-0585, pp. 28-30]

5. Canada. Promising new lithium sites in Ontario and Quebec have been slowed due to difficulties in arranging new processing capabilities for the mined material.72 An old lithium mine in Ontario, which may be revived, changed owners four times in the last ten years and had a record of serious spills of waste. Owners twice filed for creditor protection despite $110 million in support from the Province of Ontario.73 [EPA-HQ-OAR-2022-0829-0585, pp. 28-30]

6. Portugal. The national government of Portugal has proposed a massive expansion of the country's small lithium mining sector, which currently supplies lower-grade product to ceramics operations. At the local and provincial level, where the hard-rock mines would be developed, grass-roots and community-level opposition is intense. One proposed mine has already been abandoned; another is in litigation.74,75 [EPA-HQ-OAR-2022-0829-0585, pp. 28-30]

7. Serbia. The leadership of Serbia announced a deal with a large multinational mining company to create what might have been the largest hard-rock lithium mine in the world. In the face of several months of grass-roots protests, including thousands of demonstrators in Belgrade, the Serbian government reversed course and revoked the company's exploratory licenses. The objections were primarily on environmental grounds.76 [EPA-HQ-OAR-2022-0829-0585, pp. 28-30]

8. International Ocean Seabed Mining. There are vast quantities of accessible critical minerals, including lithium, resting on the floor of specific regions of the Pacific Ocean (e.g., between Mexico and Hawaii). With new technologies, they can be vacuumed from the ocean floor without the explosions and digging that characterize hard-rock mining on land. However, countries around the world have not developed an adequate consensus on environmental-protection standards for seabed mining, which was supposed to have been the function of the International Seabed Authority in Kingston, Jamaica. Most recently, the United Nations adopted the High Seas Treaty, which – if ratified by at least 60 countries – is likely to further complicate the regulatory environment for ocean seabed mining.77 [EPA-HQ-OAR-2022-0829-0585, pp. 28-30]

The US has only one active lithium mine, a small brine operation in Silver Peak, Nevada. The developer is striving to double production from 5,000 to 10,000 tons LCE by 2025.78 [EPA-HQ-OAR-2022-0829-0585, pp. 30-32]

EPA, based on a memorandum from DOE, claims that 22 promising lithium development projects are under investigation in the United States. What DOE and EPA did not disclose is that only one of the projects (Thacker Pass, Nevada) has successfully acquired a permit to operate. [EPA-HQ-OAR-2022-0829-0585, pp. 30-32]

The Thacker Pass project has, however, been delayed due to determined opposition from indigenous groups, ranchers, and environmentalists.79 A first round of litigation against the BLM permit decision led to a split decision by a federal judge, weighted in favor of BLM's permit. More litigation and protests are likely; the extent of local opposition raises questions about whether the mine will be sustainable. [EPA-HQ-OAR-2022-0829-0585, pp. 30-32]

78 Bill Dentzer. Nevada's Next Boom. Las Vegas Review-Journal. Pctober 2, 2021.

79 Ernest Scheyder. Lithium America's Delays Nevada Mine Work After Environmentalist Lawsuit. Reuters.com. June 11, 2021.

Here are several lithium project locations in the US that have encountered serious obstacles. [EPA-HQ-OAR-2022-0829-0585, pp. 30-32]

1. Borox Lake, Alvard Playa, and Whitehorse Ranch, eastern Oregon. The BLM informed the developers that lithium mining is not permitted in these areas due to a year 2,000 forest-conservation law.80 Another developer continues to explore on the border of Oregon and

Nevada, but it is one of the best remaining habitats for the sage grouse.81 [EPA-HQ-OAR-2022-0829-0585, pp. 30-32]

2. Cherryville, Gaston County, North Carolina. In September 2020 a developer announced a deal with Tesla to supply up to 30,000 tons/year LCE from a new hard-rock mine on private land outside Cherryville, Gaston County, North Carolina (near Charlotte). Initial deliveries of material to Tesla were scheduled for July 2022.82 Although the developer spent $58 million and several years on the project, the Gaston County Board of Commissioners objected to a lack of consultation outreach from the developer and expressed serious environmental concerns about the project.83 The County placed a moratorium on mining activities until local zoning regulations could be revised. Faced with determined local opposition, the developer gave up on obtaining a state permit and County approval; the project was delayed indefinitely.84 [EPA-HQ-OAR-2022-0829-0585, pp. 30-32]

3. Rhylolite Ridge, Nevada. A developer, which has already spent more than $100 million in assessment and exploration, is in the BLM environmental impact assessment phase of a new lithium mine in Nevada that could produce 24,000 tons LCE per year starting 2025-2026. The project has substantial private-sector backing and a conditional $700 millon DOE loan for a nearby processing facility. A complication occurred when the US Fish and Wildlife Service, which is part of the Department of Agriculture, determined that a desert flower, Tiehm's buckwheat, is an endangered species. The flower is apparently found only near the mine site, but the developer maintains that the location of the mine, which has been altered to reduce risk, will not threaten extinction of the flower. The project has triggered intense opposition from a national environmental group, the Center for Biological Diversity. Further delays and litigation seem likely.85 [EPA-HQ-OAR-2022-0829-0585, pp. 30-32]

Salton Sea, California. Several developers plan to use a relatively new technology, direct lithium extraction (DLE), to access lithium suspended in super-hot brine at the Salton Sea, near geothermal plants that are already extracting brine for power production.86 The projects have private sector backing and financial support from the State of California. There is another dozen or so projects around the world seeking to implement DLE, but there is only one operational DLE project in the world. It is in Argentina, where the lithium content of brine is unusually high, but even there the developer makes partial use of conventional evaporation ponds. The developer has not been able to replicate commercial-scale DLE anywhere else. A recent environmental review of DLE noted that most performance testing of DLE has not been performed on real brines. Real testing at substantial scale is necessary to assess requirements for energy, fresh water, chemicals, and waste management. Real-brine testing should evaluate several performance indicators simultaneously.87 Views of the commercial feasibility of DLE vary considerably. One estimate of the direct cost of DLE puts it in the range of $4,000/ton LCE, a bit higher than the direct costs of conventional methods but not prohibitive.88,89 [EPA-HQ-OAR-2022-0829-0585, pp. 30-32]

89 Adam Webb. Lithium Sector: Production Costs Outlook. S&P Global Market Intelligence. Spglobal.com. 2019.

Before the final rule, EPA and DOE should assess each of the 22 lithium projects, including a realistic, itemized assessment of how likely they are to be in commercial operation by 2027-2032, given the intensity of local opposition to mining. The International Energy Agency estimates new mining projects take an average of 16.5 years to move from discovery of the resource to actual production, assuming the mine starts producing at all. . The time scales in the United States are at the high end of the range in IEA's analysis, and few projects can overcome intense public opposition.90 The track record to date in the US suggests that most of the 22 lithium projects will not produce a ton of LCE.91 It should be emphasized that DOE has no authority or special expertise in the regulatory aspects of permits for new mines; that authority and expertise is housed in the Bureau of Land Management in the Department of Interior and the Forest Service in the Department of Agriculture. [EPA-HQ-OAR-2022-0829-0585, pp. 30-32]

Flaws in Standard Market Forecasts of Lithium Supply

Prestigious management-consulting and investment firms often produce consensus reports on global markets for specific commodities. EPA relies on one such report on lithium, a proprietary forecast by Wood MacKenzie, to support the proposition that global supplies of lithium will be adequate to meet global demand in the year 2032. [EPA-HQ-OAR-2022-0829-0585, pp. 32-33]

Mining specialists have dismissed such forecasts because of systematic errors in their methods. Specifically, they (1) overestimate the ease and pace at which new supplies will be developed,(2) they overestimate the percentage of new supplies that will be of battery-grade quality for electric vehicles; (3) they underestimate the amount of material lost due to low yields in cell manufacturing; (4) they underestimate the impact of pricing of high-cost production (lepidolite); and (5) they underestimate the impact of the higher costs of capital that miners now face.92 Given how common it is for new projects to falter due to local public opposition, it is startling that Wood MacKenzie does not even include public support as a formal variable in its forecast. Daniel Morgan, a mining specialist at the investment bank Barrenjoey, insists that Western companies and governments have failed to build an adequate supply chain for lithium:

“There’s a great love of throwing out lofty targets, but where the rubber hits that road, it’s not going to happen.”93 [EPA-HQ-OAR-2022-0829-0585, pp. 32-33]

92 Matt Fernley. Battery Materials Review: 2022 Yearbook. February 2023, 9.

93 James Fernyhough. Electric Vehicle Targets “impossible” Without Changes to Lithium Pipeline. Financial Times. April 13, 2022, 6.

Organization: Kentucky Office of the Attorney General et al.

C. The Proposed Rule ignores significant hurdles to the industry transformation that the rule requires.

EPA is pushing forward with this proposal at a breakneck pace and in circumstances ill-suited to the aggressive industry transformations that the Agency demands. The electrical grids are neither stable nor safe enough to handle EPA’s proposal. The country will be more energy dependent and less secure because of it. Automakers will be left without the materials they need to comply. And all the while, consumers—our citizens—will have to deal with empty government promises about vehicle pricing, utilization, and safety. In short, the Proposed Rule ignores too many aspects of this too-important issue. [EPA-HQ-OAR-2022-0829-0649, p. 10]

2. The automotive supply chain is not ready for the Proposed Rule.

The Proposed Rule’s fast-and-furious approach to electrification will also have devastating consequences for the automotive supply chain. EPA admits that “[c]urrently, the U.S. is lagging behind much of the rest of the world in critical mineral production” to so great an extent that “it is more convenient” to import minerals like nickel that are critical to build the necessary components of EVs. 88 Fed. Reg. at 29,315. But talk of convenience masks the reality that “[t]oday’s battery and minerals supply chains revolve around China”—over “half of lithium, cobalt and graphite processing and refining capacity” is located there, and “the majority of the [key mineral] supply chain . . . [is] likely to remain in China through 2030.” Global Supply Chains of EV Batteries, International Energy Agency, https://bit.ly/3MXdM3Y. At best, finalizing a rule that requires this sort of foreign dependence will deal a significant blow to our energy independence. See WV Amicus Br. at 6-17 (explaining how “forcing a quick transition to electric vehicles . . . will make automakers unreasonably dependent on foreign-controlled supply”). At worst, it will raise real threats to our national security. See Opening Br. for State Pet’rs., Texas v. EPA, No. 22-1031 (D.C. Cir. Apr. 27, 2023), ECF 1996773, at 22-24 (discussing the “well-documented history of China using its rare-earth-minerals dominance as a geopolitical weapon”). [EPA-HQ-OAR-2022-0829-0649, pp. 12-13]

What is more, demand for these rare materials will spike outside the automotive context as quickly as the Proposed Rule will spike it within. EPA recognizes this: It acknowledges that critical minerals for EV component production “are also experiencing increasing demand across many other sectors of the global economy . . . as the world seeks to reduce carbon emissions.” 88 Fed. Reg. at 29,313. The Proposed Rule also concedes that other “uncertain issues” like “permitting, investor expectations of demand and future prices, and many others” make it “difficult to predict with precision the rate at which new capacity will be brought online in the future.” Id. Yet the proposed solution is just a short “transition period” so that “a robust supply chain” can develop for these products, including new material mining and expanded processing capacity. Id. These obstacles should slow a project with even a conservative timetable; for an overhaul as rushed as the Proposed Rule, they are reason to return to the drawing board. Proceeding without more concrete, realistic projects for expanded supply chains—and more realistic timetables—is another mark of arbitrary and capricious decision-making. [EPA-HQ-OAR-2022-0829-0649, pp. 13-15]

Other concerns about the minerals' supply and their extraction processes raise still more hurdles. The Proposed Rule had to recognize that it would take an estimated "five to ten" or more years "to develop a new [lithium] mine or mineral source"—and that delay is despite "very high" industry motivation from a "very robust" demand outlook. 88 Fed. Reg. at 29,313. Yet even that estimate is likely far too rosy. Last year, one geometallurgy professor looked at what it would take to shift away from fossil fuels entirely and to these and other rare materials for a single generation. Based on 2019 mining production rates, he predicted that the necessary extraction of "battery metals like lithium, cobalt, and graphite" would take over 9,900 years, 1,700 years, and 3,200 years, respectively. Simon P. Michaux, The quantity of metals required to manufacture just one generation of renewable technology units to phase out fossil fuels, YouTube (Aug. 18, 2022), https://bit.ly/42w7Fcx; see also Simon P. Michaeux, Assessment of the Extra Capacity Required of Alternative Energy Electrical Power Systems to Completely Replace Fossil Fuels (Aug. 18, 2022), https://bit.ly/3qCU1qU. Indeed, in 2022, the global reserves of those same three metals amounted to "less than five percent of what we need [for] one generation." Id. And among those reserves, not every discovery deposit becomes a mine. Only 1 or 2 for every 1000 does, and it takes between 15 and 20 years for those few mines to become fully functional. Id. And of those, 20–30% of the mines that get up and running will eventually "go out of business because of market conditions." Id.; see also The Raw-Materials Challenge: How The Metals And Mining Sector Will Be At The Core Of Enabling The Energy Transition, McKinsey & Co. (Jan. 10, 2022), https://tinyurl.com/2ne5jt37. Throw in the fact that each of these materials has a limited life-cycle after which they must be "decommissioned and replaced," and it becomes clear that we may well need to "make batteries out of something else." Michaux, The quantity of metals required to manufacture just one generation of renewable technology units to phase out fossil fuels, supra. That whole endeavor "is not going to be easy." Id. Quite right. The Proposed Rule needs to deal with real projections for the real demand it creates. [EPA-HQ-OAR-2022-0829-0649, pp. 13-15]

The view further down the supply chain is no better. The Proposed Rule can say only that supply capacity is "rapidly forming," not that it exists now or in the near-enough future. 88 Fed. Reg. at 29,323. EPA recognizes that it is still only "a goal of the U.S. manufacturing industry to create a robust supply chain for these products." Id. (emphasis added). EPA also says that, "[i]n general, the structure of the proposed standards allows an incremental phase-in to the MY 2032 level and reflects consideration of the appropriate lead time for manufacturers to take actions necessary to meet the proposed standards." Id. at 29,239. But there is nothing "incremental" about an edict for an eight-fold increase in EV sales in eight years. See id. at 29,189, 29,329, 29,346. And there is nothing simple about the amount of time and money needed to get the still-illusory supply chain running at massive new scale. According to former auto executive-turned-industry adviser Larry Burns, "[t]he transition automakers are perusing requires building totally new factories, assembly lines and supply chains, a years-long process." Puko, supra. Automakers will have to apply "major re-engineering" that "usually takes anywhere from three to five years" per model to dozens of vehicle models in under a decade. Id. [EPA-HQ-OAR-2022-0829-0649, pp. 13-15]

Battery factories, in particular, take years to build. See Eli Leland, So You Want To Build A Battery Factory, Medium: Batteries are Complicated (July 16, 2021), https://tinyurl.com/mv4vhh3x. It takes longer still to create and sharpen production processes that yield quality and safe products that can satisfy consumer demand and federal regulators. Mistakes are too costly for it to be any other way. See Bradley Berman, Battery Experts Provide Deeper Explanations for Chevy Bolt Fires, Autoweek (Nov. 15, 2021), https://tinyurl.com/3r7879u6 (describing recall of 141,000 EVs following 16 reported fires). The Proposed Rule, however, will have "automakers rac[ing] to supplement material shortages," and risking far more than prudence allows, just to "scal[e] these facilities and operations quickly." Paige McKirahan, United States: EV Supply Chain Disruption To Ignite Disputes Over IP, M&As, And More, Mondaq (Dec. 9, 2022), https://bit.ly/3p6eXpI. This demand, in turn, "put[s] at risk the stability of mines and refineries with possible unskilled workers," and "[h]uman rights violations . . . run rampant if safe and proper processes are not identified." Id. None of this is acceptable. All of it can be avoided. [EPA-HQ-OAR-2022-0829-0649, pp. 13-15]

The Proposed Rule should also account for the reality that too-fast and too-aggressive regulation can stifle the very innovation it relies on. Even with increased governmental subsidies toward rapid EV development, mandates like the Proposed Rule will almost certainly "prompt automakers to make bigger bets on a narrower set of options for complying, which might limit innovation and progress because technology now is changing so rapidly." Puko, supra. Programs like the Renewable Fuel Standards are whittled down, contrary to Congress's intent. See WV Amicus Br., at 24-27. And changing contexts that should command our attention end up ignored, including that EV "battery technology is still evolving," which means "the U.S. may be at risk of building mines and factories to produce batteries that wind up being obsolete in a decade." Joann Muller & Jael Holzman, Why the U.S. Can't build EVs without China, Axios (Apr. 12, 2023), https://bit.ly/42iaoWS. [EPA-HQ-OAR-2022-0829-0649, pp. 13-15]

The second- and third-order consequences of choosing rushed production based on today's technologies over innovation are weighty, too. Take nickel, for example. It is possible—even likely—that later battery technologies will render it unnecessary. See 88 Fed. Reg. at 29,314 (citing battery applications that "an iron phosphate cathode which has lower energy density but does not require . . . nickel"). And that may prove to be a very good thing: "Reaching the nickel means cutting down swaths of rainforest," and "[r]efining it is a carbon-intensive process that . . . produc[es] waste slurry that's hard to dispose of." Jon Emont, EV Makers Confront the 'Nickel Pickle,' WSJ (June 4, 2023), https://bit.ly/3PdIoRH. Nickel, then, exposes "a larger contradiction within the EV industry: Though EVs are designed to be less damaging to the environment in the long term than conventional cars, the process of building them carries substantial environmental harm." Id. Rather than letting market demand and innovation explore other paths forward, the Proposed Rule locks automakers and the rest of our economy into this impossible option. EPA should slow down this endeavor and allow both safety and innovation to drive decision-making in this critically important area. [EPA-HQ-OAR-2022-0829-0649, pp. 13-15]

Organization: Kia Corporation

EPA Underestimates Market and External Challenges

EPA's proposed rule highlights the very complex challenges that lie ahead for the EV market. There are an enormous number of factors that are outside the control of automakers including manufacturing capacity, battery production, charging infrastructure, critical mineral supply, and consumer acceptance. A successful transition in the timeframe proposed will require massive changes in commitments from all sectors of the economy: vehicle suppliers, labor, utilities, charging infrastructure, home builders, mining, and mineral processing. Consumer behavior and acceptance also needs to significantly change. [EPA-HQ-OAR-2022-0829-0555, p. 6]

EPA's proposal requires automakers to sell EVs but does not propose any requirements to ensure adequate charging infrastructure to homes, highways, or businesses, or mandate utilities to have adequate capacity or provide reasonably priced high-power charging, or mandate easily accessible and affordable battery critical minerals for EV batteries. Government policies need to start today to ensure there are enough critical minerals for batteries and high-power charging. Unfortunately, there is not yet a roadmap to developing these and other essential pieces to the transition. [EPA-HQ-OAR-2022-0829-0555, p. 6]

All of the above market challenges will need to have complementary policies supporting all of the sectors outside the vehicle industry including utilities, mining, charging companies and will require them to meet targets too. It is critical that EPA take these factors into consideration when setting standards. [EPA-HQ-OAR-2022-0829-0555, p. 6]

The government's ability to implement the right complementary policies and monitoring these factors will be paramount to the success of this ambitious rulemaking. EPA standards alone cannot and will not create demand or infrastructure for EVs. [EPA-HQ-OAR-2022-0829-0555, pp. 6-7]

[*From Hearing Testimony, May 9, 2023*] Second fix the problems with electrical vehicles. The batteries need to be clean, Mr. Musk wants to create a very big mess in the northern part of the center of the country with a factory so we need to encourage batteries research such that batteries are actually clean and not made from rare earth metals that have to be mined. [S]o clean batteries and the electricity for electric vehicles are from solar and wind, that needs to be part of the solution. [From Hearing Testimony, EPA-HQ-OAR-2022-0829-5115, Day 1]

Organization: Mass Comment Campaign sponsored by Specialty Equipment Market Association (SEMA). (web) (1,488 signatures)

The Specialty Equipment Market Association (SEMA) submits the letters included below on behalf of over 1,480 men and women who work in the specialty automotive aftermarket outlining their concerns with the U.S. Environmental Protection Agency's proposed Multi-Pollutant Emissions Standards for Model Years 2027 to 2032 Light-Duty and Medium-Duty Vehicles, 88 Fed. Reg. 29,184 (May 5, 2023). SEMA members manufacture, sell, and install parts and products that make motor vehicles more fuel efficient, cleaner, and safer, employing over one million Americans and contributing over $52 billion annually to the U.S. economy. Thank you for your consideration of these comments. [EPA-HQ-OAR-2022-0829-0724]

I write in opposition to the U.S. Environmental Protection Agency's proposed multipollutant standards for light-and medium-duty vehicles (Docket ID No. EPA–HQ–OAR–2022–0829). I have serious concerns with all three of the options included in the draft rulemaking, as the EPA seeks to lower carbon emissions under timelines that effectively make electric vehicles the only option for automakers to meet the pollution limits from 2027 through 2032. [EPA-HQ-OAR-2022-0829-0724]

The large-scale shift to electric vehicles, which would comprise two-thirds of all new-car sales in the U.S. by 2032 under this proposal, will hurt workers, small businesses, and consumers while doing little to help the environment. The proposed rule would lead to fewer vehicle choices for individuals and families, reducing the selection of vehicles that fit their household budgets and unique needs. [EPA-HQ-OAR-2022-0829-0724]

This proposed rulemaking will disrupt automotive industry supply chains and eliminate large numbers of jobs in vehicle manufacturing, parts production, and repair businesses. While small businesses are the lifeblood of the American economy, they will be hit the hardest by a premature rush to have electric vehicles dominate new vehicle sales. Small, internal-combustion engine-based businesses are not receiving the billions of dollars that large automakers are to make the conversion to electric. Thirty-three percent of automotive aftermarket products purchased by consumers last year were on upgrades and accessories for internal combustion engines and drive trains. That means as much as $17 billion of small business value will be wiped out by this proposal. [EPA-HQ-OAR-2022-0829-0724]

While the goal of this proposal is to reduce the U.S. automotive fleet's carbon footprint, it simply shifts how emissions are produced. The EPA is ignoring the value of technologies produced by American workers, manufacturers, and farmers that are critical to our transportation future. Specialty automotive aftermarket businesses are leading the way through alternative fuel innovations from replacing older engine technologies with newer, cleaner versions to converting older ICE vehicles to new electric, hydrogen, and other alternative fuels. Sadly, the EPA's plans to reduce greenhouse gases and criteria pollutants do not factor this in. [EPA-HQ-OAR-2022-0829-0724]

The EPA's proposal boosts an electric vehicle supply chain dominated by China, which powers its manufacturing-base through coal-fired power plants and mines minerals for EV batteries with the use of environmental practices that we would never approve of in the United States. Emissions coming out of tailpipe matter, but so do the lifecycle emissions of building a car, constructing and charging a battery, and retiring vehicles. [EPA-HQ-OAR-2022-0829-0724]

The future of automotive technology matters to consumers, millions of automotive enthusiasts, and all the men and women who work in the industry. Accordingly, I ask that the EPA does not follow through on any of the three options outlined in this proposed rulemaking and instead pursues a rulemaking for light and medium-duty vehicles that embrace a technology-neutral approach that factors in the infrastructure that exists, the innovation we are all capable of, consumer preferences, and the lifecycle emissions of the technology that powers our vehicles. [EPA-HQ-OAR-2022-0829-0724]

Secondly, by not taking any significant steps to improve permitting for the mining of critical minerals in America, we are endangering our ability to access the minerals required for EV production. This over-reliance on foreign sources of minerals could undermine our domestic energy security and jeopardize our nation's economic independence. After seeing how international supply chains can break down during the pandemic, American consumers cannot and should not be subject to increased reliance on unstable foreign supply chains, especially concerning something as vital as personal transportation. [EPA-HQ-OAR-2022-0829-1701]

Organization: Mazda North American Operations

The proposed rule is the most stringent light duty vehicle regulation that EPA has promulgated to date. The electrification and carbon reduction goals are incredibly challenging and will require not just a coordinated effort to achieve but also solutions addressing consumer demand, affordability, charging network, power grid capacity, rare earth mineral availability, and striking the right balance regarding China policy [EPA-HQ-OAR-2022-0829-0595, p. 2]

Summary

Mazda is proud of its heritage and contributions to personal mobility, and we celebrated our 100th anniversary in 2020. Mazda has also long been an engineering leader known for innovative powertrains like the rotary engine and Skyactiv technology. [EPA-HQ-OAR-2022-0829-0595, pp. 3-4]

We look at EPA's NPRM and its preferred option through the lens of a company that is already working towards an electrified future. It's not a matter of if this transformation will happen, but when and how. Mazda, like the rest of the industry, faces many challenges: [EPA-HQ-OAR-2022-0829-0595, pp. 3-4]

- Will charging infrastructure be sufficient?

- Can the electric grid handle the increased demands?

- How will EV incentives on the federal and state level impact this shift?

- Will suppliers be able to develop and produce components like batteries (that currently require critical minerals, many from China) quickly enough and in enough volume?

- How might future laws or regulations in trade and re-shoring impact our ability to meet goals?

- Are consumers ready and willing to move away from "tried and true" internal combustion engines in numbers sufficient to meet these goals?

- Can OEMs remain sufficiently profitable to fuel the transition to EVs?

[EPA-HQ-OAR-2022-0829-0595, pp. 3-4]

Mazda strongly requests that EPA take these considerations into account and make necessary adjustments to the proposed rule as it works towards a Final Rule. We feel the Final Rule should have more realistic targets and associated ramp ups, include PHEVs, and adopt CARB's current LEV IV for criteria emissions. [EPA-HQ-OAR-2022-0829-0595, pp. 3-4]

Organization: MECA Clean Mobility

Efficient Utilization of Battery Critical Materials

MECA supports EPA's technology neutral, performance-based approach to reduce both criteria and GHG emissions from light-duty vehicles through improvements in the efficiency of today's vehicles combined with accelerated introduction of battery electric vehicles. We agree with the Agency's conclusion that projected penetration of electric vehicles will provide significant emission benefits from the light-duty fleet. However, based on current sales rates of electric vehicles, there is still considerable uncertainty in the projected pace of future electric vehicle penetration. [EPA-HQ-OAR-2022-0829-0564, pp. 26-29]

Table 3 compares the fuel economy, tailpipe & upstream greenhouse gas emissions and utilized battery capacities of equivalently sized conventional, full hybrid, plug-in hybrid and battery electric vehicles using available data from the EPA/DOE fueleconomy.gov website. [EPA-HQ-OAR-2022-0829-0564, pp. 26-29]

On a vehicle basis, the tailpipe & upstream greenhouse gas emissions of the battery electric vehicle (Tesla Model Y Long Range AWD) would avoid 311 g/mile of CO2 (i.e., 381conventional RAV4 – 70Tesla Model Y = 311) compared to avoiding 231 g/mile with the plug-in hybrid (Toyota RAV4 Prime) assuming that only 69.3% of its operation is all-electric. However, on an equivalent battery capacity basis, the last row of Table 3 [See original comment for Table 3. Comparison of Battery Capacities of Conventional, Full Hybrid, Plug-in Hybrid and Battery Electric Vehicles] shows that HEVs and PHEVs use the available battery materials more efficiently than BEVs avoiding considerably higher amounts of CO2 per kWh of battery capacity. This improved efficiency of hybrids is due to the higher rate of cycling their smaller battery capacities. [EPA-HQ-OAR-2022-0829-0564, pp. 26-29]

Table 3 displays fueleconomy.gov data with stated battery capacities for selected vehicles. It should be noted that the amount of battery material needed to manufacture each full battery electric vehicle could be deployed to manufacture five PHEVs. One can calculate the amount of CO2 reduced each year as a function of battery capacity (kWh) and miles driven. Assuming an all-electric operation of 69.3%37 of the PHEV, a far greater cumulative amount of avoided CO2 (5 x 191 g/mile = 955 g/mile of avoided CO2) can be realized by deploying the PHEVs compared to 271 g/mile of avoided CO2 realized by the operation of the one BEV. [EPA-HQ-OAR-2022-0829-0564, pp. 26-29]

37 The assumption of 69.3% electric operation for the RAV4 PHEV is found on www.fueleconomy.gov.

To fully electrify a medium-duty vehicle, a minimum of a 75 to 100kWh battery would be needed. We ran the same calculation above to compare example medium-duty vehicles with varying degrees of electrification. The result is that the latest generation full hybrid powertrain would eliminate over 700kg CO2/kWh/year, whereas a plug-in hybrid would yield 127 kgCO2/kWh/year and a BEV would yield 31 kgCO2/kWh/year. [EPA-HQ-OAR-2022-0829-0564, pp. 26-29]

These analyses illustrate that strategically deploying HEV and PHEV powertrains as well as BEVs can yield significantly greater CO2 reductions on a battery capacity basis thus reducing battery critical mineral supply chain pressures and providing fleets and manufacturers greater flexibility in achieving GHG emission goals. Further reductions in the carbon intensity of liquid fuels would complement hybrid vehicle adoption by reducing the engine-based CO2 emissions from these vehicles. [EPA-HQ-OAR-2022-0829-0564, pp. 26-29]

Organization: MEMA, The Vehicle Suppliers Associated

The success of our industry is interwoven with the success of this proposal and the ability of the government to work with industry and other stakeholders to meet significant challenges. Therefore, the rule must address: [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Supply chain challenges. The proposed rule assumes that all materials advanced vehicles, which are not available today in the quantities needed to support the massive growth in vehicle construction, will become available within sufficient time. This places a significant and unnecessary risk on manufacturers and suppliers. Furthermore, once a company has converted production to new technology lines, that company cannot easily pivot its facilities and workforce back to the previous technology if EPA projections are not realized by the mid-to-late-2020s. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

MEMA members are working to accelerate the performance and availability of clean-operating vehicle technologies and are directly contributing to their realization. Besides battery electric options, effective low- and zero-carbon technologies for future and current in-use vehicles also exist and can readily be put to use to reduce nationwide emissions and help EPA meet its climate goals. The success of this rule depends on greater inclusion of all available emissions reduction technologies, significant investment in infrastructure, careful understanding and investment in the domestic and global supply chain and ensured repair access to serve the improved and enhanced domestic vehicle fleet. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

Supply Chain Challenges Will Continue Throughout Implementation

In the supporting documents of the proposed rule, EPA catalogs all public statements of investment in and projections for future availability of critical minerals. This projected sum is then cited as evidence there will be sufficient materials for construction of the future fleet. We disagree with this optimism. To assume that all materials for advanced vehicles in the quantities needed to support the exponential growth in advanced technology vehicle production and adoption will become available exposes the automotive industry – both vehicle manufacturers and suppliers and the jobs it supports to significant, unnecessary risk. While the Infrastructure Investment and Jobs Act (IIJA) and the Inflation Recovery Act (IRA) endeavor to bring more resources to mining in the U.S. to boost supplies of critical materials, it is unclear that these provisions will resolve some of the other longstanding hurdles that inhibit mining activities in the U.S. Concerns about environmental issues often make mining projects extremely burdensome to undertake, and the associated permitting process extends the timelines past the point of practicality. EPA seems to assume in this rule that domestic mining will become more routine, but without sufficient evidence to substantiate this belief. It is our perception that in the laws passed to date will overcome of the most difficult challenges posed by trying to site mines in the U.S. [EPA-HQ-OAR-2022-0829-0644, pp. 12-13]

One way to supplement domestic mining is through increased recycling. As the EPA notes, the presence of minerals in materials and products already in the U.S., adds to the "mineral stock that is available for domestic recycling in the future." The EPA spends much of the analyses recycling discussion on battery recycling, specifically on the minerals associated with batteries. Yet, EVs will rely on many other minerals beyond those needed for batteries. Aluminum, manganese, magnesium, silicon and many other critical minerals are already located in the automotive supply chain independent of batteries, such as in the aluminum and steel in door frames and in the body in white. The domestic recycling infrastructure is not sufficiently sophisticated to recapture and return the pre- and post-consumer scrap of this material already present domestically to the automotive sector. While EPA recognizes the value that recycling can provide to stabilizing the supply of critical minerals, its assumptions about the feasibility of this recycling to supplement mined minerals is premature without more investments in infrastructure to support this work. [EPA-HQ-OAR-2022-0829-0644, pp. 12-13]

MEMA urges:

- EPA to add battery recycling and disposal costs to the analysis as part of a sustainable BEV deployment to better address scarcity of critical minerals, provide a more resilient domestic supply chain, and over time reduce the added carbon impact of battery manufacturing and associated multi-national logistics. [EPA-HQ-OAR-2022-0829-0644, pp. 12-13]

- The Biden Administration and Congress must work expeditiously secure, through trade policy, access to critical materials and expedite projects to refine critical materials in the U.S. and allied countries and encourage domestic recycling programs for other critical minerals to further expand and assure supply. [EPA-HQ-OAR-2022-0829-0644, pp. 12-13]

Additionally, EPA should consider added costs for post-warranty battery pack replacement to the RIA to capture critical mineral demands resulting from second and third owners who may have to replace/repair aged batteries after buying a used BEV. This may not factor into the cost benefit for new vehicle purchases, but it will cause further demand for critical materials. EPA should add this into the cost benefit for maintenance in Chapter 4.6.1 as well as critical mineral demands in RIA Preamble IV.C.6. While some of these retired batteries may be recycled, it will take some time for materials to build up and there will be some demand for new material that competes with production for new vehicle batteries. This is another reason EPA must forecast a more diversified, and possibly more expensive, supply chain in the RIA. [EPA-HQ-OAR-2022-0829-0644, pp. 14-15]

Organization: Minnesota Corn Growers Association (MCGA)

The proposed EPA standards for 2027 and later set very aggressive goals for reducing GHG and criteria emissions. Achieving these goals will require dramatic changes not only in vehicle design, but in the entire automotive supply chain. While the U.S. market share of BEVs will continue to expand, establishing regulations where success is solely contingent upon an unattainable tenfold increase in the production and sales of BEVs over the next eight years represents an avoidable mistake. The proposed rule would require huge investments and rapid growth in many industries, including the mining and processing of key minerals, the generation and distribution of electricity, and the recharging of electric vehicles. [EPA-HQ-OAR-2022-0829-0612, p. 3]

If the economic damages are not bad enough, the impact of EPA's forced change to BEVs may compromise our national security. Who is in favor of a move that would incentivize batteries and minerals produced and mined in countries that are hostile to the U.S. and have questionable labor standards over relying on homegrown renewable liquid fuels, along with our domestic energy sources found right here in America, much of it in the Midwest? [EPA-HQ-OAR-2022-0829-0578, p. 3]

Other concerns with BEVs are related to the supply of critical minerals for batteries. A report5 by the International Energy Agency (IEA) says “mineral demand for use in EVs and battery storage is a major force, growing at least thirty times to 2040, it has taken on average over 16 years to move mining projects from discovery to first production. These long lead times raise questions about the ability of suppliers to ramp up output. The Democratic Republic of the Congo (DRC) and People’s Republic of China were responsible for some 70% and 60% of global production of cobalt and rare earth elements respectively in 2019. The level of concentration is even higher for processing operations. China’s share of refining is around 35% for nickel, 50- 70% for lithium and cobalt, and nearly 90% for rare earth elements. High levels of concentration, compounded by complex supply chains, increase the risks that could arise from physical disruption, trade restrictions or other developments in major producing countries. Production and processing of mineral resources gives rise to a variety of environmental and social issues that, if poorly managed, can harm local communities and disrupt supply.” [EPA-HQ-OAR-2022-0829-0612, p. 5]

5 International Energy Agency, "The Role of Critical Minerals in Clean Energy Transitions", 2021; https://www.iea.org/reports/the-role-of-critical-minerals- in-clean-energy-transitions.

Toyota6 and others7 have argued for a balanced approach to emissions reductions using BEVs and other technologies, saying “perfect should not be the enemy of the good”. The battery size8 for a BEV is about 6 times larger than a PHEV (~75-145kWh vs. ~12-18kWh), and about 60 times larger than a HEV (~1.3-1.9kWh). Given the limited supply of battery materials, a large number of HEVs and PHEVs can clearly achieve substantially better GHG reductions than a small number of BEVs. [EPA-HQ-OAR-2022-0829-0612, pp. 5-6]

Organization: Mitsubishi Motors North America, Inc. (MMNA)

To determine a realistic maximum volume of EVs the market can support for each of the model years covered by the rule, we believe EPA should consider certain critical factors. Among these factors, we believe EPA must make a thorough and realistic year-by-year assessment of key factors like projected battery costs, projected supply of battery critical-minerals, projected residential and public charging infrastructure availability, projected electrical grid capacity, and consumer acceptance of BEV technology in the broader arena. [EPA-HQ-OAR-2022-0829-0682, p. 2]

Organization: National Association of Manufacturers (NAM)

Unlock Domestic Critical Minerals

The growth of electric vehicle sales has led to concern about securing mineral inputs used in EV batteries.3 EV battery production depends on five critical minerals for which the domestic supply is potentially at risk of disruption: lithium, cobalt, manganese, nickel and graphite.4 The

EPA has recognized that a robust supply chain needs to be developed through multiple production routes to support the production of EVs in the United States.5 The National Mining Association reports that Australia and Canada, two countries with environmental protections that are arguably equivalent to or even more stringent than those in the U.S., have mine permitting processes that last two to three years on average, whereas in the U.S. the permitting process averages seven to 10 years.6 Many of the raw materials for the EV batteries are still mined largely outside of the U.S.7 Developing an adequate domestic supply of these minerals will require congressional and administration action to expedite permissions for developing those resources in a responsible way. [EPA-HQ-OAR-2022-0829-0633, p. 2]

Organization: National Farmers Union (NFU)

In addition, several concerns with BEVs relate to the need for and supply of critical minerals for batteries. As noted by the International Energy Agency (IEA) and reflected in the chart below, “[i]n climate-driven scenarios, mineral demand for use in EVs and battery storage is a major force, growing at least thirty times to 2040.”15 [EPA-HQ-OAR-2022-0829-0581, p. 9]

15 International Energy Agency, The Role of Critical Minerals in Clean Energy Transitions, World Energy Outlook Special Report, at 8-9 (2021), available at https://www.iea.org/reports/the-role-of-critical-minerals-in-clean- energy-transitions.

[See original comment for bar graph of growth of selected minerals in the SDS, 2040 relative to 2020] [EPA-HQ-OAR-2022-0829-0581, p. 9]

As one potential concern regarding supply of these critical minerals, IEA has referenced long project development lead times, finding “it has taken on average over 16 years to move mining projects from discovery to first production. These long lead times raise questions about the ability of suppliers to ramp up output if demand were to pick up rapidly.”16 [EPA-HQ-OAR-2022-0829-0581, p. 9]

16 Id. at 12.

IEA also noted concerns with high geographical concentration of production, as discussed and reflected in the chart below.17 [EPA-HQ-OAR-2022-0829-0581, p. 9]

17 Id. at 10.

The Democratic Republic of the Congo (DRC) and People’s Republic of China (China) were responsible for some 70% and 60% of global production of cobalt and rare earth elements respectively in 2019. The level of concentration is even higher for processing operations, where China has a strong presence across the board. China’s share of refining is around 35% for nickel, 50- 70% for lithium and cobalt, and nearly 90% for rare earth elements. … High levels of concentration, compounded by complex supply chains, increase the risks that could arise from physical disruption, trade restrictions or other developments in major producing countries.18 [EPA-HQ-OAR-2022-0829-0581, pp. 9-10]

18 Id. at 11-12.

[See original comment for share of top three producing countries in production of selected minerals and fossil fuels, 2019] [EPA-HQ-OAR-2022-0829-0581, p. 10]

There is also growing scrutiny of environmental and social performance related to this sector. “Production and processing of mineral resources gives rise to a variety of environmental and social issues that, if poorly managed, can harm local communities and disrupt supply.”19 [EPA-HQ-OAR-2022-0829-0581, p. 10]

19 Id. at 12.

EPA should not focus on one technology. “Multiple types of relatively climate-friendly vehicles and accelerated development of sustainable substitute fuels should all be part of the picture.”27 While BEVs are part of the solution, a balanced approach to emissions reductions using BEVs and other technologies is needed.28 [EPA-HQ-OAR-2022-0829-0581, pp. 12-13]

27 Dave Foster, et al., Pathways to More Rapidly Reduce Transportation's Climate Change Impact, Issues in Science and Technology, Nov. 17, 2022; https://issues.org/reduce-vehicle-transportation-emissions-foster-koszewnik- wade-winer/.

28 Gill Pratt, (More) Straight Talk About Toyota’s Electric Vehicle Strategy, Aug. 23, 2021, https://medium.com/toyotaresearch/more-straight-talk-about-toyotas-electric-vehicle-strategy-f0aba4be40.

BEVs are not the only solution. Comparing vehicle specifications,29 the battery size for a BEV is about 6 times larger than a PHEV (~75-145kWh vs. ~12-18kWh), and about 60 times larger than a HEV (~1.3-1.9kWh). Given the limited supply of battery materials, a large number of HEVs and PHEVs can clearly achieve substantially better GHG reductions than a small number of BEVs. [EPA-HQ-OAR-2022-0829-0581, pp. 12-13]

29 See, e.g., Mark Kane, Compare Electric Cars: EV Range, Specs, Pricing & More, Updated July 1, 2022, https://insideevs.com/reviews/344001/compare-evs/.

Organization: National Parks Conservation Association (NPCA)

Lastly, to the degree through which this proposal could increase the development and permitting of domestic critical mineral mining projects to support LDV and MDV battery production, NPCA asks that EPA and the administration as a whole take necessary steps to mitigate or entirely avoid negative impacts on overburdened populations and sensitive ecosystems. This includes promoting practices such as critical mineral recycling, as well as overseeing the responsible citing of mining projects to limit harms to environmental justice communities, indigenous communities, and ecosystems within our beloved national parks. [EPA-HQ-OAR-2022-0829-0607, pp. 4-5]

Organization: Nissan North America, Inc.

Nissan appreciates the Administration’s focus on and support for advancing electrification and carbon neutrality and shares the same long-term goal of transitioning to zero emission vehicle society. However, Nissan believes that market realities, infrastructure needs, consumer impacts, and lack of battery critical mineral availability necessitate an adjustment of the GHG standard stringency in this rulemaking timeframe. [EPA-HQ-OAR-2022-0829-0594, p. 1]

These new proposed targets lose sight of the transformational change that is needed from all sectors of the U.S. economy. Automobile manufacturers such as Nissan have made and will continue to make significant investments to push the industry forward; however, such drastic and front-loaded timelines require significant changes and investments from suppliers, energy providers, mineral extraction and processing industries, battery and charging equipment manufacturers, etc. Such drastic changes to the market are nearly impossible on such a compressed timeline, particularly given the current market constraints affecting nearly all impacted sectors, such as supply-chain complications and limited availability of raw materials. This is especially true with respect to the critical minerals that are essential to battery production for EV expansion and development; EPA has not demonstrated that the critical minerals needed to meet the extremely aggressive EV penetration rates are available to be extracted in a safe, responsible, and reliable manner. Significant cooperation and organization from federal, state, and local governments will also be required to facilitate the roll-out and adoption of EVs and related charging infrastructure. [EPA-HQ-OAR-2022-0829-0594, p. 4]

Organization: North Dakota Farmers Union (NDFU)

The proposed standards for 2027 and later set very aggressive goals for reducing GHG and criteria emissions. Achieving these goals will require dramatic changes not only in vehicle design, but in the entire automotive supply chain. To achieve these goals with a heavy reliance on battery electric vehicles (BEVs) will require huge investments and rapid growth in many industries including the mining and processing of key minerals, the generation and distribution of electricity, and the recharging of electric vehicles. [EPA-HQ-OAR-2022-0829-0586, pp. 1-2]

We are concerned that a swift and dramatic shift to BEVs will be difficult to achieve. The obstacles include geopolitics, long lead times, significant capital investments, and lagging consumer acceptance. In a state like North Dakota where drivers face cold weather and long driving distances, it is difficult to imagine a large portion of the population using BEVs in four years. [EPA-HQ-OAR-2022-0829-0586, pp. 1-2]

The proposal basically assumes that BEVs will be the dominant technology for future emissions reductions. But relying on a single technology is a risky strategy. Many factors could interfere with BEV production, including the supply and cost of critical minerals, lack of BEV recharging infrastructure, slow ramp-up of wind and solar power, poor customer acceptance, and more. EPA estimates that 67% of U.S. vehicle sales will be BEVs in 2032, but other projections are lower and the U.S. lags behind other countries that are not expected to reach similar levels of sales in that timeframe.10 [EPA-HQ-OAR-2022-0829-0586, p. 5]

Organization: Paul Bonifas and Tim Considine

Energy Security & Air Pollutant Benefits: The EPA completely ignores the fundamental problem with critical mineral supply chain while simultaneously acknowledging that it exists. They claim it is outside the scope of their analysis. Cobalt is used in the manufacture of nearly all lithium-ion rechargeable batteries, including EV batteries, and 70% of the supply chain is controlled by China using African slave-labor. Moreover, rare-earth elements are required to make the permanent magnets used in EVs and China accounts for 63% of the world's rare earth mining, 85% of rare earth processing, and 92% of rare earth magnet production6. Because China controls the market, they can dictate the price of magnets, and therefore EVs, at their whim…not very "Energy Security" friendly. [EPA-HQ-OAR-2022-0829-0551, pp. 3-4]

> 6 https://www.politico.com/news/magazine/2022/12/14/rare-earth-mines-00071102

Energy Security Benefits

Though the US became a total petroleum net exporter in 2020, the EPA attempts to boast that their rule would increase the country's energy security by reducing the US's "dependance" on foreign oil46. In addition to their claim being questionable, they also completely ignore the critical mineral supply chain aspect of the country's energy security. The EPA states the fundamental problem with critical mineral supply chain while simultaneously choosing to ignore the issue: [EPA-HQ-OAR-2022-0829-0551, pp. 11-12]

46 https://www.eia.gov/energyexplained/oil-and-petroleum-products/imports-and-exports.php

"At the present time in the U.S. many of these minerals [used to create EV batteries] are commonly sourced from global suppliers and do not yet benefit from a fully developed domestic supply chain."47 [EPA-HQ-OAR-2022-0829-0551, pp. 11-12]

47 47 Page 130 of EPA's Rule - https://www.govinfo.gov/content/pkg/FR-2023-05-05/pdf/2023-07974.pdf

"Critical materials and the supply chains necessary for PEV production are, therefore, outside of our intended scope in this discussion of energy security." 48 [EPA-HQ-OAR-2022-0829-0551, pp. 11-12]

48 Page 600 of EPA's Draft Regulatory Impact Analysis - https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf

The most critical minerals for battery production include nickel, cobalt, graphite, lithium, and rare earth elements. As an example of the supply chain problems, in 2021, 70% of cobalt originated from the Democratic Republic of Congo, whose Chinese-owned cobalt mines are plagued with accusations of slave labor and human rights violations49. Cobalt is used in the manufacture of nearly all lithium-ion rechargeable batteries, including EV batteries, and 70% of the supply chain is controlled by a US adversary using African slave-labor. [EPA-HQ-OAR-2022-0829-0551, pp. 11-12]

49 https://www.npr.org/sections/goatsandsoda/2023/02/01/1152893248/red-cobalt-congo-drc-mining-siddharth- kara

To make EV supply chain and energy security matters worse, rare-earth elements (specifically Neodymium and Praseodymium) are required to manufacture the permanent magnets used in EVs. China currently dominates all aspects of rare-earth mining, refining, and magnet production. As of December 2022, China accounts for 63% of the world's rare earth mining, 85% of rare earth processing, and 92% of rare earth magnet production50. This means that even if the US were to ramp up their mining efforts, virtually all the rare earths would end up in China to be processed or produced into magnets. The extreme uncertainty of the rare earth market has recently become a national security issue51 and severely limits the supply side of the equation. Because China controls the market, they can dictate the price of magnets, and therefore EVs, at their whim. [EPA-HQ-OAR-2022-0829-0551, pp. 11-12]

50 https://www.politico.com/news/magazine/2022/12/14/rare-earth-mines-00071102

51 https://www.heritage.org/defense/commentary/americas-national-security-dependent-critical-rare-earth-minerals-and-worse

The EPA's value for Energy Security Benefits is unchanged in this real analysis because it would require a thorough quantitative investigation. However, even with this likely fictitious Energy Security Benefit staying consistent, the overall cost of the EPA's rule is still overwhelmingly negative. [EPA-HQ-OAR-2022-0829-0551, pp. 11-12]

Organization: Plug In America

The danger exists if the United States doesn't commit to rigorous emissions standards. Choosing to weaken these standards would result in the United States falling behind in the global race to develop domestic supply chains, good-paying jobs, and battery and EV manufacturing. These GHG emissions standards will continue to spur investment and innovation, allowing U.S. battery and vehicle manufacturers to thrive in the global market. Delaying the shift to electric transportation through diminished regulation will result in resources wasted on fossil-fuel technologies that will rob the United States of its international status as a technological leader. Globally, 14% of light-duty vehicles sold in 2022 were electric vehicles.3 According to the same source, in the U.S., this value is about 7.5%.The proposed GHG regulations provide a pathway to transportation electrification that will enable U.S. manufacturers to remain competitive in both domestic and global vehicle markets. [EPA-HQ-OAR-2022-0829-0625, pp. 1-2]

3 https://www.iea.org/data-and-statistics/charts/electric-car-registrations-and-sales-share-in-china-united-states-and-europe-2018-2022.

Organization: POET, LLC

The Proposed Rule's feasibility assessment is also deficient, and EPA could remedy this by crediting proven, affordable renewable fuels that achieve real-world GHG emission reductions. EPA's proposed standards rely on optimistic projections showing an extraordinarily rapid rollout of battery electric vehicle ("BEV") technologies at scale. However, EPA's modeling omits any rigorous consideration of the significant supply-chain and infrastructure developments necessary to support the LDVs needed to meet EPA's proposed standards. [EPA-HQ-OAR-2022-0829-0609, p. 5]

IV. EPA's Projections for BEVs are Overly Optimistic and Largely Ignore Significant Supply Chain and Infrastructure Concerns.

The Proposed Rule is deficient in other significant ways. It relies on overly optimistic projections for BEV adoption that fail to account for several key factors that will be essential to meeting the projected targets. POET engaged Jim Lyons of Trinity Consultants ("Trinity"), an international consulting firm specializing in, among other things, environmental sustainability, to review EPA's technology assessments. In his report, Attachment 2 to this letter, Mr. Lyons explains that EPA's forecasted BEV adoption rates "rest on a series of unreasonable, unsupported, and highly optimistic assumptions" that render those forecasts unreliable.71 The Trinity report also identifies several flawed assumptions in EPA's assessment of GHG emissions reductions from BEVs resulting from the Proposed Rule. [EPA-HQ-OAR-2022-0829-0609, p. 21]

71 Attachment 2, J. Lyons, Review of U.S. EPA's Proposed Multi-Pollutant Emission Standards for 2027 and Later Light-Duty and Medium-Duty Vehicles, at 2.

A. EPA's Projected BEV Adoption Rates Are Based on Several Flawed Assumptions.

The Proposed Rule relies on overly optimistic BEV adoption rates based on several flaws. As the Trinity Report explains, EPA is assuming "nearly 70 percent BEV penetration in MY 2032 across the combined light-duty passenger car, crossover/SUV, and pickup truck categories."72 This represents an increase in BEVs by 4 to 10 times over only a 10-year period.73 EPA also assumes that “this high level of demand for BEVs will continue unchanged through MY 2055.”74 As the Trinity Report explains in greater detail, EPA’s projections are based on several flawed assumptions that render those projections unreliable. [EPA-HQ-OAR-2022-0829-0609, pp. 21-22]

72 Id. at 2 (quotations omitted).

73 Id.

74 Id at 2.

First, EPA suggests that the worldwide supply of batteries will be sufficient to meet the demand for BEVs that EPA is projecting.75 As Trinity has shown, current demand estimates for batteries without the Proposed Rule range from 500 to 2,500 GWh per year.76 Yet EPA’s demand estimates with and without the Proposed Rule are only 1,000 GWh per year and 600 GWh per year, respectively.77 Turning to supply, EPA estimates, based on existing and announced battery capacity in North America, that industry will achieve nearly but not quite 1,000 GWh per year by 2032.78 EPA does not explain the difference between its 1,000 GWh demand estimate and other estimates showing much higher demand for EV batteries.79 Nor does it explain why the Proposed Rule is feasible if its own projections for the battery supply fall short, even slightly, than its projected demand.80 EPA also assumes that announced battery capacity in North America will materialize, when it is possible that some production facilities will not come online, and EPA’s projected 1,000 GWh per year on the supply side will not be achieved.81 Importing batteries is an option, but EPA does not acknowledge that importing may be necessary nor assess whether it would be feasible.82 [EPA-HQ-OAR-2022-0829-0609, pp. 21-22]

82 See id.

OnLocation also identifies factual issues that call into question the robustness of EPA’s assumptions regarding future EV penetration rates. For instance, EPA’s projections of BEV sales are almost nine times higher than those of EIA.122 EPA may also be making overly optimistic assumptions regarding battery manufacturing capacity and domestic lithium production.123 [EPA-HQ-OAR-2022-0829-0609, p. 27]

122 Id. at 2.

123 Id.

Battery production is a key constraint in the EV penetration rate. Supporting material on the battery production from S&P Global and Argonne National Laboratories5 are based on battery manufacturing plant announcements rather than more definitive metrics such as plants under construction. EPA has focused on lithium as the constraining critical material for battery production, and growth in domestic lithium production is based on infrastructure that has not yet been built. None of the studies referenced directly incorporate the level of U.S. EV penetration proposed in the Proposed Rule. The assumptions underlying EPA's proposed path merit further analysis by EPA and call into question the robustness of EPA's assumptions regarding future EV penetration rates. [EPA-HQ-OAR-2022-0829-0609, p. 36]

5 "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles," Federal Register Vol. 88, No. 87, pg. 29317

EPA estimates the U.S. will have more than 800 GWh of cell or battery manufacturing capacity by 2025, and 1,000 GWh by 2030, enough to supply from 10 to 13 million BEVs per year.4 This production would roughly be sufficient to meet EPA's compliance requirements. However, EPA did not explicitly consider the battery cost replacement for the current 2 million electric vehicles in the EV sales projections by 2032. Furthermore, the battery lifetime will largely depend on the consumer behavior and how often they charge the battery. Public fast chargers tend to degrade lithium-ion batteries at a quicker rate than slower home charging options. With shorter battery life, a higher battery production rate and critical material supply would be required than otherwise projected over the next 8 to 10 years. [EPA-HQ-OAR-2022-0829-0609, p. 36]

4 DRIA pg. 3-24.

Given that batteries are the key component of BEVs, it is important to examine U.S. EPA's assumptions regarding the demand, supply, and cost of batteries. Figure 30 from the Proposed Rule, reproduced below, shows forecasts of worldwide demand and supply for lithium-ion batteries through 2030 compiled by U.S. EPA from various sources. The main observation taken from Figure 30, is that by 2030 worldwide demand is forecast to be between 500 and 2500 gigawatt hours (GWh) per year without the Proposed Rule. U.S. EPA's assumptions regarding battery demand for the U.S. market both with and without the Proposed Rule are shown in Figure 31 of the Proposed Rule, also reproduced below. As shown, by 2032, U.S. EPA assumes U.S. battery demand based on vehicle manufacturer's need to comply with the Proposed Rule will be on the order of 1,000 GWh per year or about 40% of the maximum worldwide demand shown in Figure 30 compared to about 600 GWh without the Proposed Rule. Shifting to supply, Figure 30 shows forecasts of worldwide battery supply that suggest it will be more than enough to satisfy worldwide battery demand. [See original attachment for Figure 30: Future global Li-ion battery demand and production capacity, 2020-2030] [EPA-HQ-OAR-2022-0829-0609, pp. 55-56]

However, Figure 31 from the Proposed Rule shows that both existing and announced North American battery production will amount a little less than 1,000 GWh by 2032 – a volume that would not be sufficient to cover U.S. EPA's forecast of demand for batteries in U.S. light- and medium-duty vehicles. [See original attachment for Figure 31: Announced capacity for battery plants in North America, as of November 2022.] While batteries imported from other countries offer another source of supply, it is far from clear that battery supply will meet worldwide demand during the 2027 to 2032 period when U.S. EPA expects light-duty automobile manufacturers to essentially transition to the production of nothing but BEVs. In addition, U.S. EPA presents no data or analysis that suggests that all of the announced North American battery capacity will actually be online as battery demand driven by the Proposed Rule increases nor a demonstration that the likely actual worldwide supply of batteries will be sufficient to meet worldwide demand. So, in summary, even all announced North American battery production capacity will be insufficient to meet U.S. EPA's estimate of battery demand of the Proposed Rule and U.S. EPA hasn't demonstrated where that supply will come from. [EPA-HQ-OAR-2022-0829-0609, pp. 55-56]

[See original attachment for Figure 32: Annual battery production (GWh) required for BEV's in the Central analysis case of the Proposal] [EPA-HQ-OAR-2022-0829-0609, pp. 55-56]

Organization: Porsche Cars North America (PCNA)

Electromobility will need continued support from public policy.

Recent legislative actions have seeded the ground with support for electric vehicles and the beginning of a robust nationwide charging network. With specifics that continue to be defined, stakeholders are working to maximize the opportunity under these new laws to support customers with valuable purchase incentives, and to help spur the development of new electric vehicle component production and material sourcing. Understandably, the complexity of these laws results in a process that requires careful deliberation with industry representatives working hard to ensure customers have a clear understanding of the support available. Nevertheless, the support within these programs will be critical to the growth rates EPA envisions in this proposal. [EPA-HQ-OAR-2022-0829-0637, p. 3]

Organization: Renewable Fuels Association (RFA)

c. Supply of critical minerals for EV batteries

Other concerns with BEVs are related to the supply of critical minerals for batteries. A report by the International Energy Agency (IEA) says "mineral demand for use in EVs and battery storage is a major force," with supplies needing to grow "at least thirty times to 2040." The report notes that "…it has taken on average over 16 years to move mining projects from discovery to first production."33 These long lead times raise serious questions about the ability of suppliers to ramp up the output of critical minerals. [EPA-HQ-OAR-2022-0829-0602, pp. 16-18]

33 International Energy Agency, "The Role of Critical Minerals in Clean Energy Transitions", 2021; https://www.iea.org/reports/the-role-of-critical-minerals-in-clean-energy-transitions.

[See original comment for Growth of selected minerals in the SDS, 2040 relative to 2020] [EPA-HQ-OAR-2022-0829-0602, pp. 16-18]

In addition, there are national security and human rights concerns associated with the mining of critical minerals needed for EV batteries. According to IEA, the Democratic Republic of the Congo (DRC) and People's Republic of China were responsible for some 70% and 60% of global production of cobalt and rare earth elements, respectively, in 2019. The level of concentration is even higher for mineral processing operations. China's market share of global refining capacity is around 35% for nickel, 50-70% for lithium and cobalt, and nearly 90% for rare earth elements. [EPA-HQ-OAR-2022-0829-0602, pp. 16-18]

[See original comment for Production of many energy transition minerals today is more geographically concentrated than that of oil or natural gas] [EPA-HQ-OAR-2022-0829-0602, pp. 16-18]

According to IEA, "High levels of concentration, compounded by complex supply chains, increase the risks that could arise from physical disruption, trade restrictions or other developments in major producing countries…Production and processing of mineral resources gives rise to a variety of environmental and social issues that, if poorly managed, can harm local communities and disrupt supply."34 [EPA-HQ-OAR-2022-0829-0602, pp. 16-18]

34 Id.

Toyota35 and others36 have argued for a balanced approach to emissions reductions using BEVs and other technologies, saying "perfect should not be the enemy of the good." The battery size37 for a BEV is about 6 times larger than a PHEV (~75-145kWh vs. ~12- 18kWh), and about 60 times larger than a HEV (~1.3-1.9kWh). Given the limited supply of battery materials, a large number of HEVs and PHEVs can clearly achieve substantially better GHG reductions than a small number of BEVs. [EPA-HQ-OAR-2022-0829-0602, pp. 16-18]

Organization: Roy Littlefield IV

Secondly, by not taking any significant steps to improve permitting for the mining of critical minerals in America, we are endangering our ability to access the minerals required for EV production. This over-reliance on foreign sources of minerals could undermine our domestic energy security and jeopardize our nation's economic independence. After seeing how international supply chains can break down during the pandemic, American consumers cannot and should not be subject to increased reliance on unstable foreign supply chains, especially concerning something as vital as personal transportation. [EPA-HQ-OAR-2022-0829-0793, p. 1]

Organization: Senator Shelley Moore Capito et al.

These proposals are also deficient in their consideration of BEV mineral input availability and cost, and will make our nation's transportation sector reliant on foreign adversaries, including China. China currently dominates mining, extraction, and battery manufacturing for EV batteries. For example, China produces nearly 65 percent of the world's graphite, a mineral required for BEV deployment, and accounts for a third of US graphite imports.14 Yet, the US currently does not produce any natural graphite domestically. Lithium is another mineral vital to EV batteries where China dominates global production and 80 percent of yearly global lithium production is used in battery manufacturing.15 Last year, lithium prices spiked by 438 percent16 - yet EPA's proposals claim the price of these vehicles will decrease even as global demand is forecasted to grow without offsetting expansion of supply. Finally, cobalt is also essential for battery chemistry. The United States is dependent on imports for 76 percent of current domestic demand. The global leader in cobalt production is the Democratic People's Republic of Congo, with its mining sector identified as a significant violator of environmental protection and human rights, including child labor.17,18 [EPA-HQ-OAR-2022-0829-5083, p. 4]

17 Supra, note 14.

18 Combatting Child Labor in the Democratic Republic of the Congo's Cobalt Industry, US Dept. of Labor.

Further, our country is reliant on China for more than 50 percent of our imports of between 19 and 26 critical minerals with implications for BEV production.19 Policies that expand our need for imports of critical mineral EV battery inputs, without expanding domestic mining and refining capacity, will only make the US more reliant on our adversaries. Thus, claiming these regulations will make our country more energy independent and globally secure is patently false. Moreover, claims that these proposals will meaningfully address climate change or satisfy other federal priorities, such as securing supply chains, are inherently specious given their dependence upon environmental and human rights data from - in some cases hostile - foreign competitors. [EPA-HQ-OAR-2022-0829-5083, p. 5]

19 Supra, note 14.

Organization: South Dakota Department of Agriculture and Natural Resources (DANR)

National Security

EV batteries rely on lithium to operate, and recent reports indicate China could control as much as a third of the world's lithium by 2025. South Dakota does not support any regulatory effort making the United States more reliant on China. EPA should consider the potential national security implications of implementing the proposed rules as well as consider the need to, and impact of mining lithium and other battery components domestically. [EPA-HQ-OAR-2022-0829-0523, p. 2]

Organization: Specialty Equipment Market Association (SEMA)

Critical Resource Shortages

The average cost of new and used vehicles increased 5% and 30% respectively from May 2020 to May 2021 according to Edmunds.12 These increases were the result of supply chain issues during the pandemic such as the ongoing global microchip shortage, which has upended the automotive market over the last couple of years. Sadly, this proposal will exacerbate the shortage of critical components that still exists today. The draft rulemaking also raises many unanswered questions about how the U.S. is going to end its dependence on sourcing critical minerals and resources from foreign countries, including geopolitical foes such as China, that are needed to produce a dramatic increase in the supply of electric batteries for BEVs. Expanding America’s dependance on foreign entities to achieve the goals of this proposal is problematic from both a domestic and foreign policy standpoint. Additionally, it could also undermine the lofty goal of having 67% of all new motor vehicles sold in in the U.S. be BEV by 2032. [EPA-HQ-OAR-2022-0829-0596, p. 5]

12 Here's Why Car Prices are so High, and Why That Matters (Link: https://www.cnn.com/2021/07/08/business/car-prices-inflation/index.html).

Toyota has circulated information on how the critical raw materials needed for BEVs could be better allocated to achieve similar goals of reducing GHG. The information demonstrates that the same amount of raw material needed to produce just one BEV could be used to make either 6 plug- in hybrid vehicles or 90 traditional hybrid vehicles. The agency's proposed rule aims to reduce multi-pollutant emissions, but it does not consider that those 90 hybrid vehicles reduce carbon 37 times as much as a single BEV over the lifetime of the vehicles.13 However, the proposal treats hybrids unfairly, essentially blocking them out of the marketplace and defining them as “dirty.” [EPA-HQ-OAR-2022-0829-0596, p. 5]

13 Toyota's Goal: Reduce Carbon Emissions As Much As Possible, As Soon As Possible (Link: https://jalopnik.com/toyota-focusing-on-hybrids-not-electric-vehicles-1850440908).

Electrification Rates Misaligned to Market and Exceed Commitments

Stellantis fully supports comments submitted through The Alliance for Automotive Innovation (AAI or the Auto Innovators) detailing the challenges associated with EPA's overly optimistic expectation for EV market growth. Stellantis remains steadfast to delivering on our commitments to achieve an electrified future, and we acknowledge EPA's efforts with this rulemaking to help support this difficult yet critical transition. However, the proposed rule significantly underestimates the actions needed to build the targeted EV market. Addressing concerns such as manufacturing capacity, battery production, charging infrastructure, and consumer acceptance of EVs will be paramount to the success of this ambitious proposed regulation. [EPA-HQ-OAR-2022-0829-0678, pp. 2-3]

Organization: Steven G. Bradbury

Harming our national security. Finally, EPA minimizes the fact that forcing a faster switchover to EVs will threaten America's national security by making us more dependent on China and other unfriendly foreign nations for the production and processing of critical inputs required for EVs. China controls nearly 70 percent of global EV battery manufacturing capacity—including 70 percent of the world's lithium supply; 80 percent of the necessary rare earth minerals; and approximately 75 percent of the magnets needed for EV motors—and it boasts 107 of the 142 lithium-ion battery mega-factories planned or under construction in the world today (with only 9 planned for the U.S.).57 [EPA-HQ-OAR-2022-0829-0647, pp. 20-21]

57 See https://secureenergy.org/safe-urges-bipartisan-coordinated-policy-to-lead-new-tech-in-auto-industry-and-protect-against-chinese-supply-chain-dominance-in-new-report/.

The average EV battery uses about 8-10 kilograms of lithium (even more for higher performance batteries), and the world today mines a total of about 130,000 tons of lithium per year. That means if the EPA succeeds in converting 60 percent of annual U.S. car sales to EVs (about 7.8 million vehicles), those EVs (just for the U.S. market) would require 60 percent of the entire world's current production of lithium.58 [EPA-HQ-OAR-2022-0829-0647, pp. 20-21]

58 See https://pubs.usgs.gov/periodicals/mcs2023/mcs2023-lithium.pdf.

Similarly, each EV battery requires about 10 kilograms of cobalt, which translates into one metric ton for each 100 EVs and 10,000 tons of cobalt for one million new EVs. There are only between 150,000 and 190,000 tons of cobalt mined every year worldwide (the lion's share from the Democratic Republic of the Congo). Here again, if 60 percent of annual U.S. auto sales were EVs by 2030 (7.8 million vehicles), those EVs (just in the U.S.) would consume about 78,000 tons of cobalt— half the world's supply.59 [EPA-HQ-OAR-2022-0829-0647, pp. 20-21]

59 See https://pubs.usgs.gov/periodicals/mcs2020/mcs2020-cobalt.pdf.

To put these percentages in perspective, according to the International Energy Agency (IEA), "In 2022, about 60% of lithium, 30% of cobalt and 10% of nickel demand was for EV batteries" worldwide.60 Because the U.S. market accounts for less than 20 percent of new vehicle sales globally,61 and other governments, particularly China and the EU, are pushing for similar rapid transitions to EVs, the overall worldwide supply of the critical minerals needed to produce EV batteries will have to increase at a truly astounding rate in the next several years to meet the EPA's assumptions.62 [EPA-HQ-OAR-2022-0829-0647, pp. 20-21]

60 IEA, Global EV Outlook 2023: Trends in batteries, https://www.iea.org/reports/global-ev-outlook-2023/trends-in-batteries.

61 See Alex Kopestinsky, "20 In-Depth Global and US Auto Sales Statistics for 2023," Policy Advice, March 23, 2023, https://policyadvice.net/insurance/insights/us-auto-sales-statistics/.

62 See Doomberg, "Separation Anxiety," June 27, 2023, https://doomberg.substack.com/p/separation-anxiety (explaining why it is doubtful "the world can mine a sufficient amount of the necessary battery materials to meet anticipated demand").

EPA predicts all of our strategic dependencies for these inputs will vanish quickly over time, with the assist of government subsidies, as new mines open up in the U.S. and Canada and new factories are built here and production capacity is brought to our shores.63 The reality, of course, is that there is little prospect that the Biden administration or local permitting authorities will fast-track the environmental approvals needed for all of these new mining operations and production facilities, even if the projects were otherwise shovel ready. [EPA-HQ-OAR-2022-0829-0647, pp. 20-21]

63 See 88 FR at 29318-24.

On each of these points, EPA blithely asserts that the current problems, challenges, supply constraints, security risks, and limitations will all miraculously resolve themselves as the United States collectively marches forward into a happy future of EVs. Taken together, the EPA's long string of sunny assumptions, each one designed to minimize the costs and challenges of the new rules, adds up to a wholly arbitrary set of regulatory analyses. [EPA-HQ-OAR-2022-0829-0647, pp. 20-21]

Organization: Strong Plug-in Hybrid Electric Vehicle (PHEV)

The chart below for light-duty PHEVs and BEVs show the benefit of PHEVs in reducing the use of critical minerals and accounts for the difference in electric miles between BEVs and different types of PHEVs. Strong PHEV battery utilization maximizes the value of battery manufacturing and materials capacities and helps address the need for fast scale up of battery manufacturing and mineral extraction by better utilizing resources. PHEV cars and trucks, especially, Strong PHEV cars and trucks, can electrify most daily commuting miles while occasionally using some gasoline, while BEVs have a lot of battery capacity that only gets "used" on very long trips. We assert that this could be considered wasted or underutilized lithium and other battery minerals. Thus, because PHEVs use their batteries more, the USA gets more EV miles per tonne of lithium by driving PHEVs and Strong PHEVs as shown in the chart below. PHEV's smaller batteries reduce the lifecycle environmental burdens associated with battery materials, production, and end-of-life.16 [EPA-HQ-OAR-2022-0829-0646, pp. 20-21]

Organization: Tesla, Inc.

The Critical Mineral Supply Chain and the Battery Supply Chain Are Not Limiting Factors in Light-Duty BEV Deployment

Similar to infrastructure, Clean Air Act Section 202 does not direct EPA to consider upstream resource availability in promulgating standards, and so this is a factor that need not be given undue weight. More importantly, Tesla does not believe that the critical minerals and battery supply chains will constrain future U.S. manufacturing and deployment of BEVs in any vehicle class.211 There are no fundamental materials constraints when evaluating against 2023 USGS estimated resources.212 Such assertions assume (wrongly) that reserves are fixed and declining. In fact, mineral resources and reserves have historically increased – that is, when a mineral is in demand, there is more incentive to look for it and more is discovered. In comparison, to the extent that current critical minerals reserves are viewed as limiting, the agency should point to the long history of "Peak Oil" and how such predictions have never in themselves limited deployment of ICE vehicles.213 [EPA-HQ-OAR-2022-0829-0792, pp. 33-34]

211 See, 88 Fed. Reg. at 29312.

212 See, Tesla, 2023 Investor Day Presentation (March 1, 2023) at 28.

213 See e.g., Forbes, Peak Oil: The Perennial Prophecy That Went Wrong (Nov. 30, 2022) available at h ttps://www.forbes.com/sites/arielcohen/2022/11/30/peak-oil-the-perennial-prophecy-that-went- w rong/?sh=c64aabb2bbe5.

While appropriately assessing the critical minerals supply chain associated with BEVs, EPA should also note it has never undertaken the same assessment related to ICE vehicles. A sustainable energy economy actually involves a lower level of mineral extraction than a fossil fuel-based economy.214 For example, the U.S. oil and gas sector has long been dependent on critical minerals from China for use in oil and gas exploration and development drilling.215 The petroleum industry's reliance on barite has even been used as a case study on U.S. critical minerals dependence.216 Indeed, the American Petroleum Institute has been so concerned about dwindling global reserves that it altered the specifications for the type of barite used in oil and gas drilling.217 At no point has the EPA found that this supply chain constraint has impacted the fuel supply for ICE light-duty vehicles or impacted such vehicles' viability for deployment.218 Accordingly, to the extent such conditions are found in the battery supply chain, it should be anticipated that they neither diminish the viability of light-duty BEV technology nor will limit BEV deployment volumes to meet a stringent emission standard that exceeds Alternative 1. [EPA-HQ-OAR-2022-0829-0792, p. 34]

217 U.S. Geological Survey, Mineral Commodity Summaries 2020 at 29 ("In response to concerns about dwindling global reserves of 4.2-specific-gravity barite used by the oil and gas drilling industry, the American Petroleum Institute issued an alternate specification for 4.1-specific-gravity barite in 2010.) available at h ttps://pubs.usgs.gov/periodicals/mcs2020/mcs2020.pdf.

218 It should be noted that the oil and gas industry's supply chain reliance and constraints have been exemplified by its continued lobbying for exemptions from the Section 301 tariffs for steel and other inputs said to be key to the industry. See e.g., Independent Petroleum Association of America, Steel and Aluminum Tariffs & Quotas available at h ttps://www.ipaa.org/tariffs/https://www.ipaa.org/tariffs/ (highlighting supply chain dependence); Daily Energy Insider, API calls for oil, gas industry exemptions from steel tariffs (may 22, 2018) available at h ttps://dailyenergyinsider.com/news/12579-api-calls-oil-gas-industry-exemptions-steel-tariffs/.

Regardless, the significant and growing investment in the battery supply chain and manufacturing capacity and Tesla's own significant responsible sourcing efforts ensure that BEV deployment will not be limited during the proposed standard's MY 2027-2032 period. As the IEA recently found, the strong investment in BEV and energy storage will double in 2023 to $30 billion (from 2022) and has already led to a wave of new lithium-ion battery manufacturing projects around the world totaling an estimated 5.2 TWh of new capacity that could be available by 2030.219 This has already led overall investment in critical mineral development to increase 30% in 2022, including a 50% increase in lithium resource development followed by similar focuses on copper and nickel development.220 This expansion is occurring and is expanding so fast that battery manufacturing capacity is now on track to meet the 2030 milestones set out in the IEA's scenario to achieve net zero CO2 emissions by 2050.221 [EPA-HQ-OAR-2022-0829-0792, pp. 34-35]

Similarly, the IRA's domestic critical mineral processing and battery manufacturing incentives have led to exponential levels of investment in the battery supply chain.222 In early 2023, it was already estimated that there were $210 billion of announced domestic BEV manufacturing investments.223 This expansion is also happening globally with over $300 billion of announced investment in new battery gigafactories since 2019.224 The U.S. expansion is occurring so rapidly it is already exceeding official government forecasts.225 An ongoing tally of this investment shows that these investments are happening throughout the U.S.226 [EPA-HQ-OAR-2022-0829-0792, p. 35]

Tesla Development of a Robust, Secure Critical Minerals Supply Chain

As extensively detailed in Tesla's Impact Report 2022, Tesla's efforts to expand this supply chain are also accompanied with a commitment to ensuring that companies in our supply chain respect human rights and protect the environment.227 In every location touched by Tesla's supply chain, the company seeks to ensure local conditions for stakeholders are continuously improving as a result of the company's investment and sourcing decisions. This commitment is further detailed in our publicly available Responsible Sourcing Policy, Human Rights Policy, and Supplier Code of Conduct.228 These policies and our supply chain due diligence efforts are aligned with the United Nations Guiding Principles on Business and Human Rights229 and the Organization for Economic Cooperation and Development (OECD)'s Due Diligence Guidance for Responsible Business Conduct.230 [EPA-HQ-OAR-2022-0829-0792, pp. 35-36]

To that end, Tesla has taken significant steps to establish and develop a robust supply chain that will support its future deployment of its light-duty vehicles consistent with the production and deployment estimates Tesla has previously shared with the agency. More specifically, this has included developing and expanding its vertical integration up the supply chain to include expanded cell production, build out of a new cathode production facility at Gigafactory Texas, and breaking ground on the most technologically advanced lithium processing facility in Corpus Christi.231 The blueprint for this activity was originally unveiled during Tesla's Battery Day announcement.232 [EPA-HQ-OAR-2022-0829-0792, pp. 35-36]

Consistent with the Administration's focus on critical minerals, Tesla has continued to focus on creating a secure and sustainable supply chain anchored with domestic sources.233 To that end, following its Battery Day announcement, Tesla established an off-take agreement for a domestic source of lithium with plans to process the lithium hydroxide and manufacture cathode material in the U.S. – creating a first-ever wholly North American upstream advanced battery supply chain. 234 Additionally, Tesla continues to support partnerships for domestic mineral production, establishing supply agreements for North America production from Free Trade Agreement countries.235 Similarly, Tesla has worked to develop commercial relationships with companies onshoring critical mineral processing.236 [EPA-HQ-OAR-2022-0829-0792, pp. 35-36]

EPA should also consider that recycling of battery material will play a vital role in alleviating some pressure on the need to develop new critical mineral resources. To that end, Tesla seeks to reduce its reliance on primary mined materials and contribute to a more positive environmental footprint through battery and cell recycling – including ensuring that none of our batteries (manufacturing scrap or fleet returns) go to landfills and deploying equipment to recycle 100% of on-site generated manufacturing scrap across manufacturing facilities. In comparison to BEV batteries, it should also be noted the energy source for ICE vehicles – fossil fuels used in combustion – is not recyclable. [EPA-HQ-OAR-2022-0829-0792, p. 36]

Finally, in furtherance of this effort, Tesla is also supporting other emerging domestic suppliers in the advanced battery supply chain as they seek developmental support through various DOE programs, including the Critical Minerals Mining Research and Development Program237 and the Advanced Technology Vehicle Manufacturing program.238 [EPA-HQ-OAR-2022-0829-0792, p. 36]

Organization: Texas Public Policy Foundation (TPPF)

The LMD Tailpipe Rule and the market change it would engender will also make the federal government complicit in the often exploitative practices associated with rare-earth metal mining. The production and acquisition of rare-earth metals used in electric vehicle batteries is a dirty business. The extraction and processing of rare-earth metals can have serious environmental impacts, including soil and water contamination, deforestation, and habitat destruction, negatively affecting ecosystems and biodiversity. In certain areas, rare-earth metal mining has also been linked to labor rights violations, poor working conditions, low wages, child labor, and inadequate safety measures. The batteries that will power the green future the EPA seeks to create through the LMD Tailpipe Rule bear the stain of these violations of human dignity. [EPA-HQ-OAR-2022-0829-0510, p. 6]

Overarching Issues Applicable to the HD and LMD Tailpipe Rules [EPA-HQ-OAR-2022-0829-0510, p. 7]

A transition to zero emission vehicles ("ZEVs") would expose Americans to supply chain vulnerabilities that are certainly beyond EPA's authority. Wells Fargo projects a risk of shortages across virtually all of the key components of electric vehicle ("EV") batteries,1 and many of these rely on geopolitical rivals who control those supply chains.2 Accordingly, there is a sharp mismatch between the proposed rule and the availability of critical minerals essential to realizing its goals.3 Indeed, "mass electrification of the heavy-duty segment on top of the light-duty segment would substantially increase the lithium demand and impose further strain on the global lithium supply." 4 Specifically, "[t]he results suggest that global lithium resources will not be able to sustain simultaneous mass electrification of both the light duty vehicle ("LDV") and HDV segments."5 It is therefore "recommended that both the government and vehicle manufacturers should carefully consider the ambitious promotion of vehicle electrification in the heavy-duty segment."6 [EPA-HQ-OAR-2022-0829-0510, p. 7]

Minerals such as lithium and cobalt are essential for batteries. EPA does not account for the difficulty of getting these minerals. Mining for these minerals is energy-intensive, and the Chinese Communist Party (CCP) has facilitated access to domestic and foreign minerals for battery production. Lithium is mined in western China's Qinghai Province, aided by government funding, and China purchases cobalt for electric batteries from Kisanfu, in the Democratic Republic of Congo.18 The United States makes opening new mines virtually impossible, even though the jobs generated would help all Americans, particularly the poor and middle class. [EPA-HQ-OAR-2022-0829-0674, pp. 4-5]

Thus, the rule will result in a massive increase in mining in countries that have no respect for the environment or human welfare. The sorts of mining that will be conducted as a result of the rule will be bad for the environment and are frequently performed by child workers. EPA does not mention potential human rights violations. [EPA-HQ-OAR-2022-0829-0674, pp. 4-5]

18 Dionne Searcey, Michael Forsythe, and Eric Lipton, "A Power Struggle Over Cobalt Rattles the Clean Energy Revolution," New York Times, December 7, 2021, https://www.nytimes.com/2021/11/20/world/china-congo- cobalt.html (accessed April 28, 2023).

III. The Proposed Rule Would Strengthen China

The EPA rule will strengthen China's economy, because China makes nearly 80% of the world's electric batteries,28 EPA does not sufficiently examine the ramifications of this geopolitical shift. This is especially troubling because the Chinese Communist Party (CCP) is a totalitarian regime which has a poor record both on the environment and on human rights. [EPA-HQ-OAR-2022-0829-0674, pp. 6-7]

Beijing is engaged in genocide against the minority Uyghur people of Xinjiang and has imposed draconian restrictions on political freedoms in Hong Kong.29 The CCP has reduced or eliminated religious liberties for Christians and Buddhist worshippers of the Dalai Lama throughout Tibet.30 Empowering the Chinese government is fundamentally at odds with "good corporate governance." [EPA-HQ-OAR-2022-0829-0674, pp. 6-7]

28 Veronika Henze, “China’s Battery Supply Chain Tops BNEF Ranking for Third Consecutive Time, with Canada a Close Second,” BloombergNEF, November 12, 2022, https://about.bnef.com/blog/chinas-battery-supply-chain-tops- bnef-ranking-for-third-consecutive-time-with-canada-a-close-second/ (accessed April 28, 2023).

29 James J. Carafano et al., “Winning the New Cold War,” p. 24.

30 Ibid., p. 3.

Rather than using its own oil and natural gas resources, America will depend on batteries from China to run its fleet of cars. Countless other renewable energy components and technologies also depend to a large extent on Chinese supply chains. For instance, many of the components of batteries will either be sourced, processed, or manufactured in China for the foreseeable future. Middle-class Americans are losing jobs at Stellantis, Ford, and GM due to the forced switch to electric vehicles. Recent efforts to require battery manufacturing in the U.S. mask the source of the components. In contrast, none of the gasoline or diesel fuels for transportation are from China. [EPA-HQ-OAR-2022-0829-0674, pp. 6-7]

Security benefits are overstated

The study purports to find small energy security benefits by having less imported oil. See Table 200. The analysis ignores that United States can well be an oil-exporting, rather than an oil-importing country. For that reason alone, the stated energy security benefits are likely costs rather than benefits. [EPA-HQ-OAR-2022-0829-0674, p. 14]

Moreover, the United States is certainly an importer of rare-earth minerals, and products such as car batteries that depend on rare-earth minerals. Consequently, while the proposed rule may have little effect from an oil security perspective, it is likely to have a substantial and negative effect on security for imports of rare earth minerals, particularly as the control of much rare earth mineral production is in China. [EPA-HQ-OAR-2022-0829-0674, p. 14]

No analysis is provided for child labor, which almost certainly would increase with greater exploitation of rare earth minerals in developing countries and in China, and battery production in China. [EPA-HQ-OAR-2022-0829-0674, p. 14]

Organization: Toyota Motor North America, Inc.

The Proposed Rule also for the first time imposes standards on automakers for which compliance requires significant actions by third parties over which we (or EPA) have no control. First, achieving the level of BEVs required by the Proposed Rule will require massive new supplies of critical minerals, the mines to extract them, and the refining facilities to turn ore into battery-grade material. Currently, virtually the entire mineral and battery supply chain is outside the U.S. Second, it requires massive investments in home and public charging infrastructure, as well as upgrades to the electrical grid throughout the U.S. and an accelerated shift to renewable power generation. Various provisions of the IIJA and IRA directionally support some of these areas but fall significantly short of what will be needed for the expected level of electrification. And finally, the ultimate impact of these factors on vehicle costs and consumer demand are unclear, at best. The are few contingencies for automakers and our customers in the event any or all these factors stand in the way of complying with the Proposed Rule. Our comments below address these and other issues. [EPA-HQ-OAR-2022-0829-0620, pp. 8-9]

We are prepared to follow up with additional information beyond these comments. We look forward to collaborating toward a more workable Final Rule. [EPA-HQ-OAR-2022-0829-0620, pp. 8-9]

2. Critical Material Supply

Batteries account for largest cost associated with an electric vehicle. The global supply of battery critical minerals and the refining of those minerals will ultimately determine PEV costs as global demand increases nearly five-fold over the next decade1. Hundreds of new mines are needed globally to produce the critical minerals needed to support this demand. Currently, virtually all critical mineral extraction and processing are conducted outside the U.S. [EPA-HQ-OAR-2022-0829-0620, p. 9]

1 BMI Lithium Forecast, Q1 2023.

The proposal outlines various incentives, tax credits, and other mechanisms in the Inflation Reduction Act (IRA) and the Bipartisan Infrastructure Law (BIL) aimed at speeding the development of a domestic supply chain, as well as efforts the Administration and private sector are taking to aid the electrification transition. The IIJA and IRA serve as a necessary down payment on what will be needed to achieve shared electrification goals but fall far short of what is needed to achieve the proposed standards. Further, the proposal lacks an actionable plan for translating funding and goals into specific projects in a manner that will enable automakers to sell the share of BEVs required to meet the preferred alternative standards. [EPA-HQ-OAR-2022-0829-0620, p. 9]

Below is a summary of Toyota's understanding of the critical mineral landscape and supply-demand challenges over the period of the Proposed Rule, based on extensive collaboration with experts in the field. Please see Appendix A for a more detailed assessment and accompanying data. [EPA-HQ-OAR-2022-0829-0620, p. 9]

2.1. Lithium

The proposal identifies lithium as most likely to first constrain PEV production due to limited availability. EPA contends there will be ample supply of the other critical minerals through 2035 and/or there are known substitute minerals that make their availability less critical2. Therefore, the proposal's assessment of critical mineral availably is limited to a single mineral - lithium. [EPA-HQ-OAR-2022-0829-0620, pp. 10-11]

2 Multi-Pollutant Emission Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, EPA- 420-D-23-003, Draft Regulatory Impact Analysis (DRIA), April 2023, page 3-23.

EPA's analysis concludes there will be sufficient lithium supply to support the 67 percent BEV share required by the Proposed Rule and that prices will stabilize mid-decade. However, it appears this conclusion is based on a global lithium supply that in many cases may not qualify for the 30D IRA tax credits that EPA applied to most every vehicle in the supporting analyses. The proposal notes "the Inflation Reduction Act incentivizes use of domestically sourced and processed mineral products, it only ties these products to availability of the related tax incentives (primarily the Clean Vehicle Credit under 30D) and does not prohibit use of imported mineral products by manufacturers that cannot secure domestic sources. Thus, it is the global supply for lithium, not only domestically sourced supply, that potentially constrains battery production."3 [EPA-HQ-OAR-2022-0829-0620, pp. 10-11]

3 Id. at 3-24.

As described in more detail in Appendix A, the global supply of lithium is highly unlikely to satisfy the U.S. demand driven by the preferred alternative standards. Further, the supply-demand gap grows significantly when lithium sources are limited to U.S. and FTA countries that qualify for the IRA tax credits. Benchmark Mineral Intelligence (BMI) with partner RhoMotion conducted a forecast of global lithium supply versus demand through 2035. [EPA-HQ-OAR-2022-0829-0620, pp. 10-11]

The BMI study concludes 41% PEV penetration in 2030 is possible globally without consideration of available lithium under a business-as-usual base case scenario. When available global lithium supply is considered, the projected supply-demand gap constrains PEV penetration to 36% of new vehicles sold globally in 2030. A high-demand scenario incorporates the announced PEV targets for 41 leading OEMs and additional government policy aspirations which results in supply-demand deficit starting today that would require U.S. manufacturers to compete on a global scale for limited lithium - creating many unknown supply bottlenecks. [EPA-HQ-OAR-2022-0829-0620, pp. 10-11]

The BMI/RhoMotion study included a PEV mix of 88 percent BEVs and 12 percent PHEVs for 2030 in contrast to EPA's assumption of 100 percent BEVs for the proposal. The supply-demand analysis would have concluded larger shortfalls that would have occurred sooner if BMI had assumed 100 percent BEVs. The data in these supply-demand figures is for calendar year rather than vehicle model year. For the sake of this evaluation, the calendar year will be used and assumed equivalent to the previous model year (ex. 2030 calendar year is the same as 2029 model year). [EPA-HQ-OAR-2022-0829-0620, pp. 10-11]

Projected U.S. refined lithium supply (larger than U.S. mined lithium supply) is far short of the demand needed to comply with the Proposed Rule -allowing for only a 15% PEV penetration in 2030 assuming a 100 kWh average battery size. Expanding the lithium supply to FTA countries that qualify for the IRA tax credits enables higher PEV penetrations. However, the study finds that the U.S. would need to consume an implausible 99% of U.S. and FTA lithium supply to attain a 60% PEV (80% BEV/20% PHEV) share in 2030 for an assumed battery size of 100 kWh. In the more realistic case where the aggregate demand from other FTA countries in addition to the U.S. is considered, a deficit occurs after 2028 in the base case demand scenario (41% PEV in 2030) and would occur sooner and grow faster if U.S. demand is increased to attain the 60% PEV penetration in 2030 being proposed. Supply from IRA-compliant U.S. and FTA countries would support only a 25% U.S. PEV penetration in 2030 for a 100 kWh average battery size if FTA countries meet their lithium demand first before providing excess refined lithium supply to existing U.S. domestic supply. [EPA-HQ-OAR-2022-0829-0620, pp. 10-11]

Mined lithium supply from Australia, an FTA country, could potentially satisfy U.S. demand driven by the proposed standards and make the proposal's assumptions about IRA cost savings more realistic. However, 96% of Australian supply is currently sold to and refined in China, a foreign entity of concern. Quickly relocating Australian supply to a US+FTA country faces significant hurdles given existing business partnerships and the effort to establish new partnerships with capital- and operational-intensive infrastructure. [EPA-HQ-OAR-2022-0829-0620, pp. 10-11]

2.2. Graphite and Nickel

As described in Appendix A, data indicate graphite will be more constraining than lithium. The U.S. currently does not produce any natural graphite and relies on imports mainly from China. The U.S. is projected to have a combined 22k tonnes of graphite refining capacity per year by 2030. USA+FTA countries are projected to reach 203k tonnes per year.4 For an average BEV battery size of 70 kWh, the graphite produced from US+FTA countries would support 2.9 million BEVs per year in 2030 which would satisfy only 18% of the projected new vehicle sales in 2030. To comply with the 60% BEV share driven by the proposed standard in 2030, 66% of refined graphite would need to be procured from global supplies that are outside of US+FTA control and may not qualify for important IRA benefits to incentivize vehicle purchases. [EPA-HQ-OAR-2022-0829-0620, p. 12]

4 Cite BNEF "Metals Data Hub" online database, last updated Oct. 2022.

Nickel is also experiencing tight supply with a focus on mining in a single country, Indonesia, which is projected to comprise over 50% of global mined nickel battery material in 2030. Growing geopolitical and environment concerns surrounding Ni mining in Indonesia are causing instability, and it is still not known whether Treasury Department guidance will consider Indonesia as an FTA country, although Indonesia has proposed such status recently.5 [EPA-HQ-OAR-2022-0829-0620, p. 12]

5 Citation: https://www.reuters.com/world/asia-pacific/violence-indonesia-nickel-smelter-protest-kills-2-dozens- detained-2023-01-16/.

2.3. Mining

Over the next decade, projected critical mineral demand will require the development of over 300 new mines.6 EPA's projections for new mines do not account for the significant risk of announced mines failing to reach the operational stage and the extensive lead times for the successful ventures to reach efficient operation. The proposal claims significant deposits of nickel, cobalt, lithium, and graphite in the U.S. remain undeveloped. The proposal notes DOE has identified 19 mines in addition to three mines from a December 2022 study and concludes these sources could likely advance lithium sufficiency well beyond 2028. When inherent risk factors are considered, only 18 out of 50 proposed or announced lithium mining projects in the U.S. are expected to be operational by 2035, according to BMI. For those mines that do reach the production stage, lead times can take 4-7 years without delays for lithium mining and 13-19 years for new nickel mining, according to IEA. Permitting and related environmental concerns add to lead time and are more extensive in the U.S. due to strict regulations and oversight - unlike mining operations in many parts of the world. Over 70% of mineral reserves are within 35 miles of tribal lands, which can further complicate the approval process with government authorities. [EPA-HQ-OAR-2022-0829-0620, pp. 12-13]

6 Benchmark Source, More than 300 new mines required to meet battery demand by 2035 (Sep. 6, 2022); https://source.benchmarkminerals.com/article/more-than-300-new-mines-required-to-meet-batery-demand-by-2035.

2.4 Price Volatility

The economics behind the forecasted tight global lithium supply are at odds with EPA's claim that "the price for Lithium is likely to stabilize at or near its historical levels by the mid-2020s".7 In this fragile condition of tight supply, every step of complex and intertwined global operations must fall perfectly into place as planned to avoid price spikes. BMI suggests that lithium prices will stabilize, but there is ongoing risk of underestimating potential volatility resulting from future shocks to the system. [EPA-HQ-OAR-2022-0829-0620, p. 13]

7 88 Fed. Reg. at 29313.

Clearly higher mineral prices affect PEV manufacturing costs and then have a commensurate effect on sales volumes. Mining operations have an incentive to minimize risk and thus err on the side of undersupply because excess supply causes prices to drop and profits to decline. According to numerous analysts, such a situation unfolded when a temporary “excess” of global supply spurred by an increase in lithium mining projects occurred at the same time PEV sales slowed in China because of expiring subsidies. These combined events resulted in the current lower lithium prices which are expected to remain through the 2026 timeframe but are not expected to hold, as mining and refining companies will adjust supply to avoid that less profitable scenario.8 [EPA-HQ-OAR-2022-0829-0620, p. 13]

8 https://internationalbanker.com/brokerage/why-are-lithium-prices-collapsing.

3. Battery and Component Production

Toyota’s assessment of production capacity aligns with DOE’s projections referenced in the proposal where expected growth based on new plant announcements in North America is estimated to reach 838 GWh annual capacity by 2025 and 998 GWh by 2030. Just as with mining operations, there is lead time to establish a battery factory and then ramp up production. Constructing new facilities, scaling up operations, and training a new workforce is challenging and takes time. According to e-Source, it takes about 4 years to reach full scale battery production. [EPA-HQ-OAR-2022-0829-0620, pp. 14-15]

- Year 1: 75% for full year’s production

- Year 2: 85% for full year’s production

- Year 3: 87% (89.5% by end of the year) [EPA-HQ-OAR-2022-0829-0620, pp. 14-15]

3.1. Midstream Constraints

Battery manufacturing capacity is less a constraint to achieving future BEV adoption than the upstream supply chain steps for sourcing the minerals. The proposal notes preliminary projections prepared by Li-Bridge for DOE in November 2022 indicate that global supplies of cathode active material (CAM) and lithium chemical product are expected to be sufficient through 2035. 10 However, more recent assessments project shortfalls for upstream mining and the midstream processing and cathode/anode production capacity to supply the new battery factories with the necessary battery minerals. 11 Leveraging data from BMI, BNEF (Bloomberg New Energy Finance), e-Source and IHS Markit, we find that with U.S. battery manufacturing at 100 percent capacity is sufficient to meet EPA’s proposed requirements at 70 kWh average battery size. However, the production of US cathode manufacturing is in severe deficit, even to achieve the previously discussed base case of 41% PEV penetration in 2030 (Figure 1). [EPA-HQ-OAR-2022-0829-0620, pp. 15-17]

10 88 Fed. Reg. at 29319.

11 Benchmark Minerals, Report, Q1 2023.

[See original for graph, “Figure 1 U.S. Cathode Supply-Demand Forecast] [EPA-HQ-OAR-2022-0829-0620, pp. 15-17]

For this important mid-stream step of cathode manufacturing, a similar deficit of US+FTA sourced cathode material also occurs for a base case 41% BEV penetration rate in 2030. Again, production is not constrained by battery manufacturing capacity but rather by US+FTA cathode manufacturing capacity as illustrated in Figure 2. China makes up 83% of cathode manufacturing with Japan and S Korea at 15%, and the rest of the world at 2%. Because Japan and S. Korea are already included in US+FTA supply, a significant ramp up of new cathode manufacturing in IRA-compliant countries is needed to meet US base case demand and EPA proposed requirements. [EPA-HQ-OAR-2022-0829-0620, pp. 15-17]

[See original for graph, Figure 2 U.S. FTA Cathode Supply-Demand Forecast] [EPA-HQ-OAR-2022-0829-0620, pp. 15-17]

3.2. Conclusion

Battery production is less of a constraint than the materials and midstream production that feed into that process. In addition to cell manufacturing, the assessment supporting the Final Rule needs include the capacity of cathode and anode active material manufacturing and the resulting impact on battery and ultimately PEV costs. The Final Rule needs to account for the lead time associated with establishing new facilities and ramping up production operations to full scale capacity. Finally, cost assessments supporting the Final Rule need to account for the share of production that will not qualify for the IRA benefits which could affect the modeled BEV penetrations. [EPA-HQ-OAR-2022-0829-0620, p. 17]

4. Battery Costs Projections

EPA’s assessment of future battery costs is highly optimistic and inconsistent with available sources. The assessment starts with an inaccurate baseline cost for 2022 and then uses an incomplete set of forecasts to develop two trajectories which rely on assumed mid-decade price stabilization of lithium. The assessment appears to ignore the risk for price spikes arising in a tight and geopolitically sensitive market for critical minerals. Please see Appendix A on mineral supply and potential price implications. Lastly, EPA applies tax credits from the IRA 45X provision in a confusing way that could go beyond the intent of the legislation. [EPA-HQ-OAR-2022-0829-0620, p. 18]

According to Benchmark Minerals Intelligence (BMI), battery demand in North America is forecast to grow nearly five-fold between 2022 and 2030 and with that the demand for the finite supply of critical minerals such as lithium, cobalt, nickel, and graphite that go into producing batteries. [EPA-HQ-OAR-2022-0829-0620, p. 50]

The proposed rule identifies lithium as the material most likely to first constrain PEV production due to limited availability. EPA believes there will be ample supply of the other critical minerals through 2035 and/or there are known substitute minerals that make their availability less critical.1 Therefore, the proposal’s assessment of critical mineral availably is limited to a single mineral - lithium. [EPA-HQ-OAR-2022-0829-0620, p. 50]

1 Multi-Pollutant Emission Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, EPA- 420-D-23-003, Draft Regulatory Impact Analysis (DRIA), April 2023, page 3-23.

Toyota agrees lithium availability is likely to constrain global PEV production and put upward pressure on lithium pricing, but is also concerned about graphite supplies. Both minerals will be in tight supply sooner and for longer than projected by EPA's outdated sources2, which do not reflect the current market dynamics for battery demand and material supply in a rapidly changing market landscape. At a minimum, the final rule must use updated data to reflect current battery and non-battery demand, mined supply, and battery plant announcements with pragmatic supply forecasts which show that not every announcement will lead to production. [EPA-HQ-OAR-2022-0829-0620, p. 50]

2 Ibid pages 29319 to 29323 for examples.

Further, the analyses of critical material supply must distinguish the country of origin because it determines whether the IRA benefits used to justify aggressive BEV cost reductions apply. The IRA-qualifying supply of lithium, graphite, nickel, and cobalt and deserve a deeper evaluation to support the final rule. For example, nickel is also experiencing tight supply with a focus on mining in a single country, Indonesia, which is projected to comprise over 50% of global mined nickel battery material in 2030. Growing geopolitical and environment concerns surrounding Ni mining in Indonesia are causing instability, and it is still unknown whether Treasury will consider Indonesia as an FTA country as it requested.3 [EPA-HQ-OAR-2022-0829-0620, p. 50]

3 Citation: https://www.reuters.com/world/asia-pacific/violence-indonesia-nickel-smelter-protest-kills-2-dozens- detained-2023-01-16/.

1. Lithium Constrained PEV Penetration – Global

Toyota's assessment of global lithium supply and demand is more aligned with the projections of IEA and BNEF studies that project lithium mine production may not meet end-use demand after 20284. Benchmark Mineral Intelligence (BMI), leveraging transportation demand-side market data from their partner RhoMotion, forecasts global lithium supply versus demand through 2035. Figure 1 below forecasts a business-as-usual base case5 global PEV penetration at 41% in 2030 with an average battery size of 68 kWh. This assumes an unconstrained lithium supply. Taking forecast global lithium supply into account results in supply-demand a gap emerging around 2028. This widening deficit in supply leads to a constrained PEV penetration of 36% new sales in 2030. [EPA-HQ-OAR-2022-0829-0620, pp. 51-53]

4 88 Fed. Reg 29184 (May 5, 2023) at 29321.

5 For the base case, BMI "subsegments each demand market by end application, [and] considers government intervention that can impact adoption/use of application, OEM strategies and technology roadmaps, historical trends to understand consumer behaviour, economics and material availability/capacity build out to determine forecasted adoption of each application. This then amalgamates into [an] overall demand for each market by chemistry and region." The BMI analysis considers lithium demand for battery and non-battery sources (including heavy duty vehicles).

It is important to acknowledge two things. One, the supply shown in these comments utilizes the original source's (e.g. BMI, BNEF) de-risked supply scenario, meaning not 100% capacity, unless otherwise stated. Second, increased demand will motivate an increase in future supply project announcements. The challenge is how quickly the announced sources become operational and produce the quantities needed for compliance with the proposed standards. These operational challenges are discussed later in this section of our comments. Figure 1 shows the global PEV penetration rates in the base case as provided by BMI/RhoMotion, which includes incentives stemming from the Inflation Reduction Act (IRA). [EPA-HQ-OAR-2022-0829-0620, pp. 51-53]

[See original for graphs, Figure 1 Global Lithium Supply-Demand Forecast] [EPA-HQ-OAR-2022-0829-0620, pp. 51-53]

With the proposed rule essentially forcing ~60% BEVs in 2030, the global lithium gap would increase with heterogenous effects of supply-demand balance in the US and different countries, which is described further for the U.S. [EPA-HQ-OAR-2022-0829-0620, pp. 51-53]

The BMI study included a PEV mix of 88 percent BEVs and 12 percent PHEVs for 2030 in contrast to EPA's assumption of 100 percent BEVs for the proposal. The supply-demand analysis would have concluded larger shortfalls that would have occurred sooner if BMI had assumed 100 percent BEVs. The data in these supply-demand figures is for calendar year rather than vehicle model year. For the sake of this evaluation, the calendar year will be used and assumed equivalent to the previous model year (ex. 2030 calendar year is the same as 2029 model year). [EPA-HQ-OAR-2022-0829-0620, pp. 51-53]

BMI and RhoMotion have also developed a global forecast for a high-demand scenario shown in 1 which incorporates the announced PEV targets for 41 leading OEMs and additional government policy aspirations. In this scenario, the lithium supply-demand balance immediately goes into deficit. This materiality limitation demonstrates how the attainment of ambitious OEM PEV targets and government policy aspirations in aggregate, which are insufficiently considered in the proposed standards, would require US manufacturers to compete on a global scale for limited lithium creating many unknown supply bottlenecks. Lithium supply constraints are next discussed in terms of domestic US supply and then US and Free Trade Agreement (FTA) country supply. [EPA-HQ-OAR-2022-0829-0620, pp. 51-53]

2. Lithium Constrained PEV Penetration – IRA Compliant

2.1. US Domestic Supply

First and not surprisingly, the forecast clearly shows that the U.S.-based lithium mined capacity and refined capacity (de-risked supply) is able to supply only 33% and 51%, respectively, of the lithium needed for base case U.S. demand at 41% PEV penetration in 2030, with an average pack size of 70 kWh. [EPA-HQ-OAR-2022-0829-0620, pp. 54-57]

[See original for graph, Figure 2 U.S. Domestic Lithium Supply-Demand Forecast] [EPA-HQ-OAR-2022-0829-0620, pp. 54-57]

Thus, to meet base case demand requires sourcing the remaining lithium from outside of the U.S. both for mining and refining purposes. Figure 2 shows this in more detail. Domestic supply shrinks to only 32% of required lithium supply needed to satisfy a 60% PEV share for an assumed average battery size of 70 kWk (red dashed line) and only 23% the required lithium for an average 100 kWh battery (red dotted line) that is referenced in the proposal. This means for a 100 kWh battery, U.S. lithium supply could meet demand for approximately 15% PEV penetration in 2030, 45% less than 60% BEV penetration EPA is seeking through the proposal. [EPA-HQ-OAR-2022-0829-0620, pp. 53-54]

2.2. US +FTA Supply

The lithium supply-demand gap narrows but continues when sourcing is extended to the Free Trade Agreement (FTA) countries that qualify for IRA tax credits. Data from BMI, RhoMotion, e-Source and IHS Markit show (see Figure 3) that 45% of USA+FTA refined lithium supply would be needed to meet US demand for the 41% PEV base case penetration in 2030. Compliance with EPA's proposed requirements in 2030, would consume 71% of USA+FTA refined lithium supply for an average pack size of 70 kWh and 99% of USA+FTA supply for the EPA-referenced average 100 kWh battery. [EPA-HQ-OAR-2022-0829-0620, pp. 54-57]

[See original for graph, Figure 3 U.S.+FTA Lithium Supply Required to Meet Proposed 60% PEV Share] [EPA-HQ-OAR-2022-0829-0620, pp. 54-57]

When we consider the lithium demand of Free Trade Agreement countries in addition to the U.S. (i.e. US+FTA lithium), the aggregate increased demand results in a deficit after 2028 in the base case demand scenario as seen in Figure 4. If US demand is increased to attain a 60% PEV penetration in 2030, the deficit will move early relative to 2028 depending on the PEV ramp-up required to meet EPA requirements. If the FTA countries are allowed to meet their Li demand first before providing excess to U.S. domestic supply, the U.S. PEV penetration rate is constrained to 36% in 2030 with an average pack size of 70 kWh. Supply from IRA-compliant U.S. and FTA countries would support only a 25% U.S. PEV penetration in 2030 for a 100 kWh size battery if FTA countries meet their lithium demand first before providing excess refined lithium supply to existing U.S. domestic supply. [EPA-HQ-OAR-2022-0829-0620, pp. 54-57]

[See original for graphs, Figure 4 U.S.+FTA Lithium Supply-Demand Forecast]

It should be noted that FTA mined supply includes Australia, which is the largest current source of lithium (over 50% of global supply) in the world through its spodumene supply and would qualify under the IRA provisions. However, today 96% of Australian supply is currently sold to and refined in China, a foreign entity of concern.6 If the refining of Australian supply could relocate to a US+FTA country, the expanded source of lithium supply could potentially satisfy U.S. demand driven by the proposed standards and make the proposal's assumptions about IRA cost savings more realistic as illustrated in Figure 5. [EPA-HQ-OAR-2022-0829-0620, pp. 54-57]

6 https://www.globaltimes.cn/page/202207/1270447.shtml.

Quickly shifting significant amounts of the Australian mined supply would be extremely challenging. While refineries are faster to build than mines, such an undertaking could be impractical considering existing business partnerships and the effort to establish new partnerships with capital- and operational-intensive infrastructure. It would be most efficient for Australia to establish local refining; however, BMI forecasts Australian refining capacity to be about 15% of China's capacity in 2030. The Australian government has reported that it could provide 20% of the world's needed refining capacity in 2027.7 However, delays are already occurring for current refining projects and there is uncertainty as to whether Australia will be able to compete with China on prices. [EPA-HQ-OAR-2022-0829-0620, pp. 54-57]

7 https://www.power-technology.com/news/australia-to-end-dependence-on-china-for-lithium.

[See original for graph, Figure 5 U.S.+FTA Lithium Supply-Demand: Australia Supply Included] [EPA-HQ-OAR-2022-0829-0620, pp. 54-57]

3. Graphite Constraints

The proposal categorizes graphite as a substitutable material noting “the role of natural graphite in many cases can be served by artificial graphite or highly refined hard or amorphous carbon. However, lithium has no substitute in commercially produced automotive applications at this time.”8 [EPA-HQ-OAR-2022-0829-0620, pp. 57-59]

8 Multi-Pollutant Emission Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, EPA- 420-D-23-003, Draft Regulatory Impact Analysis (DRIA), April 2023, page 3-23.

Toyota understands that IRA-qualifying graphite could restrict US battery production and constrain PEV sales more so than lithium. The U.S. currently does not produce any natural graphite and must rely on imports where most originates from China. Despite growth of natural graphite mining in Africa, which is projected to take over China as the major source of graphite in the mid- 2020s9, the majority of graphite processing called spheroidization which is necessary to improve battery performance takes place in China (see Figure 6). [EPA-HQ-OAR-2022-0829-0620, pp. 57-59]

[See original for graphic, Figure 6 Countries of Origin for Graphite] [EPA-HQ-OAR-2022-0829-0620, pp. 57-59]

China controls every stage of the graphite supply chain and was responsible for almost 60 % of the world’s mined production last year and approximately nearly 99% of graphite processing because of its scale of operations, established supply, weak environmental requirements, and low resulting costs. If any portion of a battery’s raw material originates from a foreign entity of concern (including refining), the battery would not qualify for part of the consumer tax credit. [EPA-HQ-OAR-2022-0829-0620, pp. 57-59]

For synthetic graphite, there are three US companies planning to produce a combined 12k tonnes per year by 2026, up from 2k in 2022.10 Only one company is expected to process natural graphite in the US (Vidalia) with operations announced to come online in 2023 at 2.5k tonnes per year and ramp to 10k by 2026. Combined the US is projected to have 22k tonnes of graphite refining capacity per year by 2030. USA+FTA countries are projected to reach 203k tonnes per year.11 [EPA-HQ-OAR-2022-0829-0620, pp. 57-59]

10 [FN: PUREgraphite, SGL Carbon, and Amsted Graphite]

11 Cite BNEF “Metals Data Hub” online database, last updated Oct. 2022

As reference, approximately 1 kg of graphite is needed per kWh of battery capacity. For an average BEV pack size of 70 kWh, the graphite produced from US+FTA countries would support 2.9 million BEVs per year in 2030 which would satisfy only 18% of the 15,814,296 annual new vehicle sales projected in 2030.12 To comply with the 60% BEV share driven by the proposed standard in 2030, 66% of refined graphite would need to be procured from global supplies that are outside of US+FTA control and may not qualify for important IRA benefits to incentivize vehicle purchases. [EPA-HQ-OAR-2022-0829-0620, pp. 57-59]

12 Multi-Pollutant Emission Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, EPA- 420-D-23-003, Draft Regulatory Impact Analysis (DRIA), April 2023, page 4-44.

4. Mining/Processing Limitations

The proposal claims significant deposits of nickel, cobalt, lithium and graphite in the U.S. remain undeveloped primarily because of economic considerations. It also recites Biden Administration and industry efforts toward building a sustainable domestic supply chain and how the Inflation Reduction Act (IRA) and the Bipartisan Infrastructure Law (BIL) will accelerate that development. [EPA-HQ-OAR-2022-0829-0620, pp. 59-63]

However, the proposal provides no specific roadmap as to how the billions of dollars in available federal and private funds will translate into a schedule of quantified increases in domestic material supplies that will enable compliance with the proposed standards. Instead, EPA relies on anecdotal evidence such as the March 2023 DOE assessment which identified 19 additional lithium production projects in the U.S. in addition to the three BNEF had identified in a December 2022 study. With this information, EPA concluded that there will be sufficient lithium supply to meet end-use demand well beyond 2028.13 [EPA-HQ-OAR-2022-0829-0620, pp. 59-63]

13 88 Fed. Reg at 29321.

DOE's assessment of the 19 mines appears to ignore the significant uncertainty associated with starting mining operations. The prospect for a mine to reach the production stage and time that takes hinges on exploration and feasibility studies, approval and permitting processes, potential for project abandonment and delays, learning rates for new companies, and production ramp up. When these risk factors are considered, only 18 out of 50 proposed or announced lithium mining projects in the US are expected to be operational by 2035, according to BMI (see Figure 7). [EPA-HQ-OAR-2022-0829-0620, pp. 59-63]

[See original for graph, Figure 7 US Probable Lithium Mines] [EPA-HQ-OAR-2022-0829-0620, pp. 59-63]

Further, the 18 mines are expected to produce less than 14,000 tonnes lithium per year which fills only 19% of the lithium needed to attain a 60% PEV share in 2030 assuming an average battery size of 70 kWh. These relatively small and young mining operations will not be able to add a meaningful amount of IRA-qualifying minerals, much less relieve expected tight global supply. The U.S. will have more refining capacity than mining capacity, meaning it can absorb and use supply from FTA countries for US production as shown below (Figure 8). However, like the mining capacity, the refining capacity is insufficient for US demand, accounting for only 28% of US demand driven by a 60% PEV share in 2030, assuming an average battery size of 70 kWh. As refineries can come online faster than mining operations, an increasing in US or US+FTA refining capacity could reduce this gap. New mining operations are more complicated. [EPA-HQ-OAR-2022-0829-0620, pp. 59-63]

[See original for graph, Figure 8 US Probable Lithium Refineries] [EPA-HQ-OAR-2022-0829-0620, pp. 59-63]

As seen in Figure 9, reaching the operational stage of a mine entails long lead times. As provided by the IEA below, lead times for lithium mining can take 4-7 years without delays. New nickel mining operations can take 13-19 years. [EPA-HQ-OAR-2022-0829-0620, pp. 59-63]

[See original for graphic, Figure 9 Mining Project Development Lead Times] [EPA-HQ-OAR-2022-0829-0620, pp. 59-63]

In the U.S, the time to establish an operating mine can take even longer because of regulatory requirements that are stricter than many other countries in the world. Recently, the largest proposed lithium mine at Thacker Pass was approved to start operations but after years of delay.14 Repeat examples of multi-year delays in mine production and the growing number of small and young companies means there is large uncertainty in the ability of supply to ramp up to meet ambitious demand targets on shorter time scales. [EPA-HQ-OAR-2022-0829-0620, pp. 59-63]

14 cite: https://www.reuters.com/legal/us-judge-rule-thacker-pass-lithium-mine-case-within-months-2023-01-05/.

Approvals become more complex and time consuming because the reserves of critical minerals in the U.S. are tied closely with tribal lands, where over 70% of these reserves are within 35 miles of tribal lands as seen in Figure 10. Mining at Thacker Pass mentioned above also carries controversy with its overlap with sacred tribal land.15 [EPA-HQ-OAR-2022-0829-0620, pp. 59-63]

15 https://www.npr.org/2023/06/28/1184812267/western-tribes-last-ditch-effort-to-stall-a-large-lithium-mine-in- nevada.

While an increase in mining operations is necessary to meet supply, a reasonable timeline should be applied to the availability of such supply to meet demand both in terms of time-to-production and time-to-full production capacity. Data from BMI suggests it can take 1-4 years to ramp up to full operating capacity. [EPA-HQ-OAR-2022-0829-0620, pp. 59-63]

[See original for bar chart, Figure 10 Proximity of U.S. Mining Resources[[EPA-HQ-OAR-2022-0829-0620, pp. 59-63]

Finally, the resolution of environmental concerns can delay the development and opening of new mines. Environmental Sustainability and Governance issues surrounding mining are gaining increased attention. For example, particulate emissions may prove a challenge for natural graphite mines in the U.S. [EPA-HQ-OAR-2022-0829-0620, pp. 59-63]

In summary, establishing mining and processing operations and reaching full, efficient operational entails significant risk and a decade-long process if successful. It is extremely unlikely the U.S. can attain significant mining capacity in the period of the proposed standards. However, increasing refining capacity could be a means to alleviating supply deficits. [EPA-HQ-OAR-2022-0829-0620, pp. 59-63]

5 Price Volatility

Forecasts for ongoing tight global lithium supply are at odds with EPA's claim that "the price for Lithium is likely to stabilize at or near its historical levels by the mid-2020s."16 The forecast of strong demand coupled with tight supply over the next decade creates an economic recipe for price volatility. In this fragile condition, every step of complex and intertwined global operations must fall perfectly into place as planned to avoid price spikes. [EPA-HQ-OAR-2022-0829-0620, pp. 63-65]

16 Multi-Pollutant Emission Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, EPA- 420-D-23-003, Draft Regulatory Impact Analysis (DRIA), April 2023, page 3-21.

BMI suggests that lithium prices will stabilize (see Figure 11), but there is risk of underestimating potential volatility resulting from future shocks to the system. Historic price volatility has been primarily caused by localized shocks which are impossible to forecast but can have large consequences. For example, the lithium price shock below, driven by the covid-19 pandemic created supply restrictions, which increased prices and spurred supply growth, which has in turn depressed prices again. We will not know if such a spike will occur again until it happens. [EPA-HQ-OAR-2022-0829-0620, pp. 63-65]

[See original for chart, Figure 11 Historic Lithium Price Trends] [EPA-HQ-OAR-2022-0829-0620, pp. 63-65]

Price fluctuations are expected to be a by-product of transitioning the vehicle fleet to PEVs while simultaneously establishing the supply base. Demand for PEVs will be determined by prices remaining in a range consumers can afford which requires sufficient supply so only modest supply- demand gaps occur. Otherwise, demand will contract due to price spikes/volatility. Figure 12 is an image of how a too much demand relative to available supply results in price spikes that suppress demand as part of a feedback loop making it more difficult to meet any government's PEV targets. Mines and refineries seek to avoid excess supply because it results in lower prices and profits which is occurring now and expected to persist for the next few years. Thus, mines and refineries seek conditions that favor high demand and prices, erring on the side of tight or under supply. [EPA-HQ-OAR-2022-0829-0620, pp. 63-65]

[See original for graph, Figure 12 Supply-Demand Impacts on Pricing] [EPA-HQ-OAR-2022-0829-0620, pp. 63-65]

According to numerous analysts, a temporary "excess" of global supply spurred by more lithium mining projects in conjunction with slower PEV sales in China because of expiring subsidies has resulted in the current lower lithium prices which are expected to remain through the 2026 timeframe but are not expected to hold, as mining and refining companies will adjust supply to avoid that less profitable scenario.17 [EPA-HQ-OAR-2022-0829-0620, pp. 63-65]

17 https://internationalbanker.com/brokerage/why-are-lithium-prices-collapsing.

Mining economics are at odds with EPA's conclusion that "rapid growth in lithium demand has driven new development of resources and robust growth in supply, which is likely a factor in recently observed reductions in lithium price, with strong profit margins remaining - even afterward."18 [EPA-HQ-OAR-2022-0829-0620, pp. 63-65]

18 88 Fed. Reg at 29313.

6 Conclusion

A deeper analysis of global and IRA-compliant critical material supply and demand is needed to support the final rule. The proposal's high-level assessment results in overly optimistic observations that "critical battery mineral supply is likely to be adequate to meet anticipated demand, in some cases by a significant margin".19 The proposal lacks the evidence to support this finding. Demand for critical minerals today is now higher than the years referenced in the proposal due to new policy and OEM targets. Future demand growth for PEVs is unclear given the uncertain geo-political considerations and supply chain operations beyond the control manufacturers and EPA. It is highly plausible the tight supply-demand for lithium and graphite will lead to volatile prices and the proposal fails to consider how this could suppress demand and annual EV market share. The Final Rule must encompass a significantly deeper analysis based on a boarder array of sources for assessing global supply-demand by country of origin to support the use of IRA tax credits. [EPA-HQ-OAR-2022-0829-0620, pp. 65-66]

Organization: Transfer Flow, Inc

Electric vehicle technologies are the opposite of energy independence. [EPA-HQ-OAR-2022-0829-0496, pp. 2-3]

Electric vehicle battery chemistry differs significantly from traditional internal combustion engine batteries. A conventional internal combustion engine uses a typical lead-acid battery. The most common battery chemistry used in an electric vehicle is nickel manganese cobalt. The mining of the raw minerals needed to manufacture the battery packs for electric vehicles has been linked to many horrific human rights abuses.2’3’4’5’6’7’8’9 There are a limited number of locations around the world where the minerals needed to manufacture electric vehicle batteries are found. 70% of the cobalt used in electric vehicle batteries comes from a single country, the Democratic Republic of the Congo.10 80% of the battery supply chain is owned by China. [EPA-HQ-OAR-2022-0829-0496, pp. 2-3]

The United States not owning the electric vehicle battery supply chain is especially concerning when we consider the possibility of a natural disaster or, heaven forbid, an international conflict. As we have seen recently in several local domestic terrorist attacks, 11’12’13’14 an attack on the power grid could render electric vehicles located in affected regions useless. According to the United States Geological Survey, a major earthquake (M>=6.7) will likely strike California by 2032.15 We have recently seen in the wake of Hurricane Ian in Florida that electric vehicles are dangerous and ineffective in situations of natural disaster.16 [EPA-HQ-OAR-2022-0829-0496, pp. 2-3]

16 https://abc7.com/hurricane-ian-ev-car-fires-electric-cars-damaged-florida-flood-damage/12356326/

Many consumers disapprove of the government dictating which near-zero technologies they're allowed to utilize. Unfortunately, the EPA has not provided for a battery directive such as the UN has required setting sustainability requirements for batteries placed on the market, including responsible sourcing of raw materials, hazardous substances, carbon footprint, and measures to improve the collection, treatment, and recycling of these waste batteries ensuring materials recovery. Many concerned citizens do not support the human rights violations associated with mining cobalt, lithium, and other minerals required for battery manufacturing. [EPA-HQ-OAR-2022-0829-0496, pp. 3-5]

Organization: U.S. Chamber of Commerce

- Underdeveloped and unsecure supply chains for electric vehicle batteries and other components. Electric vehicles need approximately six times more minerals than a conventional vehicle, and the International Energy Agency estimates that EV- related demand for these minerals will increase almost 30-fold through 2050. The auto industry and other sectors facing growing supply chain concerns are working with the mining sector to address projected shortfalls of these critical minerals and associated refining and processing needs, but the challenge is immense. [EPA-HQ-OAR-2022-0829-0604, p. 2]

Successfully ramping up these efforts will take several years under even the most optimistic scenarios. This is a major reason why the proposed rule's aggressive and front-loaded "ramp rate" is not realistically achievable, and could in fact exacerbate energy security issues associated with China's current dominance of global critical mineral supply chains. While recently enacted R&D programs and tax incentives are certain to help attract battery manufacturing and assembly investments necessary for the downstream end of the supply chain, a more comprehensive approach including faster permitting is needed. In particular, the Chamber urges the Administration to reverse course on its opposition to domestic mining projects required to source the raw materials necessary for manufacturing EV batteries on the scale envisioned by this proposal. [EPA-HQ-OAR-2022-0829-0604, p. 2]

Organization: United Steelworkers (USW)

As our union represents the majority of unionized workers in the auto supply chain and workers in the oil sector, we have grave concerns regarding this proposed rule's impact on their livelihoods, and the negative impact that the rapid implementation of ZEVs will have on our electric grid and domestic supply chain. [EPA-HQ-OAR-2022-0829-0587, p. 1]

EPA should coordinate with the Department of Energy (DOE), the Department of Transportation (DOT), and the Department of Commerce (DOC) to better understand how its regulatory timelines correspond with the investments that will support regulatory compliance. More to this point, the Administration continues to delay rollout of the Build America, Buy

America provisions in the IIJA, which is hindering domestic manufacturing investments for a variety of products, including products contributing to the transition to low-emissions vehicles. [EPA-HQ-OAR-2022-0829-0587, p. 4]

Further, the domestic supply chain for components and the charging infrastructure isn't close to being readily available.10 This proposed rule does not strike a balance between the ambition to reduce emissions and the practicality of the disruption in the supply chain. If EPA requires automakers to achieve far-reaching standards in an unreasonable time frame, they will rely on cheap, readily available components from countries, like the People's Republic of China (PRC), where a large amount of the current ZEV supply chain is located.11 Encouraging sourcing products from the PRC and similar countries does not advance best practices to reduce our environmental footprint as the use of coal to power manufacturing facilities is still prevalent there.12 The potential offshoring of the automotive supply chain not only harms manufacturing workers and communities in the U.S., it also allows automakers to cut their costs in pursuit of lower environmental and labor standards abroad. [EPA-HQ-OAR-2022-0829-0587, p. 5]

Organization: Valero Energy Corporation

Moreover, in April 2023, Toyota sent its dealers a "Hybrid Memo" pointing out that "There are three major barriers to widespread battery electric vehicle adoption in the United States" – critical minerals, charging infrastructure, and affordability. Noting that the amount of raw materials in one BEV could be used to make 6 PHEV or 90 hybrid electric vehicles, the memo concludes that "An 'all of the above' electrification strategy is the bridge to get us to lower overall carbon emissions."127 [EPA-HQ-OAR-2022-0829-0707, pp. 25-27]

127 https://jalopnik.com/toyota-focusing-on-hybrids-not-electric-vehicles-1850440908

EPA also cites to a July 2021 Stellantis announcement regarding its "intensified focus on electrification across all of its brands."128 Yet, EPA does not consider qualifying statements like those made by Stellantis CEO Carlos Tavares in May 2022, in which he stated that he expects a shortage of EV batteries by 2024-2025, followed by a lack of raw materials for the vehicles by 2027-2028.129 Mr. Tavares has also provided that "[y]ou'll see that the electrification path, which is a very ambitious one, in a time window that has been set by the administrations is going to bump on the supply side".130 Further, in response to EPA's proposed rule, Chrysler parent Stellantis has said it remains "committed to reducing vehicle emissions," adding "we are surprised that none of the alternatives align with the President's previously announced target of 50% EVs by 2030."131 [EPA-HQ-OAR-2022-0829-0707, pp. 25-27]

128 EPA's Proposed Rule at 29191(citing to Stellantis, ''Stellantis Intensifies Electrification While Targeting Sustainable Double-Digit Adjusted Operating Income Margins in the Mid-Term,'' Press Release, July 8, 2021).

129 Reuters, "Automotive industry faces long term battery, raw material supply issues, Tavares says" (May 10, 2022) https://www.reuters.com/business/autos-transportation/automotive-industry-faces-long-term-battery-raw-material-supply-issues-tavares-2022-05-10/ (emphasis added).

130 Wayland, Michael, "Stellantis CEO warns of electric vehicle battery shortage, followed by lack of raw materials (May 24, 2022) https://www.cnbc.com/2022/05/24/stellantis-ceo-warns-of-ev-battery-shortage-lack-of-raw- materials.html.

131 Root, Al, "Car Makers Don't Love EPA's EV Plan. Here's What Ford, GM, and Others Are Saying, Barrons (April 13, 2023) https://www.barrons.com/articles/ev-epa-emissions-what-auto-makers-say-9abaedd6?ns=prod/accounts-barrons.

Further, EPA provides that "in January 2021, General Motors announced plans to become carbon neutral by 2040, including an effort to shift its light-duty vehicles entirely to zero-emissions by 2035."132 Yet GM's 10-K filed in January 2023 caveats that:133 [EPA-HQ-OAR-2022-0829-0707, pp. 25-27]

132 EPA's Proposed Rule at 29190 (citing to General Motors, ''General Motors, the Largest U.S. Automaker, Plans to be Carbon Neutral by 2040,'' Press Release, January 28, 2021).

133 GM's 10-K Annual Report for the 2022 Fiscal Year, https://investor.gm.com/static-files/54bdb095-143e-4b96- b6d5-25937910b59c (emphasis added).

"[A]ny increase in the cost, or reduced availability, of critical materials for our EV propulsion systems, including lithium, nickel, cobalt and certain rare earth metals, could lead to higher production costs for our EVs and could impede our ability to successfully deliver on our EV strategy. Further, increasing global demand for, and uncertain supply of, such materials could disrupt our or our suppliers' ability to obtain such materials in a timely manner and/or could lead to increased costs. Geopolitical risk, fluctuations in supply and demand, fluctuations in interest rates, any weakening of the U.S. dollar and other economic and political factors have created and may continue to create pricing pressure for commodities, raw materials and other inputs." [EPA-HQ-OAR-2022-0829-0707, pp. 25-27]

GM's 10-K further disclosed that its "business in China subjects [it] to unique operational, competitive and regulatory risks" and that "[i]ncreased competition, continued U.S.-China trade tensions or weakening economic conditions in China, among other factors, may result in cost increases, price reductions, reduced sales, profitability and margins, and challenges to gaining or holding market share." [EPA-HQ-OAR-2022-0829-0707, pp. 25-27]

Other auto-manufacturers have similar views. In response to EPA's proposed rule, a Hyundai spokesperson provided that "[t]he proposed vehicle emission rules released by EPA will be challenging to meet and will require further expansion of charging infrastructure, consumer incentives and supply chains".134 Regarding Tesla, after stating that the BEV manufacturer aims to produce 20 million EVs per year before 2030,135 CEO Elon Musk clarified that Tesla's target is an "aspiration, not a promise . . . we may stumble and not reach that goal".136 In June 2022, Elon Musk further stated that "[b]oth [of Tesla's] Berlin and Austin factories are gigantic money furnaces right now. It's like a giant roaring sound, which is the sound of money on fire". 137 [EPA-HQ-OAR-2022-0829-0707, pp. 25-27]

134 Root, Al, “Car Makers Don’t Love EPA’s EV Plan. Here’s What Ford, GM, and Others Are Saying, Barrons (April 13, 2023) https://www.barrons.com/articles/ev-epa-emissions-what-auto-makers-say-9abaedd6?ns=prod/accounts-barrons.

EPA’s reliance on a September 2022 Report from the Environmental Defense Fund and ERM is also similarly inadequate. Specifically, EPA states that its “Figure 1, taken from work by the Environmental Defense Fund and ERM, illustrates how these and other announcements mean that virtually every major manufacturer of light-duty vehicles is already planning to introduce widespread electrification across their global fleets in the coming years.”138 But EPA does not sufficiently consider the entirety the EDF and ERM report it relies on, which also states as follows:139 [EPA-HQ-OAR-2022-0829-0707, pp. 27-28]

138 EPA’s Proposed Rule at 29191 (citing to Environmental Defense Fund and ERM, ‘‘Electric Vehicle Market Update: Manufacturer Commitments and Public Policy Initiatives Supporting Electric Mobility in the U.S. and Worldwide,’’ September 2022).

139 EPA’s Proposed Rule at 29191 (citing to Environmental Defense Fund and ERM, ‘‘Electric Vehicle Market Update: Manufacturer Commitments and Public Policy Initiatives Supporting Electric Mobility in the U.S. and Worldwide’’ at 31, September 2022) (internal citations omitted).

“Prices of key minerals and metals, like lithium, cobalt, nickel, copper, and aluminum that are required components for battery manufacturing, increased in 2021 with this price trend predicated to continue through 2022. In recent research from IEA, cathode materials (lithium, nickel, cobalt, and manganese), essential for lithium-ion batteries, accounted for less than five percent of battery pack costs in the middle of the last decade. However, this share has risen to over 20 percent in recent years. The price of lithium and cobalt more than doubled in 2021, with lithium increasing two and a half times since the start of 2022. [EPA-HQ-OAR-2022-0829-0707, pp. 27-28]

IEA also expects that with ongoing geopolitical conflicts like the Russian invasion of Ukraine and supply being cut in China, lithium-ion battery pack prices will continue to rise. Russia is a major producer of minerals like aluminum, accounting for nearly six percent of global production, ten percent of nickel, and two percent for Class-1 nickel, the only grade used in lithium-ion batteries. According to IEA, on March 8, 2022, nickel prices soared from $25,000 per metric ton to over $100,000 per metric ton which caused the London Metal Exchange to suspend the trading of nickel for a week. [EPA-HQ-OAR-2022-0829-0707, pp. 27-28]

According to the U.S. State Department, over 80 percent of the global supply chain of rare earth elements (important components of lithium-ion batteries and other EV components) is controlled by China, and Bloomberg NEF found that China holds 77 percent of the world’s battery cell manufacturing capacity and 60 percent of the world’s component manufacturing.” [EPA-HQ-OAR-2022-0829-0707, pp. 27-28]

B. EPA fails to adequately address critical minerals supply, availability, and geopolitics.

The IEA states that "[t]his World Energy Outlook special report on The Role of Critical Minerals in Clean Energy Transitions identifies risks to key minerals and metals that – left unaddressed – could make global progress towards a clean energy future slower or more costly, and therefore hamper international efforts to tackle climate change."147 The IEA Report further provides that EVs require significant mineral inputs compared with ICE vehicles.148 For example, the typical electric car contains six times the mineral resources of a kind susceptible to supply chain disruptions and volatility. Additionally, demand for EV minerals is growing rapidly and expected to outpace production in the coming years. Further, the long lead time for the development of new mines constrains industry's ability to respond to rapid increases in mineral demand. [EPA-HQ-OAR-2022-0829-0707, pp. 29-30]

147 International Energy Agency, ''The Role of Critical Minerals in Clean Energy Transitions,'' World Energy Outlook Special Report, Revised version. March 2022. https://www.iea.org/reports/the-role-of-critical-minerals- in-clean-energy-transitions

148 Id.

A recent announcement of Chile's intention to nationalize its lithium production led to questions regarding lithium supply volatility and security, specifically in the context of EV supply chains. Other examples of geopolitical and national security risk inherent to EV supply chains include, but are not limited to, as follows: [EPA-HQ-OAR-2022-0829-0707, pp. 29-30]

"Amid growing demand for lithium in the race for electric vehicle batteries, Mexico last year nationalized the mineral and created the state-run LitioMx, or Litio Para Mexico." Recently, on February 18, 2023, Mexican President Andres Manuel Lopez Obrador signed a decree handing over responsibility for lithium reserves to Mexico's energy ministry, after nationalizing lithium deposits in April 2022. [EPA-HQ-OAR-2022-0829-0707, pp. 29-30]

- "Indonesia is home to 22% of the world's nickel reserves, and its ban on nickel ore exports since 2020 has caused major shifts in the supply chains of strategic products such as electric vehicles and rocket engines." Nickel is a crucial material in the production of EV battery cathodes. [EPA-HQ-OAR-2022-0829-0707, pp. 29-30]

Organization: Volvo Car Corporation (VCC)

Many uncertainties remain (supply chains, tariffs, infrastructure, incentives) so it is very important that government pursue policies that encourage auto industry investment and jobs, development of the electric vehicle market and advancement of motor vehicle safety. With the right complementary government policies, this rulemaking presents an opportunity for government and industry to pursue these shared goals. [EPA-HQ-OAR-2022-0829-0624, pp. 5-6]

Organization: Western Energy Alliance

Energy Security: EPA makes the specious assertion that the energy security benefits of the rule will include, "…reductions in energy security externalities caused by U.S. petroleum consumption and imports…" p. 29199 Given the huge supply of American oil and the fact that the United States is the number one oil producer in the world, EPA strains its credibility by justifying the proposed rule in such a way. Unlike the ICEV fleet with its majority consumption of American oil, EV batteries are sourced from minerals largely mined unsustainably in China and Africa, as are the minerals required for wind turbines and solar panels. Further, the U.S. lacks copper and aluminum smelting capacity required to expand the grid and it takes years to develop new mines. Without expansion, the grid is susceptible to reliability issues. [EPA-HQ-OAR-2022-0829-0679, p. 4]

EPA's cost-benefit analysis regarding energy security is troublesome, finding that the proposed rule delivers $21 billion to $42 billion in energy security benefits from reduced oil imports, but ignoring the security implications of the huge foreign mineral needs arising from the proposed rule. With huge domestic reserves of oil and the fact that Canada is the primary exporter to the United States, our country enjoys an energy security benefit in terms of oil. [EPA-HQ-OAR-2022-0829-0679, p. 4]

The supposed benefit EPA finds from reduced imports pales in comparison to the overwhelming security cost of the rule from forcing the country to becoming nearly 100% dependent on China and Africa for EVs and the minerals in them. Figure 28 of the proposed rule makes the case for us, as it shows the foreign sources of minerals, yet EPA does not analyze the security implications. In fact, EPA waves away the data on the lack of domestic sourcing with the statement that: [EPA-HQ-OAR-2022-0829-0679, p. 4]

"…the development of mining and processing capacity in the U.S. is a primary focus of efforts on the part of both industry and the Administration toward building a robust domestic supply chain for electrified vehicle production and will be greatly facilitated by the provisions of the BIL and the IRA as well as large private business investments that are already underway and continuing." [EPA-HQ-OAR-2022-0829-0679, p. 4]

As with the expansion of the grid required to achieve the aggressive EV targets, government policy that wishes to expand domestic capacity is unlikely to achieve its intended goal, given the track record of the country over the past several decades in permitting mines, long processing times for National Environmental Policy Act (NEPA) analysis, and other environmental laws that will continue to slow new mining projects. Further the very actions of this administration to constrain domestic supplies of minerals, such as EPA denying the water permit for the Pebble Mine in Alaska and the Interior Secretary withdrawing 225,594 acres in Cook, Lake, and Saint Louis counties of Minnesota from mineral leasing, belie EPA's sanguinity for domestic supply. Replicating anywhere near an equivalent for critical minerals as our current vast reserves of oil is nothing short of a fantasy, particularly by the year 2030 or 2032. The fact that the president and Congress wish to support domestic supply chains for critical minerals does not mean it will be so. [EPA-HQ-OAR-2022-0829-0679, pp. 4-5]

EPA attempts to wave away this dependency problem on page 29323: [EPA-HQ-OAR-2022-0829-0679, pp. 4-5]

"Finally, it is important to note that utilization of critical minerals is different from the utilization of foreign oil, in that oil is consumed as a fuel while minerals become a constituent of manufactured vehicles. That is, mineral security is not a perfect analogy to energy security." [EPA-HQ-OAR-2022-0829-0679, pp. 4-5]

EPA dismisses serious concerns on the viability of critical mineral access with hopes for long-term contracts, manufacturing flexibility in substituting one mineral for another as their availability ebbs and flows, and effective mineral recycling. EPA ignores the mineral needs of the grid expansion that would be necessary for this rule. However, even assuming that EPA has a point that mineral security is not the same as energy security, then there should be a corresponding quantification of the mineral security costs in the cost/benefits analysis of the rule. There should be an entry in Table 156 right along with the "Energy Security Benefits" itemized as "Critical Minerals Benefits." Were EPA to perform such an analysis, it would find a huge cost to national security from critical mineral insecurity that would easily dwarf EPA's finding of an energy security benefit from the proposed rule. [EPA-HQ-OAR-2022-0829-0679, pp. 4-5]

Affordability/Environmental Justice: EPA is assuming that although the retail price of EVs is typically higher than for comparable ICEVs at this time, the price difference will narrow or disappear as the cost of batteries and other components fall in the coming years. EPA is taking a huge leap of faith in the ability of EV manufacturers to innovate in time for the arbitrary deadlines imposed by the president and EPA through this rule. Market projections six months from now are difficult, much less nine years into the future. [EPA-HQ-OAR-2022-0829-0679, p. 7]

But recent evidence suggests that EPA's assumption is well off the mark. EV battery costs soared in 2022 due to rising raw material and battery component costs. As countries around the world attempt to reach similar arbitrary targets for EVs and renewable energy, the competition for limited supplies of raw materials will likewise grow.13 Prices for rare earth minerals have increased between 60% and 400% while prices for lithium have increased by over 300% since 2020.14 [EPA-HQ-OAR-2022-0829-0679, p. 7]

13
"EV battery costs have soared in 2022, hampering EV affordability," Stephen Edelstein, Green Car Reports, December 8, 2022.

14 Current Strategic Metals Prices, Strategic Metals Invest and D aily Metals Prices, both accessed July 5, 2023.

Organization: Wisconsin Automobile and Truck Dealers Association

Although the EPA argues the price of EVs will decline and affordability will increase, you also reference the cost of batteries and other components falling in coming years. Yet the agency acknowledges that the United States barely exists in the production of copper, nickel, cobalt, graphite, lithium, and platinum. The control of these products rests with other countries, many of them, our adversaries. How can the EPA predict the decline in price on products we do not control and on minerals that are precious and non-renewable? It is also irresponsible to make such predictions when we are currently experiencing conflicts with China and Russia and believing the United States can still procure adequate supplies from other countries. The EPA also acknowledges the United States produces large percentages of oil and natural gas. [EPA-HQ-OAR-2022-0829-0494, p. 1]

Organization: Zero Emission Transportation Association (ZETA)

The light- and medium-duty electric vehicle (LMDEV) markets are primed for rapid growth in the coming years. As discussed further in these comments, hundreds of thousands of vehicles have already been put on U.S. roadways, the diversity of available EV4 models are growing exponentially, and battery prices are falling rapidly. Significant investments are being made throughout the supply chain to support a smooth transition to mass consumer adoption of EVs. Robust EPA emissions standards will provide the regulatory certainty needed to not only ensure manufacturers continue to invest in LMDEV technologies but that the entire supply chain supporting the transition to electrification will have a clearer picture of how to plan capital expenditures today to meet the increased demand for its products over the coming years. [EPA-HQ-OAR-2022-0829-0638, p. 5]

4 Unless otherwise noted, ZETA refers to “EVs” in these comments to mean battery-electric vehicles.

c. Electrification Promotes American Economic Competitiveness

Governments around the world are setting more stringent emissions standards to align with recent announcements from global manufacturers. Ensuring U.S. regulations match or exceed these ambitions is vital in allowing certainty and encouraging investment in the industry. If the U.S. does not move more aggressively on LMDEV deployment, it risks ceding market share to other countries and regions who are moving faster, such as China, the European Union, and others. [EPA-HQ-OAR-2022-0829-0638, p. 24]

Complimentary incentives embedded in the IRA will facilitate onshoring of the EV supply chain while robust EPA emission standards will help ensure the United States becomes and remains a leader in EV technology development and manufacturing. While more work remains to craft supportive policies in other areas of the supply chain, EPA emissions standards are crucial drivers of domestic EV supply. [EPA-HQ-OAR-2022-0829-0638, p. 24]

Many countries have made commitments to accelerate EV development and deployment in their borders. An increase in EV sales is taking place across the world, but has been dominated by the Chinese market, which accounts for the majority of all new EV registrations. As of 2022, China had 10.7 million BEVs on the road and the U.S. had 2.1 million.114 Part of this dominance is due to China’s purchase incentives, high registration fees for ICEVs, a robust charging network, and national “new energy vehicle” targets.115 [EPA-HQ-OAR-2022-0829-0638, p. 24]

114 Id. at footnote 27

115 “An evaluation of government incentives for new energy vehicles in China focusing on vehicle purchasing restrictions,” Energy Policy, (October 2017) https://doi.org/10.1016/j.enpol.2017.07.057

With its own emissions targets, countries in Europe are sending strong signals about the continent’s future electric fleet. Europe is the second-largest market for EVs in the world, with 30% of the global share.116 With robust LMDV emissions standards, the U.S. would be encouraging quicker adoption of EV technology to ensure the country remains at the forefront of this global transition. Below is a list of regional and national goals for light- and medium-duty zero-emission vehicle deployment that further underscores the need for the U.S. via EPA to maintain pace with the rest of the world: [EPA-HQ-OAR-2022-0829-0638, p. 24]

116 Id. at footnote 27

- European Union: Target to reduce CO2 emissions from new cars and vans by 55% in 2030 and 100% in 2035 compared to 2021 emissions. 117 [EPA-HQ-OAR-2022-0829-0638, pp. 25-26]

- Norway: 100% of LDV sales to be zero-emission by 2025.118

- Switzerland: ZEV sales of 28% in 2025, 60% in 2030, and 100% from 2040.119

- Denmark: End the sale of new petrol and diesel cars from 2030, and PHEVs from 2035.120

- Netherlands: 100% ZEV sales by 2030.121

- United Kingdom: Phase out new petrol and diesel cars and vans by 2030. All new cars to be fully zero emission after 2035.122

- Canada: ZEV targets for light-duty sales of 20% by 2026, 60% by 2030 and 100% by 2035.123

- Chile: 100% of LDV sales will be zero-emissions by 2035, with an accompanying ban on ICE sales.124

- Korea: 50% of new sales to be ZEVs by 2025, and 80% by 2030.125

- China: "New energy vehicle" sales in key air pollution control regions to account for about 50% of new vehicle sales by 2030.126

- Japan: 100% of car sales to be electrified by 2035. 127

127 “Japan Transition to Electric Vehicles, U.S. International Trade Administration, (July 7, 2021) https://www.trade.gov/market-intelligence/japan-transition-electric-vehicles

Stringent LMDV multipollutant and GHG emissions standards will encourage more domestic investment and innovation to position the United States as a global leader in the electric vehicle space. The regulatory certainty of these standards will enable increased investment and the continued build-out of a domestic supply chain. Without stringent LMDV emissions standards, the U.S. risks ceding this vast economic opportunity to other countries, disadvantaging American businesses and workers. [EPA-HQ-OAR-2022-0829-0638, pp. 25-26]

8. The EV Supply Chain is Preparing to Support Increased Electrification

The widespread transition to electrified transportation is involving industries and companies that have not historically had a major role in supplying products to the transportation sector. Policies like EPA’s proposed LMDV multipollutant emissions standards provide regulatory certainty for the entire supply chain supporting the transition to electrification. [EPA-HQ-OAR-2022-0829-0638, p. 31]

As discussed further in this section, the supply chain is composed of discrete, yet interconnected segments that are continuing to scale up in capacity. Complementary policies in various stages of implementation today will lead to an even more robust and resilient supply chain over the MY 2027-2032 time frame covered by EPA’s proposed standards. [EPA-HQ-OAR-2022-0829-0638, p. 31]

Finalizing strong LMDV emissions standards is not only necessary for public health, climate, and economic reasons, but they are feasible for industry to implement and align with the planned and existing investments being made throughout the EV supply chain.140,141 Through ZETA, the full scope of the U.S. EV supply chain is coalesced behind the goal of 100% EV sales. [EPA-HQ-OAR-2022-0829-0638, p. 31]

140 “US and Canada Electric Vehicle Supply Chain Map,” Charged by the Book, accessed June 30, 2023 https://www.charged-the-book.com/na-ev-supply-chain-map

141 FACT SHEET: Biden-Harris Administration Announces New Private and Public Sector Investments for Affordable Electric Vehicles (April 17, 2023) https://www.whitehouse.gov/briefing-room/statements-releases/2023/04/17/fact-sheet-biden-harris-administration-a nnounces-new-private-and-public-sector-investments-for-affordable-electric-vehicles/

a. Critical Minerals Development

As projected demand for critical minerals (lithium, nickel, cobalt, manganese, copper, graphite, and rare earth elements) for use in EV batteries continues to grow–due in large part to policies such as EPA’s proposed multipollutant emission standards for LMDVs–the supply chain is preparing to meet that demand both through new extraction and processing and with additional support from recycling. [EPA-HQ-OAR-2022-0829-0638, pp. 31-32]

Beyond EPA emission standards, the section 30D New Clean Vehicle Tax Credit in the Inflation Reduction Act ensures that these critical minerals are sourced either in the United States or from free trade agreement countries. The credit is composed of two halves: qualifying vehicles will receive $3,750 for meeting each of the critical mineral and battery component sourcing requirements totaling up to $7,500.142 The stringent ramp-up of the domestic sourcing requirements in the IRA over the coming years will lead to a robust supply chain capable of delivering domestically-sourced raw and refined materials. [EPA-HQ-OAR-2022-0829-0638, pp. 31-32]

142 “Overview and Analysis: March Treasury Guidance for Clean Car Tax Credit (30D),” ZETA, (April 2023) https://www.zeta2030.org/insights/overview-and-analysis-march-treasury-guidance-for-clean-car-tax-credit-30d

A key element to the success of the supply chain’s ability to deliver the critical minerals necessary to support the transition to electrified transportation will be reforming the permitting processes for new extraction and processing operations. The Biden-Harris Administration has placed a much-needed focus on this area143 and ZETA has consistently supported reforms144 that ensure development projects are constructed quickly while meeting the strongest environmental standards. [EPA-HQ-OAR-2022-0829-0638, pp. 31-32]

143 “FACT SHEET: Biden-Harris Administration Outlines Priorities for Building America’s Energy Infrastructure Faster, Safer, and Cleaner,” (May 2023) https://www.whitehouse.gov/briefing-room/statements-releases/2023/05/10/fact-sheet-biden-harris-administration-outlines-priorities-for-building-americas-energy-infrastructure-faster-safer-and-cleaner/

144 “Critical Mineral Permitting Reform Framework,” ZETA, (May 2023) https://www.zeta2030.org/insights/critical-mineral-permitting-reform-framework

The executive branch has been just as aggressive on increasing critical mineral capacity in the U.S. In March 2022, President Biden invoked the Defense Production Act (DPA). The DPA allows the Department of Defense (DOD) to fund feasibility and modernization projects for mining and processing facilities.145 With funding from the DPA, DOD invested $120 million in a rare earths separation plant in Texas with Lynas Rare Earths.146 In February 2023, President Biden further expanded this authority to allow for large, longer-term investments in critical mineral projects. [EPA-HQ-OAR-2022-0829-0638, p. 32]

145 “Defense Production Act Title III Presidential Determination for Critical Materials in Large-Capacity Batteries,” U.S. Department of Defense, (April 5, 2022) https://www.defense.gov/News/Releases/Release/Article/2989973/defense-production-act-title-iii-presidential-deter mination-for-critical-materi

146 “Australia's Lynas gets $120 mln Pentagon contract for U.S. rare earths project,” Reuters, (June 14, 2022) https://www.reuters.com/markets/us/australias-lynas-secures-120-mln-pentagon-contract-us-rare-earths-facility-2022-06-14/

In 2022, the White House announced the American Battery Material Initiative to leverage Federal investments and activities to build both a domestic and international critical minerals supply chain in coordination with our allies.147 This complements the signing of the Minerals Security Partnership (MSP) with Australia, Canada, Finland, France, Germany, Japan, the Republic of Korea, Sweden, the United Kingdom, the United States, and the European Commission.148 This agreement outlines the ethics, environmental, and safety standards expected of critical mineral mining and processing and ensures stronger trade connections between nations. The MSP also encourages investments between governments for certain projects. This partnership may explore using loans from the Export-Import Bank of the United States to on-shore and friend-shore the supply chain. [EPA-HQ-OAR-2022-0829-0638, p. 32]

147 "Biden-Harris Administration Awards $2.8 Billion to Supercharge U.S. Manufacturing of Batteries for Electric Vehicles and Electric Grid," U.S. Department of Energy, (October 19, 2022) https://www.energy.gov/articles/biden-harris-administration-awards-28-billion-supercharge-us-manufacturing-batteri es

148 "Minerals Security Partnership," U.S. Department of State, (June 14, 2022) https://www.state.gov/minerals-security-partnership/

Federal agencies are also making efforts to improve the critical mineral supply chain. Organized by the Department of Interior, the interagency working group on mining reform has gathered experts and stakeholders to discuss potential permitting reform to support a domestic industry.149 Efforts by the working groups will include proposals to reform the Mining Law of 1872, form recommendations to bolster the supply chain, and provide community engagement best practices. [EPA-HQ-OAR-2022-0829-0638, p. 33]

149 "Interior Department Launches Interagency Working Group on Mining Reform," U.S. Department of the Interior, (February 22, 2022) https://www.doi.gov/pressreleases/interior-department-launches-interagency-working-group-mining-reform

To ensure there is a trained workforce for the critical mineral industry, the DOE and Department of Labor created a workforce development strategy, funded by the BIL.150 These efforts will include retraining in fossil-fuel and automotive communities and enhancing additional training programs across the country. All together, these actions incentivize manufacturers and developers to create an American supply of critical minerals. Since their announcement, investments in the critical mineral supply chain have dramatically expanded in the country. [EPA-HQ-OAR-2022-0829-0638, p. 33]

150 "DOE Announces $5 Million to Launch Lithium-Battery Workforce Initiative," U.S. Department of Energy, (March 18, 2022) https://www.energy.gov/articles/doe-announces-5-million-launch-lithium-battery-workforce-initiative

As EPA accurately notes in the proposed rule, there is an important distinction between energy security and mineral security. Utilization of critical minerals is inherently different from the utilization of petroleum, in that petroleum is consumed as a fuel while minerals become a component of manufactured vehicles. Supply disruptions and fluctuating prices for critical minerals are felt differently and by different parties as opposed to petroleum which has an immediate impact on consumers through higher fuel prices, as discussed in section 3(b) of these comments. In contrast, supply disruptions or price fluctuations of minerals affect only the production and price of new vehicles. [EPA-HQ-OAR-2022-0829-0638, p. 33]

Moreover, critical minerals are not a single commodity but a number of distinct commodities, each having its own supply and demand dynamics, and some being capable of substitution by other minerals. Further, while petroleum is consumed as a fuel and thus requires continuous supply, minerals become part of the vehicle and have the potential to be recovered and recycled, as discussed further in section 8(b)(ii) of these comments. [EPA-HQ-OAR-2022-0829-0638, p. 33]

i. Projected Demand for Critical Minerals

Demand for critical minerals is expected to grow substantially in the coming years. Figure 5 IEA's projected demand scenarios by 2040 relative to a 2020 baseline. [EPA-HQ-OAR-2022-0829-0638, pp. 33-34]

[See original comment for Figure 5. Mineral demand growth from new EV sales by scenario, 2040 relative to 2020]151 [EPA-HQ-OAR-2022-0829-0638, pp. 33-34]

151 "Mineral demand growth from new EV sales by scenario, 2040 compared to 2020," IEA, (October 26, 2022) https://www.iea.org/data-and-statistics/charts/mineral-demand-growth-from-new-ev-sales-by-scenario-2040-compar ed-to-2020

In a scenario that meets the goals of the Paris Climate Agreement, the share of total demand for critical minerals rises significantly over the next two decades to over 40% for copper and rare earth elements, 60-70% for nickel and cobalt, and almost 90% for lithium.152 EVs and battery storage have already displaced consumer electronics to become the largest consumer of lithium and are set to displace the stainless steel industry as the largest end user of nickel by 2040. [EPA-HQ-OAR-2022-0829-0638, pp. 33-34]

152 "The Role of Critical Minerals in Clean Energy Transitions," IEA, (May 2021) https://www.iea.org/reports/the-role-of-critical-minerals-in-clean-energy-transitions

ii. Meeting the Forthcoming Demand for Critical Minerals

As demand for critical minerals is expected to grow rapidly, it is first necessary to evaluate the current state of global production. For most minerals, production has grown in the past decade.153 However, while much of the production for certain minerals is concentrated in a handful of countries, there is reason to believe that most critical minerals demand can be met through extraction in democratic countries. According to the Carnegie Endowment for International Peace and as shown in Figure 6 below, nearly all critical mineral demand could be met through reserves in democratic countries.154 [EPA-HQ-OAR-2022-0829-0638, pp. 34-36]

153 "bp Statistical Review of World Energy," British Petroleum, (2022) https://www.bp.com/content/dam/bp/business-sites/en/global/corporate/pdfs/energy-economics/statistical-review/bp- stats-review-2022-full-report.pdf

154 Democratic countries include: Argentina, Armenia, Australia, Austria, Belgium, Bhutan, Bolivia, Brazil, Bulgaria, Canada, Chile, Finland, France, Georgia, Germany, Ghana, Iceland, Indonesia, Japan, Mexico, Mongolia, Nigeria, Norway, Peru, Poland, Portugal, Senegal, Sierra Leone, South Africa, South Korea, Spain, Sri Lanka, Sweden, Ukraine, and the United States.

[See original comment for Figure 6. Critical Minerals Potential in All Democratic Countries]155 [EPA-HQ-OAR-2022-0829-0638, pp. 34-36]

The Net Zero Industrial Policy Lab at Johns Hopkins University finds that partnerships among democratic countries would be able to produce enough minerals to enable the world to limit warming to 1.5 degrees Celsius, the more ambitious target in the Paris Climate Agreement.156 However, producing enough metals to meet these targets would require extraordinary technological and financial cooperation. [EPA-HQ-OAR-2022-0829-0638, pp. 34-36]

iii. Critical Mineral Production

ZETA members are scaling up capacity to meet the projected demand in the coming years. For example, Ioneer's Rhyolite Ridge project–located in Esmeralda County, NV–holds the largest known lithium and boron deposit in North America.159 Ioneer recently announced a mineral resource update that found a 168% increase in estimated lithium at Rhyolite Ridge.160 [EPA-HQ-OAR-2022-0829-0638, pp. 36-37]

159 Ioneer - Rhyolite Ridge, accessed May 16, 2023 https://rhyolite-ridge.ioneer.com/

ZETA member Albemarle Corp. recently announced it is aiming to spend between $1.25 billion and $1.5 billion to double its lithium hydroxide output in Australia to a volume that it estimates could power more than 2 million electric cars each year.161 Albemarle plans to build two additional processing trains at its Kemerton plant south of Perth in Western Australia, which could boost its lithium hydroxide production by 50,000 tons annually. Albemarle recently announced that it achieved an IRMA 50 level of performance in an independent third-party assessment of its lithium brine extraction and concentration site in the Salar de Atacama, using the Initiative for Responsible Mining Assurance's (IRMA) comprehensive mining standard.162 [EPA-HQ-OAR-2022-0829-0638, pp. 36-37]

Recently, ZETA member Lithium Americas provided an update on the status of its various projects around the world.163 Lithium Americas' Cauchari-Olaroz project in Argentina is expected to begin producing lithium in June 2023. Production ramp up at the Cauchari-Olaroz project is expected to produce 40,000 tonnes per year of battery-quality lithium carbonate and is targeted to be complete in Q1 2024. Domestically, Lithium Americas recently announced the start of construction activities at Thacker Pass in Nevada following receipt of notice to proceed from the Bureau of Land Management.164 [EPA-HQ-OAR-2022-0829-0638, pp. 36-37]

[See original comment for Figure 7. ZETA members key domestic lithium production projects.]

With applications well beyond just EVs, ensuring a domestically-sourced supply of copper will be critical to ensuring a rapid transition to electrified transportation. In May 2023, the Department of Energy proposed to characterize copper as critical through its inclusion on the official DOE Critical Materials List.165 In particular, DOE is recommending a designation for copper of “near-critical” in the medium term (2025-2035). To meet the forthcoming increases in demand for copper, a pair of domestic projects are currently in various stages of development: One major project that would help the U.S. with its growing demand for copper, molybdenum, silver and critical minerals is Resolution Copper in Arizona. This project has the potential to supply up to 25% of the nation’s copper demand to power America’s clean energy transition with $1 billion annually into Arizona’s economy. The project currently employs 300 people, 80% of whom live locally in rural communities within 40 miles of the project. When the mine is fully operational, Resolution Copper expects to directly employ about 1,500 workers, paying around $134 million per year in total compensation. In total, the project is expected to support 3,700 direct and indirect jobs, many of them local building trades and U.S. Steel Workers union jobs.166 [EPA-HQ-OAR-2022-0829-0638, pp. 37-38]

165 “Critical Materials Assessment,” U.S. Department of Energy, (May 2023) https://www.energy.gov/sites/default/files/2023-05/2023-critical-materials-assessment.pdf 166 See: https://resolutioncopper.com/

NewRange Copper Nickel is a 50:50 joint venture of Teck Resources Limited and PolyMet Mining Corp., holding the NorthMet and Mesaba deposits – two large, well defined resources in the established Iron Range mining region of Minnesota. The stand- alone company is creating a path to develop one of the world’s largest and lowest cost copper-nickel-PGM producing districts, unlocking a new domestic supply of critical minerals for the low-carbon transition through responsible mining, and delivering significant, multi-generational economic and other benefits to the region and beyond.167 [EPA-HQ-OAR-2022-0829-0638, pp. 37-38]

167 See: https://newrangecoppernickel.com/

Anovian, which produces synthetic graphite anodes, is investing $800 million in Georgia to build a new manufacturing facility. The company’s first large-scale facility is expected to produce 40,000 metric tons of synthetic graphite annually for lithium-ion batteries.168 [EPA-HQ-OAR-2022-0829-0638, pp. 37-38]

168 “Anovion Technologies to build $800M facility in Georgia,” Manufacturing Dive, (May 22, 2023) https://www.manufacturingdive.com/news/anovion-technologies-800m-facility-in-georgia/650808

Manganese miner Element 25 has signed a definitive agreement with automotive major General Motors to supply up to 32,500 t/y of battery-grade high-purity manganese sulfate to support GM's EV production in North America.169 [EPA-HQ-OAR-2022-0829-0638, pp. 37-38]

169 "GM signs up to Element 25's Louisiana plans," Mining Weekly, (June 26, 2023) https://www.miningweekly.com/article/gm-signs-up-to-element-25s-louisiana-plans-2023-06-26

iv. Refining and Processing

In March 2023, Albemarle announced a new lithium processing facility in South Carolina.170 Albemarle expects the facility to annually produce approximately 50,000 metric tons of battery-grade lithium hydroxide from multiple sources, with the potential to expand up to 100,000 metric tons. Production at the facility would support the manufacturing of an estimated 2.4 million electric vehicles annually. [EPA-HQ-OAR-2022-0829-0638, pp. 38-39]

170 "Albemarle Corporation Announces New U.S. Lithium Mega-Flex Processing Facility in South Carolina," Albemarle Corporation, (March 22, 2023) https://www.albemarle.com/news/-albemarle-corporation-announces-new-us-lithium-megaflex-processing-facility-in-south-carolina–

In March 2023, EVelution Energy announced a $200 million cobalt processing plant in Arizona to produce cobalt sulfate for up to 470,000 EVs per year by the time the facility is fully operational in 2026.171 [EPA-HQ-OAR-2022-0829-0638, pp. 38-39]

171 "EVelution Announces $200 Million Cobalt Production Facility in Yuma County, Arizona Commerce Authority, (March 29, 2023) https://www.azcommerce.com/news-events/news/2023/3/evelution-energy-announces-200-million-cobalt-productio n-facility-in-yuma-county

In May 2023, Tesla announced a new lithium refinery in Southwest Texas which, when completed, is expected to produce enough lithium to build about 1 million EVs by 2025.172 [EPA-HQ-OAR-2022-0829-0638, pp. 38-39]

172 "Elon Musk and Tesla break ground on massive Texas lithium refinery," Reuters, (May 8, 2023) https://www.reuters.com/business/autos-transportation/tesla-plans-produce-lithium-1-mln-vehicles-texas-refinery-el on-musk-2023-05-08/

b. Batteries

The U.S. battery manufacturing industry is quickly scaling to meet demand driven by transportation electrification. According to Argonne National Lab, between 2010 and 2021, $95 billion was invested in the U.S. battery manufacturing industry.173 This number represents 160 new or expanded critical materials processing and manufacturing facilities, with enough capacity to provide batteries for 10 million EVs each year and create 70,000 new jobs. [EPA-HQ-OAR-2022-0829-0638, pp. 39-40]

The Bipartisan Infrastructure Law allocated $1.6 billion to the Department of Energy for the funding of "new commercial-scale domestic facilities to extract and process lithium, manufacture battery components, recycle batteries, and develop new technologies to increase U.S. lithium reserves."174 In 2022, the Inflation Reduction Act 45X Advanced Manufacturing Production and Advanced Energy Project Tax Credit provided $35 per kWh in each battery cell, $10 per kWh in each battery module, 10% of the costs of production of the applicable critical materials incurred by the taxpayer. The Advanced Energy Project Tax Credit also appropriated a $10,000,000 fund for tax credits to build clean technology manufacturing facilities, including those that process, refine, and recycle critical minerals.175 Through the 45X credit, the IRA cuts nearly one third of the cost of producing batteries in the United States.176 Together, these historic provisions will drive American battery innovation, ensuring that the sector is equipped to electrify all vehicle classes as EV deployments accelerate over the coming years. [EPA-HQ-OAR-2022-0829-0638, pp. 39-40]

173 “A new look at the electric vehicle supply chain as battery-powered cars hit the roads en masse,” Argonne National Laboratory, (May 4, 2023) https://www.anl.gov/article/a-new-look-at-the-electric-vehicle-supply-chain-as-batterypowered-cars-hit-the-roads-en-masse

174 See Public Law 117-58

i. Manufacturing

There is historic momentum around battery manufacturing as it ramps up to support transportation electrification. Over the past year, battery producers have rapidly invested in new battery capacity in anticipation of strong electric vehicle sales growth. A total of 1.4 terawatt hours (TWhs) of new battery capacity was announced in just the last six months, according to Benchmark’s Gigafactory Assessment.177 The number of plants being tracked more than doubled to 379 in April from 174 plants in November 2020, according to Benchmark. Since January 2021, the U.S. private sector has announced nearly $82 billion in battery manufacturing investments, translating to 96 new or expanded processing and manufacturing plants.178 [EPA-HQ-OAR-2022-0829-0638, pp. 40-41]

177 “Battery gigafactory plans slow down in April after record 2022,” Benchmark Minerals Intelligence, (April 26, 2023) https://source.benchmarkminerals.com/article/battery-gigafactory-plans-slow-down-in-april-after-record-2022?mc_c id=f82a9ac7a8&mc_eid=be723945d8

178 New US Battery Manufacturing and Supply Chain Investments Announced Under President Biden, US Department of Energy, (February 13, 2023) https://www.energy.gov/sites/default/files/2023-02/Battery%20Supply%20Chains%20Investments%20Map.pdf

Below is a list of recently-announced investments in EV battery manufacturing, all of which will help support the transition to an electrified transportation sector: [EPA-HQ-OAR-2022-0829-0638, pp. 40-41]

- In March 2023, ZETA member LG announced a $5.5 billion investment to construct a battery manufacturing complex in Queen Creek, Arizona. The complex will consist of two manufacturing facilities – one for cylindrical batteries for EVs and another for lithium iron phosphate (LFP) pouch-type batteries for energy storage systems (ESS). LG plans to invest $3.2 billion in building a cylindrical battery manufacturing facility with a capacity of 27GWh, and $2.3 billion in LFP pouch-type battery facility with the capacity of 16GWh. Both facilities, totaling 43 GWh, plan to break ground this year and will begin production in 2025 and 2026, respectively.179 A more comprehensive list of LG’s investments in domestic battery manufacturing can be found in Appendix figure A.1. [EPA-HQ-OAR-2022-0829-0638, pp. 40-41]

- In April 2023, Hyundai Motor Co. announced it had finalized a $5 billion EV battery joint venture with SK On, a battery unit of SK Innovation Co Ltd. The plant will be located in Georgia and is expected to start manufacturing battery cells in the second half of 2025 with an annual production capacity of 35 GWh.180 [EPA-HQ-OAR-2022-0829-0638, pp. 40-41]

- In April 2023, General Motors and Samsung announced they will invest over $3 billion to build a joint venture EV battery manufacturing plant in the U.S. Expected to start production in 2026, the plant aims to have an annual production capacity of 30 GWh.181 [EPA-HQ-OAR-2022-0829-0638, pp. 40-41]

- In May 2023, ZETA member Panasonic announced that it would expand its U.S. manufacturing capacity from 38 GWh today to 200 GWh by 2030, including Panasonic's $4 billion under-construction investment in Kansas.182 [EPA-HQ-OAR-2022-0829-0638, pp. 40-41]

- In June 2023, the Ford/SK On joint venture BlueOval SK was awarded a $9.2 billion conditional loan from the Department of Energy's Loan Programs Office–the largest in the office's history. The loan will help the joint venture build two gigafactories in Kentucky and one in Tennessee. Together, the plants will enable more than 120 GWh of U.S. battery production annually and displace more than 455 million gallons of gasoline per year for the lifetime of the vehicles powered by these batteries. The project is expected to create a total of approximately 5,000 construction jobs in Tennessee and Kentucky, and 7,500 operations jobs once the plants are up and running.183 [EPA-HQ-OAR-2022-0829-0638, pp. 40-41]

iii. Alternative Chemistries

As battery manufacturing and recycling capacity ramps up, so too does the development of innovative alternative battery chemistries that will transform the range, durability, and cost of EVs. Lithium Iron Phosphate (LFP) batteries do not require nickel or cobalt, leading to reduced costs.196 Another potentially promising technology is sodium-ion batteries. Because they substitute lithium for sodium, sodium-ion batteries tend to be cheaper, and may have significant applications in lower-range EVs.197 [EPA-HQ-OAR-2022-0829-0638, p. 44]

196 “Lithium iron phosphate comes to America,” Chemical and Engineering News, (January 29, 2023) https://cen.acs.org/energy/energy-storage-/Lithium-iron-phosphate-comes-to-America/101/i4

Recent advancements in solid-state batteries have also recently been announced, most notably by Toyota which aims to commercialize the technology as soon as 2027, consistent with the MY 2027-2032 time frame covered by EPA’s proposed LMDV emissions standards.198 While there remain substantial challenges to mass adoption, solid-state batteries offer some promise in that they are more energy dense, highly stable, offer potentially faster charging times, and can be produced faster than lithium-ion batteries.199 Benchmark Mineral Intelligence forecasts that solid-state battery production will exceed 30 GWh in 2026.200 [EPA-HQ-OAR-2022-0829-0638, p. 44]

198 “Japan’s Toyota announces initiative for all-solid state battery as part of electric vehicles plan,” AP News, (June 13, 2023) https://apnews.com/article/toyota-evs-hydrogen-battery-climate-cd7730dbb9c157cf1663d39a3b39778e

As research and commercialization of alternative battery chemistries and technologies continues in the private sector, the Department of Energy’s SLAC National Accelerator Laboratory201 and Stanford University recently announced the launch of a new joint battery center at SLAC.202 It will bring together the resources and expertise of the national lab, the university, and Silicon Valley to accelerate the deployment of batteries and other energy storage solutions. Argonne National Laboratory is also researching emerging new battery technologies including lithium-air, which could offer much longer driving range compared with the lithium-ion battery,203 and lithium-sulfur, which can hold more energy than traditional ion-based batteries.204 [EPA-HQ-OAR-2022-0829-0638, pp. 44-45]

i. Impacts to EV Production from BIL and IRA Programs

Policies in the BIL and IRA are driving demand for EVs both for personal and commercial use. As discussed previously in these comments, customers are increasingly choosing to electrify and OEMs are better incentivized to meet this demand through the build out of additional domestic manufacturing capacity. As a result, EV production and model availability is rapidly expanding. [EPA-HQ-OAR-2022-0829-0638, pp. 70-71]

Analysis by the Environmental Defense Fund found that announced EV manufacturing investments from 2015 to 2023 total $31.4 billion and would lead to at least 55,800 new jobs and result in automakers being capable of producing more than 4.3 million EVs per year in 2026.254 Figure 10 below illustrates the ramp up in EV manufacturing capacity through 2026, with major manufacturing capacity additions following BIL and IRA passage. As additional announcements are made, domestic EV manufacturing capacity will continue to grow, leading to a secure domestic supply chain and thousands of new jobs. [EPA-HQ-OAR-2022-0829-0638, pp. 70-71]

254 "U.S. Electric Vehicle Manufacturing Investments and Jobs Characterizing the Impacts of the Inflation Reduction Act After 6 Months," Environmental Defense Fund, (June 2023) https://blogs.edf.org/climate411/files/2023/03/State-Electric-Vehicle-Policy-Landscape.pdf

[See original comment for Figure 10. Estimated EV manufacturing capacity following passage of the IRA and BIL, 2020-2026.]255 [EPA-HQ-OAR-2022-0829-0638, pp. 70-71]

255 Id. at footnote 253

ii. OEM Investments in EV Manufacturing

With ambitious electrification goals, OEMs are investing heavily in domestic EV manufacturing. By 2026, announced facilities alone will be able to produce about 4.3 million new electric cars and passenger trucks each year. For reference, that equals about one-third of all new vehicles sold in the U.S. in 2022.256 [EPA-HQ-OAR-2022-0829-0638, pp. 71-72]

256 "Report Finds Investments in U.S. Electric Vehicle Manufacturing Reach $120 Billion, Create 143,000 New Jobs," Environmental Defense Fund, (March 14, 2023) https://www.edf.org/media/report-finds-investments-us-electric-vehicle-manufacturing-reach-120-billion-create-143000

Here are just a few of the recent major investments that have been announced in 2023: [EPA-HQ-OAR-2022-0829-0638, pp. 71-72]

- ZETA member Tesla announced a second manufacturing plant in Nevada. The $3.6 billion facility will be focused on building their electric semi truck as well as 100GWh of battery manufacturing.257 [EPA-HQ-OAR-2022-0829-0638, pp. 71-72]

- Tesla also plans to spend upward of $770 million to expand its manufacturing facilities in Austin, Texas. The expansion will include for battery cell testing and manufacturingon-site.258 [EPA-HQ-OAR-2022-0829-0638, pp. 71-72]

- Ford plans to build 500,000 electric pickup trucks at its new $5.6 billion BlueOval City facility in Tennessee.259 The complex will also produce 40 GWh of battery cells–capable of supplying 500,000 vehicles. [EPA-HQ-OAR-2022-0829-0638, pp. 71-72]

- Ford plans to invest $1.3 billion in its Ontario plant to transition the facility to build their next-generation EVs. The facility will also assemble battery packs using cells from Ford's Kentucky battery plant.260 [EPA-HQ-OAR-2022-0829-0638, pp. 71-72]

- Toyota is investing $7.4 billion in EVs through the end of the decade.261 This includes a $2.1 billion battery plant expansion in North Carolina and an expansion of its EV assembly facility in Kentucky.262 [EPA-HQ-OAR-2022-0829-0638, pp. 71-72]

- Stellantis is planning a $155 million expansion of its three Indiana plants to produce EV drive-trains.263 This is in addition to the previously announced $3 billion in EV investment by Stellantis in the state. [EPA-HQ-OAR-2022-0829-0638, pp. 71-72]

- ZETA member Rivian is undergoing a $10 million expansion to its existing manufacturing facility in Kentucky.264 [EPA-HQ-OAR-2022-0829-0638, pp. 71-72]

- Volkswagen's Scout EV manufacturing facility in South Carolina will undergo a $2 billion investment and will be capable of producing up to 200,000 EVs each year.265 [EPA-HQ-OAR-2022-0829-0638, pp. 71-72]

- Hyundai raised its total EV investment to $28 billion over the next decade in an effort to meet its 2 million EV per year sales goal by 2030.266 [EPA-HQ-OAR-2022-0829-0638, pp. 71-72]

EPA Summary and Response

EPA acknowledges and appreciates all of the comments relating to PEV supply chain, critical minerals, and mineral security. These topics are closely interrelated, and the comments received often cover multiple aspects of these topics in varying degrees of detail. The wide diversity and volume of comments that we received on these topics represent the complexity of these issues, which we have broken down into a number of distinct themes that we individually identify and respond to in this section. Our responses to these themes collectively respond to all of the individual comments on these topics.

In general, comments in this topic area were generally concerned with issues such as the capability of global and domestic supply chains to support manufacturing of batteries and other

PEV components, the availability of critical minerals and other inputs to PEV production, and the possibility that sourcing of these items from other countries might pose a threat to national security.

Regarding the proposal's overall assessment of the supply chain, critical minerals, and mineral security, we received a variety of comments, some of which disagreed with the conclusions of our assessment and others which supported them. At the highest level, many of the concerns stated by commenters were stated as part of a broader argument that the proposed standards were too stringent; that is, that the commenter believed that the proposed standards should be weakened or even withdrawn because of their assertion that the supply chain or the availability of critical minerals could not grow fast enough to support the amount or rate of vehicle electrification that would result from the standards, or because they believed that it would create a degree of reliance on imported products that would harm national security. In contrast, other commenters supported EPA's conclusions regarding these issues and some also encouraged EPA to finalize more stringent standards, based on their view that these considerations would not prevent higher penetrations of PEV technology than anticipated in the proposal.

One major theme of the comments consisted of generalized observations about the need to develop a domestic supply chain for the inputs to PEV production. Supportive comments included recognition of the broad attention that this issue has received in the industry, and general agreement with the proposal's position that the supply chain is developing rapidly and as expected, due to market response to anticipation of increasing demand and the effect of congressional and executive action including the BIL and IRA, among other programs. These commenters often provided detailed examples of recent developments in supply chain growth and recent examples of the effect of the BIL and IRA. Adverse comments included a general citation of risk and uncertainty associated with future development of the supply chain, and with the possibility that the timeline and/or degree of BEV penetration anticipated by the proposal could not be supported by available minerals, battery manufacturing, or other aspects of the supply chain. Some specific themes among the assertions of adverse commenters were: that the proposal did not adequately address critical minerals or battery manufacturing, or was overly optimistic about the rate at which domestic minerals or manufacturing would grow; that we looked only at light-duty battery demand and not at other transportation or product sectors that use lithium-ion batteries, such as heavy-duty vehicles, stationary storage and portable devices; that the projections of manufacturing capacity did not include sufficient ramp-up time; that we should consider active material manufacturing in addition to cell manufacturing; that the proposal did not adequately address the risk associated with uncertain availability of critical minerals in the future, and in particular, that we should have quantitatively accounted for projected availability of all critical minerals rather than lithium only. Some commenters included data in their comments; for example, the Alliance for Automotive Innovation included a bespoke report by Benchmark Minerals Intelligence that examined domestic battery and mineral manufacturing capacity, and a coalition of environmental NGOs and public health organizations ("Environmental and Public Health Organizations") presented a detailed analysis of lithium availability.

Regarding our analysis of critical minerals, some commenters disagreed with our findings and others supported them. Supportive comments often pointed to examples of rapidly increasing attention to development of mineral resources in the U.S. and in nations with which the U.S. has good trade relations. These commenters also tended to emphasize current and ongoing support of the BIL and IRA in advancing such investments. Commenters who disagreed with our findings largely expressed the position that EPA did not adequately address critical minerals, or did not adequately consider the risks posed by increased demand for such products. Because mineral security is closely related to development of the domestic supply chain, comments often included references to the state of the domestic supply chain and the commenter's views on how it either is or is not advancing at a sufficient pace to allay mineral security concerns.

Regarding mineral security, some specific themes among adverse commenters were their views that the rapid growth in demand that would result from the proposal would result in either temporary or permanent reliance on nations with which the U.S. does not have good trade relations or has a large trade deficit, or would similarly result in increased reliance on imports in general. Similarly, some commenters felt that the discussion of national security in the proposal was not sufficient, pointing again to concerns about vulnerabilities resulting from a dependence on imported minerals and materials in order to manufacture vehicles or support the infrastructure they require. Some commenters specifically highlighted the possibility of increased dependence on China, which manufactures and processes much of the critical minerals and other materials commonly used in PEV manufacturing. In contrast, other commenters stated that the proposed rule would improve national security by stimulating development of the domestic supply chain, in part by providing demand certainty necessary to support investment in these areas.

Another frequent theme across many of the adverse comments was a perception of uncertainty and risk posed by supply chain, manufacturing, and critical minerals issues. These comments focused primarily on issues such as uncertainty of mineral prices and hence battery prices, or unavailability of minerals or other inputs to PEV manufacture, and more generally, to the implications of such potential developments on the ability to comply with the standards. In this context some commenters expressed the view that EPA should adopt a stringency adjustment mechanism (based, for example, on an assessment of progress in domestic critical mineral sourcing, PEV infrastructure, or other developments the commenters deem necessary to accompany increased penetration of PEVs under the standards), or else commit to revisiting the standards if it is determined that development of the supply chain, manufacturing, or critical minerals have not progressed as expected. This suggestion was often also made in the context of uncertain future progress in other external factors such as charging infrastructure, grid readiness, and similar factors (these are discussed separately in their respective sections of this RTC).

Relatedly, some commenters cited a need for complementary government policies and incentives across the various levels and branches of government to support increased market penetration of PEVs. These included, among other areas: public charging infrastructure, supply chain development, workforce training, fleet purchase requirements, support for PEV and battery recycling and end of life issues, economic and purchase incentives, consumer education, grid infrastructure, state and local measures and federal engagement with such measures, and other measures to address the cost and risk of increased PEV presence in the fleet.

Some commenters questioned our assessment that critical mineral prices and availability are likely to stabilize in the future, stating the view that factors such as rapid demand growth, international competition for resources, and adverse trade policies may prevent prices from stabilizing in the near term or even the long term. Commenters also cited the need for permitting reform and streamlining, as permitting is a major factor in the lead time necessary to develop new mineral sources. It was also suggested that the desire to source from responsible vendors that support Environmental, Social, and Governance (ESG) goals could increase the cost of purchased minerals by encouraging use of higher-cost domestic supplies. Relatedly, some commenters cited the environmental impact of developing new mines, and environmentally or socially unsound sourcing practices sometimes employed in the production of minerals in other parts of the world. Some commenters also suggested that BEVs are not an efficient use of these limited resources, and that the goals of the standards could be more effectively met with HEVs and PHEVs, which require less critical mineral content and impose less demand on infrastructure, reducing the level of risk associated with all of these issues.

Many adverse commenters expressed the view that there will not be enough critical minerals, either in the near term or the long term or both, to supply the anticipated increase in PEV penetration resulting from the standards. Some of these comments were general in nature while others referred specifically to our assessment of future annual GWh of battery manufacturing capacity which we used as a constraint on PEV penetration in the OMEGA model. They also expressed views that the timeline and/or degree of BEV penetration cannot be supported by available minerals and/or growth in domestic supplies or battery manufacturing. Some commenters expressed the view that the supply chain will not develop rapidly enough to meet the standards with the projected penetration of PEVs. These comments included positions that U.S. battery manufacturing will not ramp up fast enough, or that there is insufficient lead time for announced plants to come to full capacity, or that mining permitting and/or development of production will be too slow to meet increased demand, either globally or domestically. More specifically, in relation to the growth of the supply chain, some commenters stated the view that U.S. mineral sourcing and processing will not grow fast enough to keep pace with increasing content requirements for IRC 30D eligibility.

Some commenters stated that HEVs and PHEVs would be a better use of critical minerals than BEVs, and so EPA should have projected a greater penetration of these vehicles, or should have modeled PHEVs explicitly, and/or have adjusted inputs to result in a greater penetration of these vehicles in the compliance analysis. These commenters also stated that PHEVs and HEVs could reduce demand for critical minerals and reduce the risk associated with an uncertain future supply.

EPA has carefully considered all of the comments received. In general response to the totality of these comments, EPA notes that throughout the rulemaking process, we have taken into consideration the importance of supply chain, critical mineral, and mineral security issues as they relate to compliance with the standards. In RIA Chapter 3 and Preamble section IV, EPA acknowledges that some uncertainty exists regarding future demand and supply of minerals and mineral processing, as with any forecast of future supply and demand. We have taken them into account by evaluating their relevance and likely impact in the context of the rulemaking, and by considering evidence available in the public literature, in analyst forecasts and analyses, and through our own analyses. We have closely examined the available public literature, consulted forecasts of mineral supply, mineral cost, and future development of the supply chain as described by leading analyst firms, and assessed the general state of the industry in preparing for the demand that is already growing across the industry as well as resulting from the standards. For this final rule, we have also considered the public comments, and have also continued our consideration of the mentioned sources, as well as our ongoing consultation with industry and government agency sources (including the Department of Energy (DOE) and national labs, the

State Department, the U.S. Geological Survey (USGS), and several analysis firms). Through these latter means we have continued to collect information on production capacity forecasts, price forecasts, global mineral markets, and related topics. Importantly, we also coordinated with DOE and the National Labs, as well as with NHTSA, in their assessment of the outlook for supply chain development and critical mineral availability. The Department of Energy is well qualified for such research, as it routinely studies issues related to electric vehicles, development of the supply chain, and broad-scale issues relating to energy use and infrastructure, through its network of national laboratories. DOE worked together with Argonne National Laboratory (ANL) and coordinated this work with EPA during much of 2023. In Sections IV.C.7 of the preamble we review the main findings of this work, along with the additional information we have collected since the proposal. As in the proposal, we have considered the totality of information in the public record in reaching our conclusions regarding the influence of future manufacturing capacity, critical minerals, and mineral security on the feasibility of the final standards.

EPA has carefully considered how these factors relate to the feasibility of producing the incremental penetrations of PEVs that manufacturers may choose to produce to comply with the final standards, and to national security concerns related to critical minerals and other manufacturing inputs. The introductory text under section IV.C.7 of the preamble provides discussion of several key themes that in the proposal led us to conclude that the proposed standards were appropriate with respect to these issues, and section IV.C.7 in general explains and provides evidence for our continued assessment that the final standards, which are less stringent than the proposal in the early years of the program from MYs 2027-2031 and provide additional lead time, are also appropriate. Section IV.C.7.i of the preamble provides a general review of how we considered battery and battery component manufacturing considerations in the updated analysis, the sources we considered, and how we used this information in the analysis. Section IV.C.7.ii of the preamble examines the issues surrounding availability of critical mineral inputs. Section IV.C.7.iii of the preamble provides a discussion of the security implications of increased demand for critical minerals and other materials used to manufacture electrified vehicles. Section IV.C.7.iv of the preamble considers recycling as a source of minerals in the future. Additional details on these aspects of the analysis may be found in RIA Chapter 3.1, including 3.1.5 where we describe how we used this information to develop modeling constraints on PEV penetration for the compliance analysis.

Our updated assessment continues to support our conclusion that the stringency of the final standards is appropriate. The final standards implement a number of changes to the proposed standards and are accompanied by an updated compliance analysis, and together these developments provide additional support for EPA's assessment that the final standards are appropriate with respect to supply chain, critical minerals, and mineral security.

First, neither EPA's continued study of these issues nor the information provided in the public comments have revealed specific new information that undermines our assessment of the feasibility of the proposal. As we will discuss in the detailed responses later in this section, in general we do not find evidence in the public comments that would change our previous assessment that the observed level of investment and other activity across the global and domestic industry suggests that the industry will be well positioned to support automakers in meeting the standards. Much of the information provided by adverse commenters is of a similar nature to the information that EPA has already presented and considered in the proposal, in that they describe the same class of uncertainties associated with the future impact of mineral demand and mineral security that EPA has already considered in the proposal. Similarly, much of the information provided by supportive commenters also builds on the evidence EPA presented in the proposal about the pace of activity and overall outlook for buildout of the critical mineral supply chain. While contributing to the record, the information provided by both groups of commenters largely serves to reinforce the trends that were already identified and considered by EPA in the proposal, and largely do not identify new, specific risks or uncertainties that are not within the general scope of issues considered in the proposal. In particular, adverse comments fail to definitively identify and quantify specific and unavoidable constraints that would reasonably lead us to conclude that they cannot be addressed by the private investments, government development programs, and other industry activity that the proposal and the updated analysis shows are already underway and are continuing.[487,488] They also do not provide a specific basis for reducing the battery manufacturing GWh constraint we apply in OMEGA. Taken together, the totality of information in the public record continues to indicate that development of the critical mineral and manufacturing supply chain is proceeding both domestically and globally in a robust manner that supports the industry's compliance with the final standards, and that the likely rate of development of the domestic and global supply chain and forecast availability of critical minerals on the global market are consistent with the final standards being met at a reasonable cost and with national security goals being maintained.

Second, the central case of our updated analysis shows that the final standards can be met with significantly less demand for critical minerals than under the central case of the proposal, which is a result of several factors, including the final standards being less stringent than the proposal in the early years of the program from MYs 2027-2031, the inclusion of PHEVs which reduce the number of BEVs which have larger batteries and therefore greater minerals requirements, and updated BEV efficiency estimates. We also provide sensitivity cases and other examples that show that the standards can even be met with much lower levels of BEV penetration well below our battery manufacturing GWh constraint in OMEGA, including with no additional BEV penetration beyond that which exists today (see Sections I.B.1, IV.F and IV.G of the preamble and Chapter 12 of the RIA). Accordingly the compliance analysis indicates a reduced demand for battery production, implying reduced demand for critical minerals and supply chain development in all scenarios as compared to the proposal. Combined with our observation that private and public effort and investment in the supply chain is continuing as noted in the proposal, we find no evidence that compliance with the standards will be prevented by issues such as critical unavailability of necessary manufacturing inputs, nor that it will adversely impact national security by creating a long-term dependence on imports from adversarial countries or foreign entities of concern (FEOC) sources associated with covered nations.

Finally, although as noted previously we do not find that the public comments have identified definitive and hard constraints on the ability to meet the standards, we do note that they frequently refer more generally to uncertainty and risk associated with the possibility that such

[487] Argonne National Laboratory, "Quantification of Commercially Planned Battery Component Supply in North America through 2035," ANL-24/14, March 2024.
[488] Argonne National Laboratory, "Securing Critical Materials for the U.S. Electric Vehicle Industry: A Landscape Assessment of Domestic and International Supply Chains for Five Key EV Battery Materials," ANL-24/06, February 2024.

constraints could nonetheless develop. In addition to our response to concerns about uncertainty and risk found below, we also note that, as a normal part of our ongoing research activities, EPA will continue to study the impact of critical material cost and availability, development of the supply chain, and mineral security. As with any rulemaking, the Administrator has the discretion to propose modifications to the program through the public notice and comment process, in the case that modifications are found to be appropriate in the future to address any concrete constraints that might have developed.

In the remainder of this section we provide additional detailed responses to specific themes found in the comments.

Regarding comments that we should consider availability of critical minerals other than lithium, we have included in section IV.C.7 of the preamble and Chapter 3 of the RIA additional analysis and discussion of additional minerals such as graphite, cobalt, nickel, graphite, and manganese as well as coverage of cell components and materials, and additional coverage of lithium. Regarding comments that EPA should consider mineral demand in sectors other than light-duty automotive, the updated analysis identifies battery cell manufacturing capacity specifically for light-duty vehicles, and other aspects of the two 2024 ANL reports on battery manufacturing and critical minerals that are cited in our analysis, as well as other sources such as the BMI study on global lithium capacity, largely include consideration of the EPA heavy-duty rule and/or minerals demanded for other uses in the economy.

EPA disagrees with the Alliance comment that EPA "just assumed that lithium was the bottleneck and biggest concern." In the proposal, EPA clearly explained the reasoning for focusing particularly on lithium, which included considerations such as other minerals potentially having substitutes and the lack of a substitute for lithium. Based on its updated consideration of battery minerals and cell materials and components, including the characterizations of projected FTA, MSP, and economic ally mineral production provided in the 2024 ANL critical mineral study, EPA continues to consider lithium demand to be an appropriate basis for a GWh constraint in OMEGA modeling.

In response to comments about the need for development of the supply chain supporting the manufacture of PEVs, and about the uncertainties and risks associated with the same, EPA appreciates the additional information provided by commenters citing recent growth in the global and domestic supply chain. This information is consistent with our continued observation that development of the supply chain for PEV manufacturing inputs is receiving broad attention in the industry and is progressing in response to market forces and governmental incentives. EPA also acknowledges the arguments relating to risk and uncertainty cited by adverse commenters. Regarding these comments, EPA notes that the presence of uncertainty and risk is a common element in virtually any forward-looking analysis or plan of action. In general, in establishing appropriateness of standards, the Clean Air Act does not require that EPA must prove that every potential uncertainty associated with compliance with the standards must be eliminated a priori. It is well-established in case law that "[i]n the absence of theoretical objections to the technology, the agency need only identify the major steps necessary for development of the device, and give plausible reasons for its belief that the industry will be able to solve those problems in the time remaining. Thus, EPA is not required to rebut all speculation that unspecified factors may hinder 'real world' emission control." *NRDC v. EPA*, 655 F.2d 318, 333–34 (D.C. Cir. 1981). Thus, it is not required, nor would it be reasonable to expect, that EPA prove sufficient production capacity already exists today for technologies or inputs that are likely to be required to comply with standards in the future, nor that all potential uncertainties that can be identified regarding the development of that capacity must be eliminated. In fact, past EPA rulemakings have been technology-forcing, and so have required industry to develop and increase production of technologies for which critical inputs and production capacity were not fully developed and proven at the time. In any forward-looking analysis, uncertainty is typically approached as a matter of risk assessment, including sensitivity analysis conducted around costs, compliance paths, or other key factors. Taken as a whole, the robust set of sensitivity cases that we include in the updated analysis explore the most significant risks and uncertainties surrounding the future development of these and other issues, and show that compliance with the final standards is possible under a broad range of reasonable scenarios. Included in these scenarios are examples of pathways that would rely on fewer BEVs and more vehicles with ICE across a range of electrification (ICE vehicles, mild HEVs, HEVs and PHEVs), which would significantly reduce the demand for battery production and critical minerals.

Relatedly, in response to comments that highlight the risks associated with sourcing of minerals and processed materials from other countries, EPA understands that some inputs necessary to the production of electrified vehicle components are currently sourced from other countries. EPA notes, as discussed at length in section IV.C.7 of the preamble, that the Administration has identified a goal to advance domestic production capacity and secure supply chains for these minerals and components among FTA partners, MSP partners, and other economic allies. EPA also notes ongoing work by the Department of Energy to ensure that these materials can be recycled efficiently. We also note that use of imported materials and minerals is not unique to PEVs, but also is true for conventional vehicles, which use an array of imported and strategic materials, such as platinum and palladium for catalysts, computer chips for engine control and entertainment systems, and other parts and materials that are sourced from other countries. Materials like these were imported for use in other industries long before the recent growth in their use in electrification. While some battery chemistries include cobalt which carries environmental and other impacts depending on how it is sourced, cobalt content is being rapidly reduced and battery chemistries that do not use cobalt are already gaining market acceptance. While increased demand for critical minerals can cause costs to increase, at the same time the increased value of these materials favors their recycling, and there is little evidence to suggest that minerals that have significant market value will not provide similar incentives for recycling as other materials in the automotive sector, thus reducing demand on production from mining operations. See also our response to comments on energy security and electrified vehicles in RTC Section 21.

In response to comments that suggest that global battery production may not keep pace with demand, we continue to see evidence that global lithium-ion battery and cell production is growing rapidly and is likely to keep pace with increasing global demand. In the proposal we first noted a 2021 report from Argonne National Laboratory (ANL)[489] that examined the state of the global supply chain for electrified vehicles and included a comparison of projections of future global battery manufacturing capacity and projections of future global battery demand from various analysis firms out to 2030. The three most recent projections of capacity (from BNEF, Roland Berger, and S&P Global in 2020-2021) that were collected by ANL at that time

[489] Argonne National Laboratory, "Lithium-Ion Battery Supply Chain for E-Drive Vehicles in the United States: 2010-2020," ANL/ESD-21/3, March 2021.

exceeded the corresponding projections of demand by a significant margin in every year for which they were projected. Since the proposal, we have only seen evidence that this trend is accelerating. For example, as described in section IV.C.7.i of the preamble, more recent projections of supply have greatly exceeded the projections in the 2021 report cited above. See the discussion in Preamble IV.C.7.i after the figure titled "Future global Li-ion battery demand and production capacity, 2020-2030."

In response to comments that more time is needed for scale up of supply chains and PEV production to meet the standards, EPA disagrees. EPA notes that the final standards are less stringent than the proposal in the early years of the program from MYs 2027-2031 resulting in fewer BEVs in the central case than in the proposal, particularly in those years. We also note again the sensitivities and other examples that show that alternative compliance paths are possible that indicate lower BEV penetration and hence less demand for batteries and critical minerals (see Sections I.B.1, IV.F and IV.G of the preamble and Chapter 12 of the RIA). See also the responses to similar comments related to supply chain development throughout this section.

In response to comments that we overestimated future North American battery manufacturing capacity, or did not account for ramp up time of these facilities, or did not account for the specific use of the cells produced by manufacturing plants, EPA disagrees. Our estimates in the proposal were based on work by ANL as cited in the proposal. We note that ANL has since performed an updated study of North American battery cell manufacturing capacity[490] and we are using this study in the updated analysis. The updated study accounts for a 3-year period from beginning of production to full scale operation, based on their assessment of typical time periods experienced in new plant construction and production plans as stated by manufacturers. ANL also accounted for the intended use of the cells produced in these plants, finding that the vast majority are expected to be used in light-duty automotive applications rather than heavy-duty, stationary or consumer product applications. The updated ANL study further reinforces our assessment that automotive battery production capacity in North America is rapidly growing and is likely to meet demand in the central case of the analysis. This is consistent with the assessment provided by Benchmark Minerals for the Alliance (the "Alliance/BMI Study"), which foresees similar growth in plant manufacturing capacity, and states, "Benchmark foresees US self-sufficiency on the basis the current trend is maintained, new capacity is commissioned, and significant manufacturing credits are realized." EPA considers ANL's assessment through December 2023 to be thorough and up to date and notes that the Alliance/BMI Study was performed prior to July 2023 when it was submitted to the docket. While AFPM and API assert that "mature battery factories today rarely operate above 80 percent utilization rates," there is no indication in the cited reference[491] that this is a matter of ramp-up time or some limitation on the ability to reach full capacity, but instead appears to refer to historical rates of utilization that could just as likely reflect planning for future demand, mentioning specifically "optimism about market growth." In contrast, comments by Toyota indicate that "it takes about 4 years to reach full scale battery production," reaching 75 percent after the first year and almost 90 percent after

[490] Argonne National Laboratory, "Quantification of Commercially Planned Battery Component Supply in North America through 2035," ANL-24/14, March 2024.
[491] Xiao, M., "Lithium-ion battery production goes global," Control Engineering, January 26, 2022. Accessed on March 9, 2024 at https://www.controleng.com/articles/lithium-ion-battery-production-goes-global/

the third year.[492] While the 4-year period cited by Toyota is longer than the 3 years cited by ANL, ANL uses a linear ramp that adds capacity more slowly than the ramp shape implied by Toyota, and Toyota cites only a proprietary study by e-Source. EPA sees no reason to question the ramp rate that was determined by ANL as a result of its study and notes that due to its linear shape it is generally more conservative.

According to ANL's analysis of publicly announced cell factories in North America, as of January 2024, manufacturers in the United States could supply about 10 million new light-duty electric vehicles each year by 2030, assuming an average pack size of 80 to 100 kWh.[493] In addition, the central case of our updated compliance analysis projects a substantially lower demand for battery production than in the proposal. This is largely due to the effect of higher battery cost inputs, which reduce the penetration of BEVs in the central case, the inclusion of PHEVs which use smaller batteries than BEVs, and updated BEV efficiency inputs. After including all of these updates, projected North American automotive battery production capacity continues to meet projected demand. In the case that a shortfall were to occur, our higher battery cost sensitivity accounts for higher battery costs that might result, and as previously noted, examples of pathways that include lower BEV penetration in favor of HEVs and PHEVs would continue to exist and would place even less demand on battery production (see Sections I.B.1, IV.F and IV.G of the preamble and Chapter 12 of the RIA).

In response to comments that we should include consideration of active material manufacturing, we did consider global cathode active material manufacturing capacity in the proposal, and in the updated analysis we consider additional information regarding global and domestic manufacturing for active materials and other cell components in Preamble IV.C.7 and RIA Chapter 3. In addition to other sources, we cite the North American battery manufacturing report from ANL[494] that considered domestic manufacturing capacity for electrode active materials and other cell materials and components.

In response to comments that generally suggest that batteries and/or cells will largely be imported from other countries, we have not found evidence since the proposal that would change our observation that U.S. PEV production to date has not been particularly reliant on foreign manufacture of batteries and cells, nor that increased PEV penetration must imply such a reliance. In the proposal we noted that about 57 percent of cells and 84 percent of assembled packs sold in the U.S. from 2010 to 2021 were made in the U.S.[495,496] Continued growth in U.S. BEV sales is dominated by manufacturers such as Tesla who largely use U.S. made batteries, suggesting that this trend has continued since the cited sources were published. Considering the influence of the 45X production tax credits on the decisions of manufacturers to produce in the U.S., and our assessment that planned domestic automotive battery manufacturing capacity is

likely to meet demand under the central case, it appears likely that this trend will continue even as PEV production increases. ANL analysis suggests that North American cell production can meet projected demand through 2032.[497]

In response to comments on the potential impact of increased or highly volatile critical mineral costs on future battery costs, EPA agrees that mineral costs can pose uncertainties for predicting future battery manufacturing costs as demand for these commodities grows. This kind of potential cost impact is not unique to batteries; the same is true for critical minerals used in ICE vehicle emissions control systems, as well as other materials or components used in vehicle manufacturing generally, like semiconductors.[498] EPA acknowledges that price volatility of critical minerals and products made from them has recently affected the cost of batteries and other electrification components, as indicated, for example, by the December 2022 BNEF battery price survey that indicated battery costs had increased from 2021 to 2022. However, we also note that the most recent December 2023 BNEF survey indicates that battery costs have resumed their downward trajectory from 2022 to 2023, due in part to reduced mineral costs. In light of the most recent analyst consensus on future battery mineral prices through approximately 2029 which indicate a long period of falling and relatively stable prices, our central case battery costs appear conservative in that they are based on somewhat earlier forecasts of mineral prices that did not include this declining outlook, and omit any cost reductions through 2025 despite indications from these sources that mineral costs will be falling during that period and beyond. Therefore we consider the higher battery costs and the high and low battery cost sensitivity cases that we have included in the updated analysis as addressing these uncertainties. Further, EPA recognizes and supports efforts by the Department of Energy and the Administration to pursue initiatives that can reduce the risk associated with these materials by promoting development of the domestic supply chain and developing domestic sources for critical minerals and related technology. Many of these approaches, initiatives and programs are outlined in detail in ANL's February 2024 report on critical materials.[499] During the time frame of this rule, our assumptions for future battery costs in this final rule are consistent with projections by the Department of Energy and Argonne National Laboratory, leading analysis firms and general industry consensus. Where future costs beyond the time frame of the rule are used to determine annualized costs, we have remained conservative with respect to some projections due to these uncertainties.

In response to comments the EPA should consider the Mauler et al. study on the potential impact of mineral prices on battery costs, EPA has reviewed this study and has considered its findings in characterizing future battery costs and battery cost sensitivities within and beyond the time frame of the rule, as discussed in Preamble IV.C.2 and RIA Chapter 2. More discussion of our reference to the Mauler work and generally on battery costs and development of battery cost sensitivities can be found in those sections, and responses to comments on battery costs may be found in section 12 of this RTC.

[499] Argonne National Laboratory, "Securing Critical Materials for the U.S. Electric Vehicle Industry: A Landscape Assessment of Domestic and International Supply Chains for Five Key EV Battery Materials," ANL-24/06, February 2024.

In response to comments on the representation of increased mineral costs in BatPaC, and that the default costs of manufacturing inputs in BatPaC do not account for recent volatility or increases in mineral prices, EPA understands that prices seen in the industry have experienced a period of volatility and that price swings are difficult to represent as a set of default costs. However, our battery costs in the updated analysis do not employ the default input costs in BatPaC but instead are based on costs developed by ANL from forecasts of mineral costs provided by Benchmark Minerals Intelligence (BMI) from 2023 to 2035. According to comments from the Alliance, BMI is "a well-known, respected consultant in the area of Li-ion battery supply chains from the materials extraction to cell production stage."

In response to comments relating to the environmental impacts of increased mining for critical minerals, EPA notes that this concern applies not only to critical minerals used for PEV technology but also to all extractive activities, including oil and gas extraction which is used to provide fuel for ICE vehicles, and mining of virgin materials for numerous other products across the economy. Commenters have not established that the potential impact of incremental increases in mining activity to support PEV technology either domestically or worldwide is meaningfully different in scope or significance than other mining activities that have similar impacts. As discussed in Preamble IV.C.7 and RIA Chapter 3, EPA assesses that over the long term, recycling could significantly reduce environmental impacts that may accompany mining of virgin materials used in electrified vehicles. Additionally, EPA considered possible approaches to lessen environmental impacts from mining that may be implemented for future mining projects, including those for materials used in PEVs, including the approaches, initiatives and programs outlined in ANL's February 2024 report on critical materials.[500]

In response to comments that environmental, social and governance (ESG) considerations could impact critical mineral prices and hence battery costs, EPA agrees that some manufacturers may choose to represent these considerations in their material acquisition policies, but notes that there is little to no data to quantify the extent of this practice in the future or how it would affect material prices collectively across the industry, and the commenter did not provide such data. As noted elsewhere, our battery costs in the central case of the updated analysis are on average about 25 percent higher than in the proposal, and our high battery cost sensitivity models a 25 percent increase on top of that. The high battery cost sensitivity is meant to address the uncertain possibility of additional costs of this sort which at present are too uncertain to precisely quantify.

In response to comments that a commitment to a broad array of complementary government policies is necessary to achieve the PEV penetrations anticipated by the compliance analysis, EPA has identified a broad array of complementary policies that are oriented to this purpose. EPA notes that agency action on many of the specific policies and incentives suggested by commenters are outside the scope of this rulemaking, but we continue to monitor developments in each of these areas. It is our assessment that these areas continue to receive a large degree of attention consistent with the action of market forces and government actions necessary to address commenters' concerns. EPA notes the ongoing work of the Administration and Congress to address these areas individually and as part of an all-of-government approach, including Congressional passage of the Infrastructure Investment and Jobs Act, the CHIPS and Science

[500] Argonne National Laboratory, "Securing Critical Materials for the U.S. Electric Vehicle Industry: A Landscape Assessment of Domestic and International Supply Chains for Five Key EV Battery Materials," ANL-24/06, February 2024.

Act, and the Inflation Reduction Act. Some relevant programs include the Battery Manufacturing and Recycling Grants, Battery Material Processing Grants, Domestic Manufacturing Conversion Grants, and Advanced Technology Vehicle Manufacturing Loan Program (DOE), the 48C Advanced Manufacturing Tax Credit (DOE/DOC), and DOT's National Electric Vehicle Infrastructure (NEVI) Program and Charging and Fueling Infrastructure Grant Program. These programs are providing an unprecedented amount of federal resources and guidance to support both supply and demand for zero- and near-zero emission vehicles. EPA has also reviewed the programs, initiatives and approaches outlined in ANL's recent work on domestic battery manufacturing and critical materials and these sources provide an excellent reference for complementary policies focused both domestically and internationally.[501,502] Some commenters described the investments the auto industry and other segments of the transportation and utility sectors have made and continue to make in these areas. EPA appreciates the significance of these efforts and believes that efforts like these will continue to contribute to the advancement of clean transportation over time.

In general, although some commenters have asserted, for example, the need for "massive and coordinated" efforts on the part of "the auto industry, energy providers, mineral suppliers and the government," they do not state specifically why they feel that efforts of the sort described above either are not appropriate or fall short of what they feel is needed. For example, API states, "although Congress and the Administration have taken significant steps to accelerate this activity by funding, facilitating, and promoting the rapid growth of U.S. supply chains for these products through the IRA, BIL, and numerous Executive Branch initiatives, more will still be needed given the increase in demand." However, API does not specify what more it feels will be needed. Similarly, Toyota states that "the proposal lacks an actionable plan for translating funding and goals into specific projects" but does not state what it believes to be the elements of such a plan. Some commenters go on to suggest that the standards should therefore include an adjusting mechanism that would monitor progress in development of the supply chain, critical mineral sourcing, and other efforts and automatically adjust the stringency of the standards accordingly. EPA responds to these and similar requests for a stringency adjustment mechanism in RTC 3.3.1.

Based on the available evidence, EPA assesses that the projected level of PEV penetration indicated under the central case of the compliance analysis is consistent with trends already underway, such as the current level of sales and sales growth that is taking place, the current ramp up of charging infrastructure buildout, incentives, and other complementary policies, and the measures currently underway and planned by the industry as mentioned above and by other commenters. EPA also assesses that a wide range of actions, including investments and partnerships by the automotive industry and investments and initiatives by the federal government (for example, the Infrastructure Investment and Jobs Act that provides significant funding to the Department of Energy to promote supply chain development), indicate that (a) the automotive industry has recognized the need to establish a supply chain for electrified vehicles and is taking appropriate action to address this business need, and (b) the abovementioned federal investments and initiatives indicate that the federal government is taking appropriate

[501] Argonne National Laboratory, "Quantification of Commercially Planned Battery Component Supply in North America through 2035," ANL-24/14, March 2024.
[502] Argonne National Laboratory, "Securing Critical Materials for the U.S. Electric Vehicle Industry: A Landscape Assessment of Domestic and International Supply Chains for Five Key EV Battery Materials," ANL-24/06, February 2024.

actions to support its development. The evidence indicates that automakers are already demonstrating that they are taking appropriate steps, and that the standards adopted in this rule will encourage continued investment in supply chains by providing regulatory and market certainty.

In response to comments that EPA should implement a stringency adjustment mechanism to account for uncertainties in development of the supply chain, critical minerals, manufacturing and mineral security, comments related to a stringency adjustment mechanism are discussed in RTC 3.4.

In response to comments that HEVs and PHEVs would be a better use of critical minerals than BEVs, and that EPA should therefore have projected a greater penetration of these vehicles in the compliance analysis, EPA notes that the central case and other scenarios assessed in the compliance analysis are only projections of potential pathways for complying with the standards. Manufacturers remain free to use any combination of technologies that they find to be most effective. If, as commenters suggest, HEV and PHEV technologies are more effective and available at lower cost in the future than projected in our central analysis, or represent a more efficient use of resources that are available to a given manufacturer, the manufacturer is free to realize those benefits by doing so. Our sensitivity cases and other examples that include greater penetration of HEVs and PHEVs indicate that in such cases, compliance with the standards would remain possible.

In response to comments that the standards would cause harm to national security (including comments on the energy security and mineral security impacts of an increased penetration of PEVs), EPA disagrees. EPA first notes that we define energy security differently from mineral security, where energy security focuses on security implications of energy sourcing and mineral security focuses on security implications of critical mineral sourcing. To this end, EPA notes that the use of imported materials or minerals to build vehicles is not a direct analogy to the issue of energy security associated with use of imported petroleum, because the minerals used in production of batteries, motors, and other components are not an energy source that is consumed to power the vehicle, but rather, once supplied, remain with the manufactured vehicle for its useful life. Further, once imported, over time these materials can be recycled and thereby become a domestic source when vehicles have reached end of life. We respond to comments pertaining to energy security in RTC Section 21. Regarding mineral security, EPA finds no evidence that compliance with the standards will adversely impact national security by creating a long-term dependence on imports of critical minerals or components from unfriendly nations, or creating a vulnerability to disruption of necessary manufacturing inputs. The economic and other factors that are contributing to continued development of the supply chain today, as described previously, indicate that the industry is acting rapidly and robustly in response to anticipated demand and government development incentives to build a secure supply chain that includes both domestic sources and sources among preferred trading partners, in tandem with increasing mineral demand. Importantly, the updated analysis also projects significantly reduced battery demand in the central case and even lower demand in the more prevalent P/HEV penetration cases and other illustrative examples (see Sections I.B.1, IV.F and IV.G of the preamble and Chapter 12 of the RIA), further reducing potential exposure to these risks compared to the proposal. In fact, we assess that the final standards are likely to promote long-term national security benefits by reducing demand for petroleum, reducing the nation’s economic exposure to global price volatility of petroleum, and by providing regulatory and market certainty for the continued development of a domestic supply chain for critical minerals and clean energy technologies (as mentioned in Section IV.C.7of the preamble).

While section 202(a) does not require EPA to evaluate national security, the Administrator has nonetheless considered national security in promulgating this rule, consistent with past rulemakings.[503] Commenters raise the issue of national security implications of an increasing share of PEVs that may be driven by the standards. In response, EPA disagrees that the standards undermine national security. In fact, it is important to examine the alternative that commenters appear to be advocating, that is, that the U.S. should weaken or withdraw the standards in order to avoid an increased need for critical minerals. Under this path, business as usual would prevail, as U.S. industry would no longer be additionally motivated to meet the standards by investing in and building a secure supply chain for these products. Instead, the current prevailing industry practice of conveniently acquiring these products from the very sources that commenters identify as threats to national security would have greater incentive to continue for a longer time if not indefinitely. Indeed, as another commenter pointed out, "choosing to weaken these standards would result in the United States falling behind in the global race to develop domestic supply chains, good-paying jobs, and battery and EV manufacturing."[504] While the increased demand directly attributable to the rule would be eliminated, over the long term this may not place national security in a better position. Demand for critical minerals in the U.S. and globally is poised to grow rapidly in the coming years regardless of the existence of the standards, and failure of U.S. industry to take immediate and sustained steps to improve its position in producing and acquiring these products to address U.S. needs and to improve its competitiveness in the global market can negatively impact national security over the long run.

Regarding the comment from Western Energy Alliance that "there should be a corresponding quantification of the mineral security costs in the cost/benefits analysis of the rule," and that it would show a "huge cost to national security," EPA disagrees. EPA has separated mineral security from the traditional concept of energy security in order to relate the concept to the projections of mineral supply and demand considered in the rulemaking analysis. As discussed in section IV.C.7 of the preamble, our assessment of the available evidence indicates that the increase in PEV production projected to result from the proposed standards can be accommodated without causing harm to national security and may bring about a net benefit to national security. Commenter has not provided evidence or data to support their assertion that the rule would result in a net cost to national security or that it would exceed the projected energy security benefit of the rule.

As several commenters have noted, the domestic supply chain for critical minerals and various clean energy technologies largely lags well behind that of other countries, including China which has invested heavily in these technologies and maintains a leadership position in many of them; however, ANL analysis demonstrates that investment in the supply chain for critical minerals and batteries has expanded rapidly and is expected to continue, putting the U.S. in a better position to meet minerals and materials demand for PEVs from domestic and friendly

[503] For example, EPA has evaluated national security impacts associated with petroleum oil imports in all of our motor vehicle GHG rulemakings.
[504] Comments from Plug-In America, EPA-HQ-OAR-2022-0829-0625, pp. 1-2.

sources.[505,506] Even in the absence of the standards, development of a domestic supply chain for critical minerals and clean energy technology, which is already underway as demonstrated by the ANL reports, will be critical to maintaining national security, by maintaining competitiveness of U.S. industry as the world increasingly moves to these technologies, not just in the transportation sector but across much of the global economy. The presence of the standards therefore provides additional regulatory certainty that supports achieving this goal more rapidly than would otherwise occur, thus benefiting national security.

In response to comments that the standards should be weakened or postponed as a response to uncertainty about precise availability of minerals in the future, or the sourcing of these products, or other uncertainties related to minerals, the supply chain, or mineral security, EPA disagrees. See the discussion in section IV.C.7 of the preamble. This position is also consistent with that of leading research firms and industry analysts which regularly acknowledge the value of regulatory certainty in driving investment in their production.[507,508,509] Some commenters such as the "Environmental and Public Health Organizations" echoed this principle, stating for example, "clear regulatory signals – like EPA's vehicle emissions regulations – can create further confidence in the private sector to accelerate and expand investments." Similarly, ZETA stated, "robust EPA emissions standards will provide the regulatory certainty needed to not only ensure manufacturers continue to invest in LMDEV technologies but that the entire supply chain supporting the transition to electrification will have a clearer picture of how to plan capital expenditures today to meet the increased demand for its products over the coming years." If commenters citing concerns about national security are correct that development of a domestic supply chain for these products will be important to national security and global competitiveness of the U.S., it should also be acknowledged that it was in the absence of (i.e., prior to) this rule that U.S. domestic production capacity has lagged far behind that of China and other countries. While the domestic supply chain has already begun to develop in part as a result of rapidly growing industry attention to vehicle electrification as well as the influence of the IRA and BIL, the need to comply with the standards provides additional market certainty to improve confidence in investment in this area and is likely to lead to even faster development of the supply chain. In fact, many of the same critical minerals and the same types of production capacity are necessary not only for complying with the standards, but also for the general competitiveness of the U.S. on a global stage, at a time when the need to reduce greenhouse gases, reduce other pollutants, and produce clean energy is being recognized across the world.

The standards are thus consistent with and are likely to strongly promote the competitiveness of U.S. industry, as well as the national security benefits that accompany such an outcome.

EPA notes that the beneficial impact of CAA standards on US global competitiveness has a long pedigree. We summarized these impacts in a retrospective study of the economic impacts of the CAA mandated by Congress.[510] We generally found that peer-reviewed studies show that the Act has been a good economic investment for America. Since 1970, cleaner air and a growing economy have gone hand in hand. The CAA has created market opportunities that have helped to inspire innovation in cleaner technologies – technologies in which the United States has become a global market leader. For example, in 2018, the US environmental technologies and services industry generated approximately $345 billion in revenues and exported goods and services worth $47.8 billion, larger than exports of sectors such as plastics and rubber products. Environmental technology exports help the U.S. balance of trade, generating a $26.9 billion surplus in 2015. Air pollution control equipment alone generated revenues of $18 billion in 2008, including exports of approximately $3 billion. The size of the world market for environmental goods and services - $1.12 trillion—is comparable to the aerospace and pharmaceutical industries and presents important opportunities for U.S. industry. The final rule continues this history of EPA's environmental regulations supporting US industry and global competitiveness.

In response to comments that the standards would result in greater dependence on imports, and/or bring about geopolitical or economic disadvantages associated with such dependency (such as for example increased trade deficits), EPA disagrees. EPA acknowledges that China, and to a significant degree other countries (such as South Korea, Japan, and Indonesia), have a strong market presence or hold a leadership position with respect to the supply chain for various battery component products and various mining and processing functions related to critical minerals. EPA notes that mineral resources of all types are unevenly distributed around the world, with some countries having more naturally occurring resources of some minerals than exist in others. Similarly, some countries have invested more heavily than others in developing the resources available to them and in other countries, while others have resources but either have not invested as heavily in developing them or have discontinued production, for economic or other reasons. Accordingly, a large portion of everyday international trade is represented by trade in minerals and related products, and in some cases these minerals must be traded among countries that differ politically or economically. The U.S. has long relied on critical minerals obtained from other countries through routine international trade. For example, ICE vehicles have long relied on imported mineral products, most notably crude oil or refined crude oil products such as gasoline or diesel, and critical minerals used in catalysts. Historically, supply and cost of crude oil products have periodically created significant uncertainty for the U.S. economy and national security. The critical minerals used in emission control catalysts of ICE products, such as cerium, palladium, platinum, and rhodium, historically have also posed uncertainty and risk regarding their reliable supply. Well in advance of emission control standards of the 1970s that were premised on use of those minerals for catalyst control of pollutants, these minerals were understood to be potentially scarce and costly and to rely largely on sourcing from countries with whom the U.S. had tenuous trade relations, such as Russia and

[510] See EPA, The Clean Air Act and the Economy, https://www.epa.gov/clean-air-act-overview/clean-air-act-and-economy; EPA, Benefits and Costs of the Clean Air Act 1990-2020, the Second Prospective Study, https://www.epa.gov/clean-air-act-overview/benefits-and-costs-clean-air-act-1990-2020-second-prospective-study.

South Africa.[511] In response, over time manufacturers have engineered emission control systems to reduce the amount of these minerals that are needed, but they continue to be scarce and costly today. In this sense, the need for building a reliable supply chain for the inputs required for PEV production is similar to the need already experienced by the ICE supply chain, although for a different set of inputs. While demand for critical minerals used in PEV batteries would likely increase as a result of the standards, not all of these minerals will be imported and many can increasingly be produced domestically or secured from FTA partners and economic allies over time. EPA has reviewed and agrees with the findings of the two 2024 ANL reports that consider the current state and future outlook for the supply chain with respect to cell manufacturing and critical minerals, materials and components.[512,513] Minerals that are in fact imported also become domestic products when the vehicles that use them are recycled and the minerals reclaimed. We also note that the amount and value of critical minerals residing in a PEV for its lifetime is significantly less than the amount and value of crude oil-based fuel consumed by an ICE vehicle during its lifetime. Although some commenters have noted that the U.S. is currently a net exporter of oil, the U.S. is still a large consumer of oil. Since the price of oil is set globally, the U.S. remains largely vulnerable to events such as price shocks that affect the global oil market. Regarding comments alleging that an increased trade deficit will result from increased PEV production, EPA disagrees. Commenter did not cite specific evidence or data to show that the economic value of imports associated with PEV manufacture would necessarily increase trade deficits. Further and as noted elsewhere, EPA notes that the rule provides regulatory and market certainty for production of PEVs and related products such as batteries, battery components, and critical minerals, thereby promoting the ability of the U.S. to export these products now and in the future, offsetting the effect the commenters claim.

In response to comments that EPA should consider the costs and risks to OEMs and technology suppliers in adapting supply chains to meet the standards, particularly with respect to PEVs, EPA does in fact consider the impact of its rulemakings on various segments of the industry, including suppliers. EPA has considered the significant activity, investment, and progress that is occurring in public and private contexts to prepare the manufacturing base for PEV production at the levels of penetration anticipated during the time frame of this rule. For example, among numerous other sources as described in section IV.C.7 of the preamble and Chapter 3 of the RIA, EPA has reviewed and considered the progress and investments outlined in the March 2024 ANL reports on battery manufacturing and critical materials.[514,515] EPA considers the broad and ongoing activities outlined there and in the preamble and RIA to represent an appropriate market response to the anticipated need to meet the standards.

In response to comments relating to potential for instability in future supply, future volatility in pricing, or resiliency of the supply chain to disruption, EPA has noted elsewhere that minerals and mining have a cyclical nature and are often characterized by changes in pricing and supply as with any other cyclical market. EPA has also noted that manufacturers typically are insulated to a significant degree from volatility in spot market prices by entering into long term supply contracts, and sees no reason to doubt, as AmFree asserts, that such contracts "will continue to be offered as the demand for a limited supply of critical minerals skyrockets over the coming years." Indeed, as AFPM has noted in their public comments (see RTC section 12), "most lithium contracts are written as long-term agreements," and also makes the claim that "spot markets for battery materials are virtually non-existent," which if true would suggest that contract arrangements are standard in the industry. Further, Jeremy Michalek et al. notes that the effect of material supply disruptions on "individual automakers, and whether they experience shortages in the short-run depends on a number of factors, including the specifics of contracts in their supply chains," going on to note that "material markets, battery manufacturers, and automakers tend to respond to disruptions," and also that the rule includes "a number of flexibilities such as credit borrowing" that can help address the potential for supply disruptions rather than result in an inability to produce PEVs to comply. EPA also notes comments from Institute for Policy Integrity noting that "ICE vehicles may be susceptible to similar risks as BEVs from supply shocks due to our reliance on foreign vehicles and vehicle parts," further noting that "one-fourth of the 15,000 to 30,000 parts making up an ICE vehicle are sourced globally," and that because "ICE vehicles have far more parts and moving parts than electric vehicles […] shortages of key inputs can cause production delays and shortages."

In response to comments that permitting reform and streamlining is needed to accelerate mining development in the U.S., EPA notes that efforts are continuing across the Administration and the Department of the Interior to investigate where permitting and mining development timelines can be improved.[516,517,518] The US also has tools available, including the FAST-41 program, to improve permitting timelines and transparency. The first critical minerals project to receive FAST-41 Coverage was announced in 2023.[519] See also the discussion in section IV.C.7.ii of the preamble.

In response to comments that assert that there will not be enough critical minerals for manufacturers to comply with the standards, EPA disagrees. EPA acknowledges and appreciates the extensive report on IRA-compliant mineral and active material production conducted by

Benchmark Minerals Intelligence at the request of the Alliance (the “Alliance/BMI Study”). EPA notes that the Alliance/BMI Study’s second scenario of 100 percent BEV penetration in 2035 is beyond the rulemaking time frame of 2032 and is in excess of projected penetrations for both the proposal and the final rulemaking. EPA also notes that the Alliance describes the Alliance/BMI Study as being concerned with two questions: “(1) What is the feasibility of achieving the two demand scenarios with global supply chains; and (2) What is the feasibility of achieving these two scenarios in a manner that is compliant with the IRA 30D sourcing requirements?” However, the Alliance/BMI Study appears to only provide contextual information for the first question, and quantitatively examines feasibility only for the second question, and thus the relevance of the quantitatively derived outlooks offered by BMI in this study pertain primarily to the limited context of 30D eligibility and not to production of PEVs in general. For example, EPA does not see evidence in the Alliance/BMI Study that, as the Alliance comment asserts, “There is some risk to meeting base case demand (about half of EPA’s projected demand) even with global supply chains,” which as stated implies that BMI has concluded that global supply from all sources would not be sufficient to meet US demand alone, whereas at the same time BMI does not appear to have quantified global supply but has focused only on IRA-compliant supply. Similarly and as a further example, EPA does not find evidence in the Alliance/BMI Study for commenter’s statement that “BMI forecasts lack of upstream mining and midstream processing and cathode/anode production capacity to supply the new battery factories with the necessary battery materials,” which inaccurately suggests that BMI is identifying a hard constraint that would prevent new battery plants from operating at capacity, when the statement clearly applies only to operation using only IRA compliant inputs. Given that the Alliance/BMI Study focuses on the outlook for IRA-compliant production and not total production potentially available to the U.S. market, like much of the other mineral forecast analyses EPA has examined, it fails to definitively identify and quantify specific and unavoidable constraints that would reasonably lead us to conclude that a lack of mineral availability will prevent manufacturers from meeting the standards. First, the study focuses on IRA-compliant production, and the conclusions thus reached apply only to production of PEVs that qualify for IRC 30D and should not be misunderstood as suggesting a similar limit on production of PEVs that can contribute to compliance with the standards. That is, while domestically or FTA-sourced, non-FEOC[520] mineral content is relevant to eligibility for the 30D clean vehicle tax credit, 30D eligibility is not required for a vehicle to enter the domestic fleet and contribute to compliance with the standards. EPA thus disagrees with and finds potentially misleading the commenter’s assertion that “U.S. battery cell manufacturing and ZEV objectives are potentially limited to 15% passenger EV penetration by 2030 vs. a policy driven target of 50% for the same year,” because this statement fails to note that the cited percentage, if correct, would relate only to the fleet penetration of PEVs that are eligible for the 30D tax incentive and not to the total penetration of PEVs that can be produced and enter the fleet. To the degree that the commenter implies that 30D eligibility is an important factor in helping vehicles enter the fleet, the commenter has not considered the role of the 45W commercial clean vehicle credit in providing a similar advantage to lessees of vehicles whether or not they qualify for 30D. Second, EPA has elsewhere noted the robust rate of private investments, mining exploration, recent announcements of lithium and other mineral resource discoveries, government development programs, and other industry activity that the proposal and the updated analysis shows are already underway and are continuing. For example,

[520] FTA = free trade agreement. FEOC = foreign entity of concern, a designation used in the IRA to disqualify certain sources of content from qualifying for some tax credits.

see the discussion in preamble IV.C.7 where we review numerous sources including the February and March 2024 ANL reports that examine these issues.[521,522] EPA also notes the 45X tax credit under the IRA which provides an incentive equal to 10 percent of the production cost of critical minerals and electrode active materials in the U.S. Taken together, the totality of information in the public record continues to indicate that development of the critical mineral supply chain is proceeding both domestically and globally in a manner that supports the industry's compliance with the final standards, and that the likely rate of development of the domestic and global supply chain and forecast availability of critical minerals on the global market are consistent with the final standards being met at a reasonable cost. Further, as we have noted elsewhere, the central case of our updated analysis shows that the final standards can be met with significantly less demand for critical minerals than under the central case of the proposal, and we also provide sensitivity cases and other examples that show that the standards can be met with lower levels of BEV technology and thus lower mineral demand (see Sections I.B.1, IV.F and IV.G of the preamble and Chapter 12 of the RIA).

Regarding the Alliance's claim that "BMI forecasts North America will only be able to domestically fulfill 3.5% and 3.4% of its domestic cathode and anode demands," EPA does not find that the cited reference supports this claim. The percentages shown in the cited Figure 11 of the comment do not appear to agree with the percentages of 3.5% and 3.4% in the text, and the caption of the cited Figure appears to indicate that it depicts the percentage of global battery component supply that is provided by the U.S., and not the percentage of U.S. domestic demand that U.S. production can supply, as suggested by commenter.

In response to comments that allude to copper and aluminum posing issues similar to other critical minerals, particularly with regard to a potential shortage or that acquiring the amount of copper or aluminum needed to comply with the standards will expose the U.S. to national security risks, EPA disagrees with this view. A number of commenters suggested that demand for copper from grid development and expansion, the electric vehicle industry, charging stations, and the like would expose the U.S. to the possibility of shortages and the need to import increasing amounts of copper from hostile countries. Presently however, the majority of copper for domestic use is imported from Chile and Peru.[523] Neither country is a covered nation for purposes of the IRA, and so EPA does not regard either country as an insecure source of supply. Moreover, as documented for example in the comments of ZETA, the U.S. is developing significant copper resources; for example, cited are the currently operating Resolution Copper, Arizona project which has potential to supply up to 25 percent of the nation's copper demand, and the NewRange Copper Nickel project which commenter indicates could become one of the world's largest and lowest cost producing districts for copper, nickel, and platinum group metals. Similarly, a number of commenters suggested a potential shortage or risk exposure for aluminum due to rising demand from the sectors listed above. However, commenters have offered few specifics or references to support an impending shortage or show that demand cannot be met, and EPA sees no evidence of such a shortage; in fact, the price of aluminum has been in more or less

continual decline since it reached its peak in April of 2022. According to one analyst, “The reason for this is simple: The available supply of primary aluminum is shrinking, but the demand for that aluminum is shrinking faster, leading to a relative oversupply in the market.”[524] The closing price of aluminum at the end of February 2024 continued this trend of trading in a narrow range.[525] The U.S. produces aluminum from both primary and secondary sources, and Canada, which is an FTA partner, is one of the largest aluminum exporters to the U.S.; about 90 percent of the aluminum produced in Canada is exported to the U.S.[526] EPA does not see evidence that availability of aluminum or copper will prevent the standards from being met or pose a risk to economic or national security. For discussion and responses to comments relating to the power sector and electrical grid, see section IV.C.5 of the preamble and RTC section 18.

In response to comments related to rare earths used on magnets for electric machines, EPA does not anticipate shortages or high prices in rare earth metals that would prevent compliance with the standards, as indicated by evidence of a gradually increasing but apparently stable price outlook for rare earths used in magnets, and a generally declining outlook for other rare earths, during the time frame of the rule.[527] EPA has reached similar conclusions regarding electrical steel, and we discuss the outlook for electrical steel in detail in section 12.2.3 of this Response to Comments document.

In response to comments expressing the view that IRC 30D-compliant critical mineral sourcing and processing will not grow fast enough to keep pace with increasing content thresholds for 30D eligibility, EPA agrees that the near term outlook for most critical minerals, except for lithium, does not suggest that IRA-compliant mineral content will be sufficient for every U.S. PEV to qualify for the full 30D credit, particularly in the near term.[528] However, this does not mean that there will not be a substantial portion of vehicles that do qualify. Further, EPA notes that 30D eligibility is only one factor that can contribute to facilitating manufacturers’ adoption of PEV technology, and that other factors are also influential. In particular, 45W is not subject to mineral sourcing requirements and can provide many manufacturers similar utility to 30D in terms of making their vehicles financially attractive to consumers, for example, when vehicles are purchased for commercial use including leasing to consumers. EPA also notes that the Department of Energy has performed an analysis that indicates a substantial amount of credit can be captured on average through vehicles that qualify for 30D and others that qualify for 45W.[529] We discuss this study in section IV.C.2 of the Preamble where we discuss our assumptions for IRA credits. It is also important to note that the 45X production tax credits for U.S. production of cells and modules are not subject to mineral sourcing requirements. 45X also includes a tax credit for 10 percent of the production cost of U.S.-made critical minerals and

electrode active materials. Thus 30D is only one component of an array of incentives that collectively facilitate manufacturers' ability to adopt PEV technology to comply with the standards.

Regarding comments that suggest that EPA has not considered the benefits of domestic production and the value of facilitating and accelerating such production, EPA disagrees. We have clearly acknowledged the importance of other government programs such as BIL, IRA, and the various funding mechanisms through DOE, among many others. These programs and mechanisms are discussed at length in RIA Chapter 3 and in IV.C.7 of the Preamble. For example, results thus far of many of these programs can be found in the March 2024 ANL reports[530,531] which are reviewed there.

In response to a comment about emission impacts of long distance transportation of minerals and components, the commenter has not offered evidence or data as to how the supplies needed for PEV production are any different from the supplies already transported for ICE vehicle production, or the products and merchandise that are already transported long distances for other purposes or for use in other products. It is no less likely that over time, the growth in domestic production capacity resulting from the increased demand and market certainty created by the standards will serve to reduce emissions from long-distance imports of such materials. EPA also notes that our mobile source emissions standards under Clean Air Act 202(a) are not based on life-cycle analysis. For response to comments relating to life-cycle analysis and emissions in other parts of the economy or the world, refer to RTC 19 where we discuss life cycle analysis.

Regarding comments alluding to child labor or other abuses said to take place in the supply chain for batteries, which appear to primarily refer to cobalt production in the Democratic Republic of Congo (DRC), EPA reiterates that manufacturers are continuing to reduce cobalt content, and proven battery chemistries that do not use cobalt such as lithium-iron phosphate are already in widespread use globally and are increasing their market share in the U.S. Further, although the DRC supplies about 70 percent of global cobalt production, only a relatively small portion of cobalt produced in the DRC (estimated variously at between 10 to 30 percent) is produced in artisanal and small-scale mines (ASM) that are associated with use of child labor.[532,533,534,535] Overall, the global share of cobalt believed to come from ASM sources is

approximately 10 percent and is largely exported to China.[536,537] According to BMI, the share of ASM supply increases when prices are high, and in a May 2023 report stated that recent declines in cobalt prices had caused ASM supply to fall by "more than 50% from the peak."[538] Although business practices and standards for ethical conduct of suppliers in other countries are out of scope for this rulemaking, EPA notes that the Department of Labor operates the COTECCO project[539] which "works to address child labor in the Democratic Republic of the Congo's (DRC) cobalt supply chain, with a focus on artisanal and small-scale mining," supporting the development and implementation of "strategies to reduce child labor and improve working conditions in artisanal and small-scale mines, as well as in the broader cobalt supply chain."

Regarding comments from AFPM and AmFree related to declining mineral quality or ore quality, commenters have cited concepts that are well understood in the mining industry and have not provided data or evidence to indicate that declining quality will be a major factor in future mineral prices that is not already taken into account by forecasts of leading analyst firms. EPA's updated analysis uses estimates of future battery costs that incorporate mineral price forecasts from BMI, a respected analysis firm cited by many other commenters. Such forecasts are based on expert knowledge of the mining industry and consider a wide range of factors that are commonly expected to drive mineral prices in the future. Regarding the comment from John Graham that "mining specialists have dismissed such forecasts because of systematic errors in their methods," the cited reference[540] appears only to describe one analyst's opinion regarding the market consensus on lithium pricing specifically, and gives no indication that it represents the analyst's opinion about all analyst forecasts in general nor that such a position would be a commonly held view.

Regarding a comment from MEMA that EPA should "consider added costs for post-warranty battery pack replacement to the RIA to capture critical mineral demands resulting from second and third owners who may have to replace/repair aged batteries after buying a used BEV," EPA disagrees. See the responses to comments on battery replacement in RTC 12.2.5.

By means of our updated analysis and additional discussions and responses found in section IV.C.7 of the preamble, RIA Chapter 3 and elsewhere, we have addressed other topics raised by commenters, including but not limited to: the time necessary to permit and approve new mines, the need for investment to increase production of batteries and minerals, the role of China as a dominant player in the supply chain, the uneven distribution of minerals and processing facilities around the world, the availability of minerals and components from FTA nations and economic allies, the effect of lower mineral prices on future investment in mining, mineral quality, claims that government efforts and/or industry effort to build the supply chain or support PEVs are

insufficient, growth in battery manufacturing, sensitivity of the supply chain to disruption, and mineral security, in addition to other specific topics addressed there and/or in this section.

For response to comments that battery recycling will not come online fast enough to help with critical mineral demand, or other topics relating to battery recycling, please see the next section. Comments related to the cost of electricity to manufacture batteries are addressed in RTC 12.2.1. Additional responses to topics relating to the supply chain, critical minerals, and mineral security may be found in section IV.C.7 of the preamble.

For response to portions of the cited comments that include references to the following topics, see the indicated RTC sections or related discussion in the preamble: inclusion of PHEVs in the analysis, RTC 12.2.4; critical minerals and IRA assumptions, RTC 12.4; electrical steel, RTC 12.2.3; life-cycle analysis and/or upstream or manufacturing emissions, RTC 3.1.5 and RTC 19; employment impacts, RTC 20; energy security, RTC 21; consumer choice, affordability, or aspects of EV utility, RTC 13; battery replacement, RTC 12.2.5; or other sections that correspond to a specific topic.

15.2 - Battery recycling

Comments by Organizations

Organization: Alliance for Automotive Innovation

Additionally, recycling will not be able to satisfy society's rising demand in the near term. The current small EV market share coupled with EV batteries' long lifespan (on average between 10- 20 years59) suggests that society will not likely be able to meet the rising demand for critical minerals through recycling. [EPA-HQ-OAR-2022-0829-0701, p. 42]

59 Moscaritolo, A. (2022, June 29). EV Batteries 101: Degradation, Lifespan, Warranties, and More. PCMAG. https://www.pcmag.com/news/ev-batteries-101-degradation-lifespan-warranties-and-more

F. Other Costs of Electric Vehicles

1. Battery Recycling

It is reassuring that the Biden administration has allocated $125 million for a DOE program to advance lithium-ion battery recycling.454 Without such a program, China may be the country best positioned globally to capture the lithium recycling business, as it already has one battery recycling plant in operation and plans to build several more overseas. In summary, for the next decade or so, the shift from recycling of engines and transmissions to the recycling of lithium ion batteries is expected to impose a net cost on the U.S. economy. That cost should be included in the final regulatory impact analysis in conjunction with estimates of how the cost of battery recycling might decline with appropriate supporting policies (e.g., R&D support). [EPA-HQ-OAR-2022-0829-0701, p. 292]

454 hsps://www.energy.gov/articles/biden-harris-administration-announces-192-million-advance-battery-recycling- technology

Organization: American Free Enterprise Chamber of Commerce (AmFree)

EPA asserts that the United States will be able to bolster supply significantly by recycling minerals from spent batteries that enter the domestic market. See 88 Fed. Reg. at 29,323–24. That hope is also misplaced, especially given the proposed rule's compressed timeline. Electric-vehicle batteries cannot be recy- cled until they are retired. According to the International Energy Agency, based on "the dates of expected retirement of EV fleets and their battery chemistry compositions," recycled minerals will be able to supply less than 1 percent of projected global demand for lithium, less than 1 percent of global projected de- mand for nickel, and only 2 percent of global projected demand for cobalt by 2030. Global Supply Chains at 60. And even if those numbers increase over time, many steps will need to be taken before American companies can effectively enter the recycling space. That includes establishing "protocol or industry best practices" on how to collect and transport spent batteries to a recycling center, navigating the "increasingly complex disassembly" process, and entering ear- lier phases of the manufacturing cycle where the recycled materials can actually be used. White House Report at 106, 109–11. "[W]ithout critical material re- fining and processing and battery manufacturing capacity, the captured mate- rials from recycling end-of-life batteries will be exported for processing at for- eign facilities and re-imported in the form of processed or manufactured prod- ucts." Id. at 111. [EPA-HQ-OAR-2022-0829-0683, pp. 40-41]

Organization: American Fuel & Petrochemical Manufacturers

EPA suggests that improvements in recycling rates and enhancing recovery technologies at mines will reduce the need to develop new critical mineral sources. But this statement is misplaced. Recycling technologies for EV batteries remain nascent and cannot scale at a rate fast enough to alleviate supply shortages in the timeframe of the Proposed Rule. Moreover, even if those technologies develop at a faster than expected pace and commercial scale facilities are constructed, there will not be enough batteries to recycle to make the slightest dent in the quantity of critical minerals needed to build out EPA's projected battery demand (see Section I.A.1 for discussion of lack of critical minerals for batteries). [EPA-HQ-OAR-2022-0829-0733, p. 39]

Another critical aspect of the Proposed Rule not comprehensively considered is that recycling of the battery and related electrical components of ZEVs is in a state of infancy and poses unique materials handling and safety challenges. EPA should consider the environmental profiles of both ZEVs and ICEVs in light of the production, operation, and disposal of the vehicle (its useful life). The following list provides just some of the electric battery disposal-related issues that are likely to impact the environment and need to be addressed by EPA in the Proposed Rule:

- Battery packs could contribute 250,000 metric tons of waste to landfills for every 1 million retired ZEVs.212 [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

212 Kelleher Environmental, "Research Study on Reuse and Recycling of Batteries Employed in Electric Vehicles: The Technical, Environmental, Economic, Energy and Cost Implications of Reusing and Recycling EV Batteries", (September 2019) available at https://www.api.org/oil-and-natural-gas/wells-toconsumer/fuels-and-refining/fuels/vehicle-technology-studies.

- Less than five percent of Li-ion batteries, the most common batteries used in ZEVs, are currently being recycled "due in part to the complex technology of the batteries and cost of such recycling."213 [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

213 Gavin Harper, Roberto Sommerville, et al., NATURE, "Recycling lithium-ion batteries from electric vehicles" (Jan. 21, 2020) available at https://www.nature.com/articles/s41586-019-1682-5.

- Economies of scale will play a major role in improving the economic viability of recycling, for which currently cost is the main bottleneck. Increasing collection and sorting rates is a critical starting point.214 [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

214 IEA Report 2022

- The cathode is where most of the material value in a Li-ion battery is concentrated. Currently, there are numerous cathode chemistries being deployed. Each of these chemistries needs to be known, and then the appropriate method of recycling identified, which poses a challenge, as batteries pass through a global supply chain and all materials are not well tracked. [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

- Lithium can be recovered from existing Li-ion recycling practices but is not economical at current lithium prices. [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

- BMI forecasts that near-term recyclers are likely to use scrap material from the increasing number of gigafactories coming online versus used electric vehicle batteries. Scrap is anticipated to account for 78 percent of recyclable materials in 2025.215 [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

215 Benchmark Minerals Intelligence, "Battery production scrap to be main source of recyclable material this decade" (Sept. 5, 2022) available at https://source.benchmarkminerals.com/article/battery-production-scrap-to-be-main-source-of-recyclable-material-this-decade.

- In 2022, BMI expected over 30 gigawatt hours of process scrap to be available for recycling, growing ten-fold across the next decade. Loss rates vary by region and tend to be higher in earlier years of a gigafactory.216 [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

216 Id.

- Many 'spent' EV batteries still have 70-80 percent of their capacity left, which is more than enough to be repurposed into other uses such as energy storage and other lower- cycle applications for approximately another 10 years.217 This will extend the time that batteries and raw materials remain in use and therefore increase the demand for virgin critical minerals. [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

217 Pagliaro, M. and Meneguzzo, F., "Review Article: Lithium battery reusing and recycling: A circular economy insight," Heilyon 5: E01866 (June 15, 2019) available at https://doi.org/10.1016/j.heliyon.2019.e01866

- Clear guidance on repackaging, certification, standardization, and warranty liability of spent ZEV batteries would be needed to overcome safety and regulatory challenges reuse poses at scale.218 [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

218 IEA Report 2022.

- Recycling ZEV batteries to recover high-value metals has not been proven to a commercial scale. The majority of analysts are aligned that recycling will not become an integral supplier of raw materials until the 2030s, and at that point, only will provide approximately 20 percent of demand.219 [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

219 Benchmark Minerals Intelligence, supra at n. 105.

- Unlike ICEVs, EPA has recently stated that ZEV batteries may need to be handled as hazardous waste, further driving up the cost of such recycling efforts.220 [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

220 Letter from Carolyn Hoskinson, Director, EPA Office of Resource Conservation and Recovery, "Lithium Battery Recycling Regulatory Status and Frequently Asked Questions," (May 24, 2023).

- Whether sufficient recycling capacity can be permitted and constructed to facilitate the Proposal. [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

EPA must, therefore, conduct a full LCA to compare all environmental impacts to reasonably conclude that the Proposal will decrease environmental impacts rather than merely shift them. [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

Organization: American Petroleum Institute (API)

V. Recycling of batteries and related electrical components is in its infancy.

Another critical aspect to be considered with this proposal is that recycling of the battery and related electrical components of BEVs are in a state of infancy and poses unique materials handling and safety challenges. The environmental profiles of both BEVs and ICEVs should be considered in light of the production, operation, and disposal of the vehicle (its useful life). Electric battery disposal-related issues are likely to impact the environment and need to be addressed in EPA's proposal: [EPA-HQ-OAR-2022-0829-0641, pp. 39-41]

- Battery packs could contribute 250,000 metric tons of waste to landfills for every 1 million retired BEVs.102 [EPA-HQ-OAR-2022-0829-0641, pp. 39-41]

102 Kelleher Environmental. https://iea.blob.core.windows.net/assets/?d2a83b-8c30-4e9d-980a-52b6d9a86fdc/TheRoleofCriticalMineralsinCleanEnergyTransitions.pdf.

- The cathode is where much of the material value in a Lithium-ion battery is concentrated. Currently, there are numerous cathode chemistries being deployed. Each of these chemistries needs to be known, and then the appropriate method of recycling identified, which poses a challenge, as batteries pass through a global supply chain and all materials are not well tracked. [EPA-HQ-OAR-2022-0829-0641, pp. 39-41]

- Lithium can be recovered from existing Lithium-ion recycling practices, but it is not economical at current lithium prices. Cobalt, one of the highest supply risk materials for BEV in the short- and medium-term, is currently being profitably recovered. [EPA-HQ-OAR-2022-0829-0641, pp. 39-41]

- Benchmark forecasts near-term recyclers are likely to use scrap material from the increasing number of gigafactories coming online versus used electric vehicle batteries. Scrap material is anticipated to account for 78 percent of recyclable materials in 2025.105 [EPA-HQ-OAR-2022-0829-0641, pp. 39-41]

105 BMI (see Chart 8): https://source.benchmarkminerals.com/article/battery-production-scrap-to-be-main-source- of-recyclable-material-this-decade.

- In 2022, Benchmark expected over 30 gigawatt hours of process scrap to be available for recycling, growing ten-fold across the next decade. Loss rates vary by region and tend to be higher in earlier years of a gigafactory.106 [EPA-HQ-OAR-2022-0829-0641, pp. 39-41]

106 BMI: https://source.benchmarkminerals.com/article/battery-production-scrap-to-be-main-source-of-recyclable- material-this-decade.

- EV batteries are high-cycle batteries and are made to function for approximately 10 years, shorter time for a medium-duty vehicle. Many ‘spent’ EV batteries still have 70-80 percent of their capacity left, which is more than enough to be repurposed into other uses such as energy storage and other lower-cycle applications.107 This will extend the time that batteries and raw materials remain in use. [EPA-HQ-OAR-2022-0829-0641, pp. 39-41]

- Clear guidance on repackaging, certification, standardization, and warranty liability of spent EV batteries would be needed to overcome safety and regulatory challenges reuse poses at scale.109 [EPA-HQ-OAR-2022-0829-0641, pp. 39-41]

109 Ibid.

• Recycling BEV batteries to recover high-value metals has not been proven at commercial scale. Many analysts are aligned that recycling will not become an integral supplier of raw materials until the 2030s, and at that point, only will provide approximately 20 percent of demand.110 [EPA-HQ-OAR-2022-0829-0641, pp. 39-41]

110 BMI: https://source.benchmarkminerals.com/article/battery-production-scrap-to-be-main-source-of-recyclable- material-this-decade.

Organization: Charles Gordon

The proposed rule is intended to lead to the more rapid electrification of automobiles. Five hundred million cars, each with 1000 pounds of batteries will result in 500 billion pounds of batteries. What unexpected consequences will be caused by the manufacture, use and disposal of 500 billion pounds of batteries. [EPA-HQ-OAR-2022-0829-0747, p. 7]

Organization: Delek US Holdings, Inc.

In reality, only five percent of lithium-ion batteries for BEVs are currently recycled.48 In contrast, 99% of lead-acid batteries are currently recycled.49 Despite recognizing the novel nature of lithium-ion battery recycling (as well as other critical minerals used for ZEVs), EPA's analysis falls short in examining the broader impacts of its proposal—on energy independence, national security, and emissions of criteria pollutants.50 [EPA-HQ-OAR-2022-0829-0527, p. 10]

48 Robert Rapier, FORBES, "Environmental Implications of Lead-Acid and Lithium-Ion Batteries" (Jan. 19, 2020), available at https://www.forbes.com/sites/rrapier/2020/01/19/environmental-implications-of-lead- acid-and-lithium-ion-batteries/?sh=67ec3fe57bf5.

50 Proposed Rule at 29,319, 29,323–24.

d. BEVs cannot be recycled at the same level of ICE-powered vehicles.

EPA asserts that "minerals become part of the vehicle and have the potential to be recovered and recycled."46 This not only ignores the recycling capabilities of lead-acid batteries used in ICE vehicles, but also the limited capabilities to recycle lithium-ion batteries. The Proposed Rule once again relies on vague predictions of the future to support its unrealistic standards. For example, EPA asserts that a "growing number of private companies are entering the battery recycling market," "manufacturers are already reaching agreements to use these recycled materials for domestic battery manufacturing."47 But this is hardly sufficient to support EPA's proposal to entirely overhaul the ICE vehicle market in as few as four to seven years. [EPA-HQ-OAR-2022-0829-0527, p. 10]

46 Proposed Rule at 29,323.

3. Design for disassembly holds promise for battery recycling.

The battery design parameters listed in the Proposal, which EPA used to develop battery cost estimates, see 88 Fed. Reg. at 29299, do not include design for disassembly (Dfd), also referred to as design for recycling or design for reuse. Dfd involves factoring end-of-life into the design of the vehicle, meaning that the battery is designed to be taken apart so that cells and modules can be refurbished, reused, or replaced, or so that the battery can be more efficiently and safely disassembled for recycling. This disassembly is typically a difficult, lengthy, and therefore expensive process because Dfd is not included in the design phase.409 [EPA-HQ-OAR-2022-0829-0759, p. 151]

409 CalEPA, Lithium-ion car battery recycling advisory group report (2022), https://calepa.ca.gov/lithium-ion-car-battery-recycling-advisory-group/ (last accessed June 29, 2023).

As reuse and recycling becomes more prevalent and policies begin to require it, we expect that Dfd will also be more common. If Dfd occurs, more reuse, refurbishment and replacement will occur and batteries will have a longer lifespan, therefore reducing the amount of new batteries necessary for electrification.410 The disassembly of a battery from a vehicle and down to the cell level currently represents approximately a third of light-duty vehicle recycling costs in the United States.411 If Dfd occurs, this recycling cost will also decline, therefore leading to more prevalent recycling and greater availability of recycled supply. [EPA-HQ-OAR-2022-0829-0759, p. 151]

Organization: International Council on Clean Transportation (ICCT)

Battery re-use and recycling will be important to limit unnecessary mining and domestically maintain critical materials needed for new batteries.28 Several automakers – BMW, Ford, Geely, General Motors, Honda, Hyundai-Kia, Stellantis, Tesla, and Toyota – have announced one or more battery recycling or repurposing project in the United States.29 Figure 2 shows draft ICCT estimates of how the installed U.S. recycling capacity as of 2022 and the announced 2030 capacity compares with the projections for end-of-life batteries that could become available for recycling in the U.S. It shows that the installed capacity in 2022 (76,000 tons) is sufficient to process end-of-life batteries up to the year 2035. When also considering the recycling plants announced as of 2022, bringing the total recycling capacity to 325,000 tons, sufficient capacity is available to recycle end-of-life batteries until 2039. After which, much more recycling capacity is needed as the mass of end-of-life batteries becoming available for recycling increases swiftly between 2030-2050. Not shown in this figure are the additional tons of material from battery production scrap that become available for recycling. [EPA-HQ-OAR-2022-0829-0569, pp. 10-11]

Organization: MECA Clean Mobility

EPA should harmonize battery labeling requirements with ACC II to facilitate recycling.

MECA believes that mandated standardized battery labeling requirements to identify the chemistry and technology in the battery pack will facilitate in-use vehicle service and end-of-life battery recycling. Towards this goal, EPA should align battery labeling requirements with those required under California's ACC II light-duty regulation. We have previously noted that some important designations to consider on the label might include: cell type, chemistry, battery ratings (V, Ah, kWh etc.), and if any internal cooling or other fluids and hazardous materials are present within the battery pack to facilitate end-of-life handling. Such labeling will protect the environment, benefit repair, maintenance and recycling personnel as well as assist second life re-applications of automotive batteries and battery recycling. EPA could also consider incentive programs that support the implementation and continuous improvement of battery re-use and recycling and sustainable use of strategic battery materials. [EPA-HQ-OAR-2022-0829-0564, pp. 33-34]

Organization: MEMA, The Vehicle Suppliers Associated

MEMA urges:

- EPA to add battery recycling and disposal costs to the analysis as part of a sustainable BEV deployment to better address scarcity of critical minerals, provide a more resilient domestic supply chain, and over time reduce the added carbon impact of battery manufacturing and associated multi-national logistics. [EPA-HQ-OAR-2022-0829-0644, pp. 12-13]

Organization: Tesla, Inc.

EPA should also consider that recycling of battery material will play a vital role in alleviating some pressure on the need to develop new critical mineral resources. To that end, Tesla seeks to reduce its reliance on primary mined materials and contribute to a more positive environmental footprint through battery and cell recycling – including ensuring that none of our batteries (manufacturing scrap or fleet returns) go to landfills and deploying equipment to recycle 100% of on-site generated manufacturing scrap across manufacturing facilities. In comparison to BEV batteries, it should also be noted the energy source for ICE vehicles – fossil fuels used in combustion – is not recyclable. [EPA-HQ-OAR-2022-0829-0792, p. 36]

Organization: The Aluminum Association

Material Circularity in Support of Domestic Supply Chains is Crucial and Goes Well Beyond Batteries [EPA-HQ-OAR-2022-0829-0704, pp. 10-11]

EPA recognizes the importance of battery recycling in the proposed rule (88 FR 29323) and according to a recent study14, aluminum accounts for over 18% of the mass in a typical vehicle electric battery. Reclamation and recycling of this aluminum at battery end of life can serve as an important and needed feedstock for future battery and other raw material supply. Beyond batteries, EPA should build on the importance of reclamation and recycling to focus on additional components of the vehicle that can help support efficient vehicle development in the future, such as aluminum. Aluminum has long been recognized as a critical mineral and material for the low carbon economy of the future by agencies as varied as the USGS15, the Department of Commerce16, the Department of Defense17, and the Department of Energy18. Given this criticality and the fact that much of the primary (virgin) aluminum supply chain lies outside of the U.S. for such operations as bauxite mining, alumina refining, and smelting, domestic recycling is becoming increasingly important for the U.S. aluminum industry and its biggest consuming market, transportation applications. In addition to its supply chain value, recycling aluminum makes good environmental sense in that recycling aluminum is 95% less carbon intensive than producing primary aluminum from mined ore. Member companies, the Association itself, and automotive OEMS currently have a variety of active initiatives to keep pre-consumer scrap aluminum in closed loops for recycling and to reclaim more post-consumer scrap aluminum back into the supply chain at vehicle end of life. For example, Ford recycles as much as 20 million pounds of aluminum stamping scrap per month. This is equivalent to enough aluminum to build 30,000 F150 bodies every month19. Although these current initiatives are predominantly focused on vehicle structure and powertrain applications such as structural extrusions, body sheet, castings, and forgings, there is increasing recognition of the value of the aluminum in BEV batteries as well and the need to recycle that material at battery end of life. [EPA-HQ-OAR-2022-0829-0704, pp. 10-11]

ii. Recycling

A key component for meeting the coming demand for EV batteries and critical minerals will be recycling existing batteries at their end-of-life (EOL). As shown in Figure 8, North American battery recycling capacity is growing rapidly and as it increases in the coming years, so too will available EOL battery feedstocks as EVs on the road today will approach the end of their useful life. [EPA-HQ-OAR-2022-0829-0638, pp. 41-43]

[See original comment for Figure 8. Battery recycling projects in North America (as of May 2023)]184 [EPA-HQ-OAR-2022-0829-0638, pp. 41-43]

184 “Battery Recycling in North America as of May 2023,” Battery-News.de, (May 5, 2023) accessed June 26, 2023 https://battery-news.de/index.php/2023/05/05/batterie-recycling-in-nordamerika/

In recognition of the potential solutions that battery recycling can provide, Congress required EPA under the Bipartisan Infrastructure Law to develop battery recycling best practices and battery labeling guidelines. Congress allocated $10 million and $15 million respectively to the agency to complete these tasks by September 30, 2026.185 While there will likely be more work needed, potentially through voluntary consensus standards bodies, a framework is beginning to take shape to ensure increased recycling capacity is built out in the coming years. [EPA-HQ-OAR-2022-0829-0638, pp. 41-43]

185 See Public Law 117-58

The global market for EV battery recycling alone is estimated to reach $17.1 billion by 2030.186 By 2025, Benchmark Minerals Intelligence forecasts that scrap will account for 78% of the pool of recyclable materials.187 This growth is largely driven by the growing number of EVs approaching EOL. The volume of EOL batteries from EVs and large storage applications is less than 2 GWh today but could reach 100 GWh by 2030 and 1.3 TWh by 2040.188 [EPA-HQ-OAR-2022-0829-0638, pp. 41-43]

Below is a list of recently-announced investments in EV battery recycling, all of which will help support the transition to an electrified transportation sector: [EPA-HQ-OAR-2022-0829-0638, pp. 43-44]

- In October 2022, ZETA member Princeton NuEnergy Inc. (PNE) opened a new 500 t/a plant capable of direct recycling lithium-ion consumer electronics and EV batteries with its strategic partner, Wistron GreenTech in McKinney, Texas.189 This end-to-end facility ingests end of life batteries fully separating copper, aluminum, plastics, electrolyte, cathode and anode materials. Cathode materials are cleaned by surface etching with low-temperature plasma (LPAS™) and reformed into new cathode materials equivalent to OEM specifications that can be directly reused in battery production. The factory will be certified and commissioned in 2023. In April 2023, Princeton NuEnergy launched a US Department of Energy $12M R&D grant to expand and enhance PNE’s battery recycling production processes through ‘up-cycling’ of legacy spent cathode chemistries into newer formulations, scaling processes for direct recycling of anode materials, and enhancing recycling/reuse of all other battery components.190 [EPA-HQ-OAR-2022-0829-0638, pp. 43-44]

- In April 2023, ZETA member Redwood Materials announced a pair of partnerships to collect EOL battery feedstocks. This announcement builds on Redwood's announcement from November 2022 to recycle Panasonic's cell scrap and supply Panasonic with recycled copper foil and cathode active material.191 Rad Power Bikes will provide Redwood with e-bike batteries when they reach the end of their lifespan.192 Redwood and Volkswagen of America expanded their partnership to collect more EOL batteries from consumer electronics.193 Both announcements come following a historic announcement from the Department of Energy of a $2 billion conditional loan to Redwood to support its McCarran, NV recycling facility.194 At full production capacity, the McCarran project's anode copper foil and cathode active material output is anticipated to support the production of more than 1 million EVs per year. [EPA-HQ-OAR-2022-0829-0638, pp. 43-44]

- In May 2023, ZETA member Li-Cycle announced a partnership with Glencore to build a battery recycling hub in Portovesme, Italy, with construction expected to commence in late 2026 to early 2027. Once completed, the Portovesme Hub is expected to have processing capacity of up to 50,000 to 70,000 tons of black mass annually, or the equivalent of up to 36 GWh of lithium-ion batteries.195 [EPA-HQ-OAR-2022-0829-0638, pp. 43-44]

EPA Summary and Response

EPA acknowledges and appreciates all of the comments relating to issues surrounding battery recycling. In general, comments in this topic area were concerned with the potential for lithium-ion automotive PEV batteries to be recycled, the possibility that the recycling industry will provide recycled minerals to the supply chain, and the rate at which recycling of these minerals will grow.

Some commenters expressed positive views of battery recycling as a potential source of minerals that could substantially reduce the need for imported minerals or expanded mining of virgin materials. For example, ICCT stated, “Battery re-use and recycling will be important to limit unnecessary mining and domestically maintain critical materials needed for new batteries,” and went on to cite several automakers that have announced battery recycling or repurposing projects in the U.S. Similarly, Tesla stated, “recycling of battery material will play a vital role in alleviating some pressure on the need to develop new critical mineral resources.” ZETA stated, “A key component for meeting the coming demand for EV batteries and critical minerals will be recycling existing batteries at their end-of-life.” Other commenters expressed skepticism that recycling could meet the future demand for minerals or could not grow fast enough to make a meaningful impact in at least the near term.

EPA acknowledges the many challenges that exist in building battery recycling infrastructure and in recycling batteries themselves. These challenges are well known throughout the industry and are being addressed by companies who are developing business models based on battery recycling. In discussing the potential for recycling to supplement importation or mining of new materials over time, EPA has not relied upon an expectation of any specific amount of future recycling in order to justify its standards, and has already acknowledged in the proposal, and in this final rule, that it will take time for the recycling stream of used PEV batteries to reach scale as increasing numbers of PEVs reach the end of their useful life. EPA notes that to the degree that second life use of batteries for applications such as grid storage may delay these batteries from entering the recycling stream, this would also imply that demand for new grid storage batteries would decline by a similar amount and therefore is unlikely to represent a net increase in mineral demand.

In response to comments that only less than 5 percent of lithium-ion batteries are currently recycled, EPA disagrees that this statistic is relevant to the prospect for future recycling rates of automotive lithium-ion batteries, as it is based on recycling rates of small batteries used in consumer electronics and similar products, which are not systematically collected for recycling due to their extreme diversity of form and product integration and their small size. The much larger size of PEV batteries facilitates the economics of collection and recycling. Additionally, given the long life spans of PEV batteries, mass retirements of PEV batteries are not expected in the immediate near term, which provides more time for the appropriate policy and infrastructure for recycling to be implemented and scaled. See also the discussion of commercial recycling initiatives and the CIRCULAR program as described in ANL’s March 2024 report on critical materials.[541]

In response to comments on the need for battery recycling and/or the current availability of recycling, or that batteries will be disposed of in landfills, EPA disagrees with comments suggesting that PEV batteries must be disposed of in landfills, that recycling is not being considered or planned for, or that they otherwise are not of value for reuse or recycling. Many companies are actively pursuing business models on the recycling of materials in batteries or the reapplication of modules and cells for other purposes. EPA notes the comment from ZETA that indicates, “The global market for EV battery recycling alone is estimated to reach $17.1 billion

[541] Argonne National Laboratory, "Securing Critical Materials for the U.S. Electric Vehicle Industry: A Landscape Assessment of Domestic and International Supply Chains for Five Key EV Battery Materials,” ANL-24/06, February 2024.

by 2030," which clearly suggests that battery recycling is being recognized as a promising area of investment. EPA also notes the comment from Tesla which cites the company's practice of "ensuring that none of our batteries (manufacturing scrap or fleet returns) go to landfills and deploying equipment to recycle 100% of on-site generated manufacturing scrap across manufacturing facilities." Currently, the growth and visibility of battery recycling companies has been limited due to the fact that there does not yet exist a sufficient rate of used automotive traction batteries being generated by the in-use vehicle fleet because most PEVs on the road today have not yet reached the end of their useful life. Second-life applications, in which cells, modules, or batteries from old vehicles are used in other applications such as stationary energy storage, are likely to create additional market demand for decommissioned vehicle batteries. Further, the Department of Energy has active research programs on lithium-ion battery recycling, for example, the ReCell Center[542] and the Federal Consortium for Advanced Batteries (FCAB).[543] The Bipartisan Infrastructure Law provides more than $7 billion to promote the supply chain for batteries,[544] including funding for battery processing and manufacturing research, battery recycling research, and for local governments to establish or enhance battery collection, recycling, and reprocessing programs. Based on EPA's understanding of battery recycling and the research and commercial activity and investments surrounding it, EPA assesses that it is incorrect and unfounded to conclude that EV batteries will not be recycled, and also specifically disagrees with various commenter's erroneous allusions to "500 billion pounds" of batteries or similar calculations of battery disposal that are incorrectly based on the assumption that no automotive lithium-ion batteries will be recycled.

In response to the Alliance suggestion that EPA does not acknowledge the net cost to the economy from "the shift from recycling of engines and transmission to the recycling of lithium-ion batteries," EPA disagrees with this characterization of how battery recycling will evolve, and also with the presumption that it will represent a net cost. EPA believes that the projected gradual increase in PEV penetration anticipated by the compliance analysis is unlikely to cause engine recyclers to be compelled to rapidly shift their business to battery recycling and thereby experience a cost of retooling or retraining. The vast majority of the existing fleet consists of vehicles with engines and transmissions, and during the time frame of the rule, as these vehicles continue to approach end of life they will continue to generate a continuous stream of engines and transmissions to be recycled; even if fewer new engines and transmissions are produced over time, these recycled metals will be used in other products. Over a longer term, the recycling of batteries and cells could as likely generate new entrants to the recycling industry, pursuing new business opportunities and creating new jobs and thus could generate a net benefit (for discussion of employment, see RTC Section 20). As to the potential difference in the value of materials recovered, this depends on the battery chemistry; although some chemistries have more valuable mineral content than others, all contain significant quantities of copper and aluminum. Accessed on December 6, 2021 at https://www.energy.gov/articles/doe-fact-sheet-bipartisan-infrastructure-deal-will-deliver-american-workers-families-and-0

example, the Aluminum Association stated that "aluminum accounts for over 18% of the mass in a typical vehicle electric battery." Similarly, EPA does not agree with Alliance's comment that EPA should include in its regulatory impact analysis "estimates of how the cost of battery recycling might decline with appropriate supporting policies," as costs of this nature are outside the scope of the rule's technology cost analysis.

In response to comments that battery recycling is not growing fast enough to handle future recycling streams, EPA disagrees. We note ICCT's comment that "sufficient capacity is available to recycle end-of-life batteries until 2039," which is based on work cited in the comment and supports our assessment that the battery recycling industry is receiving an appropriate level of attention to be prepared with the technology and capacity to process the future influx of end-of-life batteries.

In response to comments that battery recycling is hindered by labeling and the diversity of chemistries, or that EPA should add battery labeling requirements to facilitate recycling, or related to design for disassembly, EPA has not yet determined how such requirements might fit within the scope of our authority under the Clean Air Act. EPA also notes that the Bipartisan Infrastructure Law included funding for EPA to develop battery recycling best practices and battery labeling guidelines, which we expect will improve this aspect of battery recycling and may serve much of the purpose that the commenters describe. We also note that design for disassembly is not included in our costing of batteries largely because of the difficulty in assigning any potential cost difference for this practice which is not widely incorporated today. In response to the AFPM's comment that EPA should "conduct a full LCA" or "consider the environmental profiles of both ZEVs and ICEVs in light of the production, operation, and disposal of the vehicle," these comments relate to life-cycle analysis for which comments are responded to in RTC 19.

In response to comments that EPA should "add battery recycling and disposal costs to the analysis," EPA disagrees that this is practical or appropriate. Batteries contain a large amount of recyclable materials that have market value, and no consensus has yet emerged to indicate that battery recycling will represent a net additional cost nor that batteries will incur a cost of disposal instead of being profitably recycled, and commenter has provided no new evidence.

Regarding various comments alluding to difficulties associated with recycling, e.g. allusion to a need for "clear guidance on repackaging, certification, standardization, and warranty liability", potential classification of used batteries as hazardous waste, transportation difficulties, and similar claims, EPA notes that commenters have not thus identified any difficulties that are not already widely acknowledged in the industry and therefore are not already being taken into account by the businesses, startups, and research initiatives that are currently working to advance the battery recycling industry. EPA also notes that it is aware of and is in the process of addressing some of the common concerns regarding recycling of lithium-ion batteries, including how universal waste handling requirements, hazardous waste recycling regulations, and other RCRA Subtitle C provisions apply to this waste stream.[545]

16 - Battery durability and warranty

Comments by Organizations

Organization: Alliance for Automotive Innovation

B. Battery Durability Provisions

1. Battery Durability Monitoring and Performance Requirements

As described in Section III-F,326 EPA is proposing to incorporate new battery durability monitoring and performance requirements for light-duty BEVs and PHEVs, and battery durability monitoring requirements for Class 2b and 3 BEVs and PHEVs, beginning with MY 2027. [EPA-HQ-OAR-2022-0829-0701, pp. 218-219]

326 NPRM at 29283.

As an initial mater, we wish to point out that the battery durability requirements are beyond the scope of EPA's statutory authority as applied to BEVs. According to EPA, the Proposed Rule's battery durability and testing requirements are anchored in section 206 of the Clean Air Act, which authorizes EPA to "test, or require to be tested in such manner as [EPA] deems appropriate, any new motor vehicle or new motor vehicle engine submitted by a manufacturer to determine whether such vehicle or engine conforms with the regulations prescribed under" [section 202]".327 By its plain terms, this provision authorizes testing requirements in order to confirm compliance with vehicle-specific emissions standards promulgated under section 202. But there are no such vehicle-specific standards for BEVs, which by their nature do not produce any emissions. To be clear, and as expressed elsewhere in this comment, Auto Innovators supports the fleetwide averaging approach of the Proposed Rule which has long been used by EPA under section 202. But the application of fleetwide averaging to BEVs is distinct from the imposition of vehicle-specific emissions standards for BEVs, which do not exist, and which would exceed EPA's authority given that section 202(a) allows EPA only to promulgate "standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engine." Because there are no "standards applicable to the emission of any air pollutant from" BEVs under section 202(a), there can be no durability testing requirements for compliance with such standards under section 206. [EPA-HQ-OAR-2022-0829-0701, pp. 218-219]

327 42 U.S.C. § 7525(a)(1) (emphasis added).

That said, we do agree that monitors in conjunction with performance requirements are important tools when it comes to ensuring proper battery operations and maintaining adequate battery health. As is laid out in both the UNECE GTR No. 22 [328] as well as this proposed NPRM, Usable Battery Energy (UBE) has been chosen as the primary metric when measuring battery durability, with a State of Certified Energy (SOCE) monitor to verify the performance and overall capacity of the battery. [EPA-HQ-OAR-2022-0829-0701, pp. 218-219]

328 UNECE EVE GTR No. 22 -https://unece.org/transport/documents/2022/04/standards/un-gtr-no22-vehicle-battery-durability-electrified-vehicles

EPA also seeks comments on the potential to include a State of Certified Range (SOCR) monitor. As stated above, EPA does not have the authority to impose battery testing and durability requirements under the CAA. specific to the SOCR monitor, Auto Innovators does not support the use of an SOCR monitor given that calculating range on a large and standardized scale can result in false readings. Should EPA move forward with battery durability requirements, we agree with EPA's proposal to use an SOCE metric as opposed to an SOCR monitor. [EPA-HQ-OAR-2022-0829-0701, pp. 218-219]

2. SOH Harmonization

Under this current NPRM, EPA is proposing new battery durability performance requirements for all light-duty PHEV and BEV, battery health monitoring and in-use accuracy for all light-and medium-duty PHEVs and BEVs, as well as warranties for PHEVs, BEVs, and FCEVs. EPA included by reference the April 2022 version of UN GTR No. 22 and has aligned durability performance that requires 70% SOCE (5ys/62k mi) and 80% (8ys/100k mi). Additionally, this will require OEMs to provide battery health (SOCE) information visible to the customer, conduct annual large data collection of this information to verify compliance to the durability requirements, as well as conduct in-use customer vehicle testing verify monitor accuracy at low, mid, and high mileage intervals for each monitor family). Finally, EPA proposes to require a minimum warranty period for batteries and certain e-propulsion components of 8years/80k miles for all PHEV, BEV, and FCEV vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 219-220]

By adopting UNECE GTR No. 22 by reference, EPA is introducing an SOH monitor based on SOCE, which differs from that in CARB's ACC II regulation. This difference will cause customer confusion and frustration with two different SOH monitors. One step to avoid such confusion would be for EPA to allow the display of the SOCE value to one decimal place, as is required by CARB's ACC II regulation, instead of to an integer as is in the NPRM. This would allow for compliance with ACC II, where SOCE display resolution requirements are based on SAE J1979-DA, in addition to being based on GTR No. 22. Furthermore, CARB provides an alternative display and accuracy from MY2027. We propose a similar method of early phase-in flexibility toward SOH display and accuracy to harmonize compliance between the NPRM and ACC II. [EPA-HQ-OAR-2022-0829-0701, pp. 219-220]

EPA's proposed in-use monitor accuracy verification would significantly increase test facility resources. Additionally, the GTR No.22 statistical approach to verification can require up to 16 vehicles per monitor family to be tested at each of the 3 mileage intervals. Also, the accuracy looks at a two-sided delta but there should only be a concern for OEM overpredicting the battery health. Any underprediction puts all the burden and risk of passing the durability requirements on the manufacturer. [EPA-HQ-OAR-2022-0829-0701, pp. 219-220]

The new battery durability requirements are tied to Tier 4 phase-in percentages regardless of "default" or "early" compliance paths for vehicles less than 6000 lbs. GVWR vehicles are required to phase-in 40% of vehicles in 2027MY. This is concerning given the long lead-times to implement customer facing information on vehicle systems. [EPA-HQ-OAR-2022-0829-0701, pp. 219-220]

If battery durability is required, it is important to align with global best practices (CARB should align as well) and harmonize with battery health monitor requirements. Additionally, we agree with EPA's SOCE health monitor that excludes the battery reserve. Virtual distance is fundamental to the V2X technologies such as vehicle-to-grid, vehicle-to-load, and vehicle-to-home to avoid concerns with meeting durability and warranty requirements. This will provide transparency to customers who use their vehicles for purposes other than propulsion and will help reduce OEM concerns over excessive V2X use. We recommend that the virtual distance be used in both the calculation of the durability mileage as well as the warranty mileage (i.e., durability/warranty miles = virtual miles + vehicle odometer miles). [EPA-HQ-OAR-2022-0829-0701, pp. 219-220]

We request that EPA align regulatory text in § 86.1815 (Battery-related requirements) to the preamble and replace the term “electric vehicles” with BEVs and PHEVs to ensure that durability and monitoring requirements apply to BEVs and PHEVS and not FCEVs. [EPA-HQ-OAR-2022-0829-0701, pp. 219-220]

Lastly, we are still unclear when it comes to a number of factors related to this proposal. As a result, we respectfully request clarification on the following: [EPA-HQ-OAR-2022-0829-0701, pp. 219-220]

-Are proposed durability and monitoring requirements tied to the Tier 4 phase-in per 86.1815? Is the same true for warranty? [EPA-HQ-OAR-2022-0829-0701, pp. 219-220]

-§ 86.1815 Battery-related requirements for electric vehicles and plug-in hybrid electric vehicles. Electric vehicles and plug-in hybrid electric vehicles must meet requirements related to batteries serving as a Rechargeable Energy Storage System from GTR No. 22 (incorporated by reference, see § 86.1). The requirements of this section apply starting in model year 2027 for vehicles at or below 6,000 pounds GVWR. These requirements apply vehicles above 6,000 pounds GVWR if they are certified to Tier 4 NMOG+NOX standards under § 86.1811–27, not later than model year 2030 [EPA-HQ-OAR-2022-0829-0701, pp. 219-220]

-If UNECE GTR No. 22 on-vehicle data parameters are required, how will this be harmonized with CARB ACC II? [EPA-HQ-OAR-2022-0829-0701, pp. 219-220]

3. Reserve Capacity Declaration Requirement

In the NPRM, EPA proposes requirements for battery durability that are applicable to BEVs and PHEVs. The requirements and general framework of the proposed battery durability program are largely identical to those outlined in GTR No. 22 [329] and broadly parallel the GTR in terms of the minimum performance requirements, as well as the hardware, monitoring and compliance requirements, the associated statistical methods and metrics that apply to determination of compliance, and criteria for establishing battery durability and monitor families. Our concerns regarding EPA’s authority for battery durability and warranty for BEVs are discussed elsewhere in these comments. [EPA-HQ-OAR-2022-0829-0701, pp. 220-221]

329 Id.

Automakers are committed to achieving full electrification and producing vehicles with a robust battery life. Strategies to achieve these battery durability standards may vary per automaker; however, one way to achieve them is to include a reserve battery capacity to be released throughout the course of a battery’s lifetime to supplement normal battery degradation. While EPA is not proposing a similar requirement, EPA requests comment on including a reserve capacity declaration requirement and use of reserve capacity information in calculating an SOCE or SOCR metric. We agree with EPA's decision to not include reserve capacity when determining battery durability and warranty. While there is additional battery capacity included in the vehicle, the energy itself is not accessible to the customer until the batteries hit a certain degradation. Therefore, we believe that a reserve capacity declaration requirement and the use of the reserve capacity information in calculating an SOCE or SOCR metric should not be required in this NPRM. [EPA-HQ-OAR-2022-0829-0701, pp. 220-221]

As a general principle, Auto Innovators supports the harmonization between EPA's Multipollutant NPRM and the UNECE GTR No. 22 as it pertains to battery durability minimum performance requirements. [EPA-HQ-OAR-2022-0829-0701, pp. 221-222]

7. IUVP Accuracy Check

We also have concerns over the In-Use Verification Program (IUVP) accuracy check that is outlined in the NPRM. EPA is proposing to implement an accuracy check for low, medium, and high mileage vehicles. Implementing and performing three different checks creates a large burden for manufacturers. Finding and locating acceptable vehicles poses a challenge in itself, let alone adding a third check point. Due to the unnecessary increase in test burden, we propose that EPA allow for a single IUVP accuracy check. [EPA-HQ-OAR-2022-0829-0701, pp. 223-224]

Under the NPRM, EPA is also requesting comment on the SOH calculation used as it pertains to measuring battery durability. Overall, we support the harmonization of CARB's ACCII standards when it comes to SOH calculations. For model years 2027 through 2028, we propose that EPA adopt CARB's standard of an 8% threshold. We agree with CARB that it is unnecessary to include a two-sided threshold. Protection from vehicle overestimation of SOH is all that is necessary under these circumstances. From model year 2029 and on, we also propose that EPA lower the threshold to 5%. This gives manufacturers the flexibility to be conservative on their estimations, while allowing the ability to adjust the threshold at a later time, if need be. We believe this is in the best interest of all parties involved. Underestimation puts the burden on OEMs by posing a risk of not hitting the 70% SOCE MPR. Therefore, we propose including this added flexibility. Furthermore, as the verification procedure for this is new, manufacturers need time to build up the knowledge to design and calibrate the monitoring function. This will require SOH data from vehicles that have been in use long enough to have significant battery degradation. A lower limit for model years 2027 and 2028, again, supports this requirement. [EPA-HQ-OAR-2022-0829-0701, pp. 223-224]

We do not believe an accuracy check should be required where there is no MPR to align with; therefore, we request that EPA not require an accuracy check for Medium Duty Vehicles and Class 2b and 3 vehicles due to the absence of an MPR. [EPA-HQ-OAR-2022-0829-0701, pp. 223-224]

C. III.F.3 Battery and Vehicle Component Warranty

1. BEV and PHEV Battery Warranty Requirements

In addition to the battery durability requirements outlined in this NPRM, EPA is also proposing a set of warranty requirements for both BEV and PHEV batteries, as well as associated electric powertrain components like inverters or electric machines.333 Historically, vehicle and vehicle part warranties are left to the respective OEMs to determine what is an appropriate agreement between the manufacturer and customer based on competition and vehicle durability. Therefore, it is our position that warranty requirements remain at the discretion of the individual OEMs. [EPA-HQ-OAR-2022-0829-0701, pp. 224-225]

333 NPRM at 29197.

2. Classification of Batteries as "Major Emission Control Components"

Utilizing the Administrator's authority mandated in Section 207(i)(1) of the CAA, EPA is proposing under this NPRM to designate high-voltage battery systems and associated powertrain components as "specified major emission control components," thus imposing a warranty period of eight years or 80,000 miles of use, whichever first occurs. Such a designation for BEVs, however, is entirely inconsistent with the statute. [EPA-HQ-OAR-2022-0829-0701, pp. 225-226]

Section 207(i)(2) enumerates a discrete list of items that qualify as "specified major emission control components," and authorizes the Administrator to designate "any other pollution control device or component" as such if certain conditions are met.334 But a BEV produces zero emissions from its battery and associated electric powertrain components. It follows that no device or component of a BEV could logically be a "pollution control device or component" that can be designated as a "specified major emission control component" under section 207(i)(2), because there are no emissions from the BEV to control.335 [EPA-HQ-OAR-2022-0829-0701, pp. 225-226]

334 42 U.S.C. § 7541(i)(2).

335 We acknowledge that this designation for PHEVs is more consistent with the statutory authorization, because the battery-electric power displaces use of the vehicle's ICE, controlling the PHEV's emissions.

The NPRM attempts to justify its counter-textual reasoning in the NPRM, but its reasoning cannot cure the fundamental legal flaw in its proposal. For instance, the NPRM claims that its "proposed warranty requirements would be equivalent to those that EPA has the authority to require and has historically applied to other specified major emission control-related components for ICE vehicles under EPA's light-duty vehicle regulations..."336 But this is a false equivalency, because ICE vehicles produce emissions, and a component in the vehicle designed to reduce those emissions (such as, for example, a catalytic converter or an electronic emissions control unit) can be considered a "major emission control component." The same cannot be said of any component of a BEV that produced no emissions. [EPA-HQ-OAR-2022-0829-0701, pp. 225-226]

336 NPRM at 29286.

Recognizing that BEVs do not have any emission themselves, the NPRM nonetheless argues that BEV batteries can be considered a major emissions control component to the extent that BEVs are used to displace ICE vehicles. This portion of the NPRM refers back to the battery durability requirements,337 which argues that a "loss of a large portion of the original driving range capability as the vehicle ages could reduce total lifetime mileage and the ability for electric miles to displace conventional miles traveled."338 Not only does this argument find no support in the statute, but it proves way too much. Just about any component on a BEV that helps it run or that is important to the consumer will impact the extent to which the BEV will continue to displace conventional miles traveled. For instance, a consumer may elect to not to drive their BEV if that vehicle's infotainment system fails completely, but that certainly would not make the infotainment system a "major emissions control component." Simply put, there is absolutely no basis in the CAA for EPA to impose any battery warranty requirements on BEVs. [EPA-HQ-OAR-2022-0829-0701, pp. 225-226]

337 NPRM at 29286 – 87.

338 Id. At 29284

4. Virtual Mileage

As electric vehicles begin to account for an increasing share of new vehicles sold within the United States and globally, Vehicle to Everything (V2X) capabilities (which may include electric grid management and storage) will also grow in importance for the adoption and utilization of electric vehicles. Many BEVs and PHEVs on the road today already possess these bidirectional capabilities, and their use will only continue to become more prominent. Therefore, this technology (and other similar battery uses) needs to be accounted for in measuring a battery's usage and health. More Specifically, as these bidirectional vehicles grow in use, degradation of the battery continues as the power is extracted from the vehicle's traction batteries. As such, that particular use of the battery should be reflected in the overall measurement of the battery's usage and health. [EPA-HQ-OAR-2022-0829-0701, p. 227]

Subject to our concerns raised on EPA's authority for battery durability and warranty for BEVs, we have the following recommendations. We propose that V2X usage should be reflected on the vehicle through the inclusion of a "virtual mileage" metric, similar to a standard odometer. Additionally, we believe the respective "virtual mileage" should also be included in the battery durability standards, as it is in the GTR. In addition to the durability standard, we also propose that virtual mileage be tied to the warranty standard as it pertains to the overall mileage threshold. These provisions will give customers a more accurate understanding of their overall battery usage, as well as help ensure that these vehicles remain on the road across multiple owners. Lastly, as we understand that EPA is incorporating GTR No. 22 by reference,339 we would like to confirm that that "virtual mileage" is included in the battery durability standard with respect to the mileage threshold. In addition to the battery durability standard, we would like "virtual mileage" to be included as a part of the mileage threshold relating to the warranty standard. [EPA-HQ-OAR-2022-0829-0701, p. 227]

339 UNECE EVE GTR No. 22 -https://unece.org/transport/documents/2022/04/standards/un-gtr-no22-vehicle-battery-durability-electrified-vehiclesOrganization: American Fuel & Petrochemical Manufacturers

EPA's proposal may impose additional costs of economic risk to individuals and small business owners who will be asked to depend on increasingly expensive infrastructure necessary to provide on-the-go fuel.232 Durable and reliable EVs are therefore critical to ensuring that projected emissions reductions are achieved by this proposed program and costs of ownership are properly presented. EPA further states that it is proposing new battery durability requirements for light-duty and medium-duty ZEVs and PHEVs but this doesn't alter EPA's concession that it is relying on other programs, like California's, to implement battery durability and a suite of other customer assurance provisions to ensure customer demand.233 EPA should consider inclusion of durability requirements in this proposal as 150 miles of range for singular battery life and 24,000-mile range of use (or two years) are well below the period of use for a comparable ICEV with a full tank of fuel and will impact consumers as there is not enough data with these technologies. [EPA-HQ-OAR-2022-0829-0733, p. 51]

232 88 Fed. Reg. 4,296 (Jan. 24, 2023) (EPA Final Rule re Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards).

233 Proposed Rule at 29,284.

Organization: BMW of North America, LLC (BMW NA)

Another important topic is the deviating rule for battery durability, battery warranty and SOH monitoring of the NPRM, compared to LEV JV. BMW NA supports the general idea to give the customers trust in the battery technology via these rules. But two different rules, depending only on the place of registration in the US, will unnecessarily confuse the customers (e.g., while buying a used vehicle in another state) and present additional hurdles toward electrification. BMW NA recommends that a single national approach should be implemented, as proposed by AAI. [EPA-HQ-OAR-2022-0829-0677, p. 4]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Zero-Emission Vehicle Assurance Measures

Widespread adoption of ZEV technologies is critical to securing emission reductions for stabilizing the climate and protecting public health. In order for these vehicles to truly deliver these benefits, ZEV technologies must similarly have appropriate durability, warranty, and other assurance measures as the technologies in their conventional gasoline-fueled counterparts. Research shows that ZEVs with similar capabilities, including range, as conventional vehicles are used just as much as their conventional counterparts, and that the same factors influence the choice to use both kinds of vehicles. 50 Conversely, a lack of assurance measures for ZEVs leads to consumer uncertainty and lack of confidence. 51 U.S. EPA's rulemaking presents a key opportunity to establish approaches that can support consumers in making the choice to purchase ZEVs. Assurance measures for ZEVs and PHEVs that, in many cases, mirror requirements for conventional vehicles are integral to this process. [EPA-HQ-OAR-2022-0829-0780, pp. 38-39]

50 Debapriya Chakraborty, Scott Hardman, and Gil Tal, Integrating Plug-in Electric Vehicles (PEVs) into Household Fleets -Factors Influencing Miles Traveled by PEV Owners in California (Aug. 31, 2021) at 1–2, 33– 34, accessible at https://escholarship.org/uc/item/2214q937 (showing that electric vehicles travel a similar number of miles per year as conventional vehicles).

51 See, e.g., ACC II ISOR pp. 23, 70 and accompanying studies.

To ensure ZEVs used to comply with California's program are designed to meet consumers' needs similarly to their conventional counterparts and therefore capable of achieving and maintaining needed emission reductions, CARB adopted a suite of ZEV assurance measures. These assurance measures include: 52 [EPA-HQ-OAR-2022-0829-0780, pp. 38-39]

52 For additional detail on the ZEV Assurance Measures established under ACC II, see: ACC II ISOR pp. 69-89 and ACC II FSOR Appendix D: Summary of Comments to ZEV Assurance Measures and Agency Response.

[EPA-HQ-OAR-2022-0829-0780, pp. 38-39]

- Minimum electric range requirements for ZEVs and PHEVs.
- Durability standards based on a vehicle's certified electric range.

- Warranty requirements for batteries and propulsion-related parts.

- Data standardization and transparency, including on-board display of the battery state of health so that consumers can see the quality of their battery.

- Requirements for manufacturers to provide highly-capable convenience charging cords and equipping vehicles with standardized, direct current fast charging inlets.

- Requirements that repair information be released to independent repair shops.

- Requirements around battery labeling to ease dismantling and recycling.

[EPA-HQ-OAR-2022-0829-0780, pp. 38-39]

CARB recommends U.S. EPA adopt CARB’s suite of ZEV assurance measures. Full alignment at the national level with these standards would reduce complexity for manufacturers and consumers and help ensure a consistent ZEV ownership experience across the U.S. [EPA-HQ-OAR-2022-0829-0780, pp. 38-39]

CARB has included specific recommendations on several key assurance measures, including battery durability, warranty, and serviceability. In addition to adopting CARB’s ZEV assurance measures, CARB also recommends U.S. EPA adopt further on-vehicle charging standards and collect additional data to inform future ZEV consumer labels. [EPA-HQ-OAR-2022-0829-0780, pp. 38-39]

Durability

CARB commends U.S. EPA for proposing to establish battery durability requirements for BEVs and PHEVs. Durability requirements provide confidence that those vehicles will provide sufficient utility for consumers to use them and ensures the needed emissions reductions from ZEV technologies are fully achieved and maintained. Strong durability and warranty requirements also support a robust used ZEV market, which will help ensure all consumers can access these clean technologies. [EPA-HQ-OAR-2022-0829-0780, p. 39]

Durability Metric

As part of its ACC II rulemaking, CARB established minimum range requirements for ZEVs and PHEVs and requires vehicle range data at the time of certification using specified test procedures. For the 2026 through 2029 MYs, CARB’s durability provisions require vehicles in a test group to be designed to maintain 70 percent or more of the certified range for 10 years or 150,000 miles, whichever comes first. For 2030 and subsequent MYs, vehicles must be designed to maintain 80 percent of the certified range. The range metric captures the whole vehicle powertrain durability rather than the battery alone. [EPA-HQ-OAR-2022-0829-0780, p. 39]

U.S. EPA has proposed to establish a durability metric based solely on battery state of health (SOH). Under U.S. EPA’s approach, other powertrain-related components like drive motors or inverters could deteriorate such that they become less efficient and reduce driving range that is readily observable to the driver yet are outside the scope of a battery-only durability requirement. CARB recommends U.S. EPA instead adopt CARB’s durability provisions, including the tie to a vehicle’s certified range because it is a more meaningful and protective metric to consumers. [EPA-HQ-OAR-2022-0829-0780, p. 39]

Reserve Battery Capacity Disclosure

While CARB strongly supports the inclusion of durability and warranty provisions for ZEVs and PHEVs, CARB notes that the SOH metric as specified in U.S. EPA's proposal may be susceptible to manipulation and offers recommendations to help remedy these concerns. U.S. EPA's proposed SOH monitor requirement that estimates, monitors, and communicates the vehicle's state of certified energy (SOCE) does not provide explicit direction to manufacturers for some implementation approaches, most notably in cases where some portion of the battery capacity is held back "in reserve" early in life and gradually opened to counteract the actual degradation. Given that the SOCE would be the current usable battery energy (UBE) expressed as a percentage of the original UBE when the vehicle was new, manufacturers could potentially undermine the intent of the SOH parameter by reporting the health as 100 percent (or even a value greater than 100 percent) well into the degradation of the battery. Failing to include reserve battery capacity in the SOH calculation could limit the credibility of the SOH parameter and undermine its ability for vehicle owners to use it to validate warranty eligibility or to properly value used ZEVs based on the amount of degradation of the battery. 53 [EPA-HQ-OAR-2022-0829-0780, pp. 39-40]

53 See, e.g., ACC II ISOR, Appendix F-7, pp. 17-18. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/accii/appf7.pdf.

As part of the ACC II ZEV assurance measures, CARB's required customer-accessible SOH monitor is used to determine if a vehicle's battery is meeting battery-specific warranty requirements. CARB requires that the SOH parameter be normalized to account for reserve UBE and ensure full transparency to consumers in degradation of the battery's ability to store energy, regardless of the manufacturer's implementation strategy. 54 To help ensure that the SOH metric is a true gauge of battery degradation, CARB urges U.S. EPA to explicitly require manufacturers to account for all the reserve UBE in the SOCE calculation. [EPA-HQ-OAR-2022-0829-0780, pp. 39-40]

54 Cal. Code. Regs., title 13, section 1962.5(c)(4)(A)4.d. For additional information on CARB's inclusion of battery state-of-health metrics in the ACC II rulemakings, see: ACC II ISOR pp. 71-72; ACC II ISOR, Appendix F-7, pp. 17-20; and Notice of Public Availability of Modified Text and Availability of Additional Documents and Information (July 12, 2022), Attachment I-1, pp. 2-3. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/accii/atti1.pdf.

Warranty

Warranty requirements are another important element to give consumers confidence in purchasing ZEVs and PHEVs. While durability requirements have the effect of ensuring vehicles in a test group, in the aggregate, are designed to have minimal degradation or deterioration such that they will meet or exceed a performance standard over the useful life period, they do not provide assurance that each individual vehicle will be free from defects or other failures. The purpose of warranty requirements, on the other hand, is to protect against individual vehicles experiencing failures or defects early in the life of the vehicle. A test group on track to meet the durability standard does not necessarily mean that there will not be individual vehicles that experience failures or defects. Likewise, individual vehicles experiencing a failure or defect does not necessarily mean that the test group as a whole will fail to meet the durability standard. [EPA-HQ-OAR-2022-0829-0780, p. 40]

In recognition of this need, CARB established warranty requirements for ZEVs and PHEVs, which are split into two parts: 1) battery warranty, which applies to BEVs and PHEVs, and 2) propulsion-related parts warranty, which applies to BEVs and FCEVs. These provisions largely track similar requirements for conventional vehicles. CARB recommends U.S. EPA adopt CARB's warranty provisions and offers specific recommendations to strengthen U.S. EPA's proposal. [EPA-HQ-OAR-2022-0829-0780, p. 40]

Battery Warranty

In order to make the warranty useful for vehicle owners, it must be tied to a meaningful and transparent metric. Internal combustion engine vehicles today are equipped with complex on-board diagnostic systems with consumer-facing warning lights that provide a clear tell-tale to the owner when a component failure has occurred at a specified level defined by CARB's onboard diagnostic requirements. Tying battery warranty to a meaningful metric is fundamental to ensuring drivers are aware of early and unexpected battery degradation and can then pursue the necessary repair. [EPA-HQ-OAR-2022-0829-0780, pp. 40-41]

CARB established its battery warranty requirements based on battery SOH. For the 2026 through 2030 MYs, CARB established an 8-year or 100,000-mile warranty for any battery that falls below 70 percent of the SOH. Beginning with the 2031 MY, the warranted SOH increases to 75 percent. While CARB commends U.S. EPA for explicitly tying battery warranty requirements to the battery durability metric, as included in the draft regulatory language in proposed 40 CFR § 85.2103(c), CARB recommends U.S. EPA implement changes to its SOH metric as CARB recommends above so that U.S. EPA's battery warranty provision would be similar to CARB's, differing only on the timeframes. [EPA-HQ-OAR-2022-0829-0780, pp. 40-41]

Propulsion-Related Parts Warranty

Non-battery propulsion-related components, such as the on-board charger, the electric motors, inverters, and battery management system, are not expected to degrade like batteries on BEVs. However, failure of such components can have detrimental effects on the efficiency, performance, range, or drivability of the ZEV and thus the ability of ZEVs to achieve and maintain their emission reductions over time if they are not warranted like their conventional vehicle counterparts. [EPA-HQ-OAR-2022-0829-0780, pp. 41-42]

CARB requires that manufacturers provide a warranty for BEVs and FCEVs, consistent with what conventional gasoline vehicles are subject to, for a minimum of 3 years or 50,000 miles, whichever occurs first (or 7 years or 70,000 miles for high-priced parts) for all propulsion-related (powertrain) components, excluding the traction battery. Under CARB's requirements, the applicable ZEV components must be warranted to be "free from defects in materials and workmanship that would cause a propulsion-related part to fail to be identical in all material respects to the part as it was described in the vehicle manufacturer's application for certification…" 55 That requirement mirrors the defects warranty conventional vehicles are subject to and helps ensure consumer confidence in ZEV technologies. [EPA-HQ-OAR-2022-0829-0780, pp. 41-42]

55 Cal. Code Regs, title 13, section 1962.8(c)(1)(B).

While CARB commends U.S. EPA for tying its battery warranty to the battery SOH metric, U.S. EPA's proposal appears to mistakenly tie all non-battery powertrain components to this same battery durability performance requirement when defining failures that merit warranty replacement. Such a connection renders the warranty requirements meaningless for those components. For example, there are no failures or degradation of electric drive motors that would reduce the amount of energy the battery can store (which is the metric used for the battery durability performance requirement). Effectively, this means warranty coverage as proposed would apply only to the battery despite the explicit reference in draft language that includes other ZEV powertrain-related components as subject to warranty. Further, even the basic 2-year and 24,000-mile emission warranty appears to cover only failures that involve exceeding the emission limits of applicable standards. Though failures of powertrain-related components impact the ability of ZEVs to achieve and maintain their emission reductions over time, as noted above, if they are not warranted like their conventional vehicle counterparts, this provision as drafted would not trigger warranty coverage for ZEV powertrain-related components as no failure of those components can cause the vehicle to emit emissions directly. [EPA-HQ-OAR-2022-0829-0780, pp. 41-42]

Therefore, CARB recommends that U.S. EPA adopt an appropriate failure metric(s) for warranty coverage for non-battery components. Ensuring warranty coverage for ZEVs that is comparable to conventional vehicles is critical to protect consumers and achieve and maintain the emission benefits from ZEV technologies. [EPA-HQ-OAR-2022-0829-0780, pp. 41-42]

Organization: Coalition for Safe Autonomous Vehicles and Electrification (SAVE)

From the perspective of our members' unique ownership and business models, there are two areas for which we request additional consideration: (1) the proposal to require a State of Certified Energy (SOCE) monitor that communicates the SOCE of the battery via a "customer-accessible display"; and (2) the proposed sampling requirements for SOCE monitor accuracy testing. [EPA-HQ-OAR-2022-0829-0608, p. 2]

First, with respect to the SOCE monitor, we surmise that the purpose of the proposed "customer-accessible display" requirement is to provide information to the vehicle owner and any potential future owner of the vehicle. We understand this information may bolster consumer confidence in Battery Electric Vehicles (BEVs) and Plug-in Hybrid Electric Vehicles (PHEVs) generally and provide specific benefit to purchasers of used BEVs and PHEVs by providing information about the state of the battery health. Because AV-EVs are fully autonomous, not capable of operation by a human driver, and owned for their useful life by the manufacturer, providing a "customer-accessible" SOCE monitor serves no benefit to customers (e.g., users of robotaxi or delivery services). One of the goals of AV-EVs is to deliver a service to customers without the burdens that come with vehicle ownership, like maintenance. Because our members are solely responsible for the servicing of our vehicles, customers can simply focus on getting themselves or their goods from point A to point B. To support EPA's goal while not unduly burdening fleet ownership models we recommend revising proposed § 86.1815(a) to maintain the language in Global Technical Regulation 22 that the monitor be available to the owner of the vehicle rather than the customer as specified in the proposed EPA regulation. [EPA-HQ-OAR-2022-0829-0608, p. 2]

Additionally, proposed § 86.1815(a) is currently written such that the customer-accessible display must monitor, estimate, and communicate the SOCE. Typically, the parameters informing the SOCE would be monitored and estimated within the Battery Management System (BMS) or a similar electronic control unit (ECU) or combination of ECUs, which often does not have a display associated with it. The SOCE estimate would then be communicated to a customer-accessible display. To improve the clarity of this requirement, we suggest the first sentence of § 86.1815(a) should be modified to read: [EPA-HQ-OAR-2022-0829-0608, p. 2]

"Manufacturers must install a system that monitors, estimates, and communicates the vehicle's State of Certified Energy (SOCE) and include information in the application for certification as described in § 86.1844. The estimate of SOCE must be made available on an owner-accessible display." [EPA-HQ-OAR-2022-0829-0608, p. 2]

Second, with respect to the proposed requirements for battery durability monitoring and sampling, we recognize the importance of ensuring battery longevity for EVs to ensure their viability as a desirable alternative to non-EVs. The SAVE Coalition, therefore, supports the goal of the proposed regulation, i.e., to assure a sufficient useful life of an EV and a robust secondary market for used EVs to enable the realization of fleet electrification and the corresponding public health benefits. In order to prove the SOCE monitor can accurately estimate the battery durability for a given monitor group in all relevant conditions, we understand that sampling of vehicles in diverse geographic and climatological locations and operating characteristics (See § 86.1815(f)(2)) is being required. However, such sampling may be difficult, if not impossible, for AV-EVs at least in the near term. [EPA-HQ-OAR-2022-0829-0608, pp. 2-3]

Fully autonomous vehicles operating on public roads today are only capable of operation in specific geographic regions or operational design domains (ODDs). These ODDs may be limited in terms of physical location or geofence, road types, vehicle speed, meteorological conditions, and other factors. Unlike privately owned vehicles, AVs are not deployed at random across the United States and will not necessarily be exposed to the wide variety of roads, speeds, and weather. The number of AV-EVs being operated on public roads is currently limited. But even as the industry scales, these vehicles may be deployed to a single city for the duration of their life or may move between cities over their lifetime. Further, many, if not all, AV-EVs will be recycled upon completion of their useful life, and will not be offered in the secondary market. Given the unique operation of AV-EVs, we request that EPA provide more flexibility in the sampling requirements to account for vehicles that are tightly controlled and only operated in specific parts of the United States. [EPA-HQ-OAR-2022-0829-0608, pp. 2-3]

Organization: Colorado Energy Office, Colorado Department of Transportation, and Colorado Department of Public Health and Environment

-We encourage EPA to coordinate its EV battery durability and warranty requirements with the maintenance and durability requirements of the ACC II program to the greatest extent possible. These provisions are critical for ensuring consumer confidence in the performance and durability of EVs in the new and used market, and alignment to the greatest extent possible can help avoid confusion for consumers, dealers, and other key stakeholders. [EPA-HQ-OAR-2022-0829-0694, pp. 2-3]

Organization: Consumer Reports (CR)

7. CR Supports Strong Consumer Protections for Batteries

CR appreciates the EPA's inclusion of provisions in the rule that would require consumer protections for batteries in EVs sold beginning in model year 2027 and beyond. When a consumer goes through the process of purchasing a new vehicle for their household, there is an expectation that their vehicle will maintain condition and reliability throughout its useful life. For consumers purchasing a zero-emission vehicle, these concerns can be exacerbated based on their lack of experience with the technology and the lower general knowledge of EV technology compared to ICE vehicles, which consumers have had to deal with for decades. While existing data on EVs has found that battery failures are usually rare, it is critical that EPA maintains strong consumer protections to give customers continued peace of mind that the vehicle they purchase will operate as advertised throughout its lifespan.48 [EPA-HQ-OAR-2022-0829-0728, pp. 23-25]

48 New Study: How Long Do Electric Car Batteries Last?, Recurrent, 2023, https://www.recurrentauto.com/research/how-long-do-ev-batteries-last.

These provisions are especially important for consumers in the secondary vehicle market. Used cars make up about 70% of sales in the automotive market.49 Further, lower income consumers are especially price sensitive to transportation costs and spend a disproportionate amount of their income on transportation.50 As more EVs enter the secondary market in the coming years, it is imperative that consumers have protections against poorly designed or manufactured batteries that diminish in capacity or fail early. The most vulnerable populations at the forefront of climate and air quality hazards need consumer protections addressing the lifetime of the vehicle, its battery, and its reparability. [EPA-HQ-OAR-2022-0829-0728, pp. 23-25]

49 In 2022 there were 36.2 million used cars and 13.7 new cars sold, so 73% of vehicles sold were used cars in 2022. This number fluctuates from year to year, but tends to stay around 70% give or take a few percentage points. Sales data from AutoNews and NADA: https://www.autonews.com/used-cars/used-car-volume-hits-lowest-mark-nearly-decade and https://www.nada.org/nada/press-releases/nada-issues-analysis-2022-auto-sales-and-2023-sales-forecas t

50 High Cost of Transportation in the United States, Institute for Transportation and Development Policy, May 2019, https://www.itdp.org/2019/05/23/high-cost-transportation-united-states/.

Additionally, while the cost of producing batteries continues to drop, the battery is still the most expensive part of an electric vehicle.51 When shifting from gasoline to electricity, it is the battery that enables the electric vehicle to eliminate tailpipe pollution and reduce greenhouse gas and other pollutants. Therefore, reduced capacity or complete failure of the battery pack represent a significant risk to emissions reductions given the potentially high cost of a replacement. Strong corresponding consumer protections regarding durability, battery health and warranties are therefore critical to the emissions and economic success of EPA's multipollutant program. [EPA-HQ-OAR-2022-0829-0728, pp. 23-25]

51 Batteries For Electric Cars Speed Toward a Tipping Point, Bloomberg, December 2020, https://www.bloomberg.com/news/articles/2020-12-16/electric-cars-are-about-to-be-as-cheap-as-gas-powered-models#xj4y7vzkg.

EPA's proposal that new EVs and PHEVs maintain minimum performance requirements for vehicle's state of certified energy (SOCE) beginning at 80% SOCE for the first five years (or

62,000 miles) and 70% SOCE for eight years (or 100,000 miles) will give consumers greater trust that their batteries will maintain a reliable state of health standard for the useful life of the vehicle. CR also appreciates EPA's inclusion of warranty provisions that cover the battery, and associated electric powertrain components of the vehicle, for eight years (or 80,000 miles.) [EPA-HQ-OAR-2022-0829-0728, pp. 23-25]

With the increased requirements surrounding battery health, it is imperative that consumers have the ability to monitor their battery's individual performance levels. CR appreciates the inclusion of language requiring accessible battery state-of-health monitors for light-duty vehicles in addition to provisions for strong testing procedures to confirm the accuracy of these monitors. Easily accessible and reliable battery state-of-health data will go a long way towards supporting a thriving used EV market. [EPA-HQ-OAR-2022-0829-0728, pp. 23-25]

CR urges the EPA to consider additional standards for vehicle batteries to maintain a strong state of certified range (SOCR) aligned with the California Air Resources Board's (CARB) Advanced Clean Cars II (ACC II) rule which requires that new vehicles sold maintain up to 80% certified range for 10 years (or 150,000 miles) to ensure consistent range-durability standards across states. [EPA-HQ-OAR-2022-0829-0728, pp. 23-25]

Organization: Dana Incorporated

ePowertrain Warranty

Under CAA section 207, manufacturers are required to provide emission-related warranties. CAA section 207(i) specifies that the warranty period for light-duty vehicles is 2 years or 24,000 miles of use (whichever first occurs), except for specified major emission control components, for which the warranty period is 8 years or 80,000 miles of use (whichever first occurs). As a supplier of ePropulsion and ePowertrain systems for light- and medium-duty vehicles, Dana supports EPA's proposal to consider the high-voltage battery serving as a renewable energy storage system for light- and medium-duty EVs and PHEVs, along with related powertrain components, as specified major emissions control components subject to a warranty requirement of 8 years/ 80,000 miles. Dana would welcome the opportunity to discuss with EPA which related powertrain components are included in this proposal. [EPA-HQ-OAR-2022-0829-0538, p. 2]

Organization: Environmental. and Public Health Organizations

X. EPA Should Adopt the Proposed Durability and Warranty Requirements, But Should Also Require State-of-Certified Range Monitors.

We urge EPA to adopt the proposed PEV durability and warranty requirements. 88 Fed.

Reg. at 29283-87. As EPA explains, the calculation of emission credits for PEVs is based on attributed mileage over their useful life. 88 Fed. Reg. at 29283. In addition to helping ensure that PEVs will in fact achieve the projected emission reductions throughout their useful lives, the warranty and durability requirements will enhance consumer confidence in PEVs and promote their faster adoption among purchasers, leading to greater air quality benefits. [EPA-HQ-OAR-2022-0829-0759, p. 90]

EPA's authority to adopt the proposed durability requirements is grounded in Section 206 of the Clean Air Act, which (read in conjunction with Section 203) provides that before introducing a new motor vehicle into commerce, a manufacturer must obtain an EPA "certificate of conformity" indicating that the vehicle complies with applicable emission standards promulgated under Section 202. 42 U.S.C. § 7525(a)(1); 42 U.S.C. § 7522(a)(1). Section 202(a)(1), in turn, requires vehicles to achieve compliance with standards throughout their "useful life," "whether such vehicles and engines are designed as complete systems or incorporate devices to prevent or control such pollution." 42 U.S.C. § 7521(a)(1). Section 206 also provides that EPA may condition the certificate of conformity "upon such terms…as [it] may prescribe." 42 U.S.C. § 7525(a)(1). The statute thus confers broad authority on EPA to ensure that PEVs (like any other motor vehicle) in fact achieve the level of emission reductions attributed to them for purposes of compliance calculations throughout their useful lives. [EPA-HQ-OAR-2022-0829-0759, p. 90]

Durability is also important for PEVs to ensure that vehicles in their second or third use cases maintain their durability and strong benefits to drivers. EPA points to several studies that highlight the importance of battery durability for PEVs, and notes that auto manufacturers are already required to "account for potential battery degradation that could result in an increase in CO2 emissions." 88 Fed. Reg. at 29283. Extending these requirements to PEVs is logical and well within EPA's authority. [EPA-HQ-OAR-2022-0829-0759, p. 90]

Manufacturers are well-equipped to meet durability requirements, which are already in place in other jurisdictions. The United Nations Global Technical Regulation No. 22 (GTR No. 22) recommends durability standards for batteries in vehicles.222 EPA notes that Agency staff chaired the informal working group that developed these standards. 88 Fed. Reg. at 29284 n.536. In the United States, the California Air Resources Board has established battery durability and warranty standards in the Advanced Clean Cars II regulations. Id. at 29284 nn.537-38. Pending approval of the ACC II waiver from EPA, at least seven states (representing approximately 25% of the United States vehicle sales market) will have enforceable battery durability and warranty requirements. Therefore, EPA's consideration of battery durability and warranty standards is aligned with global trends and policies, and we support the proposed incorporation of GTR No. 22 into EPA's final rule. [EPA-HQ-OAR-2022-0829-0759, pp. 90-91]

222 See United Nations, Addendum 22: United Nations Global Technical Regulation No. 22 § 1.A, April 14, 2022.. https://unece.org/sites/default/files/2022-04/ECE_TRANS_180a22e.pdf.

However, while EPA has chosen to incorporate many parts of GTR No. 22, the Agency has chosen not to require a monitor for the vehicles' state of certified range (SOCR), without providing a sufficient justification. EPA recognizes that the state of certified energy (SOCE) is important to track minimum performance requirements, which we support. However, EPA notes that "monitoring the state of a vehicle's full-charge driving range capability… as an indicator of battery durability performance may be an attractive option because driving range is a metric that is more directly experienced and understood by the customer." 88 Fed. Reg. at 29286. The GTR No. 22 includes a requirement for SOCR, but it is not customer-facing, while California's ACC II program requires a range metric instead of a SOCE metric. Id. As EPA notes, drivers are accustomed to think about the range of their vehicles, not the energy levels of the battery. Id. [EPA-HQ-OAR-2022-0829-0759, p. 91]

Therefore, we request that EPA require both a SOCE monitor for compliance purposes as well as a SOCR monitor within the vehicle to provide confidence and transparency to drivers about the state of health of their vehicle battery. This is especially important as the vehicles transition into the secondary market, as SOCR monitors will enhance consumer confidence in used PEVs. We also request that EPA require the SCOR be readable by the customer, in addition to regulatory authorities. [EPA-HQ-OAR-2022-0829-0759, p. 91]

We also support the proposed warranty provisions, which fall well within EPA's authority under the Clean Air Act. Section 207(a)(1) provides that manufacturers of motor vehicles must warrant that the vehicle is "free from defects in materials and workmanship which cause such vehicle . . . to fail to conform with applicable regulations" for the warranty period specified by EPA through regulation. 42 U.S.C. § 7541(a)(1). And Section 207(i)(2), which applies specifically to light-duty vehicles and light-duty trucks, establishes a warranty period for "specified major emission control components," including catalytic converters, electronic emissions control units, onboard diagnostic devices, and "any other pollution control device or component" EPA designates under that section. 42 U.S.C. § 7541(i)(2). PEV batteries and associated electric powertrain components are no different from the enumerated emission control technologies—they are "pollution control device[s] or component[s]" because they enable the control (in fact, the complete elimination) of tailpipe emissions from motor vehicles. We agree with EPA's rationale for applying warranty requirements to PEV batteries and associated electric powertrain components, 88 Fed. Reg. at 29286-87, and we recommend that EPA finalize this aspect of the Proposal. [EPA-HQ-OAR-2022-0829-0759, p. 91]

Organization: Fermata Energy

III. Recommendations regarding V2G in EPA rules and EPA's Proposed Battery Durability Monitoring and Warranty Requirements for Light-and Medium-Duty Electric Vehicles

Any eventual battery durability requirements set by EPA should account for frequent bidirectional charging (e.g. such as vehicle-to-grid) activities [EPA-HQ-OAR-2022-0829-0710, pp. 6-7]

We recognize that the EPA is proposing battery durability and warranty requirements that are less than those in Advanced Clean Cars II and we appreciate that.. However, the EPA made no mention of the need for V2G technology in light-and medium-duty BEVs and PHEVs in the proposed rule. [EPA-HQ-OAR-2022-0829-0710, pp. 6-7]

Battery degradation is an inherently complex topic; battery chemistry, temperature, use cases, the EV duty cycle, and other factors all impact battery degradation. Some V2X activities, especially those utilizing bidirectional charging capabilities, will require additional battery cycling that will impact long-term battery durability. While the exact level of cycling will depend on the specific V2X use case and could vary based on customer behavior, it is reasonable to expect that in the future most EVs could experience some incremental level of degradation due to V2X activities. [EPA-HQ-OAR-2022-0829-0710, pp. 6-7]

Given the extensive public and private benefits that V2X can offer, as detailed above, it is paramount that any battery durability and warranty requirements EPA establishes for EVs not inadvertently foreclose V2X activities, and especially V2G opportunities. Setting overly-stringent durability requirements that limit V2X activities – whether intentionally or not – conflicts with the EPA's larger mission of reducing emissions and accelerating EV adoption. [EPA-HQ-OAR-2022-0829-0710, pp. 6-7]

Final battery warranty and battery durability requirements should include a thorough understanding of the impact on V2G in light-and medium-duty vehicles so as to not discourage V2G. At a minimum, the EPA should lower the warranty requirement to account for frequent bidirectional charging and allow automakers to exclude vehicles that have done V2X from the pool of vehicles in the durability test sample. [EPA-HQ-OAR-2022-0829-0710, pp. 6-7]

We do not see any consideration of frequent use of V2G in this proposal. V2G technology is emerging in light-duty and medium-duty vehicles, and attractive use cases exist (e.g. EVs that spend many hours connected to a charger or EVSE in a fleet or for personal use, such as school buses). The concern is that overly restrictive warranty or durability requirements by the EPA could place arbitrary restrictions on V2X activities. Fermata Energy appreciates the EPA's intent to ensure consumer protection and customer satisfaction with EV ownership through robust standards and to meet the useful life requirements in the Clean Air Act. However, overly stringent requirements that constrain battery cycling could also constrain the novel set of value propositions that V2X offers and that would otherwise spur EV adoption (e.g., home backup power, payment for grid services, customer bill management, etc.). Overly stringent battery durability requirements could drive OEMs to limit the range, performance, and/or state of charge of EV batteries, or take other measures to provide for sufficient degradation margin in later years. As such, Fermata Energy believes that the EPA should consider an approach to durability and warranty requirements that balances competing factors and specifically considers the GHG benefits of V2G as a storage technology which unlocks and enables a faster, more cost-effective transition to renewable energy. [EPA-HQ-OAR-2022-0829-0710, pp. 7-8]

Furthermore, we note there are ongoing efforts by the Informal Working Group on Electric Vehicles and the Environment under the United Nations Economic Commission for Europe (UN ECE) to develop minimum performance requirements for EV batteries that include V2X considerations. This Working Group is chaired by the US Environmental Protection Agency (EPA) and includes the European Commission, individual European and Asian countries, as well as industry stakeholders from around the world. In order to account for VGI activities, the Working Group is also considering a "virtual km" mechanism, in which the energy discharged by the EV battery in bidirectional mode is converted to a km-equivalent via a predetermined formula.14 The total mileage used for confirming the compliance with the performance requirements would consist of the sum of the km driven and the virtual km. While Fermata Energy is not necessarily endorsing this specific approach or methodology, we believe that the EPA should seriously consider an agreed upon method to account for V2G battery degradation such as the UN Global Technical Regulation "virtual miles" before adopting a final regulation with durability or warranty requirements. [EPA-HQ-OAR-2022-0829-0710, pp. 7-8]

14 For example, see the following presentation on V2X virtual mileage at the 50th EVE IWG meeting: https://wiki.unece.org/download/attachments/128420289/Input%20on%20V2X%20virtual%20mileage.pptx?api=v2

In the absence of an agreed upon method to account for V2G battery degradation, OEMs may choose to reach individual battery warranty agreements with V2X services providers to approve specific equipment for use with their bidirectionally-enabled vehicles. In September 2022, Nissan approved the Fermata Energy bidirectional charger as the first bidirectional charging system for use with its all-electric LEAF vehicle in the US.15 While these sorts of battery warranty approvals are a very important development for the bidirectional charging industry, OEM approval processes can be slow. It may take years for other OEMs to negotiate these sorts of agreements with V2X charger manufacturers and service providers. An agreed-upon methodology for accounting for V2G battery degradation would be the more expedient approach to ensuring battery durability, instead of relying on individual OEM to EVSE agreements, which could take years. [EPA-HQ-OAR-2022-0829-0710, pp. 7-8]

15 https://usa.nissannews.com/en-US/releases/release-5078281d19ed36853371357c4a1a8244-nissan-approves-first-bi-directional-charger-for-use-with-nissan-leaf-in-the-us

Regarding battery warranties, Fermata Energy recommends that the EPA 1) either delay adopting battery warranty requirements to a future rulemaking when more data on V2X is available or 2) reduce the battery warranty requirement in the final regulation to account for and assume frequent vehicle-to-grid charging by battery EVs and plug-in hybrid EVs. We also recommend that the EPA explicitly state that automakers may exclude those vehicles that have done vehicle-to-building or vehicle to grid charging from the pool of vehicles in the battery durability test sample. The Advanced Clean Cars II regulation took this approach, and we recommend the EPA do the same. [EPA-HQ-OAR-2022-0829-0710, p. 8]

The EPA should add in the final regulation a small multiplier credit for vehicles that have on-board AC bidirectional chargers or are integrated with multiple DC off-board chargers. [EPA-HQ-OAR-2022-0829-0710, p. 8]

Organization: Ford Motor Company

-In the NPRM’s redline of regulatory text for 40 CFR § 86.1845-04(g), EPA states that manufacturers perform Part A in-use testing related to monitor accuracy at low-mileage (1 year), intermediate mileage (3 years), and high mileage intervals (5 years). While Ford understands EPA’s desire to ensure that battery State of Certified Energy (SOCE) monitors are accurate, this new in-use testing requirement will create additional vehicle procurement, in-use testing, and reporting burdens for electric vehicles. Additionally, the NPRM requirement to perform full MCTs on these in-use vehicles for monitor validation will add significant mileage to these vehicles (>400-500 miles), which may make it more difficult to procure in-use electric test vehicles. Since battery monitor accuracy is not expected to degrade over the 1 – 5 year in-use timeframe, Ford recommends that EPA require only the intermediate testing for Part A SOCE validation. In summary, requiring Part A in-use testing at three-time intervals is excessive since we would expect that similar SOCE accuracy trends to be present at each in-use timeframe. [EPA-HQ-OAR-2022-0829-0605, pp. 15-16]

Ford also requests that virtual mileage as referenced in GTR No.22 be included in the battery durability and warranty standards. [EPA-HQ-OAR-2022-0829-0605, pp. 15-16]

Organization: Hyundai Motor America

In addition, EPA’s assumption of no cost increase resulting from the proposed battery durability and warranty requirements is not accurate. It is true the Proposed Alternative’s requirements are on par with current product in the market when measured by years and mileage comparison. However, there are other costly requirements that accompany the battery durability proposal that do not currently exist today. For example, the development and rollout of a state of health (“SOH”) monitor meeting the State of Certified Energy (“SOCE”) requirements24 will add cost. In addition, there are compliance demonstration requirements increasing costs related to the frequency of testing and reporting. These new requirements undoubtedly come with additional cost and should be considered by EPA. [EPA-HQ-OAR-2022-0829-0599, pp. 6-7]

24 The NPRM's SOH criteria specifically call for 80 percent minimum SOCE at 5 years or 62,000 miles, and a 70 percent minimum SOCE at 8 years or 100,000 miles.

Organization: International Council on Clean Transportation

Acknowledging the significant fraction of new U.S. light- duty vehicles subject to California's regulations, ICCT recommends EPA align with California's BEV and PHEV provisions on battery durability, warranty, state of health, and other measures. Such an alignment not only ensures adequate performance of plug-in vehicles for purposes of emissions reductions, but it would protect all consumers purchasing EVs and would support the development of secondary EV markets. [EPA-HQ-OAR-2022-0829-0569, pp. 7-8]

Organization: Kia Corporation

-Kia supports adoption of United National Economic Commission Europe (UNECE) Global Technical Regulations (GTR) No. 22 Phase 1 to measure Usable Battery Energy (UBE). Kia agrees that EPA's battery state of health (SOH) requirement could help support consumer acceptance and understanding of new powertrain technology. However, Kia supports the State of Certified Energy (SOCE) as the only monitor. [EPA-HQ-OAR-2022-0829-0555, p. 3]

Kia Recommendations on EV Battery Warranty and Durability

EPA proposes new battery durability and warranty requirements for BEVs and PHEVs including 8 years or 80,000 miles for the powertrain components.15 Kia agrees that EPA's battery state of health (SOH) requirement, which communicates to the vehicle's state of certified energy (SOCE), could help support consumer acceptance and understanding of new powertrain technology. [EPA-HQ-OAR-2022-0829-0555, pp. 8-9]

15 88 Fed. Reg. 29,288.

Kia supports adoption of the United Nations Economic Commission for Europe (UNECE) Global Technical Regulations (GTR) No. 22 Phase 1 to measure Usable Battery Energy (UBE) as a durability measurement. However, Kia supports the State of Certified Energy (SOCE) as the only monitor. UBE is a prudent measurement for customers to understand the life remaining in the battery that meets or exceeds the proposed warranty requirement. [EPA-HQ-OAR-2022-0829-0555, pp. 8-9]

Kia does not support the State of Certified Range (SOCR) in addition to the SOCE. Range is highly variable on the driving and cabin conditioning habits of the owner. Further, when the vehicle is sold to a second buyer, the range prediction will reflect the previous owner's habits, and potentially could display an incorrect SOCR that could inflate or underestimate the usable range of the vehicle. As plug-in vehicles (BEV and PHEVs) continue to increase in the market, general customer understanding of battery range and durability will also increase. We support SOCE as a single measurement of the health of the battery. ICE vehicles are not required to display a SOCR because the range is extremely reliant on consumer behavior. Similarly, as the EPA proposed rule aims to be performance-based and technology neutral, plug-in electric vehicles should not be required to display a SOCR. [EPA-HQ-OAR-2022-0829-0555, pp. 8-9]

Kia does not support including the reserve capacity in the SOCE metric. The additional battery reserve capacity, intended to maintain battery integrity, is not accessible to the customer until the battery reaches a certain degradation. This amount of degradation needed to trigger accessibility to reserve battery capacity will be unique between automakers and battery cell manufacturers. Including the reserve capacity in the SOCE metric would undermine the importance of having this additional capacity: maintaining a usable capacity for the rated battery for the stated time for vehicle use, not for customers to rely on the additional battery capacity. [EPA-HQ-OAR-2022-0829-0555, pp. 8-9]

Kia Supports Including Virtual Mileage in Customer Information

Leveraging bi-directional capability of EVs, especially as these vehicles compete with stationary energy sources for cathode active materials, is paramount to future EV adoption. Utilities are currently exploring vehicle to home (V2H) and vehicle to grid (V2G) projects to enhance grid reliability and reduce additional grid resources. With the correct incentives, Vehicle to Everything (V2X) could be a useful side benefit that offsets the cost of EV ownership. The potential for these daily energy discharges of the traction battery, outside of driving events, should be properly accounted for in Usable Battery Energy (UBE). [EPA-HQ-OAR-2022-0829-0555, pp. 8-9]

Because EPA is adopting most provisions of the UNECE GTR No. 22, EPA seems to be adopting “virtual mileage” from V2X events into battery requirements. Kia proposes that the EPA extend this “virtual mileage” definition to the proposed warranty standards to accurately reflect the overall measure of the battery’s usage and health. These provisions will give customers a more accurate understanding of their overall battery usage and will ensure that these vehicles remain on the road across multiple owners. [EPA-HQ-OAR-2022-0829-0555, pp. 8-9]

Organization: Lucid Group, Inc.

Battery Warranty and Durability Requirements

Lucid supports EPA's attention to battery durability and warranty. As EPA has recognized, multiple organizations and agencies have drafted rules and guidance which provide an opportunity to harmonize various requirements where appropriate. Specifically, we respectfully request EPA consider CARB's current battery warranty under ACCII, 70% state of health (SOH) for 8 years or 100,000 miles, which aligns with EPA's proposed end point warranty. This would adequately address the agency's concern of vehicle performance during its useful life. EPA's current proposal requires a midpoint state of certified energy (SOCE) of 80% at 5 years based on UN GTR No. 22. A mid-point requirement is unnecessary if an 8-year useful life is the concern. [EPA-HQ-OAR-2022-0829-0664, pp. 5-6]

Further, the data cited by UN GTR No. 22 was based on the fleet at the time and extrapolated to show that 80% of the fleet would meet the 80% SOCE at 5 years. Given battery degradation over time is nonlinear, a mid-point requirement at this time may be premature without more real-world data. Similarly, more stringent battery standards may be appropriate when more data is available as EV penetration increases and OEMs encounter a wider variety of real-world use cases. [EPA-HQ-OAR-2022-0829-0664, pp. 5-6]

Additionally, bidirectional charging and discharging technology, such as from the vehicle to the grid, is increasingly found on vehicles. This type of cycling wears on the vehicle battery and is not captured in the mileage or age of the vehicle. Lucid suggests the agency consider how this potential wear would affect the battery warranty requirement. We believe the agency should consider a mileage equivalent or similar metric for each bidirectional charge or amount of energy delivered to the grid or number of cycles the battery undergoes. [EPA-HQ-OAR-2022-0829-0664, pp. 5-6]

Lucid supports CARB's approach to SOH calculations and battery reserve capacity and encourages EPA to consider that approach. [EPA-HQ-OAR-2022-0829-0664, pp. 5-6]

Lucid supports the use SOCE because it is a more direct metric to measure the status of degradation of the battery pack itself. As the UN GTR No. 22 indicated, estimating the SOCR includes many variables such as "measurement, test to test variability and precision of range retention calculations," which leads to greater uncertainty in that value. Providing an estimated SOCR introduces additional nuances which are unlikely to contribute to the customer's understanding of the state of degradation of their battery pack. [EPA-HQ-OAR-2022-0829-0664, pp. 5-6]

Lucid supports integrating "a customer-accessible" display that conveys the battery's SOCE. This display should be broadly interpreted and allow the data to be an option in the vehicle's infotainment system or dashboard menu. [EPA-HQ-OAR-2022-0829-0664, pp. 5-6]

Lucid Supports Warranty Requirements for Specific Components Designated as "SMECC"

EPA proposes to designate the "high-voltage battery systems and associated powertrain components" as "specified major emission control components" to require manufacturers to provide a warranty period of 8 years or 80,000 miles for those parts. Lucid supports this warranty requirement, but encourages the agency to develop an explicit list of "related powertrain components" in consultation with industry or consider defining these components as the vehicle’s drive unit or motor, inverter, transmission, and differential, if so equipped. [EPA-HQ-OAR-2022-0829-0664, pp. 5-6]

Organization: MECA Clean Mobility

MECA supports alignment with UNECE Global Technical Regulations for battery durability and consideration of phase-in to match vehicle useful life in later years. [EPA-HQ-OAR-2022-0829-0564, p. 33]

MECA supports new battery durability monitoring and performance requirements for light-duty BEVs and PHEVs, and battery durability monitoring requirements for Class 2b and 3 BEVs and PHEVs, beginning with MY 2027 in alignment with UNECE GTR No. 22 and soon to be completed GTR 22b for medium-duty vehicles. These include SOH monitors and usable battery energy (UBE) measurement requirements, vehicle range and virtual miles traveled for medium-duty vehicles with power take-off (PTO) or vehicle-to-X capability of light-duty vehicles. This information will serve to generate durability data to support future EPA programs, as well as industry and consumer needs. While the EVE IWG chose not to set an MPR for Category 2 (MDV) plug-in electric vehicles at this time, MECA supports EPA aligning with a future minimum performance requirement for MDVs when the UNECE finalizes an applicable GTR. [EPA-HQ-OAR-2022-0829-0564, p. 33]

As experience with battery durability develops, MECA requests the requirements be revisited and durability requirements be extended to match the useful life of light-and medium-duty vehicles. Most consumers expect the battery to last the life of the vehicle in these classes, and alignment of the durability period with the vehicle useful life will facilitate consumer acceptance and drive innovation in battery technology. [EPA-HQ-OAR-2022-0829-0564, p. 33]

MECA supports EPA's proposed battery and vehicle component warranty requirements.

MECA supports EPA's proposed new warranty requirements for BEV and PHEV batteries and associated electric powertrain components, such as electric machines, power electronics, and similar key electric powertrain components. We agree with the concept of building on existing high value component warranty provisions, such as emission controls. We support designating the high-voltage battery and associated electric powertrain components for light-duty electric vehicles as specified high value components subject to a warranty period of 8 years or 80,000 miles. In addition, we support the same warranty periods for components in medium-duty BEVs and PHEVs. This will give consumers confidence in the reliability of any powertrain they chose for their vehicle. [EPA-HQ-OAR-2022-0829-0564, pp. 33-34]

Organization: MEMA, The Vehicle Suppliers Associated

- Extended warranty. The necessity to clearly define the applicability of the extended warranty and the need to provide repair access to service these new vehicles. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

Warranty Provisions Must Not Preclude Choice in Repair of Exclude the Aftermarket

MEMA urges EPA to not proceed with provisions mandating longer warranties for specific BEV parts, components, and systems. Vehicle warranties undergo robust regulatory oversight by the Federal Trade Commission (FTC) under authority granted by the Magnusson-Moss Warranty Act. These regulations meet the needs of consumers by providing reasonable warranty protections while protecting consumer choice. If EPA chooses to move forward with the warranty requirements outlined in the NPRM, MEMA urges the EPA to clarify that warranty repairs can be completed at dealer or authorized repair locations, and at quality independent aftermarket repair locations. This would ensure safety, affordability, and access to warranty repairs. Any EPA warranty regulations should specify that vehicle manufacturers and consumers, in line with the Magnusson-Moss Warranty Act, can employ certified or independent repair facilities of their choice for warranty repairs. Facilities must follow manufacturer repair and warranty procedures, warranty repairs can use parts and remanufactured parts that meet manufacturer specifications, and repair procedures and appropriate specifications are made available. The repair and maintenance of in-service vehicles is critical ensuring they operate as designed I and continue to meet and emissions standards. A properly operating vehicle is critical for millions of Americans as their daily transportation. In many locations throughout the country, the nearest dealer or authorized repair facility is, at best not the most convenient option or, at worst, hours away. [EPA-HQ-OAR-2022-0829-0644, pp. 14-15]

Further, EPA has not clearly defined specific vehicle parts intended to be covered by the proposed warranty requirements, particularly those related to high-voltage battery and propulsion motors. [EPA-HQ-OAR-2022-0829-0644, pp. 14-15]

MEMA urges EPA to maintain current limitations and not expand warranty coverage to parts that have a shorter life and are a routinely replaced due to wear, or are adjacent to the warrantied parts through physical, electrical, or software connections but not the targeted component; such as sensors, filters, monitoring systems, cooling systems, HVAC, braking systems, control systems, inverters, converters, charging systems, structural systems, transmissions, other drivetrain components, electrical motors not part of the forward propulsion system, and filters. In particular, it is important that components found in both an ICE and a zero emissions vehicle not carry longer warranties for ZEVS than for ICE. We urge EPA to work with industry stakeholders, including original equipment and aftermarket suppliers and remanufacturers, to develop a list of wear and non-applicable parts and components with these criteria in mind. [EPA-HQ-OAR-2022-0829-0644, pp. 14-15]

Finally, MEMA urges EPA to consider the impact longer warranties could have on choices in consumer repair. Longer warranties could lead to monopolistic repair, resulting in delays, potential safety concerns, and increased costs for businesses and consumers. To successfully implement the warranty provisions, repair access needs include appropriate repair and maintenance information (RMI) to enable safe, educated repairs. This typically includes diagnostic codes, repair procedures, drawings, and vehicle specifications to enable safe and complete repair. This has typically been provided for other vehicle systems but is often not made available for the technologies that will be covered by the new warranty provisions. In addition, access to vehicle diagnostics and state of health, including for all items under warranty and related systems, for owners, fleets, and repair professionals, need to be provided. This includes secure over-the-air (OTA) access to vehicle diagnostics and state of health on a fair, reasonable, and nondiscriminatory (FRAND) basis. [EPA-HQ-OAR-2022-0829-0644, pp. 14-15]

MEMA urges: [EPA-HQ-OAR-2022-0829-0644, pp. 14-15]

- EPA to clarify that warranty repairs can be completed at dealer or authorized repair locations, and at quality independent aftermarket repair locations.

- EPA to not proceed with provisions mandating longer warranties for specific BEV parts, components, and systems.

- EPA to consider the impact longer warranties could have on choices in consumer repair. [EPA-HQ-OAR-2022-0829-0644, pp. 14-15]

Organization: Mercedes-Benz AG

EPA has included battery-related requirements in the NPRM for BEVs and PHEVs. These OBD provisions are misaligned and in some cases conflict with CARB’s battery-related requirements, including: [EPA-HQ-OAR-2022-0829-0623, p. 13]

1. Some low-mileage hybrid vehicles do not qualify for ZEV credits under California’s ZEV program. Therefore, these vehicles are not subject to nor have development resources allocated to comply with ZEV battery monitoring and display requirements.

EPA should align with CARB and restrict monitoring and display requirements only to BEVs with minimum 200-mile range and PHEVs Bin30 or cleaner with minimum 70-mile range, i.e., vehicles that qualify for ZEV credits under California's ZEV program. [EPA-HQ-OAR-2022-0829-0623, p. 13]

2. For the battery health display provisions, CARB requires the use of State of Health ("SOH"), while EPA has proposed to harmonize with the UNECE GTR 22 and use State of Certified Energy ("SOCE"). [EPA-HQ-OAR-2022-0829-0623, p. 13]

For battery packs without a battery reserve, the SOCE is equivalent to the SOH. However, for packs with a reserve, the EPA and CARB metrics are misaligned. This misalignment is further complicated by the fact that both agencies require a display of the battery health metric visible to drivers. Display of two different metrics will be confusing to drivers who will likely find it challenging to understand what the two different measurements of battery health indicate. [EPA-HQ-OAR-2022-0829-0623, p. 13]

Mercedes-Benz requests that EPA allow manufacturers to voluntarily comply with the CARB ACCII provisions for battery health display with respect to reserve energy in lieu of the EPA display requirement, in order to reduce consumer confusion and provide consistent information to the customer. [EPA-HQ-OAR-2022-0829-0623, p. 13]

3. With respect to enforcement provisions, the EPA proposal for SOH/SOCE accuracy provisions are misaligned with CARB's ACCII requirement. First, CARB phases-in enforcement of the 5% accuracy requirement between 2026 to 2029 MYs, while the EPA requires 100% phase-in for 2027 MY. Second, the CARB requirement includes only an upper tolerance limit, while the EPA is proposing to include both an upper and lower tolerance limit. And third, CARB uses "percentage points", while EPA uses "Percent". This difference can be understood with a simple example: 5 percentage points added to 60 = 60 + 5 = 65, while 5 percent added to 60 = (60*1.05) = 63. [EPA-HQ-OAR-2022-0829-0623, p. 13]

Mercedes-Benz requests that the EPA align their regulation to the CARB regulation for battery accuracy provisions to avoid conflicting regulatory requirements and ensure manufacturers have appropriate flexibility in meeting these upcoming requirements. [EPA-HQ-OAR-2022-0829-0623, p. 13]

Section IV: Batteries

V2X applications such as vehicle-to-grid, vehicle-to-load, and vehicle-to-home are increasingly considered key features that will support the shift to electrification. For instance, the California legislature is currently considering a mandate for all new vehicles in the state to have bidirectional charging capability starting in 2030 MY. Regardless of California's law or separate OEM efforts to advance V2G, inclusion of the parameter, "virtual distance", is fundamental to the transparent deployment of V2G technology. As such, we would like EPA to add virtual distance to the regulatory language in both the durability and warranty mileage calculation. [EPA-HQ-OAR-2022-0829-0623, pp. 15-16]

Organization: Minnesota Pollution Control Agency (MPCA)

-Align battery durability and warranty provisions with Advanced Clean Cars II (ACC II) program The MPCA encourages EPA to bring its battery durability and warranty provisions into line with the Advanced Clean Cars II program. The ACC II durability and warranty program supports the development of EVs that can replace combustion engine vehicles for similar use cases. If EVs are to become the primary vehicle type in the future, they need to be durable, and the battery life needs to be transparent to the user when purchased new and in the secondary market. Bringing the EPA program into line with the ACCII program would result in improved durability and transparency for consumers, ensure emissions standards deliver expected emission reduction and needed environmental public health benefits, and set consistent expectations for manufacturers nationwide. Seven states representing roughly 20 percent of the new light-duty vehicle market have already adopted ACC II, and several others are expected to follow. More closely aligning EPA's durability and warranty provisions with those in ACC II will make it easier for consumers, used automobile dealers, and others to compare the battery state of health for EVs subject the ACC II regulations with those subject to EPA's final rule. [EPA-HQ-OAR-2022-0829-0557, p. 5]

Organization: National Association of Clean Air Agencies (NACAA)

Finally, NACAA recommends that EPA include provisions in the final rule that align with ACC II regarding data standardization, durability, warranty, minimum mileage range labeling, charging and serviceability requirements. [EPA-HQ-OAR-2022-0829-0559, p. 8]

Organization: National Tribal Air Association (NTAA)

Vehicle Durability

The proposed requirements for battery durability and warranty are exceedingly important. Many Tribal communities are distant from comprehensive vehicle maintenance and repair facilities. Alaskan Native Villages are particularly vulnerable to the high costs of vehicle operations. The NTAA supports these provisions that will improve extended battery life and vehicle reliability. [EPA-HQ-OAR-2022-0829-0504, p. 3]

Organization: Nissan North America, Inc.

V. Battery Durability Proposal

Nissan understands the critical importance of battery performance to achieving overall electrification goals. As a result, Nissan has committed to significant investments in research and development of state-of-the-art battery technology, including a focus on development and implementation of ASSBs in future EV offerings. Nissan supports EPA's proposal to largely align its battery durability requirements with the requirements set out in UENCE GTR No. 22. Nissan also supports EPA's proposal to not adopt a reserve capacity declaration requirement or State of Certified Range ("SOCR") monitor. Nissan supports the use of Usable Battery Energy ("UBE") as the primary metric for measuring battery durability. [EPA-HQ-OAR-2022-0829-0594, pp. 7-8]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC)

D. Proposed EV Battery Durability and Warranty Provisions

NESCAUM and the OTC support EPA's proposal to include minimum battery durability requirements and warranty provisions for BEV and plug-in hybrid electric vehicle (PHEV) batteries and associated electric powertrain components. Batteries and associated electric powertrain components are emission control devices that allow BEVs to operate with zero tailpipe emissions and reduce emissions from PHEVs. By requiring manufacturers to demonstrate that test groups of BEVs and PHEVs meet battery durability requirements throughout their useful lives, EPA will be able to assess whether BEVs and PHEVs will operate as expected over time. Warranty requirements protect consumers against individual vehicles that experience failures or defects. [EPA-HQ-OAR-2022-0829-0584, pp. 11-12]

As EPA surmises, emission control components covered by warranty are more likely to be repaired or replaced as needed. Thus, working in tandem, the durability and warranty provisions will ensure that EPA's emissions standards deliver expected emission reductions and needed environmental and public health benefits. In addition, these provisions are integral to instilling consumer confidence in the performance and durability of BEVs and PHEVs, not only when new, but also in secondary markets. [EPA-HQ-OAR-2022-0829-0584, pp. 11-12]

To the maximum extent possible, NESCAUM and the OTC encourage EPA to align the durability and warranty provisions in its final rule with those in the ACC II regulations. As mentioned above, seven states representing roughly 20 percent of the new LDV market have already adopted ACC II, and several others are expected to follow. More closely aligning EPA's durability and warranty provisions with those in ACC II will make it easier for consumers, used automobile dealers, and others to compare the battery state of health for BEVs and PHEVs subject the ACC II regulations with those subject to EPA's final rule. [EPA-HQ-OAR-2022-0829-0584, pp. 11-12]

Organization: POET, LLC

Another issue with U.S. EPA's battery cost assessment is that it appears to completely ignore the impact of the cost of the proposed battery durability and warranty provisions of the Proposed Rule. These new regulatory requirements will clearly impose costs on battery manufacturers and automakers which will ultimately be passed on to consumers and should be included in U.S. EPA's analyses. [EPA-HQ-OAR-2022-0829-0609, p. 58]

Organization: Rivian Automotive, LLC

Battery Durability and Warranty Requirements

Rivian believes reasonable battery durability standards and consumer-facing transparency in battery health will support the EV market's growth and success. EPA's proposal to include a durability requirement in the L/MDV standards evolves the regulation for a vehicle market in which EVs will dominate. Consistent with our position during the development of California's ACCII regulations, Rivian believes aligning EPA's requirements with Global Technical Regulation ("GTR") 22 will establish a practicable standard that can be harmonized on a global basis. In the NPRM, EPA sought comment on various aspects of its proposed approach to establishing and testing for durability and warranty standards. Rivian addresses several of these in turn below. [EPA-HQ-OAR-2022-0829-0653, p. 13]

Disclosing Battery Reserve Capacity

Unlike CARB's ACCII durability program, EPA does not propose to require manufacturers to disclose reserve capacity that they initially withhold from consumers.41 Disclosing reserve capacity involves tradeoffs but can serve compelling interests. While it burdens automakers with an additional compliance obligation, it supports consumers who benefit from additional product transparency—particularly in the used vehicle market. As a fundamental principle, if manufacturers elect to use larger batteries and/or withhold capacity for purposes of complying with durability requirements, consumers should be informed and aware. [EPA-HQ-OAR-2022-0829-0653, p. 14]

Asymmetric information in this regard could undermine consumer confidence and incentivize hidden battery upsizing among manufacturers. There is also the matter of regulatory harmonization across CARB and EPA programs. Ultimately, we believe there are benefits to requiring disclosure of battery reserve capacity and EPA might wish to consider establishing a requirement in this or a future rulemaking.42 [EPA-HQ-OAR-2022-0829-0653, p. 14]

41 13 C.C.R. §1962.5.

42 Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, 88 Fed. Reg. 87 (May 5, 2023) (revising 40 C.F.R. Parts 85, 86, 600, 1036, 1037, and 1066, 29,286.

In the event of a failure in a durability testing group, EPA clearly provides for the removal of compliance credits attributed to the failing vehicles from a manufacturer's credit bank. Rivian supports this proposed penalty but seeks clarification on its scope. Would the credit removal apply only to GHG credits or also to NMOG and NOx? Rivian believes NMOG and NOx credits should be subject to the same penalty in the event of a durability testing failure. [EPA-HQ-OAR-2022-0829-0653, pp. 14-15]

Establishing Additional Components as Specified Major Emission Control Components ("SMECCs")

EPA proposes to define "associated powertrain components" as SMECCs under the Clean Air Act. Rivian understands the agency's rationale and does not necessarily object to this action, but additional clarity would aid our evaluation of the proposal's full implications. EPA should clearly define the components proposed to qualify as SMECCs under the new regulations: the NPRM provides only examples in the preamble.44 California regulations already define "propulsion-related parts" for purposes of the ACCII warranty requirements and could serve as the basis for identifying SMECCs.45 EPA should also clarify how anti-tampering rules would apply to components newly defined as SMECCs in scenarios where maintenance work is performed. Overall, we anticipate complexity in implementing this aspect of the proposal. The agency and affected manufacturers will likely benefit from compliance workshops following rule finalization to establish clear and practicable implementation guidance. [EPA-HQ-OAR-2022-0829-0653, pp. 14-15]

44 Id. at 29,286.

45 13 C.C.R. §1962.8.

Other Considerations

Vehicle-to-everything ("V2X") capabilities could introduce complexity, especially with respect to warranties and consumer-facing transparency regarding a battery's state of health.

Rivian did not see discussion of V2X capability or its impact on durability and warranty in EPA's rule documentation and requests clarity on the extent to which the agency considered the issue. As V2X capabilities see greater use across more EV models, EPA will likely need to evaluate the interaction of these applications with the durability and warranty standards proposed. Accounting for diverse V2X capabilities across manufacturers, not to mention varying approaches to marketing the technology, might favor a degree of regulatory flexibility. [EPA-HQ-OAR-2022-0829-0653, pp. 14-15]

One key issue to consider is whether, with EPA approval, manufacturers could account for V2X-related battery degradation in setting warranty terms and evaluating durability. [EPA-HQ-OAR-2022-0829-0653, pp. 14-15]

Organization: Sierra Club et al.

We appreciate the EPA's proposal, which moves our vehicles in the right direction. However, the final emissions standard for light-duty vehicles should: [EPA-HQ-OAR-2022-0829-0668, p. 2]

-Establish protective zero-emission vehicle durability and warranty requirements [EPA-HQ-OAR-2022-0829-0668, p. 2]

Organization: Southern Environmental Law Center (SELC)

EPA should adopt strong certification, durability, and warranty requirements.

Beyond more stringent numeric standards, EPA also proposes important improvements to vehicle certifications, durability, and warranty requirements. These changes will help to ensure light-and medium-duty vehicles run cleanly under a greater range of operating conditions across the lifetime of a vehicle—which we support. However, we urge EPA to consider ways that these provisions can be aligned with California's Clean Cars program. [EPA-HQ-OAR-2022-0829-0591, p. 10]

Organization: Stellantis

Battery Durability & Warranty Requirements are Beyond EPA's Scope

EPA has proposed new battery durability performance requirements for all light-duty PHEVs and BEVs, battery health monitoring and in-use accuracy for all light-and medium-duty PHEVs and BEVs, as well as warranties for PHEVs, BEVs, and FCEVs. [EPA-HQ-OAR-2022-0829-0678, p. 17]

Stellantis concurs with Auto Innovators' comment that battery durability requirements are beyond the scope of EPA's statutory authority for BEVs. EPA's authority covers emissions standards under CAA section 202, but there are no applicable air pollutant emissions standards for BEVs, which do not produce any such emissions. Similarly, EPA lacks the authority to prescribe warranty standards for BEV powertrain and associated components that do not emit any air pollutants. Stellantis agrees with Auto Innovators that warranty requirements are typically left to the respective OEMs to determine and should here as well be addressed by individual OEMs. EPA should not attempt to reach into the regulatory realm of consumer protection as it relates to battery durability and warranty; EPA's jurisdiction does not reach so far. Stellantis agrees with Auto Innovators that the stringent new durability, testing, and warranty provisions in the proposed rule do not comport with the CAA. [EPA-HQ-OAR-2022-0829-0678, p. 17]

Stellantis fully supports all technical AAI comments and recommendations on EPA's proposed battery durability and warranty requirements. [EPA-HQ-OAR-2022-0829-0678, p. 17]

Organization: Strong Plug-in Hybrid Electric Vehicle (PHEV)

Regarding battery durability and battery warranties, we are concerned that bi-directional charging was not considered. We request a more reasonable proposal in the final rule that assumes frequent bi-directional charging for the warranty requirement allows automakers to exclude from the durability test sample any BEV or PHEV that has been used for vehicle-to-grid or vehicle-to-building. As described in our recommendation 4 below, vehicle-to-grid and vehicle-to-building provide substantial benefits to society and to consumers. Therefore, EPA in its final rulemaking should carefully avoid unintentionally discouraging the development of this market with warranty and durability requirements for PHEVs (and BEVs) that are too stringent. We understand that there are many factors to consider including consumer protection, useful life requirements in the Clean Air Act, but the benefits to consumers, utility ratepayers and the environmental benefits of V2G and vehicle to building should also be considered. We understand that EPA does not propose durability and warranty requirements as strict as those in Advanced Clean Cars II. Even so, bidirectional charging should be addressed in the final rule, and the most practical way to do this is to make the test sample exception that was adopted in the Advanced Clean Cars II regulation. [EPA-HQ-OAR-2022-0829-0646, pp. 8-9]

Organization: Tesla, Inc.

EPA's Proposed Durability Standards Are Reasonable

Building consumer assurance is a key factor towards achieving significantly higher levels of BEV penetration. Tesla agrees with EPA that consumers should have access to information regarding the state of battery health (SOH), especially those considering the purchase of a used BEV or when filing a warranty claim. As further noted, durability monitoring can ensure emission reduction benefits are met and provide integrity to credit trading. [EPA-HQ-OAR-2022-0829-0792, pp. 26-27]

In providing such information, Tesla has favored a SOH monitor based upon battery capacity because it is directly proportional to vehicle range, depends on the least test conditions, can easily be run with an onboard diagnostic procedure, and can be verified with simple measurement equipment. Nonetheless, Tesla recognizes and participated in proceedings developing the UN GTR 22 and agrees with EPA's general adoption of the GTR 22 and a SOH monitor communicating the battery's state of certified energy (SOCE) based upon usable battery energy (UBE).167 Tesla also supports the agency's decision to not require a state of certified range (SOCR) monitor as development of an accurate SOCR monitor is far more difficult and burdensome than developing an SOCE monitor.168 Accurate SOCR monitoring would require, among other things, customizing road load test for each vehicle that can be programmed on the dynamometer. Such a testing burden would add significant cost to BEV deployment. Consistent with implementation of an SOH monitor and accuracy testing, Tesla believes the flexibility provided in the monitoring family definition provides assurances to manufacturers that deployment of similar monitors across different vehicle lines does not create any undue or repetitive SOCE testing burdens and cost. [EPA-HQ-OAR-2022-0829-0792, pp. 26-27]

168 Id., at 29288.

Imposing specific minimum durability performance requirements on BEVs provides no emissions reduction benefit. BEVs do not emit tailpipe (or evaporative) criteria pollutants and changes in battery durability and retained range do not alter this fact. Unlike emission controls in ICE vehicles, BEVs are also not vulnerable to defeat devices and tampering.169 Requiring durability standards can cause greater tailpipe emissions by harming the rate of BEV uptake through imposition of substantial new costs and designs with reserved battery capacity. Tesla respectfully submits that any speculative benefit from consumer assurance provisions such as minimum performance requirements must be balanced against increased up-front costs on BEVs, which are likely to slow consumer uptake and thereby increase emissions. Moreover, as the DOE has documented, BEV range continues to accelerate as the technology is deployed.170 As BEV range increases, the loss of incremental battery capacity over time (due to expected degradation) will matter less to consumers. [EPA-HQ-OAR-2022-0829-0792, pp. 26-27]

170 U.S. DOE, FOTW #1290, May 15, 2023: In Model Year 2022, the Longest-Range EV Reached 520 Miles on a Single Charge (May 15, 2023) available at h ttps://www.energy.gov/eere/vehicles/articles/fotw-1290-may-15-2023-model-year-2022-l ongest-range-ev-reached-520-miles.

Tesla believes the proposed minimum performance requirement (MPR) for the SOH are set at reasonable and achievable levels.171 Further, the decision not to implement a MPR for Class 2b and 3 will facilitate greater early adoption in those segments. For testing purposes, defining the battery family definition is best served by allowing manufacturers to utilize the criteria mentioned in the proposed regulation such as maximum specified charging power, method of battery thermal management, battery (cathode) chemistry and the net power of the electrical machines.172 This is far preferred over defining the families based on battery capacity which would create multiple families for the same vehicles with the same battery types and chemistry but different battery capacity. While establishing a 90 percent pass requirement for battery family monitor exceed the passage rates set in the ACC II durability provisions, Tesla agrees with the agency’s flexible approach allowing manufacturer to use good engineering judgment in determining the statistically adequate and representative in-use vehicle data for testing.173 [EPA-HQ-OAR-2022-0829-0792, p. 27]

171 88 Fed. Reg. at 29285, Table 64.

172 Id., at 29288. Tesla notes EPA should provide further guidance of the definition of “net power of electrical machines.”

173 See 13 CCR § 1962.4 (d).

EPA should not encourage manufacturers to overcome the durability threshold by creating larger batteries with hidden capacity that can slowly be accessed as the battery degrades. Encouraging this approach is fundamentally flawed. BEV customers, just like other light-duty vehicle customers, will have guarantees of performance from the manufacturer. Hidden capacity is adding cost for more performance than what the customer sought in their vehicle, will unnecessarily raise BEV prices, and dampen deployment of the best emissions reduction technology currently available. Encouraging full access to the battery (with reliable SOCE monitoring) allows for maximum utility of deployed products over the entire life -something that is fundamental to the Tesla customer experience and should be incorporated into good public policy. Accordingly, Tesla supports the agency in not requiring over capacity declarations.174 Requiring reserve capacity declarations could have the perverse effect of communicating unwarranted battery upsizing as beneficial and incent consumers to choose less efficient vehicles-. [EPA-HQ-OAR-2022-0829-0792, p. 28]

174 88 Fed. Reg. at 29286.

Under EPA’s proposal, manufacturers would be required to warrant a battery and associated powertrain components are free from defects in materials and workmanship which cause the deterioration of the battery SOH to less than 80% UBE for eight years or 80,000 miles, whichever occurs first, starting MY 2027.175 [EPA-HQ-OAR-2022-0829-0792, p. 28]

175 Id.

Tesla supports a minimum warranty requirement as it may eliminate low-lifetime battery pack designs and deployment. Tesla notes that the proposed 80% UBE level exceeds the industry norm. If EPA chooses to exceed the current industry standard, most, if not all, OEMs would be unable to avoid significant warranty costs and liability without significant additional costs to each vehicle. These additional warranty costs will be passed on to customers and increase BEV cost, again dampening BEV uptake. [EPA-HQ-OAR-2022-0829-0792, p. 28]

Currently, Tesla warrants a Model 3 real-wheel drive vehicle for 8 years or 100,000 miles, whichever comes first, with minimum 70% retention of battery capacity over the warranty period.176 As noted, most other OEMs offer similar warranty coverage.177 Other Tesla vehicle models extend the warranty to either 120,000 or 150,000 miles.178 The proposed escalating liability to 80% of the SOH of the battery pack will be a consequential requirement and likely add significant costs. [EPA-HQ-OAR-2022-0829-0792, pp. 28-29]

178 Id.

Battery pack replacement is much more expensive than ICE replacement of an emissions control system or transmission. For example, estimates place battery pack replacement and labor in the range from a high end of around $16,000179 to $5,500.180 Regardless, if 35% of vehicles were to fail warranty, it represents an average added cost of between $5,600 and $1,925 per car. These figures also do not take into consideration the significant new investment manufacturers will need to make in remanufacturing facilities that seek to repurpose the exchanged battery packs. [EPA-HQ-OAR-2022-0829-0792, p. 29]

179 See, Recurrent, Costs of Electric Car Battery Replacement available at https://www.recurrentauto.com/research/costs-e v-battery-replacement

180 Consumer Report, Pay Less for Vehicle Maintenance with an EV (Sept. 26, 2020) available at https://www.consumerreports.org/car-repair-maintenance/pay-less-for-vehicle-maintenance-with-an-ev/

Accordingly, Tesla advocates warranty thresholds more consistent with the industry standard and adoption of a standard of 8-year, 80,000 miles warranty with 70% UBE. Battery technology and capacity retention may improve, and Tesla is actively pursuing ways to improve lifetime capacity while also decreasing cost, increasing range and, fast charge performance attributes necessary for the widescale adoption of BEVs.181 However, estimating the precise trajectories of this research and development and technological breakthroughs and deployment more than five years out is extremely difficult and should not serve as a basis for an overly prescriptive warranty requirement. [EPA-HQ-OAR-2022-0829-0792, p. 29]

181 Tesla also continues to make significant investments in advancing EV, solar, and battery storage technology with over $1.1B dedicated to research and development in 2021 alone. See Tesla, SEC Form 10-K (Jan. 26, 2022) at 39 available at h ttps://www.sec.gov/Archives/edgar/data/1318605/000156459021004599/tsla-10k_20201231.htm; See also, InsideEVs, Tesla Spends Least On Ads, Most On R&D: Report (Mar. 25, 2022)(reporting that Tesla spends $2,984 per car on R&D and that such spending is three times the industry average and higher than Chrysler, Ford, and GM's R&D budgets combined) available at h ttps://insideevs.com/news/575848/tesla-highest-research-development-no-a ds/?utm_source=feedburner&utm_medium=email.

Organization: The Heritage Foundation (Kevin Dayaratna and Diana Furchtgott-Roth)

On page 4-34, when referring to maintenance costs over the 225,000-mile life of a vehicle, EPA does not mention the need for battery replacement. [EPA-HQ-OAR-2022-0829-0674, p. 10]

While EPA does not address this issue directly in any of its cost analysis, they do open the door to scrutiny and show their hypocrisy a bit by mentioning the battery durability standards in 1-4, 1-5, and 1-6. Based on the UN standards, a battery capable of supplying its platform with a range of 300 miles when new would be considered within the standard so long as it could provide 240 miles of range after 5 years or 62,000 miles. Additionally, it would remain within that standard if it could provide 210 miles of range to its associated platform after 8 years or approximately 100,000 miles. It only continues to degrade from there. [EPA-HQ-OAR-2022-0829-0674, p. 10]

In the table below, the initial data is from the UN standard and the rest is calculated from there based on linear degradation of the battery throughout its lifecycle. The reality is that the degradation would be faster than this and fast charging used to compete with ICE vehicle refuel times will only exacerbate the degradation. I have also placed a couple helpful links below that support this claim. [EPA-HQ-OAR-2022-0829-0674, p. 10]

A potential counter argument is that the CARB standard is more stringent. However, when looking at the tables it is clear that only 70% of the vehicles must achieve the CARB standard vs 90% of vehicles with the UN standards. So, while the wages of retained usable power are higher, the allowable wage of vehicles failing to meet the standard is higher. [EPA-HQ-OAR-2022-0829-0674, pp. 10-11]

Organization: Valero Energy Corporation

EPA’s cost estimates for future battery packs also ignore the customer-readable battery state-of-health monitor proposed by EPA as a new requirement under this rulemaking.209 [EPA-HQ-OAR-2022-0829-0707, pp. 38-40]

209 EPA’s Proposed Rule at 29284.

Organization: Volkswagen Group of America, Inc.

Comments on EV Topics

VWGoA requests a single battery minimum performance requirement instead of the current two points NPRM. It is appropriate for the EPA to utilize the requirements outlined in UN GTR No. 22; it is noteworthy that the GTR also allows the discretion to enforce just one of the two minimum performance requirements. Volkswagen recommends the EPA adopt the single minimum performance requirements set point of 70% SOCE over 8 years/100k miles. Choosing the longer-term minimum performance requirements of the two proposed, the EPA simplifies compliance checks and reduces regulatory complexity without sacrificing the long-term usefulness of the battery systems of electric vehicles. CARB has implemented a single set point for 70% battery SOH at 8 years/100k miles. Aligning the EPA's minimum performance requirements with CARB's battery SOH requirement would be a step towards harmonizing standards. [EPA-HQ-OAR-2022-0829-0669, pp. 11-12]

Battery State of Health

Harmonization of Battery State of Health Calculation

Volkswagen would like to bring attention to the discrepancy in SOH calculation by the treatment of how battery reserve capacity is utilized between EPA's NPRM proposal and the requirements of CARB's LEV IV regulations. [EPA-HQ-OAR-2022-0829-0669, pp. 11-12]

EPA's NPRM adheres to the UN GTR No. 22, which excludes battery reserve capacity in the SOH calculation. CARB's LEV IV regulation requires a unique SOH calculation that includes the reserve capacity. This would require displaying two different health monitor results when a reserve capacity is used. This situation could easily lead to confusion for consumers. Volkswagen strongly encourages EPA to work with CARB to collaborate on a single solution regarding SOH calculation. [EPA-HQ-OAR-2022-0829-0669, pp. 11-12]

Harmonization of Battery State of Health (SOH) Measurement Method

Volkswagen recommends the EPA specify the state of certified energy (SOCE) display in whole numbers, rather than in decimals. This modification would enhance readability and simplify the customer experience. Volkswagen requests harmonization of the NPRM requirements with CARB's LEV IV regulations. [EPA-HQ-OAR-2022-0829-0669, pp. 11-12]

Organization: Volvo Car Corporation (VCC)

VCC supports either the battery durability requirements within this NPRM or the CARB battery durability requirements effective 2026MY and beyond. However, we strongly encourage EPA to fully harmonize these requirements with the CARB requirements. [EPA-HQ-OAR-2022-0829-0624, pp. 4-5]

Organization: Wisconsin Department of Natural Resources

In addition, EPA is proposing a wide range of program revisions and amendments, including battery durability and warranty requirements for light-duty and medium-duty plug-in vehicles. [EPA-HQ-OAR-2022-0829-0507, p. 1]

Organization: Zero Emission Transportation Association (ZETA)

The following comments relate to the proposed requirements for battery durability:

-ZETA notes that EV batteries have a variety of potential non-propulsion applications that IC engines do not. As a result, these applications may cause the battery to go through wear cycles that are unrelated to reducing on road mobile source emissions. The proposed requirements for battery durability could disincentivize those applications and we encourage EPA to consider ways to uphold the intent of the MPR without disincentivizing non-propulsionary battery applications, including the use of good engineering judgment in determining statistically relevant in-use battery degradation. [EPA-HQ-OAR-2022-0829-0638, pp. 29-30]

-ZETA recommends EPA remove the battery durability MPR of 80% at 5 years or 62,000 miles (midpoint) but retain the 70% at 8 years or 100,000 miles endpoint. Battery degradation may not be linear and depends on a large number of factors.137 An MPR that assumes linear degradation could result in vehicles needing to be recalled despite still meeting the 70% at 8 years or 100,000 miles endpoint if they were allowed to continue operating. [EPA-HQ-OAR-2022-0829-0638, pp. 29-30]

137 "Optimizing the operation of energy storage using a non-linear lithium-ion battery degradation model," Applied Energy, (March 1, 2020) https://www.sciencedirect.com/science/article/pii/S0306261919320471?via%3Dihub

-In regards to the GTR No. 22 "Part B" compliance test under the durability requirements, EPA notes in the proposed rule preamble that "In the case that a durability family fails the Part B durability performance requirement, manufacturers would have to adjust their credit balance to remove compliance credits previously earned by those vehicles."138 ZETA supports this penalty, however, we request clarification that forfeited compliance credits include all relevant credits generated by vehicles within the applicable durability family, not just GHGs. [EPA-HQ-OAR-2022-0829-0638, pp. 29-30]

138 See 88 FR 29286 (May 5, 2023)

The following comments relate to the proposed requirements for emissions control device warranties: [EPA-HQ-OAR-2022-0829-0638, p. 30]

-ZETA requests clarity on what vehicle components constitute "associated powertrain components." While the preamble to the proposed rule includes some discussion on what components may be included: "e.g., electric machines, inverters, and similar key electric powertrain components,"139 a more exhaustive list would provide additional clarity for manufacturers and support a more thorough assessment of this aspect of the proposal. [EPA-HQ-OAR-2022-0829-0638, p. 30]

139 Id. at footnote 138

-ZETA's member companies stand by the durability of their products and many of them have their own warranties. While we support EPA's proposed warranty requirements, we note that designating the electric battery and associated powertrain components as "specified major emission control components" under the Clean Air Act could subject these components to additional regulatory requirements and rules. Specifically, we are concerned about the uncertainty in how EPA's anti-tampering rules may apply to these components and request EPA clarification on how enforcement would be applied to different scenarios where work may need to be performed on these components. [EPA-HQ-OAR-2022-0829-0638, p. 30]

EPA Summary and Response

EPA acknowledges and appreciates all of the comments relating to battery durability and warranty provisions. Comments on this topic included a number of distinct themes that we individually identify and respond to in this section. Additional responses in the context of the final durability and warranty standards may be found in preamble section III.G.2 and III.G.3. Additional responses in the context of test procedures and certification requirements may be found in RTC 6.1 and 6.2.

In general, comments in this area related either to the value and relevance of EPA's proposed regulation of battery durability and/or battery warranty, or to specific aspects of the proposed durability and/or warranty provisions. Comments on the value and relevance of the provisions included statements of support for the importance of ensuring battery durability and warranty for PEVs, as well as comments expressing the position that the provisions are not within EPA's authority. Comments on specific aspects of the proposed provisions included requests to strengthen or weaken the proposed durability and/or warranty program, requests to align with the California ACC II battery durability and warranty program, and various requests to consider adding, eliminating, or modifying one or another element of either program.

A large number of commenters, including BMW, CARB, Consumer Reports, Dana, "Environmental and Public Health Organizations," Lucid, MECA, NTAA, NESCAUM/OTC, Rivian, Sierra Club, SELC, Tesla), expressed general support for the provisions and their intent of promoting battery durability. For example, Tesla agreed with EPA's general adoption of GTR No. 22 and a state of health monitor communicating the battery's state of certified energy based upon usable battery energy. Tesla also stated that durability monitoring can be useful to ensure emission reduction benefits are met, and to provide integrity to credit trading. Several environmental NGOs and supplier organizations indicated support of PEV durability and warranty requirements, and referenced statutory language supporting these measures. Tesla advocated for warranty thresholds more consistent with the industry standard, and adoption of a standard 8-year, 80,000 miles warranty with 70 percent UBE. Lucid requested that EPA consider CARB's current battery warranty under ACC II, which is 70 percent SoH for 8 years or 100,000 miles, and aligns with EPA's proposed end point durability standard.

The Alliance for Automotive Innovation ("the Alliance"), whose comments were echoed by Stellantis, questioned EPA's authority to establish battery durability and warranty requirements. The Alliance, however, also agreed that battery degradation monitors and performance requirements are important tools for battery operation and state of health, and provided recommendations for modifying the program. "Environmental and Public Health Organizations", in contrast to the Alliance, provided commentary supporting EPA's authority.

Commenters' positions varied regarding how the proposed durability and warranty program based on GTR No. 22 should exist alongside the California Air Resources Board (CARB) ACC II durability and warranty program (referred to here as the "CARB program"). Several commenters (Kia, Nissan, Rivian, Tesla) expressed general support or preference for the proposed program being based on GTR 22. Some commenters stressed the differences between the proposed durability program and the CARB program, and stated that it would be difficult for OEMs to comply with two different sets of requirements. Commenters within this group suggested a variety of solutions, including: aligning certain aspects of the proposed program the CARB program; adopting the CARB program instead of the proposed program; or accepting compliance with the CARB program in lieu of compliance with the proposed program. Colorado Energy Office et al., Consumer Reports, Mercedes-Benz, MPCA, NESCAUM/OTC, SELC, and Volvo encouraged EPA to fully harmonize with CARB, while similarly, BMW recommended adopting a single national approach. In contrast, Nissan and "Environmental and Public Health Organizations" supported adoption of GTR No. 22 as proposed. The Alliance for Automotive Innovation and the "Environmental and Public Health Organizations" both stated that EPA should align with global best practices. Mercedes recommended that EPA allow voluntary compliance with the CARB ACC II provisions in lieu of EPA requirements; similarly, several environmental NGOs and state organizations recommended that EPA should align with the CARB regulation to avoid conflicting regulatory requirements, such as for example, differences in the treatment of reserve capacity. CARB recommended that EPA also adopt the full suite of consumer assurance provisions under ACC II.[546] Some commenters noted a difference in state of health monitor display requirements between the proposed program and the CARB program. The Alliance recommended allowing the display of the SOCE value to one decimal place, as is required by the CARB program. Volkswagen preferred display in whole numbers, rather than decimals, and encouraged EPA to work with CARB to collaborate on a single solution regarding SOH calculation. Others more generally recommended that EPA work with CARB to modify aspects of the CARB program. The Alliance recommended that we require fewer than the three separate IUVP monitor accuracy checks under Part A, as the CARB program does not require that many. Commenters also recommended a phase-in for SOCE monitor accuracy tolerance, like CARB's allowance of an 8 percent tolerance in 2027 and 2028, and 5 percent thereafter. Mercedes pointed out that the CARB program would not apply to BEVs with sub-200 mile driving range or PHEVs with sub-70 mile range, as these are not considered eligible for ZEV credit under the CARB program, and suggested that EPA should likewise limit the EPA program to vehicles above these range levels.

EPA also requested comment on the inclusion of a requirement for an SOCR monitor and associated reporting requirements as specified in GTR No. 22. Automakers expressed general support for basing the MPR on a metric of usable energy, or SOCE, as specified in GTR No. 22, and not on SOCR. Several expressed specific opposition to a range-based metric or SOCR, while the “Environmental and Public Health Organizations” encouraged use of both SOCE and SOCR.

In the proposal, EPA recognized that the California Air Resources Board durability program includes a specific provision that requires manufacturers to disclose and account for any battery reserve capacity that the manufacturer has chosen to initially withhold from use for release later in the life of the vehicle to maintain driving range or usable energy capacity after degradation has occurred. This provision of the California regulation is meant to allow consumers to know the state of chemical degradation of the battery independently of apparent range or energy capacity. Although EPA did not propose a requirement to disclose reserve battery capacity, in recognition of CARB’s inclusion of this parameter, the agency requested comment on including a reserve capacity declaration requirement and use of reserve capacity information in calculating an SOCE or SOCR metric. The Alliance, Kia, Nissan, and Tesla supported not including battery reserve in the SOCE metric, while others (CARB, Lucid, Rivian) supported it; Volkswagen did not express a preference but recommended that any requirement be harmonized between EPA and CARB. Tesla recommended that EPA should not encourage manufacturers to overcome the durability threshold by creating larger batteries with hidden capacity that can slowly be accessed as the battery degrades, and supported EPA in not requiring over capacity declarations, but to encourage full access to the battery (with reliable SOCE monitoring). Lucid supported the CARB approach to SoH calculations and battery reserve capacity and encouraged EPA to consider that approach. Rivian indicated that there are benefits to requiring disclosure of battery reserve capacity and EPA might wish to consider establishing a requirement in this or a future

[546] California’s suite of assurance measures includes: a minimum electric range for BEVs and PHEVs; durability standards based on a vehicle’s certified electric range; warranty requirements for batteries and propulsion-related parts; data standardization and transparency, including on-board display of the battery state of health so that consumers can see the quality of their battery; requirements for manufacturers to provide highly-capable convenience charging cords and equipping vehicles with standardized, direct current fast charging inlets; requirements that repair information be released to independent repair shops; and, requirements around battery labeling to ease dismantling and recycling.

rulemaking. CARB felt that failing to include reserve battery capacity in the SOH calculation could limit the credibility of the SOH parameter and undermine its ability for vehicle owners to use it to validate warranty eligibility or to properly value used ZEVs based on the amount of degradation of the battery, and urged EPA to explicitly require manufacturers to account for the reserve UBE in SOCE calculation.

We also received comment relating to the virtual mileage provision of GTR No. 22, which accounts for use of the battery for purposes other than propulsion of the vehicle (e.g., vehicle-to-building (V2B) or vehicle-to-grid (V2G) applications). This provision had wide support among manufacturers. Some commenters noted that GTR No. 22 included virtual mileage provisions and expressed uncertainty over whether the EPA program proposed to include the virtual mileage provision in either the durability mileage or the warranty mileage used for compliance purposes.

EPA received a variety of comments regarding minimum performance requirements (MPR) and their enforcement. Some commenters considered the requirements to be too stringent, while others suggested that they could be more stringent. VW recommended that EPA should adopt a single performance requirement of 70 percent at 8 years/100k miles. Tesla supported the proposed MPR as reasonable and achievable, while also advocating for a flexible approach allowing the manufacturer to use good engineering judgment in determining the statistically adequate and representative use of vehicle data. Tesla also supported the decision not to implement an MPR for medium-duty vehicles (MDVs).

In response to comments that regulation of battery durability or warranty is outside of the Agency's regulatory authority, EPA disagrees.

At the outset we note that some commenters, including the Alliance for Automotive Innovation ("the Alliance") questioned EPA's authority to adopt durability and warranty requirements for batteries in BEVs. The Alliance, however, also agreed that battery degradation monitors and performance requirements are important tools for battery operation and state of health, and provided recommendations for modifying the program. Here we first address this threshold issue.

EPA disagrees that regulation of battery durability is outside of the Agency's regulatory authority. As is described in further detail in the sections below, EPA's authority to set and enforce durability requirements for emission-related components like batteries is an integral part of its title II authority. Durability requirements ensure that vehicle manufacturers and the vehicles they produce will continue to comply with emissions standards set under 202(a) over the course of those vehicles' useful lives. Such authority arises both out of section 202(a)(1) and 202(d) (relating to a vehicle's useful life) and section 206(a)(1) and 206(b)(1) (relating to certification requirements for compliance). As is described in detail in the following section, EPA has exercised its authority to set emission durability requirements across a variety of emission-related components for decades.

EPA also disagrees that it lacks the authority to set warranty standards for BEVs. EPA has already set emission warranty standards under section 207(a) in 2010 for all components that are used to obtain GHG credits that allow the manufacturer to comply with GHG standards, which includes BEV, PHEV, and hybrid batteries.[547] EPA was not challenged on those standards. To the extent the Alliance's comment challenges EPA's ability to set warranty requirements generally for any component that is used to obtain GHG credits that allow the manufacturer to comply with GHG standards, it is out of time.

The Alliance is mistaken in suggesting that there is no way for EPA to require an emission-less vehicle to warrant at time of sale that it is "designed, built, and equipped so as to conform, at time of sale with applicable regulations under [section 202(a)(1)…. and … for its useful life, as determined by [section 202(d)].") Section 207(a)(1). In fact, automakers warrant at the time of sale that each new vehicle is designed to comply with all applicable emission standards and will be free from defects that may cause noncompliance. They do so with respect to all emission-related components in the manufacturer's application for certification, which include batteries. These provisions comport entirely with section 207 of the Act.[548]

The Alliance suggests that EPA does not have authority to set durability or warranty requirements because BEV batteries are not emission-related for two reasons. First, the Alliance argues that because BEVs do not themselves emit, EPA does not have authority to set vehicle specific standards for them, and EPA's warranty and durability authorities rely on EPA's ability to set vehicle specific standards. EPA does have the authority to set vehicle-specific standards for BEVs as part of the "class" of LDVs. See Section III.G.2 of the preamble. In addition, EPA has already set vehicle-specific standards for BEVs--the in-use standards applicable to all members of the LDV class.

The Alliance argues second that a component only counts as emission-related if its failure would allow the vehicle to continue operating, but with higher emissions. In fact, EPA has set durability requirements for diesel engines (see 40 CFR 86.1823-08(c)), failure of which could cause the vehicle to stop operating. Similarly, Congress explicitly provided that electronic control modules (ECMs) (described in the statute as "electronic emissions control units) are "specified major emissions control component[s]" for warranty purposes per section 207(i)(2); failure of ECMs can also cause the vehicle to stop operating, and not necessarily increase the emissions of the vehicle.

BEV batteries are emission-related components--thus providing EPA authority to set durability and warranty requirements applicable to them--for two reasons. First, they are emission-related by their nature. Durability and warranty requirements for batteries are not, to use the Alliance's analogy, like requiring a warranty for a vehicle component like a vehicle's "infotainment system" that has no relevance to a vehicle's emissions. Integrity of a battery in a vehicle with these powertrains is vital to the vehicle's emission performance; integrity of its "infotainment system" is not. It would be wrong to say that a component that allows a vehicle that would otherwise emit to operate entirely without emissions is not inherently emission-related.

---

[547] See 75 FR 25486.

[548] The Alliance's comment argues in passing that EPA does not have the authority to designate a BEV battery as a "specified major emission control component" with an 8 year or 80,000 mile warranty because it is not a "pollution control device or component." That term is not defined in the Act; for the reasons described in this section, EPA believes that BEV batteries are "pollution control device or component[s]" for the same reasons they are "emission related components."

Second, for warranty and durability purposes, EPA has consistently considered a component to be "emission related" if it relates to a manufacturer's ability to comply with emissions standards, regardless of the form of those standards. For standards to be meaningfully applicable across a vehicle's useful life, EPA's assessment of compliance with such standards necessarily includes an evaluation of the performance of the emissions control systems, which for BEVs (and PHEVs) includes the battery system both when the vehicle is new and across its useful life. This is particularly true given the averaging form of standards that EPA uses for GHG emissions (and which the Alliance continues to support), and which most manufacturers choose for demonstrating compliance. For EPA to determine the level at which to set fleet average standards, the Agency needs to have confidence that the emissions reductions—and thus credits generated —by each BEV and PHEV introduced into the fleet are reflective of the real world. Ensuring that BEVs and PHEVs contain durable batteries is important to assuring the integrity of the averaging process: vehicles will perform in fact for the useful life mileage reflected in any credits they may generate. Put another way, durable batteries are a significant factor in vindicating the averaging form of the standard: that the standard is met per vehicle, and on average, per fleet throughout the vehicles' useful life. The battery durability provisions finalized in this rulemaking allow for confidence that the batteries installed by vehicle manufacturers are durable and thus support the standard.

In addition to EPA's general authority to promulgate durability requirements under sections 202 and 206, EPA has additional separate and specific authority to require on-board monitoring systems capable of "accurately identifying for the vehicle's useful life as established under [section 202], emission-related systems deterioration or malfunction." Section 202(m)(1)(A).[549] As we discuss at length in this section, EV batteries are "emission-related systems," and thus EPA has the authority to set durability monitoring requirements for such systems over the course of a vehicle's useful life.

In response to comments that EPA should work with CARB to modify aspects of the CARB program, EPA considers modification of the CARB program to be outside the scope of this rulemaking.

The Alliance and Ford Motor Company requested that EPA require only one battery monitor accuracy check instead of requiring checks at low, medium, and high mileage to verify the SOCE monitors are accurate. The Alliance noted that the CARB program requires only a single check. Ford expressed concern that procuring vehicles will be difficult and the required testing will add an additional 400 to 500 miles on a procured vehicle. As Ford does not expect the accuracy of the state-of-certified-energy monitor to change during the first 5 years of BEV operation, Ford proposed that EPA only perform monitor accuracy testing at the 3 year interval and not also test at 1 and 5 year intervals.

In response, EPA acknowledges that the CARB program requires fewer in-use accuracy checks than the EPA program. The EPA program, however, relies explicitly on the accuracy of the monitor in determining compliance with the MPR. Therefore we do not agree that the presence of fewer IUVP accuracy checks under the CARB program is necessarily relevant to the

[549] Section 202(m)(1)(A) specifically applies to light duty vehicles and light duty trucks, but section 202(m)(1) allows EPA to "promulgate regulations requiring manufacturers to install such onboard diagnostic systems on heavy-duty vehicles and engines," which provides concurrent authority for the MDV battery monitoring requirements discussed in this section.

EPA program. Through its experience contributing to development of GTR No. 22 and continued study of battery durability and monitoring, EPA finds that the additional benefit of checks at multiple intervals for assessing and assuring compliance outweighs the marginal costs of conducting additional checks. Carryover provisions apply to monitor testing as described in 40 CFR 86.1839-01(c), making it unnecessary to continue testing for every model year within a monitor family. Further, monitor accuracy at an early point in the vehicle's life when little change in SOCE would be expected does not necessary imply similar accuracy when the battery has aged and a larger change would be expected. This indicates that at least two checks are necessary to establish longevity of accuracy. However, EPA notes commenters' concerns with having more checks than necessary. EPA has considered the needs of the program and finds that two checks, one at 2 years and 20,000 miles and another at 4 years and 40,000 miles are sufficient to establish monitor accuracy. This also aligns with existing IUVP practice which includes only two checks. EPA has therefore revised the program to include two accuracy checks. See 40 CFR 86.1811-27, 86.1845-04(g) and 86.1839-01(c).

Regarding comments recommending that there be no accuracy check for MDVs, EPA disagrees. EPA continues to consider the accuracy check to be an important component of the program for both LDVs and MDVs. Although EPA has not yet determined that including MDVs under the durability MPR is appropriate at this time, EPA considers battery durability to be relevant to MDVs for the same reasons it is relevant to LDVs, and the presence of a monitor to provide knowledge of the battery state of health is important in both cases. Further, the presence of a monitor implies that the monitor should be accurate. EPA also notes that its work contributing to further development of GTR No. 22 may include extending the GTR MPR to MDVs. Experience with the accuracy of MDV monitors in its own durability program will be important to EPA's decision of whether or not to extend EPA MPR requirements to MDVs in the case that EPA finds it appropriate to do so in a future rulemaking.

Regarding CARB's recommendation that we adopt the full suite of ACC II ZEV assurance measures, and also adopt "further on-vehicle charging standards and collect additional data to inform future ZEV consumer labels," EPA agrees that the ZEV assurance measures are likely to be supportive of ZEV adoption but has not determined whether or not these measures are appropriate at the national level.

In response to recommendations that EPA should adopt certain specific provisions of the CARB program (for example, inclusion of battery reserve in SoH calculation, phase-in of monitor accuracy tolerance, exempting shorter-range BEVs or PHEVs from requirements, OBD requirements and data parameters, basis on percentage points vs. percent, etc.), EPA believes that the CARB program and the proposed program based on GTR No. 22, in their entirety, are similarly effective, but that each program achieves that effectiveness by operating as a whole, and may become less effective if specific requirements from one program were moved into or out of the context of the other. For example, the CARB performance requirement is nominally more stringent in miles and years than the EPA MPR, but this is offset to some degree by requiring a smaller percentage of vehicles in a test group to pass. The CARB program also differs from the GTR in its test groupings in ways that are consistent with this difference, while the GTR adopts test groupings that specifically address the importance of monitor accuracy under its specific structure. To preserve the integrity of each program as designed, EPA is generally not taking an approach of adopting specific individual elements of the CARB program at this time. For example, EPA does not consider phase-in of monitor accuracy tolerance as allowed under the CARB program to be as appropriate under the EPA program because the latter has an explicit reliance on accuracy of the monitor for determination of compliance under Part B, and the development of GTR No. 22 specifically concluded that a five percent tolerance was appropriate. Similarly, mathematical features such as use of percentage points or percent derive from the statistical methods applicable to each program and were determined to be appropriate in the specific context of each program.

Regarding the number of decimal places for the monitor, EPA clarifies that for purposes of an on-board SOCE value, the on-board value shall have a resolution of at least 1 part in 100 and the value used in the compliance calculation shall be reported as the nearest whole number from 0 to 100 as specified in the GTR. The on-board value stored on the vehicle may have greater resolution as long as the value used in the calculation is as specified above. For the value displayed to the operator, GTR No. 22 anticipates that "the resolution for the customer values shall be determined in agreement with the authorities." EPA will accept a display value that is displayed with one decimal place if the on-board value satisfies the above criteria.

In response to comments that EPA should accept compliance with the CARB program in lieu of the federal program, EPA agrees that this would promote harmonization between the two programs. As described above, EPA considers the CARB durability program, when viewed in its entirety as designed, to be no less effective at achieving the intent of the EPA durability program. EPA has also assessed both programs carefully and has concluded that it is possible for manufacturers to comply with both programs simultaneously. Manufacturers who will have to comply with the CARB program will often also have to comply with GTR No. 22 in other international jurisdictions, which is very similar to the EPA program. However, EPA agrees with commenters' concerns that complying with both CARB and EPA durability programs may require more effort than complying with only one. Accordingly, EPA will accept manufacturer compliance with the entirety of the CARB ACC II durability program in lieu of the EPA durability program. To utilize this optional pathway, manufacturers must declare their intention to do so, in which case their compliance with the CARB durability program will be deemed as compliance with the EPA durability program. Regardless of whether a manufacturer chooses to follow the CARB or the EPA program, failure to comply with the chosen program will result in the same credit loss penalty as under the EPA program.

EPA considers the addition of the option to comply with the CARB durability program in lieu of the EPA durability program to be responsive to the various requests to adopt certain specific elements of the CARB program, considering the need to avoid compromising the integrity of either program.

In response to comments on inclusion of an SOCR monitor and/or enforcement of an SOCR-based performance requirement, EPA continues to assess that SOCE is sufficient at this time as a basis for the MPR. To this point, EPA notes that at this time GTR No. 22 requires only that an SOCR monitor be implemented and does not use it for enforcement of the MPR. EPA has not yet determined that requiring an SOCR monitor in addition to an SOCE monitor is necessary to achieve the intent of the durability program in the context of this rulemaking. EPA will continue to consider whether the addition of an SOCR monitor is necessary as part of a potential future rulemaking, and will continue to follow development of GTR No. 22 with respect to this issue, but at this time is electing not to include this requirement in the final standard, as proposed.

EPA also notes that its decision not to include an SOCR monitor does not imply that the agency necessarily believes that an SOCR monitor is not desirable or practical to implement. To this end, EPA notes that some commenters appeared to be confused on the nature of an SOCR monitor as described by GTR No. 22, for example, the comment from Kia that stated in support of not including SOCR that "ICE vehicles are not required to display a SOCR because the range is extremely reliant on consumer behavior." EPA disagrees with the suggestion that the SOCR metric is somehow subject to the well-known difficulty of predicting the actual range of a vehicle under variable real-world conditions and variable driver habits and behavior. Instead, SOCR is an estimate of what the certification label range would be at the current point in the vehicle's life if the vehicle were tested according to the certification range test procedure that was used when the vehicle was new. That is, just as with SOCE, SOCR is an estimate of a result of a controlled-condition test, and is in no way related to variables such as consumer behavior or on-road conditions.

Several commenters (the Alliance, Fermata Energy, Kia, Lucid, Rivian, and ZETA) expressed uncertainty as to whether virtual mileage was included in the proposed program and whether it applied to durability mileage, warranty mileage, or both. Ford and Mercedes-Benz requested that the virtual mileage provision be applied to both the battery durability requirements and warranty provisions. In response to these comments, EPA clarifies that virtual mileage as defined in GTR 22 applies to the EPA program but only for durability, that is, virtual mileage is applicable only to the mileage used for determining compliance with the durability provisions, as defined in GTR No. 22. EPA notes that the virtual mileage provision originates in EPA's adoption of GTR No. 22, and as such is applicable only to the durability provisions. GTR No. 22 does not include warranty provisions, and so the mileage used for warranty under the EPA program does not include virtual mileage. EPA retained the virtual mileage provision in the context of durability for the purpose of maintaining consistency with the GTR design and structure, and not for the purpose of potentially extending the provision to other mileage-related aspects of our regulations.

Regarding the Alliance's suggestion that virtual mileage be indicated on an odometer-like display, EPA prefers to remain aligned with the GTR requirements in which the virtual mileage is retrieved from onboard data.

EPA disagrees with comments that express the belief that, as one commenter said, the proposal did not include "consideration of frequent use of V2G." The virtual mileage provision of GTR No. 22 is clearly oriented to this purpose. EPA agrees with comments expressing the view that vehicle-to-grid and vehicle-to-building offer a potential opportunity to help serve the grid and provide additional functionality to consumers.

As an alternative to the inclusion of virtual mileage, some commenters suggested that EPA should exclude vehicles that were used for V2G or V2B from warranty coverage, or "lower the warranty requirement to account for frequent bidirectional charging." EPA continues to assess that such provisions are not necessary. We note that the warranty mileage, which does not include virtual mileage, is only 80,000 miles compared to the durability mileage of 100,000 miles. This reduced stringency largely addresses commenters' concerns regarding warranty mileage and likely levels of V2G or V2B usage.

Some commenters who may have been uncertain as to whether or not virtual mileage applied to the durability mileage went on to suggest that EPA should exclude vehicles that were used for

V2G and V2B from the durability test sample. EPA considers our clarification with respect to inclusion of virtual mileage to address this comment.

In response to comments suggesting that the minimum performance requirement (MPR) is too stringent, EPA disagrees. The MPR is derived from GTR No. 22 which was developed with extensive input, leadership, and participation from EPA and thus it reflects what EPA considers to be an appropriate framework and set of requirements for ensuring battery durability, including the choice of MPR. The MPR is very similar to warranty coverage already provided by vehicle manufacturers, indicating that the MPR described in the proposal is satisfactory and achievable. As also noted in section III.G.2 of the preamble, manufacturers are already providing warranty coverage similar to what is required by the final durability and warranty requirements.[550,551,552,553,554] EPA considers the example of current warranty coverage to be a reasonable starting position to provide consistency across the market. Regarding comments that warranty terms are not necessarily applicable to a compliance context, see the discussion of related comments in section III.G.2 of the preamble. EPA is therefore finalizing the proposed MPR.

In response to comments that the battery durability and/or warranty requirements would increase battery manufacturing cost and that EPA should account for this cost, EPA disagrees. Because the durability minimum performance requirement and the minimum battery warranty are similar to currently observed industry practices regarding durability performance and warranty terms as mentioned above, EPA continues to assess that these requirements will not result in a significant increase in battery manufacturing costs, and commenters did not provide compelling evidence or strong supporting data regarding cost increases that they believe would result from these requirements.

Regarding comments that EPA did not account for the cost of complying with battery durability and warranty requirements (e.g. from Hyundai, POET LLC, and Valero), or that it will add significant cost to the vehicle, EPA disagrees. As stated above, the MPR is very similar to existing warranty requirements and as such EPA does not assess that it will add significantly to the cost of the vehicle. EPA also assesses that the instrumentation and algorithmic requirements of the SOCE monitor are very similar to existing battery state of health monitoring features that manufacturers already implement to support needs such as, for example, informing the battery management system of battery state of health and evaluating warranty claims. As such EPA has not identified any significant additional manufacturing cost, and commenters did not provide

such data. As with other technologies manufacturers add to comply with standards, EPA accounts for direct manufacturing cost and does not individually account for research and development costs which are accounted for through our use of an retail price equivalent (RPE) factor of 1.5 applied to direct manufacturing costs, such as the cost of the battery. RPE is discussed in Chapter 2.5.4 of the RIA.

Several commenters (Lucid, Volkswagen, ZETA) recommended that EPA adopt only the 8 year, 100,000 mile requirement of the MPR, and not the 5 year, 62,000 mile midpoint requirement. EPA acknowledges that GTR No. 22 allows the possibility of local jurisdictions adopting either or both of the requirements. EPA agrees that requiring only the later requirement may reduce test burden. (as opposed to a battery design that degrades more rapidly in earlier years, which would tend to increase the potential impact of lost range capacity on the total mileage the vehicle can attain over its life). Also, the 5-year requirement allows for an earlier compliance decision if a vehicle is on track to fail the 8-year standard. In EPA's view, these substantial compliance benefits outweigh the added burdens of additional testing. For these reasons we are retaining the 5 year requirement in the program.

The Alliance recommended that, in 40 CFR § 86.1815 of the regulatory text, that we replace the term “electric vehicles” with “BEVs and PHEVs” to exclude FCEVs from monitoring and durability requirements. Fuel cell vehicles were not included within the technical analysis or scope of GTR No. 22 and EPA has not yet determined that the monitoring and durability requirements developed under GTR No. 22 are appropriate for FCEVs. Accordingly, EPA has made the requested change to § 86.1815.

The Alliance also requested clarification on whether or not the durability and monitoring requirements are tied to the Tier 4 phase-in per § 86.1815. EPA clarifies that there are no phase-in provisions with regard to the battery durability standards, which begin in model year 2027.

Regarding recommendations that we adopt the most recent versions of SAE J1634 (2021) and J1711 (2023), please see Section III.G of this preamble, Electric Vehicle Test Procedures.

The SAVE Coalition recommended that we revise § 86.1815(a) to specify that the monitor estimate of SOCE should be made available on an “owner-accessible” display rather than a “customer-accessible” display, to accommodate situations such as autonomous transportation services, where the customer of the autonomous service is not the owner of the vehicle. EPA agrees that "customer" may be ambiguous in this application; however, we also believe that using the term "owner" might be interpreted as excluding lessees or other parties with a legitimate interest in the state of health of the battery. EPA is clarifying the regulatory text by changing "customer-accessible" to "operator-accessible." As the customer of a fully autonomous transport service is not an operator, EPA believes that this modification addresses the commenter's concern.

The SAVE Coalition also recommended flexibility regarding geographic requirements for sampling in the case of autonomous vehicles that may be restricted to a certain geographic location. EPA understands the theoretical situation described by the commenter, however, EPA also notes that few vehicles operate in such fleets today, and even fewer if any are vehicles that only exist as a vehicle model solely for the purpose of participating in that captive fleet (i.e. are completely unique from any vehicle models sold to the general public, which would exist in far greater numbers outside of the fleet described by the commenter). Accordingly, EPA does not consider the theoretical situation described by the commenter to require specific action at this time.

Some commenters requested clarification as to whether the removal of compliance credits earned by vehicles that fail the durability requirement applies only to GHG credits earned, or also to NMOG+NOX credits earned. In the proposal, EPA stated that in the case of failure to meet the durability requirements, “manufacturers would have to adjust their credit balance to remove compliance credits previously earned by those vehicles,” and the regulatory text stated “the manufacturer must adjust all credit balances to account for the nonconformity.” EPA clarifies that for BEVs, this provision applies to both GHG credits and NMOG+NOX credits, and for PHEVs, only to GHG credits. As explained in section III.G.2.I of the preamble, given the fleet average nature of both the GHG and NMOG+NOX standards, EPA needs to have confidence that the emissions reductions (and thus credits generated by each BEV and PHEV introduced into the fleet) are reflective of actual performance for the useful life mileage reflected in any credits they may generate. Credit removal for failing the durability requirement, specifically the Minimum Performance Requirement, only applies to LD BEVs and PHEVs. In the case of BEVs, the credits affected include GHG and $NMOG+NO_X$ credits. For PHEVs, although PHEVs earn both GHG and NMOG+NOX credits, the credits affected include only GHG credits. PHEV credits for NMOG+NOx would not need to be forfeited because testing to determine compliance with NMOG+NOx standards is based on charge-sustaining mode when the engine is operating, and NMOG+NOX emissions in this mode are not generally impacted by the amount of grid energy that can be stored in the battery.

EPA notes that some commenters appeared to interpret the 5 percent tolerance for monitor accuracy under Part A as a two-sided delta, that is, that the monitor would be judged to fail if it shows a value either 5 percent over or 5 percent under the test value. For example, the Alliance indicated that a 2-sided threshold is not necessary, because protection from overestimation is all that is needed. EPA clarifies that the statistical method defined in GTR No. 22, and the way it is used to determine compliance with the MPR, only considers the monitor to fail the accuracy test if it is more than 5 percent over the test value (i.e., is overly optimistic).

EPA also clarifies that Annex 3 of GTR No. 22 applies only in jurisdictions where WLTP is used. The quantities that represent $UBE_{measured}$ and $UBE_{certified}$ for the purpose of part 6.3.2 of GTR No. 22 in the context of this rule are specified in the regulatory text.

EPA disagrees with the comment from MEMA that expresses the view that SMECC warranties are not required due to the existence of warranties under the Magnusson-Moss Warranty Act. Section 207 of the CAA expressly authorizes the Administrator to require the warranty requirements in this final rule. These requirements support the emissions reduction goals of CAA as discussed elsewhere in these responses.

Several commenters (Lucid, MEMA, Rivian, ZETA) indicated that EPA should clarify the meaning of “associated powertrain components.” ZETA specifically recommended adopting a closely related CARB definition. In response, EPA has revised 40 CFR § 85.2103(d)(1)(v) of the regulatory text which now clarifies that the provision applies to "all components needed to charge the system, store energy, and transmit power to move the vehicle."

ZETA and Rivian requested that EPA clarify how anti-tampering rules would apply to components newly defined as SMECCs in scenarios where maintenance work is performed. EPA clarifies that the statutory provisions continue to apply. Annex 1 of GTR No. 22 specifies that vehicles that have had the battery replaced or repaired, or have been used for racing, are exempted from Part A testing.

In the proposed regulatory text, EPA explicitly tied the warranty failure criteria to the durability requirement, i.e. an individual vehicle would be deemed as eligible for warranty battery repair if it retains less than 80 percent SOCE at 5 years or 62,000 miles, or less than 70 percent SOCE at 8 years or 80,000 miles (although the MPR for durability states 100,000 miles, warranty is set at 80,000 miles by statute). The Alliance stated that EPA should not specify warranty failure criteria at all, and should not tie it to the MPR failure criteria, on the grounds that they felt that warranty should be determined by the manufacturer and might legitimately vary between different types of products. In contrast, CARB and other commenters supported the warranty requirement, and CARB supported EPA's explicitly tying battery warranty failure criteria to the durability performance requirement.

In response to the comments that EPA should not specify warranty failure criteria (for example, specifying the SOCE level that would trigger a warranty repair), EPA continues to find that the proposed warranty requirements are equivalent to those that EPA has the authority to require and has historically applied to other specified major emission control-related components for ICE vehicles under EPA's light-duty vehicle regulations, and are similarly implemented and under the authority of CAA section 207. See also our extended discussion of warranty above. However, we acknowledge that for analogous warranty requirements as they have pertained to emissions related ICE powertrain components under the same statute, EPA has in the past specified only the years and mileage and not the exact failure criteria that would trigger a warranty repair. This has largely been possible because of the way OBD requirements are integrated with the emissions rules, in that a material failure of a combustion-engine emission component to perform as designed (due to any number of potential failure modes) would ultimately result in increased tailpipe emissions that would in turn activate a malfunction indicator lamp (MIL) that serves as evidence that a warranty repair is needed. In the case of a PEV high-voltage battery, current regulations and OBD specifications do not provide for a MIL to illuminate in response to a battery that has an SOCE monitor reading below the MPR minimum, and EPA has not yet determined whether it is appropriate to do so. Accordingly EPA had proposed to tie the battery warranty failure criteria to the MPR criteria to provide a clearer definition of what constitutes the need for a warranty repair. However, in light of the comments received and additional research, EPA has reconsidered the appropriateness of doing so. While EPA considers a Part A-validated SOCE monitor that is installed on all the vehicles in a durability group to be sufficiently accurate to use for determining collective compliance of a durability group based on a large sample, based on the current record, EPA finds that it is possible that on an individual vehicle basis, an individual SOCE monitor may be less definitive in establishing the true SOCE for that individual vehicle (due to variations in recent use conditions, a specific defect, etc.) At this time, EPA expects that a manufacturer would therefore legitimately prefer to evaluate the need for an individual warranty repair by performing an individual evaluation of the vehicle battery rather than relying solely on the estimate provided by the monitor. Further, although EPA has determined that the SOCE values of 70 percent and 80 percent for the respective mileages of 62,000 and 100,000 miles (respectively) under the MPR are appropriate, the warranty statute specifies a mileage of 80,000 miles which lies between the two. Based on our further review of the record, EPA is not making a final determination at this time as to whether it is appropriate to simply interpolate between the two, or if the shape of a typical degradation curve would suggest a different value as more appropriate. Finally, EPA also notes that it did not propose specific failure criteria that would be applicable to related (non-battery) powertrain components (inverters, motors, etc.) which, like the high-voltage battery, are also not tied to MIL functionality. Accordingly at this time we are not tying the battery warranty performance criterion to the durability performance requirement. Instead, we are retaining the 8-year and 80,000 mile warranty duration as specified by the statute, but are allowing the manufacturer to specify the percentage SOCE that will trigger a warranty repair at that point in the vehicle's life, and also requiring the manufacturer to (a) clearly disclose the warranted percentage SOCE to the customer in writing prior to sale, and (b) establish, describe, and disclose an evaluation method that will be used by the manufacturer to determine that percentage SOCE has fallen below the warranted percentage, and show to EPA's satisfaction that it is accurate and reliable. EPA believes that these provisions combined with manufacturers' competitive need to offer a strong warranty will provide the intended degree of protection and transparency to the customer until additional data is available allowing EPA to determine an appropriate SOCE level for the 80,000 mile point. EPA also notes that this is a minimum warranty, and many manufacturers already offer a longer battery warranty for competitive reasons and are likely to continue doing so.

This also addresses the comment from CARB which pointed out that the "proposal appears to mistakenly tie all non-battery powertrain components to this same battery durability performance requirement when defining failures that merit warranty replacement. Such a connection renders the warranty requirements meaningless for those components." CARB went on to recommend that EPA adopt "an appropriate failure metric(s) for warranty coverage for non-battery components." EPA agrees with CARB's observation that the SOCE stipulation is not applicable to associated powertrain components, and the removal of the explicit connection as described above addresses this comment. For these components EPA is specifying only the years and mileage terms and not specific failure criteria. As stated above, EPA did not propose and has not yet determined an appropriate failure criteria for these components, because just as with combustion-engine components, a variety of conceivable failure modes exist and EPA has not yet determined the most appropriate metrics for each component that could be monitored to detect a defect.

Regarding the comment from AFPM that EPA is "relying on other programs, like California's, to implement battery durability… to ensure customer demand," EPA disagrees. EPA does not rely on the CARB program to ensure customer demand, nor to implement battery durability, as evidenced by the EPA durability program which is distinct from the CARB durability program. In the context commenter may be referring to, EPA mentions the CARB program only as supporting evidence that battery durability has been identified as an important issue by other regulatory bodies. Although the final standards include an option for manufacturers to comply with the CARB durability program in lieu of the EPA durability program, this is offered as a flexibility for manufacturers and does not constitute a reliance on the CARB program since EPA also offers its own separate durability program.

Regarding the comment from AFPM that "EPA's proposal may impose additional costs of economic risk to individuals and small business owners who will be asked to depend on increasingly expensive infrastructure necessary to provide on-the-go fuel," the reference cited by commenter indicates that this comment is addressed to the heavy-duty rulemaking and is out of scope for this rulemaking. Regarding the statement by same commenter that “EPA should consider inclusion of durability requirements in this proposal as 150 miles of range for singular battery life and 24,000-mile range of use (or two years) are well below the period of use for a comparable ICEV with a full tank of fuel and will impact consumers as there is not enough data with these technologies,” EPA is unable to determine what precisely this comment means or whether the comment indicates support or opposition to durability standards. EPA is not proposing standards related to “150 miles of range for singular battery life” nor “24,000-mile range of use.”

Regarding the request by Fermata Energy to include a “small multiplier credit for vehicles that have on-board AC bidirectional chargers or are integrated with multiple DC off-board chargers,” the commenter failed to explain with reasonable specificity why such a multiplier was appropriate. EPA has not determined whether or not a credit for such purpose is appropriate or necessary at this time.

Regarding MEMA’s request to “clarify that warranty repairs can be completed at dealer or authorized repair locations, and at quality independent aftermarket repair locations,” and commenter’s views on the “impact longer warranties could have on choices in consumer repair,” and related comments related to consumer choice, this is outside the scope of the proposal. EPA notes, however, that under section 207(c)(3), each manufacturer “shall furnish with each new motor vehicle or motor vehicle engine written instructions for the proper maintenance and use of the vehicle or engine by the ultimate purchaser and such instructions shall correspond to regulations which the Administrator shall promulgate.” These instructions “shall not include any condition on the ultimate purchaser’s using, in connection with such vehicle or engine, any component or service (other than a component or service provided without charge under the terms of the purchase agreement) which is identified by brand, trade, or corporate name; or directly or indirectly distinguishing between service performed by the franchised dealers of such manufacturer or any other service establishments with which such manufacturer has a commercial relationship, and service performed by independent automotive repair facilities with which such manufacturer has no commercial relationship….”[555]

Further, EPA does not agree that longer warranties would necessarily limit choice and MEMA did not clarify exactly how or why they expect this to happen. Regarding MEMA’s comment that “it is important that components found in both an ICE and a zero emissions vehicle not carry longer warranties for ZEVS than for ICE,” and that EPA “not expand warranty coverage to parts that have a shorter life and are a routinely replaced due to wear, or are adjacent to the warrantied parts through physical, electrical, or software connections but not the targeted component,” EPA agrees that in general, ICE vehicles and BEVs should be subject to similar expectations for parts shared by both that serve a similar function in both. EPA has revised 40 CFR 85.2103(d)(1)(v) of the regulatory text to clarify that the provision applies to "all components needed to charge the system, store energy, and transmit power to move the vehicle." It is not EPA’s intention to extend warranty coverage beyond these components nor that the definition include items such as wear parts or other minor parts whose analog in an ICE vehicle serves the same function and is not covered by an analogous emissions warranty.

[555] The provision also allows the Administrator to waive the statutory requirement in certain cases.

Regarding Tesla's comments that "battery durability provides no emissions reduction benefit" and relatedly that minimum performance requirements "must be balanced against increased up-front costs," EPA disagrees with the first and agrees with the latter. EPA has described the importance of battery durability to achieving emissions reductions previously in these responses and in the preamble. EPA has balanced this need with cost by selecting performance requirements that are similar to those of GTR No. 22 and current practices in the industry. We also note Tesla's support of the MPR as being "set at reasonable and achievable levels." Regarding Tesla's view that "the proposed 80% UBE level exceeds the industry norm" for warranty, EPA disagrees, and notes that Tesla appears to have associated the 80 percent SOCE level with the 8 year/80,000 mile warranty term, when in fact the 80 percent SOCE level is associated only with the 5 years or 62,000 miles MPR; in fact, the proposed standards would have specified a 70 percent SOCE level (which EPA assesses as being common industry practice) at 8 years/80,000 miles (less stringent than common industry practice). The final standards, as noted previously, allow the manufacturer to specify the SOCE level that will apply to the 8 year/80,000 mile warranty term.

For response to comments on durability and monitor grouping requirements, and other topics related to test procedures and test groups related to the durability and warranty program, please refer to Sections 6.1 and 6.2 of the response to comments document and Section III.G.3.iii of the preamble.

For response to comments relating to battery replacement, see Section 12.2.5 of the responses to comments document.

17 - Charging infrastructure

<u>Comments by Organizations</u>

Organization: 25x'25 Alliance, et al.

The undersigned parties offer the following comments on EPA's proposed rule, "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles." We write these comments because we believe that the proposed rules would establish an overly aggressive, high-risk program that would be counterproductive in achieving the agency's environmental and health objectives. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

In establishing or revising Clean Air Act Section 202(a) standards, EPA must consider issues of technological feasibility, cost of compliance, and lead time. Among other things, that means the agency must look closely at the impact of its proposed standards on net emissions of air pollutants and their associated public health effects, impacts on the automotive industry, impacts on the vehicle purchasers/consumers, energy security, and safety, and how the proposed approach would compare to other possible rulemakings. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

EPA's review of relevant factors in the current proposal is seriously deficient. The chief failure comes because the agency elides two distinct types of feasibility: the technological feasibility of electric vehicles as a part of the fleet and the technological feasibility of electric vehicles as the whole of the fleet. We do not dispute the former, but overwhelming evidence disproves the latter. First, there are no established supply chains capable of supplying the raw materials to manufacture the millions of vehicles needed—just over the next decade—to supply the projected market. Second, the infrastructure necessary to support these vehicles, particularly recharging infrastructure, is not and will not be available in the necessary timescales. The high density of chargers needed in major metropolitan areas and vast web of chargers needed to span the rural areas of the Country will require tremendous planning and investment. The long lead times associated with new renewable generation means that this added marginal electric load will be powered by natural gas and coal for the foreseeable future. And current prices, lack of infrastructure, and public opinion militate strongly against the conclusion that a ten-fold increase in the annual sales of electric vehicles will occur in the next eight years. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

The failings of the proposed rule follow almost entirely from EPA's decision to "bet the farm" on electric vehicles. The agency would be far better served by taking a more holistic approach. There are 281 million internal combustion engine vehicles on the road today and 100 million more will be built in the next two decades. All of these vehicles could be improved—and for far less than what EPA's proposal would cost—with an improvement in fuel quality. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

SEE ORIGINAL COMMENT FOR PIE CHART of Role for Liquid Fuels [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

SEE ORIGINAL COMMENT FOR BAR GRAPH of EPA-Projected Cumulative U.S. Sales 2023-2032 [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

EPA is statutorily obligated to explore this approach. Section 202(a)(3)(A)(ii) requires that, "in establishing classes or categories of vehicles or engines for purposes of regulations under this paragraph, the Administrator may base such classes or categories on gross vehicle weight, horsepower, type of fuel used, or other appropriate factors." 42 U.S.C. § 7521(a)(3)(A)(ii) (emphasis added). There are many ways EPA could consider the type of fuel as a means of settings its regulations: through the consideration of life-cycle emissions under the agency's Section 202 powers, through increased volumes of low-carbon renewable fuels under the Renewable Fuel Standard, through alternative, low-carbon certification fuels, or through Section 211(c) rulemaking—as the proposal itself suggests. These options are not beyond the scope of this rulemaking but are obvious alternatives to EPA's current all-electric approach. And "the failure of an agency to consider obvious alternatives has led uniformly to reversal." Spirit Airlines, Inc. v. DOT, 997 F.3d 1247, 1255 (D.C. Cir. 2021). [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

EPA must consider these alternatives, and would be well served to issue a new proposed multipollutant rule that: [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

1) incorporates requirements to improve fuel quality by [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

-establishing a higher federal octane standard while allowing higher blends of ethanol; and

-"incenting the reduction of carbon and aromatic compounds via reformulation or alternatively increasing ethanol blending. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

2) provides incentives for automakers to produce flex-fuel vehicles by [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

-creating alternative certification pathways for higher ethanol blends; and

-correcting the problems with R-Value and CO2 penalty that other commentors have identified and re-establishing the Volumetric Conversion Factor in the fuel economy calculation algorithm. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

3) adopts a life-cycle analysis approach to calculating and comparing emissions from different technologies. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

Embracing and enabling a pathway to improve fuel quality will increase and accelerate emission reductions, improve public health, help achieve environmental justice goals, provide greater versatility, and improve reliability all at less cost. This pathway is available to EPA and the consideration of it is demanded by the Clean Air Act. The best and most recent data suggests that the adoption of even mid-level ethanol blends would reduce pollution emissions at least as much as EPA's electrification approach, and at far less cost.i Even if EPA's electrification program could be successful—and as explained above, it cannot—a complimentary fuel improvement would double EPA's projected emissions reduction. The current rule takes this option off the table and leaves those pollutants in the air. EPA could do far better. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

1 See "Higher Ethanol Blends Support the Transition to a Low-Carbon Future," Brian West, SAE Update, February 2023, pp2-6) National adoption of mid-level ethanol blends is available, feasible, and lower cost than current gasoline. https://www.nxtbook.com/smg/sae/23UPD02/index.php#/p/2

Organization: Advanced Energy United

Digital permitting processes could also alleviate bottlenecks in EVSE infrastructure. The Department of Energy's SolarApp+ is a model program that has saved customers and contractor valuable time and money on solar installations by standardizing and streamlining permitting processes in localities across the U.S. Policymakers across the country should consider a similar approach to slash soft costs for the permitting of EV charging infrastructure. Investment alone cannot satisfy new demand. We must enable streamlined permitting processes if we are to meet the Biden Administration's goal of building 500,000 new charging stations. [EPA-HQ-OAR-2022-0829-0695, p. 5]

However, it is crucial to build the EVSE infrastructure to meet this changing automotive landscape. Simply put, consumers and businesses can only take advantage of the 30D and 45W tax credits if the infrastructure is there to satisfy demand. Ensuring this infrastructure buildout will enable effective implementation of the EPA's rule and accelerate the transition to 100% electrified transportation. Fortunately, the IRA's companion legislation – the Infrastructure Investment and Jobs Act (IIJA) -can help in this effort. IIJA included $7.5 billion in funding as a part of the National Electric Vehicle Infrastructure (NEVI) formula program, which provides states with resources to deploy charging stations. The pieces are in place to make the transition from the internal combustion engine to EVs, we just need to put them together. [EPA-HQ-OAR-2022-0829-0695, p. 6]

Organization: Alliance for Automotive Innovation

EPA underestimates battery costs; unrealistic BEV sales assumptions

The NPRM substantially underestimates the cost of batteries while overestimating the availability of consumer and manufacturing tax credits. For example, the Proposed Rule assumes that in 2029, the combination of cost reductions from installing larger batteries in BEVs and incentives from Inflation Reduction Act (IRA)5 Sections 30D, 45W, and 45X results in consumer incentives and battery production tax credits that substantially exceed the battery cost. If cost reductions and incentives eliminate the entire cost of EV batteries, it is little wonder the EPA model suggests a massive increase in sales of long-range BEVs. However, we do not believe these assumptions are realistic. Moreover, while vehicle cost and affordability are critical to success, they are just one set of factors in the transformation to electric vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 4-5]

5 H.R.5376 -117th Congress (2021-2022): Inflation Reduction Act. (2022, August 16). Available at htps://www.congress.gov/bill/117th-congress/house-bill/5376/text.

Beyond BEV affordability, success of this regulation will be determined by factors outside of the vehicle; the U.S. is sorely behind in this effort (despite over the $150 billion of private sector investment thus far) and the NPRM does little to address these factors. Current charging and fueling infrastructure is inadequate (particularly residential charging), the grid resources are at least 5 to 10 years away (without even factoring in the additional demand for grid resources from the heavy-duty vehicle sector facing similar concerns in a concurrent EPA rulemaking6), and battery critical minerals (except lithium), which primarily determine the affordability and availability of EVs, are minimally addressed in the NPRM. [EPA-HQ-OAR-2022-0829-0701, pp. 4-5]

6 U.S. Environmental Protection Agency, Proposed Rule: Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3 (for Model Years 2027-2032), 88 Fed. Reg. 25,926 (Ap. 27, 2023). Hereinafter "EPA HD GHG NPRM)."

No requirements to support required EVs or the drivers that must buy them

The NPRM and all the requirements set forth to date focus solely on the sale of BEVs. They propose no requirements to ensure that infrastructure will be available at homes, businesses, public event venues, highway corridors, transportation hubs, or other public locations. They contain no requirements to provide hydrogen or hydrogen fueling stations, or for utilities to quickly bring reasonably priced high-power charging (5-20 megawats (MW)) to highway service plazas, fleet locations, city centers, or transportation hubs. They do not address the need for battery critical minerals to power everything from light-, medium-, and heavy-duty vehicles, energy storage systems (ESS), lawn and garden equipment, laptops, cell phones, forklitis, and airport services—not just in the United States, but around the world. [EPA-HQ-OAR-2022-0829-0701, p. 5]

To support the vehicle requirements proposed, all these changes are necessary in under 10 years. For perspective, 10 years is the time required to obtain the necessary permits for a mine in the United States. Once permitted, another ten years could elapse before the mine produces at capacity. Ten years is also close to the time required to bring 20 MWs of power to a single location in the United States. Consequently, to the extent we need critical minerals and high-power charging, we must start today. Yet, there is no plan to do so. There is no roadmap to developing these essential pieces necessary for the transformation. Nor is there a commitment from EPA for ongoing monitoring of these factors as the EV market develops over the duration of EPA's proposed standards. [EPA-HQ-OAR-2022-0829-0701, p. 5]

Automakers are committed to electrification. The industry publicly agreed in August 2021 that BEVs, PHEVs, and FCEVs could constitute 40 to 50% of new vehicle sales by 2030 with the right combination of supportive measures. Some, but not all, of those supportive measures have started, but they are nowhere near complete and certainly not suffcient to support the even higher requirements in the proposed regulations that substantially leapfrog that target. [EPA-HQ-OAR-2022-0829-0701, p. 5]

In August of 2021, Auto Innovators and our members announced support for a goal of achieving 40-50% U.S. new light-duty vehicle market share of EVs (including BEVs, PHEVs, and FCEVs) nationally by 2030, with the right complementary policies,19 including but not limited to: [EPA-HQ-OAR-2022-0829-0701, pp. 26-27]

-Expand and scale the charging network to EV volumes required by the proposed rule.

-Update widely applicable and comprehensive Federal EV incentives and apply at point of purchase.

-Develop domestic battery supply chain (raw material mining, processing, manufacturing, and recycling).

-Implement fleet purchase requirements.

-Commitment to purchase EVs for federal fleets.

-Increase research & development to accelerate cost reduction of batteries and EV components.

-Educate consumers and increase EV awareness. [EPA-HQ-OAR-2022-0829-0701, pp. 26-27]

Though the federal government has made progress toward achieving these policy enablers, significant and crucial gaps remain. For example: [EPA-HQ-OAR-2022-0829-0701, pp. 26-27]

-The Bipartisan Infrastructure Law (BIL)20 committed $7.5B to expand public charging nationwide. This is a good down payment on the needed charging infrastructure, but only represents a fraction of what is needed to support the market projected by EPA. Moreover, thus far, almost two years after the BIL was signed, not a single electric vehicle charger has been installed with the federal funding allocated to states. [EPA-HQ-OAR-2022-0829-0701, pp. 26-27]

19 Alliance for Automotive Innovation Press Release, Auto Innovators: Aligning Policies for a Cleaner Future (Aug. 5, 2021), available at htps://www.autosinnovate.org/posts/press-release/aligning-policies-for-a-cleaner-future.

20 Infrastructure Investments and Jobs Act, Pub. L. No. 117-58 (2021), https://www.govinfo.gov/app/details/PLAW-117publ58.

-Unfortunately, the administration removed a pathway in the Renewable Fuel Standard Set Rule for Renewable Volume Obligations for 2023-2025 for EVs to generate credits by using electricity produced from biogas to charge (also known as e-RINs). This proposal would have provided a complementary approach to EPA's multipollutant rule, including supporting and encouraging both EVs and renewable sources of energy, as well as to the overall goal of decarbonizing the transportation sector. [EPA-HQ-OAR-2022-0829-0701, pp. 26-27]

2. Infrastructure

Reliable, convenient, affordable, and ubiquitous access to charging and hydrogen fueling stations is critical to EV drivers and the feasibility of the rules proposed in the NPRM. [EPA-HQ-OAR-2022-0829-0701, pp. 76-79]

For BEV and PHEV charging, residential charging is the single most important location. Virtually every study133 shows that 80-90% of charging occurs at home. Home charging is clearly preferred since it is 2-3x cheaper, vastly more convenient, and far more reliable than public charging. However, public charging stations are critical too -not only easing perceived "range anxiety" concerns but also substantially increasing consumer awareness of the technology. [EPA-HQ-OAR-2022-0829-0701, pp. 76-79]

133 For example, see Alexander, Mat, Noel Crisostomo, Wendell Krell, Jeffrey Lu, and Raja Ramesh. July 2021. Assembly Bill 2127 Electric Vehicle Charging Infrastructure Assessment: Analyzing Charging Needs to Support Zero-Emission Vehicles in 2030 – Commission Report. California Energy Commission. Publication Number: CEC-600-2021-001-CMR. Or Eric Wood, Clément Rames, Mateo Muratori, Sesha Raghavan, and Marc Melaina. National Renewable Energy Laboratory, April 2017, National Plug-In Electric Vehicle Infrastructure Analysis

FCEVs cannot be sold until hydrogen fueling stations are in place; there is no reliable hydrogen fueling outside of California (57 of the 58 hydrogen stations in the U.S. are in California). [EPA-HQ-OAR-2022-0829-0701, pp. 76-79]

Nonetheless, FCEVs can plan an important role in electrification particularly for customers that do not have access to charging at home or the workplace, or applications that require towing, which significantly reduces BEV range, or driving longer distances where short refueling times like gasoline fueling process are important. [EPA-HQ-OAR-2022-0829-0701, pp. 76-79]

The need for infrastructure (both EV charging and hydrogen) is tied not only to new vehicle sales but also to the total population of EVs on the road. We cannot afford to fall behind, which is exactly what is occurring today. [EPA-HQ-OAR-2022-0829-0701, pp. 76-79]

The IIJA includes $5 billion in formula funding for states to establish a nationwide EV charging network. While this is a good first step, as of today, no chargers have been installed under the IIJA, and every day the U.S. is falling behind the needed number of chargers. While early adopters and affluent single-family homeowners might tolerate the lack of public charging, mainstream, lower-income, and rural drivers that are needed for sales to reach 30, 40, or 60%, are less likely to be so tolerant. [EPA-HQ-OAR-2022-0829-0701, pp. 76-79]

[See orignal comment for: Figure 25: Number of publicly available non-proprietary Chargers (Auto Innovators)] [EPA-HQ-OAR-2022-0829-0701, pp. 76-79]

An assessment by the California Energy Commission concluded that 700,000 public and shared private chargers are needed to support 5 million EVs, amounting to a ratio of 7 EVs per public and shared private charger.134 At the end of the first quarter of 2023, there were about 134,000 public charging outlets across the country and 3.34 million EVs on the road, a ratio of 25 EVs per charger. For charging to meet the 7:1 ratio, more than 342,000 additional chargers are needed today, which is two and a half times the currently available non-proprietary chargers across the U.S. Looking to the future, based on current sales and BEV penetration rates projected in the NPRM, there could be as many as 40 million BEVs135 on the road by 2030. Using a ratio of 7:1, this would suggest that 5.8 million public and shared private chargers are needed. As shown in Figure 26, President Biden's goal of 500,000 public chargers136 hardly dents the need for more public and shared private charging. [EPA-HQ-OAR-2022-0829-0701, pp. 76-79]

134 Alexander, Mat, Noel Crisostomo, Wendell Krell, Jeffrey Lu, and Raja Ramesh. July 2021. Publication Number: CEC-600-2021-001-CMR.

135 Based on EPA OMEGA model output of 38M cumulative BEV sales 2022-2030MY combined with existing U.S. EV registrations and adjusted for vehicle scrappage.

136 https://www.whitehouse.gov/briefing-room/statements-releases/2021/12/13/fact-sheet-the-biden-harris-electric-vehicle-charging-action-plan/

Figure 26: 2030 Model Year Anticipated Infrastructure Needs [EPA-HQ-OAR-2022-0829-0701, pp. 76-79]

Moreover, the U.S. is falling further behind in installing publicly available chargers for the number of EVs that are being sold. More than 305,000 new EVs were added to the roads in the first quarter of 2023, but only 7,802 new chargers were added,137 a ratio of 39 new EVs for every new public port, and more than five times higher than the recommended ratio of 7:1. [EPA-HQ-OAR-2022-0829-0701, pp. 76-79]

137 htps://www.autosinnovate.org/posts/papers-reports/Get%20Connected%20EV%20Quarterly%20Report%202023%20Q1.pdf

JD Power EV Index calculates a score on a scale of 100 points every month to demonstrate the advancement of EVs toward parity with ICE vehicles. The index is broken into six sub-categories, one being infrastructure readiness. Figure 27 below shows the April 2023 JD Power infrastructure assessment at 27 out of 100 points in their EV index as infrastructure continues to lag EV growth.138 [EPA-HQ-OAR-2022-0829-0701, pp. 76-79]

138 JD Power (n.d.). JD Power EV Index. JD Power EV Index. Retrieved June 10, 2023, from https://www.jdpower.com/business/evindex

Figure 27: Charging Infrastructure Growth. [EPA-HQ-OAR-2022-0829-0701, pp. 76-79]

Source: JD Power EV Index report, April 2023 [EPA-HQ-OAR-2022-0829-0701, pp. 76-79]

It is also important to ensure low-to moderate-income (LMI) and multi-family dwelling (MFD) residents have access to the low-cost, convenient, and reliable level 2 (L2) home charging that more affuent single-family homeowners enjoy. MFD residents, however, often face the greatest, most costly, and burdensome obstacles to installing residential EV charging. For MFD residents, the additional costs to upgrade the electrical panel, install conduit between the electrical panel and their parking space, and the logistical challenges of securing building owner approval, coordinating the billing with the building owner, and persuading an owner to make a long-term investment on a rental property, make it challenging to have convenient residential charging in an MFD. [EPA-HQ-OAR-2022-0829-0701, p. 79]

Renters, low-income, and MFD residents could be forced to charge at public chargers, which is far more expensive, less reliable, and vastly less convenient. This is unreasonable, and EPA and its federal counterparts should ensure this population has the same access to L2 home charging as affuent single-family homeowners. [EPA-HQ-OAR-2022-0829-0701, p. 79]

a) European Union Alternative Fuel Infrastructure Regulation (AFIR)

As discussed, growth of nationwide charging infrastructure is one of the most important market features needed to establish a robust and EV-dominated market. Without a widely available charging network, compliance with regulations that demand electric vehicles cannot be achieved. The European Union recognizes and addresses this with the recent passing of the Alternative Fuel Infrastructure Regulation (AFIR).139 [EPA-HQ-OAR-2022-0829-0701, pp. 79-80]

139 htps://theicct.org/wp-content/uploads/2023/04/AFIR-EU-Policy-Update-A4-Final.pdf

The AFIR sets legally binding targets for the deployment of alternative fuel infrastructure, including EV charging availability for passenger cars, vans, trucks, and buses. The regulation assigns objective requirements for each E.U. member state specifying both the amount of combined charging output required for each registered EV, as well as the maximum distance between available charging points. As shown in Figure 28, each E.U. state must ensure a total output of at least 1.3kW for each registered BEV and 0.8kW for each registered PHEV. [EPA-HQ-OAR-2022-0829-0701, pp. 79-80]

Figure 28: Alternative Fuel Infrastructure Regulation (AFIR) Car, Truck, Van Charging Requirements per Registered Vehicle [EPA-HQ-OAR-2022-0829-0701, pp. 79-80]

Technology Minimum Available Charging Power Per Registered EV

BEV 1.3 kW

PHEV 0.8 kW [EPA-HQ-OAR-2022-0829-0701, pp. 79-80]

Distance-based targets specifying the maximum kilometers between charging stations are assigned for core travel corridors (Trans-European Transport Network or TEN-T) and expand to all smaller roads included in the TEN-T in 2030. As shown in Figure 29, by 2030 300kW of fast-charging capacity will need to be available every 60 km in each direction of the entire Trans-European Transport Network. [EPA-HQ-OAR-2022-0829-0701, pp. 79-80]

Figure 29: Alternative Fuel Infrastructure Regulation (AFIR) Car, Truck, Van Charging Distance-Based Requirements [EPA-HQ-OAR-2022-0829-0701, pp. 79-80]

Date Scope of Requirements Minimum Power Every 60km

December 31, 2025 Core Trans-European Roads 400 kW

December 31, 2027 Core Trans-European Roads

50% of smaller roads 600 kW

300 kW

December 31, 2030	All Trans-European Roads	300kW
December 31, 2035	All Trans-European Roads	600 kW

[EPA-HQ-OAR-2022-0829-0701, pp. 79-80]

The AFIR demonstrates that the deployment of infrastructure is required to build a successful EV market. It also demonstrates that the deployment of these enablers cannot be left to model projections, assumption, or chance. EPA should follow the E.U.'s lead and implement similar complementary mechanisms that treat market enablers as a necessity to achieving the electrification targets of the NPRM. Otherwise, consumer adoption of such technologies will lag due to the lack of reliable charging and refueling stations. [EPA-HQ-OAR-2022-0829-0701, pp. 79-80]

C. Infrastructure

Large-scale market adoption of EVs is contingent on charging/refueling infrastructure being in place to support those vehicles. We believe it is appropriate to use the ratio of one public charging point/refueling station being required per every seven EVs on the road to get EVs to usage and convenience parity with ICE vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 86-87]

A scalable target adjustment would be applied to each model year based on the deployed charging/refueling infrastructure deficit and total number of EVs on the road for any given year. There are a variety of sources for tracking this infrastructure from the Department of Energy to various 3rd party sources. There are also a variety of 3rd party sources for tracking EV registrations. Thus, EPA would have available suitable source(s) to reference each year for this data. A target adjustment would be determined, for example, using the following formula: [EPA-HQ-OAR-2022-0829-0701, pp. 86-87]

Adjustment (lnfr) = Adjustment (max) * (EV (total) / 7) – CRP) / (EV (total) / 7)

Where

Adjustment (lnfr) = Infrastructure adjustment (g/mi)

Adjustment (max) = 10 g/mi

EV (total) = Total number of EVs on the road (BEV + PHEV + FCEV)

CRP = Total number of publicly available charging/refueling points

[EPA-HQ-OAR-2022-0829-0701, pp. 86-87]

Using the example of 26 million EVs being on the road in 2030 and 2.5 million total public charging/refueling points, the target adjustment would be calculated as follows: [EPA-HQ-OAR-2022-0829-0701, pp. 86-87]

Credit (lnfr) = 10 g/mi * (26,000,000 / 7) – (25,000,000) / (26,000,000 / 7) = 3.3 g/mi [EPA-HQ-OAR-2022-0829-0701, pp. 86-87]

EPA would publish the annual result of this adjustment calculation at the same time as the other two target adjustment mechanisms. [EPA-HQ-OAR-2022-0829-0701, pp. 86-87]

Automakers are and will continue to do their part in building vehicles to support electrification goals. However, automakers should not be penalized for critical aspects in EPA's modeling projections that are outside of their control. The proposed market-based target adjustment system would allow for year-by-year adjustments to be made within the framework of a rule that would reffect a more accurate and fair way to address the recognized uncertainties of the market. If these EV market enablers develop as projected by EPA, then these adjustments will be negligible. However, if these key enablers do not develop as projected, these adjustments could be the difference between a successful rule and a failed rule. [EPA-HQ-OAR-2022-0829-0701, pp. 86-87]

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

Beyond critical minerals, the United States lacks adequate infrastructure for electric vehicle charging and hydrogen refueling. Developing the necessary infrastructure would cost billions of dollars in funding and require immediate planning and coordination. Even if enough new charging stations could be built, the Nation's electricity grids could not currently supply them with sufficient power. And batteries and fuel cells present an array of documented safety risks, including spontaneous fires and explosions that have resulted in death, injuries, and extensive property damage. All of these considerations would further stifle electric-vehicle adoption. [EPA-HQ-OAR-2022-0829-0683, pp. 4-5]

b. The Nation's Charging and Hydrogen Refueling Infrastructure Is Underdeveloped

Even if manufacturers could produce light-and medium-duty electric vehi-cles in the volumes and variety necessary to make compliance possible, their deployment still would be stunted by the Nation's inadequate charging and hy-drogen refueling infrastructure. [EPA-HQ-OAR-2022-0829-0683, pp. 42-43]

Charging Infrastructure. If the proposed rule were adopted, American driv-ers would need access to a robust network of home, workplace, and public chargers. Home charging is often accomplished through Level 1 or Level 2 ports, which provide approximately 5 and 25 miles of range per hour, respec-tively. See Draft RIA at 4-21; Dep't of Energy, Alternative Fuels Data Ctr., Developing Infrastructure to Charge Electric Vehicles, https://ti-nyurl.com/3buv474m ("Developing Infrastructure"). Workplace charging is often offered in a Level 2 option. See Michael Nichols, Estimating Electric Vehicle Charging Infrastructure Costs Across Major U.S. Metropolitan Areas, ICCT, at 1 (Aug. 2019) ("Estimating Electric Vehicle Charging"). And public charging— which is critical to drivers without access to home or workplace charging, those who travel long distances, and those who use their vehicles for commercial or ride-sharing purposes—is offered at a Level 2 option or, more preferably, a "di-rect-current" or "DC" fast charging port, which provides approximately 100 to 200 or more miles of range per thirty minutes. See Draft RIA at 4-23; Dep't of Energy, Developing Infrastructure; Philipp Kampshoff et al., Building the Electric-Vehicle Charging Infrastructure America Needs, McKinsey & Co., at 8–9 (Apr. 18, 2022) ("Building Electric-Vehicle Charging Infrastructure"); Nichols, Estimating Electric Vehicle Charging at 2–3. [EPA-HQ-OAR-2022-0829-0683, pp. 42-43]

The number of charging ports currently available do not come close to meet-ing this need. According to EPA, the amount of electric vehicles projected un-der its proposed rule would require 12 million home, 400,000 workplace, and 110,000 public charging ports in 2027—the first year that the proposed rule would be in effect. Those numbers would balloon to 75 million home, 12.7 million workplace, and 1.9 million public chargers, respectively, by 2055. 88 Fed. Reg. at 29,309; Draft RIA at 5-31. Developing this infrastructure would come at a high cost to families and businesses across the country. The agency projects that the required installations will cost between $1 billion and $1.6 bil-lion by 2027, and between $96 billion and $140 billion by 2055. See Draft RIA at 5-36. Some studies suggest that the costs may be much higher. See, e.g., Gordon Bauer et al., Charging Up America: Assessing the Growing Need for U.S. Charging Infrastructure Through 2030, ICCT, at i (July 2021) (estimating that the cost of 2.4 million workplace and public chargers would alone reach $28 bil-lion). [EPA-HQ-OAR-2022-0829-0683, pp. 42-43]

EPA assumes that the extraordinary costs for developing this charging in-frastructure will be covered by federal incentives and funding, as well as private investment. See, e.g., 88 Fed. Reg. at 29,307. But these sources fall far short of establishing that the billions of dollars needed will be readily available and ef-fectively implemented by the time the proposed rule would take effect. [EPA-HQ-OAR-2022-0829-0683, p. 43]

• EPA relies on a tax credit in the IRA that it claims will cover up to 30 percent of the cost of charging equipment. Id. at 29,308. But that credit applies only when the charging equipment is located within low-income or non-urban area census tracts, and it covers only up to $1,000 for res-idential charging equipment and $100,000 for public charging equip-ment. Id. [EPA-HQ-OAR-2022-0829-0683, p. 43]

• EPA also points to $7.5 billion in federal funding that the Bipartisan Infrastructure Law provides to build out a network of public charging stations. Id. at 29,195, 29,307. But the goal of that federal funding pro-gram is to develop only 500,000 public charging stations—just over a quarter the amount EPA projects as necessary under its proposed rule in the period EPA analyzed (2027-2055)—meaning that the remainder must come from other sources. Cf. Kampshoff, Building Electric-Vehicle Charging Infrastructure at 2 (noting that "even the addition of half a mil-lion public chargers could be far from enough"). [EPA-HQ-OAR-2022-0829-0683, p. 43]

As to private investment, EPA cites investments announced by electric companies, auto manufacturers, and charging network providers. See 88 Fed. Reg. at 29,307–08. Some investments, however, are more lim- ited than the proposed rule acknowledges. For example, EPA highlights that General Motors is partnering with charging provider FLO "to de- ploy as many as 40,000 L2 ports," id. at 29,308, but the companies made clear that a portion of these ports will be located in Canada, see Emma Jarratt, FLO to Supply 40,000 Chargers to GM for Dealerships Across Canada and the United States, Elec. Autonomy Canada (Dec. 8, 2022), https://ti- nyurl.com/5xn39ju4. More importantly, EPA does not attempt to quantify the total amount of investment pledged, the number of charging ports that the investments will provide, and the overall timing of their deployment—all of which are critical to EPA's assumption that private investment will bridge the expanding gap in charging infrastruc- ture by the time the proposed rule would take effect. [EPA-HQ-OAR-2022-0829-0683, pp. 43-44]

Moreover, even if federal and private investment were adequate to deploy enough chargers in the aggregate nationwide to enable compliance with EPA's proposed rules, multiple practical issues—including chargers' location, speed, and compatibility—would remain. Those concerns must be addressed before EPA can plausibly conclude that the infrastructure will be sufficient to meet the needs of drivers. [EPA-HQ-OAR-2022-0829-0683, pp. 43-44]

To begin, there is a serious gap in home charging for drivers that do not live in single-family homes. A report released by the National Renewable Energy Laboratory shows that there are only 1,179 charging ports at multi-family resi-dences across the entire country. See Abby Brown et al., Electric Vehicle Charging Infrastructure Trends from the Alternative Fueling Station Locator: Third Quarter 2022, NREL, at 21 (Mar. 2023) ("Charging Infrastructure Trends"). That number is far too low given that there are over 550,000 apartment buildings with five or more units, and over 2.2 million apartments with between two and four units in the United States. See Characteristics of Apartment Stock, Nat'l Multifamily Hous. Council, https://tinyurl.com/nhnsrsea (last accessed June 25, 2023). If EPA intends for the majority of drivers to switch to electric vehicles by 2032, sub-stantial progress will need to be made in installing home charging ports in these multi-family residential buildings. But doing so is both expensive and logisti-cally difficult. "Higher costs for home charging upgrades generally correspond to a greater number of wall and floor penetrations, total circuit distance, or ser-vice upgrades," all of which exist in "attached homes and apartments." Nich-ols, Estimating Electric Vehicle Charging at 6. Drivers living in apartment build-ings also might not plan on staying in the same residence long enough to justify the effort of persuading landlords to install enough (or any) charging units. And even when such drivers relocate, in choosing another residence they may have many other considerations to weigh besides the availability of on-site charging. [EPA-HQ-OAR-2022-0829-0683, pp. 44-45]

There is also a significant gap in public charging stations for drivers that live in poor and rural communities. "Current charger installations tend to be lo-cated in higher-income areas, following the location of early EV sales." Kampshoff, Building Electric-Vehicle Charging Infrastructure at 9. And in Califor-nia—the state with the most public charging stations in the country—only 6,000 of the nearly 80,000 stations are located in rural counties, despite the fact that those counties make up 60 percent of the state's landmass; are home to 14 percent of the state's population; and contain "sought-after destinations" like national parks, wildlife areas, lakes, trails, and campgrounds. Angel Barajas, California's Rural Areas Risk Being Left Out in EV Push, Gov't Tech. (June 1, 2022) ("California's Rural Areas"), https://tinyurl.com/4k8wb38d. In Wyoming, there are only 169 public charging ports statewide. Charette, EV Transition. The lack of available public charging stations "is endemic across rural areas" and poses a major obstacle to EPA's planned shift to electric vehicles. Id. According to one study, seven out of ten people who do not own an electric vehicle report that "the areas near their homes lack a significant number of chargers." Kampshoff, Building Electric-Vehicle Charging Infrastructure at 10. Thus, even if EPA is right about the total number of public charging stations that can be de-veloped by the compliance period, their geographic distribution is an equally important, but inadequately addressed, consideration. [EPA-HQ-OAR-2022-0829-0683, pp. 44-45]

Beyond geographic distribution of chargers, electric-vehicle drivers have re-ported that their experience with public charging is "often unsatisf[actory]" due to "speed, cost, availability (including both free and working chargers), and safety of charging locations." Kampshoff, Building Electric-Vehicle Charging In-frastructure at 14. For example, many drivers prefer DC fast charging—which as noted can provide 100-200 miles of range per 30 minutes of charging time— over Level 1 and Level 2 chargers, which provide only a small fraction of that output and thus can make charging away from home impractical. But very few public stations offer that DC fast-charging option. Nationwide, there are a mere 7,406 stations with DC fast charging ports—amounting to only 14 percent of all public chargers. See Dep’t of Energy, Alternative Fuels Data Ctr., Alternative Fueling Station Locator, https://tinyurl.com/4xjsc3x6 (last accessed June 14, 2023); Dep’t of Energy, Developing Infrastructure. And even among that limited number, there are three different types of DC fast charging connectors (the equipment that is “plugged into a vehicle”), with the “majority” being on the Tesla network. Brown, Charging Infrastructure Trends at viii. As a result, electric-vehicle drivers may “need to travel longer distances to find a station with the right connector type.” Greenhouse Gas Emissions Standards for Heavy-Duty Vehi-cles: Phase 3, Draft Regulatory Impact Analysis, EPA, at 68 (Apr. 2023) (“Heavy Duty Draft RIA”). Ensuring the availability of accessible, fast charging equip-ment at public stations across the country is therefore a critical piece of the infrastructure puzzle. See Brown, Charging Infrastructure Trends at vii (“Building out the country’s network of public DC fast chargers is critical to supporting EV adoption in the United States.”). But EPA does not explain—and likely does not know—how much of the federal funding or private investment it high-lights will be used to install fast-charging equipment. See 88 Fed. Reg. at 29,307–09. [EPA-HQ-OAR-2022-0829-0683, pp. 45-46]

In addition to speed, electric-vehicle drivers face problems with interopera-bility and consistency across public charging stations. As EPA highlighted in the parallel proposed rulemaking for heavy-duty vehicles, there are “[c]ommu-nication protocols” between chargers and vehicles that “facilitate the flow of key information important for charging and billing.” Heavy Duty Draft RIA at 69. Thus, without standardization, electric-vehicle drivers may pull up to a charging port only to realize that they cannot use it. Drivers also report that “[p]ricing systems” at public charging stations “can vary considerably.” Kampshoff, Building Electric-Vehicle Charging Infrastructure at 14. Pricing may be by the minute or by kilowatt-hour, and it may differ depending on membership. Id. This means that “[i]t isn’t always easy to tell which option offers better value, and payment is often a hassle.” Id. [EPA-HQ-OAR-2022-0829-0683, pp. 45-46]

Each of these problems must be resolved before a widespread shift to elec-tric vehicles is plausible. “[E]ven in cases where consumer appetite for ZEVs is high, a lack of adequate charging infrastructure could hold the market back and potentially stall progress.” Marie Rajon Bernard et al., Deploying Charging Infra-structure to Support an Accelerated Transition to Zero-Emission Vehicles, ZEV Tran-sition Council, at 4 (Sept. 2022). And multiple studies report that charging is a top concern among prospective electric-vehicle buyers. See, e.g., Barajas, California’s Rural Areas (“[C]oncerns remain, including hesitant consumers wary of ‘range anxiety,’ the fear of being stranded without the ability to recharge, or in some cases not having access to charging capacity at their apartment complex or work.”); Kampshoff, Building Electric-Vehicle Charging Infrastructure at 1 (“[N]early half of US consumers say that battery or charging issues are their top concerns about buying EVS.”); Nichols, Estimating Electric Vehicle Charging at 1 (“Exactly how much charging infrastructure will be needed and what it will cost are top questions for prospective electric vehicle owners.”). Until ade-quate home, workplace, and public charging infrastructure develops at the rate, in the places, and at the quality desired by consumers, consumers are unlikely to purchase anything close to the volume of electric vehicles that EPA intends to mandate that manufacturers provide. The agency has not offered a reasonable basis for assuming that the necessary expansions and improvements are possible, let alone likely, within less than a decade. [EPA-HQ-OAR-2022-0829-0683, pp. 46-47]

Hydrogen Refueling Infrastructure. Although EPA's proposed rule for light-and medium-duty vehicles assumes that manufacturers will comply primarily by integrating battery-electric vehicles into their fleets, see 88 Fed. Reg. at 29,329, 29,331, 29,343, the agency states that fuel-cell vehicles provide another compliance option, id. at 29,194, 29,252. The state of hydrogen refueling, how-ever, is even worse than that of charging infrastructure. Although EPA does not discuss hydrogen refueling in the proposed rule or draft regulatory impact analysis, it made clear in connection with the parallel heavy-duty rule that every step of this supply chain is underdeveloped. See Heavy Duty Draft RIA at 81–86. For example, today there are only 58 public hydrogen refueling stations in the entire country, 57 of which are in California. See Dep't of Energy, Alternative Fuels Data Ctr., Alternative Fueling Station Counts by State (Public), https://ti-nyurl.com/385e5nk2 (last accessed June 14, 2023).5 To provide any national refueling network, let alone a robust one, operations would need to scale up dramatically and rapidly. EPA does not explain whether, how, or when that will happen, making fuel-cell vehicles even less attractive to consumers than battery-electric ones. Emissions standards premised on the adoption of fuel-cell vehicles are not feasible. [EPA-HQ-OAR-2022-0829-0683, p. 47]

5 There are also 16 private stations. See Dep't of Energy, Alternative Fuels Data Ctr., Alternative Fueling Station Counts by State (Private), https://tinyurl.com/4xc8jfcs (last accessed June 14, 2023).

Organization: American Fuel & Petrochemical Manufacturers

I. EPA's Proposal Does Not Comprehensively Address Cross-Cutting Issues

EPA's desire to remake the automotive sector creates significant energy and national security concerns and stresses an aging electrical grid subject to increasing demand. In glossing over these issues, EPA fails to adequately consider the mineral, metal, electricity generation, transmission, distribution, and charging infrastructure requirements necessary for the Proposed Rule to be feasible. This is alarming and undermines our energy security. We lack the supply of domestically sourced minerals and metals needed to build batteries and transmission lines and, contrary to the legislative intent of U.S. laws such as the Bipartisan Infrastructure Law ("BIL") and Inflation Reduction Act ("IRA"), we will have to rely on foreign countries to fulfill the Proposed Rule's mandate. [EPA-HQ-OAR-2022-0829-0733, p. 4]

Even if we could import vast quantities of mineral resources, EPA's electrification mandate is unobtainable. We face a limited supply of copper, which is a critical mineral needed to build out the transmission grid to supply electricity to charging stations. We also do not have near the vehicle charging infrastructure necessary to power the mandated number of ZEVs. Rather than conducting a clear-eyed assessment of these challenges, EPA erroneously assumes that all the necessary conditions to enable its proposal will happen on its aggressive timeline. This conclusion dismisses or outright ignores a multitude of evidence to the contrary. [EPA-HQ-OAR-2022-0829-0733, p. 4]

EV charging infrastructure, range, and charging time remain top concerns for nearly half of U.S. customers.139 OEMs expect that ZEV penetration will not be uniform across markets, with larger impact in markets with more low carbon intensity electricity and greater electrical grid reliability.140 Toyota announced that regional energy variation is the reason Toyota will provide a diversified range of carbon neutral options to meet the needs and circumstances in every country and region.141 Toyota believes optionality facilitates the ability to adapt to change, while selecting a single option is an attempt to predict the future in uncertain times.142 [EPA-HQ-OAR-2022-0829-0733, pp. 31-32]

142 Id.

As discussed in more detail below, consumer market demand will not, and cannot, increase to meet the Proposal's required supply. Charging capabilities, which creates range anxiety, is a key apprehension for nearly half the U.S. consumer market. EVs have less range, both technically and practically. As noted by J.D. Power, "[T]he majority of EVs provide between 200 and 300 miles of range on a full charge."147 This same article, however, also noted that EVs with less than 200-mile ranges (such as the 2022 Nissan Leaf at 149 miles or the 2022 Mazda MX-30 at 100 miles) are "either affordable or focused on performance."148 With respect to longer range vehicles, claimed vehicle ranges of up to 516 miles are available, but this range comes at considerable cost. The number 1 range-rated vehicle by Car and Driver, the 2023 Lucid Air, carries a base price of $113,650. And while three out of the ten top-rated EVs by Car and Driver were more "reasonably priced" from $44,630 to $56,630, all other models within the top 10 cost anywhere from $74,800 to $110,295.149 [EPA-HQ-OAR-2022-0829-0733, pp. 32-33]

147 See Sebastian Blanco, List of EVs Sorted by Range (Sept. 1, 2022), www.jdpower.com/cars/shopping-guides/list-of-evs-sorted-by-range.

148 Id.

Moreover, the time it takes to charge a ZEV compared to fueling an ICEV deters ZEV adoption.150 Depending on the type of vehicle (ZEV v. PHEV) and charger (Level 1, Level 2, or Direct current fast charging equipment ("DCFCs")), charging times from empty to 80 percent charged can range from 40-50 hours (Level 1 charging) to 20 minutes to one hour (DCFC), although most PHEVs on the market do not work with DCFCs.151 In early 2023, a Boston Globe survey around the Boston metropolitan area found DCFC chargers were unreliable, going offline for weeks or months at a time.152 Since close to two-thirds of U.S. households do not purchase new vehicles, lower-income people are more likely to purchase less expensive, early generation PEVs with less range and using a Level 1 or Level 2 charger requires longer charge times.153 These extended recharging times remain a barrier to EV adoption.154 [EPA-HQ-OAR-2022-0829-0733, p. 33]

150 EVBox, EV Box Mobility Monitor (June 2022). Available at evbox-mobility-monitor-2022-intl.pdf (a study of EV adoption in France, Germany, the Netherlands, and the UK revealed that excessive charging time remains a deterrent to EV adoption).

153 Hardman, Scott, et al. "A Perspective on Equity in the Transition to Electric Vehicles." MIT Science Policy Review, 20 Aug. 2021, sciencepolicyreview.org/2021/08/equity-transition-electric-vehicles/.Accessed 29 June 2023.

154 Exro, Barriers to electric vehicle adoption in 2022. Available at Barriers to Electric Vehicle Adoption: The 4 Key Challenges (exro.com).

EPA requests comment on their approach to determining charging time, as set forth in the DRIA, Chapter 4.155 EPA's analysis is contingent on unsupported assumptions regarding (1) U.S. consumers' adoption of and ability to purchase more expensive ZEVs (see Sections IV.B.2 and IV.E.2.ii); (2) the type of ZEV purchased (used ZEVs or PHEVs compatible with slower charging units or new ZEVs that can use DCFC) (Section IV,B.2 addresses charging times); (3) the availability of critical minerals and metals to expand the supply of reliable and renewable electricity (see Section I.B); and (4) the availability of reliable and affordable charging for all users (see Sections IV.B.4). Given the flaws in EPA's methodology that omits significant data sources and other factors and makes unsupported assumptions, EPA should revise its analysis concerning charging time and continue with promulgating a final rule for future emissions standards, that accounts for the reality of today's automotive market and not the public pronouncements of the automotive industry, a single state or group of states, or other unsupported estimates of future market growth. [EPA-HQ-OAR-2022-0829-0733, pp. 33-34]

155 88 Fed. Reg. at 29,367.

4. EPA ignores the lack of reliable ZEV charging

The Proposal's success is partially contingent on the availability of "equitable, affordable charging."169 Currently, ZEV charging is most available in metropolitan areas, with less investment occurring outside urban areas.170

169 Joann Muller, "The electric car revolution hinges on equitable, affordable charging," Axios, Feb. 8, 2023. Available at The electric vehicle revolution hinges on equitable, affordable charging (axios.com).

170 S&P GLOBAL MOBILITY, "EV Chargers: How Many Do We Need?" (Jan. 9, 2023), available at https://press.spglobal.com/2023-01-09-EV-Chargers-How-many-do-we-need.

While a significant percentage of the charging installations deployed today are Level 2 EVSEs, dual charging installations to enable the flexibility of LD as well as MD and HDV charging will become increasingly important. DCFCs will enable broader market coverage, even for LDVs used in applications where they cannot sit for 6 hours and charge during off-peak, lower-cost electricity periods. As utility companies gear up to provide infrastructure installations, we should not minimize the impact of supply chain shortages/strains on the cost of materials necessary for installing supporting charging infrastructure in the short time ahead to 2032. [EPA-HQ-OAR-2022-0829-0733, pp. 36-37]

The DRIA admits its charging simulations to estimate charging network size excluded medium-and heavy-duty vehicles, which are also subject to EPA's EV mandate.174 While these commercial vehicles may spend most of their time charging at private depot stations, these are mobile, commercial vehicles that will need to use (and strain) the charging network. It is arbitrary and capricious for EPA to omit those vehicles from its simulations. [EPA-HQ-OAR-2022-0829-0733, p. 37]

174 DRIA at 5-39, n. 107.

Moreover, many available chargers are unreliable. A recent study on the reliability of fast chargers found that in 22.7 percent of the cases studied, chargers were nonfunctional because of "unresponsive or unavailable touchscreens, payment system failures, charge initiation failures, network failures, or broken connectors," and 4.9 percent of charging cable were too short to reach an EV's charge port.175 Similarly, in a J.D. Power study, owners in high EV volume markets like California, Texas and Washington are finding the charging infrastructure inadequate and plagued with non-functioning stations.176 This is a significant technological issue that calls into question the viability of the existing charging network as well as future deployments. Similarly, in a J.D. Power study, owners in high EV volume markets like California, Texas and Washington are finding the charging infrastructure inadequate and plagued with non-functioning stations.177 [EPA-HQ-OAR-2022-0829-0733, pp. 37-38]

176 J.D. Power. Press Release, "2022 U.S. Electric Vehicle Experience (EVX) Public Charging Study." J.D. Power, 17 Aug. 2022, www.jdpower.com/business/press-releases/2022-us-electric-vehicle-experience-evx-public-charging-study. Accessed 28 June 2023.

Demand charges can be punishing, and in some cases make or break the business case for transition from ICEVs to ZEVs, particularly for fleets and vehicles that require DCFC charging. Other considerations for high-reliability use cases should include provisional back-up power system considerations, which depend upon back-up generators or expensive stationary energy storage batteries. Absent comprehensive understanding of the dynamics between increased ZEV use and charging infrastructure needs, OEMs and consumers are vulnerable. [EPA-HQ-OAR-2022-0829-0733, pp. 37-38]

v. Costs to upgrade electricity generation, transmission, and distribution

For EPA to achieve its GHG reduction aspirations in this Proposed Rule, all three of these challenges must be met: (1) sufficient materials to manufacture the required EVs, chargers, and grid upgrades, (2) consumer willingness to substitute ZEVs for ICEVs currently for sale, and (3) a low-carbon power generation grid capable of reliably supplying energy for this mode of transportation. Combined with other issues, such as a disorderly transformation of the generation base as conventional units are replaced with intermittent resources, raises questions of the grid's ability to reliably meet consumer demand on a regional basis. Despite these challenges, EPA incredibly assumes no increase in the cost of electricity to consumers (whether EV owners or others) associated with the proposed rulemaking. EPA underestimates the cost of electricity to all consumers, including EV owners, and omits the cost of grid upgrades and distributed energy resources have been excluded from these estimates.260 [EPA-HQ-OAR-2022-0829-0733, pp. 56-57]

260 U.S. Department of Energy, National Renewable Energy Laboratory, "The 2030 National Charging Network: Estimating U.S. Light-Duty Demand for Electric Vehicle Charging Infrastructure." June 2023. https://driveelectric.gov/files/2030-charging-network.pdf.

EPA incorrectly assumes that ZEV owners will pay the national average residential electricity price to charge their vehicles. EPA fails to consider that the majority of ZEVs in the U.S. are located in utility service territories with some of the highest electricity rates in the country and that the average EV owner currently pays a much higher price to charge their ZEV at home than the national average residential electricity rate. Given that EV penetration has varied widely across the U.S., it would be arbitrary to assume that EVs will, unlike in the past, penetrate uniformly across the U.S. and thus that the average electricity price would be representative of the actual cost electricity. For example, California, which has roughly 40 percent of all registered ZEVs in the U.S., has a residential electricity rate that is roughly double the national average. Considering that EPA is modeling its rule after a California-like approach to mandate ZEVs, it would be more appropriate for EPA to assume similar real-world costs (at a minimum, given California's temperate climate). Moreover, EPA fails to consider that mandating such a high ZEV sales rate will necessarily require exponential increases in commercial ZEV charging at rates that are currently three, four or five times higher than the current national average residential electricity rate, depending on location and charging speed. Those customers who are not homeowners and not able to install their own charging stations and take advantage of charging at low-cost times will be adversely impacted. Instead, EPA uses a residential rate for electricity and does not consider peak power or time of use charges. California electric prices rose 42 percent -78 percent between 2010 and 2020 and are projected to rise an additional 50 percent by 2030 as shown in Figure 9. [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

SEE ORIGINAL COMMENT FOR Historic and Forecasted Residential Average Rates Based on Most Recent 5-year Average Rate Increase. Figure 9: [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

Source: Michael Shellenberger, Twitter (citing California Public Advocate's Office data), April 27, 2021). [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

Heaping additional demand for EV charging into this market could exacerbate already high electricity prices. This will be especially impactful to lower-income homeowners who may not be able to install dedicated charging units, forcing them to pay more out of pocket for charging during peak demand periods.265 [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

265 Hardman, Scott, et al., "A Perspective on Equity in the Transition to Electric Vehicles." MIT Science Policy Review, (Aug. 20 2021), available at https://sciencepolicyreview.org/2021/08/equity-transition-electric-vehicles/ (accessed June 29, 2023).

EPA must revise its analysis to account for realistic electricity prices. The proposed ZEV mandate will require an enormous investment in power generation and distribution, resulting in nationwide increases in electricity bills that EPA has not considered. Of course, considering the additional trillions of dollars in costs would paint a clear picture that the costs of forced electrification far exceed even the inflated benefits EPA presented in the Proposed Rule. [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

vi. Charging infrastructure costs

EPA vastly underestimates the cost to build the required charging infrastructure. Even as new ZEVs are ready to enter into production, auto industry representatives have acknowledged the necessary infrastructure for electric vehicles continues to lag.266 In 2020, there were a total of 103,582 publicly available non-proprietary charging outlets in U.S. (30 percent of which are located in 14 counties) for 3.04 million EVs on the road, a ratio of 29 EVs per charger.267 In 2022, 51 percent of all new chargers were added in 2 percent of U.S. counties, with California adding 25 percent of the 2022 new charging capacity and 160 counties adding only one charger.268 And the pace of installing new public chargers is not keeping up with current and projected EV sales, as the ratio of registered EVs to new chargers in 2022 was 38 to one.269 [EPA-HQ-OAR-2022-0829-0733, pp. 58-59]

268 Id.

269 Id.

A 2023 EV Charging Station Report based on DOE's Alternative Fuel Data Center data highlights as the number of ZEVs in the U.S. increased by 42 percent, but the growth in public charging outlets increased by only 12 percent during the same time.270 According to S&P Global's Mobility Special Report, U.S. charging infrastructure is not nearly robust enough to fully support a maturing electric vehicle market, and ZEV charging stations will need to quadruple between 2022 and 2025 and grow more than eight-fold by 2030.271 There is lower investment into charging systems outside of major metro markets.272 Of the 3,100 counties and city-counties in the U.S., 63 percent had five or fewer chargers installed; 39 percent had zero; and 53 percent of counties added no new chargers in 2022.273 [EPA-HQ-OAR-2022-0829-0733, pp. 58-59]

271 S&P Global Mobility. "EV Chargers: How Many Do We Need?" News Release Archive, (Jan. 9, 2023), https://press.spglobal.com/2023-01-09-EV-Chargers-How-many-do-we-need (accessed June 28, 2023).

272 S&P Global Mobility. "EV Chargers: How Many Do We Need?" News Release Archive, (Jan. 9 2023), https://press.spglobal.com/2023-01-09-EV-Chargers-How-many-do-we-need, (accessed June 28, 2023). Currently EV charging is concentrated in high-income urban areas in California, Colorado, Massachusetts, Maryland, New Jersey, New York, and Oregon. Phillipp Kampshoff, et al., McKinsey & Co., "Building the electric-vehicle charging infrastructure America needs" (Apr. 18, 2022) available at https://www.mckinsey.com/industries/public-sector/our-insights/building-the-electric-vehicle-charging-infrastructure-america-needs.

273 Alliance for Automotive Innovation. Get Connected Electric Vehicle Quarterly Report, Fourth Quarter 2022. See also S&P Global Mobility. "EV Chargers: How Many Do We Need?" News Release Archive, 9 Jan. 2023, https://press.spglobal.com/2023-01-09-EV-Chargers-How-many-do-we-need. Accessed 28 June 2023 (Texas currently has about 5,600 Level 2 non-Tesla and 900 Level 3 chargers, but by 2027 S&P Global Mobility forecasts the state will need about 87,500 Level 2 and 7,800 level 3 chargers – more than ten times the current number of Level 2 and 3 chargers -to support an expected the expected 1.1 million EVs at that time)

EPA also did not include any cost of power distribution upgrade needed for EVSE installation, citing large uncertainty. While uncertainty may exist, EPA cannot assume there is no cost associated with this required upgrade. The National Renewable Energy Laboratory ("NREL") published new estimates of the need for ZEV charging infrastructure investment that finds: [EPA-HQ-OAR-2022-0829-0733, pp. 59-60]

"A cumulative national capital investment of $53–$127 billion in charging infrastructure is needed by 2030 (including private residential charging) to support 33 million PEVs. The large range of potential capital costs found in this study is a result of variable and evolving equipment and installation costs observed within the industry across charging networks, locations, and site designs. The estimated cumulative capital investment includes: [EPA-HQ-OAR-2022-0829-0733, pp. 59-60]

-$22–$72 billion for privately accessible Level 1 and Level 2 charging ports

-$27–$44 billion for publicly accessible fast charging ports

-$5–$11 billion for publicly accessible Level 2 charging ports.274 [EPA-HQ-OAR-2022-0829-0733, pp. 59-60]

274 National Renewable Energy Laboratory, The 2030 National Charging Network: Estimating U.S. Light-Duty Demand for Electric Vehicle Charging Infrastructure, June 26, 2023, at vii. Available at https://www.nrel.gov/docs/fy23osti/85654.pdf.

Clearly, these cost estimates are vastly higher than the $7 billion in costs that EPA claims is needed over an even longer time frame. Given a general linear relationship between ZEV charging infrastructure costs and the number of registered ZEVs, it is reasonable to estimate (using the DOE numbers) a cost adder for charging infrastructure to each ZEV of (at least) $1,606 to $3,848. These costs are not shown by EPA and EPA's failure to account for them is arbitrary and unreasonable. Moreover, note that DOE's estimate excludes "the cost of grid upgrades and distributed energy resources."275 [EPA-HQ-OAR-2022-0829-0733, pp. 59-60]

275 Id.

The BIL provides up to $7.5 billion to install 500,000 public chargers nationwide by 2030. "However, even the addition of half a million public chargers could be far from enough. In a scenario in which half of all vehicles sold are ZEVs by 2030—in line with federal targets—McKinsey estimates that America would require 1.2 million public EV chargers and 28 million private EV chargers by that year.276 All told, the country would need almost 20 times more chargers than it has now."277 EPA must address charger investment and reliability by more than just referencing EV subsidies in recent legislation. [EPA-HQ-OAR-2022-0829-0733, pp. 59-60]

276 McKinsey, "Building the Electric Vehicle Charging Infrastructure America Needs," (Apr. 18, 2022), available at America's electric-vehicle charging infrastructure | McKinsey; see also S&P Global, "EV Chargers: How Many Chargers DO We Need?, (Jan. 9, 2023) (millions of chargers are needed).

277 Id.

Organization: American Highway Users Alliance

More specifically, EPA's proposal in this docket appears to be premised on huge and rapid growth in the portion of light-duty and medium-duty vehicles that are electric powered (EVs) as well as on rapid transformation of the marketplace in a number of related areas that are not the subject of the proposed regulation. EPA seems to have made favorable assumptions on many issues bearing on the feasibility of the proposal, including as to the issues set forth below. The Highway Users, on the other hand, drawing on the expertise of its members, questions that, within the MY 2027 – 2032 timeframe of the proposed rule, all or most of the following will occur, that -- [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

- high-speed and other electric charging stations will be sufficiently available to service light-duty and medium-duty EVs in quantities and locations sufficient to encourage customers to buy EVs, [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

- electric utilities can timely provide connections from the electric grid to those charging stations, or hydrogen fueling stations – and provide the refueling and charging connections at reasonable cost, [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

- the electric grid will have the capacity to meet the demand for electricity that will be required to support increased electrification of trucks, buses, and passenger cars, even if the connections can be timely made to charging stations (both public and private) that do not yet exist in sufficient numbers, [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

- charging times can be reduced sufficiently to encourage customers to buy these EVs, [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

- major industries, including vehicle manufacturers and their suppliers, can implement major changes in vehicles as rapidly as the NPRM assumes (given the limited current market penetration of these EVs), [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

- there will be an adequate supply of rare earth and other critical minerals, and the ability to process them, with those minerals being so essential to the manufacture of EVs and batteries, [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

- with a large portion of such minerals being sourced and/or processed overseas, including in China and Africa, whether the national interest in sourcing and processing such minerals in the United States can be met, and [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

- potential customers of these EVs will proceed to purchase them in sufficient quantity, notwithstanding significantly higher up-front costs, uncertain availability of charging facilities, and other concerns. [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

This last consideration is highly important because if the potential customers of these EVs do not become actual customers to a sufficient extent, the manufacturers are unlikely to produce the vehicles in the quantities EPA has estimated will be required to be compliant with the regulations, in turn greatly reducing the benefits of the proposal as EPA estimated. [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

Feasibility of the proposal is highly questionable and benefits are likely overestimated

Organization: American Petroleum Institute (API)

3. Compounding concern resources will also be used for HDV, on the same timeframe.

EPA released the proposals for LMDV and HDV simultaneously – and the programs have the same proposed implementation timeline of 2027-2032. API has serious concerns about the implications of this timing. Both proposed programs are significantly flawed in that they rely on resources and infrastructure that are not yet ready. Even with EPA's projections regarding the use of BIL and IRA funding, the transportation industry will be competing for the same resources to successfully stand up both programs simultaneously. Furthermore, the availability of and process for obtaining such funding is not certain. [EPA-HQ-OAR-2022-0829-0641, p. 15]

v. Infrastructure.

1. Leadtime and deployment.

API, and many other stakeholders, are concerned about the lack of infrastructure for the LMD ZEV market.39 Even coupled with significant tax credits and incentives, consumers likely will not purchase new LMD ZEVs in the volumes that would be required by the proposal without a reliable charging infrastructure. [EPA-HQ-OAR-2022-0829-0641, p. 15]

> 39 Khan, Hafiz Anwar Ullah; Price, Sara; Avraam, Charalampos; Dvorkin, Yury. “Inequitable Access to EV Charging Infrastructure.” New York University, Tandon School of Engineering. February 2022. https://rosap.ntl.bts.gov/view/dot/61454.

A critical part of relying on an EV for transportation is the ability to charge the battery. According to J.D. Power,58 EV owners in markets with a high volume of EVs are experiencing problems with charging. Even with the high growth rate of EV chargers, satisfaction has flat-lined and a “shortage of public charging availability” is the main reason car buyers avoid EVs. [EPA-HQ-OAR-2022-0829-0641, p. 19]

> 58 J.D. Power. “Growing Electric Vehicle Market Threatens to Short-Circuit Public Charging Experience, J.D. Power Finds.” August 2022. https://www.jdpower.com/business/press-releases/2022-us-electric-vehicle-experience-evx-public-charging-study.

Organization: BlueGreen Alliance (BGA)

At the same time, EPA must consider that the manufacturing investments from the Inflation Reduction Act and Bipartisan Infrastructure Law will take time to achieve their full production capacity. EPA should coordinate with DOE, the U.S. Department of Transportation (DOT), and the U.S. Department of Commerce (DOC) to ensure that the manufacturing investments from the Inflation Reduction Act and Bipartisan Infrastructure Law will be fully leveraged to support regulatory compliance. Programs like the Battery Manufacturing and Recycling Grants (DOE), the Battery Material Processing Grants (DOE), the Domestic Manufacturing Conversion Grants (DOE), the 48C Advanced Manufacturing Tax Credit (DOE/DOC), the Advanced Technology Vehicle Manufacturing Loan Program (DOE), the National Electric Vehicle Infrastructure (NEVI) Program (DOT), and the Charging and Fueling Infrastructure Grant Program (DOT) all provide unprecedented federal resources that manufacturers and fleet owners can leverage to support both supply and demand for low-and zero-emission light-and medium-duty vehicles. However, these programs take time to bear fruit—whether that means a complete public, affordable, and interoperable EV charging network, or a robust domestic supply chain for vehicles eligible for the battery component and critical mineral requirements of the 30D Clean Vehicle Tax Credit. [EPA-HQ-OAR-2022-0829-0667, pp. 8-9]

It is essential to workers and communities that these programs be carefully designed and implemented, with robust stakeholder engagement. This helps ensure that they adhere to Justice40 requirements and new Build America, Buy America provisions that are critical to ensuring that federal programs support domestic manufacturing investments that are fully supported by their communities. [EPA-HQ-OAR-2022-0829-0667, pp. 8-9]

With that, EPA must account for the time it takes to convert federal awards and allocations into actual domestic production capacity and critical on-the-ground infrastructure. EPA should coordinate with DOT and DOE to fully assess the availability of charging and fueling infrastructure for electric vehicles, and related grants and loans. [EPA-HQ-OAR-2022-0829-0667, pp. 8-9]

Organization: BMW of North America, LLC (BMW NA)

BMW NA, together with the Alliance of Automotive Innovators, has already agreed with Biden Administrations' stated goal of reaching 40-50% sales of electric vehicles within the market by 2030. Achieving this goal will only be possible if the framework conditions allow the market to develop -i.e. charging infrastructure, availability of critical raw materials and the overall cost situation for xEVs. [EPA-HQ-OAR-2022-0829-0677, p. 2]

At this time, BMW NA does not believe that the necessary framework conditions, especially infrastructure, are advancing as necessary to achieve the targets set forth in the Proposed Rule. Therefore, we share the concerns expressed by the Alliance of Automotive Innovators that these targets cannot be met without massive and coordinated efforts of the auto industry, energy providers, mineral suppliers and the government. [EPA-HQ-OAR-2022-0829-0677, p. 2]

The charging infrastructure deployment within the United States must be accelerated even beyond the targets identified in the Infrastructure Act of 500.000 charges. In fact, BMW NA believes these figures have to increase by about five-fold (a study of the California Energy Commission projects, that a 700,000 public and shared private chargers are necessary for 5 Mio. ZEV1 . Different sources assuming 25 to 44 Mio ZEVs on the US streets in 20302). [EPA-HQ-OAR-2022-0829-0677, p. 2]

1 https://www.energy.ca.gov/data-reports/ repo rt s/ electric -vehicle-charging-infrastructure-assessment-ab-2127

2 https:/ / ww w.mckinsey.com/ industries/public-sector/our-insights/building-the-electric-vehicle-charging-infrastructure-america-needs

Organization: BorgWarner Inc.

BorgWarner appreciates the Administration’s support for and recommends prioritization of DCFCs for EV infrastructure and coordination of hydrogen infrastructure. [EPA-HQ-OAR-2022-0829-0640, pp. 4-5]

BorgWarner applauds the Administration’s support for EV charging infrastructure. BorgWarner recommends that EPA prioritize DCFC charging capabilities in publicly-funded infrastructure projects to foster consumer adoption, futureproof site investments, and facilitate vehicle-to-grid (V2G) bidirectional charging, which becomes more critical to enable sustainable grid management, grid resilience, utilization, and national security protection. [EPA-HQ-OAR-2022-0829-0640, pp. 4-5]

In its Proposal, EPA acknowledges the additional needs and costs associated with charging infrastructure BorgWarner agrees and reiterates its support for current Build America Buy America (BABA) requirements. BorgWarner has made the capital investment to comply with the BABA requirements and should not have that competitive advantage taken away through an open-ended waiver of the BABA requirements. BorgWarner also asks EPA to require UL certification as a national certification standard to provide consistency, quality, safety, and compliance throughout the system. [EPA-HQ-OAR-2022-0829-0640, pp. 4-5]

4 Federal Register, Vol. 88, No. 87, May 5, 2023, Page 29311

Hydrogen combustion engines (H2ICE) are a cost-effective advanced technology that can make a significant positive impact to the environment, and we urge EPA to recognize H2ICE as a technology solution in the Proposal, especially for heavier MD applications. As the IRA and IIJA are providing billions of dollars for the development of a hydrogen economy, EPA should support these efforts with program incentives. [EPA-HQ-OAR-2022-0829-0640, pp. 4-5]

BorgWarner supports the proposed adjustments to compliance credits. BorgWarner agrees with EPA's proposed changes to the current compliance credits offered for BEVs, PHEVs and fuel cell electric vehicles (FCEVs). Credits can serve as a valuable tool to incentivize the development of new vehicle technologies and should be used to create new technology pathways. Once these technologies are clearly established, EPA should eliminate these credits. Offering credits once a technology is established could potentially disincentivize new innovations in efficiency-and performance-improving vehicle technologies. We also agree with EPA's decision to discontinue air conditioning credits under the new standard. [EPA-HQ-OAR-2022-0829-0640, pp. 4-5]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Charging Standards

To the extent that manufacturers comply with U.S. EPA's proposed standards with BEVs and PHEVs, the demand for charging infrastructure will increase significantly. While these vehicles offer a variety of benefits to consumers, vehicle charging is a persistent concern and barrier to electric vehicle adoption in consumer studies. To truly support increased ZEV penetration, it is important for policymakers and manufacturers to reduce barriers that could otherwise discourage consumer selection of a BEV or PHEV. In the ACC II program, CARB adopted several charging-related requirements to help increase access to home charging and standardize the charging experience. 59 CARB encourages U.S. EPA to explore opportunities to standardize charging requirements as a component of its ZEV assurance measures and offers the following specific recommendations as particularly appropriate in the national context. [EPA-HQ-OAR-2022-0829-0780, pp. 42-43]

59 Cal. Code Regs., title 13, section 1962.3; see also ACC II Final Statement of Reasons, Including Summary of Comments and Agency Response Appendix D Summary of Comments to ZEV Assurance Measures and Agency Response, pp. 69-74.

Vehicle-to-Infrastructure Integration

As the infrastructure for BEVs expands and becomes more standardized, vehicles themselves have a role in providing a reliable, consistent, and convenient charging experience for consumers. BEVs also have the unique opportunity to support grid stability in the future through "vehicle-to-grid" systems. However, to broadly realize these consumer and grid service benefits, vehicles must be able to communicate with the chargers themselves, known as electric vehicle supply equipment (EVSE), in a standardized way. [EPA-HQ-OAR-2022-0829-0780, pp. 43-44]

International Organization for Standardization (ISO) 15118 is a set of communication and charging management standards intended for use between vehicles and EVSE, including a customer convenience feature referred to as Plug & Charge. To help ensure consistent and successful use of charging infrastructure, CARB recommends that U.S. EPA require manufacturers to integrate these industry-developed standards into the design of future BEVs. CARB notes that several automakers have already introduced or will introduce U.S. vehicles that can support some portions of these standards, especially the Plug & Charge feature, including Audi, BMW, Daimler, Porsche, Lucid, Volkswagen, 60 and Ford. 61 Standardized deployment of vehicle-to-infrastructure communication across the industry will reduce barriers to BEV adoption and maximize benefits. [EPA-HQ-OAR-2022-0829-0780, pp. 43-44]

60 In a joint comment to the California Public Utilities Commission on its February 2018 Staff Report on the Vehicle-Grid Integration (VGI) Communication Protocol Working Group, Audi, BMW, Daimler, Lucid, Porsche, and VW stated their intention to implement ISO 15118 on their future vehicles, including the Plug & Charge feature. https://www.cpuc.ca.gov/-/media/cpuc-website/files/legacyfiles/o/6442457082-oems-final-comments-vgi-wg-draft-report-correction-v2.pdf

61 Ford. "Charging Your Mustang Mach-E." https://www.ford.com/mustang/ev-charging/mache/. Accessed June 15, 2023.

Specifically, CARB recommends that, for future BEVs, U.S. EPA require manufacturers to: [EPA-HQ-OAR-2022-0829-0780, pp. 43-44]

- Implement and conform to ISO 15118-3 Vehicle to grid communication interface – Part 3: physical and data link layer requirements, 62 [EPA-HQ-OAR-2022-0829-0780, pp. 43-44]

- Implement and conform to ISO 15118-2 Vehicle to grid communication interface – Part 2: Network and application protocol requirements 63 and ISO 15118-20 Vehicle to grid communication interface: Part 20: 2nd generation network layer and application layer requirements, 64 and [EPA-HQ-OAR-2022-0829-0780, pp. 43-44]

66 ISO 15118-5:2018.

CARB notes several important benefits associated with widespread deployment of harmonized communication standards between the vehicle and the charging infrastructure. First, drivers will see the benefit of a simplified public charging user experience. Plug & Charge allows drivers to establish their electric charging preferences and input payment information once, providing a more seamless charging experience. With widespread implementation of Plug & Charge, drivers charging their vehicle at a compatible public EVSE will be able to simply plug in their vehicle and walk away while the vehicle and the EVSE communicate and manage the charging session accordingly. [EPA-HQ-OAR-2022-0829-0780, pp. 44-45]

Second, vehicle-to-grid connectivity could enable BEVs to provide important grid services. Implementation of the communications protocols outlined in the suite of ISO 15118 standards is a key step to enable this functionality by ensuring that the vehicle and the EVSE are coordinated on the bi-directional flow of electricity during grid support services. CARB agrees with U.S. EPA’s findings that grid reliability is not expected to be adversely affected by the modest increase in electricity demand associated with electric vehicle charging. 67 California’s grid has historically expanded and evolved as consumer demand for electricity services has grown, including with the recent emergence of electric vehicles. This trend is reflected in the historical expansion of the national grid as noted in U.S. EPA’s proposal. However, BEVs can further support grid resilience with their unique ability to fuel on a flexible schedule depending on the driver’s and the grid’s needs. Drivers with access to residential charging could also realize greater opportunities to reduce their total cost of ownership by potentially selling electricity back to the grid or powering their homes during peak times. Furthermore, BEVs have already been demonstrated to be able to function as back-up power devices during emergencies, and standardized implementation of this protocol could make such activities even more seamless in the future. [EPA-HQ-OAR-2022-0829-0780, pp. 44-45]

67 CARB. Response to Comments on the Draft Environmental Analysis Prepared for the Advanced Clean Cars II Program. August 2022. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/accii/acciirtc1.pdf.

Third, requiring implementation of these communication standards on the vehicle aligns with—and maximizes the benefits from—recent infrastructure planning and funding. The federal government is making unprecedented investments in charging infrastructure through the Infrastructure Investment Jobs Act. The law set aside $5 billion to build a National Electric Vehicle Infrastructure (NEVI) network that will enable widespread travel across the nation. 68 As part of deploying the NEVI funds, the Joint Office of Transportation and Energy set minimum requirements that NEVI-funded EVSE must meet including minimum payment standards, minimum power, minimum number of ports, and collection of reliability metrics. One of these requirements is the implementation of Plug & Charge on direct current fast chargers (DCFC), utilizing the ISO 15118 suite of standards outlined above. 69 The California Energy Commission is also taking steps in this direction by requiring public chargers it partially or fully funds to install EVSE designed to be compatible with the ISO 15118 suite of standards. 70 Matching vehicle requirements with NEVI implementation will harmonize communication flow between vehicles and charging stations, reducing the number of potential points of failure to communicate in the charging ecosystem. [EPA-HQ-OAR-2022-0829-0780, pp. 44-45]

Direct Current Fast Charging Standardization

CARB agrees with U.S. EPA’s findings that the increased deployment of ZEVs will require more charging infrastructure to be installed. For this infrastructure to be most effective, CARB recommends that U.S. EPA require manufacturers to standardize vehicle charging inlets. In particular, direct current fast charging (DCFC) will play a key role in charging away from home both for longer travel trips and for those without convenient access to home or workplace charging. Making sure that consumers can easily access charging and that all BEVs are DCFC capable can help increase uptake of ZEVs, better ensure they can be effectively used by second and third owners, and help fully realize emission benefits from U.S. EPA’s proposed standards. Currently, three distinct DCFC inlets exist on BEVs deployed in the U.S.: CHAdeMO, SAE Combined Charging System (CCS1) Type 1 (SAE J1772), and Tesla’s North America Charging Standard connector. Having three different DCFC inlets, standards, and communication protocols can lead to inconsistent and unnecessarily complex charging experiences for consumers, including interoperability and charging reliability concerns. [EPA-HQ-OAR-2022-0829-0780, pp. 45-46]

Most manufacturers are already utilizing the SAE J1772 CCS1 standard in current vehicle production. In 2020, the CCS1 inlet was on 13 available BEV models and only 2 BEV models came with the CHAdeMO inlet. For the 2022 MY, 45 BEV models have the CCS1 inlet, with only 2 vehicle models remaining with the CHAdeMO inlet. 71 The federal government is also already investing in CCS1 infrastructure through the NEVI program, which requires that each funded DCFC port have at least one CCS1 connector. 72 However, in Spring 2023, Ford and General Motors both announced partnership with and future implementation of Tesla’s North America Charging Standard on their vehicles. 73, 74 These moves by industry electric vehicle leaders are significant and continued lack of standardization could lead to more confusion in the market and decentralization of resources toward solving those issues that most plague reliable charging for electric vehicles. [EPA-HQ-OAR-2022-0829-0780, pp. 45-46]

Improved Charging Time Information

CARB recommends required disclosure of charging speed information at the time of certification to ensure the data exists to support an improved label-reported charge time that is more relevant than what is disclosed today. On today’s label, a single charge time is presented, representing the time it takes to fully charge a completely depleted battery at the maximum Level 2 charge rate the vehicle is designed to accept. However, in-use vehicle data suggests that this is not a charge condition relevant to typical consumer behavior as vehicle owners would rarely, if ever, fully deplete the battery. CARB recommends charging time data be required to be submitted at the time of certification to represent the full spectrum of rate of charge versus battery state of charge for typical residential charging. This could allow for a future label that, for example, determines the most meaningful value to display is the time it takes to recover to the manufacturer's default or recommended routine maximum state of charge (e.g., 80 percent) after a typical day's usage of a defined number of miles (e.g., 35 miles) on a commonly available Level 2 capable circuit. [EPA-HQ-OAR-2022-0829-0780, pp. 47-48]

Additionally, CARB recommends similar disclosure of DCFC rates such that a future label could also meaningfully disclose recharging times a driver could expect at a public charging station. Like the relevance of highway speeds for determining range, DCFC rates are most relevant for consumers stopping mid-travel on long trips or for consumers without routine access to home or workplace charging. In both cases, they may be looking for useful information relevant to charging as quickly as possible from a largely (but not fully) depleted state of charge. Disclosure of charge rate data could provide the necessary information to support a label with the most meaningful data determined through future analysis. Examples of meaningful data could include the time to recover from the most typical state of charges observed at DCFC stations for starting and ending charge events or number of miles of range recovered per 10-minute charge events. Such information, presented in a concise and consistent manner on the label, would provide valuable information for consumers to shopping for a BEV most suitable for their needs. [EPA-HQ-OAR-2022-0829-0780, pp. 47-48]

Infrastructure Costs

Level 2 Charging Infrastructure Costs

CARB recommends that U.S. EPA adjust its infrastructure cost discussion to include additional residential charging options that are currently being implemented and may help reduce overall charging infrastructure costs. In particular, CARB recommends that U.S. EPA accounts for the possibility of low power Level 2 charging, defined as a 208/240 volt 20-ampere minimum branch circuit and a receptacle that is used for charging a BEV or PHEV. 81 [EPA-HQ-OAR-2022-0829-0780, p. 50]

81 CALGreen code: 2022 California Green Building Standards (Title 24 Part 11), Chapter 2.

In California, the State's building agencies must provide a cost analysis for any building code proposal. 82 CARB supports California's building agencies in developing BEV charging provisions for newly constructed buildings and preparing the required estimates of expected costs for vehicle charging requirements. 83 California's Green Building Standards Code ("CALGreen") now requires 25 percent of spaces in multi-family housing developments to have a low power level 2 charging receptacle. 84 [EPA-HQ-OAR-2022-0829-0780, p. 50]

82 California Government Code §11346 and subsequent.

83 California Health and Safety Code §18930.5(b); Cal. Code Regs, title 24, part 1.

84 See Cal. Code Regs., title 24, pt. 11.

Based on its technical analysis in support of CALGreen, CARB finds U.S. EPA's cost analysis to be conservative as it focuses on the installation of Level 2 chargers operating on 40 amperes. CARB's cost analysis focused on the hardware costs (including labor) required to support a low power Level 2 charging receptacle, which is significantly less expensive to install than a Level 2 EVSE. CARB estimates the cost of installing a low power Level 2 charging receptacle to be $781 to $1,477 (including labor) as compared to U.S. EPA's cost estimate of $3,300 for a 240-volt AC outlet installation to $4,100 for a Level 2 EVSE port in non-single-family homes (non-SFH). While California is the only state to require the installation of low power Level 2 charging receptacles, other states could reference CALGreen as a starting point for their building codes. If other states adopt similar requirements of installing low power Level 2 charging receptacles during new construction, the cost to install charging infrastructure in non-SFHs may be significantly less when compared to installing Level 2 EVSE or an outlet that can support a Level 2 EVSE or a Level 2 EVSE in the same number of multifamily housing developments. [EPA-HQ-OAR-2022-0829-0780, p. 50]

Charger investments

CARB agrees with U.S. EPA's findings that that the increased investment in charging infrastructure will aid in the deployment of ZEVs. Although U.S. EPA mentions many important infrastructure investments to date, CARB has identified additional programs to add to the "PEV Charging Infrastructure Investments" section of the DRIA that will further the deployment of ZEVs as an economical means of complying with the emission standards. [EPA-HQ-OAR-2022-0829-0780, pp. 50-51]

CARB recognizes that U.S. EPA has included some of Electrify America's investments such as the charging partnerships the company has with auto manufacturers, the $450 million investment from Siemens and Volkswagen Group, and the partnership between TravelCenters of America and Electrify America. However, it is unclear if these investments by Electrify America are a part of the Volkswagen settlement of $1.2 billion in the U.S. 51or this reason, CARB recommends that U.S. EPA ensures its summary of public and private investments includes Electrify America's $1.2B settlement that has supported deployment of infrastructure nationwide. CARB also recommends including Walmart's plans to install chargers at locations throughout the country, 85 and 7-11's charging network called 7Charge that will be installed at select locations. 86 [EPA-HQ-OAR-2022-0829-0780, pp. 50-51]

85 Leading the Charge: Walmart Announces Plan To Expand Electric Vehicle Charging Network. April 6, 2023. Accessed May 26, 2023. https://corporate.walmart.com/newsroom/2023/04/06/leading-the-charge-walmart- announces-plan-to-expand-electric-vehicle-charging-network

D. Sales of Zero-Emission Vehicles Are Projected to Continue Growing at a Dramatic Rate

Zero-emission-vehicle technologies107 are the most effective tailpipe emission control technologies available to date, and demand for zero-emission vehicles specifically has exploded in recent years. In response to this demand, significant public and private investments across the country continue to be made to build sufficient charging infrastructure and develop the domestic battery supply chain, and these investments are projected to keep pace with the dramatic growth of the zero-emission vehicle market. There is every reason to expect this growth to continue. [EPA-HQ-OAR-2022-0829-0746, p. 18]

107 The term "zero-emission-vehicle technologies" includes batteries with on-board chargers and hydrogen stored in a fuel cell stack that transforms chemical energy into electrical energy to propel a vehicle.

Recent congressional actions demonstrate the federal commitment to substantial electrification of the transportation sector. In 2021, Congress passed the Bipartisan Infrastructure Law, which allocates $7.5 billion to building out a national network of electric vehicle chargers, $7 billion to ensure domestic manufacturers have the critical minerals and other components necessary to make electric vehicle batteries, and $10 billion for clean transit and school buses.110 In 2022, Congress passed the CHIPS and Science Act, which invests $52.7 billion in America's manufacturing capacity for the semiconductors used in electric vehicles and chargers.111 Later in 2022, Congress passed the Inflation Reduction Act, which provides $7,500 to buyers of new electric vehicles and $4,000 to purchasers of pre-owned electric vehicles.112 Additionally, the Inflation Reduction Act provides billions of dollars to support vehicle manufacturers' expansion of their domestic production of clean vehicles,113 and billions to support battery production in the United States and mining and processing of critical minerals needed for battery cells and electric motors.114 The Inflation Reduction Act also allocates billions to upgrade the nation's power grid in order to help address the new surge in grid demand from electric vehicles.115 [EPA-HQ-OAR-2022-0829-0746, pp. 18-19]

2. States and the Power Sector Are Rapidly Expanding Electric Vehicle Charging Infrastructure

State and local governments are proactively engaged in ensuring a robust electric vehicle supply equipment ("EVSE") charging infrastructure to support wider electric vehicle adoption, including, but certainly not limited to, our States and Cities. For example, the California Energy Commission's Electric Vehicle Infrastructure Project has directed over $180 million in rebates to encourage the installation of public direct-current fast charger ("DCFC") and Level 2 chargers,125 supporting a current statewide network of 1,737 public DCFC stations (comprising 8,814 DCFC ports) and 13,015 public Level 2 stations (30,099 Level 2 ports).126 California, Oregon, and Washington have adopted low-carbon fuel/clean fuel standards that support EVSE installation through the generation of tradeable credits.127 New Jersey's Department of Environmental Protection has awarded grants for 2,980 charging stations with 5,271 ports at 680 locations. Maine directed $3.15 million from the Volkswagen litigation settlement and $10 million from the New England Clean Energy Connect settlement toward expanding the state's DCFC network along key corridors,128 and has allocated a further $8 million to electric vehicle charging from American Rescue Plan funds.129 New York's EVolve program has committed $250 million to install 800 new EV fast charging stations throughout the state by 2025, including along major highway corridors.130 New York has awarded more than $13 million in grants to cover municipalities' eligible costs toward the installation of Level 2 EV charging stations, DCFC stations, and hydrogen fuel cell filling stations.131 Washington has awarded more than $10 million in Zero-Emission Vehicle Infrastructure Partnership grants and announced $30 million more for 2023-25.132 Massachusetts has required that charging stations for public use be installed at all service plazas located on the Massachusetts Turnpike by July 1, 2024.133 [EPA-HQ-OAR-2022-0829-0746, pp. 21-22]

Utilities and private EVSE companies have committed significant resources to expanding charging infrastructure.142 New Jersey utilities have committed $215 million for make-ready infrastructure for public, multi-unit dwelling and workplace charging stations, and residential chargers. New York utilities' EV Make-Ready Program has a budget of $701 million allocated to support the development of electric vehicle infrastructure.143 As EPA notes, an alliance of over 60 investor-owned and municipal electric companies and electric cooperatives in 48 States and D.C. have formed the National Electric Highway Coalition to deploy fast-charging infrastructure seamlessly across major transportation corridors "by the end of 2023."144 State legislatures and public utility commissions (PUCs) are actively engaged in supplementing utilities' existing efforts with additional resources and authority.145 [EPA-HQ-OAR-2022-0829-0746, pp. 22-24]

144 Edison Electric Institute, National Electric Highway Coalition, available at https://www.eei.org/issues-and-policy/national-electric-highway-coalition; see 88 Fed. Reg. at 29,308.

145 Last year, for example, Indiana's legislature approved a law to empower its PUC to conduct pilot programs to expand public EVSE and study their impact on distribution grids. Indiana H.B. 1221 (signed Mar. 11, 2022), https://iga.in.gov/legislative/2022/bills/house/1221#document-7bf5903c.

EPA correctly recognizes that increased EV adoption and the build-out of EVSE infrastructure implies an increase in electricity demand, which EPA estimates at less than 0.4% in 2030 to approximately 4% in 2050. 88 Fed. Reg. at 29,311. The Regional Transmission Organizations ("RTOs") and Independent System Operators ("ISOs"), which are responsible for procuring sufficient generation and transmission capacity within their footprints, are already taking into account projected EV adoption to plan over a 10-20 year horizon. ISO New England and Texas's ERCOT, for example, both incorporate electrification forecasts into their capacity planning and conclude that grid capacity will continue to meet demand with substantial reserve margins.146, 147 These detailed planning processes apply the RTOs' and ISOs' considerable expertise, data, and analytical resources to ensure a reliable and adequate grid.148 States are likewise active in this area. For example, in 2016, Assembly Bill 2868 in California required utilities to procure 500 MW of distributed energy storage resources, above and beyond a 1,325 MW utility storage target set under Assembly Bill 2514 (2010). Hawai'i is a national leader in customer-sited distributed energy resources (such as rooftop and community solar power), with 88,000 systems in use across Hawaiian Electric's five-island service territory.149 And, in 2018, the Massachusetts legislature adopted an Energy Storage Initiative Target, which calls for 1,000MWh of energy storage by the end of 2025.150 [EPA-HQ-OAR-2022-0829-0746, pp. 25]

146 ISO New England, 2023–2032 Forecast Report of Capacity, Energy, Loads, and Transmission, sheets 1.1, 1.2, 1.7 (May 1, 2023), available at https://www.iso-ne.com/system-planning/system-plans-studies/celt (finding grid capacity will exceed peak summer and winter loads through 2032, taking into account transportation and heating electrification).

147 Texas NEVI State Plan, at 23-25, available at https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/tx_nevi_plan.pdf (discussing reserve

margins for grid capacity far outstripping the “theoretical maximum energy consumption” from proposed EVSE build-out).

148 See, e.g., California ISO, 2022-2023 Transmission Plan (Apr. 3, 2023), available at https://stakeholdercenter.caiso.com/RecurringStakeholderProcesses/2022-2023-Transmission-planning-process

149 Hawaiian Electric, Customer Energy Resources for Hawai’i (May 2021), https://www.hawaiianelectric.com/documents/products_and_services/customer_renewable_programs/20210503_customer_energy_resources_for_hawaii.pdf.

150 An Act to Advance Clean Energy, 2018 Mass. Acts., ch. 227, § 20.

Our States and Cities add three observations to EPA’s analysis of costs and lead time. First, EPA’s projected costs likely overstate the actual costs attributable to reaching the standards in the allotted lead time, due to conservative assumptions in EPA’s no-action case that omit the myriad state and local actions to promote electric vehicle adoption. See supra 18-21; CARB Comment at 16. Second, state and local agencies are implementing ambitious programs to ready power grids and charging infrastructure for the increased adoption of electric vehicles and the associated increase in electricity demand, which further supports EPA’s feasibility analysis. Third, although internal-combustion-engine vehicles will make up a smaller portion of the national fleet, it is imperative that EPA’s standards continue to encourage the application of feasible, cost-effective emission-reduction technologies to these vehicles, as they still represent a significant source of GHG, criteria, and toxic pollutant emissions. [EPA-HQ-OAR-2022-0829-0746, p. 33]

2. State and Local Actions Are Facilitating the Necessary Generation, Transmission, and Charging Infrastructure to Support the Projected Compliance Pathway

While EPA only needs to consider the costs of regulatory compliance incurred within the allotted lead time, Coalition for Responsible Regulation, 684 F.3d at 128, EPA also considers the demands on the power sector from projected compliance with the proposed and alternative standards. 88 Fed. Reg. 29,309-312. We agree with EPA’s assessment that the projected modest increase in electricity demand (0.04 to 2% over the course of the regulated model years) is more than manageable. This is especially true when compared to other historical and current examples of rapid demand increases that the power sector successfully met, see 88 Fed. Reg. at 29,311 (noting widespread adoption of air conditioning in 1960s and 1970s and 21st-century growth of data centers and server farms),188 and given Congress’s significant investments in transmission, generation, and charging infrastructure in the Bipartisan Infrastructure Law’s NEVI Formula Program and the Inflation Reduction Act. Draft RIA, at 5-14 (Tables 5-2 & 5-3); 88 Fed. Reg. at 29,307-08. Part D.2 of the Background section, supra at 21-25, provides examples of some of the actions our States and Cities are taking, including under the NEVI Formula Program, to ensure there is sufficient charging infrastructure to support the projected electric vehicle penetration rate. [EPA-HQ-OAR-2022-0829-0746, p. 35]

188 See also White House Office of Science and Technology Policy, Climate and Energy Implications of Crypto-Assets in the United States (Sep. 2022), at 14-15, available at https://www.whitehouse.gov/wp-content/uploads/2022/09/09-2022-Crypto-Assets-and-Climate-Report.pdf (estimating U.S.-based cryptocurrency mining operations for Bitcoin alone to consume “33 to 55 billion kWh per year, or 0.9% to 1.4% of total U.S. electricity usage in 2021”).

Organization: CALSTART

2. Infrastructure

Infrastructure is an acknowledged real near-term challenge. However, infrastructure is a solvable challenge, rather than a long-term barrier. Major federal, state, and private investments outline a realistic path to scale that will create the necessary infrastructure to meet demand where people live, work, and play. [EPA-HQ-OAR-2022-0829-0618, pp. 4-5]

For example, in the public charging arena, NEVI and CFI are bringing historic investments to expand availability and access to public charging. These investments are helping to achieve the goal of 500,000 EV Level 2 and DC Fast Chargers (DCFC) EV chargers by 2030. [EPA-HQ-OAR-2022-0829-0618, pp. 4-5]

The funding will more than triple the current number of EV chargers and make public charging significantly more accessible for EV owners.4 [EPA-HQ-OAR-2022-0829-0618, pp. 4-5]

4 htps://www.whitehouse.gov/briefing-room/statements-releases/2023/02/15/fact-sheet-biden-harris-administration-announces-new-standards-and-major-progress-for-a-made-in-america-national-network-of-electric-vehicle-chargers/

Additionally, Charge@Work is a DOE-funded National Workplace Charging Program administered by CALSTART that is helping over 1,000 employers across the country provide charging solutions to their employees. The Charge@Work program will add over 100,000 ports at workplaces across the country. Even for drivers who do not have access to home charging, Charge@Work is making it easier for drivers to go electric by engaging employers to become part of the solution. [EPA-HQ-OAR-2022-0829-0618, pp. 4-5]

Additionally, the recent moves by industry participants to align with Tesla’s North American Charging Standard (NACS) offer a positive way forward for the industry as it moves towards a superior charging user experience which will further accelerate EV adoption and unlock mass market vehicle electrification. Further, a charging network that is used by all EVs has the potential for optimized, high utilization which translates to better returns to capital and faster reinvestment to expand the charging network. [EPA-HQ-OAR-2022-0829-0618, pp. 4-5]

Organization: Charles Gordon

INCONVENIENCE TO PEOPLE

The rapid elimination of new gas-powered cars creates real inconvenience for ordinary people. Those who live in apartment buildings will have to find charging stations where it will take 30 minutes to recharge. This will particularly hurt the poor and minorities. Long trips by car will require careful planning and 30-minute interruptions to recharge. Towing large trailers will be virtually impossible. This is added to the existing inconvenience of more expensive washing machines which take 60 minutes to wash a load-not 30 and dishwashers which take 2 hours to poorly wash dishes. [EPA-HQ-OAR-2022-0829-0747, p. 7]

It may be hard to put a dollar amount on this inconvenience, but it is real nonetheless. EPA needs to take that inconvenience into account when it reviews the proposed rule. [EPA-HQ-OAR-2022-0829-0747, p. 7]

Organization: Chevron

4. Feasibility and implementation.

Chevron is concerned that the rapid increases in forecasted BEV sales rate are optimistic and may overstate the benefits of the proposals. The proposals may limit choices and increase costs for consumers, including those in economically disadvantaged groups and smaller businesses. [EPA-HQ-OAR-2022-0829-0553, p. 6]

BEV sales forecasts may rely on optimistic expectations for increased electricity generation and charging infrastructure. EPA should conduct an assessment to account for the costs and timing associated with upgrades to the nation's grid infrastructure, including new and upgraded generation, transmission, and distribution, and the costs associated with the installation of public and private electric vehicle chargers. If it is not feasible to complete expansion and improvements for the current grid, it may not be possible to meet the additional demand created by the proposed regulation. [EPA-HQ-OAR-2022-0829-0553, p. 6]

Organization: Clean Fuels Development Coalition (CFDC) et al.

These aggregate costs include:

- Vehicle charging infrastructure. This includes not only the low $120 billion in EVSE costs the proposal projects, 88 Fed. Reg. 29,367, but also billions more in surrounding infrastructure. [EPA-HQ-OAR-2022-0829-0712, pp. 5-6]

III. The Proposed Rule is Not Feasible for Other Reasons.

While the proposal's gross misstatement of vehicle technology costs is the primary reason EPA's proposal is not feasible, the agency also overlooks many other important aspects of the problem. Despite EPA's hopeful projections, very few American want to buy electric vehicles and even fewer will at the prices they will inevitably command. Non-binding company commitments and (unlawful) regulations designed to enforce these commitments do little to change this. Even if consumers did want to purchase these electric vehicles in the volumes EPA projects, the proposal fails to confront several barriers to its rapid electrification plans, including limits on the supply of minerals necessary to manufacture batteries, inadequate charging infrastructure and electrical supplies, and the complex interactions between this rule and other proposed rules all of which will further hinder this development. In light of these many barriers, it is unreasonable for the agency to conclude that compliance with its proposed emission standards is feasible. [EPA-HQ-OAR-2022-0829-0712, pp. 25-26]

E. There will not be enough charging infrastructure to persuade skeptical consumers to adopt battery electric vehicles in the numbers EPA projects.

Another reason the proposal is not feasible is a dearth of charging infrastructure. Currently, electric vehicle charging infrastructure is "inadequate and plagued with non-functioning stations." Dan Zukowski, EV charging infrastructure is "inadequate and plagued with non-functioning stations": J.D. Power, SmartCitiesDive (Feb. 22, 2023), https://www.smartcitiesdive.com/news/ev-charging-infrastructure-inade-quate-non-functioning-stations/643148/. An on-going study by J.D. Power found that charge point unreliability has increased 50% from 2021 to January 2023, from 14% to 21%. Id. This unreliability has led to high rates of dissatisfaction with public charging stations among electric vehicle owners. Id. This dissatisfaction is worse in states with higher numbers of electric vehicles and in large cities with high-density housing. Id. [EPA-HQ-OAR-2022-0829-0712, pp. 30-31]

This is likely to get worse. "[T]he rate of EV adoption is" already "growing at a rate that is almost double that of charger installation growth rates" and "the construction of new charging stations is not keeping up with the demand." Id. [EPA-HQ-OAR-2022-0829-0712, pp. 30-31]

Further, as detailed below, the electric grid is simply not ready for the massive increase in charging infrastructure necessary for the proposed rule to be feasible. "In a little over a decade … rapid EV growth alone could increase peak electricity demand by up to 25%." Mark Golden, Charging Cars at Home at Night is Not the Way to Go, Stanford Study Finds, Stanford News (Sep. 22, 2022), https://news.stanford.edu/press-releases/2022/09/22/charging-cars-honight-not-way-go/. Recent research found that "when [electric vehicle] penetration hits 30% to 40% of cars on the road, the grid will experience significant stress." Id. Without significant infrastructure improvements to support this charging, the proposal will not be feasible. [EPA-HQ-OAR-2022-0829-0712, pp. 30-31]

A. The proposal underestimates the cost for charging infrastructure.

According to EPA, its proposed rule would require 12 million home, 400,000 workplace, and 110,000 public charging ports in 2027. 88 Fed. Reg. 29,309; DRIA at 5-31. This would increase to 75 million home, 12.7 million workplace, and 1.9 million public chargers, respectively, by 2055. Id. Developing this infrastructure would come at a high cost. The proposal suggests that these installations would cost between $96 billion and $140 billion by 2055, and $21 billion just between 2027 and 2032. See DRIA at 5-36. [EPA-HQ-OAR-2022-0829-0712, pp. 33-34]

But even these costs are a dramatic underestimate. This June, the Department of Energy published new estimates of the need for electric charging infrastructure investment that found that "[a] cumulative national capital investment of $53–$127 billion in charging infrastructure is needed by 2030 (including private residential charging) to support 33 million PEVs." U.S. Department of Energy, National Renew-able Energy Laboratory, The 2030 National Charging Network: Estimating U.S. Light-Duty Demand for Electric Vehicle Charging Infrastructure (June 2023). https://driveelectric.gov/files/2030-charging-network.pdf. These estimates included between $22 and $72 billion for privately accessible Level 1 and Level 2 charging ports, $27 and $44 billion for publicly accessible fast charging ports, and $5 and $11 billion for publicly accessible Level 2 charging ports. And notably, the "cost of grid upgrades and distributed energy resources [were] excluded from these estimates." Id. [EPA-HQ-OAR-2022-0829-0712, pp. 33-34]

DOE's projected costs are for only 33 million vehicles. EPA projects that approximately 54 million electric vehicles will be on the road in 2032. Given the general linear relationship between electric vehicle charging infrastructure costs and the number of electric vehicles in the fleet, it is reasonable to estimate a cost of between $1,606 and $3,848 for charging infrastructure per electric vehicle. This means charging infrastructure would cost up to $207 billion total and $59 billion for just the 15 million additional vehicles EPA projects its proposal will require by 2032. EPA's failure to account for these costs—and the added costs of "grid upgrades and distributed energy resources"—would be arbitrary and capricious. [EPA-HQ-OAR-2022-0829-0712, pp. 33-34]

Organization: Colorado Energy Office, Colorado Department of Transportation, and Colorado Department of Public Health and Environment

In response to EPA's request for comments on specific aspects of the rule, we offer the following suggestions to ensure the rule is as successful as possible: [EPA-HQ-OAR-2022-0829-0694, pp. 2-3]

-Regarding criteria pollutants, we urge EPA to consider ways to align these proposed standards with California, and in doing so to avoid any backsliding in remaining conventional vehicles sold, while avoiding a scenario in which OEMs are forced to divert investment away from transportation electrification and towards technology advancement on conventional vehicles. We are concerned that the criteria standards in the EPA draft rule could have this unintended effect. [EPA-HQ-OAR-2022-0829-0694, pp. 2-3]

-We urge EPA to consider investments in charging infrastructure as an option for manufacturers to achieve compliance credit. For years, EPA has included a broad range of crediting options to add flexibility to the program in ways that support its underlying goals. At the state and local level, one of the greatest challenges we face is completing robust and varied networks of public and private charging infrastructure so that travelers can travel where they want to go without range anxiety. We appreciate new funding in IIJA, but achieving this goal will require all the tools in the toolbox. We strongly urge EPA to utilize its credit program to incentivize companies investing in the charging networks which benefits consumers and will facilitate more public private partnership around this critical need. [EPA-HQ-OAR-2022-0829-0694, pp. 2-3]

-EPA requested comment on whether to consider a future rulemaking for gasoline fuel property standards to further reduce PM emissions. Colorado supports EPA exercising its authority under CAA 211(c) to develop gasoline property standards in a future rulemaking. Cleaner fuel standards will complement the vehicle emissions standards proposed in the current rulemaking by addressing emissions from the existing ICE vehicle fleet, as well as the vehicles that will be produced during the phase-in and operative periods of the proposed vehicle emissions standards. [EPA-HQ-OAR-2022-0829-0694, pp. 2-3]

Organization: Consumer Energy Alliance (CEA)

Struggling with access to affordable transportation, however, is just one of the equity impacts that has not been addressed by the U.S. EPA How will U.S. EPA address the systemic inequity and energy injustice issues embedded in this rule beyond the financial burden that will be caused? [EPA-HQ-OAR-2022-0829-0788, pp. 3-4]

For example, the practical use of EVs benefit wealthier users as well. Charging infrastructure Is a critical component for EV usage, with access to chargers (and specifically fast chargers) a major consideration in purchasing an EV. Wealthier users are far more likely to live In single family homes where installation of a fast charger costing thousands of dollars is simply a matter of fact. Lower income families who are more likely to reside in apartments or rented properties do not have the option of installing their own personal dedicated fast chargers. [EPA-HQ-OAR-2022-0829-0788, pp. 3-4]

Even the location of charging infrastructure tends to benefit the wealthier, whiter, male demographic that makes up 75% of the individuals who purchase EVs. A recent MIT study on EVs and equity noted 7: [EPA-HQ-OAR-2022-0829-0788, pp. 3-4]

"According to Hsu and Fingerman (43], Black and Hispanic neighborhoods only had 0.7 times the access to public chargers as the no-majority reference group in California. They also determined that even when income, proximity to the nearest highway, and multi-family housing were controlled for, White-majority census block groups were 1.5 times more likely to have access to public charging stations compared to Black-and Latino-majority census block groups." [EPA-HQ-OAR-2022-0829-0788, pp. 3-4]

7 sciencepolicvreview.org/2021/08/equity-transition-electric-vehicles/

They also noted that public charging, when available to lower income communities, typically costs more than home charging stating: [EPA-HQ-OAR-2022-0829-0788, pp. 3-4]

"This higher cost would disproportionately affect low-income households who already pay a higher proportion of their income towards transportation." [EPA-HQ-OAR-2022-0829-0788, pp. 3-4]

By creating disparities in access to the "fuel" through charging network realities this further exacerbates the differences in transportation equity between rich and poor. Combine that with what is sure to be higher electricity prices from the requisite generation, distribution and transmission infrastructure buildout required to meet growing electricity demand as is often the case the poor will just keep getting poorer. [EPA-HQ-OAR-2022-0829-0788, pp. 3-4]

Organization: David Manley III

Of course, while the proposed rule benefits China without significantly reducing global temperatures, American consumers are penalized because (a) while gas-powered cars take five or 10 minutes to refill, recharging an electric vehicle can take 45 minutes, and personal mobility, including road trips, will be adversely effected since EVs require longer and more frequent interruptions for charging, (b) The common American cannot afford EVs as EVs were on average $11,981 more expensive than gas-powered cars at the end of 2022, and today, for example, the electric version of the Ford F-150 pickup truck, the best-selling vehicle in America, costs an additional $26,000 over the gasoline-powered one while Tesla’s EVs start at $39,000 for a Model 3 and go up to nearly $100,000 for a Model X — prices much higher than most families can afford, and (c) American consumers will have to deal with electric power availability problems (even with bidirectional charging that has a negative aspect) as the power grids will not have the capacity to deal with the increased load. [EPA-HQ-OAR-2022-0829-0513, p. 1]

Organization: Doug Peterson

It is going to be extremely challenging to build enough public charging infrastructure to keep up with our rapidly growing fleet of BEVs. Lack of charging infrastructure is currently one of the main barriers to BEV adoption, and the problem is bound to get worse. BEV owners with no access to home charging will place much greater demands on public chargers than early adopters who tend to utilize their own charging equipment. Current BEV owners typically use their own equipment for roughly 80% of their charging needs, and automakers pair larger battery packs with faster onboard chargers to facilitate overnight home charging at 240 volts. As BEVs scale up, renters will make up a larger percentage of BEV owners and demand for Level 3 public chargers will increase dramatically. Even if Level 3 charging speeds improve significantly, there is going to be chronic congestion at public charging stations. Renters will be disproportionally impacted by the inconvenience, and inequitable access to electric fuel will compel them to stick with readily available gasoline. These challenges are surmountable, but they are made more difficult by poor BEV fuel economy. [EPA-HQ-OAR-2022-0829-0500, pp. 12-13]

An inefficient fleet of BEVs will also increase the amount of electricity that needs to be transmitted to distant locations along major transportation corridors. It is entirely feasible to generate enough additional electricity to keep up with a growing fleet of BEVs, but getting the electricity where it needs to be to facilitate long distance travel is going to be a slow endeavor, and very expensive. If an urgent transition away from gasoline is to succeed, we need a fleet of highly efficient BEVs that does not exacerbate the significant difficulties associated with the distribution of electric auto fuel. It is especially important that we maximize BEV efficiency in the near term. The electric fleet cannot grow faster than the requisite fueling infrastructure, and immediate efforts to optimize BEV fuel economy will reduce this significant limitation on their proliferation [EPA-HQ-OAR-2022-0829-0500, pp. 12-13]

Organization: Edison Electric Institute (EEI)

II. Electric Companies Are Building Infrastructure To Accommodate The Electrification Of The Transportation Sector.

EEI member companies are leading the charge to ready the market for widescale adoption of light-, medium-and heavy-duty EVs. EEI members are making investments and offering programs designed to help their customers overcome barriers to EV adoption, while also supporting existing EV users and year-over-year growth in the EV market. Many of these programs help to deploy and/or offset the cost of EV charging infrastructure in homes, workplaces, public locations, as well as for fleet operators. To date, more than 30 states and the District of Columbia have approved electric company customer programs and investments totaling more than $4.2 billion.17 Further, EEI members are leading by example with their own fleets by setting individual fleet electrification goals that put them on track to electrify more than a third of their fleet vehicles by 2030. [EPA-HQ-OAR-2022-0829-0708, pp. 6-7]

17 See EEI, Electric Transportation Biannual State Regulatory Update (Apr. 2023), https://www.eei.org/-/media/Project/EEI/Documents/Issues-and-Policy/Electric-Transportation/ET-Biannual-State-Regulatory-Update.pdf.

However, EPA notes that several stakeholders have raised concerns that “slow growth in ZEV charging and refueling infrastructure can slow the growth of heavy-duty ZEV adoption, and that this may present challenges for vehicle manufacturers ability to comply with future EPA GHG standards.” 88 Fed. Reg. 25,934. EEI member companies have addressed similar infrastructure build out issues in the past. Like those issues, these concerns can be addressed through deliberate effort and collaboration among electric companies, fleet operators, and stakeholders, including planning for increased demand, customer engagement, and fleet electrification. [EPA-HQ-OAR-2022-0829-0708, pp. 6-7]

A. Electric companies can accommodate increased energy demand.

As EPA notes, the electric power sector has a long history of accommodating growth in electricity demand from the adoption of new technologies, including electric home appliances, residential and commercial air conditioning, and data centers. See id. At 25,983. Electricity use from EVs today is modest. Argonne National Lab estimates the approximately 2.3 million EVs on the road as of the end of 2021 consumed 6.1 terawatt-hours of electricity in that year, or about 0.16 percent of the total electric sales to U.S. customers in that year.18 As EPA also notes, the increase in electricity use resulting from the Proposed Rule also will be modest, increasing electricity end-use by less than 3 percent in 2055. See id. On a macro-level, meeting the increased energy usage from electric truck adoption as contemplated in the Proposed Rule will not be a significant challenge for the electric power sector. Meeting the location-specific power needs of large electric vehicle (EV) charging facilities can be a more pressing challenge. [EPA-HQ-OAR-2022-0829-0708, pp. 7-9]

However, this is a challenge that can be addressed with deliberate effort and collaboration among electric companies, fleet operators, and stakeholders. [EPA-HQ-OAR-2022-0829-0708, pp. 7-9]

18 See Gohlke, et al., Assessment of Light-Duty Plug-in Electric Vehicles in the United States, 2010 – 2021, https://publications.anl.gov/anlpubs/2022/11/178584.pdf and U.S. Energy Information Administration, Electric Power Monthly

Electric companies can accommodate localized power needs at the pace of customer demand, provided appropriate customer engagement and enabling policies are in place. The power required by a customer is essential when considering the infrastructure needed at the facility level, because the capacity of the local distribution circuit is sized to meet the peak power requirements of customers on that circuit. Some large EV charging facilities have power requirements in the tens of megawatts (MW). Electric companies are well accustomed to serving facilities with those types of power needs, but large fleet customers differ from traditional electric customers (e.g., commercial or industrial buildings) in several important aspects. These aspects include, but are not limited to: [EPA-HQ-OAR-2022-0829-0708, pp. 7-9]

• Construction timelines: A new, large commercial building with a multi-MW power demand, for example, will typically have a multi-year construction timeline, giving the local electric company time to plan and make appropriate upgrades to the electric distribution system serving that customer. A fleet operator, in contrast, may be able to procure vehicles and complete construction on a multi-MW charging facility in a matter of months. This creates a potential misalignment between the fleet operators' timeline to procure vehicles and charging equipment and the electric company's timeline for making the necessary system upgrades to provide power to that facility. [EPA-HQ-OAR-2022-0829-0708, pp. 7-9]

• Customer familiarity with procuring electric power: Commercial and industrial electric customers are used to working with electric companies for the operation of their facilities as part of their normal course of business, including working with electric companies as part of the construction process for launching new facilities. In particular, national corporate customers often have long-standing relationships with the electric companies that serve them. Electric companies typically assign these customers an account manager, given their scale and complexity. A fleet operator, in contrast, is used to procuring diesel to operate its vehicles, and may consider procuring electricity in the same paradigm. Fleet operators may be small electricity users today and thus that division may not yet be considered a managed account for the electric company. However, EEI members have identified this issue and are expanding their working relationship with these customers. [EPA-HQ-OAR-2022-0829-0708, pp. 7-9]

- Uncertain and dynamic load profiles: The power usage throughout the day, known as the “load profile,” of typical commercial and industrial buildings is well understood (e.g., large retail store, data center, or manufacturing facility). Typical load profiles for electric fleet customers are not yet well understood and often hypothetical given the early stage of electric truck commercialization. A fleet charging load profile is the product of many factors, including the routes of the vehicles, the state of charge of the EV when returning to the facility, the number of operating shifts, etc. Unlike a typical commercial building, the load profile of a fleet facility could also drastically change with a change in vehicle operations (e.g., changing from a one-shift to two-shift operation). This uncertainty adds complexity for electric companies when determining how best to serve the power requirements of a fleet customer. [EPA-HQ-OAR-2022-0829-0708, pp. 7-9]

These factors could result in misalignment between expectations and reality regarding the timing, cost, and complexity of procuring electric power for fleet charging. Electric companies are taking a multi-pronged approach to remedy this potential misalignment, as discussed in the following sections. [EPA-HQ-OAR-2022-0829-0708, pp. 7-9]

In New York, the Public Service Commission opened a proceeding in April to address barriers to medium-and heavy-duty electric vehicle infrastructure. In particular, the order recognizes that “proactive planning for the grid infrastructure needed to serve future electrification load must anticipate the location and magnitude of future demand” and notes an analogy to previous policies in which the commission directed the electric companies in New York to “develop proactive planning processes to anticipate the need for local transmission and distribution system upgrades to enable the renewable interconnections required to achieve the State’s renewable energy goals.”23 [EPA-HQ-OAR-2022-0829-0708, pp. 14-15]

23 State of New York Public Service Commission, Case 23-E-0070, Proceeding on Motion of the Commission to Address Barriers to Medium-and Heavy-Duty Electric Vehicle Charging Infrastructure.

EPA’s assessment that “there is sufficient time for the infrastructure, especially for depot charging, to gradually increase over the remainder of this decade to levels that support the stringency of the proposed standards for the timeframe they would apply” is accurate. 88 Fed. Reg. 25,999. As seen above, EEI members actively are planning for and deploying infrastructure today. However, the increased deployment of this infrastructure over the next decade and beyond will not happen on its own. Proactive planning processes, whether initiated by the relevant electric company or state regulatory commission, will be critical to accommodate fleet electrification to meet customer expectations and planning requirements, while also providing affordable and reliable service. [EPA-HQ-OAR-2022-0829-0708, pp. 14-15]

IV. Electric Company Policies and Programs Can Help Reduce Capital and Operational Costs for Fleet Electrification Customers.

Many EEI members over the last decade have sought regulatory approval from their state regulatory commissions to accelerate transportation electrification by reducing customer barriers to adoption. As of March 2023, and as mentioned supra, electric transportation filings from 62 electric companies in 35 states and Washington, D.C. have totaled more than $4.2 billion. The majority of these investments support the deployment of EV charging infrastructure at customer locations, and a significant portion is targeted to fleet customers. These programs can help reduce the cost that the customer would otherwise pay for the installation of EV charging infrastructure, which is a commonly cited barrier to EV charging infrastructure deployment.25 Further, electric companies can work with fleet customers to help manage their EV charging to occur at non-peak times. This can reduce operational costs for the fleet customer and improve utilization of the electric system, which puts downward pressure on rates for all customers.26 [EPA-HQ-OAR-2022-0829-0708, pp. 16-17]

25 An oft cited barrier to adoption for some customers is the low utilization of EV charging stations. Traditional electric rates for commercial customers include a demand component designed to recover the fixed costs of delivery electricity. With low utilization (such as a public EV charging station or some fleet charging use cases), the effective electric price can be higher than a customer with the same demand but higher utilization. Many electric companies offer or are exploring commercial rates or other programs that reduce some of the demand charge exposure for these low utilization customers. See Cappers, et al., A Snapshot of EV-Specific Rate Designs Among U.S. Investor-Owned Electric Utilities, https://emp.lbl.gov/publications/snapshot-ev-specific-rate-designs.

26 See, e.g., Metz, et al., Distribution System Investments to Enable Medium- and Heavy-Duty Vehicle Electrification – A Case Study of New York, https://www.edf.org/media/worth- investment-report-finds-utilities-fleet-owners-consumers-benefit-when-utilities-cover.

EPA notes that “there is considerable uncertainty associated with future distribution upgrade needs, and in many cases, some costs may be borne by utilities rather than directly incurred by BEV or fleet owners” in explaining why it models these costs as part of the infrastructure cost analysis. 88 Fed. Reg. 25,983. In general, the upgrades to the local electric system needed to bring sufficient power to the site may be known as “electric company-side make-ready” or “front-of-the-meter” infrastructure and includes but is not limited to poles, vaults, service drops, transformers, mounting pads, trenching, conduit, wire, cables, meters, other equipment as necessary, and associated engineering and civil construction work. Front-of-the-meter infrastructure is distinct from infrastructure on the customer side of the meter (“behind-the-meter”), which includes the supply infrastructure (conduit and wiring to bring power from the service connection to the charging station, and the associated installation costs, sometimes known as “customer-side make-ready”) and the charging equipment, sometimes known as Electric Vehicle Supply Equipment (EVSE). [EPA-HQ-OAR-2022-0829-0708, pp. 16-17]

Front-of-the-meter infrastructure is generally installed, owned, and operated by the electric company. However, the costs associated with front-of-the-meter infrastructure may be borne by the site host customer in full or in part if the costs exceed an allowance as determined by the electric company’s line-extension and/or service extension policy. These costs may also be known as “contributions in aid of construction.” [EPA-HQ-OAR-2022-0829-0708, pp. 17-20]

Modeling these front-of-the-meter infrastructure costs is inappropriate for the following reasons. First, estimating distribution upgrade costs may be beyond the scope of EPA’s analysis, as it is not clear that a similar scope of analysis is applied to traditional liquid fuels. For example, the analogous cost comparison for internal combustion engine vehicle would include cost considerations for fleet operators either 1) installing refueling stations at their own facilities, or 2) the embedded cost of fuel retailers’ business operations in the cost of diesel or gasoline. [EPA-HQ-OAR-2022-0829-0708, pp. 17-20]

Second, as described above, distribution upgrades are highly location specific. The costs associated with these upgrades are also highly variable, depending on the upgrade requested by the customer and the local distribution capacity. As stated in EEI's Preparing to Plug In Your Fleet guide, "the grid can expand as needed to accommodate the needs of any customer, but the time and resources needed to make the required upgrades are highly dependent on the specific facility and the circuit that serves it."27 [EPA-HQ-OAR-2022-0829-0708, pp. 17-20]

27 See EEI, Preparing To Plug In Your Fleet – 10 Things to Consider, https://www.eei.org/-/media/Project/EEI/Documents/Issues-and-Policy/Electric-Transportation/PreparingToPlugInYourFleet.pdf.

Third, the share of any distribution costs that the customer may bear varies as a matter of policy. Some electric companies have or are seeking approval for line extension allowances to cover some or all of these costs for serving EV charging infrastructure. In California, for example, legislation required electric companies in the state to file tariffs that would authorize them to "design and deploy all electrical distribution infrastructure on the utility side of the customer's meter for all customers installing separately metered infrastructure to support charging stations, other than those in single-family residences." This policy prompted tariffs from EEI members Pacific Gas & Electric (PG&E), San Diego Gas & Electric (SDG&E), and SCE that essentially allow electric companies to invest in more of the electric company-side infrastructure costs as part of the standard distribution system investment. [EPA-HQ-OAR-2022-0829-0708, pp. 17-20]

Fourth, EEI expects that the majority of fleets to electrify in the next several years will be those with return-to-base operations, which enables depot charging that is owned and operated by the fleet itself. Public charging, analogous to the existing gas station model, will be needed to serve long-haul electric trucks, but that opportunity will be limited in the near-term by battery capabilities. However, there are many new refueling models emerging, including but not limited to: fleet charging facilities owned by third parties and accessed by fleet operators through a reservation or subscription system; charging-as-a-service companies that disintermediate the fleet operator from the electric company, owning and operating the charging equipment at a customer facility and assessing the fleet operator a fully-bundled, flat charging fee (e.g., $/kWh); and transportation-as-a-service companies that provide the vehicle and charging to a fleet operator, such that the fleet operator pays a fully-bunded, flat service feel (e.g., $/mile). In all of these models, the fleet operator itself is not exposed to the front-of-the-meter infrastructure costs, but rather these costs are borne by a third party that then recoups all of its costs through their charging or service fees. [EPA-HQ-OAR-2022-0829-0708, pp. 17-20]

In conclusion, EPA is justified in not modeling front-of-the meter costs because doing so would result in an apples-to-oranges comparison to liquid fuels, those costs are site-specific and variable, the recovery mechanism of those costs depends upon state-specific policies, and fleet-operators may not always bear those costs. [EPA-HQ-OAR-2022-0829-0708, pp. 17-20]

Front-of-the-meter infrastructure is generally installed, owned, and operated by the electric company. However, the costs associated with front-of-the-meter infrastructure may be borne by the site host customer in full or in part if the costs exceed an allowance as determined by the electric company's line-extension and/or service extension policy. These costs may also be known as "contributions in aid of construction." [EPA-HQ-OAR-2022-0829-0708, pp. 17-20]

Modeling these front-of-the-meter infrastructure costs is inappropriate for the following reasons. [EPA-HQ-OAR-2022-0829-0708, pp. 17-20]

Fourth, EEI expects that the majority of fleets to electrify in the next several years will be those with return-to-base operations, which enables depot charging that is owned and operated by the fleet itself. Public charging, analogous to the existing gas station model, will be needed to serve long-haul electric trucks, but that opportunity will be limited in the near-term by battery capabilities. However, there are many new refueling models emerging, including but not limited to: fleet charging facilities owned by third parties and accessed by fleet operators through a reservation or subscription system; charging-as-a-service companies that disintermediate the fleet operator from the electric company, owning and operating the charging equipment at a customer facility and assessing the fleet operator a fully-bundled, flat charging fee (e.g., $/kWh); and transportation-as-a-service companies that provide the vehicle and charging to a fleet operator, such that the fleet operator pays a fully-bunded, flat service feel (e.g., $/mile). In all of these models, the fleet operator itself is not exposed to the front-of-the-meter infrastructure costs, but rather these costs are borne by a third party that then recoups all of its costs through their charging or service fees. [EPA-HQ-OAR-2022-0829-0708, pp. 17-20]

In conclusion, EPA is justified in not modeling front-of-the meter costs because doing so would result in an apples-to-oranges comparison to liquid fuels, those costs are site-specific and variable, the recovery mechanism of those costs depends upon state-specific policies, and fleet-operators may not always bear those costs. [EPA-HQ-OAR-2022-0829-0708, pp. 17-20]

Organization: Electric Drive Transportation Association (EDTA)

Infrastructure is growing alongside the plug-in fleet – nearly 54,000 public stations, with more than 139,000 outlets, are in operation. Tesla has committed to making at least 3,500 of its U.S. Supercharger stations and 4,000 Level 2 charging docks available to all brands of electric vehicles by the end of next year. [EPA-HQ-OAR-2022-0829-0589, p. 1]

The build-out of direct current fast charging infrastructure (DCFCs), particularly, will require substantial public and private investment, as well as coordination between users, power and infrastructure providers and permitting authorities. DCFCs enable bidirectional V2G, future-proof site installation and provide on-demand fast charge that will enhance commercial and consumer confidence. [EPA-HQ-OAR-2022-0829-0589, p. 2]

Organization: Elizabeth Boynton

I understand that the effect of this rule would reduce the sale of gas cars from 94% of new cars sold down to just 33% in 9 years. Regardless, a policy that would artificially manufacture an increased demand for Electric Vehicles (EVs) at this time may be well-meaning but I believe is bad policy for many reasons, including those listed below: [EPA-HQ-OAR-2022-0829-0568, p. 1]

From a practical standpoint, I anticipate needing to buy a new vehicle in the next few years. I don't want to be economically coerced into buying an EV because my options were limited by the Biden administration's attempt to regulate gas-powered vehicles out of the market. As distasteful as they may be to some, gas powered vehicles are still more reliable, less expensive, have a longer travel range than EVs and the infrastructure to support demand for fuel is there. EVs are impractical for longer travel that may include crossing desert environments, which are plentiful around where I live in Phoenix, Arizona, where running out of charge could be a death sentence. [EPA-HQ-OAR-2022-0829-0568, p. 1]

Additionally, I don't want to wait the 15 minutes to several hours for my battery to charge, as is the indicated time in a March 7, 2018 CleanTechnica article. More recently, an April 19, 2023 US News and World Report article entitled, "How long does it take to charge an electric car?" states, "There's really no way to nail down exactly how long it takes to charge an electric vehicle, but there are certainly reliable estimates." Reliable estimates for multiple variables that result in a charging time still well beyond the time it takes me to fill my tank at the pump. [EPA-HQ-OAR-2022-0829-0568, p. 1]

Organization: Energy Innovation

IV. The combined impact of federal, state, and private investments on infrastructure deployment will help meet the needs of an increasingly electrified LDV/MDV fleet over the next decade. [EPA-HQ-OAR-2022-0829-0561, p. 2]

We appreciate the EPA's thorough investigation into BEV charging infrastructure to support increased electrification of the light- and medium-duty vehicle sector. We agree with the EPA's assessment that charging infrastructure deployment and investments are well underway, and likely to accelerate. [EPA-HQ-OAR-2022-0829-0561, p. 20]

Estimates vary on the level of investment needed to support widespread transportation sector electrification, depending on the timeframe and percentage of BEVs assumed. For example:

-Analysis by Atlas Public Policy shows that to achieve 100 percent passenger EV sales by 2035 and put the nation on the path to full electrification, over $87 billion in investments in charging infrastructure will be needed over the next decade, including $39 billion for public charging.54 [EPA-HQ-OAR-2022-0829-0561, p. 20]

-The 2035 2.0 study's DRIVE Clean Scenario estimates the U.S. would require approximately 270,000 public chargepoints for LDVs and 35,000 MDV/heavy-duty truck chargepoints each year for the next 30 years, which would cost approximately $6.5 billion annually between now and 2050.55 [EPA-HQ-OAR-2022-0829-0561, p. 20]

-According to the ICCT, the U.S. needs to spend roughly $30 to $35 billion on public charging infrastructure by 2030 to achieve the widespread adoption of light- and heavy-duty ZEVs as described in the ZEV Declaration and the Global Memorandum of Understanding (MOU) on Zero- Emission Medium- and Heavy-Duty Vehicles.56 [EPA-HQ-OAR-2022-0829-0561, p. 20]

54 Lucy McKenzie and Nick Nigro, "U.S. Passenger Vehicle Electrification Infrastructure Assessment: Results for Light-Duty Vehicle Charging"(Atlas Public Policy, April 28, 2021), https://atlaspolicy.com/wp-content/uploads/2021/04/2021-04-21_US_Electrification_Infrastructure_Assessment.pdf.

56 Slowik et al., "Analyzing the Impact of the Inflation Reduction Act on Electric Vehicle Uptake in the United States."

55 "Public Charging for Electric Cars and Trucks Can Be Built Quickly and Cost Effectively," 2035 2.0, n.d., https://www.2035report.com/transportation/public-charging/.

Fortunately, a combination of federal, state, utility, and private investments and incentives are poised to fill the need for charging infrastructure. [EPA-HQ-OAR-2022-0829-0561, p. 20]

At the federal level, the BIL contains $7.5 billion to develop a nationwide EV charging network, targeting rural and underserved areas.57 To date, all 50 states are moving forward with plans to develop over 75,000 miles (as of July 2022) of EV charging corridors, via funding allocated through the National Electric Infrastructure Program. [EPA-HQ-OAR-2022-0829-0561, p. 20]

57 "Updated Fact Sheet: Bipartisan Infrastructure Investment and Jobs Act," The White House Briefing Room, August 2, 2021, https://www.whitehouse.gov/briefing-room/statements-releases/2021/08/02/updated-fact-sheet-bipartisan-infrastructure-investmentand-jobs-act/.

The IRA also extends the 30C Alternative Fuel Refueling Infrastructure tax credit for private investments in qualified clean-vehicle infrastructure for 10 years, as follows: [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

-Individual credit of 30 percent of installed costs, up to $1,000 per charger, provided the infrastructure is installed in a qualified census tract where the poverty rate is at least 20 percent, in a non-metropolitan area where median family income is ≤ 80 percent of the statewide median family income, or a metropolitan area where median family income is ≤ 80 percent of the statewide median family income or metropolitan area median family income. [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

-Commercial tax credit of 30 percent up to $100,000 per charger (up from the prior $30,000-per-location cap).58 [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

58 Sara Baldwin and Robbie Orvis, "Implementing the Inflation Reduction Act: A Roadmap for Federal and State Transportation Policy" (Energy Innovation LLC, October 2022), https://energyinnovation.org/wp-content/uploads/2022/11/Implementing-the-Inflation-Reduction-Act-A-Roadmap-For-Federal-And-State-Transportation-Policy.pdf.

These incentives for charging infrastructure will support private investments in a more robust national network, and new eligibility requirements will help expand businesses and individuals install EV charging access to better serve EV drivers, especially in currently underserved communities. [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

States are also playing a leading role. According to the State of Sustainable Fleets' 2023 Market Brief, "funding commitments have increased in California and within a handful of other states, thus driving up the average annual funding that will target the clean fuel market to approximately $32 billion on average per year during the next four to five years,"59 far exceeding expectations of funding before the BIL and IRA. See Figure 16. [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

59 "The State of Sustainable Fleets: 2023 Market Brief" (Gladstein, Neandross & Associates (GNA), May 2023), https://cdn.stateofsustainablefleets.com/2023/state-of-sustainable-fleets-2023-market-brief.pdf, 15-16.

[See original attachment for figure "Annual Public Incentive Funding for the Next 4-5 Years"] [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

State-funded programs aimed at EV charging deployment, including among the largest state markets, are well on their way to meeting future charging infrastructure demand. [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

[See original attachment for table of leading state-funded programs as of March 2023] [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

Figure 17. Leading state-funded programs for investment in EV charging as of March 2023. Source: Atlas Public Policy, available at: https://atlaspolicy.com/wp-content/uploads/2023/05/Investment-in-Publicly-Accessible-EV-Charging.pdf. [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

The private sector and charging companies are also moving quickly to take advantage of new incentives and funding. According to Atlas Public Policy, private investment in public EV charging has increased considerably in the last five years, rising from under $200 million in 2017 to nearly $13 billion by early 2023.60 For example: [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

60 Nick Nigro, "Investment in Publicly Accessible EV Charging in the United States (2023)" (Atlas Public Policy, May 2023),

https://atlaspolicy.com/wp-content/uploads/2023/05/Investment-in-Publicly-Accessible-EV-Charging.pdf.6. [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

-Pilot Company and Volvo Group signed a letter of intent to co-develop a charging network across Pilot and Flying J travel centers, catered specifically toward medium-and heavy-duty EVs. Pilot has more than 750 locations across 44 states and six Canadian provinces.61 [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

-Cumulative private investments in EV charging by different infrastructure providers, including the auto industry, totaled just over $13 billion as of March 2023.62 [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

-Companies like Electrify America, General Motors, Freightliner, Tesla, and Mercedes are rapidly expanding investments in charging infrastructure to meet increasing demand for EVs. See Figure 18. [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

61 Scooter Doll, "Pilot Co. Will Expand Charging Network to Heavy-Duty EVs with Help of Volvo Group," Electrek, November 15, 2022, https://electrek.co/2022/11/15/pilot-co-expand-charging-network-heavy-duty-evs-with-volvo-group/.

62 Nigro, "Investment in Publicly Accessible EV Charging in the United States (2023)."

[See original attachment for graph described below] [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

Figure 18. Cumulative private investment in EV charging over time by company. Source: Atlas Public Policy, available at: https://atlaspolicy.com/wp-content/uploads/2023/05/Investment-in-Publicly-Accessible-EV-Charging.pdf. [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

Utilities are also investing in EV charging at scale, and more states are authorizing utility investments to support widespread and equitable access to more customers. Total approved utility investments for transportation electrification totaled $5.230 billion as of December 2022. See Figure 19. [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

[See original attachment for table described below] [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

Figure 19. Leading states with approved utility investments in public charging. The table also includes the number of DCFC and L2 ports per million residents as of 2021. "Other States" accounts for the remaining 42 states and the District of Columbia. Source: Atlas Public Policy, available at: https://atlaspolicy.com/wp-content/uploads/2023/05/Investment-in-Publicly-Accessible-EV-Charging.pdf, 21. [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

In summary, national trends combined with historic investments are poised to fill the charging gap and meet the need for increased BEV adoption resulting from more stringent EPA tailpipe rules. In addition, the sizable investment needed will be shared across federal, state, and local governments, the private sector, and utilities, ensuring a more cost-effective charging network for future BEV drivers. [EPA-HQ-OAR-2022-0829-0561, pp. 20-24]

Organization: Energy Strategy Coalition

Members of this coalition are already engaging in long-term planning to meet the increased demand for electricity attributable to vehicle electrification, and the LMDV Proposal will provide a regulatory backstop supporting further investments in electrification and grid reliability. Demand for electricity will increase under both the LMDV Proposal and the recently-proposed Phase 3 Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles ("HDV Proposed Rule"),4 but the electricity grid is capable of planning for and accommodating such demand growth and has previously experienced periods of significant and sustained growth. Moreover, historic growth in demand and generation resources does not reflect the investments that will be made under the Infrastructure Investment and Jobs Act ("IIJA") and the Inflation Reduction Act ("IRA") to support the deployment of new renewable and zero-carbon generation resources, energy storage and charging infrastructure. Coalition members are already making investments in the resources and infrastructure needed to support transportation electrification and realize the benefits that integration of EVs can provide to the electricity grid. The Coalition encourages EPA to work closely with state and local partners and other federal agencies to ensure that deployment of this infrastructure occurs on the pace and scale needed to achieve the EV penetration-rates contemplated by these proposals, while ensuring grid reliability. [EPA-HQ-OAR-2022-0829-0610, pp. 1-2]

4 Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles—Phase 3, 88 Fed. Reg. 25,926 (published April 27, 2023).

II. The proposed rule supports long-term planning and investment

Long-term planning and investment for vehicle electrification is a business imperative for the Coalition's members and a necessary element of their efforts to provide affordable, clean, and reliable power to their customers. By setting a clear trajectory for vehicle electrification that complements existing regulatory and market forces, EPA's LMDV and HDV proposals facilitate further investment in the generation and charging infrastructure needed to meet increased demand associated with electrification of the vehicle fleet. [EPA-HQ-OAR-2022-0829-0610, pp. 1-2]

Even before the LMDV and HDV proposals, market forces and government incentives were projected to greatly increase the rate of vehicle electrification. As EPA notes, "virtually every major manufacturer of light-duty vehicles is already planning to introduce widespread electrification across their global fleets in the coming years." 5The IRA is now providing significant incentivies for automakers to accelerate these commitments through generous subsidies for EV purchases. These include up to $7,500 in tax credits for new EVs,6 $4,000 for used EVs,7 as well as incentives for the commercial purchase of light-and medium-duty vehicles.8 The IIJA also provides significant incentives to support vehicle electrification, including $7.5 billion in funding for installation of public charging and other alternative fueling infrastructure,9 and funding for the Department of Energy's ("DOE") Building a Better Grid Initiative, which allocates $2.5 billion to support the development of nationally significant transmission lines, $2.3 billion to strengthen and modernize the power grid against wildfires and other extreme weather exacerbated by climate change, and $10.5 billion to improve grid resilience and grid flexibility (including by supporting transmission and distribution infrastructure).10 [EPA-HQ-OAR-2022-0829-0610, pp. 1-2]

10 See, e.g., Building a Better Grid Initiative, GRID DEPLOYMENT OFFICE, DEPARTMENT OF ENERGY https://www.energy.gov/gdo/building-better-grid-initiative.

III. Coalition members are investing in EV charging infrastructure

Members of this Coalition have begun making significant investments in the charging infrastructure for electric passenger cars and trucks: [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

-National Grid recently received approval for a $206 million initiative to enable up to 32,000 additional charging ports in Massachusetts.23 [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

-The New York Power Authority will have up to 400 fast chargers installed or in construction through its EVolve NY program by the end of 2025.24 [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

-The Pacific Gas and Electric Company ("PG&E") has successfully installed through March 2023 over 5,700 charging ports through its EV Charge Network, EV Fleet, EV Fast Charge and EV Schools programs.25 To aid with equity efforts to expand EV charging, PG&E recently launched its Empower EV program, which offers income-eligible households up to $2,500 in financial incentives for the installation of a Level-2 charger and any necessary service panel upgrades,26 as well as its Multifamily Housing and Small Business EV Charger program, which will install Level 1 and Level 2 EV chargers at multifamily housing units, not-for-profit organizations and small businesses, at no cost for sites located in a priority community.27 [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

-Austin Energy provides rebates of up to $1,200 and $4,000 for customers installing Level 2 charging stations at their homes and workplaces respectively.28 [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

-The Sacramento Municipal Utility District ("SMUD") offers up to $1,000 toward residential charging equipment and installation costs through its Charge@Home program.29 [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

-Constellation Energy Corporation's venture arm (Constellation Technology Ventures, or "CTV") has invested in portfolio companies focused on EV and charging infrastructure.30 [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

Footntoe 30: For instance, CTV invested in Qnovo, which offers a solution suite that uses advanced computation to optimize the chemical reactions within lithium-ion batteries, resulting in faster charging, increased daily run times, and longer battery lifetimes. See Constellation Technology Ventures, https://www.constellationenergy.com/our-work/innovation-and-advancement/technology-ventures.html. [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

Coalition members are making these investments in part because of the benefits that EVs can provide to grid reliability. EVs' primary near-term grid benefits stem from their enablement of load shifting—whether from periods of higher load demand to periods of lower load demand, or from periods of more carbon-intensive power generation to periods where more renewable energy is available.31 Load shifting can involve both deferral (to avoid charging during periods of peak load) and more targeted scheduling (to take advantage of periods of excess energy supply).32 In addition to enhancing grid reliability, load shifting can also reduce customer electricity rates, increase the value of renewable energy investments (by maximizing usage of excess solar energy produced during the day), and mitigate the need for equipment upgrades (e.g., increased storage capacity to accommodate excess solar energy).33 [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

For example, PG&E has partnered with the BMW Group to explore ways to incentivize EV drivers to shift their charging times to support grid reliability.34 This program—called ChargeForward— first kicked off in 2015 and moved into its third phase in 2021.35 Building on the success of the first two phases, phase three expanded the program's scope to 3,000 EV drivers (from prior pilots of 100 and 400 drivers in phases one and two).36 Phase two of ChargeForward demonstrated the ability to shift nearly 20% of charging from a particular hour to another time and to shift up to 30% of charging to a particular hour.37 SMUD is also engaged in a managed charging pilot program with BMW, Ford, and GM, and is planning to add Tesla vehicles to the pilot as well, targeting participation of around 2,000 vehicles through 2024.38 [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

Coalition members are also exploring Vehicle-to-Grid (“V2G”) technology, through which EVs can send power back to load sources (e.g., homes) and the grid from their batteries. While still in the early stages of development, V2G technology can offer reliability benefits by serving as a grid resource during periods of peak demand.39 PG&E and BMW recently extended their ChargeForward partnership until March 2026 and, as part of that program, will conduct a field trial of V2G-enabled vehicles in order to explore their potential to increase grid reliability.40 In addition, PG&E has announced vehicle-grid integration (“VGI”) pilot programs with Ford41 and General Motors to test the ability of EVs to provide backup power to homes.42 SMUD is also in the process of conducting an electric school bus V2G demonstration project with the Twin Rivers Unified School District.43 SMUD is planning to expand the program to additional school districts and is also pursuing other projects to explore V2G capabilities for light-duty EVs.44 [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

IV. EPA should work closely with state and local partners to ensure deployment of the resources and infrastructure needed to accelerate transportation electrification while maintaining grid reliability

EPA's LMDV Proposal will help support deployment of the charging and generation resources needed to meet anticipated demand from vehicle electrification. Yet effective and efficient deployment of these resources will require coordination among electric utilities, state public utility commissions, and local governments to factor load from EVs into long-range resource planning and to permit the distribution and transmission system upgrades and new generation and storage resources needed to serve that load. To ensure these resources are deployed on the pace and scale needed to support vehicle electrification and grid reliability, EPA should coordinate closely with federal, state and local agenices to remove deployment barriers and emphasize the benefits that vehicle electrification can provide to the electricity grid, public health, and the climate. [EPA-HQ-OAR-2022-0829-0610, pp. 13-14]

Organization: Environmental. and Public Health Organizations

XVII.Ongoing Investments in Charging Infrastructure and Efforts to Ready the Grid for Widespread EV Charging Justify Stronger Standards.

In this section, we explain in detail how charging infrastructure and the electric grid are well-positioned to support strong final standards—and in particular, Alternative 1 with a steeper increase in stringency after 2030. [EPA-HQ-OAR-2022-0829-0759, p. 108]

A.Economic theory and historical precedent show that infrastructure buildout will occur at the pace and scale needed to support vehicle electrification.

EPA should reject arguments that the buildout of charging and grid infrastructure cannot occur at the pace and scale needed to support expanded vehicle electrification, which are unreasonably pessimistic and inconsistent with both economic theory and historical precedent. These arguments rely on the classic "chicken-and-egg" scenario said to be presented by ZEV sales and charging infrastructure, where each side of the market waits for the other. But EPA need not and should not wait for infrastructure to fully mature before finalizing strong standards. EPA's standards themselves will send a strong signal to the market to undertake the infrastructure investments needed to accommodate a gradual rise in vehicle electrification,283 such that increased ZEV sales and infrastructure buildout will occur in relative tandem and reinforce each other. As one analyst sums it up: "The chicken-and-egg conundrum is being solved. Investments in the space and the adoption of EVs [a]re happening much faster than many analysts expected, and this is also accelerating the build-out of the charging network."284 [EPA-HQ-OAR-2022-0829-0759, pp. 108-109]

283 Environmental regulation itself, of course, can lead to technology innovation and market development. See generally Jaegul Lee et al., Forcing Technological Change: A Case of Automobile Emissions Control Technology Development in the US, 30 Technovation 249 (2010); Margaret R. Taylor, Edward S. Rubin, & David A. Hounshell, Regulation as the Mother of Innovation: The Case of SO2 Control, 27 Law & Policy 348 (2005); James Lents et al., Chapter II: The regulation of automobile emission: A case study, in Environmental Regulation and Technology Innovation: Controlling Mercury Emissions from Coal-Fired Boilers (Marika Tatsutani & Praveen Amar eds., 2000) https://www.nescaum.org/documents/rpt000906mercury_innovative-technology.pdf.

The economic literature on indirect network effects and two-sided markets shows that an increase in BEV sales can be expected to stimulate associated infrastructure development. In a study on flex-fuel vehicles fueled by E85 (85% ethanol), Corts (2010) found that growth in sales of flex-fuel vehicles due to government fleet acquisition programs led to an increase in the number of retail E85 stations.285 That relationship held true across all six Midwestern states analyzed, despite differences in those states' E85 subsidies and tax credits.286 The author concluded that the results "confirm the basic validity" of the theory underlying government fleet purchase requirements: that increasing the "base of alternative fuel vehicles can spur the development of a retail alternative fuel distribution infrastructure."287 [EPA-HQ-OAR-2022-0829-0759, p. 109]

285 Kenneth S. Corts, Building out alternative fuel retail infrastructure: Government fleet spillovers in E85, 59 J. Env't Econ. & Mgmt. 219, 219-20 (2009).

286 Id.

287 Id at 231.

Recent economic research has confirmed this relationship in the context of ZEVs and charging infrastructure specifically. An influential study by Li et al. (2017) found that "EV demand and charging station deployment give rise to feedback loops" and that "subsidizing either side of the market will result in an increase in both EV sales and charging stations."288 Similarly, Springel (2021) found "evidence of positive feedback effects on both sides of the market, suggesting that cumulative EV sales affect charging station entry and that public charging availability has an impact on consumers' vehicle choice."289 The BIL and IRA subsidize both sides of the market, offering significant incentives for both ZEV purchases and the construction of charging infrastructure. Economic theory therefore supports the proposition that strong final standards, particularly in combination with the BIL and IRA's large financial incentives, will facilitate expansion of charging and grid infrastructure.290 [EPA-HQ-OAR-2022-0829-0759, p. 109]

289 Katalin Springel, Network Externality and Subsidy Structure in Two-Sided Markets: Evidence from Electric Vehicle Incentives, 13 Am. Econ. J.: Econ. Pol'y 393, 426 (2021).

290 See id. at 394 (noting that "the presence of positive feedback amplifies the impact of both types of subsidies"), 415 ("positive feedback loops between the charging station network and total all-electric vehicle sales amplify the impact of both types of subsidy").

Economic theory has in fact played out in Norway, where ZEV sales and infrastructure both expanded rapidly over the span of about a decade. There, the "path to charging point saturation started by stimulating more demand for EVs."291 In other words, Norway did not wait for infrastructure to fully mature before beginning its transition to cleaner cars. Rather, rising ZEV sales themselves "helped trigger a spike in demand for charging stations."292 [EPA-HQ-OAR-2022-0829-0759, pp. 109-110]

The concept that charging infrastructure will adequately scale up over time also finds support in an analogous historical example: the buildout of roads and gasoline refueling infrastructure in the early 20th century to serve the United States' growing fleet of automobiles. The country's exponential growth in automobile sales—first exceeding 1,000 in 1899 and growing to 1 million by 1916293—preceded the establishment of an extensive network of both suitable roads294 and filling stations.295 The buildout of road and refueling infrastructure unfolded over long time horizons and in a variety of ways, adapting to the needs of the automobile fleet as it changed and grew. Paving and other road improvement efforts began on a small scale in cities, where automobiles were initially concentrated; efforts to improve rural roads and construct highways happened a decade or more later, as motorists began to expand their driving beyond cities.296 Similarly, in the case of refueling infrastructure, a network of modern filling stations did not spring up until well after automobiles had grown in popularity.297 Before that, refueling needs were met through varied and dispersed "non-station" methods such as cans of gasoline sold at general stores, barrels at repair garages, mobile fuel carts, curb pumps, and home refueling pumps, which emerged at various times as the demand for gasoline increased.298 Road and refueling infrastructure therefore exhibited a "long-term, adaptive and portfolio approach"299 that, over the span of several decades, satisfied the shifting needs of the growing ranks of automobile owners. [EPA-HQ-OAR-2022-0829-0759, p. 110]

Geels, The Dynamics of Transitions in Socio-technical Systems: A Multi-level Analysis of the Transition Pathway from Horse-drawn Carriages to Automobiles (1860–1930), 17 Tech. Analysis & Strategic Mgmt. 445, 460, 467-68 (2005) (discussing the gradual expansion and improvement of road infrastructure in the 1910s and 1920s to accommodate growth in and changes to automobile travel).

295 Marc W. Melaina, Turn of the century refueling: A review of innovations in early gasoline refueling methods and analogies for hydrogen, 35 Energy Pol'y 4919, 4922 (2007) (noting that "the takeoff period for gasoline stations occurred between 1915 and 1925, but exponential growth in vehicles began around 1910, so the rise of gasoline filling stations followed rather than preceded the rise of gasoline vehicles").

296 Geels, at 467-68.

297 Melaina, at 4922.

298 Id. at 4924-27.

299 Id. at 4932 (discussing refueling infrastructure).

That approach holds important lessons for this rulemaking. As detailed elsewhere in this comment letter, the introduction of ZEVs into the total on-road fleet will occur gradually. See Figure V.C-1 & Figure V.D-1, supra; Table XVII.G-1 (L/MD PEVs as a Share of Total On-Road-L/MD Fleet, 2026-2040), infra. Economic theory and historical precedent show that growth in ZEV sales and infrastructure buildout will occur in relative tandem, with infrastructure responding over time commensurate with the evolving needs of the ZEV fleet. And in finalizing these standards, EPA will send a strong market signal that will facilitate infrastructure development at the pace and scale needed to support compliance with the standards. EPA must reject unfounded chicken-and-egg arguments questioning whether infrastructure will respond to rising demand. [EPA-HQ-OAR-2022-0829-0759, pp. 110-111]

B. EPA neglects to account for other significant sources of federal funding for ZEVs and charging infrastructure.

The Proposed Rule states: “The Bipartisan Infrastructure Law (BIL) provides up to $7.5 billion over five years to build out a national PEV charging network.”300 However, as also noted in the Proposed Rule, there are many other programs funded by the BIL that could provide significant additional funding: “Other programs with funding authorizations under the BIL that could be used in part to support charging infrastructure installations include the Congestion Mitigation & Air Quality Improvement Program, National Highway Performance Program, and Surface Transportation Block Grant Program among others.”301 To illustrate the point, consider the two largest programs funded by the BIL, the National Highway Performance Program ($148 billion over five years) and the Surface Transportation Block Grant program ($72 billion over five years). A portion of those funds could be invested in EV charging infrastructure and other investments that reduce emissions by reducing the need to drive. The block grant program is explicitly designed to be versatile and is available for a wide range of uses. In fact, it was originally created in the 1991 transportation law to encourage states to move beyond the interstate highway-building era into investments in other improvements to our transportation system,302 and Congress has added more uses since then. If, say, 20% of the funding provided by just those two programs were directed to EV charging infrastructure, it would provide $44 billion in additional federal funding.303[EPA-HQ-OAR-2022-0829-0759, p. 111]

300 88 Fed. Reg. at 29307.

303 See Deron Lovaas & Max Baumhefner. What if States Turn Pavement Into Charging Stations? (May 16, 2022), at https://www.nrdc.org/bio/deron-lovaas/what-if-states-turn-pavement-charging-stations (last accessed June 30, 2023).

And even without accounting for a portion of the National Highway Performance Program and Surface Transportation Block Grant (the two largest funding allocations made by the BIL), Atlas Public Policy’s inventory reveals there is a total of over $50 billion in BIL funding for which ZEVs and charging infrastructure are eligible expenses (see Figure XVII.B-1 below).

Figure XVII.B-1: ZEV Funding in the Bipartisan Infrastructure Law304

C. The Alternative Fuel Refueling Property Tax Credit extended by the IRA is not restricted to rural areas, but instead to areas that are not urban.

The Proposed Rule states that under the IRA, “residents in low-income or rural areas would be eligible for a 30% credit for the cost of installing residential charging equipment up to a $1,000 cap.”305 However, the word “rural” does not appear in IRA § 30C, which defines “eligible census tracts” for the Alternative Fuel Vehicle Refueling Property credit “as any census tract which (I) is described in § 45D(e), or (II) is not an urban area.”306 The distinction is important because there are many areas that have not been classified as rural that cannot rightly be classified as urban. For example, if the U.S. Department of the Treasury classifies a census tract as not urban if more than 10% of the blocks within the census tract are designated as rural census blocks (to ensure those who live in rural blocks are not unduly denied access just because they happen to live next to urban blocks), tens of millions more Americans and businesses would have access to these important tax credits. This approach has been recommended to Treasury by a diverse coalition of industry associations, individual companies, environmental, consumer, and environmental justice groups, and other stakeholders.307 EPA should correct its characterization of § 30C and should convey to Treasury that adopting the broadly-supported approach described above would support strong vehicle standards. [EPA-HQ-OAR-2022-0829-0759, p. 112]

305 88 Fed. Reg. at 29308.

306 26 U.S.C. § 30C(c)(3)(B).

307 Ltr. from Max Baumhefner et al. to U.S. Dep’t of the Treasury, June 2023 (attached to this comment letter; signatories include Natural Resources Defense Council, Alliance for Automotive Innovation, American Council on Renewable Energy, Ample, CALSTART, ChargePoint, Clean Energy Works, Earthjustice, Elders Climate Action, Electrification Coalition, Environmental Defense Fund, EV Charging for All, EVBox, Forth Mobility, Green Latinos, International Brotherhood of Electrical Workers, International Parking & Mobility Institute, Itselectric, League of Conservation Voters, National Association of Convenience Stores, National Consumer Law Center, NATSO, Navistar, Plug in America, Representing America's Travel Plazas and Truck Stops, Rivian, Sierra Club, SIGMA: America's Leading Fuel Marketers, TeraWatt, Transportation for America, Union of Concerned Scientists, and Volvo Group North America).

D. A more complete inventory reveals $67 billion in announced investments in charging infrastructure, including $33 billion dedicated to light-duty vehicles and $4 billion that could support light-duty vehicles.

EPA also correctly identifies that there has been “rapid growth in the broader market for charging infrastructure serving cars or other electric vehicles.”308 New charging infrastructure announcements are occurring every week, showing the public and private sectors’ commitment to building out infrastructure to support vehicle electrification. The Proposed Rule’s description of recently announced investments in charging infrastructure underscores the fact that significant progress is being made.309 However, this narrative should be supplemented by a more comprehensive inventory of the public, private, and utility sectors. As of March 31, 2023, Atlas Public Policy (Atlas) estimates $67 billion dollars in charging infrastructure investments that have been announced by the public, private, and utility sectors but not yet installed as charging ports in the ground.310 Table XVII.D-1 provides a summary of tallied investment amounts, which include: [EPA-HQ-OAR-2022-0829-0759, p. 113]

-$33 billion in announced, unspent investments for LDV charging;

-$30 billion in announced, unspent investments for medium- and heavy-duty vehicle charging; and

-$4 billion in announced, unspent investments for use across any vehicle class. [EPA-HQ-OAR-2022-0829-0759, p. 113]

308 U.S. EPA, Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles—Phase 3, 88 Fed. Reg. 25926, 25934(Apr. 27, 2023).

309 88 Fed. Reg. at 29308-09.

310 Atlas Pub. Pol'y, Announced EV Infrastructure Funding (June 15, 2023).

Table XVII.D-1: Estimated U.S. Charging Infrastructure Investments Announced but Not Yet In the Ground, as of March 31, 2023

[See original attachment for Table XVII.D-1]. [EPA-HQ-OAR-2022-0829-0759, pp. 113-114]

These totals include public sector (e.g., Charging and Fueling Infrastructure Discretionary Grant funding, state funding commitments, and modeled estimates of 26 U.S. Code § 30C tax credit payments), private sector (e.g., automaker and charging service provider), and utility program investments.311 [EPA-HQ-OAR-2022-0829-0759, p. 114]

311 Note that these figures do not include funding for hydrogen fuel cell vehicles. Regarding the § 30C tax credit, Atlas assumes that 1) all qualifying projects receive the tax credit, 2) on average, qualifying projects will receive tax credits worth 18% of covered costs, and 3) that Treasury will classify a census tract as not urban if more than 10% of the blocks within the census tract are designated as rural census blocks, as recommended by multiple stakeholders described in Section XVII.C. The estimated Low Carbon Fuel Standard value is based on modeling from Dean Taylor Consulting for California, Oregon, and Washington and does not include capacity credits. It uses a 2023 – 2032 EV adoption trajectory for those three states that meets President Biden's LDV goal of 50% ZEV sales share by 2030 (which is lower than the trajectory modeled in the EPA's proposed vehicle emission standards), an MDHD EV adoption curves modeled on the EPA's proposed emissions regulations for MD and HD vehicles, and modeling from Atlas's INSITE tool of MWh demanded by MDHD vehicles. Utility program investments include approved investor-owned utility programs with an EV charging element. Amounts are unspent program dollars as of the most recent program report available as of March 31, 2023. If no program report was available, Atlas used the percentage of time remaining in the approved program schedule to estimate the unspent proportion of program funding.

Even Atlas's tally of private sector commitments is likely incomplete. Private sector actors often do not announce their investment plans, and are especially unlikely to do so if they are investing in home, depot, or workplace charging. Tallied private sector commitments exclude an estimated $3.0 billion in capital raised by charging companies (including ChargePoint, EVgo, Blink, and Volta), some percentage of which is expected still to be invested in charging hardware and installation. [EPA-HQ-OAR-2022-0829-0759, p. 114]

The scale of these announced investments reflects a strong and growing deployment of public and private charging infrastructure that, even in advance of the finalization of the Proposed Standards, has begun to set the stage for a robust charging network. Additional analyses have emphasized the growing momentum in infrastructure deployment; for example, an International Energy Agency report noted that "there has been a substantial upswing in investment in EV charging infrastructure, which has doubled in 2022 compared to the previous year."312 [EPA-HQ-OAR-2022-0829-0759, p. 114]

312 IEA, World Energy Investment 2023, at 50 (2023), https://iea.blob.core.windows.net/assets/54a781e5-05ab-4d43-bb7f-752c27495680/WorldEnergyInvestment2023.pdf

E. Increased access to Tesla's large and growing supercharger network will accelerate PEV adoption.

Recent announcements from Tesla, Ford, GM, Rivian, and Volvo that will allow more drivers to access Tesla's SuperCharger network bolster the case for strong vehicle standards. As shown in Figure XVII.E-1 and Figure XVII.E-2, this effectively doubles the number of public fast charging locations and connectors available to a majority of the EV market.

Figure XVII.E-1: J1772Combo and Chademo DC Fast Charging Ports313

F. Barriers to the installation of charging infrastructure identified in the Proposal are being removed.

Barriers to the timely installation of charging infrastructure are being removed, which will allow investments at an even greater pace and scale.

Most of the challenges associated with energizing charging infrastructure in a timely manner are being faced in California, which has to date the highest percentage of electric LDVs on the road. Thankfully, a state law enacted in 2022 provides California's investor- and publicly-owned utilities with data necessary to inform grid planning to accommodate high levels of EV charging, requires those utilities to propose proactive grid investments in their General Rate Cases to comply with ZEV regulations (as well as a long list of other laws, standards, and requirements), and directs the California Public Utilities Commission (CPUC) and local utility governing boards to ensure the proposed investments are consistent with achieving the state's goals and regulations.315 In May 2023, Southern California Edison (SCE) filed its General Rate Case, which includes such proactive investments.316 [EPA-HQ-OAR-2022-0829-0759, p. 116]

315 California Assembly Bill 2700 Transportation electrification: electrical distribution grid upgrades. (2021-2022). https://leginfo.legislature.ca.gov/faces/billNavClient.xhtml?bill_id=202120220AB2700.

316 Southern California Edison, What you should know about SCE's general rate case (May 2023), at https://energized.edison.com/stories/sce-details-investments-to-advance-electric-grid-reliability-resilience-and-readi ness (last accessed June 30, 2023).

In addition, the California Senate recently voted 32-to-8 to advance new legislation (Senate Bill 410, "Powering Up Californians Act") that builds upon existing law to accelerate short-term energization timelines for EV charging and to ensure timely grid investments needed to electrify "light-duty, medium-duty, and heavy-duty vehicles and off-road vehicles, vessels, trains, and equipment" consistent with state law requiring economy-wide carbon neutrality by 2045, and "federal, state, regional, and local air quality and decarbonization standards, plans, and regulations."317 The legislation also establishes a balancing account to recover associated costs, which would ensure that Pacific Gas & Electric (PG&E) and San Diego Gas & Electric (SDG&E) do not have to wait several years for their next General Rate Cases to propose investments like those recently proposed by SCE (and it would also allow SCE to propose subsequent investments before its next rate case that could not be predicted when its current rate case was filed). [EPA-HQ-OAR-2022-0829-0759, p. 116]

317 California Senate Bill 410. (2023). https://leginfo.legislature.ca.gov/faces/billTextClient.xhtml?bill_id=202320240SB410.

Utilities across the country are also already planning for and deploying solutions to address increased vehicle electrification as their customers adopt PEVs to improve fleet economics and performance. Utilities and their customers will benefit from the ability to plan ahead for any significant infrastructure requirements. The regulatory certainty provided by this rulemaking can aid this planning. [EPA-HQ-OAR-2022-0829-0759, p. 116]

Regulatory certainty can also help ensure that investments not only maintain strong electric service but improve it, while at the same time lowering costs. SCE President and CEO Steve Powell noted: “if we leverage the electric vehicle load and have that work for consumers as well, that whole idea of vehicle-to-grid, there can be real value in helping alleviate a lot of the infrastructure investments that need to happen,” ultimately lowering overall energy bills for customers.318 Similarly, Seattle City Light, in its Transportation Electrification Strategic Investment Plan, stated that “[w]hile there are system costs associated with increased transportation electrification (e.g., distribution and transmission infrastructure upgrades), with proactive utility planning and intervention, the system benefits (e.g., new revenue) are estimated to outweigh the costs, spreading the economic benefits of transportation electrification to all customers.”319 This will require action from regulators as well to help shape and approve these proactive and critical investments. As RMI recommended, “regulators can fulfil [sic] their responsibility for ensuring prudent and least-cost grid investments while proactively planning by using new information.”320 [EPA-HQ-OAR-2022-0829-0759, p. 117]

318 Casey Wian, Transportation Electrification Gains Momentum: Edison International and SCE outline plans to seize the “huge opportunity” of preparing the grid for exponential EV growth, Energized, (Feb. 1, 2023), https://energized.edison.com/stories/transportation-electrification-gains-momentum.

320 Ari Kahn et al., RMI, Preventing Electric Truck Gridlock: Meeting the Urgent Need for a Stronger Grid 16 (2023), https://rmi.org/insight/preventing-electric-truck-gridlock/.

In addition, the historic investments of the BIL and IRA are helping utilities build a stronger, cleaner grid and prepare for advanced electrification while minimizing customer costs. Duke Energy, for example, has stated that “[the BIL] provides an important down payment on the infrastructure and incentives that are needed to electrify transportation and secure the grid,” and “[the IRA] can create significant cost savings for our customers.”321 New York utilities have indicated that they will be applying for $900 million in grants from the BIL and IRA to advance grid resilience.322 National Grid in particular notes that “EV charging make-ready infrastructure is identical to electric infrastructure that serves other purposes, this is the kind of work electric utilities do every day,”323 and that “areas of the [BIL] funding are enabling increased investment.”324 [EPA-HQ-OAR-2022-0829-0759, p. 117]

323 Comments of National Grid to USDOT/FHWA on Docket No. FHWA-2021-0022, at 11 (Jan. 26, 2022), https://downloads.regulations.gov/FHWA-2021-0022-0150/attachment_1.pdf.

324 Id. at 10.

Grid operators around the country are also beginning to incorporate EV planning into existing planning structures. For example, the Minnesota Public Utilities Commission has shifted investor-owned utility transportation electrification planning and reporting requirements to the integrated distribution planning process to account for increasing linkages between EV planning and distribution system planning.325 Incorporating robust EV planning in existing planning structures can help ensure those processes account for EV adoption, even where the utility business units responsible for those areas of planning may be distinct. Furthermore, combined planning processes can create administrative efficiencies that help expedite time-sensitive planning needs. On the transmission planning side, regional grid operators, such as the Midcontinent Independent System Operator, have already begun to think about how transportation electrification will affect total energy needs and the timing of annual peaks in electricity demand.326 Strong vehicle standards give grid operators a reliable EV forecast against which to plan in processes that are already underway. [EPA-HQ-OAR-2022-0829-0759, p. 118]

Finally, parties are working across sectors and industries to reduce barriers to charging deployment. Utilities, public utility commissions and other state regulators, grid operators, charging providers, and others can and have already begun to coordinate and plan for increased vehicle electrification. Examples include: [EPA-HQ-OAR-2022-0829-0759, p. 118]

-The National Charging Experience Consortium (ChargeX) is a collaborative effort between Argonne National Laboratory, Idaho National Laboratory, NREL, BEV charging industry experts, consumer advocates, and other stakeholders whose mission is “to work together as BEV industry stakeholders to measure and significantly improve public charging reliability and usability by June 2025.”327 [EPA-HQ-OAR-2022-0829-0759, p. 118]

327 Idaho Nat’l Lab’y, National Charging Experience Consortium, https://inl.gov/chargex/ (last visited June 13, 2023).

-The National EV Charging Initiative brings together automakers, power providers, PEV and charging industry leaders, labor, and public interest groups to “develop a national charging network for light, medium, and heavy-duty vehicles and inspire deeper commitments from state leaders, the administration and each other."328 [EPA-HQ-OAR-2022-0829-0759, p. 118]

328 EV Charging Initiative, https://www.evcharginginitiative.com/ (last visited June 13, 2023).

-The National Association of State Energy Officials and the American Association of State Highway and Transportation Officials partnered with the U.S. Joint Office of Energy and Transportation to hold a series of convenings to coordinate on a range of topics, including ZEV infrastructure and utility planning needs.329 These convenings brought together State Departments of Transportation officials, State Energy Offices, and other key partners. [EPA-HQ-OAR-2022-0829-0759, pp. 118-119]

329 Nat'l Ass'n State Energy Officials (NASEO) & the Am. Ass'n State Highway & Transp. Officials (AASHTO), Building a National Electric Vehicle Charging Infrastructure Network: Regional EV Meetings Key Themes, Takeaways, and Recommendations from the States (not dated), https://www.naseo.org/data/sites/1/documents/publications/NASEO_AASHTO_Regional%20EV%20Meetings%20 Summary_%20Final.pdf.

-PG&E and BMW of North America are testing a "vehicle-to-everything technology that will improve grid reliability and help EV customers lower their electric bills by exporting power back to the grid during peak demand periods." PG&E notes that "[t]he utility and automotive industries are creating a transformative clean energy future together."330 [EPA-HQ-OAR-2022-0829-0759, p. 119]

330 BMW Group, More Power To You: BMW of North America and PG&E Start V2X Testing in California (May 16, 2023), https://www.press.bmwgroup.com/usa/article/detail/T0417218EN_US/more-power-to-you:-bmw-of-north-america-a nd-pg-e-start-v2x-testing-in-california.

-NREL and Volvo collaborated on a research paper regarding challenges and opportunities of commercial ZEVs, noting:

Coordination between disparate and historically unconnected stakeholders, including state agencies, local governments, automotive manufacturers, fleets, energy infrastructure and utility companies, and research and academia will be required to ensure a smooth and timely transition to ZEVs. This paper, a joint research and industry perspective, is one such example of cross-sectoral collaboration.331 [EPA-HQ-OAR-2022-0829-0759, p. 119]

331 Matteo Muratori, et al., Road to zero: Research and industry perspectives on zero-emission commercial vehicles, iScience, May 19, 2023, https://www.cell.com/action/showPdf?pii=S2589-0042%2823%2900828-3, at 7.

These examples show that the relevant stakeholders are already stepping up to plan for and accommodate the charging and grid needs associated with greater vehicle electrification.

Fundamentally, charging infrastructure challenges are being addressed, as evidenced by the progress described above. We are not starting from scratch and do not need to replicate the gasoline and diesel refueling network to electrify vehicles. The electric grid is already nearly ubiquitous; it only needs to be extended at the fringes. These actions benefit utility shareholders and customers alike by removing barriers to investment in charging infrastructure. As explored in more detail below, America's utilities have a long history of accommodating significant growth. [EPA-HQ-OAR-2022-0829-0759, p. 119]

In sum, the private and federal infrastructure investments EPA has identified justify strong standards, and barriers to additional investment are actively being removed. Furthermore, as noted above, EPA's inventory of federal, public, and private investments that already justifies increasingly stringent vehicle standards is incomplete; and a more complete inventory justifies stronger standards. [EPA-HQ-OAR-2022-0829-0759, p. 119]

4. PEV charging is already putting downward pressure on electric rates, to the benefit of all utility customers.

Because much PEV charging can be accomplished when there is spare capacity on the grid, charging can spread the costs of maintaining the system over a greater volume of electricity sales, reducing the per-kilowatt-hour price of electricity to the benefit of all customers. This has already been demonstrated in the real world. [See original comment for XVII.G-4]. [EPA-HQ-OAR-2022-0829-0759, p. 128]

In fact, empirical data compiled by Synapse Energy Economics shows that PEV drivers are not being subsidized by other utility customers and, in fact, they are putting downward pressure on rates. Between 2011 and 2020, PEV customers across the United States contributed more than $1.7 billion in net revenue to the body of utility customers.350 [See original comment for XVII.G-4]. [EPA-HQ-OAR-2022-0829-0759, p. 128]

350 Melissa Whited, Tyler Fitch, Jason Frost, Eric Borden, Courtney Lane, Ben Havumaki, Sarah Shenstone-Harris & Elijah Sinclair, Electric Vehicles Are Driving Rates Down 1 (June 2023), https://www.synapse-energy.com/sites/default/files/Electric%20Vehicles%20Are%20Driving%20Rates%20Down%20Factsheet.pdf.

The results shown in Figure XVII.G-4 compare the new revenue the utilities collected from PEV drivers to the cost of the energy, capacity, transmission, and distribution system upgrades required to charge those vehicles, plus the costs of utility PEV infrastructure programs that are deploying charging stations for PEVs. In total, PEV drivers contributed an estimated $1.7 billion more than associated costs. That net revenue is returned to the body of utility customers in the form of electric bills that are lower than they would otherwise be. [See original comment for XVII.G-4]. [EPA-HQ-OAR-2022-0829-0759, p. 128]

Figure XVII.G-4: Total Utility Revenues vs. Total Costs Associated with PEVs (2011-2020)351

351 Id. at 3.

[See original comment for XVII.G-4]. [EPA-HQ-OAR-2022-0829-0759, p. 129]

XXIII. BEV Charging Times Are Constantly Improving and Are Not a Constraint on Strong Standards.

Taking refueling considerations into account, BEV charging times are consistent with setting strong final standards. Charging technologies have come a long way in recent years, increasing in their capability to deliver more energy to a vehicle in the same unit of time. EPA notes that its assumptions for BEV refueling times are outdated, 88 Fed. Reg. at 29200, and that is indeed the case. EPA's analysis assumes 100 miles of driving added for each hour of charging as the "charge rate" across all BEVs. DRIA at 4-29. That equates to an average power delivery of just over 30 kilowatts, using the current on-road fleet average BEV efficiency.595 While power delivery during a charging session does taper off as the vehicle battery approaches a full charge, the average power delivery for mid-trip charging events will be much higher than 30 kW. Those events are likely to be done with fast charging, where available, and the availability of high-powered, fast charging will expand greatly leading up to and through the lifetimes of vehicles sold during the period of the Proposed Standards. [EPA-HQ-OAR-2022-0829-0759, p. 182]

595 David Reichmuth, Jessica Dunn, & Don Anair, Driving Cleaner, Union of Concerned Scientists (July 2022) at 20, https://www.ucsusa.org/sites/default/files/2022-07/driving-cleaner-report_0.pdf.

Not only is consumer demand for fast charging for mid-trip fueling pushing the market in the direction of higher-powered ports, the minimum power requirements for federal programs, as well as some state programs, ensure the market will meet those consumer needs in a timely manner. For example, the minimum standards and requirements for the National EV Charging Formula Program specify that each charging location must have at least four charging ports that can deliver 150 kW (or higher) simultaneously. 88 Fed. Reg. at 12754. A 150 kW port would deliver closer to 450 miles of range in an hour, greatly reducing the disbenefit of refueling time associated with BEVs. That number of miles per hour of charging is really a theoretical construct, as the hourly output is more energy than light- and medium-duty vehicle batteries can hold. A vehicle would not spend a full hour fueling at a 150 kW charging station, even if the battery is fully depleted. [EPA-HQ-OAR-2022-0829-0759, p. 182]

The hourly charging speed of a 150 kW station is, however, a useful apples-to-apples comparison to the 100 miles/hour figure used in EPA’s analysis. It suggests that many vehicles will charge nearly four and a half times faster than the speed assumed in the analysis. Still other vehicles may use even faster charging for their mid-trip events, with chargers on the market approaching 350 kW, for vehicles that can accept that output.596 Thus, EPA’s charging rate assumption could be quadrupled (and the refueling time disbenefit for BEVs greatly reduced) and still result in a conservative assumption that leaves room for vehicles that may do some mid-trip charging at more moderate DC charging power levels. [EPA-HQ-OAR-2022-0829-0759, p. 183]

596 Andrei Nedelea, 800V EV Charging Will Drastically Reduce Waiting Times At The Charger, Inside EVs (June 5, 2020), https://insideevs.com/features/427039/800-volt-charging-to-change-industry/.

Organization: Environmental Defense Fund (EDF) (1of 2)

V. Sufficient infrastructure, electric grid capacity, and policies exist to support strong standards.

EPA reasonably considered additional factors, including ZEV infrastructure, in projecting ZEV deployment in its proposal. Recent analyses indicate that buildout of EV infrastructure and the electric grid distribution capacity are sufficient to support EPA's proposed standards. Significant federal, state, and private investments are already being made to grow EV infrastructure. And states and utilities are initiating processes to ensure adequate infrastructure to meet demand. [EPA-HQ-OAR-2022-0829-0786, pp. 51-52]

A. Federal, state, and private investments support fast-growing infrastructure.

Investment in the infrastructure required to support rapid ZEV proliferation has already begun. Federal, state, and private parties have directed substantial resources into developing widespread charging networks and driving technological innovation. Together, these investments are laying the groundwork for protective standards. [EPA-HQ-OAR-2022-0829-0786, pp. 51-52]

In 2022, President Biden publicly committed to building out a national network of 500,000 EV chargers by 2030.123 The federal government has made significant investments towards building the infrastructure necessary for a ZEV future with The Inflation Reduction Act (IRA) and Bipartisan Infrastructure Law (BIL). Both laws are putting billions of dollars towards building out charging networks and updating the grid to support the transition to ZEVs. [EPA-HQ-OAR-2022-0829-0786, pp. 51-52]

123 Fact Sheet: Biden-Harris Administration Announces New Standards and Major Progress for a Made-in-America National Network of Electric Vehicle Chargers, https://www.whitehouse.gov/briefing-room/statements-releases/2023/02/15/fact-sheet-biden-harris-administration-announces-new-standards-and-major-progress-for-a-made-in-america-national-network-of-electric-vehicle-chargers/.

Multiple provisions of the IRA will boost the development of infrastructure to support light-duty ZEVs. The Alternative Fuel Refueling Property Credit will directly fund charging infrastructure in low-income and rural areas.124 Qualifying businesses and individuals can be reimbursed for up to 30 percent of the cost of installing charging equipment in these areas, substantially reducing the costs of this equipment.125 The Congressional Joint Committee on Taxation estimates this credit will cost almost $2 billion over its lifetime, demonstrating the sizeable impact it will make in driving additional investments from private parties.126 The Advanced Energy Project Credit allocates $10 billion for facilities manufacturing advanced energy technologies, which includes manufacturing of charging and refueling infrastructure for ZEVs as well as grid modernization components.127 Other provisions fund grants for infrastructure buildout in nonattainment areas,128 and fund improvements to electricity generation and transmission.129 [EPA-HQ-OAR-2022-0829-0786, p. 52]

124 Inflation Reduction Act of 2022, P.L. 117-169, § 13404.

125 Inflation Reduction Act of 2022, P.L. 117-169, § 13404.

126 Joint Committee on Taxation, Estimated Budget Effects of the Revenue Provisions of Tile I—Committee on Finance, of an Amendment in the Nature of a Substitute to H.R. 5376, “An Act to Provide for Reconciliation Pursuant to Tile II of S. Con. Res. 14,” as Passed by the Senate on August 7.2-22, and Scheduled for Consideration by the House of Representative on August 12, 2022, JCX-18-22, https://www.jct.gov/publications/2022/jcx-18-22/.

127 Inflation Reduction Act of 2022, P.L. 117-169, § 13501.

128 Inflation Reduction Act of 2022, P.L. 117-169, § 60101.

129 Inflation Reduction Act of 2022, P.L. 117-169, § 50144, 50145, 50151, 50152.

The BIL is another source of considerable federal investment in infrastructure development. Through its National Electric Vehicle Infrastructure (NEVI) and Charging and Fueling Infrastructure (CFI) discretionary grant programs, the law allocates $7.5 billion in funding explicitly towards building out ZEV charging and refueling infrastructure.130 The NEVI program directs the Federal Highway Administration (FHWA) to provide funding to states to deploy EV charging stations to build an interconnected and reliable charging network. The FHWA has already announced its first set of plans under the program, which includes investment in all 50 states plus the District of Columbia and Puerto Rico.131 This first round of NEVI investment is set to bring EV charging to 75,000 miles of highway across the country.132 The

CFI program provides additional funding for FHWA administered grants to state and local authorities for development of publicly accessible charging infrastructure.133 [EPA-HQ-OAR-2022-0829-0786, pp. 52-53]

130 Infrastructure, Investment and Jobs Act of 2021, P.L. 117-58, 135 Stat. 445, 1421. Infrastructure, Investment and Jobs Act of 2021, P.L. 117-58, 135 Stat. 445, 1421.

131 U.S. Department of Transportation, Historic Step: All Fifty States Plus D.C. and Puerto Rico Greenlit to Move EV Charging Networks Forward, Covering 75,000 Milles of Highway (Sep. 27, 2022), https://www.transportation.gov/briefing-room/historic-step-all-fifty-states-plus-dc-and-puerto-rico-greenlit-move-ev-charging.

132 U.S. Department of Transportation, Historic Step: All Fifty States Plus D.C. and Puerto Rico Greenlit to Move EV Charging Networks Forward, Covering 75,000 Milles of Highway (Sep. 27, 2022), https://www.transportation.gov/briefing-room/historic-step-all-fifty-states-plus-dc-and-puerto-rico-greenlit-move-ev-charging.

133 U.S. Department of Transportation, Biden-Harris Administration Opens Applications for First Round of $2.5 Billion Program to Build EV Charging in Communities & Neighborhoods Nationwide, https://www.transportation.gov/briefing-room/biden-harris-administration-opens-applications-first-round-25-billion-program-build.

On top of these programs, the BIL authorized more than $40 billion combined for the Congestion Mitigation & Air Quality Improvement Program, National Highway Performance Program, and Surface Transportation Grant Block Program.134 These programs are not dedicated exclusively to charging, but constructing and installing charging infrastructure is an eligible activity under each of them. Additional funding from the BIL provides grants to states and local governments for reducing transportation carbon pollution, which will fund additional infrastructure investments.135 [EPA-HQ-OAR-2022-0829-0786, pp. 52-53]

134 Infrastructure, Investment and Jobs Act, P.L. 117-58, § 11115.

135 Infrastructure, Investment and Jobs Act, P.L. 117-58, § 11403.

The ambition of these federal investments is being matched by infrastructure funding in many states, especially in states that have adopted, or are planning to adopt, California's Advanced Clean Cars II (ACC II) rule. For example, the California Energy Commission's (CEC) Clean Transportation Program announced it plans to invest $900 million for light-duty charging infrastructure through 2026.136 The CEC estimates the plan will result in 90,000 new EV chargers across the state, more than doubling the state's existing network and helping it meet its goal of having 250,000 chargers by 2025.137 Colorado has likewise made significant investments in preparing for a transition to ZEVs. The state's Charge Ahead Colorado Program provides grants that fund 80% of the cost of charging stations up to certain maximums based on type of charging equipment.138 [EPA-HQ-OAR-2022-0829-0786, p. 53]

136 California Energy Commission, CEC Approves $2.9 Billion Investment for Zero-Emission Transportation Infrastructure (Dec. 14, 2022), https://www.energy.ca.gov/news/2022-12/cec-approves-29-billion-investment-zeroemission-transportation-infrastructure.

138 Colorado Energy Office, Charge Ahead Colorado, https://energyoffice.colorado.gov/charge-ahead-colorado.

B. Independent analysis commissioned by EDF shows existing and announced public charging infrastructure is on track to support increased passenger vehicle electrification.

A new study by WSP for EDF submitted along with our comments summarizes the existing public charging infrastructure in the U.S., the future public charging infrastructure needs based on EPA's proposal, and quantifies the announced EV charger deployment and investment and how it compares to those needs.139 In this analysis, WSP conducted an extensive survey of charger deployment announcements to quantify the extent of the government and industry investment in public charging in the U.S. To the best of our knowledge, this is the first analysis that has attempted to quantify both the current state of the market and the cumulative impacts of future investments. [EPA-HQ-OAR-2022-0829-0786, pp. 53-54]

139 U.S. Public EV Charging Infrastructure Deployment: Announced investment will rapidly expand publicly available charging, WSP for EDF (June 2023), https://blogs.edf.org/climate411/wp-content/blogs.dir/7/files/WSP-US-Public-EV-Charging-Infrastrcuture-Deployment-July-2023.pdf (Attachment U).

The analysis finds that as of June 2023 there were 58,000 existing public EV charging stations in the U.S. These stations host 155,700 ports that provide electricity to vehicles – 2% are Level 1, 78% are Level 2 and 20% are DCFC chargers (Figure 17). [EPA-HQ-OAR-2022-0829-0786, pp. 53-54]

[See original attachment for Figure 17: U.S. Public EV Charging Infrastructure] [EPA-HQ-OAR-2022-0829-0786, pp. 53-54]

Source: U.S. Department of Energy, Alternative Fuel Database (June 19, 2023) [EPA-HQ-OAR-2022-0829-0786, pp. 53-54]

WSP estimates the number of public chargers that will be added to the current network over the next five years based on public announcements and commitments made by federal, state, and private organizations. Since 2021, based on a conservative estimate considering only the most concrete announcements, more than $21.5 billion in investments have been announced, which will result in over 800,000 new charger ports coming online before 2030 (Table 14). [EPA-HQ-OAR-2022-0829-0786, pp. 54-57]

[See original attachment for Table 14: Announced Public Charging Ports and Investments] [EPA-HQ-OAR-2022-0829-0786, pp. 54-57]

Source: WSP, U.S. Public EV Charging Infrastructure Deployment

The pace of charger announcements increased markedly since the passage of the Inflation Reduction Act, representing 4.5 times the number of current public chargers, and underscoring the impact of recent federal policy in spurring the expansion (Figure 17). [EPA-HQ-OAR-2022-0829-0786, pp. 54-57]

[See original attachment for Figure 17: EV Charger Announcement Timing] [EPA-HQ-OAR-2022-0829-0786, pp. 54-57]

Source: WSP, U.S. Public EV Charging Infrastructure Deployment [EPA-HQ-OAR-2022-0829-0786, pp. 54-57]

In the Draft RIA for the proposal, EPA estimates that approximately 1,075,000 new Level 2 chargers and 135,000 new DCFC public chargers will be needed by 2030 to accommodate increasing numbers of EVs on the road, as a result of BAU and the proposed standards.140 WSP's analysis finds that existing and already announced public EV charger deployments will provide at least 70% of the public chargers needed in the U.S. by 2030 under EPA's current proposed rule. For DCFC, existing and announced chargers account for more than 100% of the needed DCFC chargers past 2032. [EPA-HQ-OAR-2022-0829-0786, pp. 54-57]

140 U.S. Environmental Protection Agency (EPA) Multi-Pollutant Emissions Standards for Model Year 2027 and Later Light-Duty and Medium-Duty Vehicles Draft Regulatory Impact Analysis, April 2023, Figure 5-15.

When WSP further accounted for less concrete announcements, by assuming 25% of these softer announcements would materialize, along with 50% of unawarded grants resulting in previously unaccounted for charging ports, the analysis found announced investments would result in the deployment of well over 100% of the required chargers in 2030, 1.7 million ports. [EPA-HQ-OAR-2022-0829-0786, pp. 54-57]

The combination of market forces and incentives from recent federal policy have attracted a wide array of players to invest in public charger deployments. The analysis identified investments by 29 state governments, 18 charge network providers, 10 retailers, 7 vehicle manufacturers, 6 toll road operators, along with utilities, truck and service station operators, and fleet owners. [EPA-HQ-OAR-2022-0829-0786, pp. 54-57]

For example, Walmart announced it will install publicly available DCFC chargers at all of its retail locations in the U.S. by 2030 – and nearly 90% of Americans live within 10 miles of a Walmart.141 Hertz and bp announced plans to build out a national network of EV fast charging infrastructure to accelerate the adoption of electric vehicles, bringing charging infrastructure to Hertz locations across America, including major cities such as Atlanta, Austin, Boston, Chicago, Denver, Houston, Miami, New York City, Orlando, Phoenix, San Francisco, and Washington, DC.142 Hertz's goal is to make one-quarter of its fleet electric by the end of 2024 while bp aims to invest $1 billion in EV charging in the US by 2030. Pilot Company, General Motors, and EVgo have partnered to build a coast-to-coast network of 2,000 high power 350 kW fast chargers at Pilot and Flying J travel centers along American highways, with the first 200+ chargers expected to be available for use by drivers in 2023.143 And General Motors and FLO announced a collaborative effort with dealers to install up to 40,000 public Level 2 EV chargers in local communities by 2026 through GM's Dealer Community Charging Program.144 As shown in Figure 18, WSP found that these private sector deployments along with NEVI and other nationwide grant programs would dramatically expand the EV charging network nationwide. ii. EV charging has the potential to benefit the grid through managed charging and other programs.

Multiple studies have found that through managed charging, increases in EV adoption and charging will not meaningfully increase peak demand on the grid. In their study investigating the grid impacts of BEV adoption in Dallas and New York City, Needell, Wei, and Trancik found that "delayed home charging nearly eliminates the increase in the evening demand for electricity…even for BEV penetration levels well over 50%." Additionally, they found that "workplace charging emerges as a simple and effective solution for abating both the peak increase and the over-supply of [solar generation]."162 A 2019 article in IEEE Electrification Magazine found that through managed charging, the peak demand from EVs in California could be cut to one-eighth of the size without managed charging leaving the increases within the margins for most residential feeders.163 [EPA-HQ-OAR-2022-0829-0786, p. 60]

Organization: Fermata Energy

V2X bidirectional charging is a win-win-win investment: many benefits accrue: [EPA-HQ-OAR-2022-0829-0710, pp. 4-6]

- Achieves EPA's environmental goals. Just like stationary storage, V2X bidirectional charging platforms can reduce carbon and criteria pollutant emissions from generators by shifting electricity consumption to the cleanest hours of the day and removing the need for dirty thermal peaker electricity generation. However, V2X is more cost-effective than stationary storage, as ratepayers don't have to pay for purchase of the EV battery and can accelerate the renewable transition. [EPA-HQ-OAR-2022-0829-0710, pp. 4-6]

- Provides grid services. With V2X bidirectional charging, utilities gain a low-cost energy storage resource to help integrate renewable energy into the electric grid by shifting energy, providing resource adequacy, and ancillary services (Figure 3). For example, modeling by the CPUC currently projects 14,700 MW of new energy storage is needed in CA by 2032 to support the integration of renewables but only 2,185 MW is operational today.9,10 V2X, with supportive policies, can provide many thousands of MW by 2030. [EPA-HQ-OAR-2022-0829-0710, pp. 4-6]

[See original attachment for Figure 3 -Grid services and value from different Vehicle-Grid-Integration technologies]11 [EPA-HQ-OAR-2022-0829-0710, pp. 4-6]

11 California Energy Commission, March 2019, Distribution System Constrained Vehicle-to-Grid Services for Improved Grid Stability and Reliability, (Link: https://www.energy.ca.gov/sites/default/files/2021-06/CEC-500-2019-027.pdf) Figure 42

- Lower vehicle ownership costs. EV owners can earn money by selling electricity back to the grid, significantly cutting the cost of vehicle ownership. Offsetting the cost of owning and maintaining an EV supports equitable access to EVs, particularly those EVs in the used car market, such as the low-income EV driving community. [EPA-HQ-OAR-2022-0829-0710, pp. 4-6]

- Increased resiliency. Unidirectional charging is a grid load. V2X bidirectional charging cost-effectively supports grid resilience. During blackouts and extreme weather events, such as Public Safety Power Shutoffs (PSPS) in CA, EV owners can power their homes, businesses, and critical infrastructure. [EPA-HQ-OAR-2022-0829-0710, pp. 4-6]

- Ratepayer benefits. EV adoption has already been shown to significantly benefit utility ratepayers and V2X technology can further those benefits.12 For example, a 2018 CEC study projects $1 billion in annual ratepayer benefits if 50% of chargers were V2X capable.13 V2X technology also improves driver economics which would likely drive further EV adoption and even greater ratepayer benefits. [EPA-HQ-OAR-2022-0829-0710, pp. 4-6]

12 Electric Vehicles Are Driving Electric Rates Down, Synapse Economics, 2019, Electric Vehicles Benefit All Utility Ratepayers, Forbes, 2019 (Link: https://www.forbes.com/sites/jeffmcmahon/2019/02/01/electric-vehicles-benefit-all-utility-customers-as-much-as-their-owners/)

13 Distribution System Constrained Vehicle-to-Grid Services for Improved Grid Stability and Reliability, (Link: https://www.energy.ca.gov/sites/default/files/2021-06/CEC-500-2019-027.pdf) CEC 2018, Table 8, High PEV Forecast Scenario

The promise of bidirectional charging (AC or DC) to address air pollution, GHG emissions, and challenges to the electric grid is very significant with BEVs and PHEVS in medium-and light-duty vehicles. While we understand the desire by the EPA to simplify the regulation and reduce the use of bonus multiplier credits, we believe a small bonus credit in this regulation is justified and needed to unlock this technology because of the large emissions reduction benefits and other grid services enabled by bidirectional charging as described in Section II above. The EPA has a long history of providing multiplier credits to emerging technologies and we strongly encourage the EPA to adopt in the final regulation a modest multiplier credit for light-duty and medium-duty passenger vehicles that appropriately phases out over time. This multiplier should apply to automakers with vehicles that have on-board AC inverters for bidirectional charging and for vehicles that can show they have integrated with many brands of off-board DC fast chargers. This approach will not only will help enable the emerging V2G industry, but it will also help consumers achieve lower operating costs,16 reduce GHG and traditional pollutants from fossil fueled power plants by shifting electricity use to renewable energy in the cleanest hours of the day, and reduce the need for high-emitting peaker plants. V2G also provides a zero-emission, lower cost alternative to high-emitting portable back-up generators, and saves utility ratepayers money with a low-cost resource as compared to battery stationary storage. [EPA-HQ-OAR-2022-0829-0710, p. 8]

16 See footnote 11

By implementing our recommendations, the EPA has a unique opportunity to help the emerging V2G industry, consumers, and the power generation and transportation industries. Fermata Energy appreciates the opportunity to provide these comments and welcomes a more in-depth dialogue on this and offers itself as a resource on V2X topics for EPA. [EPA-HQ-OAR-2022-0829-0710, p. 8]

Organization: Ford Motor Company

Ford is enthusiastic and optimistic about the ICE-to-ZEV transition, and we are already delivering electrified light-and medium-duty EVs at scale. While we remain optimistic, we are also mindful of the considerable challenges and uncertainties that lie ahead. The pace of electrification has been and may continue to be limited by many factors and forces, many of which are outside the control of vehicle manufacturers. These include the availability of critical minerals for battery manufacturing, the need to allocate finite resources between EV programs and efforts toward incremental reductions in emissions from ICE vehicles, consumer demand especially as we proceed beyond early-adopters to the majority of new vehicle purchasers, economic turbulence, geopolitical events, and, of course, electric vehicle charging infrastructure. [EPA-HQ-OAR-2022-0829-0605, pp. 2-3]

Charging infrastructure is not currently adequate to support even a fraction of the higher EV population that the US will have in the coming years. While federal and state programs are improving the availability of charging infrastructure, there will continue to be hesitation from many prospective EV buyers due to real (and perceived) lack of adequate infrastructure, and that will limit EV growth. [EPA-HQ-OAR-2022-0829-0605, p. 7]

Organization: Fred Reitman

No charging infrastructure. Cars and trucks run low on gasoline and need refueling. Electric batteries run down and need recharging. Here the similarities end. The infrastructure to refuel gasoline and diesel-powered engines has been in place for over half a century so locations to quickly refuel are abundant in urban areas and even in rural areas are sufficient. By contrast there are comparatively few on-road locations to recharge EV batteries. The batteries take a long time to recharge, and recharging cannot even begin until vehicles already in line have charged. Wait times can easily exceed an hour. People are busy and don’t have the time to sit and wait. They have to get to work. They have to pick up the kids. And many other things. The idea of mandating EVs before there are enough locations to recharge batteries is not acceptable. [EPA-HQ-OAR-2022-0829-0432, p. 1]

Electric grid cannot support this. The electric grid is remarkable engineering. But there is little reserve capacity and the grid is overtaxed. EV charging will stress the grid and is sure to result in brownouts and blackouts, which are dangerous during winter when power is needed for heating homes. Brownouts and Blackouts are already a problem in some states. This rule if finalized would only make the problem worse. [EPA-HQ-OAR-2022-0829-0432, p. 1]

Organization: GROWMARK, Inc.

Our system's approach to fuel and energy business is to provide the fuel and energy sources that our customers want and use. We do not prefer or advocate for one technology over the other, but we feel that the proposed rule will cause a tremendous burden on farmers and rural Americans, where the lack of charging infrastructure will make the conversion to EVs at the rates necessitated by this proposed rule extremely difficult. Furthermore, current EVs lack the capabilities that internal combustion engine (ICE) vehicles currently have, which are vital for farmers as they work to feed our nation and the world. Additionally, we feel that the prioritization this proposed rule places on EVs ignores the tremendous potential of biofuels as a low-carbon fuel source, especially given the current realities of carbon intensity for EVs and biofuels. [EPA-HQ-OAR-2022-0829-0560, p. 1]

Lack of Charging Infrastructure in Rural Areas

Rural America lacks the charging infrastructure needed to support the adoption of EVs at the level that would be required by these standards. According to the most recent trend report from the National Renewable Energy Laboratory, rural areas (which make up almost 93% of U.S. land area) have the smallest number of EV charging ports by a wide margin, and it is the smallest category in terms of growth of EV charging ports as well.2 Rural Americans would therefore be expected to travel much further distances and face much greater burdens to access public charging infrastructure for EVs. [EPA-HQ-OAR-2022-0829-0560, pp. 1-2]

2 Brown, A., Cappellucci, J., White, E., Heinrich, A., & Cost, E. (2023, May). Electric vehicle charging infrastructure trends from the alternative fueling station locator: Fourth quarter 2022. National Renewable Energy Laboratory.

Organization: Growth Energy

In contrast, it is not as simple to convert to EV technology. Doing so at scale requires massive investments in both charging infrastructure and the electric power sufficient to support massive new electricity demand. Developing sufficient charging infrastructure can be difficult in rural areas and in locations where there are competing land uses. And developing additional electric power faces multiple challenges—the country will need significantly more electric capacity and, for EVs to have their intended GHG reduction benefits, that additional electric generation will need to be relatively low-carbon. For example, converting vehicles used in the Appalachian region rapidly to EVs and powering them by increasing loads on existing coal-fired power plants would not have the significant benefits claimed by the proposed rule. [EPA-HQ-OAR-2022-0829-0580, p. 6]

Organization: HF Sinclair Corporation

c. The Proposed Rule Is Not Technologically Feasible Within the Required Timeframe

The Clean Air Act does not direct EPA to drive emission standards for regulated pollutants to zero as quickly as possible. Rather, under section 202(a)(2), EPA must ensure that any standards are issued with sufficient lead time "to permit the development and application of the requisite technology, given appropriate consideration to the cost of compliance within such period."40 For EPA's aggressive PEV mandates, the "requisite technology" not only includes manufacturing the vehicles themselves but also the underlying charging infrastructure necessary to power these vehicles. Here, EPA has not demonstrated that sufficient charging stations, utilities, and other infrastructure needed to support the deployment of an electrified fleet within the Proposed Rule's contemplated timeline is possible. Without the ability to charge the PEVs EPA will be requiring OEMs to produce, the Proposed Rule is nonsensical. Furthermore, according to a recent study, 23% of 657 public charging stations in the San Francisco Bay area were broken, and a big charging company, ChargePoint, had an operational success rate of just 61%.41 [EPA-HQ-OAR-2022-0829-0579, pp. 10-11]

40 42 U.S.C. § 7521(a)(2).

41 NYT, "A Frustrating Hassle Holding Electric Cars Back: Broken Chargers," (Aug 16, 2022), available at https://www.nytimes.com/2022/08/16/business/energy-environment/electric-vehicles-broken-chargers.html.

Take Virginia as a representative example highlighting the gap between the Proposed Rule's required infrastructure and that which is actually feasible. According to a report by the Consumer Energy Alliance, attached herein, Virginia currently has 7.6 million light-duty vehicles on the road. Assuming Virginia transitions to 100% PEV by 2035, the state would need an additional 35.5 billion kWh of generation – equivalent to the generation required to power almost 70% of the homes in the state. And to maximize the zero-emission benefit of PEVs, this generation would need to come from zero-emitting sources such as nuclear or renewables (ignoring, for a moment, the energy intensity required to construct these resources). But 35.5 billion kWh corresponds to either 4 new nuclear reactors in the state or over 450,000 acres of off-shore windfarms. Neither of which is remotely feasible under the Proposed Rule.42 [EPA-HQ-OAR-2022-0829-0579, pp. 11-12]

42 CONSUMER ENERGY ALLIANCE, "Freedom to Fuel: Consumer Choice in the Automotive Marketplace," August 2023 [hereinafter, "CEA Study"]. Nor has EPA shown that the electric grid itself can meet this increased demand. As highlighted by the North American Electric Reliability Corporation ("NERC"), certain high-risk areas do not today meet resource adequacy criteria, posing significant concern about adding even more demand to the grid.43 This risk is further exacerbated by EPA's new carbon dioxide standards for fossil-fuel fired power plants, proposed shortly after the Proposed Rule and not otherwise considered in the Proposed Rule, that may rapidly phase out affordable base-load generation.44 Far from what the Proposed Rule requires, the infrastructure upgrades to support a U.S. LD fleet that is only 7% PEV would require an additional $75-125 billion, which would be passed on from utilities directly to customers.45 Today, energy insecure households, defined as those that are unable to adequately meet basic household energy needs because of cost, pay 26 cents more per square foot in energy costs as compared to energy secure households.46 This disparity will only increase as infrastructure upgrades to accommodate the increased load from PEVs is passed along to ratepayers.

43 North American Electric Reliability Corporation, 2022 Long-Term Reliability Assessment (Dec. 2022), 21, available at https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2022.pdf (indicating that increased demand projections may lead to reliability concerns for the electric grid, especially as dual-peaking or seasonal peaking times change with increased electrification).

44 See Proposed Rule, “New Source Performance Standards for Greenhouse Gas Emissions From New, Modified, and Reconstructed Fossil Fuel-Fired Electric Generating Units; Emission Guidelines for Greenhouse Gas Emissions From Existing Fossil Fuel-Fired Electric Generating Units; and Repeal of the Affordable Clean Energy Rule,” 88 Fed. Reg. 33,240 (May 23, 2023).

45 CEA Study at 8 (noting that the average price to consumers in New Mexico would be $117-195 per year).

46 EIA, “U.S. energy insecure households were billed more for energy than other households,” (May 30, 2023) available at https://www.eia.gov/todayinenergy/detail.php?id=56640.

Absent a comprehensive understanding of the interplay between PEV manufacturing and charging infrastructure, vehicle manufacturers are left in vulnerable position. If the underlying infrastructure cannot support the influx of PEVs, or if consumers perceive the requisite infrastructure is not available or reliable, consumers will simply not purchase PEVs in the quantities requires for OEMs to meet the proposed standards. Case in point, Toyota has publicly stated that given the three major barriers to widespread PEV adoption—1) the availability of sufficient critical minerals; 2) a sufficient nation-wide charging infrastructure; and 3) overall affordability—“the most immediate way to reduce carbon emissions is through a mix of electrified options, which includes battery electric, plug-in hybrid, and hybrid vehicles.”47 [EPA-HQ-OAR-2022-0829-0579, pp. 11-12]

47 Forbes, “Toyota Says Public Charging Not Ready for Pure EVs,” (May 20, 2023) available at https://www.forbes.com/sites/brookecrothers/2023/05/20/toyota-admits-inconvenient-truth-about-electric-vehicle-ev-charging-time-prius-prime-rav4-prime/?sh=2b7ed7ab38b1.

As mentioned above, charging capability is a key apprehension for nearly half the U.S. consumer market. 66 Importantly, successful implementation of the Proposed Rule depends on consumer choice as much as depends on technological improvements. But, in California as an example, consumer discontinuance occurs at a rate of 20% for plug-in hybrid electric and 18% for PEVs—once again based on the dissatisfaction with the convenience or availability of charging.67 [EPA-HQ-OAR-2022-0829-0579, pp. 14-16]

66 Phillipp Kampshoff, et al., McKinsey & Co., “Building the electric-vehicle charging infrastructure America needs” (Apr. 18, 2022) available at https://www.mckinsey.com/industries/public-sector/our-insights/building-the-electric-vehicle-charging-infrastructure-america-needs.

67 See EPA-HQ-OAR-2022-0829-0077, Abstract (Content restricted for copyright), available at https://www.regulations.gov/document/EPA-HQ-OAR-2022-0829-0077.

Organization: Hyundai Motor America

We are also concerned the sheer scale of BEV penetration proposed through MY 2030 may not be supported by the current energy grid. In their 2030 National Charging Network report, the National Renewable Energy Laboratory found that 26-35 million electric charging ports will be necessary to support the estimated 30-42 million PEVs expected to be on the roads by 2030 nationwide. They found that affordable home charging will be the main energy source but that it “must be complemented by reliable public fast charging.” Assuming a mid-point of 33 million PEVs, they specifically estimate that 2.68 million private Level 1 and Level 2 charging ports will be needed at homes, workplaces, and multi-unit dwellings (“MUDs”), 1 million public Level 2 charging ports will be needed near homes and workplaces which include high-density neighborhoods, office buildings and retail outlets, and 182,000 public fast charging ports along highway corridors and in local communities.11 Per the U.S. Department of Energy Alternative Fuels Data Center, there are currently 54,078 public charging stations comprised of both Level 2 and direct current fast charging ("DCFC").12 Assuming roughly that each station has 2 ports (this varies by charging station), there are currently 108,156 charging ports showing a need for 891,844 Level 2 charging ports in 7 years. [EPA-HQ-OAR-2022-0829-0599, pp. 3-4]

11 "The 2030 National Charging Network: Estimating U.S. Light-Duty Demand for Electric Vehicles Charging Infrastructure," Page 6, National Renewable Energy Laboratory, June 27, 2023.

12 Alternative Fuels Data Center, Electric Vehicle Charging Station Locations, Accessed June 28, 2023.

In addition, state readiness to successfully implement the ACC II ZEV Regulation remains an outstanding question. We are concerned there simply is not enough time to delivery key infrastructure to support the ACC II ZEV Regulations in Section 177 States ("S177 States"). Many of the current S177 States that have adopted the ACC II ZEV Regulation lack the necessary charging infrastructure to support even the MY 2026 ZEV requirements. Further, several states are on track to become first-time S177 States and are significantly even farther behind in terms of infrastructure and other supportive ZEV policies to ensure regulatory success. To the degree the No Action case assumes equal success of the ACC II ZEV Regulations among S177 States, it overlooks the realities on the ground. These assumptions carry forward risk into the Proposed Rule with an overly ambitious objective for BEV penetration ramp from the current starting point nationwide of under five percent BEV sales today.13 For purposes of forecasting the No Action case, we caution against equating compliance credits 1:1 with BEV penetration. Notably, the ACC II ZEV Regulation includes PHEVs and FCEVs – coincidentally consistent with Executive Order 14037. These are just a few assumptions we encourage the EPA to reconsider in its No Action case. [EPA-HQ-OAR-2022-0829-0599, pp. 3-4]

13 Experian EV Registration database, 2022 Calendar Year through Q1 2023 Calendar Year. Accessed May 10, 2023.

State Investment and Readiness is Paramount.

We appreciate the Administration's commitment to supporting EV infrastructure development through the enactment of the Infrastructure Investment and Jobs Act, Pub. L. 117-58 (enacted 2021). However, infrastructure sufficient to support the BEV penetration levels in the Proposed Alternative would have required significant funding and planning well before 2021. Long lead times to approve and build federal and state EV infrastructure represent the biggest barrier to establishing a robust national PEV charging network by 2030. A significant percentage of U.S. drivers continue to be apprehensive about BEVs citing range anxiety and charge time concerns, underscoring the urgent need to vastly expand charging infrastructure – including significant public investments in DCFC. To meet the BEV penetration rates in the Proposed Alternative, we will need to increasingly attract customers with limited or no at home charging capabilities. For these reasons, extensive national charging availability presents perhaps the most daunting consumer hurdle to PEV adoption. [EPA-HQ-OAR-2022-0829-0599, pp. 4-5]

At Hyundai we are proud to offer our customers two-year complimentary free charging through Electrify network of over 3,000 EV chargers, coast-to-coast.14 Hyundai's Electrify America partnership not only results in customer savings but also helps to ease range anxiety. Such infrastructure efforts and incentives by automakers are important to demonstrate commitment to PEV technology and to our customers but they are no substitute for the larger scale solutions that must come from federal and state acceleration of these networks to enable the bold vision of the Administration. Non-S177 States are particularly important, not only with regard to infrastructure but also for financial assistance (e.g., state incentives for vehicles and charging) and PEV consumer education. All these policies must work in lock step to achieve EPA's goal. To date there is not enough investment, planning, and coordination to achieve the BEV targets set forth in the Proposed Alternative. [EPA-HQ-OAR-2022-0829-0599, pp. 4-5]

14 Hyundai's Electrify America Program.

Organization: Illinois Corn Growers Association

Enormous advances have been made in electric vehicle technology in the last two decades and there is strong auto industry commitment to eventually replace internal combustion engine powered vehicles with electric ones. There are, however, still technological and economic challenges in creating products that meet consumer expectations. In addition, there are many things that must happen to support electric vehicles, many of which are outside the control of automakers. [EPA-HQ-OAR-2022-0829-0532, pp. 1-2]

These include: [EPA-HQ-OAR-2022-0829-0532, pp. 1-2]

-Increasing the electrical generating capacity in the U.S to provide the power to replace the energy now supplied by gasoline.

-Switching the source of energy used to generate this electricity from fossil fuels to zero-carbon sources such as wind, solar, nuclear and hydroelectric.

-Upgrading the electrical grid to move this additional power from the point of generation to the point of vehicle recharging.

-Installing recharging stations in nearly every home with an electric vehicle and enough public charging stations to give electric vehicles the same utility as the gasoline powered vehicles they are intended to replace.

-Securing enough raw materials to build the large batery packs needed to give electric vehicles the range consumers demand.

-Upgrading the nation's roads, bridges and parking structures to ensure they can absorb the extra weight of inherently heavier electric vehicles. [EPA-HQ-OAR-2022-0829-0532, pp. 1-2]

Thus, even if in the next eight years automakers, suppliers and retailers can retool their businesses to supply an estimated 7.5 million new vehicles in 2032 and beyond, it is far from assured that: [EPA-HQ-OAR-2022-0829-0532, pp. 1-2]

-The marketplace is willing to buy that many vehicles in spite of their higher purchase cost, charging requirements, limited utility and extremely high batery replacement costs.

-The mines can extract enough raw materials to build the bateries necessary to build these vehicles, especially since it is expected that electric utilities will be buying huge bateries made of the same materials to deal with the intermit nature of wind and solar energy.

-The electric utilities can provide enough electricity.

-The electric grid has been upgraded to handle the new demand, again considering that not only vehicles but residential and commercial heating systems, railroads and even ships will be converting from fossil fuels to electricity. [EPA-HQ-OAR-2022-0829-0532, pp. 1-2]

Given the uncertainty that automakers can meet the proposed Multi-Pollutant Emissions Standards through electric vehicles alone, what other new technologies are available for compliance? [EPA-HQ-OAR-2022-0829-0756, p. 3]

Organization: Illinois Farm Bureau (IFB)

These independent comments shared the following sentiments to USEPA: [EPA-HQ-OAR-2022-0829-0532, pp. 1-2]

- “Rural America does not now have any of the infrastructure to implement this proposed rule, nor will it ever have the infrastructure to support an all-electric fleet. Because of the distances we have to travel to access goods and services and the small population base, it will never be economically feasible to put the needed charging infrastructure in place.”
-“Not enough thought has gone into the negative side of EV vehicles. So many resources will have to be put into the infrastructure of new charging areas while there is already a system in place. With the unreliability of electricity in rural areas, EVs will put many in danger during times of emergency. Rural areas have many more miles that need to be driven to get anywhere. Please put extra thought into how this affects everyone, not just cities.” [EPA-HQ-OAR-2022-0829-0532, pp. 1-2]

-“If thought through, individuals would realize that EVs are not environmentally efficient nor cost-effective. The mining of resources for batteries is not environmentally friendly.” [EPA-HQ-OAR-2022-0829-0532, pp. 1-2]

Organization: International Council on Clean Transportation (ICCT)

EPA’s proposed rule, along with sustained commitments will help build out the charging infrastructure needed to support accelerated electrification.10 Norway – the world’s electric vehicle sales share leader – achieved nearly 80% EV sales in 2022 with one public charger for every 26 EVs.11 Significant resources are already being dedicated to charging in the United States, including the $7.5 billion allocation from the IIJA as well as several billions of dollars in power utility and private sector investment.12 For example, British Petroleum announced plans to invest $1 billion in EV charging in the U.S. by 2030.13 Automakers are investing too – GM, working with its dealers, aims to install up to 40,000 public charging stations across the U.S. and Canada.14 Globally, Bloomberg New Energy Finance expects $100 billion to be spent to grow charging infrastructure in the next 3 years alone.15 In parallel, state infrastructure planning is underway, with all 50 states, DC, and Puerto Rico submitting and receiving approval for their National Electric Vehicle Charging Network plans in 2022.16 New research by WSP and EDF find that the expected growth in public charging from announced deployments will provide at least 70% of the infrastructure needed by 2030 to meet the BEV projections in EPA’s proposal; for DC fast chargers, the announced investments sum up to over 100% of the amount needed by 2030.17 These announcements and investments indicate that the pace and scale of U.S. charging infrastructure deployment is on track to support the projected BEV market shares in EPA’s proposal. [EPA-HQ-OAR-2022-0829-0569, pp. 8-9]

B. Charging Infrastructure

Adequate charging infrastructure is crucial to support electrification of the auto industry. The EPA must incorporate a more realistic projection of charging infrastructure build-out in the proposed standards. We are concerned that the EPA relies too heavily on the projected federal investment that is intended to support ZEV infrastructure,22 and instead, should take the sentiment of vehicle manufacturers into greater consideration. The Alliance for Automotive Innovation has made clear that current charging infrastructure is not enough to support compliance with the proposed standards.23 According to the DOE's most recent report on EV charging infrastructure trends the rate of charging infrastructure deployment is not paced to meet the Biden Administration's goal of 500,000 charging ports by 2030.24 This uncertainty highlights the need for flexibility. [EPA-HQ-OAR-2022-0829-0614, pp. 8-9]

22 Id. at 29294 ("New legislation also has provided significant incentives for both the manufacture and purchase of PEVs, and the expansion of charging infrastructure").

23 Alliance for Auto Innovation, Auto Perspective on Coming EPA Emissions Rules (April 6, 2023), https://www.autosinnovate.org/posts/communications/Auto%20Perspective%20on%20Coming%20EPA%20Emissi ons%20Rules.pdf.

24 Brown, Abby, Jeff Cappellucci, Emily White, Alexia Heinrich, and Emma Cost. 2023. Electric Vehicle Charging Infrastructure Trends from the Alternative Fueling Station Locator: Fourth Quarter 2022 at viii.. Golden, CO: National Renewable Energy Laboratory. NREL/TP-5400-85801. https://www.nrel.gov/docs/fy23osti/85801.pdf.

The proposed standards should better reflect that federal investment and incentives will take time to reach maturity and that the market and consumer demand will lag further behind. To put it simply, customers will not purchase ZEVs unless charging infrastructure and energy costs fit their needs and lifestyles, no matter what vehicles manufacturers offer customers. Given this uncertainty, GHG standards could also incorporate flexibilities for manufacturers should national charging infrastructure and grid capacity not meet the necessary levels to support compliance. We strongly encourage the EPA to modify the standards to better reflect the availability of charging infrastructure. [EPA-HQ-OAR-2022-0829-0614, pp. 8-9]

Organization: Jack Spencer

Even should low-income Americans procure an EV, their lack of access to charging stations will likely further diminish any potential fuel savings. The proposed rule's Draft Regulatory Impact Analysis acknowledges on page 11-12 that low-income households often will not have access to residential charging stations and will therefore have higher fuel costs and "larger overall energy burden." [EPA-HQ-OAR-2022-0829-0681, p. 3]

Organization: Jaguar Land Rover NA, LLC (JLR)

Relationship to Other Regulations

The targets proposed by EPA are extremely ambitious and the projected BEV penetrations required to meet the standards exceed that of the California Air Resources Board (CARB) Advanced Clean Cars II regulation, with a trajectory to achieve 100% ZEV by 2035MY (as shown in Figure 3 below). [EPA-HQ-OAR-2022-0829-0744, pp. 7-8]

In 2022, California's ZEV market share was over three times higher than the federal US BEV share.9 It is important that EPA acknowledges the inequality between California and non-S177 states. CARB are a world leader in the pursuit of the 100% ZEV goal, with years of incentives and effort involved to get to this point. EPA cannot assume that all states will follow a similar route and the regulation must balance the various adoption curves across the country. [EPA-HQ-OAR-2022-0829-0744, pp. 7-8]

9 Office of Governor Gavin Newsom -California ZEV Sales Near 19% of All New Car Sales in 2022(Jan 2023) https://www.gov.ca.gov/2023/01/20/california-zev-sales-near-19-of-all-new-car-sales-in-2022/

Targets imposed on the automotive industry must be linked to and contingent on the successful roll-out of a comprehensive and accessible charging infrastructure network. The current ratio of public chargers in the US is around 1 charger for every 24 EVs11. While we recognize progress made to date in the roll-out of charging infrastructure, it is vital that this grows proportionally with the increase in uptake of EVs to remain within the EU recommended ratio of 1 public charger per 10 vehicles12 especially as these ratios are based on countries with a much greater population density compared to the United States. With more than 131,200 public chargers across the US, half (65,300) of them are concentrated across five states. (California, New York, Florida, Texas and Massachusetts)13 [EPA-HQ-OAR-2022-0829-0744, pp. 7-8]

JLR urges EPA to re-evaluate the proposed stringency of the regulation so that the required BEV share does not exceed CARB's targets. [EPA-HQ-OAR-2022-0829-0744, pp. 7-8]

Organization: John Graham

Third, building a robust national network of public charging stations for BEVs will not occur overnight. There are no good business models for public charging in rural areas and small towns; and, as yet, there is no practical solution for millions of people who live in multi-unit dwellings with no place at home to charge their BEVs. [EPA-HQ-OAR-2022-0829-0585, p. 9]

Organization: Kentucky Office of the Attorney General et al.

Furthermore, the Proposed Rule implicates "question[s] of deep economic and political significance," King v. Burwell, 576 U.S. 473, 486 (2015), due to the huge "number of people affected," United States Telecom Ass'n v. Fed. Commc'ns Comm'n, 855 F.3d 381, 423 (D.C. Cir. 2017) (Kavanaugh, J., dissenting from the denial of rehearing en banc). Because "Americans place a high value on car ownership," almost 92% of households have at least one vehicle, and over 22% have access to at least three. Car Ownership Statistics 2023, Forbes (May 8, 2023), https://bit.ly/3NnPXnn. A regulation affecting so many people is bound to collide with "a significant portion of the American economy," West Virginia, 142 S. Ct. at 2608 (cleaned up), and require "billions of dollars in spending by private persons or entities," id. at 2621 (Gorsuch, J., concurring) (quoting King, 576 U.S. at 485). By EPA's own estimate, technology increases "through 2055 are estimated at $260 billion to $380 billion." 88 Fed. Reg. at 29,344. [EPA-HQ-OAR-2022-0829-0649, pp. 6-7]

The Proposed Rule somewhat attempts to deal with this concern by predicting that sales will increase as consumers become more familiar with EVs as they see broader "charging infrastructure" and more electric cars "on the road." 88 Fed. Reg. at 29,189. But that raises another buyer-focused concern that makes it even less likely consumers will change their purchasing habits to the extreme degree EPA predicts. For people who "rely on street parking," park in a garage over 25 feet from a power source, or own a condo where the building association is not willing to "pay for upgrading the electrical panel or service," where and how to charge a new electric car is a real concern. Rachel Kurzius, Considering an electric vehicle? Here's how to prep your home for one, Wash. Post (Sept. 26, 2022), https://bit.ly/3N4Y3zZ. Even for the slowest and most basic "Level 1" charging option, potential EV customers are out of luck; their "home probably can't accommodate" an EV. Id. And those who are able to upgrade their home parking situations may find themselves in a long line as the need for more complex and expensive charging mechanisms grows at a fast clip. See EV Chargers: How many do we need?, S&P Global (Jan. 9, 2023), https://bit.ly/3X1xFeM (predicting that the EV population uptick will require "about 700,000 Level 2 and 70,000 Level 3 chargers deployed, including both public and restricted-use facilities," 1.2 million and 109,000 nationally by 2027, and 2.13 million and 172,000 by 2030, "all in addition to the units that consumers put in their own garages"). [EPA-HQ-OAR-2022-0829-0649, pp. 15-16]

Even those who already own EVs may be in for some unpleasant surprises. A recent study concluded, for example, that "[t]he vast majority of electric vehicle owners [who] charge their cars at home in the evening or overnight" are "doing it wrong" and should instead "move to daytime charging at work or public charging stations" so as to not overwhelm the grids. Golden, supra. But standard electricity pricing "charg[es] commercial and industrial customers big fees based on their peak electricity use." Id. "This can disincentivize employers from installing chargers, especially once half or more of their employees have EVs." Id. Some of these vehicle owners may thus be left in a vehicle-charging no-man's land. [EPA-HQ-OAR-2022-0829-0649, pp. 15-16]

Organization: Kevin Murphy

I'm interested in participating in the public hearing on vehicle emissions standards. [EPA-HQ-OAR-2022-0829-0440, p. 1]

I am now driving my second hybrid, and I have an EV on order. For short drives, under 30 miles round trip, my hybrid is fully electric. For long drives the car's hybrid mode gets 10 mpg more than the all-gas mode. Charging stations are not easily available -limited in number, high percentage of them out of service, the demand for roadside recharge is high, the time required to recharge is long. Long range Hybrids are the way to go. [EPA-HQ-OAR-2022-0829-0440, p. 1]

Organization: Kia Corporation

EPA Underestimates Market and External Challenges

EPA's proposed rule highlights the very complex challenges that lie ahead for the EV market. There are an enormous number of factors that are outside the control of automakers including manufacturing capacity, battery production, charging infrastructure, critical mineral supply, and consumer acceptance. A successful transition in the timeframe proposed will require massive changes in commitments from all sectors of the economy: vehicle suppliers, labor, utilities, charging infrastructure, home builders, mining, and mineral processing. Consumer behavior and acceptance also needs to significantly change. [EPA-HQ-OAR-2022-0829-0555, p. 6]

EPA's proposal requires automakers to sell EVs but does not propose any requirements to ensure adequate charging infrastructure to homes, highways, or businesses, or mandate utilities to have adequate capacity or provide reasonably priced high-power charging, or mandate easily accessible and affordable battery critical minerals for EV batteries. Government policies need to start today to ensure there are enough critical minerals for batteries and high-power charging. Unfortunately, there is not yet a roadmap to developing these and other essential pieces to the transition. [EPA-HQ-OAR-2022-0829-0555, p. 6]

All of the above market challenges will need to have complementary policies supporting all of the sectors outside the vehicle industry including utilities, mining, charging companies and will require them to meet targets too. It is critical that EPA take these factors into consideration when setting standards. [EPA-HQ-OAR-2022-0829-0555, p. 6]

Organization: Marie Gluesenkamp Perez, and Mary Sattler Peltola, Members of Congress, Congress of the United States

We are writing to express our concerns about the impacts the Environmental Protection Agency's (EPA) new proposed rules, Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles and Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3 may have on rural communities. [EPA-HQ-OAR-2022-0829-0522, p. 1]

Like you, we believe climate change is a threat to communities across the country, and the federal government plays a critical role in developing a clean energy apparatus and helping our communities improve air quality. However, in making that transition, we cannot leave rural communities or working families behind. The administration's Executive Order 14037 and subsequent National Blueprint for Transportation Decarbonization set an ambitious goal for 50 percent of new passenger cars to be electric vehicles (EVs) by 2030. Last year's Inflation Reduction Act included many concrete policies promoting EV production that will drive costs down and improve affordability. We are concerned the EPA, along with the Department of Transportation (DOT) and the Department of Energy (DOE), have not done enough work to ensure rural communities will have the necessary charging infrastructure in place to make widespread EV adoption possible. The imposition of additional regulations in the auto market without key infrastructure investments will reduce consumer choice, which is a recipe for disaster in rural America. [EPA-HQ-OAR-2022-0829-0522, p. 1]

Rural communities, like ours, have more unique transportation and service options compared to cities or suburbs. Like many people who live in rural America, we spend a fair amount of time traveling, whether on or off the road system to get where we need to go. When your job, your pharmacy, or your child's daycare is over an hour away, you need to know that your car, snow machine, or ATV, will get you there and back. The ability to refuel a gas-powered vehicle quickly is valuable given the daily realities of rural life. That option is available because our country has a robust network of gas stations, and the requisite gas infrastructure, to support communities of all kinds. An equally robust infrastructure for EV charging must exist before this transition takes place to ensure working people and rural communities have consumer choices similar to cities and suburbs. And that infrastructure, especially fast-charging options, is not being built fast enough in many rural areas. EV charging programs included in the Infrastructure Investment and Jobs Act will help, but federal agencies remain focused on travel corridors along interstate highways, leaving many rural communities behind. [EPA-HQ-OAR-2022-0829-0522, pp. 1-2]

Washington's third congressional district has fewer than 100 level 2 and DC fast chargers available to the public, and they are largely concentrated in just two cities. Alaska has only 60 publicly available EV charging stations. In Congresswoman Gluesenkamp Perez' home county of Skamania, there are only two EV charging stations right now, and both are located at resorts. In Congresswoman Peltola's borough of Bethel, along with all the other boroughs of Western Alaska, there are zero EV charging stations. As DOT has acknowledged, the costs of installing EV chargers in rural areas can be higher, especially for direct current fast charging stations, because they are more likely to require expensive electrical service upgrades. Furthermore, for many working families, installing an EV charger at home remains out of reach, especially for those who don't own their homes. Bottom line: for EVs to be a meaningful and workable emissions reduction solution in rural America, we must have a ubiquitous and affordable charging infrastructure with access to abundant, cheap electricity. That simply does not exist right now. [EPA-HQ-OAR-2022-0829-0522, p. 2]

We are only four years away from model year 2027, and we are concerned the EPA's regulations are not paired with a plan to ensure adequate charging infrastructure on such a short timeline. Installing hundreds of thousands of new EV chargers and upgrading associated electrical infrastructure will also require tens of thousands of electricians. We are already experiencing a nationwide shortage of qualified electricians – anyone who's currently waiting six months for a residential electrician knows this all too well. Workforce shortages, particularly for those in the trades, are even more acute in rural communities. We want to ensure the EPA has considered the significant workforce development challenges that must be addressed to train electricians for a large-scale roll out of EV charging infrastructure. [EPA-HQ-OAR-2022-0829-0522, p. 2]

We request that the EPA, DOT, and DOE respond to the following questions: [EPA-HQ-OAR-2022-0829-0522, pp. 2-3]

1. What have the EPA, DOT, and DOE done to ensure rural communities are not left behind in the transition to electric vehicles?

2. Is there a clear and detailed deployment plan for electric vehicle charging infrastructure in rural areas?

3. How do the EPA and DOE anticipate potential shortages of trained electricians will impact the deployment of charging infrastructure? Further, have agencies evaluated the disparate impacts these shortages may have in rural communities?

4. Beyond using limited Inflation Reduction Act funding, how do the EPA, DOT, and DOE plan to address existing and future shortages of trained electricians?

5. Going forward, how do the EPA, DOT, and DOE plan to work together to ensure public charging infrastructure is abundant and accessible in rural areas? [EPA-HQ-OAR-2022-0829-0522, pp. 2-3]

We also request that you share how you plan to deploy necessary EV charging infrastructure in a timeframe that matches the implementation of the proposed rules. Building out this infrastructure will ensure that rural communities are not disproportionately impacted and left behind in a changing market. While it is critically important that we move toward a clean energy future, it must be a future that works for all Americans, including those in rural areas. [EPA-HQ-OAR-2022-0829-0522, pp. 2-3]

Organization: Mass Comment Campaign sponsoring organization unknown (118 signatures)

I am writing to express my opposition to the proposed tailpipe emissions rule outlined in EPA-HQ-OAR-2022-0829. As proposed, I believe these regulations for light-duty vehicles go too far, reduce consumer choice, and fail to include safeguards to address serious infrastructure, resource, and funding shortfalls. [EPA-HQ-OAR-2022-0829-1701]

Firstly, the country's current charging infrastructure is inadequate to support a forced shift towards electric vehicles. Charging infrastructure is not yet fully developed or accessible in many regions of the country. Forcing consumers to transition to EVs without ensuring sufficient charging infrastructure could place undue burdens on drivers across the country. [EPA-HQ-OAR-2022-0829-1701]

Organization: Mazda North American Operations

The proposed rule is the most stringent light duty vehicle regulation that EPA has promulgated to date. The electrification and carbon reduction goals are incredibly challenging and will require not just a coordinated effort to achieve but also solutions addressing consumer demand, affordability, charging network, power grid capacity, rare earth mineral availability, and striking the right balance regarding China policy [EPA-HQ-OAR-2022-0829-0595, p. 2]

Summary

Mazda is proud of its heritage and contributions to personal mobility, and we celebrated our 100th anniversary in 2020. Mazda has also long been an engineering leader known for innovative powertrains like the rotary engine and Skyactiv technology. [EPA-HQ-OAR-2022-0829-0595, pp. 3-4]

We look at EPA's NPRM and its preferred option through the lens of a company that is already working towards an electrified future. It's not a matter of if this transformation will happen, but when and how. Mazda, like the rest of the industry, faces many challenges: [EPA-HQ-OAR-2022-0829-0595, pp. 3-4]

-Will charging infrastructure be sufficient?

-Can the electric grid handle the increased demands?

-How will EV incentives on the federal and state level impact this shift?

-Will suppliers be able to develop and produce components like batteries (that currently require critical minerals, many from China) quickly enough and in enough volume?

-How might future laws or regulations in trade and re-shoring impact our ability to meet goals?

-Are consumers ready and willing to move away from "tried and true" internal combustion engines in numbers sufficient to meet these goals?

-Can OEMs remain sufficiently profitable to fuel the transition to EVs? [EPA-HQ-OAR-2022-0829-0595, pp. 3-4]

Mazda strongly requests that EPA take these considerations into account and make necessary adjustments to the proposed rule as it works towards a Final Rule. We feel the Final Rule should have more realistic targets and associated ramp ups, include PHEVs, and adopt CARB's current LEV IV for criteria emissions. [EPA-HQ-OAR-2022-0829-0595, pp. 3-4]

Organization: MECA Clean Mobility

EPA should work with other agencies, like the Joint Office on Energy and Transportation, in setting minimum charger efficiency standards to ensure that infrastructure funds are spent on chargers with the best utilization of electric power. [EPA-HQ-OAR-2022-0829-0564, pp. 34-35]

The prioritization of building forward-looking vehicle charging infrastructure is critical to the penetration of electric vehicles. Furthermore, analogous to vehicle electronic design and material selection impacts to electric vehicle efficiency, similar approaches can be used to improve charger efficiency in delivering the maximum power to the vehicle. [EPA-HQ-OAR-2022-0829-0564, pp. 34-35]

While overnight charging at lower power may be appropriate for most light-duty vehicle use and certain medium-duty vehicle applications, we recommend the EPA prioritize the planning and building of direct current fast chargers (DCFC). The planning of public DCFCs is indispensable to allow in-service electric vehicles to address unforeseen day-to-day vehicle use variables (i.e., weather, traffic conditions, needed route changes, etc.). The availability of strategically placed, publicly accessible DCFCs prevents vehicles becoming inoperable due to these use variables, allowing vehicles to be rapidly charged and quickly placed back into service while minimizing interruptions to vehicle operations, traffic disruptions from vehicle strandings and maximizing the utilization of available space for heavy-duty vehicle recharging. [EPA-HQ-OAR-2022-0829-0564, pp. 34-35]

DCFC is also crucial to address long-term medium-duty vehicle charging needs. Many commercial EVs will need to achieve fast charging times to encourage fleet owners to transition to e-mobility. This is particularly true for those vehicle operators who do not have access to charging at their own facilities. EV fleet adopters with slower rate overnight charging should also diversify their charging assets with DCFCs to have more flexibility as their fleets grow and unforeseen needs arise to charge vehicles and return them to service. [EPA-HQ-OAR-2022-0829-0564, pp. 34-35]

Additionally, DCFCs futureproof infrastructure investments by allowing fleet operators to immediately convert and deploy BEVs while also allowing them to remain up to date with advancements in battery technology. Vehicle batteries are quickly improving in size, chemistry, energy density, and efficiency resulting in increased vehicle range. This range improvement will, however, require faster charging capabilities. While medium-duty BEV vehicles typically require larger batteries with increasing power density than light-duty vehicles, DCFCs enable quicker and more efficient charging of these vehicles. In addition, site and infrastructure owners maximize their investment because DCFCs enable site-readiness for future DCFC expansions while allowing the best utilization of available space and higher turnover of serviced vehicles. [EPA-HQ-OAR-2022-0829-0564, pp. 34-35]

DCFCs also allow for bidirectional charging which futureproofs infrastructure investment further by providing support for increasing electricity demand. Vehicle-to-Grid (“V2G”) technology can help address energy use and manage peak demand times and costs, as well as serve as backup power during an outage. As EV adoption increases, this technology becomes more critical to enable sustainable grid management, grid resilience, utilization, and national security protection. [EPA-HQ-OAR-2022-0829-0564, pp. 34-35]

MECA also recommends the EPA consider national certification, such as UL Certification, for EV supply equipment to provide consistency, quality, safety, efficiency and compliance. A Certificate of Compliance will mean the product has passed a series of rigorous tests to demonstrate performance, safety, quality, and serviceability, while enhancing sustainability, strengthening security, and managing risk. National certification also supports local permitting efficiency, therefore, helps fast track deployment of charging stations. [EPA-HQ-OAR-2022-0829-0564, pp. 34-35]

For these reasons, MECA urges EPA to work with other government agencies, such as the Joint Office for Transportation and Energy, and industry to develop national standards for minimum charger efficiency which will ensure the efficient energy utilization and lowest operating cost for electric vehicles. With regards to technology, several suppliers of vehicle power electronics are applying similar electric efficiency technology innovation to the development of more efficient chargers to minimize switching losses and deliver maximum power to the battery. This is important to consumers and fleets as charging losses reduce the total energy to the battery and increase operating cost. Furthermore, it is important to the environment because these losses represent electricity that is generated but never used. The difference in electric efficiency between the first generation of chargers, that are deployed in the field today, and the advanced, second-generation chargers can be as much as 10-20%. This becomes significant as electric vehicle penetration increases into the future. [EPA-HQ-OAR-2022-0829-0564, pp. 34-35]

Organization: MEMA, The Vehicle Suppliers Associated

The success of our industry is interwoven with the success of this proposal and the ability of the government to work with industry and other stakeholders to meet significant challenges. Therefore, the rule must address: [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

• The need for regulatory certainty. The final rule must contain an effective mix of feasible, demonstrated technology along with emerging technology, leaving options to improve emissions reductions in today's advanced propulsion designs. This will foster innovation in a coordinated direction, aligned with U.S. policy, but not mandate application of a narrowly defined technology path to make a positive impact on the country's urgent environmental goals. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

• The influence of other technologies -including internal combustion engines fueled by hydrogen and other renewable carbon-neutral fuels -which can impact measurable environmental improvements at scale technologies can provide immediate improvement to the environment. This is important not only for environmental improvements but for environmental justice in providing cleaner consumer vehicles immediately to communities living and working close to busy streets, highways, and other transportation networks. Inclusion of all technologies that can decarbonize the transportation sector will foster the necessary growth in manufacturing capacity, vocational performance, infrastructure improvements, and consumer acceptance. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Technology Neutrality and BEV Emissions. EPA should ensure that battery electric vehicles (BEV) are included in metrics for vehicle-to-vehicle comparison by assigning a metric that captures the pollutant emissions related to BEV operation, aligned with national electricity generation figures. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Challenges in our nation's infrastructure and power grid. MEMA appreciates the significant public investments being made to support clean transportation infrastructure. As these new investments in highways and main corridors are deployed, federal and state incentives are needed to further expand the EV charging and refueling infrastructure in areas that connect these major thoroughfares. Urban industrial centers will need focused buildout while rural areas will need thoughtful rollouts to achieve an effective EV charging infrastructure. These buildouts must include Direct Current Fast Charge (DCFC) and vehicle-to-grid (V2G) bidirectional charging. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Supply chain challenges. The proposed rule assumes that all materials advanced vehicles, which are not available today in the quantities needed to support the massive growth in vehicle construction, will become available within sufficient time. This places a significant and unnecessary risk on manufacturers and suppliers. Furthermore, once a company has converted production to new technology lines, that company cannot easily pivot its facilities and workforce back to the previous technology if EPA projections are not realized by the mid-to-late-2020s. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Workforce challenges. A significant increase in skilled workers will be needed to support the implementation of this rule and long-term success thereof [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Extended warranty. The necessity to clearly define the applicability of the extended warranty and the need to provide repair access to service these new vehicles. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

MEMA members are working to accelerate the performance and availability of clean-operating vehicle technologies and are directly contributing to their realization. Besides battery electric options, effective low-and zero-carbon technologies for future and current in-use vehicles also exist and can readily be put to use to reduce nationwide emissions and help EPA meet its climate goals. The success of this rule depends on greater inclusion of all available emissions reduction technologies, significant investment in infrastructure, careful understanding and investment in the domestic and global supply chain and ensured repair access to serve the improved and enhanced domestic vehicle fleet. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

Infrastructure

To achieve the ambitious vision for U.S. charging infrastructure needed to rapidly electrify a high proportion of new vehicles, as noted above, EPA must work closely with other U.S. government agencies to help ensure that the dozens of programs in the Inflation Reduction Act (IRA) and Bipartisan Infrastructure Law (BIL), and others still needed to support the transition, are effectively deployed by the federal government. While it is true that agencies are -so far -

rolling out these programs expeditiously, strong coordination of these initiatives is needed to realize nationwide transportation transformation. [EPA-HQ-OAR-2022-0829-0644, p. 11]

V2G bidirectional charging technologies can provide a transformational opportunity to help address the nation's energy crisis while also decarbonizing the transportation sector. The use of bidirectional charging installations, for fleet and private vehicles, can help stabilize local grid activity and balance load versus demand.9 Besides grid load balancing, the use of vehicle batteries as energy sources can also offset local energy production demands and further improve grid resiliency and national security. [EPA-HQ-OAR-2022-0829-0644, p. 11]

9 This notice is one example of "grid services vehicles can provide" according to the US DOE https://content.govdelivery.com/accounts/USEERE/bulletins/3594aae

EPA should include deployment of Direct Current Fast Chargers (DCFCs) and bi-directional charging impacts and benefits in the RIA. While overnight charging at lower power may be appropriate for certain applications, DCFCs can better meet the long-term charging needs of consumers and fleet operators of light-duty and medium-duty vehicles. Many EVs will need to achieve fast charging times to encourage consumers, fleet owners and operators to transition to electric vehicles. Further, medium-duty vehicles often have duty cycles that require faster, higher power charging due to their on-demand jobs. DCFCs can help address these charging time and operator confidence issues. Similarly, providing a diversity of charging options to all EV adopters offers access and flexibility which facilitates consumer confidence in EVs and help futureproof infrastructure investments. [EPA-HQ-OAR-2022-0829-0644, pp. 11-12]

With respect to existing fleet and future ICE vehicles sales, we note the European Union is exploring renewable fuels as a way to reduce net emissions and decrease dependency on outside energy sources.10 The U.S. can do the same, and EPA can and should lead this initiative. [EPA-HQ-OAR-2022-0829-0644, pp. 11-12]

10 https://europe.autonews.com/environmentemissions/eu-german-deal-outlines-legal-path-e-fuel-future

The European Union Alternative Infrastructure Regulation has made significant requirements on states. making the necessary infrastructure investment. [EPA-HQ-OAR-2022-0829-0644, pp. 11-12]

As an example of how EPA might compel State and Regional infrastructure buildout, we note below how the European Union has approached this challenge: [EPA-HQ-OAR-2022-0829-0644, pp. 11-12]

As part of EU's "Fit for 55" package the EU has agreed on a direction forward March 2023 that ensures fast charging availability at distance-based intervals along the trans-European transport network (TEN-T). https://theicct.org/publication/afir-eu-april2023 [EPA-HQ-OAR-2022-0829-0644, pp. 11-12]

1) Member states will be required to ensure publicly available chargers with power output capable to support BEV deployment

2) The AFIR established targets for urban nodes for trucks and busses.

3) Member States will be required to ensure installation of a fast-charging pool every 60km in each direction along the TEN-T (Trans-European Transport Network) with milestones for completion in 2025, 2027, and 2030. [EPA-HQ-OAR-2022-0829-0644, pp. 11-12]

Additionally, in Appendix 1, MEMA has prepared a chart that reviews current CA state and federal actions to support ZEV transition. [EPA-HQ-OAR-2022-0829-0644, pp. 11-12]

MEMA urges:

• EPA to identify and address additional paths and actions within its authority to expand state and regional EV infrastructure investments, to include DC Fast Charge installations. [EPA-HQ-OAR-2022-0829-0644, pp. 11-12]

Organization: Minnesota Corn Growers Association (MCGA)

The proposed EPA standards for 2027 and later set very aggressive goals for reducing GHG and criteria emissions. Achieving these goals will require dramatic changes not only in vehicle design, but in the entire automotive supply chain. While the U.S. market share of BEVs will continue to expand, establishing regulations where success is solely contingent upon an unattainable tenfold increase in the production and sales of BEVs over the next eight years represents an avoidable mistake. The proposed rule would require huge investments and rapid growth in many industries, including the mining and processing of key minerals, the generation and distribution of electricity, and the recharging of electric vehicles. [EPA-HQ-OAR-2022-0829-0612, p. 3]

Organization: Minnesota Pollution Control Agency (MPCA)

To support the rapid electrification of our transportation system, Minnesota is making significant investments to support EV adoption, including expanding infrastructure. Minnesota recently adopted an EV purchase incentive and EV-ready building codes requirement. Other examples of EV investments in Minnesota include: [EPA-HQ-OAR-2022-0829-0557, pp. 3-4]

-The Volkswagen Corporation (VW) violated air pollution standards for its diesel cars and sport utility vehicles. As part of the national legal settlement, Minnesota received $47 million to spend on projects to replace older, more polluting diesel vehicles and install electric vehicle charging infrastructure. Minnesota has invested the maximum-allowed 15% of our VW settlement funds in electric vehicle charging. Grants have funded 60 stations statewide, bringing the total miles of EV fast-charging corridors to 3,600. All stations from the first two phases of funding will be installed by early 2024. Between 2024 and 2027, there will be $1.76 million available for additional EV charging grants [EPA-HQ-OAR-2022-0829-0557, pp. 3-4]

-The federal National Electric Vehicle Infrastructure (NEVI) program provides funds for states to build electric vehicle charging infrastructure along highway corridors. The NEVI program provides $68 million to Minnesota and requires a $17 million match. The Minnesota Electric Vehicle Infrastructure Plan describes how Minnesota will spend the first year of NEVI program funds. Minnesota's plan identifies potential exits along the I-35 and I-94 Alternative Fuels Corridors for fast charger installation. The Minnesota Department of Transportation (MnDOT) will conduct site feasibility analyses and manage a competitive site selection process in 2023 to install fast chargers at 16 sites. The Minnesota Legislature established a state electric vehicle program and provided $13.6 million in one-time funding as a match to available federal funds in the 2023 session. The program allows MnDOT to grant NEVI funds to install, operate, and maintain EV charging stations outside of highway right-of-way. Minnesotans can expect to see the first round of fast chargers installed with NEVI funds by the end of 2024. [EPA-HQ-OAR-2022-0829-0557, pp. 3-4]

-In the Twin Cities metropolitan area, the Metropolitan Council is also investing in transportation electrification. The council completed an Electric Vehicle Planning Study in 2022 to understand the marketplace and charging landscape and identify strategies to accelerate EV adoption in the Twin Cities. With the opportunity to compete for funds from the Bipartisan Infrastructure Law's Charging and Fueling Infrastructure Program, Minnesota could expand EV charging further. [EPA-HQ-OAR-2022-0829-0557, pp. 3-4]

-The Minnesota Public Utilities Commission has found that EVs are both an opportunity and a challenge for the electric power sector and has therefore directed Minnesota's investor-owned utilities to take steps to encourage cost-effective integration of EVs and plan for their adoption. Minnesota's utilities have developed and begun implementing a variety of programs to support EV adoption, including home charging and rate design, as well as public charging investments.6 [EPA-HQ-OAR-2022-0829-0557, pp. 3-4]

Organization: Missouri Corn Growers Association (MCGA)

Monumental challenges in implementing this rule.

Notwithstanding the vast challenges to everyday Americans, the aggressiveness of EPA's proposal raises immediate doubt about whether such targets are feasible within the required timeframe. The rule gives a wholly unrealistic and false impression the U.S. has a robust and reliable public EV charging infrastructure ready to accommodate the vast number of BEVs. MCGA members driving Missouri's rural roads know this is not the case. In addition, most American families will find BEVs' dismal range, extended charge time, shortage of maintenance technicians, and poor performance under heavy loads and extreme temperatures both frustrating and entirely impractical for everyday personal and business needs. [EPA-HQ-OAR-2022-0829-0578, p. 2]

Organization: Missouri Farm Bureau (MOFB)

Similar to EPA's proposed HD rule, this proposal picks winners and losers by doubling-down on electric vehicle (EV) technology, while increasing in adoption in the light-duty sector, only represents 8.4 percent of light-duty production in MY 2022.2 While the proposed rule cites a reduced total cost of ownership, EPA estimates it will raise "average upfront per-vehicle costs to meet the proposed standards to be approximately $1,200 in MY 2032, as estimated using 2020 dollars."3 The proposed rule estimates that in order for automakers to comply with the emissions standards, Battery Electric Vehicles (BEVs) will comprise up to 67 percent of new passenger vehicle sales by 2032 and up to 46 percent of medium-duty vehicle sales.4 In addition to increased purchase costs for EVs, MOFB is concerned about the lack of available public charging stations to accommodate the vast number of EVs mandated by this rule, especially in rural Missouri where most of our members live and work. [EPA-HQ-OAR-2022-0829-0590, pp. 1-2]

4 Ibid., 29189, 29331.

Organization: Mitsubishi Motors North America, Inc. (MMNA)

To determine a realistic maximum volume of EVs the market can support for each of the model years covered by the rule, we believe EPA should consider certain critical factors. Among these factors, we believe EPA must make a thorough and realistic year-by-year assessment of key factors like projected battery costs, projected supply of battery critical-minerals, projected residential and public charging infrastructure availability, projected electrical grid capacity, and consumer acceptance of BEV technology in the broader arena. [EPA-HQ-OAR-2022-0829-0682, p. 2]

Organization: National Association of Convenience Stores (NACS) et al.

II. Proposed Electrification Timelines are Unworkable.

The challenges associated with electrifying the light-and medium-duty fleet cannot be understated. EPA projects that the Proposed Rule will result in 67 percent of light-duty vehicles sold in 2032 being electric. That figure is an average of 78 percent electric sedans, 68 percent electric pickups and 62 percent electric crossover and SUVs.3 Conversely, EPA estimates that in the absence of any regulations, electric vehicles would make up only 39 percent of new sales in 2032.4 [EPA-HQ-OAR-2022-0829-0628, pp. 3-4]

3 Proposed Rule at 29,329 (Table 80).

4 Reputable estimates on how quickly EV sales will increase vary widely. S&P Global Mobility estimates that by 2030, EVs will be 40 percent of new vehicle sales. The Energy Information Administration, on the other hand, estimates that EVs will be 17 percent of new vehicle sales by 2030. McKinsey has the highest estimate and projects that EVs will be 48 percent of new vehicle sales by 2030. Given these varying estimates – all from highly respected sources – the Agency should exercise caution about consumers' willingness to purchase, and manufacturers' ability to deliver, EVs at the rates required by the Proposed Rule. Writing rules on its own does not mean that challenges related to supply chains for making the vehicles or consumer sentiment will change.

These timelines are entirely untethered from the market's capabilities. Most prospective EV drivers will need fast, high-powered on-the-go charging solutions before they're comfortable buying an EV.5 Although fuel retailers are very active in the National Electric Vehicle Infrastructure Program ("NEVI" Program) and other federal and state funding opportunities, it remains unacceptably difficult to identify a viable business case for installing EV charging stations. Unless those obstacles are permanently removed, these challenges will remain regardless of what the final rule demands. [EPA-HQ-OAR-2022-0829-0628, pp. 3-4]

5 Consumer Reports, "Battery Electric Vehicles and Low Carbon Fuel: Overview of Methodology," April 2022, https://article.images.consumerreports.org/prod/content/dam/surveys/Consumer_Reports_BEV%20AND%20LCF% 20SURVEY_18_FEBRUARY_2022.

Most of these impediments involve an electricity market structure that was not designed for – and is thus incompatible with – the retail fuel market. Many fuel retailers have installed EV charging stations at their outlets, utilizing any number of business models and ownership structures. Very few, if any, of these investments are profitable on a self-sustaining basis. The structural impediments to the profitability of public EV charging are too significant to overcome These existing investments should therefore be interpreted as “beta tests” by companies exploring the charging space, rather than indicators of a viable, sustainable business model. [EPA-HQ-OAR-2022-0829-0628, pp. 3-4]

We are confident that the right combination of policy incentives and signals will enable the market to overcome any barriers that exist today. We simply fail to understand the rationale for leaving emission reduction opportunities on the table while we work toward those aspirational objectives. The best way to address practical impediments to electrification is to inject flexibility into the Proposed Rule while simultaneously promoting near-term emissions reductions through the use of multiple technologies, including renewable liquid fuels. [EPA-HQ-OAR-2022-0829-0628, pp. 3-4]

No one solution will decarbonize transportation energy. What policymakers think is the best solution today may be surpassed by subsequent ingenuity and innovation. Sound policy should not stifle innovation by mandating specific solutions. Instead, policy should set performance goals and let the market – guided by consumers – innovate to find the best way to meet those goals. [EPA-HQ-OAR-2022-0829-0628, pp. 3-4]

II. Electrification Timelines Proposed Under the Rule are Divorced from Reality.

EPA projects that the Proposed Rule will result in 67 percent of light-duty vehicles sold in 2032 being electric. That figure is an average of 78 percent electric sedans, 68 percent electric pickups and 62 percent electric crossover and SUVs.5 Conversely, EPA estimates that in the absence of any regulations, electric vehicles would make up only 39 percent of new sales in 2032.6 The extraordinary pace of electrification mandated under this rulemaking is entirely divorced from the world in which consumers and the broader marketplace operate. [EPA-HQ-OAR-2022-0829-0648, p. 4]

5 Proposed Rule at 29,329 (Table 80).

6 Reputable estimates on how quickly EV sales will increase vary widely. S&P Global Mobility estimates that by 2030, EVs will be 40% of new vehicle sales. The Energy Information Administration, on the other hand, estimates that EVs will be 17% of new vehicle sales by 2030. McKinsey has the highest estimate and projects that EVs will be 48% of new vehicle sales by 2030. Given these varying estimates—all from highly respected sources—the Agency should exercise caution about consumers’ willingness to purchase, and manufacturers’ ability to deliver, EVs at the rates required by the Proposed Rule. Promulgation of this Proposed Rule, alone, does not mean that challenges related to supply chains for making the vehicles or consumer sentiment will change.

The challenges to electrification cannot be overstated and will require an unprecedented effort irrespective of regulatory mandates. Public charging deployment is a principal obstacle. In the Proposed Rule, EPA catalogs many of the federal incentives currently in place for charging infrastructure, suggesting that these policies may ameliorate many of these challenges.7 This suggestion is short-sighted and incorrect. Subsidies alone will not create a long-term, sustainable proliferation of EV charging stations. For electrification policies to succeed in the long term, there must be a competitive, public charging market to refuel electric vehicles.8 Cars will need places to refuel, and private companies need a financial justification to spend capital to install charging stations. [EPA-HQ-OAR-2022-0829-0648, p. 4]

7 Proposed Rule at 29,307.

8 EV charging policy should promote competitive market dynamics and work with consumers' existing behavior and fuel retailers' real estate and business infrastructure. In a competitive market, private dollars will make sure infrastructure is there to meet consumers' needs. Without these market-oriented policies in place as a foundation for any public investment, there is a very real risk that public dollars spent will be stranded and wasted in ways that do not serve an appreciable number of consumers and ultimately do little to combat EV range anxiety.

a. Near-to Medium-Term Charging Capabilities

At present, only 8.64 percent of the new light-duty vehicles sold in the United States are EVs (including both BEVs and PHEVs).9 Even so, EV uptake has far outpaced the development of the public charging infrastructure that is necessary to accommodate those new EVs on the road. Last year, according to data reported by the U.S. Department of Energy's Alternative Fuels Data Center, EV sales increased 65 percent nationally, while public EV charging stations grew by less than 15 percent over the same period.10 Further, the limited growth of public charging has not happened equitably. A recent report from the Alliance of Automotive Innovation warned that, in 2022, 63 percent of U.S. counties have five or fewer chargers and 39 percent of U.S. counties have zero chargers.11 In the United States, 30 percent of all EV charging infrastructure is in just 14 counties—or 0.4 percent.12 Though Congress has appropriated limited funds designed to mitigate that gap, on their own, grant programs such as the National Electric Vehicle Infrastructure Program are insufficient to catalyze a nationwide network of EV chargers. [EPA-HQ-OAR-2022-0829-0648, p. 6]

9 ALLIANCE FOR AUTOMOTIVE INNOVATION, "Get Connected Electric Vehicle Quarterly Report" (Jun. 2023) available at https://www.autosinnovate.org/posts/papers-reports/Get%20Connected%20EV%20Quarterly%20Report%202023%20Q1.pdf.

10 Abby Brown, et al., "Electric Vehicle Charging Infrastructure Trends from the Alternative Fueling Station Locator: Second Quarter 2022," (2022) available at https://afdc.energy.gov/files/u/publication/electric_vehicle_charging_infrastructure_trends_second_quarter_2022.pdf.

11 ALLIANCE FOR AUTOMOTIVE INNOVATION, "Get Connected Electric Vehicle Quarterly Report » (2023) available at https://www.autosinnovate.org/posts/papers-reports/Get%20Connected%202022%20Q4%20Electric%20Vehicle%20Report.pdf.

12 Early uptake of EVs has been inequitable, with the benefits of EV ownership disproportionately falling to wealthier Americans, those with more education, and those more likely to own a home. Access to public charging infrastructure is particularly important in facilitating EV uptake among communities that are less likely to own a single-family home, and therefore will have inconsistent access to at-home charging.

The extent to which EV penetration is outpacing public charging station deployment is changing the landscape of the EV market. A 2022 nation-wide, representative survey by Consumer Reports and the University of Chicago found that 61 percent of Americans point to "not enough public charging stations" as the primary issue preventing them from buying or leasing an EV.13 In fact, 2022 was the first year in which the study found that 'access to charging' exceeded 'upfront cost' as the greatest barrier to consumers purchasing an EV.14 Analytics firm J.D. Power and Associates also found that a lack of public charging is directly preventing EV adoption, writing "public charging infrastructure consistently scores low in satisfaction. It's the exceptional use case—like a vacation road trip—that's holding shoppers back."15 [EPA-HQ-OAR-2022-0829-0648, p. 6]

13 CONSUMER REPORTS, "Battery Electric Vehicles and Low Carbon Fuel: Overview of Methodology," (Apr.2022) available at https://article.images.consumerreports.org/prod/content/dam/surveys/Consumer_Reports_BEV%20AND%20LCF% 20SURVEY_18_FEBRUARY_2022.

14 Id.

15 J.D. POWER 2023, "U.S. Electric Vehicle Consideration (EVC) Study" (Jun. 15, 2023) available at https://www.jdpower.com/business/press-releases/2023-us-electric-vehicle-consideration-evc-study.

This trend threatens the development and durability of transportation electrification. A 2021 study from the University of California at Davis Institute for Transportation Studies found that almost 20 percent of EV owners in California switched back to a gas vehicle because of the difficulty of consistently charging their vehicle16—this is in the state with the best-developed EV charging infrastructure in the nation by an order of magnitude. [EPA-HQ-OAR-2022-0829-0648, p. 6]

16 Scott Hardman and Gil Tal, "Understanding Discontinuance among California's Electric Vehicle Owner" (Apr. 26, 2021) available at https://doi.org/10.1038/s41560-021-00814-9.

b. Refueling Challenges Unique to Electric Vehicles

The Associations' members, including many of the largest privately held companies in the United States, have invested meaningful resources into analyzing business development opportunities associated with EV charging station investments.17 These companies' respective teams include grant-writing specialists to help them access various federal and state grant opportunities,18 and electricity market and utility specialists to assess and interface with their potential "fuel suppliers" for EV charging stations. Many of the Associations' member companies have installed EV charging stations at their outlets, utilizing any number of business models and ownership structures. Very few, if any, of these investments are profitable on a self-sustaining basis where a private business consistently earns a profit on EV charging events. These existing investments, including the investments cited by EPA in the Proposal, should therefore be interpreted as "beta tests" by companies exploring the charging space rather than indicative of a viable, sustainable business model. [EPA-HQ-OAR-2022-0829-0648, pp. 6-7]

17 The Agency itself cites many of the Associations' members investments in charging infrastructure. Proposed Rule at 29,309.

18 The Associations actively supported the development of the National Electric Vehicle Infrastructure ("NEVI") and Alternative Fuel Corridor grant programs that were included in the Infrastructure Investment and Jobs Act. Our members are in the process of analyzing and applying for grant opportunities. These programs will make a meaningful difference in mitigating the upfront capital expenditures associated with installing EV charging stations. Absent additional policy incentives or market reforms, however, the grant programs will not enhance the business case for investing in charging stations as a means of generating a profit by selling electricity to EV drivers. EPA has an extraordinary opportunity to supplement these EV charging grant programs by encouraging greater investment in charging stations through eRINs.

To be successful, the on-the-go refueling experience for EVs should be as similar as possible to the conventional refueling experience to which consumers are accustomed.19 Fuel retailers are well positioned to offer fast, safe, and convenient EV charging services because they have a keen understanding of consumer preferences and tendencies. This fact is essential when it comes to adoption of EVs—the transition to EVs will require what was previously a quick stop to become a 30-minute consumer experience. Currently, it takes the driver of a passenger vehicle approximately two to three minutes to complete a refueling experience. It takes the driver of an EV, however, 20 to 40 minutes to recharge at a Direct Current Fast Charger ("DCFC"), depending upon the vehicle and the capacity of the charger available. [EPA-HQ-OAR-2022-0829-0648, pp. 6-7]

19 Placing chargers only in individual garages in private homes, apartment buildings, and parking lots cannot combat the notion of "range anxiety" as effectively as fuel retailers offering that service. Most renters across the nation do not have garages, nor do many homeowners. Even those Americans that do have garages often do not have space in their garage for the total number of vehicles their family drives, nor do they have the electrical capacity in their garage to support a charger or multiple chargers. This is also true for workplaces; many Americans, especially those working in low-income jobs, will not have the option, for a variety of reasons, to charge at work. Consumers must have viable charging options available outside of their home or workplace for widespread vehicle electrification to take place.

Consumers must also be able to trust that the charging stations they visit will be functional, an issue that has increasingly presented a significant problem. We see this playing out today throughout the country in situations where chargers are owned and operated by entities—often utilities—that do not have a financial incentive to keep them in good working order.20 If EV charging is not both available and reliable in the neighborhoods consumers want to visit, as well as along Interstates where consumers travel, many Americans simply will not purchase an EV, no matter the price.21 [EPA-HQ-OAR-2022-0829-0648, pp. 6-7]

20 One in every five consumer attempts to charge their EV failed in 2022. See Hannah Lutz, AUTOMOTIVE NEWS "EV Drivers Struggle with Declining Reliability of Charging Network," (Feb. 8, 2023) available at https://www.autonews.com/mobility-report/ev-drivers-struggle-declining-reliability-charging-network.

21 Low-income communities and communities of color are disproportionately likely to need access to regular public charging in order to own an EV. Deploying public charging infrastructure, thereby supporting the ability of all Americans to own an EV, would also help to reduce air pollution and improve air quality in low-income communities. Any light-duty vehicle electrification policy that forsakes a central focus on public charging should be amended to consider low-income Americans and the communities in which they reside.

At present, there are several impediments that make it challenging for private businesses to identify a pathway to profitability with respect to EV charging. Most of these impediments involve an electricity market structure that was not designed for—and is thus incompatible with— the retail fuel market. Importantly, these challenges have not defrayed the intent of the Associations' members in invest in public charging. They do, however, threaten to depress EV adoption by creating a market in which the industry relies on government incentives rather than being incentivized by the free market. [EPA-HQ-OAR-2022-0829-0648, pp. 6-7]

i. Electricity Pricing Schemes Are Antiquated

Foremost among these market impediments is an antiquated electricity pricing scheme that utilities are slow and reluctant to modernize. Many states are exacerbating this problem by allowing utilities to pass through the costs of EV charging stations to all of their customers on their monthly utility bill, rather than having EV drivers pay for the costs of refueling their own vehicles. Rising electricity prices, in conjunction with softer gas prices, made EVs more expensive to fuel than gas-powered cars at the end of 2022.22 [EPA-HQ-OAR-2022-0829-0648, pp. 7-8]

22 See ANDERSON ECONOMIC GROUP, "Gas-Powered Cars Cheaper to Fuel than Electric in Late 2022" (Jan. 24, 2023) available at https://www.andersoneconomicgroup.com/cars-gas-powered-cheaper-to-fuel-than-electric-in-late-2022/.

There are no purchasing options or pricing structures for retailers to provide electricity as a fuel. Retailers with EV chargers today are forced to pay retail prices for electricity with high demand charges. There is no business case for buying electricity at retail prices and selling electricity at retail prices. Regulated utilities that own and operate their own charging stations are not subject to demand charges and thus have an insurmountable competitive advantage over anyone else in that market. This situation has dramatically reduced private sector investments in EV charging stations. The Agency can best promote its electrification goals by addressing this market disparity. [EPA-HQ-OAR-2022-0829-0648, pp. 7-8]

ii. Economics of Public EV Charging

As noted above, to keep up with EV sales growth, the U.S. public fast charging network will need to grow drastically.23 The economics of vehicle charging, however, are simply insufficiently attractive to impel the charging network that a fully, or even partially, electrified fleet would need.24 [EPA-HQ-OAR-2022-0829-0648, p. 8]

23 Stephen Edelstein, GREEN CAR REPORTS "Study: Pace of US EV Adoption Requires 8X Charger Growth by 2030" (Jan. 13, 2023) available at https://www.greencarreports.com/news/1138424_study-pace-of-us-ev-adoption-requires-8x-charger-growth-by-2030.

24 Brennan Borlaug et al., TRANSPORTATION RESEARCH PART D: TRANSPORT AND ENVIRONMENT 114, "Public Electric Vehicle Charging Station Utilization in the United States" (Jan. 1, 2023) available at https://doi.org/10.1016/j.trd.2022.103564.

Internal data collected from our members mirrors what was already understood by economists: that only where utility demand charges are very low and utilization rates higher than anticipated do they expect a positive return on their investment. DC fast charger investments are capital-intensive, costing $150,000–$200,000 to install even in locations with existing utility service and sufficient open space. Unfortunately, even where support is available to defray this capital investment, the cost structure to operate and maintain these chargers on an ongoing basis makes their economics extremely challenging. [EPA-HQ-OAR-2022-0829-0648, p. 8]

Charging station owners—like most commercial electric power customers—foot the bill for energy costs per kilowatt hour (kWh). Unlike a conventional electricity consumer, however, commercial businesses that own charging stations are burdened by demand charges that reflect total maximum power demand (in kW) over a given period. [EPA-HQ-OAR-2022-0829-0648, p. 8]

Demand charges have rendered the total cost of operating a DCFC practically insurmountable for private industry. Adding just two DCFCs to a convenience store typically increases its demand charges from under $1,000 per month to almost $4,500 per month. Because demand charges are a function of peak demand, they remain fixed no matter how often a given charger is utilized. This means that the relative cost per kWh delivered is very high for chargers with low utilization. Most chargers today have very low utilization, and this is expected to continue for many years in most markets.25 [EPA-HQ-OAR-2022-0829-0648, p. 8]

25 Though not directly related to this rule, vesting the owners and operators of public charging stations with the ability to generate electric Renewable Identification Numbers (eRINs) under the Renewable Fuel Standard (RFS) is one potential way to incentivize our membership to make significant investments in EV charging. Importantly, our members have indicated that even with the expected low utilization rate, if eRINs could be generated by owners of public charging stations, installations with a projected negative rate may be shifted to a positive rate of return. Importantly, if the Agency allows charging station operators to generate eRINs, it will incentivize the installation of new state-of-the-art fast chargers. This could create a virtuous cycle in this industry, reducing the price of electricity sold, thereby increasing charging station utilization rates, and further improving the economics of charging infrastructure. New investments in charging, in turn, will support EV adoption and the Agency's broader electrification goals.

Organization: National Automobile Dealers Association (NADA)

B. EPA Must Adjust Its Infrastructure Assumptions to Reflect Reality.

Another critical factor creating uncertainty for the market adoption of EVs is the unreliability and unavailability of charging infrastructure. The infrastructure needed to support EPA's projected EV market penetration requires both an increased capacity for electricity generation and a more comprehensive transmission system than exists today. At a minimum, new and expensive conduits, transformers, and power lines will be necessary. Infrastructure installations of this magnitude will involve major construction projects subject to permitting requirements, supply chain delays, and environmental and safety mandates. Even assuming that these upgrades will be economically feasible, they will take several years and long lead times to fully develop and deploy. EPA notes that IIJA and IRA funding and incentives will help to address some of these concerns, but the agency fails to provide a sober assessment of the nature and extent of the significant infrastructure needs, buildout timelines, and costs associated with its proposal.55 EPA must revisit and adjust its assumptions to reflect these critical considerations. [EPA-HQ-OAR-2022-0829-0656, pp. 12-13]

55 88 Fed. Reg. at 29307-12.

1. Dealer Infrastructure Costs and Lead Times.

As mentioned, franchised dealerships are investing billions in the infrastructure and equipment to sell and service EVs. Household and commercial customers will require refueling infrastructure at their homes and businesses and will require expansive and reliable public refueling infrastructure networks to support the effective use of the EVs contemplated by EPA's proposed standards. With respect to franchised dealerships alone, the typical dealership will require the following facility and infrastructure upgrades to sell and service EVs: [EPA-HQ-OAR-2022-0829-0656, p. 13]

- Two EV chargers (Level 2 or DCFC) to ensure availability for sales and service;
- Service lifts with higher weight capacity;
- Service bays that can accommodate additional lift heights of approximately six feet to facilitate high-voltage battery maintenance and removal;
- Battery storage and quarantine containers;56 and

• Workplace safety and emergency response training to navigate the potential dangers associated with vehicle high-voltage systems and components. [EPA-HQ-OAR-2022-0829-0656, p. 13]

56 EV battery temperatures must remain at approximately 70 to 75 degrees, depending on the manufacturer. When an EV comes in for repair, the drive battery may be removed or disconnected from the low-voltage system (12-volt) which maintains its temperature. For example, for body work that requires painting, the drive battery may need to be removed due to high paint booth temperatures, especially during paint curing. When drive batteries are removed, they require special storage. The optimal scenario involves a separate storage building that is temperature-controlled and has a ventilation system. Industry guidelines suggest 50 feet of separation between stored drive batteries and a service facility. Ventilation is critical both around and underneath drive batteries. And when drive batteries are damaged, they can leak fluoride gas, which is heavier than air. This gas is highly flammable and can contribute to a chemical reaction in the battery cells leading to a thermal runaway or fire.

The costs involved in these investments can easily exceed $1,000,000 per dealership. The ability and timeline to make facility upgrades and install chargers will vary significantly by dealership location, the utility upgrades necessary, and permitting lead times. Some locations may need minimal to no utility upgrades for charger installation, but in most cases, electrical infrastructure (e.g., trenches, distribution transformers, switchboards, and conduit) must be upgraded or installed to accept the high-power service necessary to support several chargers. [EPA-HQ-OAR-2022-0829-0656, p. 13]

EPA notes power needs as low as 200 kW could require the installation of a distribution transformer.57 But EPA fails to acknowledge that utilities are facing significant transformer supply chain issues with an average delivery lead time of 12-18[58] months (which only is expected to increase). Dealerships requiring distribution transformer upgrades will be unable to begin selling and servicing EVs in quantity until they are completed. Further, dealerships that rent or lease their buildings or real estate may be unable to install chargers due to lease restrictions on property and building modifications. [EPA-HQ-OAR-2022-0829-0656, pp. 13-14]

57 88 Fed. Reg. at 29311.

58 Robert Walton, Utilities sound alarm over distribution transformer shortage as procurement times surpass 1 year and costs triple, Utility Drive (Dec. 19, 2022). See also Paul Ciampoli, Proposed efficiency standards for distribution transformers would worsen shortages, POWER GRID INTERNATIONAL (March 31, 2023).

Dealership investments are being made now in preparation for an anticipated future market demand. NADA urges EPA to accurately assess the cost and timing of the EV refueling infrastructure necessitated by its proposed standards. [EPA-HQ-OAR-2022-0829-0656, pp. 13-14]

2. Public Charging Shortfalls.

EPA has not adequately considered the impact of its proposal on public charging demand and potential shortfalls associated with the proposal's aggressive EV sales projections. There are about 140,000 publicly accessible charging ports in operation today,59 far less than what the Edison Electric Institute (EEI) says will be needed in 2030, let alone what will be needed to accommodate the new EV sales the proposal projects will occur between MYs 2027 and 2032. In fact, EEI estimates that 12.9 million charge ports will be needed to support the 26.4 million EVs it projects to be on U.S. roads by 2030, including more than 2.6 million charge ports in workplaces and public locations.60 EEI further concludes that, despite significant planned investments, a charging infrastructure gap61 will result in a 68 percent shortfall in publicly accessible DCFC charging ports in 2030, stating: “the number of DCFC ports needed in 2030 to meet projected demand is more than double the planned DCFC ports.”62 [EPA-HQ-OAR-2022-0829-0656, p. 14]

60 Id. at 10, 12.

61 Charles Satterfield et al., Electric Vehicle Sales and the Charging Infrastructure Required Through 2030, EDISON ELECTRIC INSTITUTE (June 2022).

62 Id. at 15. The image above shows the planned DCFC ports and includes investments by state and federal governments, automakers, electric companies, and the National Electric Highway Coalition. See Id. at 13-15.

[See original comment for pie chart titled “2030 Estimated DC Fast Charging Port Shortfall; 140,000 Ports Needed] [EPA-HQ-OAR-2022-0829-0656, p. 14]

AAI has also found that an infrastructure gap exists, stating that “more than 342 thousand additional chargers are needed today, which is two and a half times the currently available chargers across the U.S. as of March 31, 2023.”63 [EPA-HQ-OAR-2022-0829-0656, p. 15]

63 See Get Connected EV Quarterly Report 2023 Q1.pdf (autosinnovate.org), p. 9.

A newly-issued National Renewable Energy Laboratory (NREL) report is consistent with the findings made by EEI and AAI.64 NREL concludes that the U.S. will need at least 1.2 million public charging ports, including 182,000 DCFC ports, at a cost of $31–$55 billion to meet the charging demand from a projected 33 million EVs on the road by 2030.65 NREL estimates that, as of March 2023, only some $23.7 billion has been committed through funding by the IIJA, private firms, state and local governments, and electric utilities for projects to meet this need.66 NREL submits that, “with long-term market certainty grounded in accelerating consumer demand” additional “public and private investments will put the United States on a path to meeting the [public charging] infrastructure needs” summarized in its report.67 [EPA-HQ-OAR-2022-0829-0656, p. 15]

64 See The 2030 National Charging Network: Estimating U.S. Light-Duty Demand for Electric Vehicle Charging Infrastructure (driveelectric.gov)

65 See id. at vi-vii, 35-36, 49, and 58.

66 See id. at 58.

67 Id.

These reports are concerning in that they show that significant additional public charging infrastructure, and billions more in investment dollars, are needed to meet future demand based on projected 2030 new EV market penetration levels that are considerably lower than what EPA projects, in some cases by more than 50 percent! The proposal’s discussion on this topic is woefully inadequate. Simply put, it would be unconscionable for EPA to issue standards effectively requiring that well over 60% of new light-duty vehicle sales be plug-in electric vehicles in MY 2032 when critical concerns exist regarding the deployment of public charging infrastructure necessary to support such sales.68 EPA does appear to estimate the costs for deploying the charging infrastructure it believes will be needed to support the aggressive EV rollout it projects, but provides no analysis showing how those needs can be met.69 [EPA-HQ-OAR-2022-0829-0656, p. 15]

68 88 Fed. Reg. at 23907-10; DRIA at 5-22 – 5-32. EPA's insufficient estimates regarding the number of charging ports needed to support large numbers of plug-in electric vehicles were calculated for MY 2027 and MY 2055 only.

69 88 Fed. Reg. at 29311-12.

Given that public charging infrastructures gaps have already been identified, the mere existence of public and private investments in publicly accessible charging projects alone does not negate the very likely possibility of public charging shortfalls stemming from EPA's proposal. Reliable charging infrastructure is critical to the successful mass market adoption of light-and medium-duty EVs. EPA must fully account for the projected public charging demands of its proposal and clearly demonstrate that shortfalls will not exist. [EPA-HQ-OAR-2022-0829-0656, p. 15]

Organization: National Propane Gas Association (NPGA)

Charging infrastructure has not kept pace and the EPA's projections of charging infrastructure growth are aspirational at best.4 The goals of the Proposed Rule are likely unachievable, and the EPA should suspend consideration of the proposed rule until it can evaluate the impact of the grants for charging infrastructure under the Inflation Reduction Act, and if BEV production targets can meet anticipated demand for the model years covered. [EPA-HQ-OAR-2022-0829-0634, pp. 1-2]

3 Proposed Rule at 29329.

4 Proposed Rule at 29368.

Organization: National Rural Electric Cooperative Association (NRECA)

Specifically, within the proposed rule section on PEV Charging Infrastructure Considerations, EPA states:1 "there may be additional infrastructure needs and costs beyond those associated with charging equipment itself. While planning for additional electricity demand is a standard practice for utilities and not specific to PEV charging, the buildout of public and private charging stations (particularly those with multiple high-powered DC fast charging units) could in some cases require upgrades to local distribution systems…However, there is considerable uncertainty associated with…future distribution upgrade needs, and we do not model them directly as part of our infrastructure cost analysis." [EPA-HQ-OAR-2022-0829-0575, p. 2]

1 Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, 88 Fed. Reg. 29,311 (May 5, 2023).

Specific Costs for EPA to Consider Incorporating in the Proposed Rule's Analysis [EPA-HQ-OAR-2022-0829-0575, pp. 3-4]

Again, we urge EPA to update its analysis to account for the costs needed to make updates to the grid to support transportation electrification as envisioned in this proposal. Grid upgrade costs for EV charging will vary by region, neighborhood, cooperative, circuit, and feeder.

However, to illustrate the types and ranges of costs that EPA should account for, we provide the following costs sourced from four different cooperative regions, broken down by charge level:

- Residential (Level 1 and Level 2): One out of three households will need an expanded electric panel to accommodate 240 V Breakers. If a household purchases two electric vehicles, then four slots on a breaker will be needed to accommodate this load. The average cost will be approximately $4,000 for a Level 2 residential charger with a panel upgrade. [EPA-HQ-OAR-2022-0829-0575, pp. 3-4]

-- Upgrading panel (20% of panels must be upgraded) – can start around $600 [EPA-HQ-OAR-2022-0829-0575, pp. 3-4]

-- Transformer upgrades - $2,600 and climbing [EPA-HQ-OAR-2022-0829-0575, pp. 3-4]

-- Service wire gauge upgrades to accommodate higher amperage - $3,000 [EPA-HQ-OAR-2022-0829-0575, pp. 3-4]

- Public (Level 2 and DC Fast Charging (DCFC)): For commercial sites, transformer upgrade needs will vary. Most sites will already have three-phase power available; however, in very rural locations single-phase power will need to be upgraded to three-phase. If transformers do need to be upgraded on a three-phase line, then three transformers will need to be upgraded. [EPA-HQ-OAR-2022-0829-0575, pp. 3-4]

-- Level 2 charger including panel - approx. $4,000 on average [EPA-HQ-OAR-2022-0829-0575, pp. 3-4]

-- National EV Infrastructure Program (NEVI)-Compliant DCFC - approx. $25,000-

$150,000 [EPA-HQ-OAR-2022-0829-0575, pp. 3-4]

- Transformer - $25,000 - $40,000 (reflects current prices for three transformers) [EPA-HQ-OAR-2022-0829-0575, pp. 3-4]

- Service entrance - $3,000-$4,000 [EPA-HQ-OAR-2022-0829-0575, pp. 3-4]

- Metering package (including instrumentation, voltage transformers (PT) and current transformers (CT) - $2,000 [EPA-HQ-OAR-2022-0829-0575, pp. 3-4]

- Line extension, if required (site dependent) - $50,000 - $75,000 [EPA-HQ-OAR-2022-0829-0575, pp. 3-4]

Circumstances vary across cooperatives, but some of these costs will be borne directly by the consumer- members and others will be paid for by the cooperative. Regardless, these costs help to illustrate more accurately the investment it will take to implement on EPA's proposed rule. [EPA-HQ-OAR-2022-0829-0575, pp. 3-4]

We note that these costs reflect a snapshot estimate in time and are likely to increase, particularly due to the significant challenges and delays utilities are facing in their supply chains, which are contributing to an unprecedented shortage of the most basic machinery and components essential to ensure the continued reliability of the electric grid. Electric cooperatives are waiting a year, on average, to receive distribution transformers. Additionally, lead times for large power transformers have grown to more than three years. And orders for electrical conduit have been delayed five-fold to 20 weeks with costs ballooning by 200 percent year-over-year. As a result, new projects are being deferred or canceled, and electric cooperatives are concerned about their ability to respond to major storms due to depleted stockpiles. We expect these supply chain challenges to persist with the increased demand for electrification projects being incentivized by the U.S. federal government. All these delays will likely impact the cost and timing of charging infrastructure buildout needed to support the transportation. [EPA-HQ-OAR-2022-0829-0575, pp. 3-4]

EPA should update its analysis in the proposed rule to account for the significant grid investments that may be needed to support transportation electrification as laid out in the proposal. As detailed above, these costs may be significant and should not be shouldered by the electric cooperatives serving this new load. Again, electric cooperatives are consumer-owned and operate at cost on a not-for-profit basis. They also serve 92% of the nation's persistent poverty counties. Affordability is critical to electric cooperatives and the consumer-members they serve, and any new costs imposed on an electric cooperative are ultimately borne by the consumers at the end of the line. EPA should update its analysis to ensure it more accurately represents the costs associated with electrifying both LDVs and MDVs, which could be significant across the country. [EPA-HQ-OAR-2022-0829-0575, p. 4]

Organization: National Tribal Air Association (NTAA)

Electrified Vehicles

As noted in the announcement of the proposed standards, "EPA's proposal builds upon a proliferation of announcements by automakers that collectively signal a rapidly growing shift…toward zero-emission technologies, including electrification"5. This anticipated reliance on hybrid, plug-in hybrid, and fully electric power trains may be disproportionately burdensome and costly in Indian country. Far too many homes on many reservations lack access to an electric grid. Further, vehicle reliance on centralized or individual battery charging sites as anticipated in the proposed regulations presents a huge challenge. [EPA-HQ-OAR-2022-0829-0504, p. 3]

5 Biden-Harris Administration Proposes Strongest-Ever Pollution Standards for cars and trucks to Accelerate Transition to a Clean – Transportation Future, USEPA News Release, April 12, 2023

The NTAA is well aware of many initiatives to enhance the deployment of renewable energy technologies to support the nation's electricity demand. We actively participate in meetings, webinars, forums, etc. as programs emerge under the Bipartisan Infrastructure Law, Inflation Reduction Act, and other climate change – related initiatives. The NTAA continues to formally comment on EPA proposals that emerge which have the potential to impact Indian country. NTAA remains concerned about realistic access to funding and other resources that are essential to advance renewable energy in Tribal communities and are necessary to transition vehicle fleets as anticipated by the proposed light-duty and medium-duty vehicle emissions standards. [EPA-HQ-OAR-2022-0829-0504, p. 3]

Conclusions

The NTAA appreciates this opportunity to comment on the proposed rule regarding "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles." We agree with the EPA's stated urgency to improve our air quality and to mitigate climate change5. The proposed vehicle emissions standards and related provisions can be important elements in addressing these critical needs. We support the proposed rule including Alternative 1 to the proposed greenhouse gas emissions standards. The anticipated shift to electric vehicle fleets must, however, be coincident with greatly enhanced electric infrastructure in many Tribal communities. [EPA-HQ-OAR-2022-0829-0504, p. 3]

5 Biden-Harris Administration Proposes Strongest-Ever Pollution Standards for cars and trucks to Accelerate Transition to a Clean – Transportation Future, USEPA News Release, April 12, 2023

Organization: Nissan North America, Inc.

Nissan appreciates the Administration's focus on and support for advancing electrification and carbon neutrality and shares the same long-term goal of transitioning to zero emission vehicle society. However, Nissan believes that market realities, infrastructure needs, consumer impacts, and lack of battery critical mineral availability necessitate an adjustment of the GHG standard stringency in this rulemaking timeframe. [EPA-HQ-OAR-2022-0829-0594, p. 1]

Organization: North American Subaru, Inc.

As articulated by Auto Innovators, to reach 67 percent ZEV sales by 2032 a host of supportive policies is required. Consumers will demand affordability, ease of charging, and a vehicle that meets performance needs in all-weather conditions. The Bipartisan Infrastructure law included $7.5 billion to speed the deployment of EV charging infrastructure across the United States. While this investment in public charging is an important signal to EV-wary consumers, more is needed, particularly In multifamily unit dwellings and in places where Subaru customers love to go, often outside the city limits including camping and outdoor recreational areas. And of growing concern is the reliability and maintenance of installed charging stations. This issue presents another potential inhibitor for EV adoption, including equity concerns.3 [EPA-HQ-OAR-2022-0829-0576, pp. 2-3]

3 Rempel, Cullen, Bryan, Cezar (2022). Report: Reliability of Open Public Electric Vehicle Direct Current Fast Chargers. https://papers.ssrn.com/sol3/papers.cfm?abstract_id+4077554.

Organization: North Dakota Farmers Union (NDFU)

The proposal basically assumes that BEVs will be the dominant technology for future emissions reductions. But relying on a single technology is a risky strategy. Many factors could interfere with BEV production, including the supply and cost of critical minerals, lack of BEV recharging infrastructure, slow ramp-up of wind and solar power, poor customer acceptance, and more. EPA estimates that 67% of U.S. vehicle sales will be BEVs in 2032, but other projections are lower and the U.S. lags behind other countries that are not expected to reach similar levels of sales in that timeframe.10 [EPA-HQ-OAR-2022-0829-0586, p. 5]

10 Stauffer, N. W. (2021, April 29). China's transition to electric vehicles: By 2030 40 percent of vehicles sold in China will be electric; MIT research finds that despite benefits, the cost to consumers and to society will be substantial. MIT News. Retrieved from https://news.mit.edu/2021/chinas-transition-electric-vehicles-0429.

Organization: Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC)

D. Deployment of Federal Funding

The recently enacted Bipartisan Infrastructure Law (BIL) and the Inflation Reduction Act (IRA) provide billions of dollars of funding to advance transportation electrification including substantial funding for state governments. Combined with state and federal financial incentives for ZEVs and charging and fueling infrastructure, and other market-enabling policies, the LDV and MDV market segments are primed for rapid and widespread electrification. [EPA-HQ-OAR-2022-0829-0584, p. 7]

The NESCAUM and OTC states are already beginning to deploy the $5 billion made available through the National Electric Vehicle Infrastructure program to accelerate installation of public charging and other alternative fueling infrastructure, and the $5 billion Clean School Bus grant program for zero-emission school buses and technology. Additional funding will be available soon through the $7.25 billion Low or No Emission and Grants for Buses and Bus Facilities programs, the $2.5 billion Charging and Fueling Infrastructure program, the $1 billion Clean Heavy-Duty Vehicle program, and many other new and existing federal programs for which activities that support transportation electrification are eligible. All of the NESCAUM and OTC states recently submitted applications for the $5 billion Climate Pollution Reduction Grant Planning and Implementation programs, which require states to develop and implement priority and comprehensive climate action plans to reduce economy-wide GHG emissions. [EPA-HQ-OAR-2022-0829-0584, p. 7]

Organization: Paul Bonifas and Tim Considine

Moreover, the EPA claims unrealistically low residential electricity charging rates while simultaneously admitting that low-income households won’t have access to, nor be able to afford installation of, residential charging ports. The EPA admits that low-income households will have to rely on commercial charging ports that cost 2-3 times more3, yet they don’t consider this in their net impact calculations. The EPA’s rule will have a negative impact on the entire population but will disproportionately negatively impact the poorest Americans. Correcting for these EPA oversights leads to a more realistic fuel “savings” of NEGATIVE $108 billion, a $998 billion cost increase from the EPA’s calculations. [EPA-HQ-OAR-2022-0829-0551, pp. 2-3]

3 Page 601 of EPA’s Draft Regulatory Impact Analysis - https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf

Organization: POET, LLC

EPA relies on BEVs making up an astounding 67 percent of LDVs by model year (“MY”) 2032.4 EPA’s modeling largely ignores the significant infrastructure needed to support those BEVs and offers little to no concrete evidence that this infrastructure will be ready in time. [EPA-HQ-OAR-2022-0829-0609, p. 5]

4 See U.S. EPA, Proposed Rule, Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, 88 Fed. Reg. 29184, 29329 (May 5, 2023) (finding that under the proposal “penetration of BEVs increases by almost 30 percentage points over this 6-year period, from 36 percent in MY 2027 up to 67 percent of overall vehicle production in MY 2032”)

There are issues with U.S. EPA's assumptions regarding electric vehicle supply equipment (EVSE) which are presented in Chapter 5.3.1 of the DRIA. The most notable of these can be seen in DRIA Figures 5-16 and 5-17 which show the number of EVSE ports required under the Proposed Rule and the No Action Case. The difference in required EVSE ports in 2055 is about 20 million (90 to 70). [EPA-HQ-OAR-2022-0829-0609, p. 60]

However, as shown in Figure 9-2 of the DRIA in 2055 the difference in BEV populations under the two cases is about 80 million (160 to 80). What this means is that U.S. EPA is assuming that the doubling of BEV penetration will require only a 30% increase in the number of available ESVE ports. While it may be possible that more BEVs will share EVSE outlets if BEV populations grow, U.S. EPA has done nothing to justify the values used in the BEV assessment. Because U.S. EPA understates the likely need for EVSE, it also underestimates the cost of EVSE that will be incurred due to the Proposed Rule. [EPA-HQ-OAR-2022-0829-0609, p. 60]

Organization: Porsche Cars North America (PCNA)

Electromobility will need continued support from public policy. [EPA-HQ-OAR-2022-0829-0637, p. 3]

Recent legislative actions have seeded the ground with support for electric vehicles and the beginning of a robust nationwide charging network. With specifics that continue to be defined, stakeholders are working to maximize the opportunity under these new laws to support customers with valuable purchase incentives, and to help spur the development of new electric vehicle component production and material sourcing. Understandably, the complexity of these laws results in a process that requires careful deliberation with industry representatives working hard to ensure customers have a clear understanding of the support available. Nevertheless, the support within these programs will be critical to the growth rates EPA envisions in this proposal. [EPA-HQ-OAR-2022-0829-0637, p. 3]

Other areas important to consumer adoption can benefit from additional policy development. Further work is needed to reduce barriers to electrification such as streamlining building codes to futureproof new construction to ease the installation of charging at homes, apartments, and workplaces. The magnitude of the challenge related to a robust charging infrastructure is becoming increasingly clear with updated reports such as the Department of Energy's 2030 assessment.1 This single report indicates a total investment of $53-127 billion dollars for private and public charging which does not even include costs associated with grid upgrades to support the 26 million plus ports that are estimated to be needed. Consumers won't be satisfied with roadblocks that make owning an electric car more complicated than a gasoline model. Actions are also needed to help lower the cost of electricity as a fuel to ensure that EVs are competitive and attractive against gasoline models. Policy makers and the auto industry must also continue to find wins in other regulatory programs. EPA's recently finalized Renewable Fuel Standard for 2023-2025 regrettably was unable to finalize the innovative and robust proposal for "eRINs". This proposal that was supported by Porsche could have opened the door for continued growth in electricity derived from biogas and used transportation fuel and to further incentivize growth in the electric vehicle market. Porsche appreciates the need for EPA to consider the wide range of input they received on this proposal and will work proactively to support near-term regulatory actions to finalize this valuable, supportive policy. [EPA-HQ-OAR-2022-0829-0637, p. 3]

1 The 2030 National Charging Network: Estimating U.S. Light-Duty Demand for Electric Vehicle Charging Infrastructure, US Department of Energy, 2023

Organization: Rivian Automotive, LLC

Infrastructure Development Will Build on Strong Industry Momentum

EPA rightly identifies the importance of ubiquitous and reliable EV charging to achieve the transportation electrification goals supported by this rulemaking. Rivian is actively investing in the Rivian Adventure Network, a nationwide fast charging network, with a focus on reliability and enabling access to areas not historically serviced by existing charging networks. From the perspective of both an all-electric automaker and charging network provider, we applaud the EPA's thorough analysis and modeling of the impact of this rulemaking on charging infrastructure, energy sector emissions, and electric grid infrastructure. The Draft Regulatory Impact Analysis ("DRIA") addresses concerns around these key topic areas and contextualizes them within the many active policies, regulations, and funding opportunities that have created tangible momentum in transportation electrification nationwide. [EPA-HQ-OAR-2022-0829-0653, pp. 15-17]

This momentum can be seen in domestic EV manufacturing investments and the commitments to EV-only sales by Audi, Fiat, Volvo, Mercedes-Benz, General Motors and Honda.46 With increasing confidence around the availability of EVs now and into the future, the charging infrastructure needed for those vehicles has also seen significant domestic investment from a range of industry players. Since August 2022, 11 charging manufacturers have announced additional manufacturing investments in the U.S. to meet growing demand, including Siemens, ABB E-mobility and SK Signet.47 Two of the world's largest oil and gas companies, Shell and BP, have acquired existing charging network providers, Volta and AMPLY Power, respectively—a demonstration of their intentions to increase their investment in charging infrastructure in the US.48, 49 These investments coupled with the opportunities coming out of the Bipartisan Infrastructure Law and the Inflation Reduction Act have been key forcing mechanisms for critical discussions around how to expedite and scale the roll out of charging infrastructure nationwide. [EPA-HQ-OAR-2022-0829-0653, pp. 15-17]

Rivian is encouraged by the efforts currently underway across state and federal agencies, private companies, national labs, and non-profits to address the key challenges and opportunities with scaling charging infrastructure. One of those challenges is the impact of widespread electrification on the electric grid infrastructure. We applaud EPA for acknowledging this challenge as it is a top concern for many industry stakeholders, but also an area where significant attention is being paid. For example, EPRI has launched its EVs2Scale 2030 initiative, which is focused on increasing collaboration between industry and utilities to increase communication around commercial fleet electrification plans and utility capacity mapping.50 Several deliverables are planned by the group, including key tools focused on helping utilities across the country receive the necessary buy-in from their decision makers to plan for the grid upgrades necessitated by transportation electrification. In addition, as noted in the DRIA, NREL recently published a quantitative needs assessment by state and city for a national charging network focused on personally owned, light-duty vehicles.51 The granularity of the analysis available on the state and city level52 will allow it to serve a similar function as the EPRI effort—increasing utilities' awareness of the forthcoming load on their systems, thus providing more time to make necessary grid upgrades. Overall, increasing transparency and information flow with the broad range of utilities operating in the US will be critical to achieving the electrification goals this rulemaking aims to help meet. [EPA-HQ-OAR-2022-0829-0653, pp. 15-17]

51 Wood, E., B. Borlaug, M. Moniot, D.-Y. Lee, Y. Ge, F. Yang, and Z. Liu, National Renewable Energy Laboratory, The 2030 National Charging Network: Estimating U.S. Light-Duty Demand for Electric Vehicle Charging Infrastructure (2023), NREL/TP-5400-85654.

52 See data files for Wood, E., B. Borlaug, M. Moniot, D.-Y. Lee, Y. Ge, F. Yang, and Z. Liu, National Renewable Energy Laboratory, The 2030 National Charging Network: Estimating U.S. Light-Duty Demand for Electric Vehicle Charging Infrastructure (2023), NREL/TP-5400-85654, available at https://data.nrel.gov/submissions/214.

In addition to increasing collaboration with utilities, leveraging load management technologies to reduce the need for additional build out of grid capacity will be imperative. As the DRIA notes, there are many commercially available technologies able to manage charging load, from smart charging to mobile and stationary storage, to vehicle grid integration. In recent years, these technologies have demonstrated their ability to subtract years from their project energization timeframes or even enable the completion of a project that would have otherwise been unable to proceed if a full-nameplate upgrade was required. [EPA-HQ-OAR-2022-0829-0653, pp. 15-17]

While we acknowledge new distribution infrastructure will be necessary, we agree with EPA that commercially available load management technology can leverage the inherent flexibility of EV charging use cases and insert much-needed efficiency into EV-related distribution grid planning and buildout processes. Per EPA's analysis in Figure 5-15 in the DRIA, the majority of charging will be needed at home and at work, which is where load management technologies are particularly impactful due to long dwell times with maximum charging flexibility. [EPA-HQ-OAR-2022-0829-0653, pp. 15-17]

Overall, increased transparency around the location and scale of future charging load will enable utilities and their decision makers to make necessary investments in the electric grid infrastructure as well as increase their adoption of load management technologies. Therefore, we view the near-term finalization of Alternative 1 as a critical step to build on the existing momentum described above and continue it into 2027 and beyond. [EPA-HQ-OAR-2022-0829-0653, pp. 15-17]

Organization: Roy Littlefield IV

Firstly, the country's current charging infrastructure is inadequate to support a forced shift towards electric vehicles. Charging infrastructure is not yet fully developed or accessible in many regions of the country. Forcing consumers to transition to EVs without ensuring sufficient charging infrastructure could place undue burdens on drivers across the country. [EPA-HQ-OAR-2022-0829-0793, p. 1]

Organization: Scott Wilson

You will have read also that EVs are unaffordable. Actually, there are 18 new EV models below the average new car price in the US. (see attached) You will have read there is no charging infrastructure. Not true, since any home with electricity near a parking place can support an EV. However, more long-distance highway charging is needed and is the motivation for the administration's NEVI charger program. You will have read that the grid can't support an EV fleet. Major electric utility trade groups point out that off-peak charging will become widespread. It's notable also that 124 business entrepreneurs, executives, and academics have submitted favorable comments. [EPA-HQ-OAR-2022-0829-0515, p. 1]

Organization: Senator Shelley Moore Capito et al.

In addition, there remains a lack of support infrastructure capacity to implement the sweeping transition envisioned in these proposals, particularly for the heavy-duty vehicle category. While the Infrastructure Investment and Jobs Act provides states funding for electric vehicle charging infrastructure, charging technology and deployment continues to focus on passenger and commercial vehicles, not on heavy-duty vehicles. The White House has noted that 72 percent of goods in this country are moved by truck, placing the industry and the center of our critical supply chains and economic competitiveness.5 Efficient and reliable charging infrastructure for heavy-duty vehicles is essential for the sort of transition to electric trucks that the EPA has proposed. However, the technology is nowhere near ready to meet the demand necessary to keep our supply chain moving at the same rate it is today. Charging heavy-duty vehicles requires significantly more expensive conduits and transformers, and consumes vastly more electricity, than what is necessary for charging light-and medium-duty vehicles. Heavy-duty vehicle charging takes longer and is required more frequently than liquid fueling due to electric trucks having reduced range compared to conventional diesel vehicles. This proposal will result in increased curb weight for heavy-duty vehicles due to the significant weight of batteries, leading to reduced payload capacity and ultimately more heavy-duty vehicles on our roadways to move the same amount of freight. This shift may have highway safety implications and create increased congestion on our nation's roadways. In short, the charging technology for heavy-duty vehicles is not readily available and it will take many more years to develop and deploy if it is even economically feasible, making compliance with the EPA' s proposal for heavy-duty vehicles unattainable for the foreseeable future. [EPA-HQ-OAR-2022-0829-5083, p. 2]

5 The Biden-Harris Administration Trucking Action Plan to Strengthen America's Workforce, The White House (Dec. 16, 2021).

The situation for infrastructure to support charging of light-and medium-duty vehicles is only slightly better, with your Agency touting the availability of 130,000 public chargers in its press release announcing its proposals.6 Setting aside their significant reliability issues and lack of broad geographical availability, even a rapid expansion of the number of operational chargers is unlikely to meet the demand for the electrification of two-thirds of the new vehicle fleet by 2032. For reference, 2022 was the worst year for US car sales in a decade with 13.7 to 13.9 million new vehicles sold due to inflation, economic uncertainty, and supply chain disruptions.7 Two--thirds of that depressed sales figure would still represent more than 9 million new vehicles per year being added to the cumulative demand on public charging infrastructure by 2032. [EPA-HQ-OAR-2022-0829-5083, pp. 2-3]

6 Biden-Harris Administration Proposes Strongest-Ever Pollution Standards for Cars and Trucks to Accelerate Transition to a Clean-Transportation Future, US EPA (Apr. 12, 2023).

7 Wayland, Michael. Automakers are cautiously optimistic for a 2023 rebound after worst new vehicles sales in more than a decade, CNBC (Jan. 6, 2023).

Organization: South Coast Air Quality Management District

5. Prioritize infrastructure funding in regions with accelerated ZEV requirements. The proposed rule understandably devotes considerable attention to the significant funding provided by the Bipartisan Infrastructure Law and Inflation Reduction Act that can support this rule. We are encouraged by this substantial investment; however, we suggest U.S. EPA consider how funding will be allocated with priority to non-attainment regions with the highest public health need. California is arguably well ahead of the rest of the nation in deploying zero emission technologies, and our experience in these early deployments highlights key challenges where funding can help to address and accelerate the adoption of ZEVs in our region. Consideration and preferential funding allocations should be given to states, like California, with advanced requirements for ZEV adoption which are needed to attain federal clean air standards. The ZEV regulations in California will require additional costs that can inhibit the deployment of zero emission vehicles at the scale needed to meet air quality standards. Funding support and targeted investments in regions with the highest public health need can help overcome many of these barriers. [EPA-HQ-OAR-2022-0829-0659, p. 3]

Organization: Specialty Equipment Market Association (SEMA)

Government Subsidies

The Federal Government has invested billions of dollars to fund infrastructure projects to support the expansion of BEV charging infrastructure. These investments, which are outlined more below, come on the heels of the Biden Administration's 2021 Electric Vehicle Charging Action Plan to drive American leadership forward on clean cars, and by setting an ambitious target of 50% of electric vehicle (EV) sales shares in the U.S. by 2030.1 [EPA-HQ-OAR-2022-0829-0596, p. 3]

1 FACT SHEET: The Biden-Harris Electric Vehicle Charging Action Plan (Link: https://www.whitehouse.gov/briefing-room/statements-releases/2021/12/13/fact-sheet-the-biden-harris-electric-vehicle-charging-action-plan/).

The Bipartisan Infrastructure Law made a $5 billion investment in electric vehicle charging that will put the U.S. on the path to creating a network of 500,000 chargers across the states. Even with this multi-billion-dollar investment, the nation will still be well short of the projected

1.2 million public chargers that will be needed before 2032 under this proposal. The Department of Energy Loan Program Office (LPO) has also promised roughly $17 billion in loan availability for the Advanced Technology Vehicles Manufacturing (ATVM) Loan Program to support the domestic battery supply chain.2 [EPA-HQ-OAR-2022-0829-0596, p. 3]

2 Department of Energy: Critical Materials Loans & Loan Guarantees (Link: https://www.energy.gov/sites/default/files/2021-06/DOE-LPO_Program_Handout_Critical_Materials_June2021_0.pdf).

Charging Infrastructure Issues

One of the greatest shortcomings of this proposal is that it does not recognize marketplace realities. According to a report from McKinsey about the charging infrastructure needed to implement this rulemaking, it estimates that the U.S. will need to build and deploy approximately 1.2 million more public chargers by 2032. That amounts to an estimated 400 new chargers per day. This would require an 800% increase compared to the daily average of 50 new public chargers deployed last year in this country.14 The federal government's investments in infrastructure will not meet the projected demand with the current proposal creating more uncertainty for consumers that switching to a BEV will be right for them. [EPA-HQ-OAR-2022-0829-0596, pp. 5-6]

14 McKinsey & Company: Building the electric-vehicle charging infrastructure America needs (Link: https://www.mckinsey.com/~/media/mckinsey/industries/public and social sector/our insights/building the electric vehicle charging infrastructure america needs/building the electric-vehicle-charging-infrastructure-america-needs-vf.pdf).

The unintended consequences of these regulations will be extremely far-reaching, adversely impacting both rural and urban vehicle owners. Consumers in rural areas who are forced to drive long distances for work and other necessities may struggle to meet their needs for convenient charging requirements. Urban consumers will struggle in a BEV-centric market due to the lack of charging stations accessible for people who park on the street or in parking garages that cannot meet the need for charging significant numbers of BEVs. [EPA-HQ-OAR-2022-0829-0596, pp. 5-6]

Organization: Stellantis

Electrification Rates Misaligned to Market and Exceed Commitments

Stellantis fully supports comments submitted through The Alliance for Automotive Innovation (AAI or the Auto Innovators) detailing the challenges associated with EPA's overly optimistic expectation for EV market growth. Stellantis remains steadfast to delivering on our commitments to achieve an electrified future, and we acknowledge EPA's efforts with this rulemaking to help support this difficult yet critical transition. However, the proposed rule significantly underestimates the actions needed to build the targeted EV market. Addressing concerns such as manufacturing capacity, battery production, charging infrastructure, and consumer acceptance of EVs will be paramount to the success of this ambitious proposed regulation. [EPA-HQ-OAR-2022-0829-0678, pp. 2-3]

In August of 2021, Stellantis along with the rest of industry through the Auto Innovators, announced support of the Biden administration's goal of achieving 40-50% electrification of the U.S. new light-duty vehicle market by 2030. Foundational to this commitment was the need for stakeholders outside the automotive industry to deliver and execute policies essential for such a significant technology transition: [EPA-HQ-OAR-2022-0829-0678, pp. 3-4]

-Expand and scale the charging network to the EV volumes required

-Update federal EV incentives and apply at point of purchase

-Develop domestic battery supply chain (raw materials, manufacturing, and recycling)

-Implement fleet purchase requirements for EVs (including government fleets)

-Increase research & development to accelerate cost reduction of batteries and EV components

-Increase consumer awareness of EVs [EPA-HQ-OAR-2022-0829-0678, pp. 3-4]

Although there has been progress towards delivering on these essential EV market enablers, significant gaps remain. For example: [EPA-HQ-OAR-2022-0829-0678, pp. 3-4]

The Bipartisan Infrastructure Law (BIL) makes investments in electric vehicle charging that will put us on the path to a network of 500,000 chargers3 – although this is a good down payment on the needed charging infrastructure, it only represents a fraction of what is needed to support the market projected by EPA. [EPA-HQ-OAR-2022-0829-0678, pp. 3-4]

3 FACT SHEET: The Biden-Harris Electric Vehicle Charging Action Plan | The White House

-The Inflation Reduction Act (IRA) committed significant funds to incentivize the purchase of EVs [EPA-HQ-OAR-2022-0829-0678, pp. 3-4]

– however these incentives come with criteria that exclude many EV models today, and pending guidance from the IRS likely could exclude more in the future. [EPA-HQ-OAR-2022-0829-0678, pp. 3-4]

-The IRA also provides an incentive to produce the needed batteries helping to offset their cost – however this only applies to the U.S., ignoring the global supply chain needed to support a 40-50% U.S. EV market. [EPA-HQ-OAR-2022-0829-0678, pp. 3-4]

Despite these major gaps, the EPA in its proposed rule incorrectly assumes these policy actions represent a complete answer to achieve a 40-50% market. EPA's proposed rule extends even further by assuming a "perfect" transition to a battery electric vehicle (BEV) only market at 60% in 2030MY – exceeding the commitment made to President Biden, the Administration's National Blueprint for Transport Decarbonization, and the Stellantis Dare Forward commitment. [EPA-HQ-OAR-2022-0829-0678, pp. 3-4]

These EV penetrations are greater than those of the most mature and forward leaning EV markets in the U.S. Figure 1 below summarizes the electrification rates projected by the EPA proposed rule against the penetration rates required in California's ZEV mandate as part of their recent Advanced Clean Cars II (ACC II) program. California, the most mature EV market in the U.S., will require at least 34% BEVs in 2027, increasing to 54% in 2030, and reaching 66% in 2032. EPA's proposed rule exceeds these California rates in every year from 2027-2032 and by as much as 6% in 2030. [EPA-HQ-OAR-2022-0829-0678, pp. 3-4]

SEE ORIGINAL COMMENT FOR TABLE Industry Average Electrification Rates Figure 1-EV Requirements of EPA NPRM vs. CARB ZEV Mandate and Biden Executive Order [EPA-HQ-OAR-2022-0829-0678, pp. 3-4]

Essential to note is that EPA in this rulemaking is proposing federal standards that will apply across all 50 states, including in places where infrastructure, incentives, and other market enablers for EV adoption lag significantly. For example, Figure 3 below shows the current state of national infrastructure versus what the California Energy Commission (CEC) says will be required to support an EV market at the scale projected for the 2030MY timeframe. [EPA-HQ-OAR-2022-0829-0678, pp. 4-5]

Stellantis fully supports AAI comments that predict there could be as many as 40M EVs on the road needing more than 5.8M public chargers by 2030, a threshold that 500,000 (0.5M) additional chargers targeted by the BIL does not come close to achieving. Even if the estimate of EVs on the road is significantly reduced by 35% to 26M vehicles on the road by 2030 – the conclusion does not change. Figure 3 shows that even with a much lower assumption of 26M EVs on the road, there would still need to be 3.8M public chargers compared to the 700,000 (0.7M) the BIL is scoped to deliver when combined with the 0.2M public chargers available today – less than one-fifth of what is needed. [EPA-HQ-OAR-2022-0829-0678, pp. 4-5]

Additionally, approved funding is only the first step to deployment of a new infrastructure – property needs to be purchased and chargers need to be installed and available to the public, which takes time. [EPA-HQ-OAR-2022-0829-0678, p. 5]

SEE ORIGINAL COMMENT FOR 2030MY Anticipated Infrastructure Need (Based on Estimate of 26M EVs in 2030MY) Figure 3-Estimated public chargers needed based on 26M EVs on the road (based on CEC Electric Vehicle Charging Infrastructure Assessment -AB 2127) [EPA-HQ-OAR-2022-0829-0678, p. 5]

These assessments represent estimates for light-duty vehicles. The charging needs for medium-duty vehicles – also required to grow dramatically by the EPA's proposed rule – is much larger. Per the CEC, medium and heavy-duty vehicles, due to their much larger batteries and need for faster charging times require closer to a 1 to 1 ratio of public charger availability to electric vehicles on the road. The infrastructure challenge is clear: to grow the EV market there needs to be a dramatic increase in charging infrastructure, but as of now there is only a partial commitment to achieve this essential market enabler. [EPA-HQ-OAR-2022-0829-0678, p. 5]

At a House Committee on Energy and Commerce hearing on driving affordability held on June 22, 2023, Rep. Dingell (D-MI) raised concerns with EPA Principal Deputy Administrator Goffman on what happens under the NPRM if companies cannot reach BEV as 67% of new vehicle sales in 2032, consumers cannot afford EVs, the charging stations aren't there, and the assumptions and forecasting EPA relies upon are not viable. Mr. Goffman's response included a reference to a possible market assessment review. Stellantis believes the Auto Innovators' recommended ongoing market-based target adjustment system to be the best embodiment of a direct market review. However, Stellantis could support an additional market-based review that is both objective and transparent in reaching the necessary adjustments to allow this rule to be reasonable and achievable given the large amount of uncertainty with how these key market enablers will develop over the next decade. At a minimum, Stellantis supports EPA adding modules to its annual EPA Automotive Trends Reports that capture important metrics such as the number of public EV charging stations deployed and percent of EVs purchased. [EPA-HQ-OAR-2022-0829-0678, p. 7]

Organization: Steven G. Bradbury

Requiring massive expenditures in electric charging infrastructure. If finalized as proposed, the EPA's emissions rules will hold America's automotive freedom hostage to the need for huge new investments in electric infrastructure throughout the U.S. Again, EPA largely minimizes the portion of these infrastructure costs that would appropriately be attributable to its regulatory actions and downplays the impact. [EPA-HQ-OAR-2022-0829-0647, p. 18]

Organization: Strong Plug-in Hybrid Electric Vehicle (PHEV)

There are several other ways to look at the PHEV cost question. For example, PHEVs result in significant savings to society due to reduced infrastructure investment for both home and away- from-home infrastructure compared to BEVs. For Strong PHEVs that can match long-range BEVs in GHG reduction when battery manufacturing is included, the lower cost of infrastructure can be in the tens of billions of dollars even with modest percentages of Strong PHEVs in use. We encourage EPA to model this cost savings in a scenario. [EPA-HQ-OAR-2022-0829-0646, pp. 22-23]

Strong PHEVs do not need public charging and can rely on fleet-only or home-only charging which reduces the societal cost (e.g., grid upgrades, public incentives for charging stations). For example, this translates to less expense for and impact on the grid including new transformers, distribution feeders and substations compared to battery EVs. PHEVs reduce the need for fast charge stations and potentially for other types of away-from-home charging stations. [EPA-HQ-OAR-2022-0829-0646, pp. 27-28]

- Strong PHEVs charging in residential or fleet applications have less cost to the grid because they typically charge at home or depots at lower kW levels than battery electric vehicles. Allowing Strong PHEV cars and trucks to be eligible will help with several scale-up issues including reducing the pressure to quickly scale up away-from-home and depot DC fast chargers and facilities for battery production and mineral extraction. [EPA-HQ-OAR-2022-0829-0646, pp. 27-28]

- Strong PHEVs do not need public charging (fleet or home only charging is adequate) and use smaller batteries which means more efficient use of mineral resources especially in the near-term. See Appendix C in this letter. [EPA-HQ-OAR-2022-0829-0646, pp. 27-28]

Organization: TCW Inc.

Yet another significant consideration is our nation's ability to provide enough electricity to charge commercial BEV's. While California is "leading the way" on ZEV integration, the state doesn't generate enough power for their consumption needs today. [EPA-HQ-OAR-2022-0829-0452, p. 1]

https://truckingresearch.org/2022/12/06/new-atri-research-evaluates-charging-infrastructure-challenges-for-the-u-s-electric-vehicle-fleet/ [EPA-HQ-OAR-2022-0829-0452, p. 1]

Organization: Tesla, Inc.

The Tesla Supercharger network reliably serves quick charging needs to BEV drivers on road trips with limited time to charge, and without access to charging at home or at the workplace.27 As of April 2023, there are more than 4,900 Supercharger locations globally and more than 45,000 Supercharger stalls. In the U.S., there are approximately 2,000 Supercharger locations and more than 21,000 Supercharger stalls capable of charge rates up to 250 kW. Superchargers are located in all fifty States, the District of Columbia, and Puerto Rico, representing approximately 60% of the DCFC plugs operational today in the U.S. In February 2023, in conjunction with the White House, Tesla announced it will open at least 3,500 Superchargers in the U.S. to non-Tesla vehicles.28 Further, recently Ford announced it will be adopting the North America Charging Standard (NACS) and will partner with Tesla to allow Ford vehicles – including BEV like Mach-E and the F-150 Lightning – to utilize the Tesla Supercharger network.29 Similarly, General Motors,30 Volvo,31 Polestar32 and Rivian33 have announced that they will also be adopting the NACS standard and several electric vehicle charging manufacturers, including ABB,34 Flo,35 and BTC Power36 also announced that they would be supplying NACS capable chargers moving forward. Numerous charging providers have also followed suit.37 [EPA-HQ-OAR-2022-0829-0792, pp. 5-6]

SEE ORIGINAL COMMENT FOR Figure 1: Tesla Global Delivery Volume and Job Growth [EPA-HQ-OAR-2022-0829-0792, pp. 5-6]

In any event, deployment of adequate charging infrastructure is already, and will be, available commensurate with the rate of BEV uptake supported by more stringent rules than the agency proposes. EPA's analysis of this issue should focus on when the standards come into effect: to the extent EPA has authority to consider infrastructure issues, it would be under its authority to have the regulation take effect "after such period as the Administrator finds necessary to permit the development and application of the requisite technology,"186 which necessarily entails a predictive judgment about what the infrastructure capacities would be in the future (including in response to the proposed rule), rather than being limited to the status quo. For example, in the past EPA has considered whether technology would "would be perfected early enough to allow its mass production and installation."187 [EPA-HQ-OAR-2022-0829-0792, p. 30]

186 42 U.S.C. § 7521(a)(2) (emphasis added).

187 NRDC v. EPA, 655 F.2d 318, 324 (D.C. Cir. 1981).

While the proposal focuses its attention on non-residential charging, the agency should more robustly recognize the role of residential charging.188 In the U.S. there are approximately 82 million single family homes most of which are a capable of providing Level 1 and 2 BEV charging.189 As DOE indicates 80% of EV charging is done at home due to the convenience and low cost of residential charging and strategies for addressing the increase in electricity demand are readily available.190 Further, as the EPA notes, the IRA's extension of the Alternative Fuel Refueling Property Tax Credit through Dec 31, 2032, will support individual home owners investment in significantly expanding residential charging.191 [EPA-HQ-OAR-2022-0829-0792, p. 30]

191 See, Draft RIA at 5-26.

Additionally, the agency unduly dampens the rate of Level 3 charging deployment by utilizing cost estimates for DCFC installation that are dramatically higher than Tesla's experience. Tesla has established the lowest cost in the industry and shown the costs to be more than 50% below current industry averages.192 EPA utilizes a mid-range DCFC cost of $153,000 per charging port for a 250 kW DCFC port. In comparison, Tesla costs are under $40,000 per deployed DCFC port.193 This overestimation of the cost of deployment indicates that the agency underestimates the volume of DCFC that can be deployed based on expected investment levels. Importantly, EPA should recognize, as Tesla's figures exemplify, that non-utility ownership of BEV charging stations is associated with significantly reduced cost of installation.194 Further, charging technology, like vehicle technology, is also maturing as more suppliers and manufacturing facilities are coming online and the cost of installation will continue to decline.195 [EPA-HQ-OAR-2022-0829-0792, pp. 30-31]

Rapid and Expansive Investment in Charging Infrastructure Supports Stringent Multi-Pollutant Light-Duty Emission Standards

As EPA notes, investments in BEV charging infrastructure have grown rapidly in recent years and will continue to accelerate.196 Moreover, a number of new Congressionally enacted policies will also facilitate greater and rapid deployment of charging infrastructure sufficient to support more robust light-duty standards.197 The Bipartisan Infrastructure Law (IIJA) bipartisan infrastructure and investment and jobs act invests $7.5 billion to build out the first-ever national network of EV chargers. IIJA also created the Charging and Fueling Infrastructure Discretionary Grant Program to deploy publicly accessible charging and fueling infrastructure and provides for $2.5 billion over five years for the program.198 At the end of March 2023, FHWA issued a notice of funding opportunity to solicit applications for grants totaling up to $700 million to deploy charging and alternative fueling infrastructure projects. Half of the $700 million is allocated for electric vehicle and other infrastructure located on public roads or in other publicly accessible locations, while the other half is allocated for charging and alternative fueling infrastructure located along designated alternative fuel corridors. [EPA-HQ-OAR-2022-0829-0792, pp. 31-32]

198 Infrastructure Investment and Jobs Act, P.L 117-58 (Nov. 15, 2021), Section 11401.

In addition to the federal investments in charging facilitated by the IIJA, the IRA's Section 30C provides significant tax incentives for the deployment of private capital into charging infrastructure for both light and heavy-duty vehicles.199 It allows for up to $100,000 for each charger with no limit on how many chargers a fleet can purchase and install at one site; this will drive significant new private investment. Similarly, tax incentives for building efficiency will also benefit EV charging installations.200 PWC recently predicted that the BEV charging market will grow ten-fold by 2030.201 Another new analysis establishes BEV charger annual installed capacity will overtake distributed solar for the first time in 2023 and will reach 41 GW by 2027 and the BEV charging infrastructure market will reach US $20 billion by 2027, led by the residential Level 2 (US $6.5 billion) and public DC fast-chargers (US $5.6 billion) segments.202 Further, the International Energy Agency (IEA), in its 2022 Trends in Charging Infrastructure study, reported that already "the United States counts about 22,000 fast chargers, of which nearly 60% are Tesla superchargers."203 Notably, Tesla plans to double the size of our Supercharging network in the next 18-24 months.204 Other automakers are following in Tesla's footsteps and entering into EV charging partnerships and investments as well.205 Similarly, fossil fuel companies are reorienting investment around BEV infrastructure.206 Investment in charging infrastructure will be further enhanced by state rebates and incentive programs. Numerous incentives that will also facilitate new charging infrastructure have been established and enacted.207 [EPA-HQ-OAR-2022-0829-0792, pp. 31-32]

The HD Tailpipe Rule Will Devastate Trucking

Former Supreme Court Justice Breyer stated in Whitman v. Am. Trucking, 531 U.S. 457 (2001), that the Clean Air Act “does not require the EPA to eliminate every health risk, however slight, at any economic cost, however great, to the point of ‘hurtling’ industry over ‘the brink of ruin.’” Id. at 494. In the Whitman case the Supreme Court vacated the 1997 NAAQS because of the poor science and lack of discernable criteria underlying them. Likewise here, no scientific data requires the EPA to enact the most stringent tailpipe emission limits conceivable. [EPA-HQ-OAR-2022-0829-0510, pp. 4-5]

Electric trucks typically have a higher upfront purchase price compared to traditional diesel trucks. The HD Tailpipe Rule will effectively bar diesel trucks from sale, forcing trucking companies seeking to replace their fleet to take on more costs to do so. This will strain the financial resources of some companies, especially smaller ones. Shifting from diesel trucks to electric ones will also require adapting to new technologies and training drivers to effectively operate electric vehicles. This transition period will likely lead to disruptions in the supply chain and additional costs — both temporal and monetary — for trucking companies. [EPA-HQ-OAR-2022-0829-0510, pp. 4-5]

Moreover, the availability of charging stations for electric trucks is currently poor and still developing. It is certainly not as extensive as refueling stations for diesel trucks, and retrofitting existing truck stops for electric charging will place immense strain on electrical infrastructure and the national grid, especially in rural communities often frequented by truckers traveling the nation’s highways, causing prices to skyrocket for average Americans. [EPA-HQ-OAR-2022-0829-0510, pp. 4-5]

The resulting chaos will limit the range and flexibility of electric trucks for long-haul journeys. Electric trucks already have limited range compared to diesel trucks, particularly when fully loaded. This will mean more frequent charging, adjustment to trucking routes, and overall shipping delays, negatively affecting operational efficiency. And even if the myriad infrastructure issues involved in getting power to truck refueling stations were solved or mitigated, the electricity used to charge electric trucks would still primarily come from America’s most reliable and abundant power source: fossil fuels. [EPA-HQ-OAR-2022-0829-0510, pp. 4-5]

In effect, the HD Tailpipe Rule will force truckers to spend substantial financial and human resources to comply with ultra vires government regulations that fail to make even a marginal dent in global issue of changing climate. [EPA-HQ-OAR-2022-0829-0510, pp. 4-5]

The LMD Tailpipe Rule Will Unnecessarily Harm Consumers

Similarly, the LMD Tailpipe Rule is regulatory overkill that will harm average Americans and limit innovation. To start, stricter emissions regulations will increase manufacturing costs for automakers. This will lead to higher sticker prices for vehicles, pricing low-to middle-class Americans out of the automotive market, leaving them stranded with little recourse or dependent on public transit, eventually depressing the job market. The government should not place the burden for green energy on the least fortunate Americans, adding yet another obstacle to their economic climb. [EPA-HQ-OAR-2022-0829-0510, pp. 5-6]

Automakers will rush to convert their fleets to feature either all or mostly electric vehicle models, disadvantaging new car buyers in areas without existing electric charging infrastructure. In the same vein, as mentioned above, the strain placed on the electric grid caused by millions of Americans charging their vehicles will cause electric prices to rise markedly and lead to “brown-outs.” See, e.g. Nadia Lopez, Race to zero: Can California’s power grid handle a 15-fold increase in electric cars?, CALMATTERS (Feb. 6, 2023), https://calmatters.org/environment/2023/01/california-electric-cars-grid/ (“State officials claim that the 12.5 million electric vehicles expected on California’s roads in 2035 will not strain the grid. But their confidence that the state can avoid brownouts relies on a best-case — some say unrealistic — scenario: massive and rapid construction of offshore wind and solar farms, and drivers charging their cars in off-peak hours.”). [EPA-HQ-OAR-2022-0829-0510, pp. 5-6]

Additionally, electric cars have limited range and require long recharging sessions, and the infrastructure to support the sudden transition to electric vehicles that the LMD Tailpipe Rule would cause simply does not exist. Rural and low-income communities, the people most affected by this regulation, likely will be the last to receive said recharging infrastructure. [EPA-HQ-OAR-2022-0829-0510, pp. 5-6]

Finally, EPA should assess impacts to the national economy as a result of potentially accelerating ZEV freight transport that would cease to be reliable or functional outside of a geographically confined network of charging/fueling infrastructure and support systems. [EPA-HQ-OAR-2022-0829-0510, p. 7]

Organization: The Heritage Foundation (Kevin Dayaratna and Diana Furchtgott-Roth)

Charging will also cost more. The new power plant rules will regulate carbon dioxide and other so-called greenhouse gas emissions from both new and existing natural gas and coal-fired power plants, and require carbon capture systems or a switch to hydrogen fuels.5 These commercially unproven systems for capturing carbon are costly and will be passed on to consumers in the form of higher electricity rates. Drivers will find it more expensive to use electricity for all purposes, including charging their electric vehicles, harming poor and middle-class drivers the most. EPA does not address its new power plant rules in this rule. [EPA-HQ-OAR-2022-0829-0674, pp. 2-3]

5 Environmental Protection Agency, “Greenhouse Gas Standards and Guidelines for Fossil Fuel-Fired Power Plants,” May 15, 2023, https://www.epa.gov/stationary-sources-air-pollution/greenhouse-gas-standards-and-guidelines-fossil-fuel-fired-power (accessed May 18, 2023).

Mandating electric vehicles would reduce Americans’ standard of living. Back in the early 1900s, when Henry Ford started producing cars, only rich Americans could afford them. Throughout the 20th century cars became less expensive, and many households can afford not one but two. Cars are already becoming more expensive, and the proposed rule accelerates that trend, taking America back a century, where new cars will be only for the rich. EPA does analyze declines in standards of living. [EPA-HQ-OAR-2022-0829-0674, pp. 3-4]

Recharging an electric vehicle from empty can take over an hour, compared to 5 minutes to fill up with gas.11 If there is a line to use the charging station the wait can double. Most people do not want to let their EV battery go below 20%, and the charging rate goes down when it is charged over 80%.12 Throughout America the poor rarely have access to indoor garages for overnight charging, and in most large cities, such as New York City, the middle-class also have no access to indoor charging. Using charging stations on the street, if available, risks theft of expensive charging cables. EPA does not account for this lack of convenience. [EPA-HQ-OAR-2022-0829-0674, pp. 3-4]

Organization: The Mobility House et al.

Additionally, PCS can save customers and ratepayers through avoided infrastructure investments. Pacific Gas and Electric (PG&E) of Northern California reported that sites that used Automated Load Management (ALM), a form of PCS, to dynamically modulate and reduce EV charging to meet site infrastructure needs saved $30,000 -$200,000 per site in avoided infrastructure upgrades. 1 [EPA-HQ-OAR-2022-0829-0657, p. 2]

1 Pacific Gas and Electric Company Electric Vehicle Charge 2 Prepared Testimony, pages 2-9 – 2-10, October 26, 2021.

Organization: Toyota Motor North America, Inc.

While our attached comments cover a range of issues for EPA’s consideration, the five below summarize the most critical: [EPA-HQ-OAR-2022-0829-0620, p. 2]

1. The proposed standards are expected to result in a new vehicle sales mix of 67% BEV by 32MY. Achieving such a high penetration is almost entirely dependent on factors outside our control. As discussed in more detail in our attached comments, hundreds of new mines are needed globally to produce enough critical minerals to support so many BEVs. The sources for those minerals are almost exclusively outside the U.S., as is most of the mineral processing to turn the ore into usable battery-grade material. And the charging infrastructure (both in-home and public) needed to support that level of electrification is far from where it needs to be. Recent legislation and incentives are directionally supportive but appear far short of what is needed. EPA should adjust the standards in the proposed rule to account for these major uncertainties

over which automakers have little control, but for which we face significant compliance and brand/reputation ramifications should they not come to bear. Compliance cannot be based on factors over which we have no control. [EPA-HQ-OAR-2022-0829-0620, p. 2]

The Proposed Rule also for the first time imposes standards on automakers for which compliance requires significant actions by third parties over which we (or EPA) have no control. First, achieving the level of BEVs required by the Proposed Rule will require massive new supplies of critical minerals, the mines to extract them, and the refining facilities to turn ore into battery-grade material. Currently, virtually the entire mineral and battery supply chain is outside the U.S. Second, it requires massive investments in home and public charging infrastructure, as well as upgrades to the electrical grid throughout the U.S. and an accelerated shift to renewable power generation. Various provisions of the IIJA and IRA directionally support some of these areas but fall significantly short of what will be needed for the expected level of electrification. And finally, the ultimate impact of these factors on vehicle costs and consumer demand are unclear, at best. The are few contingencies for automakers and our customers in the event any or all these factors stand in the way of complying with the Proposed Rule. Our comments below address these and other issues. [EPA-HQ-OAR-2022-0829-0620, pp. 8-9]

We are prepared to follow up with additional information beyond these comments. We look forward to collaborating toward a more workable Final Rule. [EPA-HQ-OAR-2022-0829-0620, pp. 8-9]

5. GHG Program

The Proposed Rule fails to demonstrate the penetration of BEVs assumed for compliance with the proposed standards is feasible. The proposal notes “While emission standards set by the EPA under CAA section 202(a)(1) generally do not mandate use of particular technologies, they are technology-based, as the levels chosen must be premised on a finding of technological feasibility.”17 CAA section 202(a)(1) states “Any regulation prescribed under paragraph (1) of this subsection (and any revision thereof) shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.”18 [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

17 88 Fed. Reg at 29232.

18 42 U.S.C. § 7521(a)(2).

The aggressive ramp up of BEVs (see Table 1) required to comply forces a rapid transformation of how vehicles are manufactured, driven, fueled, and serviced. As such, “leadtime and requisite technology” must extend to the availability of critical minerals, the readiness of a sustainable battery supply chain and fueling infrastructure, as well as other market-related factors that will affect the price and consumer demand of BEVs. [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

[Table 1 Annual BEV Penetration Assume for Compliance w/ Proposed Standards: [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

MY 2027: BEV Share 36

MY 2028: BEV Share 45

MY 2029: BEV Share 55

MY 2030: BEV Share 60

MY 2031: BEV Share 63

MY 2032: BEV Share 67] [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

Today's PEV support system clearly cannot meet the needs of the future envisioned by the proposal. Our comments explain why the proposal lacks a clear justification for how the support system will be in place over the period of the proposed standards. Neither EPA nor auto manufactures can control the timing or outcomes of these essential support measures. [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

Therefore, it is disappointing that EPA removed the e-RIN proposal from the RFS set rule as it is one of the few measures for which EPA has direct authority to provide at least some level of assistance in supporting the EV shares required in the GHG proposal. After a muti-year collaboration with the auto industry, a valuable policy tool for establishing PEV markets and promoting clean energy has been lost. [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

Finally, EPA has taken a more measured view of technology risk and uncertainty in past vehicle emissions rulemakings in which technology costs were lower and automakers had significantly more direct control over managing their technology development, deployment, and sales mix to comply. In this Proposed Rule, EPA appears to be taking a much more cavalier approach to risk, lead time, and ensuring the "requisite technology" is available, despite the high cost of BEVs, the massive uncertainty around mineral supplies, the significant investment needed in charging infrastructure and the power grid, and the uncertain market demand for BEVs. The standards in the Final Rule should be adjusted to better account for market uncertainties. [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

Organization: Transfer Flow, Inc

A major concern for consumers is how they would charge an electric vehicle. For citizens living in apartment buildings or utilizing on-street parking, managing an electric vehicle would be inconvenient and challenging. The image below from Deloitte's 2022 Global Automotive Consumer Study17 illustrates consumer powertrain preferences for their next vehicle, which are not aligned with the EPA's proposed Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles. [EPA-HQ-OAR-2022-0829-0496, pp. 3-5]

17 https://www2.deloitte.com/content/dam/Deloitte/global/Documents/Consumer-Business/us-2022-global-automotive-consumer-study-global-focus-final.pdf

[See original attachment for "Consumer powertrain preferences for their next vehicle"]

Electric Vehicles require the ramp-up of many new electricity-generating power plants to provide enough power to charge all the projected electric vehicles, and then those electricity-generating power plants must rely heavily on carbon capture technologies to keep the emissions from these electricity-generating power plants out of the atmosphere. Current carbon capture technologies are experimental and may prove dangerous.22 [EPA-HQ-OAR-2022-0829-0496, pp. 3-5]

22 https://www.huffpost.com/entry/gassing-satartia-mississippi-co2-pipeline_n_60ddea9fe4b0ddef8b0ddc8f

In many places, such as rural environments or for use in utility vehicles, electric vehicles are not a practical solution. Utility companies working on phone lines, power lines, and performing construction work all need reliable power sources that can be used for transporting people and powering equipment, as well as function when the electric power grid may be in need of repair. Electric vehicles do not have a network in remote areas or the energy density to effectively transport and power auxiliary equipment needed to, among other functions, install or perform repairs to electric power lines. [EPA-HQ-OAR-2022-0829-0496, pp. 3-5]

Pacific Gas and Electric (PG&E), two years after the historical Dixie Fire, is still powering affected Californians with diesel-powered generators as the infrastructure required to bring electricity into homes has still not been rebuilt. Citizens living in these affected areas would need to charge electric vehicles using electricity created from diesel generators, and the logistics of that simply do not make sense. [EPA-HQ-OAR-2022-0829-0496, pp. 3-5]

For a myriad of reasons, people may be hesitant to adopt electric vehicle technology. Near-zero technologies are going to be more agreeably adopted if consumers feel they have a choice of which near-zero technology works best for them. In Northern California, many citizens affected by various wildfires still harbor animosity towards PG&E for negligently causing various wildfires that have ruined thousands of people's lives. In 2020 PG&E pled guilty to 84 counts of manslaughter for starting the historically devastating Camp Fire.23 Many citizens affected by these wildfires don't want electric vehicles because they don't believe they can trust PG&E. Not encouraging a choice of which near-zero technology consumers choose to implement runs the risk of having the opposite intended effect. Consumers will likely choose to hold on to their old, dirtier vehicles, defeating the intended purpose. [EPA-HQ-OAR-2022-0829-0496, pp. 3-5]

Organization: U.S. Chamber of Commerce

-Inadequate EV charging infrastructure. It is widely regarded that consumer acceptance of and interest in electric vehicles is highly dependent on the existence of a sufficient nationwide network of EV charging infrastructure. As noted in the proposed rule, the bipartisan Infrastructure Investment and Jobs Act provides $7.5 billion of Federal Highway Administration funding for charging infrastructure deployment efforts that provide an important start for this effort. However, implementation of these programs has barely begun, and there is ample evidence that even their successful and on-time execution will leave the U.S. far short of the number of charging stations necessary to support the proposal's expectation of nearly 70% EV sales in 2032. Addressing this shortcoming is fundamental to overcoming consumer reluctance to EV adoption. The Chamber encourages EPA to work with automakers, utilities, the Department of Energy, and state governments to adjust phase-in timelines of this rulemaking to correspond to realistic expectations of EV charging infrastructure buildout. [EPA-HQ-OAR-2022-0829-0604, p. 2]

Organization: U.S. Conference of Catholic Bishops (USCCB)

The greater adoption of EVs can be good for society and the environment when incentives are directed to consumers who will use EVs extensively, such as single-vehicle households, ride sharing drivers, used car buyers and middle-and lower-income households.24 In addition, some aspects of EV infrastructure subsidies, such as in the geographical distribution of charging stations, tend to reflect and perpetuate "disparities across race and income."25 A modified proposed rule should address these concerns with a strategy to allocate EV resources to middle- and low-income households, and also favor users who will be inclined to use the EV for the necessary number of miles so that it produces a net environmental benefit. [EPA-HQ-OAR-2022-0829-0540, pp. 4-5]

24 Hardman, S. et al., Aug. 30, 2021, https://sciencepolicyreview.org/2021/08/equity-transition-electric-vehicles/

25 "The result shows a similar overall pattern of access disparities between the race and ethnicity groups, but the access gap is larger than that found for public chargers overall… The odds of having publicly-funded charger access in Black and Hispanic majority CBGs is less than half of that in White-majority CBGs." Hsu, C. & Figerman, K. 'Public electric vehicle charger access disparities across race and income in California', https://www.sciencedirect.com/science/article/pii/S0967070X20309021.

The EPA's numerous regulations that promote human and ecological health, reduce GHG, and promote the common good are commendable. In these times of growing ecological challenges, increased inequality, and fiscal pressures, aggressive environmental standards must also respect economic and social considerations, driving our nation towards an "energy revolution" that provides "not only sustainable, efficient and clean energy, but also energy that is secure, affordable, accessible and equitable."26 For these same reasons, the light-duty vehicle standards should be improved and optimized to benefit primarily low-and middle-income Americans to reduce racial and economic disparities. [EPA-HQ-OAR-2022-0829-0540, pp. 4-5]

Organization: Valero Energy Corporation (Valero)

1. The EVSE (charging infrastructure) installation costs adopted by EPA are unrealistic.

Table 5-14 of the Draft Regulatory Impact Analysis ("DRIA") summarizes the ranges of costs that EPA considered for EVSE hardware and installation.3 Recent estimates by EV charging station vendors and in DOT-approved state EV Infrastructure Deployment Plans project significantly higher EVSE costs than used by EPA in their cost analysis, ranging from $500,000 to $1.2 million in capital expenditures for a minimally-compliant NEVI charging station containing four simultaneously operable 150 kW CCS ports (i.e., $125,000 - $300,000 per DC-150 kW port).4,5,6,7 [EPA-HQ-OAR-2022-0829-0707, pp. 1-3]

3 DRIA at 5-32 and 5-33.

7 U.S. DOT Fiscal Year 2022/2023 EV Infrastructure Deployment Plans (accessed May 20, 2023), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/. See plans submitted by and approved for Alabama, Alaska, Colorado, District of Columbia, Idaho, Indiana, Iowa, Kentucky, Louisiana, Minnesota, Mississippi, Nebraska, North Dakota, Ohio, Oklahoma, Rhode Island, South Dakota, Texas, and Wyoming.

Beyond the EVSE hardware and installation costs, EPA fails to consider annual operating and maintenance costs for EVSE, estimated by the District of Columbia to run $1,000 per Level 2 charger and $1,400-$2,000 per Level 3 DC fast charger.8 [EPA-HQ-OAR-2022-0829-0707, pp. 1-3]

8 Government of the District of Columbia, “District’s Electric Vehicle Infrastructure Deployment Plan” at 13 (2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/dc_nevi_plan.pdf.

Although EPA acknowledges that upgrades to electricity distribution systems may be required to meet the charging loads associated with EVSE, it immediately dismisses the costs, explaining that

“EPA acknowledges that there may be additional infrastructure needs and costs beyond those associated with charging equipment itself. While planning for additional electricity demand is a standard practice for utilities and not specific to PEV charging, the buildout of public and private charging stations (particularly those with multiple high-powered DC fast charging units) could in some cases require upgrades to local distribution systems. For example, a recent study found power needs as low as 200 kW could trigger the need to install a distribution transformer while a load of 5 MW or more could require upgrades to feeder circuits or the addition of a feeder breaker.”9 [EPA-HQ-OAR-2022-0829-0707, pp. 1-3]

9 DRIA at 5-34 to 5-35.

“There is considerable uncertainty associated with future distribution upgrade needs as well as with the uptake of the technologies and approaches discussed above that could reduce upgrade costs, and we do not model them directly as part of our infrastructure cost analysis.”10 [EPA-HQ-OAR-2022-0829-0707, pp. 1-3]

10 DRIA at 5-36.

Regardless of who is paying, upgrades to electrical infrastructure are real impacts associated with EVSE installation and come with real costs. In their EV Infrastructure Deployment Plans, several states quantify the cost of electrical system upgrades needed to accommodate EVSE, including:

• Idaho cites that “charging stations installed with NEVI formula funds must be able to provide a power output of at least 600kW. In Idaho, most NEVI sites will require transformer upgrades. Additional improvements such as installing new feeder lines and completing substation upgrades also may be needed. At the very least, new electrical upgrades for a new transformer cost approximately $20-30,000.”11 [EPA-HQ-OAR-2022-0829-0707, pp. 1-3]

11 Idaho Transportation Department, “2022 State of Idaho Electric Vehicle Infrastructure Baseline Plan” at 38 (August 1, 2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/id_nevi_plan.pdf.

• Indiana cites that "Utilities estimated investment between $50,000 to $125,000 to serve 600kW per station with locations requiring significant system upgrades totaling greater than $1 million. Upgrades could include new transformers, trenching, concrete/asphalt work, conduit, underground vaults, new conductor, and other miscellaneous equipment to serve the DCFC. Respondents expressed they would not deny an installation from proceeding. However, as expressed above, costs may be prohibitive for the prospective customer at certain locations."12 [EPA-HQ-OAR-2022-0829-0707, pp. 1-3]

12 Indiana Department of Transportation, "Indiana Electric Vehicle Infrastructure Deployment Plan" at 37 (July 29, 2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/in_nevi_plan.pdf.

These utility costs may not be borne solely by individual customers; in some cases, these costs will ultimately be passed on to ratepayers. EPA fails to acknowledge these costs and fails to assess the cumulative cost burden resulting from the concurrent increase in electrical demand resulting from implementing the proposed LMD vehicle rule in the same time frame it seeks to force electrification of the heavy-duty vehicle fleet. [EPA-HQ-OAR-2022-0829-0707, pp. 1-3]

EPA should evaluate the merits of all fuels and vehicle technologies on a full lifecycle basis. For example, EPA states that "[i]n December 2022, Toyota announced plans to introduce 30 BEV models by 2030".125 But EPA's Proposed Rule should also meaningfully consider following statements from Toyota in the same announcement:126 [EPA-HQ-OAR-2022-0829-0707, pp. 25-27]

125 EPA's Proposed Rule at 29191 (citing to Toyota Motor Corporation, ''Video: Media Briefing on Battery EV Strategies,'' Press Release, December 14, 2021. Accessed on December 14, 2021).

126 Toyota Motor Corporation, "Video: Media Briefing on Battery EV Strategies,'' Press Release, December 14, 2021 (emphasis added).

• "We are living in a diversified world and in an era in which it is hard to predict the future. Therefore, it is difficult to make everyone happy with a one-size-fits-all option. That is why Toyota wants to prepare as many options as possible for our customers around the world." [EPA-HQ-OAR-2022-0829-0707, pp. 25-27]

• "If the energy that powers vehicles is not clean, the use of an electrified vehicle, no matter what type it might be, would not result in zero CO2 emissions." [EPA-HQ-OAR-2022-0829-0707, pp. 25-27]

Moreover, in April 2023, Toyota sent its dealers a "Hybrid Memo" pointing out that "There are three major barriers to widespread battery electric vehicle adoption in the United States" – critical minerals, charging infrastructure, and affordability. Noting that the amount of raw materials in one BEV could be used to make 6 PHEV or 90 hybrid electric vehicles, the memo concludes that "An 'all of the above' electrification strategy is the bridge to get us to lower overall carbon emissions."127 [EPA-HQ-OAR-2022-0829-0707, pp. 25-27]

127 https://jalopnik.com/toyota-focusing-on-hybrids-not-electric-vehicles-1850440908

EPA also cites to a July 2021 Stellantis announcement regarding its "intensified focus on electrification across all of its brands."128 Yet, EPA does not consider qualifying statements like those made by Stellantis CEO Carlos Tavares in May 2022, in which he stated that he expects a shortage of EV batteries by 2024-2025, followed by a lack of raw materials for the vehicles by 2027-2028.129 Mr. Tavares has also provided that "[y]ou'll see that the electrification path, which is a very ambitious one, in a time window that has been set by the administrations is going to bump on the supply side".130 Further, in response to EPA's proposed rule, Chrysler parent Stellantis has said it remains "committed to reducing vehicle emissions," adding "we are surprised that none of the alternatives align with the President's previously announced target of 50% EVs by 2030."131 [EPA-HQ-OAR-2022-0829-0707, pp. 25-27]

128 EPA's Proposed Rule at 29191(citing to Stellantis, ''Stellantis Intensifies Electrification While Targeting Sustainable Double-Digit Adjusted Operating Income Margins in the Mid-Term,'' Press Release, July 8, 2021).

129 Reuters, "Automotive industry faces long term battery, raw material supply issues, Tavares says" (May 10, 2022) https://www.reuters.com/business/autos-transportation/automotive-industry-faces-long-term-battery-raw-material-supply-issues-tavares-2022-05-10/ (emphasis added).

130 Wayland, Michael, "Stellantis CEO warns of electric vehicle battery shortage, followed by lack of raw materials (May 24, 2022) https://www.cnbc.com/2022/05/24/stellantis-ceo-warns-of-ev-battery-shortage-lack-of-raw-materials.html.

131 Root, Al, "Car Makers Don't Love EPA's EV Plan. Here's What Ford, GM, and Others Are Saying, Barrons (April 13, 2023) https://www.barrons.com/articles/ev-epa-emissions-what-auto-makers-say-9abaedd6?ns=prod/accounts-barrons.

Further, EPA provides that "in January 2021, General Motors announced plans to become carbon neutral by 2040, including an effort to shift its light-duty vehicles entirely to zero-emissions by 2035."132 Yet GM's 10-K filed in January 2023 caveats that:133 [EPA-HQ-OAR-2022-0829-0707, pp. 25-27]

132 EPA's Proposed Rule at 29190 (citing to General Motors, ''General Motors, the Largest U.S. Automaker, Plans to be Carbon Neutral by 2040,'' Press Release, January 28, 2021).

133 GM's 10-K Annual Report for the 2022 Fiscal Year, https://investor.gm.com/static-files/54bdb095-143e-4b96-b6d5-25937910b59c (emphasis added).

"[A]ny increase in the cost, or reduced availability, of critical materials for our EV propulsion systems, including lithium, nickel, cobalt and certain rare earth metals, could lead to higher production costs for our EVs and could impede our ability to successfully deliver on our EV strategy. Further, increasing global demand for, and uncertain supply of, such materials could disrupt our or our suppliers' ability to obtain such materials in a timely manner and/or could lead to increased costs. Geopolitical risk, fluctuations in supply and demand, fluctuations in interest rates, any weakening of the U.S. dollar and other economic and political factors have created and may continue to create pricing pressure for commodities, raw materials and other inputs." [EPA-HQ-OAR-2022-0829-0707, pp. 25-27]

GM's 10-K further disclosed that its "business in China subjects [it] to unique operational, competitive and regulatory risks" and that "[i]ncreased competition, continued U.S.-China trade tensions or weakening economic conditions in China, among other factors, may result in cost increases, price reductions, reduced sales, profitability and margins, and challenges to gaining or holding market share." [EPA-HQ-OAR-2022-0829-0707, pp. 25-27]

Other auto-manufacturers have similar views. In response to EPA's proposed rule, a Hyundai spokesperson provided that "[t]he proposed vehicle emission rules released by EPA will be challenging to meet and will require further expansion of charging infrastructure, consumer incentives and supply chains".134 Regarding Tesla, after stating that the BEV manufacturer aims to produce 20 million EVs per year before 2030,135 CEO Elon Musk clarified that Tesla's target is an "aspiration, not a promise . . . we may stumble and not reach that goal".136 In June 2022, Elon Musk further stated that "[b]oth [of Tesla's] Berlin and Austin factories are gigantic money furnaces right now. It's like a giant roaring sound, which is the sound of money on fire".137 [EPA-HQ-OAR-2022-0829-0707, pp. 25-27]

134 Root, Al, "Car Makers Don't Love EPA's EV Plan. Here's What Ford, GM, and Others Are Saying, Barrons (April 13, 2023) https://www.barrons.com/articles/ev-epa-emissions-what-auto-makers-say-9abaedd6?ns=prod/accounts-barrons.

C. EPA's consideration of ZEV infrastructure is inadequate and insufficient.

As described in Valero's comments on EPA's Heavy Duty Vehicle ("HDV") Phase 3 proposal,149 EPA has not adequately assessed and accounted for ZEV infrastructure readiness. EPA's LMDV proposal similarly neglects an honest and accurate assessment of ZEV infrastructure readiness. [EPA-HQ-OAR-2022-0829-0707, pp. 30-31]

149 Comments of Valero Energy Corporation, June 16, 2023, posted at https://www.regulations.gov/comment/EPA-HQ-OAR-2022-0985-1566

As EPA acknowledges in the preamble, auto manufacturers have pointed out that charging infrastructure must be addressed in addition to the technological feasibility of making electric vehicles.150 EPA seems to assume that the "powerful incentives" provided by IRA funding are sufficient to address this issue. However, because IRA credits are intended to expand charging access in low-income and rural communities, they are not available to incentivize charger installation in urban areas or in areas exceeding certain average-income or poverty-rate thresholds.151 Further, while the BIL provides $7.5B in funding for the National Electric Vehicle Infrastructure (NEVI) Formula Program, this level of funding is not remotely sufficient to address the cumulative $53-127B investment needed to support growth from approximately 3.1 million charging ports in 2022 to estimated 28 million charging ports needed by 2030.152 [EPA-HQ-OAR-2022-0829-0707, pp. 30-31]

150 Proposed Rule at 29341.

151 https://www.evconnect.com/blog/the-impact-of-inflation-on-ev-charging; https://www.foley.com/en/insights/publications/2022/08/ev-charging-station-tax-credits-are-back

152 National Renewable Energy Laboratory, "The 2030 National Charging Network: Estimating U.S. Light-Duty Demand for Electric Vehicle Charging Infrastructure," June 2023, available at https://www.nrel.gov/docs/fy23osti/85654.pdf.

Further, EPA does not consider the impact of charger performance and consumer experience on consumer acceptance of electric vehicles. A report by the National Renewable Energy Laboratory (NREL) on electric vehicle charging infrastructure development notes that "This analysis envisions a future national charging network that is strategic in locating the right amount of charging, in the right locations, with appropriate charging speeds. However, this vision is irrelevant if the public concludes that charging infrastructure is ultimately unreliable. Even if a relatively small amount of infrastructure fails drivers, this could negatively impact the public's perception of electric mobility."153 There is good reason for NREL to raise this concern. A national survey of 26,500 charging attempts at Level 2 and Level 3 public stations found that 20% failed to obtain a charge.154 Common reasons for failure included software glitches, payment processing errors, and vandalism. In 75% of the failures, the charger was out of service. [EPA-HQ-OAR-2022-0829-0707, p. 31]

Footnote 153: Id.

154 Hannah Lutz, "Negative Charge: One in Five Charging Attempts Failed in 2022, JD Power Data Shows," Automotive News, February 13, 2023.

This type of consumer frustration may cause drivers who initially purchase electric vehicles to return to ICE vehicles, a phenomenon known as "discontinuance." For example, a 2021 UC Davis study found that approximately 20% of California drivers who bought a BEV between 2023 and 2018 replaced that vehicle with an ICE vehicle. Seventy percent of those drivers cited lack of access to charging infrastructure as a basis for their decision.155 [EPA-HQ-OAR-2022-0829-0707, p. 31]

155 Hardmand, S., Tal, G."Understanding discontinuance among California's electric vehicle owners." Nature Energy 6, 538-545 (2021). https://doi.org/10.1038/s41560-021-00814-9

Despite these indications that both the availability and the performance of charging stations may be a significant impact on consumers' willingness to purchase or to keep EVs, EPA does not consider the limitations of charging infrastructure in determining that the proposed rule is feasible. [EPA-HQ-OAR-2022-0829-0707, p. 31]

E. EPA does not adequately consider potential grid reliability impacts.

As part of its evaluation of potential economic impacts to the welfare of Americans and businesses, EPA must assess grid reliability impacts stemming from the proposed rule's forced electrification of the LD and MD transportation sector. Reliance on BEVs may have unintended, negative consequences, especially in relation to the electricity generation sector. In addition, EPA needs to accurately predict the number of additional chargers that will be needed to support the anticipated BEV population. At present, charging infrastructure is inadequate to meet the country's transportation needs.227 [EPA-HQ-OAR-2022-0829-0707, pp. 41-42]

227 See JD Power, "2023 U.S. Electric Vehicle Consideration (EVC) Study," June 15, 2023, and JD Power, "2023 U.S. Electric Vehicle Experience (EVX) Home Charging Study," March 16, 2023.

EPA should also consider the effects of the proposal on electricity prices, as low-income populations often spend a larger percentage of their earnings on essential utilities compared to the rest of the United States. Reliance on electric vehicles has been shown to spur increases in load and demand during peak periods, which impact electricity prices. Because EPA lacks expertise in the area of electrical grid management and economics, EPA should consult with other agencies and credible experts in these areas in order to adequately evaluate these impacts.304 EPA should ensure that the proposal meets reliability and affordability criteria and helps EJ communities make informed decisions about their own energy needs. Additionally, EPA's EJ assessment fails to acknowledge the likelihood that many owners will lack access to residential charging, which will substantially increase their operating expenses. Consistent reliance on fast charging also shortens electric vehicle battery life, resulting in a need to replace the battery and/or the vehicle more frequently. [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

304 See, West Virginia, 142 S.Ct. at 2612-13 (stating that EPA admitted that opining on trends in electricity transmission, distribution, and storage requires technical and policy expertise not traditionally needed in EPA regulatory development and finding that there is little reason to think Congress assigned such decisions to the EPA).

If EJ is truly a commitment for EPA, it should carefully consider criticisms like those leveled by The Two Hundred, which point out the disproportionate impacts to working and minority communities as a result of California's climate approach regarding electrified transport; those impacts and concerns remain true, and indeed are magnified under the proposed standards.305 [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

305 See Plaintiffs' Complaint, The Two Hundred for Homeownership, et al. v. California Air Resources Board, et al., No. 1:22-CV-01474.

It is critical from the outset to design standards to minimize the potential for price shocks and supply disruptions. As written, the proposal ultimately benefits electric vehicle manufacturers at the expense of disadvantaged communities by subsidizing unaffordable transportation that is not fit for the purposes of commuting to and from EJ communities. At minimum, EPA should perform a thorough EJ assessment specific to its LDV proposal that is comprehensive of both transport challenges and impacts faced by EJ stakeholders and the government-wide Justice40 Initiative [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

The average purchase price of EV cars in 2022 was approximately $65,000, which is more than what 46 percent of American households earn in income in a year.306 While the average "used" EV sold for $42,895 in March of 2023.307 While EPA's DRIA anecdotally indicates that "emerging consensus suggests that purchase price parity is likely to occur by the mid-2020's for some vehicle segments and models"308, Ford CEO Jim Farley told attendees at its 2023 Capital Markets Days that EV cost parity may not come until after 2030.309 Moreover US auto makers are focusing their efforts on producing higher priced electric SUVs and trucks, including Fords $100,000 F150 Lightening Platinum310 and GM's announcement that its luxury brands, Cadillac and Buick, will be its first all-electric product lineups.311 While smaller EV's like the Chevy Bolt, touted by the Biden Administration as being affordable alternatives, are being discontinued.312 The reality is that most middle-and lower-income families simply cannot afford to purchase a new or used EV, even when taking into account available tax incentives and rebates. In fact, middle – and lower -income families are more likely to purchase older used vehicle, due to their lower upfront costs, and to hold onto those vehicles for longer periods.313 [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

313 Supporting Lower-Income Households' Purchase of Clean Vehicles: Implications From California-wide Survey Results, UCLA Luskin Center for Innovation, 2020

Organization: Volkswagen Group of America, Inc.

Transformation to e-mobility requires a supporting ecosystem

Volkswagen is fully committed to electrification. However, there are concerns about the current market and subsequent market response. [EPA-HQ-OAR-2022-0829-0669, p. 2]

The prerequisite to achieving ambitious EV sales targets is a supporting EV ecosystem, including as a priority, a comprehensive, interoperable and integrated charging infrastructure network across the U.S. Investment is needed to make high power charging available along all interstates, provide charging solutions in metropolitan areas with limited off street parking, and provide high-speed charging at destination locations, rural areas and in the workplace. [EPA-HQ-OAR-2022-0829-0669, p. 2]

Range anxiety remains one of the prime customer concerns. To improve customer acceptance, Volkswagen suggests that EV penetration targets be linked to EV infrastructure rollout. Volkswagen recommends that the Biden Administration introduce a comparable approach to the approved EU Alternative Fuel Infrastructure Directive. Owning and using an electric vehicle must be comparable to owning an ICE vehicle, with no charging concerns and no cost of ownership concerns. [EPA-HQ-OAR-2022-0829-0669, p. 2]

Organization: Western Energy Alliance

Refueling Time: EPA makes the unfounded claim that the benefits of the rule will include, "…the value of reduced refueling time needed to refuel vehicles" (p. 29199) Assuming "…time spent refueling vehicles would be reduced due to the lower fuel consumption of new vehicles…" (p. 29200) is simply absurd. EPA seems to be willfully twisting the well-know disadvantage of long EV charging times. Whereas an ICEV takes a matter of minutes to refuel, charging times can be over an hour. Even fast charging stations, if available without a long wait due to their scarcity, require 30 minutes for 125 miles and an hour for 250 miles, well in excess of ICEV refueling times but with vastly less range.9 [EPA-HQ-OAR-2022-0829-0679, pp. 5-6]

9 "How Long Does It Take to Charge an Electric Car?", J.D. Power, March 26, 2020.

Limited charging infrastructure could drag refueling times to hours beyond what is needed by the driver. Further, were EPA's projection that 67% of new sales of light-duty and 46% of medium-duty vehicles will be EVs by 2032 attained, the strain on the grid would mean governments and utilities would likely enforce refueling times after hours, well past when a driver would need. Californians, just days after learning of the state's ban on ICEVs by 2035, were asked not to charge their EVs during the peak hours of 4 – 9pm because of the strain on the grid.10 Rather than being a benefit, EPA should consider how this rule would limit Americans mobility, as limited electricity capacity would cause drivers to run out of fuel when they need it for vital activities such as driving to work and school while making long roadtrips impractical. For example, the Wisconsin Electric Vehicle Infrastructure (WEVI) plan includes

comprehensive state strategies and actions to facilitate the electrification of Wisconsin's transportation system.2 The plan also assesses potential agency efforts to advance electrification and the deployment of electric vehicle
charging infrastructure. These actions, in concert with additional federal investments, will help support the growing demand for electrified vehicles in the state. [EPA-HQ-OAR-2022-0829-0507, p. 2]

2 Available at: https://wisconsindot.gov/Pages/projects/multimodal/electrification.aspx

Organization: Zero Emission Transportation Association (ZETA)

Recent trends suggest charging deployment is keeping pace with vehicle deployment. The Department of Energy’s Alternative Fuels Data Center has mapped over 139,000 individual charging ports across 54,100 public EV charging stations in the U.S.–and that doesn’t include at-home charging where a majority of charging occurs. Coupled with the $7.5 billion in federal IRA investments to expand our national charging network and billions of dollars in private capital means we’re well on track today to meet the EV charging needs of tomorrow. [EPA-HQ-OAR-2022-0829-0638, p. 2]

SmartCharge New York Managed Charging Case Study

In 2017, Con Edison launched SmartCharge New York program with the goal of instilling grid-beneficial charging behavior in parallel with the upswing in electric vehicle adoption. The goal was to influence driver behavior at the inflection point of transitioning from combustion-engine fueling to electric battery charging and have drivers default to grid-optimizing charging activity. Program participants received a free cellular-enabled device that plugs into the vehicle’s diagnostic port that allowed Con Edison to track time, energy, and power consumed when charging in the utility’s service territory. Incentives encourage drivers to 1) avoid charging during the system peak (2 PM to 6 PM) during summer weekdays from June to September, and 2) charge overnight from 12 AM to 8 AM. Incentives were initially paid off-bill through gift cards to the customer’s business of choice, such as Amazon, Starbucks, or Home Depot. [EPA-HQ-OAR-2022-0829-0638, p. 56]

As electric vehicle adoption continues to rise, managing charging behavior will grow increasingly important in maintaining a healthy and reliable grid. Since its inception, the SmartCharge New York program has evolved to meet customer needs and program objectives. Starting in 2023 for example, the program was overhauled to allow participation through a mobile application and payments are now issued through Venmo or Paypal, in line with participant feedback. This shift also changed the way the program collects data, favoring more cost-effective vehicle onboard telematics or networked electric vehicle supply equipment such as a Wi-Fi-enabled charger or charging cable. This enables the program to scale efficiently with the market and give a greater number of drivers insight into their behavior and how that activity translates to incentive earnings. [EPA-HQ-OAR-2022-0829-0638, p. 56]

In light of the EPA announcement of its heavy-duty and light/medium-duty proposed emissions standards, Con Edison released the following statement: [EPA-HQ-OAR-2022-0829-0638, pp. 56-57]

"Con Edison applauds the Environmental Protection Agency's efforts to rev up the market for electric vehicles, which will improve the air in the communities we serve and help in the fight against climate change. [EPA-HQ-OAR-2022-0829-0638, pp. 56-57]

A rapid shift to mass EV adoption looks more achievable all the time, with vehicle options expanding and new charging stations being built across New York City and Westchester County, including locations that serve the needs of disadvantaged communities. [EPA-HQ-OAR-2022-0829-0638, pp. 56-57]

Con Edison will continue to support the EV market's development through investment in the grid and by offering a range of programs, from incenting new chargers to managing the grid impact by rewarding drivers for charging overnight."219 [EPA-HQ-OAR-2022-0829-0638, pp. 56-57]

219 "Con Edison Supports Effort to Encourage Electric Vehicle Adoption," Con Edison Media Relations, (April 12, 2023) https://www.coned.com/en/about-us/media-center/news/2023/04-12/con-edison-supports-effort-to-encourage-electri c-vehicle-adoption

5. SRP

When EVs were still in the early stages of adoption, SRP recognized the importance of exploring ways to identify EV households and analyze their charging behavior in order to help prepare for greater EV uptake in the future. It was also important to begin engaging customers who were EV drivers in order to understand their interests and their charging patterns and assess ways to influence charging behaviors. [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

In 2014, SRP launched "EV Community" (EVC)—a program that offers customers a $50 bill credit for each EV they register (up to two vehicles per household)—as a means to incentivize EV drivers to identify themselves and engage with SRP. Participants provide basic information about the electric vehicle and the type of charger they use. This provides a way for SRP to learn more about EV customers and their charging behavior and needs while offering them an incentive to help support EV growth in the region. There are currently more than 7,500 customers enrolled in the program. [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

While EVC members only account for a small number of total EV households, they are a fair overall representation of the EV customer base since all price plans are included, as well as households with one vs. two EVs. The program offers SRP a good platform for analysis, including the type of cars they drive (PHEV, BEV, brand, etc.) and the charge levels they use. In addition, SRP found that EVC members are willing to share information and are eager to participate in future pilot programs. [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

The EVC program also provides SRP with a method and channel to promote their Electric Vehicle Price Plan, a special time-of-use pricing plan which offers EV drivers the most opportunity to save on EV charging costs by charging during super off-peak times (between 11 PM and 5 AM). Load research has shown that this program has been highly effective at shifting EV charging loads away from peak periods. [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

The EVC program has helped SRP plan and prepare the grid for widespread EV adoption by enabling them to: [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

-Anticipate load growth. A pilot study with EVC members that monitors their EV driving and charging behavior through data telematics devices enables SRP to estimate typical consumption and charging load profiles per EV. [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

-Understand the impacts of EV charging on the grid. EVC data is used to model the impacts of EV charging on the electric grid, identify when transformers and wires may need to be upgraded, and understand when and how customers need to charge. [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

-Recruit for Managed Charging pilot programs. The EVC program and channel have enabled SRP to recruit participants for additional Managed Charging pilot programs to test other active control technologies to control EV charging load on the grid. [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

-Survey participants for insights. EVC members are surveyed regularly to get more data on their charging behaviors, including their use of home, workplace, and public charging and their satisfaction with EVs overall. [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

-Engagement. EVC participants receive regular newsletters and other communications with EV-related information. [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

In addition to fleet charging, the site will also function as an innovation hub, allowing Duke Energy to collect data around charger use, performance, management, and energy integration with various generation resources. It will also allow for the development of managed charging algorithms for fleets connected to the bulk power system or integrated with renewables and storage—which can be utilized to minimize the upgrades needed to the distribution system, easing the transition to electrifying fleets. Identifying EV charging technologies and how they may be used to power any type of fleet with vehicles (ranging from class 1) will help develop a model to show the industry a clear, integrated, and cost-effective path to fleet electrification. [EPA-HQ-OAR-2022-0829-0638, p. 59]

Duke Energy is teaming up with Daimler Truck North America and Electrada on this important work. Electrada, an electric fuel solutions company, is providing funding for research and demonstration efforts. For fleets seeking to electrify, Electrada invests all required capital “behind the meter” and delivers reliable charging to the fleet’s electric vehicles through a performance contract, eliminating the complexity and risk that fleets face in transitioning to this new source of fuel. Electrada’s investment in the depot allows Duke Energy to focus on programs that simplify adoption for electric fleet customers and distribution system performance to support the predictable addition of electric load over time. [EPA-HQ-OAR-2022-0829-0638, p. 59]

By the end of 2023, fleet operators will be able to experience a best-in-class, commercial-grade fleet depot integrated with energy storage, solar, and optimization software. Moving to zero-emission vehicles in this sector allows North Carolina to seize the large economic potential of the transition and generate billions in net benefits for the state. Projects like Duke Energy’s fleet performance center will be key for fleet owners across the state to take advantage of the cost savings of transitioning to electric vehicles. That said, fleet owners exploring electrification should engage their electricity provider early and often to identify and address site-specific considerations. As fleet electrification accelerates, it will be important for electricity providers and policymakers to identify best practices to proactively plan for fleet electrification, including readying the distribution grid. [EPA-HQ-OAR-2022-0829-0638, p. 59]

6. Duke Energy

Electric fleet commitments are increasing as companies with ambitious sustainability goals work to decarbonize operations. Fleet owners are also seeking ways to take advantage of the cost savings available by transitioning to EVs. However, programs for fleet electrification and managed charging options are still limited to date. [EPA-HQ-OAR-2022-0829-0638, pp. 58-59]

When transitioning to an electric fleet, it is important that fleet managers understand the full scope of charging multiple vehicles while maintaining fleet operations and that larger MHDVs bring with them additional factors to consider. Fleet owners who have electrified fleets without consulting experts or an electric provider have likely been experiencing avoidable operational and technological issues. Long-term energy cost and performance risk are also potential issues for fleets and can hinder mainstream fleet electrification technology development if not managed correctly. [EPA-HQ-OAR-2022-0829-0638, pp. 58-59]

Duke Energy's significant experience and large customer base make it well-positioned to design and implement fleet electrification and charging programs. Duke Energy is building a first-of-its-kind performance center that will model and accelerate the development, testing, and deployment of zero-emission light-, medium-, and heavy-duty commercial electric vehicle EV fleets. The site will be located in North Carolina at Duke Energy's Mount Holly Technology and Innovation Center and incorporate microgrid integration. [EPA-HQ-OAR-2022-0829-0638, pp. 58-59]

The fleet electrification center will provide a commercial-grade charging experience for fleet customers evaluating or launching electrification strategies—reinforcing reliability, clean power, and optimization by integrating solar, storage, and microgrid controls software applications. The center will be connected to both the Duke Energy grid—charging from the bulk electric system—and to 100% carbon-free resources through the microgrid located at Mount Holly. This project is the first electric fleet depot to offer a microgrid charging option. [EPA-HQ-OAR-2022-0829-0638, pp. 58-59]

7. Xcel Energy

Xcel Energy is committed to electrifying all of its light-duty fleet and 30% of its medium-and heavy-duty fleet by 2030, equating to over 2,500 EVs. It's part of their vision to be a net-zero energy provider by 2050 and enable one out of five vehicles to be electric in the areas they serve by 2030. This will save customers $1 billion annually on fuel by 2030 and deliver cleaner air for everyone. [EPA-HQ-OAR-2022-0829-0638, pp. 59-60]

With a fleet that includes iconic bucket trucks, all-terrain service vehicles, and a host of pickup trucks and pool cars across eight states, achieving these goals will be no small feat, but an important one. There are notable hurdles, yet evolving technology presents solutions. [EPA-HQ-OAR-2022-0829-0638, pp. 59-60]

Electrifying the Marquee Fleet Vehicle

Xcel Energy is the first electric provider in the nation to add an all-electric bucket truck to its fleet. The truck features two electric sources: one for the drivetrain and one for the lift mechanism. It has a 135-mile driving range and can operate the bucket for an entire workday on a single charge. Crews are collecting data from real working conditions in Minnesota and Colorado that will be used to inform further improvement to the vehicle's technology and operation. [EPA-HQ-OAR-2022-0829-0638, pp. 59-60]

Optimizing Charging to Minimize Grid Impacts

To support a growing electric fleet, over 1,200 EV chargers must be brought into service by 2030, which will result in an electric load increase of 71 megawatts. Charge management techniques enable low-cost charging for this growing electric fleet. It's a sophisticated approach to optimize charging times by using time-of-day and grid demand efficiencies and builds on the expertise Xcel Energy has developed through offering managed charging programs to customers in multiple states. [EPA-HQ-OAR-2022-0829-0638, pp. 59-60]

For fleets, overnight charging schedules make the most sense. Demand and rates are lower, and renewable wind sources are ample at that time. Yet, fast charging outside of these time periods may be required to help larger vehicles make it through a workday. This is when charging schedules need to be customized and highly specific. [EPA-HQ-OAR-2022-0829-0638, pp. 59-60]

d. Charging Infrastructure

Although the majority of charging needs will be ultimately met through at-home or near-home charging, a fully electrified transportation system will also require a robust public charging network—one which the sector is already deploying. As of June 2023, there were 140,000 individual Level 2 and DC fast charging ports across 54,000 public EV charging stations in the U.S.224 A 2022 study by McKinsey & Company projected that the U.S. will need 1.2 million public EV charging stations to accommodate forecasted EV deployments by 2030.225 A more recent June 2023 NREL study226 analyzed U.S. progress towards building out an accessible network of public EV chargers and found that: [EPA-HQ-OAR-2022-0829-0638, pp. 62-63]

224 U.S. Department of Energy's Alternative Fuels Data Center, accessed June 23, 2023 https://afdc.energy.gov/fuels/electricity_locations.html#/analyze?fuel=ELEC

225 "Building the electric-vehicle charging infrastructure America needs," McKinsey & Company, (April 18, 2022) https://www.mckinsey.com/industries/public-and-social-sector/our-insights/building-the-electric-vehicle-charging-in frastructure-america-needs

226 "The 2030 National Charging Network: Estimating U.S. Light-Duty Demand for Electric Vehicle Charging Infrastructure," National Renewable Energy Laboratory, (June 2023) https://driveelectric.gov/files/2030-charging-network.pdf

-The United States is on track to install a network of 1.2 million public chargers by 2030, keeping up with rapidly growing demand for EVs. [EPA-HQ-OAR-2022-0829-0638, pp. 62-63]

-Of the 1.2 million charging ports, about 1 million are expected to be Level 2 charging, providing convenient, low-cost charging to meet a variety of daily needs, with the remaining charging ports being DC fast chargers that are critical to driver confidence and longer distance travel. [EPA-HQ-OAR-2022-0829-0638, pp. 62-63]

-Building out a public charging network will require between $31 and $55 billion of cumulative public and private capital investment and will help unlock hundreds of billions of dollars of consumer savings from reduced fuel and maintenance costs. [EPA-HQ-OAR-2022-0829-0638, pp. 62-63]

As discussed further below, industry is continuing to rapidly build out EV charging capacity both as a result of private investment and with support from billions of dollars in federal funding. [EPA-HQ-OAR-2022-0829-0638, pp. 62-63]

Strong EPA LMDV emissions standards that encourage vehicle manufacturers to transition to EVs sends market signals to the charging industry that provide the certainty needed to make proactive infrastructure and manufacturing investments. [EPA-HQ-OAR-2022-0829-0638, pp. 62-63]

i. EVSE Manufacturer and Operator Statements on EPA Standards

As discussed, robust LMDV emissions standards encourage vehicle manufacturers to transition to EVs, which in turn sends market signals to the charging industry that provide the certainty needed to make proactive infrastructure and manufacturing investments. A clearer picture of future electric vehicle supply equipment (EVSE) demand enables manufacturers and network operators to plan and allocate capital accordingly. Below are statements by ZETA's EVSE providers in response to EPA's announcement of these proposed standards: [EPA-HQ-OAR-2022-0829-0638, pp. 63-64]

-"EVgo applauds the EPA for proposing ambitious tailpipe emissions standards. These standards would accelerate the transition to electric vehicles and result in cleaner air, healthier communities, and create jobs across the country. More EVs demands more EV charging and we will continue to expand our fast charging network to provide the infrastructure to support the growing EV market."227 [EPA-HQ-OAR-2022-0829-0638, pp. 63-64]

-ChargePoint on EPA emissions standards: "This proposal, in addition to state and federal funding programs like NEVI, will undoubtedly lead to more investment in EVs and chargers. Over our 15 year history, we have ensured charging infrastructure deployment kept pace with EV adoption, and we are well-positioned to meet the increased demand these standards will generate."228 [EPA-HQ-OAR-2022-0829-0638, pp. 63-64]

-ChargePoint on EPA emissions standards: "As EV charging infrastructure buildout continues, more EV models become available and regulatory efforts ramp up, EV adoption will continue to grow rapidly and ChargePoint will be there to support drivers who need a charge. We see ambitious regulations like these as an opportunity, not a barrier, to sustainable business growth, and we will continue working with policymakers to ensure that policy helps individuals, businesses and the environment alike."229 [EPA-HQ-OAR-2022-0829-0638, pp. 63-64]

227 EVGo on LinkedIn, accessed May 10, 2023 https://www.linkedin.com/posts/evgo_biden-administration-proposes-toughest-auto-activity-70544878136810 25024-gCc0/

228 ChargePoint on LinkedIn, accessed June 26, 2023 https://www.linkedin.com/posts/chargepoint_biden-harris-administration-proposes-strongest-ever-activity-70522887 57399441408-xX54/

229 "New EPA vehicle emissions regulations to accelerate EV production, adoption and infrastructure," ChargePoint, (May 18, 2023) https://chargepoint.com/blog/new-epa-vehicle-emissions-regulations-accelerate-ev-production-adoption-and-infrastructure

ii. Impacts to EVSE Deployment from BIL and IRA Programs

With over $7.5 billion available across multiple programs, the Bipartisan Infrastructure Law represents the nation's largest ever investment in increasing Americans' access to EV chargers. Through the BIL's $5 billion National Electric Vehicle Infrastructure (NEVI) Formula Program, the federal government is partnering with private industry to build out a national charging network along key highway corridors. As of September 2022, the Federal Highway Administration approved formal plans submitted by all 50 States, the District of Columbia, and Puerto Rico and as of June 2023, multiple states had released requests for proposals from organizations seeking access to NEVI funds. The design of these state application processes through the NEVI Formula Program will help drive EVSE standardization, which will in turn improve reliability and consistency in the consumer-facing charging experience. Separately, the BIL's Charging and Fueling Infrastructure (CFI) Discretionary Grant Program allocates another $2.5 billion towards installing EV chargers in communities where people live and work. [EPA-HQ-OAR-2022-0829-0638, pp. 64-65]

As charging deployment continues to increase, the distribution of this network, not just its size, risks limiting electrification—especially in rural areas. In response, the Biden-Harris Administration has taken a comprehensive approach to EVSE build-out, recognizing the diverse demographics, landscapes, and types of communities throughout the United States. Ubitquity and visibility are important components of a national EVSE network deployment. The Department of Transportation has put together separate toolkits to guide EVSE deployment in both urban230 and rural231 areas. Both toolkits go through an explanation of electric mobility basics, as well as the benefits and challenges that are specific to individuals, communities, and transit operators in their respective region types. Both expand on public-private partnership opportunities, as well as best practices for early planning and financing. With respect to EVSE, DOT has identified three levels of EVSE planning: community, corridor, and site. These toolkits are intended to guide private, state, and local entities as they implement federal funding and engage in other equitable, thorough EVSE deployment strategies. [EPA-HQ-OAR-2022-0829-0638, pp. 64-65]

230 "Charging Forward: A Toolkit for Planning and Funding Urban Electric Mobility Infrastructure," U.S. Department of Transportation, (June 2023) https://www.transportation.gov/urban-e-mobility-toolkit

231 "Charging Forward: A Toolkit for Planning and Funding Rural Electric Mobility Infrastructure," U.S. Department of Transportation, (June 2023) https://www.transportation.gov/rural/ev/toolkit

The tax credits provided in the Inflation Reduction Act , specifically the Alternative Fuel Vehicle Refueling Property Tax Credit232 are critical to helping ensure the continued availability of products necessary for a fully-electrified transportation sector. By targeting investments toward rural and lower-income residents, the credit incentivizes individuals and commercial operators to install charging stations at their homes and private entities. Retailers, local businesses, or commercial fleet operators can also utilize the credit to offset the costs of installing charging infrastructure on their property, enabling them to attract and retain customers. [EPA-HQ-OAR-2022-0829-0638, p. 65]

232 See 26 U.S.C. § 30C

Taken together, the funding in the NEVI and CFI programs under the BIL and the Alternative Fuel Vehicle Refueling Property Tax Credit in the IRA will lead to significant buildout of EV charging in communities, at homes and businesses, and along high-traffic highway corridors. [EPA-HQ-OAR-2022-0829-0638, p. 65]

iii. Recent Trends in Public EVSE Deployment

The number of chargers in the U.S.—public, private, and residential— is on track for rapid growth in the next several years. To meet the Administration's goal of deploying 500,000 chargers by 2030, the U.S. Department of Energy's Alternative Fuels Data Center (AFDC) notes that the deployment rate will have to significantly increase. As discussed, public funding is helping to spur deployments, while private investment in public EV charging has increased considerably in the last five years rising from under $200 million in 2017 to nearly $13 billion by early 2023.233 As the national EVSE network expands, growth tracked by the AFDC found that between 2015 and 2020, the number of EVSE ports in the U.S. more than doubled and in 2021 the number of ports grew 55% year-over-year.234 This is growth that occurred before the impacts of both the IRA and BIL took effect. [EPA-HQ-OAR-2022-0829-0638, pp. 65-66]

233 "Investment in Publicly Accessible EV Charging in the United States," (2023) Atlas Public Policy https://atlaspolicy.com/wp-content/uploads/2023/05/Investment-in-Publicly-Accessible-EV-Charging.pdf

234 "Electric Vehicle Charging Infrastructure Trends," Alternative Fuels Data Center, https://afdc.energy.gov/fuels/electricity_infrastructure_trends.html

Even without incentives, EV charging has generally kept pace with the rollout of EV deployment, as shown in Figure 9 below. [EPA-HQ-OAR-2022-0829-0638, pp. 65-66]

[See original comment for Figure 9. Trends in Light-Duty EV Deployment vs. Public Charging Infrastructure Deployment]235,236 [EPA-HQ-OAR-2022-0829-0638, pp. 65-66]

235 "LDV Total Sales of PEV and HEV by Month (updated through March 2023)," Argonne National Laboratory, (March 2023) https://www.anl.gov/sites/www/files/2023-04/Total%20Sales%20for%20Website_March2023_0.pdf

236 U.S. Department of Energy Alternative Fuels Data Center, accessed May 2, 2023 https://afdc.energy.gov/data/10964

Deployments of both LDEVs and charging infrastructure have followed an upward growth trajectory in recent years. Deployments of both products are well correlated with a value of 0.982 between light-duty vehicles and EVSE ports. As such, recent trends suggest that charging infrastructure should not be a limiting factor in expanded EV deployment. [EPA-HQ-OAR-2022-0829-0638, pp. 65-66]

As a national public charging network continues to take shape, there are multiple efforts underway to help EV drivers locate and access charging infrastructure. As mentioned previously, the AFDC maintains a database of public charging stations with route-planning functionality embedded in the tool.237 NREL recently announced the launch of an interactive map showing EV charging locations near national parks.238 ZETA member Rivian is incorporating EV charging locations into their vehicles' onboard display.239 Google Maps will now suggest charging stops on shorter trips, include a 'very fast' filter for charging station searches, and will show users in search results when a location has a charging station on-site.240 [EPA-HQ-OAR-2022-0829-0638, pp. 66-67]

237 U.S. Department of Energy Alternative Fuels Data Center, accessed May 2, 2023 https://afdc.energy.gov/fuels/electricity_locations.html#/find/nearest?fuel=ELEC

238 “New Interactive Map Shows EV Charging Stations Near National Parks,” National Renewable Energy Laboratory, (April 2023) https://www.nrel.gov/news/program/2023/new-interactive-map-shows-ev-charging-stations-near-national-parks.html

239 Rivian on LinkedIn, accessed June 26, 2023 https://www.linkedin.com/posts/rivian_rivian-adventurousforever-careersintech-activity-7077710678597238784-Yif P

240 Google is adding some new features for EVs with built-in Google Maps,” The Verge, (February 8, 2023) https://www.theverge.com/2023/2/8/23589724/google-maps-ev-charging-built-in-features

iv. Future State of EVSE Deployment

EVSE manufacturers and operators are regularly announcing investments to build out charger manufacturing capacity to ensure customers can meet their residential charging needs as well as publicly-accessible chargers for longer-duration trips. While many are detailed in the White House EV Accelerator Challenge fact sheet,241 the ZETA members below have made the following announcements: [EPA-HQ-OAR-2022-0829-0638, pp. 67-68]

241 Fact Sheet: Biden-Harris Administration Announces New Private and Public Sector Investments for Affordable Electric Vehicles (April 17, 2023) https://www.whitehouse.gov/briefing-room/statements-releases/2023/04/17/fact-sheet-biden-harris-administration-a nnounces-new-private-and-public-sector-investments-for-affordable-electric-vehicles/

-In January 2023, ZETA member ABB e-Mobility announced manufacturing operations in Columbia, South Carolina. This will significantly reduce delivery and lead times for DC fast-chargers in the U.S., enabling charging developers, owners, and operators to deploy reliable chargers more quickly. Since 2010, ABB has invested $14 billion in the U.S. with plant expansions, operational improvements, state-of-the-art equipment, products, and people, making it the company’s largest market. With approximately 20,000 employees in more than 40 manufacturing and distribution facilities, ABB is investing, growing, and serving across America through industries that create jobs, encourage innovation, and achieve a more productive, sustainable future.242 [EPA-HQ-OAR-2022-0829-0638, pp. 67-68]

-In April 2023, ZETA member Enel announced plans to add at least two million chargers, including home systems, in North America by 2030.243 [EPA-HQ-OAR-2022-0829-0638, pp. 67-68]

-In April 2023, ZETA member Siemens announced the opening of its latest EV charger manufacturing facility where the company will manufacture EV chargers specifically designed to serve the U.S. market. The facility is the company’s second U.S. EV charging manufacturing hub and will contribute to the company’s goal to build 1 million EV chargers for the U.S. market. The new facility will support the creation of 100 new jobs at the site and across its regional supply chain footprint. It will also be operated in part by Wyntron, an existing partner in Siemens eMobility’s manufacturing ecosystem.244 [EPA-HQ-OAR-2022-0829-0638, pp. 67-68]

-In April 2023, ZETA member FLO opened its first U.S. manufacturing facility in Auburn Hills, Michigan. Available starting in 2024, the FLO Ultra charging stations can charge most EVs to 80% in 15 minutes, depending on vehicle type, and are built to meet both NEVI and Buy America requirements. FLO’s Level 2 CoRe+ and CoRe+ MAX chargers are currently being assembled at the facility as preparations for the production of FLO Ultra chargers are underway. The chargers produced in Auburn Hills will contribute to the 250,000 chargers FLO plans to bring to the U.S. market by 2028. In that time span, FLO expects the facility to create and support 730 jobs.245 [EPA-HQ-OAR-2022-0829-0638, pp. 67-68]

-In June 2023, SK Signet launched a new $15 million facility in Texas to expand EVSE manufacturing. The factory is expected to produce ultra-fast chargers for over 10,000 EVs per year, generating up to 183 jobs by 2026.246 [EPA-HQ-OAR-2022-0829-0638, pp. 67-68]

From national retailers to local businesses, organizations are announcing their intent to host charging infrastructure on their property, enabling them to attract and retain customers. In some instances, these chargers could supplant at-home or curbside charging for certain individuals where such chargers may be less accessible. The following announcements from recent months indicate the benefits retailers see in becoming an EVSE site host: [EPA-HQ-OAR-2022-0829-0638, p. 68]

-In January 2023, TravelCenters of America announced it would be purchasing 1,000 Electrify America DC fast charging stations and plans to install them at 200 travel stops over the next five years.247 [EPA-HQ-OAR-2022-0829-0638, p. 68]

-In February 2023, bp announced plans to invest $1 billion in EV charging across the U.S. by 2030, helping to meet demand from Hertz’s expanding EV rentals.248 [EPA-HQ-OAR-2022-0829-0638, p. 68]

247 “More Electrify America EV chargers are coming, this time at TravelAmerica rest stops,” The Verge, (January 30, 2023) https://www.theverge.com/2023/1/30/23577696/electrify-america-travelcenters-petro-ev-dc-fast-chargers

248 “bp plans to invest $1 billion in EV charging across US by 2030, helping to meet demand from Hertz’s expanding EV rentals,” Hertz Newsroom, (February 15, 2023) https://newsroom.hertz.com/news-releases/news-release-details/bp-plans-invest-1-billion-ev-charging-across-us-203 0-helping

-In February 2023, fast casual sandwich shop Subway announced plans to assist their franchise owners with installing multiple stand alone fast charge stations for their customers at multiple locations.249 [EPA-HQ-OAR-2022-0829-0638, p. 69]

-In March 2023, ZETA member Uber and bp Pulse announced a new global mobility agreement which will see the companies work together to help accelerate Uber’s commitment to become a zero-tailpipe emissions mobility platform in the US, Canada and Europe by 2030 and globally by 2040. Under the terms of the agreement, bp intends to offer bespoke deals to drivers on the Uber platform that are tailored to each market, including providing incentives for them to charge with bp pulse. The two companies will also explore working together on convenience and fuel offers. bp has a global network of almost 21,000 branded retail sites that offer fuel as well as food for now and for later with retail partners, and facilities such as toilets.250 [EPA-HQ-OAR-2022-0829-0638, p. 69]

-In March 2023, the convenience store 7-eleven launched its own EV fast charging network of DC chargers called 7charge. Consumers who use 7charge will pay rates based on the energy they consume or time spent charging, based on specific local regulations.251 Currently the company's chargers are in Colorado, Florida, Texas, and California. The company is also planning to launch a Maryland location soon. [EPA-HQ-OAR-2022-0829-0638, p. 69]

-In April 2023, Walmart announced plans to install new EV fast-charging stations at thousands of Walmart and Sam's Club locations across the country. This would be in addition to the almost 1,300 DC fast-charging stations already available at more than 280 [EPA-HQ-OAR-2022-0829-0638, p. 69]

U.S. facilities. With a store or club located within 10 miles of approximately 90% of Americans, the company is uniquely positioned to deliver a charging option that will help make EV ownership possible whether people live in rural, suburban or urban areas.252 [EPA-HQ-OAR-2022-0829-0638, p. 69]

-In May 2023, Boston based LNG Electric, an EV charging technology company, announced its plans to install Level 2 and DC charging stations at more than 13,000 hotels across the U.S.253 The company intends to develop this infrastructure over the next five to six years with the first chargers going in this past May. Ultimately, LNG Electric aims to create a charging network that covers 10-15% of the US hospitality market. The company's first set of chargers will be deployed at Hilton and Marriott hotels in Florida, Ohio, and Illinois. [EPA-HQ-OAR-2022-0829-0638, p. 69]

EPA Summary and Response

Summary:

EPA acknowledges and appreciates all the comments received on charging infrastructure, which include both broad comments on future infrastructure needs, availability, and deployment as well as specific suggestions on the NPRM infrastructure assessment and cost analysis.

Vehicle manufacturers, dealers, and representatives of the fuels industry, among others, raised concerns stating that charging infrastructure is inadequate today and that the pace of deployment is not on track to meet levels needed if the proposed standards are finalized. Commenters cited a variety of recent studies and other sources that project future infrastructure needs. The Alliance for Automotive Innovation (the "Alliance"), BMW, and Stellantis cited a recent California Energy Commission report that assessed infrastructure needs in California and found that to support 5 million PEVs in the state by 2030 would require about 700,000 public and shared private EVSE ports. Commenters noted that this is equivalent to a ratio of one EVSE port needed for every seven PEVs and cautioned that current public infrastructure is not keeping up. For example, the Alliance said, "Moreover, the U.S. is falling further behind in installing publicly available chargers for the number of EVs that are being sold. More than 305,000 new EVs were added to the roads in the first quarter of 2023, but only 7,802 new chargers were added, a ratio of 39 new EVs for every new public port, and more than five times higher than the recommended ratio of 7:1." Jaguar Land Rover made a similar point by noting that an EU directive recommends one public port for every 10 electric vehicles. Multiple commenters (e.g., AFPM and SEMA) cited recent work from McKinsey, which estimated that by 2030 1.2 million EVSE ports would be needed. AFPM, CFDC et al. Hyundai, NADA, Porsche, Rivian, and Valero all referenced a 2023 national charging network assessment conducted by NREL for estimates of future infrastructure needs or associated costs, with some noting that the study found that by 2030 about 1 million public L2 and 182,000 DCFC ports would be needed to support about 33 million PEVs (along with many more private EVSE ports). AFPM cited an S&P Global report that found charging will need to increase by a factor of eight by 2030 while NADA cited a report by EEI, which estimated planned investments will support fewer than half as many DCFC ports as would be needed in 2030. Multiple commenters cited reports on charging infrastructure trends from DOE's Alternative Fuels Data Center to caution that the pace of infrastructure deployment is insufficient, e.g., with NACS et al. citing a report from the second quarter of 2022, and saying that public stations increased by under 15 percent while EV sales rose by 65 percent in the same timeframe. Commenters also cited work by Atlas, ICCT, and JD Power to indicate that significantly more EVSE ports will be necessary to meet future needs.

Multiple commenters raised concerns that current public charging infrastructure is concentrated in select parts of the country, with some (e.g., GROWMARK, IFB, MCGA, MOFB, SEMA, TPPF, and Marie Gluesenkamp Perez et al.) noting particular challenges for rural areas. For example, Growmark said, "According to the most recent trend report from the National Renewable Energy Laboratory, rural areas (which make up almost 93% of U.S. land area) have the smallest number of EV charging ports by a wide margin, and it is the smallest category in terms of growth of EV charging ports as well." Other commenters (e.g., the Alliance, AmFree et al., CEA, the Heritage Foundation, Subaru, and Transfer Flow) discussed access and affordability challenges for those without residential charging capabilities or in multi-family dwellings, and for low-income consumers.

Manufacturers and others (e.g., American Highway Users Alliance, API, Chevron, Ford, Hyundai, NACS et al., Subaru, and UAW) cautioned that customers may not buy PEVs if sufficient charging infrastructure is not available. Toyota commented that infrastructure availability is largely out of the control of manufacturers but would be critical to complying with the proposed standards if finalized.

While they recognized the importance of the BIL and the IRA in supporting the buildout of charging infrastructure, multiple commenters (e.g., AmFree et al., Stellantis, and Valero) expressed concerns that far more funding would be needed with some characterizing BIL funds as a 'good downpayment'. The Alliance further noted, “Moreover, thus far, almost two years after the BIL was signed, not a single electric vehicle charger has been installed with the federal funding allocated to states.” AmFree et al. and Valero cautioned that census tract restrictions limit the applicability of the IRA tax credit applicable to charging infrastructure. Regarding private investments, the National Association of Convenience Stores et al. noted that while some members have installed charging stations as ‘beta tests’, there are challenges to overcome before such private investments become a sustainable business model.

The Alliance, Stellantis, Nissan, and U.S. Chamber of Commerce, VW, among others, recommended that EPA monitor infrastructure deployment after the final rulemaking and/or link the stringency of the standards to infrastructure buildout. For example, the Alliance recommended that EPA directly incorporate an adjustment mechanism into the stringency levels of the standards that scales with infrastructure deployment. Several commenters pointed to other regulations as positive examples of how EPA could address infrastructure availability concerns. For example, MEMA and VW noted that EU’s “Alternative Fuel Infrastructure” Regulation requires member states to deploy charging stations at designated intervals.

We also received comments from states, non-governmental organizations, electrification groups, electric vehicle manufacturers, and utilities (e.g., CARB, California Attorney General’s Office et al., CALSTART, EEI, EDTA, Energy Innovation, EDF, ICCT, MPCA, NESCAUM and OTC, Rivian, Tesla, Wisconsin Department of Natural Resources, and ZETA) highlighting the many public and private investments in charging infrastructure that have been announced or are already underway, along with a new analysis submitted by EDF. The analysis found that, taken together, these investments are putting the U.S. on track to meet charging infrastructure needed in 2030 if the proposed standards were finalized.

Some commenters (e.g., Energy Strategy Coalition, Environmental Public Health Organizations, Tesla, ZETA) noted that EPA finalizing stringent standards would provide certainty to manufacturers, EVSE providers and others and spur further investments in charging infrastructure. For example, a comment from Environmental and Public Health Organizations addressed the ‘chicken-and-egg conundrum’ (i.e., that EVSE providers will not build out infrastructure without having assurance of demand, but vehicle purchasers will not buy without initial assurance of adequate supporting charging infrastructure) saying EPA should not wait on finalizing standards. The commenter cited historical precedent in other areas (e.g., E85 stations to support flex-fuel vehicles) and economic theory to support the point that sufficient charging infrastructure will be built to meet demand.

EPA also received comments on infrastructure deployment and challenges. In particular, many commenters (e.g., AFPM, AmFree et al., CFDC et al., HF Sinclair Corporation, NACS et al., Subaru, and Valero) raised concerns about charging infrastructure reliability. Long charging times were also raised as a potential barrier to consumer adoption of PEVs. Several commenters (e.g., AFPM, BorgWarner, and MECA) suggested that DC fast charging (DCFC), which has shorter charge times, will therefore be particularly important in infrastructure buildout; some commenters also said that DCFC better facilitates managed and bidirectional charging, and is important for futureproofing infrastructure.

Manufacturers and others (e.g., Advanced Energy United, American Highway Users Alliance, HF Sinclair, Hyundai, NADA, NRECA, Stellantis and Toyota) raised concerns about the lead time for deploying charging infrastructure. Advanced Energy United suggested permitting reform to standardize and streamline the process could help reduce delays and associated soft costs. Several commenters discussed utility interconnection times and supply chain issues, particularly those connected to distribution system upgrades. For example, NADA stated that current lead times of 12 to 18 months for transformers could increase, while NRECA noted a lead time of over three years for "large power transformers." EEI and Rivian highlighted proactive steps utilities and industry can take to plan for charging stations and, in some cases, reduce the need for grid upgrades.

We also received comments on the cost analysis we conducted for the proposed rulemaking. Several commenters stated that EPA underestimated EVSE costs. For example, both AFPM and CFDC et al. pointed to what the commenters characterized as a significant discrepancy between EPA's overall estimated EVSE costs in the NPRM and those in the 2030 charging network assessment conducted by NREL. Valero stated that EPA underestimated EVSE costs per port and provided an estimated range of $125,000 to $300,000 per DC-150 kW port drawn from state NEVI plans and EVSE providers as an example of current costs. On the other hand, CARB suggested that our residential charging costs for multi-family dwellings may be too high and recommended that we account for lower-power L2 receptacles, which will be required in some new buildings in California. Tesla commented that our assumed DCFC costs are too high, noting that Tesla's costs for a 250-kW port are less than $40,000 compared to EPA's assumed $153,000. Valero stated that EPA should include the cost of EVSE maintenance in its analysis.

For the NPRM analysis, EPA estimated the EVSE port needs for light-duty PEVs but noted that it did not assess EVSE costs for medium-duty PEVs. AFPM commented, "While these commercial vehicles may spend most of their time charging at private depot stations, these are mobile, commercial vehicles that will need to use (and strain) the charging network. It is arbitrary and capricious for EPA to omit those vehicles from its simulations." POET expressed a different concern about EPA's EVSE port estimates, noting what it characterized as a relatively small difference between the port needs under proposed rule and no-action cases for 2055 considering larger differences in PEV penetration in those two scenarios.

EPA received comments both on the electricity prices we used in the NPRM analysis, and on additional costs that commenters said should be included in the FRM analysis. Several commenters (e.g., Paul Bonifas and Tim Considine, CEA, and Valero) thought EPA's use of residential electricity charging rates underestimated charging costs given that some households don't have access to lower-cost home charging. Other commenters also noted the higher costs associated with public charging, which may happen during peak hours and include higher time of use rates and demand charges among other costs. AFPM cautioned that EPA's use of national average electricity rates is inappropriate given that ZEVs could be concentrated in areas with higher electricity rates such as California. AFPM also stated that increased demand from EV charging could increase electricity prices whereas a comment from Environmental and Public Health Organizations stated that EV charging could actually reduce electricity prices for all users by taking advantage of unused grid capacity (e.g., at night) and distributing system costs that would be incurred anyway over more electricity sales. In its comments, the Heritage Foundation stated its belief that electricity prices will increase over time due to power plant regulations.

Multiple commenters (e.g., AFPM, NRECA, and Valero) said that EPA should account for the cost of distribution or other grid upgrades associated with charging infrastructure and NRECA provided cost estimates associated with panel upgrades, transformers upgrades, service wire upgrades, line extensions, and metering among other categories. However, EEI said that EPA was justified in its decision not to model costs of distribution upgrades in the NPRM. EEI stated that these costs will be site specific, who bears the costs (utilities vs. site host customers) will vary, and accounting for these costs would be inconsistent with the approach EPA has taken for liquid fuels, in which comparable upgrades are not directly accounted for in fleet costs. The Mobility House et al. noted the use of automated load management could reduce the need for upgrades.

As described in Chapter 4 of the RIA, EPA evaluates the cost associated with refueling time. The Western Energy Alliance questioned EPA's analysis, noting that charging times for EVs are significantly longer compared to refueling time for ICEs. On the other hand, a comment from Environmental and Public Health Organizations noted that the EPA's charge rate assumption of 100 miles of driving added per hour of charging is far too low given that mid-trip charging events are likely to occur using DCFCs, suggesting "EPA's charging rate assumption could be quadrupled (and the refueling time disbenefit for BEVs greatly reduced) and still result in a conservative assumption that leaves room for vehicles that may do some mid-trip charging at more moderate DC charging power levels."

Response:

As an initial matter, EPA notes that it anticipates automakers will employ a wide variety of control technologies, applied to ICE, hybrid, and electric powertrains, to meet the final standards and will continue to offer a diverse variety of vehicles for the duration of these standards and beyond. For example, under our central case modeling (which is only one estimate of a possible compliance path for the industry), in MY 2032, 29 percent of new vehicles would be non-hybrid ICE vehicles (with an additional 3 percent hybrid vehicles). We anticipate that the flexibilities offered by the final rule will enable manufacturers who choose to meet the final rule through producing more PEVs to deploy PEVs in areas and at volumes that meet consumer demand. At the same time, EPA agrees that continued expansion of reliable charging infrastructure supports higher rates of PEV adoption.

As discussed in Preamble Section IV.C.4 and RIA Chapter 5.3, public charging has been growing rapidly in the past few years with more than 160,000 public electric vehicle supply equipment (EVSE) ports available in the U.S. today.[556,557] As shown in the range of projected future infrastructure needs cited by commenters, estimates for future infrastructure needs vary widely in the literature. We note that these variations reflect different assumptions about PEV adoption, driving and charging behavior, residential charging access, and the mix of EVSE by power levels, among other factors. As described in RIA Chapter 5.3, we analyzed EVSE port needs under our final rule and a no-action case from 2027 to 2055.[558] Under an Interagency Agreement between EPA and the U.S. Department of Energy, NREL simulated PEV charging demand for eight unique charging types and locations: home L1, home L2, depot L2, work L2, public L2, and public DCFC at 150 kW, 250 kW, and 350 kW power levels. The analysis framework utilized to estimate charging demand was adapted from the framework used in the NREL study, "The 2030 National Charging Network: Estimating U.S. Light-Duty Vehicle Demand for Electric Vehicle Charging Infrastructure,"[559] which was cited by multiple commenters, though the PEV adoption scenarios developed were specific to EPA's final rulemaking analysis. We anticipate that the highest number of ports will be needed at homes across the full analysis period. For example, as seen in RIA Table 5-11, in 2030, we estimate approximately 33 million EVSE ports will be needed under the final rule, of which about 30 million are residential ports. We estimate just under one million public Level 2 ports, 780,000 workplace L2 ports, and 170,000 public DCFC ports will also be needed along with 360,000 depot L2 ports to support medium-duty vehicle charging. (See RIA Chapter 5.3.2 for a more complete discussion of our analysis.)

Regarding comments from the Alliance and Stellantis on public charging needs, EPA disagrees that one public EVSE port will be needed for every seven PEVs. NREL's national charging network assessment estimated that to support 33 million PEVs in 2030, about 1.25 million public EVSE ports (including 182,000 DC fast charging ports) would be needed,[560] along with 26.8 million private ports (most at single family homes, but also at multi-family homes and workplaces). That yields a ratio of one public EVSE port needed per 26 PEVs. This fits well within a range of other recent studies examining public infrastructure needs. An ICCT report looking across a dozen studies published between 2018 to 2021 found that two-thirds of the

U.S. DOE Alternative Fuels Data Center, "Alternative Fueling Station Locator." Accessed January 10, 2024, at https://afdc.energy.gov/stations/#/analyze?country=US&fuel=ELEC.

[557] If we include EVSE ports that are temporarily unavailable for maintenance or other short-term causes, the number of ports is over 170,000. (Source: U.S. DOE Alternative Fuels Data Center, "Alternative Fueling Station Locator." Accessed March 9, 2024, at https://afdc.energy.gov/stations/#/analyze?country=US&fuel=ELEC&status=E&status=T. U.S. DOE Alternative Fuels Data Center, "Alternative Fueling Station Locator.")

[558] The final rule and no-action cases used throughout the PEV charging infrastructure cost analysis were based on a preliminary analysis compared to the final compliance modeling. While annual PEV charging demand is generally higher in the compliance scenarios relative to those in the preliminary analysis (with annual differences of between plus and minus five percent), cumulative electricity consumption associated with PEV charging from 2027 to 2055 in the final rule compliance scenario is only four percent higher for the action case (the final standards) and one percent higher in the no-action case, compared to the preliminary analysis used to assess PEV charging infrastructure needs and costs.

[559] Wood et al., "The 2030 National Charging Network: Estimating U.S. Light-Duty Demand for Electric Vehicle Infrastructure," 2023. Accessed December 18, 2023, at https://driveelectric.gov/files/2030-charging-network.pdf.

[560] Ibid. (Note: See Figure ES-1 for EVSE port counts in the public network.)

estimates (including its own) fell between 20 and 40 PEVs per public EVSE port.[561] A new report conducted by ICF for the Coordinating Research Council, which assessed infrastructure needs for the level of PEV adoption in the proposed rule, found one public EVSE port would be needed for every 34 light-duty PEVs.[562] While the S&P Global article cited by some commenters[563] projected that 2.3 million public chargers would be needed to support 28 million PEVs in 2030—yielding a relatively low ratio of one port per 12 PEVs—the McKinsey article cited by commenters[564] estimated that 1.2 million public chargers would be needed to support 44 million electric passenger cars in 2030, yielding a ratio of just one public port needed for about every 37 light-duty PEVs. There was approximately one public EVSE port for every 26 PEVs on the road as of the third quarter of 2023,[565] suggesting that the overall level of public charging infrastructure deployment is generally keeping pace with PEV adoption based on comparisons with recent national assessments.

The ratio of one public EVSE port per every seven PEVs suggested by some manufacturers was based on a 2021 California assessment conducted by CEC.[566] However, as the commenters noted, this ratio was calculated from CEC's projected needs for both public and shared private EVSE ports, which includes a large number of EVSE ports at multi-unit dwellings and workplaces. In addition, we note that the infrastructure scenario in CEC's report was specific to California and may not be applicable nationally. For example, the share of PEVs with residential charging access in a given area may vary based on the mix of housing types (e.g., single-family or multi-family homes), household incomes, and other factors.[567] The CEC study assumed the number of PEVs with residential charging access in California was under 70 percent,[568] much

[568] See Table 5 in Alexander et al. 2021.

lower than the 90 percent assumption in NREL's national assessment.[569] In general, less access to home charging will increase the need for public or other non-residential charging infrastructure. We also note that CEC released an updated version of its charging infrastructure assessment in August 2023.[570] It projects that to support 7.1 million PEVs in 2030, just over 408,000 public (L2 and DCFC) ports will be needed, at a ratio of one public port per 17 PEVs, along with just over 600,000 shared private ports at workplaces and multi-family housing.[571]

We agree with commenters that keeping up with charging needs as PEV adoption grows will require continued infrastructure investments and appreciate the many comments we received that highlight plans and commitments for charging infrastructure buildout. NREL's national charging network assessment estimated that between $31 billion and $55 billion would be needed by 2030 for public infrastructure, noting that $24 billion in investments from public and private sources had already been announced as of March 2023.[572] The White House estimates that as of January 2024 total investments to expand the U.S. charging network had grown to over $25 billion.[573] Furthermore, there are many public and private parties investing in charging infrastructure, including federal, state, and local governments, automakers, utilities, charging companies, and retailers among others. These parties are already responding to the market that is developing for infrastructure, and we see no reason to believe they won't continue to meet infrastructure demand as the PEV market grows. See RIA Chapter 5.3.1 for a summary of ongoing and planned charging infrastructure investments.

We also agree with commenters who said that finalizing strong standards will itself spur additional investments in charging infrastructure. This is not an unprecedented situation with respect to CAA section 202 standards. For example, when EPA required the removal of lead from gasoline, an entire new parallel fuel distribution system was developed to dispense the new unleaded gasoline. See Preamble section III.B. Other examples where new distribution systems arose to ensure delivery of fuels necessary to vehicular pollution control include the infrastructure to supply diesel exhaust fluid (used to support selective catalytic reduction) and ultra low sulfur diesel fuel (used to support diesel particulate filters). We thus see that there can be successful market responses to demand created by a section 202 standard, including successful responses from entities not regulated by the standard.

We acknowledge comments, e.g., from NACS et al., that in certain periods, EV sales may rise faster than public charging stations. However, as discussed in RIA Chapter 5.3, when looking at the overall trend in infrastructure deployment from DOE's Alternative Fueling Station Locator,

573 The White House, "FACT SHEET: Biden-Harris Administration Announces New Actions to Cut Electric Vehicle Costs for Americans and Continue Building Out a Convenient, Reliable, Made-in-America EV Charging Network," January 19, 2024. Accessed at https://www.whitehouse.gov/briefing-room/statements-releases/2024/01/19/fact-sheet-biden-harris-administration-announces-new-actions-to-cut-electric-vehicle-costs-for-americans-and-continue-building-out-a-convenient-reliable-made-in-america-ev-charging-network/.

we see a rapid expansion over the past few years with the number of ports more than doubling from 74,000 ports at the end of 2019 to over 160,000 today.[574] And, with many public and private investments announced or underway (as described in RIA Chapter 5.3), we anticipate significant additional growth in advance of, and throughout, the timeframe of the standards. With respect to the comment citing an EEI report,[575] which estimated planned investments will support fewer than half of the 140,000 DCFC ports it estimated as being needed in 2030, we note that this assessment was released in June 2022 and, therefore, would not include planned investments announced since then. A survey by EDF and WSP (submitted as part of EDF's comments)[576] found that, as of June 2023, over $21.5 billion in commitments had been announced. The authors estimate that this will support over 800,000 new EVSE ports by 2030, including 250,000 DCFC ports—significantly higher than EEI's estimate of DCFC needs. As noted above, the White House estimates an even higher total of $25 billion in investments had been announced as of January 2024.[577] Given the increasing adoption of PEVs, the significant regulatory factors supporting that adoption—including BIL, IRA, and the regulatory certainty provided by the final rule—as well as the considerable economic incentives for EVSE suppliers and stations, we think it is reasonable to expect that additional investments will be made over the coming years in charging infrastructure to support the market's levels of PEV adoption. To put it differently, given the increasing adoption of PEVs, the deployment and operation of EVSE stations is a highly valuable business opportunity, and market participants are thus highly likely to avail themselves of this opportunity and meet demand. We do acknowledge lead time constraints associated with permitting and infrastructure, as discussed further below and in RTC 18, but our review of the evidence does not identify any hard constraints that would preclude the levels of increased infrastructure associated with the central case, particularly in light of the additional lead time provided by the final rule relative to the proposal.

As commenters noted, the U.S. government is making large investments through the BIL and the IRA. This includes extending and modifying a tax credit, through which residents in low-income or non-urban areas are eligible for a 30 percent credit for the cost of installing residential charging equipment up to a $1,000 cap and businesses are eligible for up to 30 percent of the costs associated with purchasing and installing charging equipment in these areas (subject to a $100,000 cap per item) if prevailing wage and apprenticeship requirements are met. We acknowledge the points made by some commenters that census tract restrictions limit the applicability of this tax credit. However, a map developed by DOE showing eligible census tracts

[577] The White House, "FACT SHEET: Biden-Harris Administration Announces New Actions to Cut Electric Vehicle Costs for Americans and Continue Building Out a Convenient, Reliable, Made-in-America EV Charging Network," January 19, 2024. Accessed at https://www.whitehouse.gov/briefing-room/statements-releases/2024/01/19/fact-sheet-biden-harris-administration-announces-new-actions-to-cut-electric-vehicle-costs-for-americans-and-continue-building-out-a-convenient-reliable-made-in-america-ev-charging-network/.

suggests that stations installed in a large majority of the U.S. may qualify,[578] and as noted by the White House, two-thirds of Americans live in these areas.[579] We also note that this tax credit can help to expand both residential and public charging infrastructure in rural areas. We acknowledge that some areas of the country may experience higher growth in the number of charging stations and PEVs relative to other areas of the country; as noted above, we anticipate that ICE vehicles will continue to be sold throughout the timeframe of this rule.

Regarding the Alliance's comment that no NEVI-funded stations had yet been deployed, we note that it is normal for it to take time to initiate a new funding program, develop program guidance, receive and review applications, make awards, and for awardees to start projects. Initial plans for all 50 states, DC, and Puerto Rico covering FY22 and FY23 funds were approved in September 2022, and together, the $1.5 billion in funding will help deploy or expand charging infrastructure on about 75,000 miles of highway.[580] Since the publication of the proposal, NEVI-funded stations have opened in Ohio, New York, and Pennsylvania.[581] At least another 30 states are actively soliciting proposals and making awards, suggesting many more station openings will be coming soon.[582]

As discussed in RTC Section 3.4, EPA disagrees with comments from manufacturers who recommended that EPA incorporate an adjustment mechanism into the stringency levels of the standards that scales with infrastructure deployment. EPA has assessed charging infrastructure as part of our assessment of the feasibility of these standards, and as discussed above, expects that charging infrastructure will continue to rapidly grow to meet demand. Moreover, as previously noted, we agree with commenters who said that finalizing standards will send clear market signals to spur additional investments in charging infrastructure. By contrast, including an automatic stringency adjustment would eliminate the predictability and certainty of the standards, which would lessen this market signal.

EPA agrees with commenters that in addition to deploying sufficient charging infrastructure, it must be reliable. In September 2023, the Joint Office of Energy and Transportation (JOET) announced that up to $100 million in NEVI funding would be available to increase reliability of

the existing charging infrastructure network with funds going to repair or replace EVSE ports.[583] This will complement efforts of the National Charging Experience (ChargeX) Consortium.[584] Launched in May 2023 by JOET and led by U.S. DOE labs, the ChargeX Consortium will develop solutions and identify best practices for common problems related to the consumer experience, e.g., payment processing and user interface, vehicle-charger communication, and diagnostic data sharing. See RIA Chapter 5.3 for additional efforts underway to support infrastructure reliability.

EPA also recognizes that it takes time for EVSE providers to develop charging site plans for their facility, obtain permits, purchase equipment, and have it installed. While permitting times will likely vary based on applicable state or local jurisdiction, specifics of the station site, and other factors, we note as one example that Electrify America reported that, in 2022, permitting took an average of 13 weeks for its U.S. "ultra-fast" DCFC stations.[585] We agree with Advanced Energy United that streamlining the permitting process could reduce infrastructure deployment times though we note that such policies are outside the scope of this rulemaking. As discussed by multiple commenters, infrastructure lead times will be longer if distribution upgrades are needed. We also acknowledge comments on supply chain challenges, in particular with respect to lead times for transformers. See RTC Section 18 for a discussion of the grid component supply chain and other distribution system considerations, including strategies to reduce the need for distribution system upgrades and associated lead times. With respect to EVSE manufacturing, we note that about forty companies have announced over $500 million of investments in U.S. facilities to construct charging equipment, with planned domestic production capacity of more than 1,000,000 chargers (including 60,000 DCFCs) annually.[586,587] As discussed in RTC Section 3.3, EPA is finalizing standards with a more gradual ramp-in of GHG stringency, i.e. that are less stringent than the proposed standards for each year from 2027 through 2031. This means manufacturers will be able to deploy GHG emissions reducing technology more gradually in the early years of the program, and also have more time take advantage of ongoing expansion of public charging infrastructure previously discussed.

As described in RIA Chapter 5.3.2, we estimate the costs to deploy the number of EVSE ports needed each year (2027─2055) to achieve the modeled network sizes for the final rule and a no-action case. For the proposal, we sourced hardware and installation costs for each EVSE port from several studies and we requested comments on any additional estimates we should consider. AFPM and CFDC et al. commented that EPA's overall estimated EVSE costs were significantly lower than those presented in NREL's national charging network assessment (Wood et al.

2023).[588] It is important to clarify that the EVSE cost estimates presented in DRIA Chapter 5 and used in the NPRM cost benefit analysis did not reflect the total EVSE costs under the proposal, but rather the difference in EVSE costs between the proposed rule and a no-action case. Therefore, these costs are not directly comparable to the estimates of how much cumulative investment would be needed for charging infrastructure by 2030 in Wood et al. 2023. Nonetheless, it is correct that the assumed hardware and installation costs per EVSE port in Wood et. al 2023, which was published after the NPRM, are generally higher than those EPA assumed in the NPRM analysis, and we agreed with commenters that it was appropriate to update our costs. For the final rule analysis, we have updated our assumed upfront hardware and installation costs for work and public EVSE ports to align with Wood et al. 2023 in order to reflect more up-to-date information.[589] We note that the resulting updated cost for each DC-150 kW port in our FRM analysis is $154,200, which is within the range Valero provided in its comments as an example. We also acknowledge CARB's and Tesla's comments on lower L2 residential costs for multi-family housing and DCFC costs, respectively. Given these lower costs identified by CARB and Tesla, and the potential for these lower costs to be experienced more widely in future years, our EVSE cost assumptions may be conservative. See RIA Chapter 5.3 for a more complete discussion of the hardware and installation costs we assumed for each EVSE type in our FRM analysis.

We agree with AFPM that it is important to account not only for infrastructure to support light-duty PEVs, but also for medium-duty PEVs. We have updated our FRM analysis accordingly. See RIA Chapter 5.3 for a description of how we estimated depot and public charging needs for medium-duty PEVs in our EVSE cost analysis for the FRM. Regarding POET's comment on EVSE port counts in 2055, we note that EVSE port count estimates have been updated for the final rulemaking (see Table 5-23 and Table 5-24 in the RIA). We also note that port needs do not scale directly with the number of PEVs. For example, as described in RIA Chapter 5.3.2, we model more sharing of home and depot EVSE ports as PEV adoption grows. More broadly, the number and mix of EVSE ports needed will depend not only on the absolute number of PEVs, but also on the characteristics of the PEVs (e.g., energy consumption rate and battery capacity), vehicle miles traveled, and other factors (see RIA Chapters 5.1 and 5.3 for more information on how port counts are estimated in the FRM analysis.)

We agree with Valero that there will be maintenance costs associated with public L2 and DCFCs. As we discuss in RIA Chapter 5.3, while we did not directly model these costs, we assume all EVSE ports have a 15-year equipment lifetime, and after that must be replaced at full cost. This assumption likely overestimates costs as some EVSE providers may opt to upgrade existing equipment rather than incur the cost of a full replacement. Some installation costs such as trenching or electrical upgrades may also not be needed for the replacement.

For the NPRM analysis, we used AEO 2021 residential electricity rates to reflect the cost to charge. EPA agrees with commenters that it is more appropriate for the electricity price to reflect a mix of rates across consumer classes rather than just a residential electricity rate. As described in RIA Chapter 5.2, we model future electricity prices for the final rulemaking with the Retail

---

[588] Wood et al., "The 2030 National Charging Network: Estimating U.S. Light-Duty Demand for Electric Vehicle Infrastructure," 2023. Accessed December 18, 2023, at https://driveelectric.gov/files/2030-charging-network.pdf.
[589] As noted in RIA Chapter 5.3.2, Wood et al. drew from various data and literature sources, including the studies that were used as sources for hardware and installation costs for workplace and public L2 ports and DCFC ports in the NPRM.

Price Model associated with the Integrated Planning Model (IPM). IPM models the power sector, including changes to power generation based on future demand scenarios. We conducted IPM runs for a no-action case and a final rule policy or "action" case based upon Alternative 3 from the proposed rule with the addition of heavy-duty vehicle charge demand based on an interim scenario developed from for the Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3 Proposed Rule. We agree with commenters that it is appropriate to consider the geographic allocation of charge demand, and we have modeled this in our IPM runs described above.[590] The resulting impacts to power generation from IPM were then input to the Retail Price Model to estimate average electricity prices, weighted by the amount of electricity used by each consumer class (e.g., residential, commercial, and industrial) and in each region. We used this approach to estimate electricity prices in the FRM, as opposed to AEO, because we can better model demand under the final rule policy case discussed above with IPM (including geographic allocation).

In the NPRM we acknowledged that certain stations, particularly those with many high-power DCFCs, may require upgrades to the distribution system; however, we did not include the associated costs in our assessment of PEV charging infrastructure. We agree with commenters that it is appropriate to include distribution system upgrade costs in the final rulemaking analysis, and as described in RIA Chapter 5.2.4, we have incorporated these costs within the electricity prices. See RIA Chapter 5.4 and RTC Section 18 for a more detailed discussion of the distribution system considerations and a new DOE analysis we utilized to estimate the distribution upgrade costs.

In response to comments on consumer concerns related to range anxiety and the time it takes to charge, see RTC Section 13. Many refueling events for electric vehicles would be expected to occur either overnight where the vehicle is parked or during the workday, neither of which require extra time from the driver. However, some charging events will require drivers to take extra time to charge, especially when drivers are in the midst of an extended road trip. As described in RIA Chapter 4.3.5, EPA estimates the cost of time spent refueling. We agree with commenters who recommended that we update this analysis for the final rulemaking. In particular, we concur with the comment from Environmental and Public Health Organizations that our assumed charge rate of 100 miles of added driving range per hour is too low and that mid-trip charging events are likely to occur using DCFCs. We use an updated value of 400 miles of added driving range per hour of charging for our FRM analysis, which is consistent with the commenter's recommendation.

Comments on the impact of EPA's proposed powerplant rule under Section 111 of the Act are related to a separate regulatory action and thus beyond the scope of this rulemaking. If and when that rule is finalized, EPA will account for the costs of that rule in that proceeding.

18 - Power sector and grid reliability considerations

[590] See Chapters 5.1 and 5.2 for a more complete description of the power sector modeling used in the final rulemaking analysis, including the development of hourly charging load profiles to reflect the time of day that charging occurs at the regional level.

Comments by Organizations

Organization: Alliance for Automotive Innovation

B. Comparison of EPA's Projected U.S. BEV Market Share to Other Projections

EPA projects that manufacturers can reach 60% BEV U.S. market share by 2030 and 67% share by 2032. In context, for all light-duty auto sales in 2022, less than 6% were BEV (or just over 7% when including PHEVs). Effectively, EPA's proposed BEV requirements would be roughly ten times higher than 2022 levels. [EPA-HQ-OAR-2022-0829-0701, pp. 28-29]

Given the degree of electrification that EPA projects in association with its proposed standards, it is helpful to compare EPA's projections to those of industry analysts. EPA does provide some third-party projections of U.S. BEV market share, but does so only in the context of supporting its finding that demand for BEVs is rapidly increasing.22 [EPA-HQ-OAR-2022-0829-0701, pp. 28-29]

22 NPRM at 29189.

Auto Innovators compares EPA's projections23 to those of the U.S. Energy Information Agency (EIA),24 S&P Global Mobility,25 Bloomberg,26 Benchmark Minerals Intelligence (BMI),27 and the International Council on Clean Transportation (ICCT)28 in Figure 1. EPA's projections exceed those of other government agencies (EIA) and of the industry and financial analysts (S&P Global Mobility, Bloomberg, and BMI). The only projection close to EPA's is that from ICCT (a well- known non-governmental organization that advocates for stronger standards), but EPA's projections still exceed even those of ICCT. While projections can and certainly do vary based on input assumptions, EPA has not adequately explained how increasing GHG standards in and of itself would enable greater BEV-only market share than those projected by multiple other analyses that include both BEVs and PHEVs. [EPA-HQ-OAR-2022-0829-0701, pp. 28-29]

23 For this assessment, Auto Innovators used EPA's projected BEV market share from the ACC II sensitivity case for the proposed standards. (NPRM at 29335, Table 108.)

24 U.S. Energy Information Administration, Annual Energy Outlook 2023, High Uptake of the IRA side case, Table 38. (Market share calculated by Auto Innovators based on EV sales and total sales of light-duty vehicles.)

25 S&P Global Mobility, U.S. light vehicles sales forecast by propulsion system design (Jan. 2023). Obtained via personal correspondence. Used with permission.

26 Bloomberg NEF, Electric Vehicle Outlook 2023 (Jun. 2023) at 22 (Figure 30; reflects BloombergNEF economic transition scenario). Data obtained via BloombergNEF subscription.

27 Benchmark Minerals Intelligence, 1Q2023 model for Auto Innovators (proprietary).

28 The International Council on Clean Transportation, Analyzing the Impact of the Inflation Reduction Act on Electric Vehicle Uptake in the United States (Jan. 2023) at 27. (Table A5, IRA Moderate with increased state ACC II adoption scenario.)

The projection from S&P Global Mobility, a well-respected third-party analyst of the automotive industry, suggests approximately 47% EV market share (including PHEVs) in 2030 and 59% in 2032. In comparison, EPA projects a BEV-only market share of 61% by 2030 and 67% in 2032 under its proposed standards. The projection from Bloomberg is very similar to that of S&P Global Mobility, reaching 51% combined EV sales in 2030 and 60% combined EV sales by 2032. The S&P Global Mobility and Bloomberg projections are generally consistent with Auto Innovators belief that 40-50% EV market share by 2030 is an aspirational, yet achievable goal if suffcient complementary policies are in place. [EPA-HQ-OAR-2022-0829-0701, pp. 28-29]

[See original comment for Figure 1: Comparison of EPA-projected BEV market share under the proposed standards to projections from EIA, S&P Global Mobility, Bloomberg, and ICCT.] [EPA-HQ-OAR-2022-0829-0701, pp. 28-29]

4. Modeling the geographic diffusion of BEVs is important for accurately gauging the customer acceptance of the national standards.

The OMEGA least-cost compliance modeling suggests that, by model year 2032, 67% of new vehicle sales will be BEVs, a remarkably different figure than the 8% BEV share observed in the U.S. in early 2023. [EPA-HQ-OAR-2022-0829-0701, pp. 284-285]

Modeling a highly segmented and geographically dependent market as a single entity is spurious. The agency's assumption that all consumers will respond with the same elasticity of demand pegged to the same diffusion of innovation curve is simplistic and not appropriate. As we know, there are many factors outside of the relative price of powertrains that come into play when purchasing a new vehicle. These include the robustness of the charging ecosystem, inclement weather, relative price of fuels, and even political affiliation. [EPA-HQ-OAR-2022-0829-0701, pp. 284-285]

It is crucial that EPA model accurately the diffusion of BEVs into different parts of the country, since the pattern of spatial diffusion influences key issues in this rulemaking: [EPA-HQ-OAR-2022-0829-0701, pp. 284-285]

-the amount of electricity required to support BEVs in different areas;

-the degree of grid investments and public-charging investments required to support BEVs;

-the amount of emissions from the electric utility sector (as some regions are more carbon intensive than others);

-and the prospects for customer acceptance of BEVs (as regions vary in attitudes toward BEVs, the pace of the public charging build out, cold weather climates, and the availability of state incentives and public outreach to facilitate BEV deployment). [EPA-HQ-OAR-2022-0829-0701, pp. 284-285]

In its analysis EPA adapts a "vehicle adopter model" (VAM) developed by the National Renewable Energy Laboratory. The model includes some plausible predictor variables such as income, housing type, housing tenure, population density, and rural vs urban location. The authors also acknowledge the model omits crucial variables relevant to predicting whether a household will purchase or lease a BEV such as environmental attitudes, interest in advanced technology, whether the household has a place at home or at work to charge their BEV, commuting distance, and long-trip frequency. The model explained little of the variation in BEV ownership in the sample (R-square = 0.04). The authors explain that the model seemed to perform better statistically at the county level, but with so many omitted variables it seems doubtful the model coefficients are useful for prediction. A deeper problem is that the data set included only 224 households that owned at least one BEV, about 6% of the sample, and it is not clear whether the sample is representative of the U.S. Since the 224 households are, as the authors note, early BEV adopters, it seems unlikely that information about them will be relevant in predicting which households adopt BEVs as the technology diffuses from 8% of new vehicle purchasers in early 2023 to 67% in 2032. For the purposes of the rulemaking, it is more important to model carefully, for example, those who are open to a BEV but have not yet purchased one. The authors were careful to state that their results have limited utility [EPA-HQ-OAR-2022-0829-0701, pp. 284-285] :

The absolute values of the estimates and the predictive capability of the model are not the priorities for this purpose—instead, we emphasize the relative scale of these coefficients (for example, how much influence housing type has on PEV adoption compared with income). [EPA-HQ-OAR-2022-0829-0701, pp. 284-285]

EPA then decided to use the absolute coefficients to forecast PEV adoption, exactly contrary to what the authors suggested. [EPA-HQ-OAR-2022-0829-0701, pp. 284-285]

Auto Innovators appreciates that EPA may have been inclined to use this survey because the results can be linked to the IPM model of the electric utility sector. Unfortunately, the survey and modeling have so many weaknesses for use in this rulemaking that a different modeling strategy is required [EPA-HQ-OAR-2022-0829-0701, pp. 284-285].

In the long run, Auto Innovators suggests that EPA develop an improved BEV adopter model.

3. EPA Fails to Adequately Assess the Availability of Electricity Generation, Distribution, and Transmission

Despite the potential for increased demands on domestic energy generation and generation capacity,156 EPA offers little to no support that these demands will be sufficiently met.

Similarly, EPA's DRIA offers scant analysis regarding the costs associated with meeting these increased infrastructure and energy generation/capacity needs beyond the flawed reliance on various legislative actions, such as the BIL and IRA.157

Consequently, EPA is pushing a single technology at a pace that cannot be adopted within the time frame of its own proposal.158 [EPA-HQ-OAR-2022-0829-0733, p. 34]

156 See, e.g., U.S. DRIVE, "Summary Report on EVs at Scale and the U.S. Electric Power System" (Nov. 2019), available at https://www.energy.gov/eere/vehicles/articles/summary-report-evs-scale-and-us-electric-power-system-2019 (summarizing impacts of light-duty vehicles on energy generation and generation capacity alone and acknowledging several potential challenges without including analysis of medium-and heavy-duty ZEVs).

157 See, e.g., Salma Elmallah et al., Can distribution grid infrastructure accommodate residential electrification and electric vehicle adoption in Northern California? (Nov. 9, 2022), available at https://iopscience.iop.org/article/10.1088/2634-4505/ac949c (projecting that upgrades needed solely for the PG&E service area in Northern California, which serves 4.8 million electricity customers and is subject to aggressive targets for both EV adoption and electrification of residential space and water heating will add at least $1 billion and potentially $10 billion to PG&E's rate base).

158 DRIA at 5-28.

Organization: Charles Gordon

INTRODUCTION and SUMMARY

I recommend that EPA withdraw this rulemaking. The earlier rules and the subsidies of the Inflation Reduction Act will lead to a greater reduction of CO2 with less controversy.

In addition, the proposal is attempting to force faster adoption of electric cars than the infrastructure can support.

Natural gas power plants cannot be replaced by solar and wind fast enough and more importantly transmissions line cannot be built quickly enough because of local opposition. [EPA-HQ-OAR-2022-0829-0747, p. 3]

Organization: Environmental. and Public Health Organizations

G. EPA's conclusion that LDV charging will not compromise the reliability of the electric grid is supported by empirical data.

EPA observes that LDV charging is not anticipated to adversely impact electric grid reliability:

U.S. electric power utilities routinely upgrade the nation's electric power system to improve grid reliability and to meet new electric power demands. For example, when confronted with rapid adoption of air conditioners in the 1960s and 1970s, U.S. electric power utilities successfully met the new demand for electricity by planning and building upgrades to the electric power distribution system. Likewise, U.S. electric power utilities planned and built distribution system upgrades required to service the rapid growth of power-intensive data centers and server farms over the past two decades. U.S. electric power utilities have already successfully designed and built the distribution system infrastructure required for 1.4 million battery electric vehicles. Utilities have also successfully integrated 46.1 GW of new utility-scale electric generating capacity into the grid.332 [EPA-HQ-OAR-2022-0829-0759, p. 121]

332 88 Fed. Reg. at 29311 (citations omitted).

These conclusions are supported by empirical evidence from California, which already has more than 1.3 million PEVs on the road.333 While some pundits have claimed EV charging is already straining the grid, triggering service disruptions, those claims have been debunked.334 And root cause analysis from the California Independent System Operator (California ISO) showed that PEVs are not what has strained the grid.335 Indeed, empirical evidence shows that PEV charging has been accommodated with minimal required grid upgrades and that EV charging can be shifted to hours of the day when there is plenty of spare grid capacity. Since 2011, CPUC has required the utilities it regulates to report annually on costs associated with accommodating PEV charging and on the charging patterns of PEVs on different utility rates.336 As summarized by Synapse Energy Economics, utility grid upgrades required to accommodate PEV charging to this point in those service territories are essentially rounding errors compared to the costs of maintaining the electrical grid: [EPA-HQ-OAR-2022-0829-0759, p. 121]

Co., Joint IOU Electric Vehicle Load Research and Charging Infrastructure Cost Report 10th Report (Mar. 31, 2022), https://www.cpuc.ca.gov/-/media/cpuc-website/divisions/energy-division/documents/transportation-electrification/1 0th-joint-iou-ev-load-report-mar-2022.pdf.

Even in the service territories with the most EVs, the observed costs have been minor. For instance, in California where EV adoption has been markedly higher than other states, EV-related distribution upgrade costs appear minor compared to total distribution costs. Despite the fact EVs are often more concentrated in many neighborhoods and distribution circuits, California utilities collectively spent less than 0.03% of their total distribution-related expenses on distribution system upgrades associated with residential EV adoption.337 [EPA-HQ-OAR-2022-0829-0759, p. 121]

Furthermore, as detailed below, the projected growth in electricity demand over the coming years is well within the range of past historical load growth. Additionally, the industry is already responding to and preparing for increased electrification as more fleets and individuals adopt PEVs, and it has a wide range of tools, practices, and partnerships in place to continue to maintain a strong and reliable grid. [EPA-HQ-OAR-2022-0829-0759, p. 121]

3. EVs can lower the cost of managing an increasingly dynamic electric grid.

Third-party analyses have found that PEVs, if deployed strategically, can improve grid operations. For example, PEVs can "contribute significantly to grid stability" and provide value to the grid through "deferred or avoided capital expenditure on additional stationary storage, power electronic infrastructure, transmission build-out, and more."344 Additionally, utilities can deploy proven and emerging rate designs that ensure utilities recover costs, reliably serve PEV charging load, improve PEV owner experience, and take advantage of grid strengthening services from these vehicles.345 [EPA-HQ-OAR-2022-0829-0759, pp. 126-127]

Researchers from Lawrence Berkeley National Laboratory estimate that using smart charging of light-duty PEVs as a means to comply with California's energy storage procurement mandate (designed to facilitate the integration of renewable energy) would save utility customers approximately $1.5 billion because it is cheaper to use batteries customers have already purchased on four wheels than to pay private companies to deploy standalone battery storage.346 The same study also found that enabling "vehicle-to-grid" (V2G) technology, allowing PEVs to supply power back to the grid during times of stress, could save $13-15 billion in stationary battery costs.347 "By displacing the need for construction of new stationary grid storage, EVs can provide the dual benefit of decarbonizing transportation while lowering the capital costs for widespread renewables integration," the researchers concluded.348 [EPA-HQ-OAR-2022-0829-0759, p. 127]

348 Id. at 1.

Focusing on the Midwest to underscore the point, researchers concluded that very high levels of renewable energy penetration in the Midcontinent Independent System Operator region could result in "negative valleys" (requiring excess renewable energy to be exported or curtailed), but that "[c]ontrolled (EV) charging [both smart charging and smart discharging back onto the grid] is able to reduce these negative valleys, and with sufficient numbers of EVs can eliminate them altogether, obviating the need for either export of excess renewable generation or curtailment."349 This would provide both increased environmental benefits by facilitating the integration of high levels of renewable generation and significant customer benefits. Put simply, it is cheaper to pay individual utility customers to use batteries on wheels they have already bought and paid for than it is to pay corporations to buy big batteries and park them on the grid. [EPA-HQ-OAR-2022-0829-0759, p. 128]

(last accessed June 30, 2023).

4. PEV charging is already putting downward pressure on electric rates, to the benefit of all utility customers.

Because much PEV charging can be accomplished when there is spare capacity on the grid, charging can spread the costs of maintaining the system over a greater volume of electricity sales, reducing the per-kilowatt-hour price of electricity to the benefit of all customers. This has already been demonstrated in the real world. [EPA-HQ-OAR-2022-0829-0759, p. 128]

In fact, empirical data compiled by Synapse Energy Economics shows that PEV drivers are not being subsidized by other utility customers and, in fact, they are putting downward pressure on rates. Between 2011 and 2020, PEV customers across the United States contributed more than $1.7 billion in net revenue to the body of utility customers.350 [EPA-HQ-OAR-2022-0829-0759, p. 128]

350 Melissa Whited, Tyler Fitch, Jason Frost, Eric Borden, Courtney Lane, Ben Havumaki, Sarah Shenstone-Harris & Elijah Sinclair, Electric Vehicles Are Driving Rates Down 1 (June 2023), https://www.synapse-energy.com/sites/default/files/Electric%20Vehicles%20Are%20Driving%20Rates%20Down%20Factsheet.pdf.

The results shown in Figure XVII.G-4 compare the new revenue the utilities collected from PEV drivers to the cost of the energy, capacity, transmission, and distribution system upgrades required to charge those vehicles, plus the costs of utility PEV infrastructure programs that are deploying charging stations for PEVs. In total, PEV drivers contributed an estimated $1.7 billion more than associated costs. That net revenue is returned to the body of utility customers in the form of electric bills that are lower than they would otherwise be. [EPA-HQ-OAR-2022-0829-0759, p. 128]

Organization: John Graham

Table 1 also shows that the lifecycle emissions advantage of the BEV is larger in the states that have adopted zero-emission vehicle (ZEV) mandates than in states that have not adopted ZEV mandates. This difference reflects that fact that the average reliance on coal and oil for electricity production is much less prevalent in ZEV states (6.9%) than in non-ZEV states (31.2%).100 Since the incremental effect of the EPA rule will be felt predominantly in the non-ZEV states, the most appropriate comparison for this rulemaking is HEV emissions versus BEV emissions in non-ZEV states. [EPA-HQ-OAR-2022-0829-0585, p. 35]

100 EPA. eGRID with 2021 Data. Released January 30, 2023, https://www.epa.gov/egrid/summary-data.

The central case in the DRIA ignores this reality by assuming that no states have adopted zero emission vehicle mandates. There is a sensitivity case where state ZEV mandates are considered in an alternative baseline, but the sensitivity case does not actually assume full implementation of the state-level mandates. Instead, it uses a BEV adopter model with a state-ZEV variable that is not properly specified (this weakness is acknowledged by the authors of the model).101

As a result, even the sensitivity case assumes, incorrectly, that the EPA rule will have a large impact on BEV adoption in the ZEV states. In the final rule, EPA should fix this problem, making sure that the BEV-adoption impact of the rule is concentrated in the non-ZEV states (since the state regulations and ancillary state policies will handle BEV deployment in the ZEV states). We also recommend a specific marginal emissions comparison of BEVs versus HEVs in each of the non- ZEV states. [EPA-HQ-OAR-2022-0829-0585, p. 35]

101 https://www.nrel.gov/docs/fy22osti/81065.pdf (especially p. 18). .

Organization: National Association of Manufacturers (NAM)

Manufacturers are committed to the communities in which they live and serve. Constant innovation, investment and dedication make manufacturers leaders in environmental stewardship and sustainability as they continue to drive our economic growth and prosperity. Modern manufacturing is a clean and efficient, technology-driven industry that is dedicated to the planet and its people. The NAM's members are committed to ensuring that progress continues. [EPA-HQ-OAR-2022-0829-0633, pp. 1-2]

Auto manufacturers have been making historic investments to ensure that more zero emissions vehicles are available for American motorists. As the Environmental Protection Agency finalizes its light and medium-duty vehicle emissions standards, it should structure them to allow manufacturers in the U.S. to meet market demand and remain globally competitive. To achieve these goals, we recommend the following approaches to the proposed rulemaking. [EPA-HQ-OAR-2022-0829-0633, pp. 1-2]

Infrastructure Needed

According to the Department of Energy's draft National Transmission Needs Study released in February 2023, the national electric transmission infrastructure would need to grow 57% by 2035 to reach the Biden administration's clean energy goals for the light-, medium-and heavy-duty vehicle industries.1 Yet at the historical pace of approximately 1% annual growth for these infrastructure projects,2 the transmission system could require more than half a century for the administration to achieve its stated goals for the next decade. As such, the rulemaking must recognize the realities and limitations of current infrastructure. Manufacturers continue to urge administration officials and congressional leaders to prioritize policies, including critical permitting reforms, that would strengthen transmission systems and infrastructure and speed up their growth. [EPA-HQ-OAR-2022-0829-0633, pp. 1-2]

1 https://www.energy.gov/gdo/national-transmission-needs-study

2 https://repeatproject.org/docs/REPEAT_IRA_Transmission_2022-09-22.pdf

Organization: Paul Bonifas and Tim Considine

This rule is like the Clean Power Plan proposed by the Biden Administration. The US Energy Information Administration conducted a study of the Clean Power Plan and found that average retail electricity rates would increase upwards of 3-7%.13 Taking the mid-range of this price increase, or 5%, the proposed rule would raise the previous electric rate increase of 55% to 58% and increase electricity costs for EV charging from EPA's estimate of $460 billion to $728 billion. [EPA-HQ-OAR-2022-0829-0551, p. 5]

13 https://www.eia.gov/analysis/requests/powerplants/cleanplan/

This $728 billion in higher electricity expenditures more than offsets the savings in reduced liquid fuel spending of $620. On balance, the fuel cost savings are a NEGATIVE $108 billion in contrast to EPA's estimated pre-tax fuel savings of $890 billion. This is a nearly $1 trillion difference. So, under rather conservative but realistic assumptions and elementary economic analysis, the proposed EV rule will not save consumers money but instead will lead to higher electricity costs, especially for poor and lower to middle class households living in rental units. [EPA-HQ-OAR-2022-0829-0551, p. 5]

Organization: Travis Fisher

Specifically, the EPA's DRIA regarding the impact of the Proposed Rule on the cost and reliability of electricity in the U.S. is gravely flawed. It should be redrafted to enable the EPA Administrator to give appropriate consideration to the cost and safety factors of the Proposed Rule, as required by section 202 of the Clean Air Act.1 Further, the DRIA should address the interactions between the Proposed Rule and other EPA rules—including the recently proposed rule on greenhouse gas emissions from power plants2—as required by Executive Order 12866.3 As written, the Proposed Rule: [EPA-HQ-OAR-2022-0829-0655, p. 1]

1. Violates section 202 of the Clean Air Act by failing to adequately consider:

A. Impaired bulk power system reliability and [EPA-HQ-OAR-2022-0829-0655, p. 1]

B. Increased retail electricity prices; [EPA-HQ-OAR-2022-0829-0655, p. 1]

EPA Summary and Response

We received many comments from the public related to the final rule. These comments dealt with several subjects, including generation capacity, transmission capacity, distribution capacity, differences in results between various emissions models and inventories, infrastructure upgrade costs, and electricity rates. A summary of these comments as well as EPA's response appears below.

Summary

Topic: Electric Power System: Generation Capacity

We received three comments related to generation capacity from the public. Two of the comments expressed concern that the EPA did not adequately consider the generation system capacity, while one comment agreed with EPA's assessment that adequate generation system capacity currently exists and will so for the duration of this final rule. These commenters included: American Fuel & Petrochemical Manufacturers, Charles Gordon, and Environmental and Public Health Organizations.

Topic: Electric Power System: Transmission Capacity

We received four comments related to transmission capacity from the public. Three of the comments expressed concern that the EPA did not adequately consider the transmission system capacity, while one comment agreed with EPA's assessment that adequate transmission system capacity currently exists and will so for the duration of this final rule. These commenters included: American Fuel & Petrochemical Manufacturers, Charles Gordon, Environmental and Public Health Organizations, and National Association of Manufacturers (NAM).

Topic: Electric Power System: Distribution Capacity

We received two comments related to distribution system from the public. One comment expressed concern that the EPA did not adequately consider the distribution system capacity, while another comment agreed with EPA's assessment that adequate distribution system capacity currently exists and will so for the duration of this final rule. These commentors included: American Fuel & Petrochemical Manufacturers and Environmental and Public Health Organizations.

Topic: Electric Power System Reliability

We received three comments related to the electric power sector reliability from the public. Two of the comments expressed concern that the EPA did not adequately characterize possible degradation to the electric power system, while another comment agreed with EPA's assessment that this final rule will not result in significant material harm to electric power system reliability. These commenters included: American Fuel & Petrochemical Manufacturers, Environmental and Public Health Organizations, and Travis Fisher.

Topic: Emissions Modeling

We received one comment related to emissions modeling. The one comment expressed concern that EPA's emissions modeling in support of this final rule was inaccurate. This comment was from John Graham.

Topic: Infrastructure Upgrade Costs

We received two comments related to infrastructure upgrade costs from the public. These comments expressed concern that the EPA did not adequately consider the benefits and/or costs associated with infrastructure upgrade costs. These commenters included: American Fuel & Petrochemical Manufacturers and Paul Bonifas and Tim Considine.

Topic: Electricity Rates

We received two comments related to the electricity rates from the public. These comments expressed concern that the EPA did not adequately consider decreases and/or increases in electricity rates. These commenters included: Environmental and Public Health Organizations, and Travis Fisher.

Response:

EPA conducted extensive electric power sector modeling analyses in which it concluded that there is adequate generation and transmission capacity required to meet the electric load demands imposed by the final rule. Moreover, the modeling analyses confirmed that there is adequate generation and transmission capacity to meet North American Electric Reliability Corporation (NERC) reliability standards, including those for reserve capacity. Our analyses demonstrate that the impacts of both this rule alone and combined with the Heavy-Duty Phase 3 Rule do not adversely affect resource adequacy and grid reliability. These impacts result in anticipated power grid changes that 1) are consistent with key National Electric Reliability Corporation (NERC) assumptions, 2) that are consistent with historical trends and empirical data, and 3) are consistent with goals, planning efforts and Integrated Resource Plans (IRPs) of industry itself. In response to commenters that claimed the cumulative impacts of the final rule and certain EPA proposed rules relating to the electric generating sector would adversely affect resource adequacy and grid reliability, we also performed an analysis of cumulative impacts and assessed that these cumulative impacts were unlikely to adversely affect resource adequacy or grid reliability. For additional discussion of these topics, see RIA Chapter 5: Electric Power Sector and Infrastructure Impacts and the Technical Memorandum for Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, and Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3 Docket ID No Numbers. EPA-EPA–HQ–OAR–2022–0829 and EPA-HQ-OAR-2022-0985.

EPA also conducted extensive and first-ever, national-level distribution system modeling analyses in conjunction with the U.S. Department of Energy (DOE), the National Renewable Energy Laboratory (NREL), and the Lawrence Berkeley National Laboratory (LBNL) in support of this final rule. The study found that: the benefits of vehicle electrification to consumers outweigh the estimated cost of charging infrastructure and grid upgrades; incremental distribution grid investment needs represent approximately 3 percent of current annual utility investments in the distribution system; and incremental distribution grid investment needs decrease by 30% with basic managed charging techniques.

The study also underscored the additional benefits that managed electric vehicle charging confers to the distribution system, such as the ability to defer distribution system upgrades. With managed charging, the final standards provide significant distribution system benefits, both financially and in terms of their ability to defer necessary distribution system upgrades. By more-effectively utilizing existing electric power system assets, managed electric vehicle charging has been shown to help reduce overall electricity costs by allowing for the deferral of electric power system upgrades, with deferment potential of between 5 and 15 years over the 2021–2050 period (Kintner-Meyer et. al., 2022). While such deferrals reduce immediate capital expenditures for electric power system operators, they also extend the functional lifespan of these assets, provide electric utility planners with additional time to more-effectively schedule and coordinate needed distribution system upgrades, consider cost-effective planning options, and help mitigate supply chain shortages for electric power system components. For additional discussion, see Chapter 5: Electric Power Sector and Infrastructure Impacts and the joint DOE-NREL-LBNL-EPA Technical Report for the Transportation Electrification Infrastructure Study (TEIS).

When considering emissions from various electric vehicles, one commentor cited estimates from eGRID, a spreadsheet data source produced by EPA. eGRID is a useful, static spreadsheet-based tool for approximating electric power plant emissions. For rulemaking purposes involving the electric power sector, EPA uses the Integrated Planning Model (IPM), a multi-regional, dynamic, deterministic linear programming model of the U.S. electric power sector. It provides projections of least-cost capacity expansion, electricity dispatch, and emission control strategies for meeting energy demand and environmental, transmission, dispatch, and reliability constraints. The inherent differences between eGRID, a static dataset, and IPM, a dynamic optimization model used to develop the final rule, likely account for the emissions differences encountered by the commentor. In other words, eGRID is a list of electric power sector assets that says nothing about the conditions or times during which they may be called upon to operate, whereas IPM is a tool that determines the least-cost set of these assets, which vary with time, that achieve a policy objective. As such, EPA finds that IPM, and not eGRID, is the more suitable tool for purposes of modeling the effects of this rule.

When discussing transmission system concerns, one commentor cited a statistic from the Department of Energy (DOE) DRAFT National Transmission Needs Study. However, the DRAFT National Transmission Needs Study cited by the commentor was superseded by the FINAL National Transmission Needs Study. Further, the internet link provided by the commentor for the DRAFT report links, instead, to the FINAL report. A search for the DRAFT report was fruitless as was a search of the FINAL report for the statistic in question.

One commentor cited differences between the 2050 results of EPA's IPM emissions modeling conducted in support of this final rule and the Energy Information Administration's (EIA) Annual Energy Outlook 2023 (AEO2023).

For this final rule, we conducted extensive electric power sector generation modeling analyses using EPA's Power Sector Modeling Platform v6. To generate projections used in the Annual Energy Outlook 2023 (AEO2023), EIA uses the National Energy Modeling System (NEMS). The modeling assumptions used in EIA's NEMS differ from the modeling assumptions used in EPA's Power Sector Modeling Platform v6 and likely account for the perceived differences in 2050 results. EPA's IPM model differs and EIA's NEMS model in many ways. For instance:

- Total electric demand assumed in IPM to support the final rule is higher than that used by EIA in NEMS for AEO2023.

- Regional distribution of electricity demand assumed in IPM to support the final rule differs from that used by EIA in NEMS for AEO2023. EPA has carefully considered the regional impacts of our regulation, and we believe accounting for such regional impacts is important given regional differences between motor vehicle use as well as the electric sector.

- IPM uses additional (incremental) EV demand incorporated to the total demand compared to AEO (NEMS). Given that this rule is associated with increases in electricity demand, we believe using up-to-date total electric demand numbers reflecting those increases in IPM is appropriate.

- EPA rules are not fully reflected in AEO modeling, and AEO modeling does not capture the effects of the expiration of tax credits in later years of the IRA. We believe that reflecting existing regulations in the baseline is important in assessing the impacts of our action; this is also consistent with Circular A-4. Over the course of this rulemaking EPA has also worked closely with DOE and carefully evaluated IRS guidance in assessing the impacts of relevant IRA provisions, and our analysis fully accounts for this updated information.

- EPA updates the generation fleet information (retirements and new capacity additions) frequently, based on both EIA data, public comments, and EPA research;

- EPA incorporates and models various state-level environmental regulations in detail and updates them frequently;

When reviewing EIA's AEO, the Congressional Research Service (CRS) noted that a "challenge with AEO projections is that they tend to be less accurate as they go farther out into the future" (Lawson, A. J. et. al. 2020B). The CRS is a public policy research institute of the United States Congress that operates within the Library of Congress, works primarily and directly for members of Congress and their committees and staff on a confidential, nonpartisan basis.

The CRS also notes that "EIA's projections have been criticized for not taking into account potential changes in laws and regulations. Some critics argue that this presents a misleading reference upon which many policy and investment decisions are made. Others argue EIA insufficiently accounts for policy or technology changes in its projections" (Lawson, A. J. et. al. 2020A).

EIA announced in early 2023 that it will postpone the release of AEO 2024, because NEMS "…requires substantial updates to better model hydrogen, carbon capture, and other emerging technologies." Further, the next AEO release is scheduled for 2025 and will "…more comprehensively address existing laws and regulations in the Reference case, including up-to-date provisions in the Inflation Reduction Act and regulatory actions that could be finalized in the coming months." This is the first time in its 41-year history that the AEO will not be published.

For the above reasons, EPA believed that using IPM is appropriate for purposes of modeling this rule. In sum, EPA devoted considerable time and resources, including in consultation with DOE, in assuring that the IPM would accurately model the impacts of this rulemaking, for example, accounting for additional electricity demand due to EVs associated with this rulemaking and reflecting the latest EPA and State regulations relevant to the power sector. By contrast, AEO2023 does not accurately account for these important factors

One commentor suggested that EPA's final rule "Violates section 202 of the Clean Air Act by failing to adequately consider: A. Impaired bulk power system reliability and B. Increased retail electricity prices." EPA notes that the Clean Air Act Section 202 does not specifically list these factors. Nonetheless, EPA did in fact consider both grid reliability and retail electricity prices.

One commentor was supportive of EPA's final rule, stating that the increase in expected future electricity demands is consistent with past precedent; that electric vehicle-related distribution upgrade costs will be minor compared to total distribution costs; that electric vehicles can lower the cost of managing the electric power system; and reduce the curtailment of renewable electricity. This commenter also added that electric vehicles should provide downward pressure on electricity prices for electric vehicle users and non-users.

18.1 - Electrical distribution level and transmission level reliability

Comments by Organizations

Organization: 25x'25 Alliance, et al.

The undersigned parties offer the following comments on EPA's proposed rule, "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles." We write these comments because we believe that the proposed rules would establish an overly aggressive, high-risk program that would be counterproductive in achieving the agency's environmental and health objectives. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

In establishing or revising Clean Air Act Section 202(a) standards, EPA must consider issues of technological feasibility, cost of compliance, and lead time. Among other things, that means the agency must look closely at the impact of its proposed standards on net emissions of air pollutants and their associated public health effects, impacts on the automotive industry, impacts on the vehicle purchasers/consumers, energy security, and safety, and how the proposed approach would compare to other possible rulemakings. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

EPA's review of relevant factors in the current proposal is seriously deficient. The chief failure comes because the agency elides two distinct types of feasibility: the technological feasibility of electric vehicles as a part of the fleet and the technological feasibility of electric vehicles as the whole of the fleet. We do not dispute the former, but overwhelming evidence disproves the latter. First, there are no established supply chains capable of supplying the raw materials to manufacture the millions of vehicles needed—just over the next decade—to supply the projected market. Second, the infrastructure necessary to support these vehicles, particularly recharging infrastructure, is not and will not be available in the necessary timescales. The high density of chargers needed in major metropolitan areas and vast web of chargers needed to span the rural areas of the Country will require tremendous planning and investment. The long lead times associated with new renewable generation means that this added marginal electric load will be powered by natural gas and coal for the foreseeable future. And current prices, lack of infrastructure, and public opinion militate strongly against the conclusion that a ten-fold increase in the annual sales of electric vehicles will occur in the next eight years. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

Organization: Advanced Energy United

However, in order to fully realize the benefits of this new fuel source, we must consider innovative approaches that will effectively manage that electric load and mitigate potential grid impacts. In the draft regulatory impact assessment for the Phase 3 rule, the EPA rightly recognized that grid constraints will be a challenge, and the likely necessity of a variety of approaches to reduce the need or scale of upgrades.2 While some solutions to this challenge will require the engagement of state and federal policymakers, others are already being deployed by innovative companies across the advanced energy industry. [EPA-HQ-OAR-2022-0829-0695, p. 2]

2 Multi-Pollutant Emissions Standard for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles -Draft Regulatory Impact Analysis p 5-35 https://nepis.epa.gov/Exe/ZyPDF.cgi/P10175J2.PDF?Dockey=P10175J2.PDF

Building out a decarbonized electric grid with advanced energy technologies—and the infrastructure necessary to ensure its stability—will require the innovation and speed demonstrated by President Roosevelt's Arsenal of Democracy. In response to the need for tanks, weapons, and planes, American companies like Ford, GM, and Boeing ramped up manufacturing production and began making the technologies, equipment, and parts necessary to bolster Allied efforts. That is the kind of American innovation that we will need—and have begun to see—from leading automakers and new market entrants as they increase their share of EVs. For instance, Ford and Sunrun have teamed up to pair the energy storage capabilities of the all-electric F-150 Lightening with rooftop solar. In a similar vein, Rivian has indicated an interest in implementing bi-directional charging—vehicle-to-load—software into their vehicles which would alleviate grid constraints and improve resiliency. This technology turns an EV into a mobile battery. This could yield immense benefits to grid resiliency and provide helpful energy storage for commercial buildings and homes. [EPA-HQ-OAR-2022-0829-0695, p. 2]

In addition to hardware solutions to manage grid impacts from electric LDVs, software-based managed charging solutions (sometimes called automated load management or power control systems) serve a similar role to mitigate the need for electrical distribution system upgrades. [EPA-HQ-OAR-2022-0829-0695, p. 2]

II. Case Studies

Below are three brief case studies that show how these proven technologies have helped to alleviate grid constraints and benefit consumers. [EPA-HQ-OAR-2022-0829-0695, pp. 2-3]

Case Study 1:

Dedicated EVSE companies like FreeWire Technologies are mitigating stumbling blocks on the road to decarbonized transportation. Their battery-integrated charging technology "solves grid constraints by packaging charging infrastructure, grid infrastructure, and energy storage into a fully-integrated compact solution."3 These ultrafast chargers provide enhanced grid resiliency options during peak demand and can support critical facilities during outages and charge vehicles at 200kW in 15 minutes.4 [EPA-HQ-OAR-2022-0829-0695, pp. 2-3]

3 FreeWire Technologies. (27 April, 2022). FreeWire Technologies Announces $125 Million Series D Financing to Accelerate Deployment and Development of Next-Gen EV Charging Technology and Energy Management Services. https://freewiretech.com/freewire-technologies-announces-125-million-series-d-financing/

4 FreeWire Technologies. (2023). FAQ. https://freewiretech.com/faq/#:~:text=Visit%20the%20Boost%20Charger%20web,200%20miles%20in%20 15%20minutes.

Case Study 2:

Octopus Energy has employed a demand response program in the United Kingdom called Intelligent Octopus, which demonstrates the potential for managed charging to reduce grid pressures and the costs associated with overbuilding the distribution system. A customer simply sets their preferences in an app (specifying when they need the EV charged and the state of charge that is needed) and the platform will automatically charge the cars at times where there is abundant, low-cost energy, helping to balance out demand and supply on the grid while saving customers money. Intelligent Octopus enrollment has grown from 600 EVs since it was launched in January 2022 to over 45,000 EVs today, providing 250 MW in shiftable load resources. Intelligent Octopus was launched for EV drivers in Texas in February. [EPA-HQ-OAR-2022-0829-0695, p. 3]

Case Study 3:

Irish Post issued an RFP to electrify 100 parking sites across the country for its mail fleet of trucks, vans, and cars. Understanding that they were working with constrained grid conditions, Irish Post included load management capability as a requirement so as to avoid the cost and time delays of extensive local grid upgrades. [EPA-HQ-OAR-2022-0829-0695, p. 3]

A general contractor and The Mobility House (TMH) won the RFP and deployed 2800 22 kW AC chargers and 180 DC chargers ranging from 22-50 kW while avoiding an estimated 50 MW of utility upgrades across all sites. At a subset of 31 sites using exclusively 32 Amp chargers, TMH's load management technology enabled the team to safely install and operate EVSE nameplate capacity exceeding the main site panel capability by an average of 200-300%. This allowed an average of eight extra EVSEs per site to be installed without upgrading service, saving Irish Post time and money as they electrified their fleet while allowing all EVSEs access to their full nameplate capacity when needed and serving their mobility needs with no adjustments in driver behavior. [EPA-HQ-OAR-2022-0829-0695, p. 3]

Case Study 4:

Vehicle-to-grid (V2G) technology allows an electric vehicle (EV) to draw energy from the grid (typically during periods of low cost & low demand) and discharge energy back to the grid (during periods of high cost & high demand). V2G technology also helps reduce energy costs associated with owning and operating EV fleets. An increasing number of electric utilities, like National Grid in Massachusetts, support programs that pay electric fleets and other battery storage resources to discharge energy, turning them into revenue-generating assets without disrupting normal operations. In the summers of 2021 & 2022, Highland Electric Fleets piloted V2G technology in battery storage from electric school buses. 10+ MWh was discharged to the Massachusetts grid across 158 hours, generating $2,300. [EPA-HQ-OAR-2022-0829-0695, pp. 3-4]

Case Study 5:

The San Diego-based company Nuvve is a global leader in vehicle-to-grid (V2G) technology with deployments on five continents. In the US, Nuvve is focused on the school bus market. Electrified school bus fleets represent an excellent candidate for V2G given the large batteries and the long dwell times. School buses are often idle for months at a time during the summer when additional grid capacity is at a premium. The U.S. Environmental Protection Agency (EPA) acknowledges the potential of electrified school bus fleets to provide V2G services.5 [EPA-HQ-OAR-2022-0829-0695, p. 4]

5 See U.S. EPA, What if Electric School Buses Could be Used to Supply Power When Off Duty? Available at https://www.epa.gov/greenvehicles/what-if-electric-school-buses-could-be-used-supply-power-when-duty.

Nuvve is the only company, working collaboratively with San Diego Gas & Electric (SDG&E), to have successfully developed an electric school bus (ESB) V2G pilot program in California. Six 60 kW bidirectional chargers and six V2G capable Lion Electric school buses were deployed at Cajon Valley Union School District. Using Nuvve's GIVe software platform, these buses participated in 10 Emergency Load Reduction Program (ELRP) events from August 17th through September 9th through SDG&E.6 The host school district was paid $2/kWh for V2G exports helping to reduce the total cost of ownership of its ESB fleet. Nuvve has additional V2G deployments totaling over 1 MW under development in California. In addition, Nuvve has multiple projects under development in other states including Oregon, Utah, Nevada, Colorado, Texas, Illinois, Florida, and Rhode Island. [EPA-HQ-OAR-2022-0829-0695, p. 4]

6 See SDG&E and Cajon Valley Union School District Flip the Switch on Region's First Vehicle-to-Grid Project Featuring Local Electric School Buses Capable of Sending Power to the Grid available at https://www.businesswire.com/news/home/20220726006137/en/SDGE-and-Cajon-Valley-Union-School-District-Flip-the-Switch-on-Region%E2%80%99s-First-Vehicle-to-Grid-Project-Featuring-Local-Electric-School-Buses-Capable-of-Sending-Power-to-the-Grid.

III. Technology Impacts

Managed charging with both hardware-and software-based solutions is an essential strategy to reduce infrastructure costs for fleet charging depots. Depot charging is likely to account for nearly 90% of fleet operating needs, with vehicles on average having 14 hours of downtime per day.7 Managing these vehicles' charging load to avoid peak periods can substantially reduce the need to upgrade both the facility's infrastructure and the utility-side infrastructure, compared to an unmanaged charging scenario in which vehicles charge simultaneously during peak periods. A recent NREL study found that managed charging in the MHD sector can reduce distribution system investment costs by up to $1,090 per EV per year.8 [EPA-HQ-OAR-2022-0829-0695, pp. 4-5]

7 Perspectives on Charging Medium-and Heavy-Duty Electric Vehicles, NREL, December 2021. https://www.nrel.gov/docs/fy22osti/81656.pdf

8 Electric Vehicle Grid Integration, NREL. https://www.nrel.gov/transportation/project-ev-grid-integration.html

In 2021 testimony filed at the California Public Utilities Commission, Pacific Gas & Electric stated that utilizing these load management technologies could reduce the originally requested capacity by more than 50%, which resulted in cost savings ranging from $30,000 to $200,000 per project.9 [EPA-HQ-OAR-2022-0829-0695, pp. 4-5]

9 PGE testimony 2-9-210 https://docs.cpuc.ca.gov/PublishedDocs/SupDoc/A2110010/4240/417398449.pdf

A 2023 report from Synapse Energy Economics, leveraging data and tariffs from ConEd and National Grid, found that managed charging reduced site peak load by 15% and 5% respectively.10 This data reflects the more rigid charging needs and schedules of fleet vehicles, but is significant, nonetheless. The cost savings associated with managed charging are also likely to lead to faster economic return on investment for fleets in the process of electrification. [EPA-HQ-OAR-2022-0829-0695, p. 5]

10 MHDV Integration Costs Report, Synapse, April 2023. https://acrobat.adobe.com/link/track?uri=urn%3Aaaid%3Ascds%3AUS%3Ab0fd0780-9882-3a25-9ef2-f8c73bd80c92&viewer%21megaVerb=group-discover

The implementation of managed charging policies are a critical factor to speed overall adoption of light-duty electric vehicles in line with the EPA's rulemaking. As emissions standards steadily increase and EVs proliferate on our roads, it is likely that demand for electricity will rise beyond what managed charging can save. This new demand will call for added transmission capacity and resiliency measures, vehicle-grid integration, smart charging, and bidirectional charging/ V2G, and other innovative solutions. Without proactive planning and buildout of charging infrastructure, the U.S. is at risk of failing to meet its ambitious, and laudable, goals for transportation emissions reductions. A 2021 study by the Brattle Group estimated that investments in transmission would have to reach $25 billion in order to charge 20 million EVs.11 To fully unlock these investments, the U.S. will need to undertake permitting reform, to streamline transmission projects and free up interconnection queues. [EPA-HQ-OAR-2022-0829-0695, p. 5]

11 Sergici, S., Hagerty, M., & Long, L. (1 June, 2020). Electric Power Sector Investments of $75-125 Billion Needed to Support Projected 20 Million EVs by 2030, According to Brattle Economists. Brattle Group. https://www.brattle.com/insights-events/publications/electric-power-sector-investments-of-75-125-billion-needed-to-support-projected-20-million-evs-by-2030-according-to-brattle-economists/

Digital permitting processes could also alleviate bottlenecks in EVSE infrastructure. The Department of Energy’s SolarApp+ is a model program that has saved customers and contractor valuable time and money on solar installations by standardizing and streamlining permitting processes in localities across the U.S. Policymakers across the country should consider a similar approach to slash soft costs for the permitting of EV charging infrastructure. Investment alone cannot satisfy new demand. We must enable streamlined permitting processes if we are to meet the Biden Administration’s goal of building 500,000 new charging stations. [EPA-HQ-OAR-2022-0829-0695, p. 5]

Organization: Alliance for Automotive Innovation

Beyond BEV affordability, success of this regulation will be determined by factors outside of the vehicle; the U.S. is sorely behind in this effort (despite over the $150 billion of private sector investment thus far) and the NPRM does little to address these factors. Current charging and fueling infrastructure is inadequate (particularly residential charging), the grid resources are at least 5 to 10 years away (without even factoring in the additional demand for grid resources from the heavy-duty vehicle sector facing similar concerns in a concurrent EPA rulemaking6), and battery critical minerals (except lithium), which primarily determine the affordability and availability of EVs, are minimally addressed in the NPRM. [EPA-HQ-OAR-2022-0829-0701, pp. 4-5]

6 U.S. Environmental Protection Agency, Proposed Rule: Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3 (for Model Years 2027-2032), 88 Fed. Reg. 25,926 (Ap. 27, 2023). Hereinafter “EPA HD GHG NPRM).”

No requirements to support required EVs or the drivers that must buy them

The NPRM and all the requirements set forth to date focus solely on the sale of BEVs. They propose no requirements to ensure that infrastructure will be available at homes, businesses, public event venues, highway corridors, transportation hubs, or other public locations. They contain no requirements to provide hydrogen or hydrogen fueling stations, or for utilities to quickly bring reasonably priced high-power charging (5-20 megawats (MW)) to highway service plazas, fleet locations, city centers, or transportation hubs. They do not address the need for battery critical minerals to power everything from light-, medium-, and heavy-duty vehicles, energy storage systems (ESS), lawn and garden equipment, laptops, cell phones, forklitis, and airport services—not just in the United States, but around the world. [EPA-HQ-OAR-2022-0829-0701, p. 5]

To support the vehicle requirements proposed, all these changes are necessary in under 10 years. For perspective, 10 years is the time required to obtain the necessary permits for a mine in the United States. Once permitted, another ten years could elapse before the mine produces at capacity. Ten years is also close to the time required to bring 20 MWs of power to a single location in the United States. Consequently, to the extent we need critical minerals and high-power charging, we must start today. Yet, there is no plan to do so. There is no roadmap to developing these essential pieces necessary for the transformation. Nor is there a commitment from EPA for ongoing monitoring of these factors as the EV market develops over the duration of EPA's proposed standards. [EPA-HQ-OAR-2022-0829-0701, p. 5]

Automakers are committed to electrification. The industry publicly agreed in August 2021 that BEVs, PHEVs, and FCEVs could constitute 40 to 50% of new vehicle sales by 2030 with the right combination of supportive measures. Some, but not all, of those supportive measures have started, but they are nowhere near complete and certainly not suffcient to support the even higher requirements in the proposed regulations that substantially leapfrog that target. [EPA-HQ-OAR-2022-0829-0701, p. 5]

b) Electricity Price Impacts on Costs of Battery Production

Electricity prices have an indirect effect on the cost of producing EVs because the supply chain of an EV is much more energy-intensive than the supply chain for an ICE vehicle. At battery manufacturing facilities, for example, large furnaces are required to evaporate the solvents from the coated electrodes; since battery cells are sensitive to moisture, cell assembly must occur in a dry room, which incurs high electricity costs. [EPA-HQ-OAR-2022-0829-0701, pp. 60-61]

State and national policies are shifting electricity generation from fossil fuels and nuclear power to renewables, especially wind and solar. At low levels of renewables, the effect on electricity prices may be minimal. Moreover, the cost disadvantages of renewables are declining over time, but the renewables transition may increase electricity prices at higher levels of renewables penetration and will likely raise them further when investments are made (e.g., in grid-scale energy storage solutions) to address the intermittent nature of wind and solar. [EPA-HQ-OAR-2022-0829-0701, pp. 60-61]

It is difficult to estimate how much electricity prices will rise in a precise time frame (e.g., 2024-2026) because they are often determined in utility rate-setting processes in each of the 50 states, and the EIA forecasts of future electricity prices do not account for all the policy changes that are underway or will soon be adopted to promote or compel increased use of renewables. [EPA-HQ-OAR-2022-0829-0701, pp. 60-61]

One way for the agencies to bound the potential magnitude of rising electricity prices is to undertake a scenario analysis where all of the U.S. – residences and businesses – face the higher electricity prices now experienced by Germany or the State of California, both jurisdictions that have made determined efforts to boost renewables and phase out coal and nuclear power. Germany has the highest household electricity prices in Europe, about $0.30 per kWh. In May 2021, the average price of residential electricity in California was $0.21 per kWh, about 7%

higher than the price in May 2020. In the U.S. as a whole, the average residential electricity price is about $0.13-0.14 per kWh. [EPA-HQ-OAR-2022-0829-0701, pp. 60-61]

The electricity prices paid by businesses need to be analyzed separately, as they tend to be higher than the residential rates (in part due to demand charges). The business rate for electricity is appropriate to use when computing the energy costs in the supply chain of battery production. [EPA-HQ-OAR-2022-0829-0701, pp. 60-61]

A detailed analysis of global supply chains is required. In the case of lithium, for example, agencies need to consider the price of electricity where the lithium is mined, where the lithium is processed, where the lithium is used in cathode production, where the battery cells are made, and where battery packs are assembled. Electricity prices vary significantly around the world, However, EPA projects 100% of battery cells will be produced in the U.S. by 2027 and growing critical mineral production. A detailed analysis of global supply chains is required. In the case of lithium, for example, agencies need to consider the price of electricity where the lithium is mined, where the lithium is processed, where the lithium is used in cathode production, where the battery cells are made, and where battery packs are assembled. As more of the lithium-ion battery supply chain develops in the U.S., the analysis of U.S. electricity prices on battery costs will be more straightforward. [EPA-HQ-OAR-2022-0829-0701, pp. 60-61]

Renters, low-income, and MFD residents could be forced to charge at public chargers, which is far more expensive, less reliable, and vastly less convenient. This is unreasonable, and EPA and its federal counterparts should ensure this population has the same access to L2 home charging as affuent single-family homeowners. [EPA-HQ-OAR-2022-0829-0701, p. 79]

It is also important to ensure low-to moderate-income (LMI) and multi-family dwelling (MFD) residents have access to the low-cost, convenient, and reliable level 2 (L2) home charging that more affuent single-family homeowners enjoy. MFD residents, however, often face the greatest, most costly, and burdensome obstacles to installing residential EV charging. For MFD residents, the additional costs to upgrade the electrical panel, install conduit between the electrical panel and their parking space, and the logistical challenges of securing building owner approval, coordinating the billing with the building owner, and persuading an owner to make a long-term investment on a rental property, make it challenging to have convenient residential charging in an MFD. [EPA-HQ-OAR-2022-0829-0701, pp. 80-82]

2. Statutory Authority

Auto Innovators shares EPA’s goal of addressing climate change by achieving a net-zero carbon transportation future, as part of an ambitious, comprehensive, and national strategy. The Proposed Rule, however, contemplates a rapid and transformative nationwide shift to electrification that may be well beyond what the industry or market can bear now or in the foreseeable future. Given the significant policy and economic consequences that would flow from this restructuring of the nation’s vehicle market, and the breadth and unprecedented nature of EPA’s proposed action, clear congressional authorization is required for the Proposed Rule. EPA lacks this clear authorization. [EPA-HQ-OAR-2022-0829-0701, pp. 89-92]

The Proposed Rule seeks to use Clean Air Act section 202 rulemaking to force an extraordinary transformation of the nation’s vehicle fleet away from ICE-based vehicles to BEVs, and it is not at all clear that the level of consumer demand and infrastructure that exists now and is expected in the future can support the expedited, aggressive timeline in the Proposed Rule. The Proposed Rule does not include an explicit electrification target, and EPA states that “a compliant fleet under the proposed standards will include a diverse range of technologies.”152 But in practice, the stringency of the proposed standards is such that automakers will have no choice but to convert to BEV fleets on a massive scale. This is the result not only of the Proposed Rule’s GHG emissions standards, but also its criteria pollutant standards and its tightening of credit programs and other flexibilities. [EPA-HQ-OAR-2022-0829-0701, pp. 89-92]

152 NPRM at 29187.

As EPA notes, BEVs accounted for 5.8% of the new U.S. light-duty passenger vehicle market in 2022.153 Moreover, EPA’s MY 2023-2026 GHG emissions standards that were finalized at the end of 2021 projected only a 17% light-duty penetration rate for both BEVs and PHEVs by MY 2026.154 Despite this low rate of consumer acceptance, the Proposed Rule projects a light-duty BEV penetration rate of 67% by MY 2032, up from 36% in MY 2027.155 Importantly, in the absence of these and other strict regulatory programs (such as California’s ZEV mandate), EPA projects a significantly lower MY 2032 BEV penetration rate of only 39%.156 It is unclear from EPA’s analysis how the regulations alone justify a 28 percentage point increase in BEV market between having regulations versus not. This is particularly concerning given that EPA’s no-action analysis presumably includes the same level of existing supportive mechanisms such as the IRA and IIJA, assumptions for infrastructure development, and other market-enabling features. [EPA-HQ-OAR-2022-0829-0701, pp. 89-92]

153 Id. at 29189

154 See Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards, 86 Fed. Reg. 74434, 74485, Table 33 (Dec. 30, 2021).

155 NPRM at 29329, Table 80.

156 Id. at 29329, Table 81.

In other words, a staggering increase in the implementation and adoption of BEV technology underpins the Proposed Rule and is the central means by which the rule effectuates its contemplated emissions reductions. But this shift to electrification is not a simple matter of swapping one technology for another. The mass adoption of BEVs on the scale required for compliance with the Proposed Rule’s standards requires a much broader transformation in the way vehicles are manufactured, purchased, fueled, serviced, and disposed of. Indeed, the Proposed Rule would reorder much of the U.S. automobile industry—which supports roughly 10.3 million American jobs and $558 billion in annual car sales, and about 6% of the U.S.’s Gross Domestic Product (GDP).157 Consumers must be willing to purchase BEVs at mass scale; the power sector must be able to generate and deliver adequate electricity158—which itself will contribute to emissions—while maintaining grid reliability and otherwise meeting consumer and industrial demand; adequate charging infrastructure must be available; batteries and other components must be manufactured at an increasing rate, critical minerals sourced, and supply chains developed. These needs must be met not only for light-duty vehicles, but also for medium-and heavy-duty vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 89-92]

157 See Economic Insights, Alliance for Automotive Innovation, https://www.autosinnovate.org/resources/insights.

158 In addition to increasing electricity capacity, utilities are also facing a transition in technology types and more renewable sources, as proposed under the "Greenhouse Gas Standards and Guidelines for Fossil Fuel-Fired Power Plants" [88 FR 33240, May 23, 2023].

As expressed throughout this comment, we have serious concerns that the market will not be able to bear the requirements of the Proposed Rule and that those requirements will not be feasible given these considerations. Compliance will impose significant costs, and require extraordinary effort, on the part of regulated parties—costs which will be passed along to consumers. Setting such stringent standards has the potential to create a significant market disruption, with consequences not only for the automobile industry but for the entire U.S. economy. [EPA-HQ-OAR-2022-0829-0701, pp. 89-92]

In other words, the Proposed Rule is enormously consequential for the automobile industry, and for the economy and consumers as a whole. The Proposed Rule's provisions insert EPA into crucial policy tradeoffs and debates, such as concerns about the extraction and supply of critical minerals overseas, or the need to maintain a reliable, efficient electric grid.159 These considerations range far afield from the traditional ambit of section 202 rulemaking, delving into areas that are the subject of other regulatory schemes, or within the unique purview and authority of other agencies and other branches and levels of government. In short, the dramatic shift toward electrification required by the Proposed Rule implicates issues of tremendous political, economic, and social significance. [EPA-HQ-OAR-2022-0829-0701, pp. 89-92]

159 See, e.g., NPRM at 29311-24.

Nor is such a transformative rule, with such wide-ranging implications, a typical feature of section 202 rulemaking. We acknowledge that some past EPA section 202 rules, most notably the MY 2023-2026 rule, have contemplated greater deployment of EVs as one of many options for complying with emissions standards. The Proposed Rule, however, is different not merely in degree but in kind, seeking to impose what is, at bottom, a mandate toward nationwide electrification. Such a proposal amounts to an unprecedented assertion of power on the part of EPA. [EPA-HQ-OAR-2022-0829-0701, pp. 89-92]

"[A]n enormous and transformative expansion in EPA's regulatory authority" such as this necessitates "clear congressional authorization," as Congress is expected to "speak clearly if it wishes to assign to an agency decision of vast 'economic and political significance.'"160 But section 202 does not confer such clear authority. Section 202 authorizes EPA to promulgate "standards applicable to the emission of any air pollutant" from vehicles; it does not empower EPA to force a historic shift in the makeup of the nation's entire vehicle fleet. In the absence of plain statutory authorization, such a decision, and the tradeoffs and consequences it entails, properly belongs to Congress. [EPA-HQ-OAR-2022-0829-0701, pp. 89-92]

160 Utility Air Regulatory Group v. E.P.A., 573 U.S. 302, 324 (2014) (quoting FDA v. Brown & Williamson Tobacco Corp., 529 U.S. 120, 160 (2000)).

The Proposed Rule frequently cites to the IIJA, also known as the "Bipartisan Infrastructure Law,"161 and the Inflation Reduction Act.162 To the extent EPA purports to rely on either statute as providing a legal basis for the Proposed Rule,163 it should not do so. No provision of the IIJA or the IRA expands or modifies EPA's regulatory authority under section 202 or the Clean Air Act more broadly. Nor can these laws be considered to have implicitly altered EPA's authority. After all, "implied amendments require 'clear and manifest' evidence of congressional intent,"164 and "neither courts nor federal agencies can rewrite a statute's plain text to correspond to its supposed purposes."165 Those conditions are not satisfied here. [EPA-HQ-OAR-2022-0829-0701, pp. 89-92]

164 Sackett v. E.P.A., 598 U.S , 2023 WL 3632751, at *13 (U.S. May 25, 2023) (internal quotation omitted).

165 Landstar Exp. America, Inc. v. Fed. Maritime Comm'n, 569 F.3d 493, 498 (D.C. Cir. 2009).

We reaffirm that we are fundamentally supportive of EPA's goals of reducing GHG emissions and transitioning to a net-zero carbon transportation future. Section 202 standards have a place in this effort, as we have previously expressed. We remain concerned, however, that the extraordinary and unprecedented nature of the Proposed Rule places it outside the bounds of EPA's statutory authority. [EPA-HQ-OAR-2022-0829-0701, pp. 89-92]

3.NMOG+NOx Cold FTP Fleet Average

EPA proposes to set a cold FTP NMOG+NOx fleet average requirement of 300 mg/mile, excluding ZEVs.258 EPA requests comment on whether a 400 mg/mile vehicle cap should be used instead of a fleet average.259 [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

258 NPRM at 29262.

259 NPRM at 29262.

Auto Innovators prefers a fleet average requirement, but requests a value of 300mg/mi for LDV+LDT1 and 400mg/mi for LDT2+HLTD+MDPV for the following reasons: [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

At -7 °C, emission reduction right after engine start-up and during catalyst warm-up is the key factor. Large displacement engines (V6, V8, etc.) inevitably have substantially higher emissions at engine startup before the catalyst is warmed up. For downsized turbocharged engines, the amount of heat supplied to the catalyst decreases due to the relationship between the recovery of the exhaust energy by the turbocharger and the heat capacity of the turbocharger itself; thus, the warm-up time tends to be longer than that of an engine without a turbocharger. During this longer warm-up time when the catalyst is in a semi-active state, the heavier vehicle with a turbocharger under high running load conditions has much higher emissions than other vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

According to the DRIA, EPA developed the proposal based on the test results of three models. The results of these three models certainly meet 300 mg/mi. However, due to differences in exhaust system layout (i.e., front catalyst distance from the engine) and engine control from these models, there are some models that cannot achieve both emission reduction before catalyst warm-up and early catalyst warm-up at a high level under -7 °C condition. There are also vehicles that are heavier than the vehicles EPA tested. [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

Developing technology to adapt these vehicles to 300 mg/mi would require diverting substantial resources from electrification [EPA-HQ-OAR-2022-0829-0701, pp. 147-148] :

1.For emission systems development and evaluation, update and/or increase of chassis dynamometer system testing to make it possible to reproduce cold temperature condition is necessary. [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

2.Development of pistons and injectors for better combustion and designing arrangement of emission purification devices are necessary. When changing the catalyst system (increase in the amount of precious metals, increase in the number of cells), increase in costs occurs. [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

Regarding the 300 mg/mile fleet average, EPA proposes that the family emission limit (FEL) be set to a resolution of 0.1 g/mile (100 mg/mile).260 An FEL set to only a single decimal place (i.e., 0.x g/mile) provides very little flexibility among different vehicles. We recommend that EPA allow an FEL resolution to three decimal places (i.e., 0.xxx g/mile). [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

260 NPRM at 29436.

We also note that although EPA describes the 300 mg/mile fleet average as excluding ZEVs in the preamble,261 the proposed 40 C.F.R. § 86.1811-27(c)(3)(i) regulatory text does not reflect that exclusion.262 Auto Innovators agrees with the exclusion and recommends updating the regulatory text accordingly. [EPA-HQ-OAR-2022-0829-0701, pp. 147-148]

261 NPRM at 29262.

262 NPRM at 29420.

Below is PM data from another round robin program from 2022 run by the same certification laboratories and EPA (Figure 49). The 2-standard deviation limit around the EPA mean is 0.56 mg/mile. The all-laboratory average 2-standard deviation is 0.48 mg/mile. The variability from laboratory to laboratory at a 95% confidence level is almost as high as the proposed FTP PM standard of 0.5 mg/mile. The offset between the initial baseline tests' average and the confirmatory tests' average is more 0.37 mg/mile, or more than 25% change within the same laboratory. [EPA-HQ-OAR-2022-0829-0701, pp. 160-164]

SEE ORIGINAL COMMENT FOR Figure 49: FTP PM test results from a 2022 automaker/EPA interlaboratory correlation program. [EPA-HQ-OAR-2022-0829-0701, pp. 160-164]

Results from another recent interlaboratory round robin program from 2022 are shown in Figure 50 for a vehicle with a FTP PM emission level below 1 mg/mile. The lab to lab offset is evident here, which cannot be explained. The average 2-standard deviation from all labs is 0.065 mg/mile, or about 13% of the 0.5 mg/mile standard. The offset between Laboratory 2 and Laboratory 1 confirmatory testing at the end is is 0.27 mg/mile, or 54% of a 0.5 mg/mile standard. The offset between the initial baseline tests' average and the confirmatory tests' average is about a 21% change within the same laboratory. [EPA-HQ-OAR-2022-0829-0701, pp. 160-164]

E. Comments on Estimated Social benefits of the CO2 Standards

In this section, Auto Innovators comments on the major categories of estimated social benefits for the CO2 performance standards for model years 2027-2032. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

1. Local/Regional Air Quality benefits from Control of Criteria Air Pollutants

The DRIA estimates that the present value of the quantified health benefits from criteria air pollution control range from $64 billion to $290 billion, depending on the discount rate and the dose-response study used for PM2.5 and mortality. This range is so large that it overlaps the lower agency estimate of the Proposed Rule's climate benefits ($83 billion to $1 trillion). Auto Innovators believes that the agency's estimates are not consistent with the findings in the peer-reviewed scientific literature and are exaggerated. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

The final regulatory impact analysis should acknowledge that the peer-reviewed scientific literature does not generally support the agency's claim that a shift from ICEs to BEVs in the light-duty sector will reduce criteria air pollution across the country. In 2021, Burnham et al. of Argonne National Laboratory (DOE) presented a regional U.S. lifecycle analysis of the impact of BEVs through 2050, accounting for upstream emissions of criteria air pollutants at the powerplant. The abstract of their paper concludes as follows: [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

We generated state-level emission factors using a projection from 2020 to 2050 for three light-duty vehicle types. We found that BEVs currently provide GHG benefits in nearly every state, with the median state's benefit being between approximately 50% to 60% lower than gasoline counterparts. However, gasoline vehicles currently have lower total NOx, urban NOx, total PM2.5, and urban PM2.5 in 33%; 15%; 70%; and 10% of states, respectively. BEV emissions will decrease in 2050 due to a cleaner grid, but the relative benefits when compared to gasoline vehicles do not change significantly, as gasoline vehicles are also improving over this time. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

The results of this study concerning total PM2.5 are especially concerning because the agency's quantified criteria-pollutant benefits in this rulemaking are dominated by an alleged advantage of BEVs with respect to PM2.5 control. Moreover, the lifecycle analysis by Burnham et al. (2021) is published in the peer-reviewed literature, while the agency's lifecycle inputs and analysis have not been peer reviewed by qualified experts. For the final rule, Auto Innovators believes it is unwise for the agency to rely on its lifecycle analysis of criteria air pollutant control as a primary rationale for the final rule. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

Insofar as criteria air pollution control is considered a primary rationale for a rule that regulates CO2 emissions, we recommend that the agency go beyond an analysis of average ICE emissions and consider "best-in-class" vehicle emissions in the baseline. For example, in a peer-reviewed contribution, Winker et al. (2018) compared HEVs and BEVs in terms of criteria air pollution emissions. When the upstream emissions from BEVs are included, they find that BEV emissions are 0.06 grams per mile (NOx) while average HEV emissions are 0.004 grams per mile (NOx and HC). The results of Winkler et al. are consistent with an earlier paper by Michalek et al. (2011), which found that HEVs and PHEVs, with small battery packs, are environmentally and economically superior to BEVs. Thus, HEVs may be a superior technological option for criteria air pollution control than BEVs, at least in some regions of the country and until the upstream and manufacturing emissions of BEVs are controlled. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

In any event, any net reductions in PM2.5 emissions (primary or PM2.5 precursors) accomplished by the revised CO2 standards will not provide public health benefits that are additive to the emissions reductions accomplished by EPA's other mobile-source and stationary-source programs for criteria air pollutants. The public health benefits are not additive, as we explain below, because of the way Congress designed the Clean Air Act, structured state implementation plans, and the way EPA defined emissions limits and nonattainment on a community-by-community basis. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

Specifically, reductions in vehicle emissions do not provide additive benefits to public health because the structure of the Clean Air Act allows the states to include national changes in mobile source emissions in their state emissions inventories and implementation plans for attainment of the National Ambient Air Quality Standards. In nonattainment areas and areas close to nonattainment, states and localities are disinclined to impose any more limits on stationary source emissions than is necessary to meet EPA's air-quality standards. If state and local limits are unduly strict, new factories may be built in other states and localities where the state implementation plans are not as strict on new stationary sources. (In attainment areas, where PM2.5 health benefits might also be considered, there is the complication of the Prevention of significant Deterioration (PSD) doctrine that needs to be evaluated). Thus, the practical impact of diminished mobile source emissions, at the margin, is somewhat less pressure on stationary sources to meet the requirements described in state implementation plans. Thus, there are benefits from further reductions in mobile source emissions under the Proposed Rule, but they are likely to be realized in reduced compliance costs for stationary sources rather than as public health benefits from reduced overall exposures to PM2.5. The magnitude of the compliance cost savings is likely to be a small fraction of the estimated public health benefits that the agency has claimed, given EPA estimates that the benefits of PM control vastly exceed costs in the stationary source arena. At a minimum, Auto Innovators suggests presentation of two alternative approaches for calculating the benefits of PM2.5 control: one where the benefits are expressed as compliance-cost savings for stationary sources and one – as developed in the DRIA – where the benefits of PM2.5 control are expressed as public health gains. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

Auto Innovators made a similar public comment on the DRIA supporting the 2023-2026 rules. In the final rule, Auto Innovators' comment was ignored in the agency's "Response to Comment" document. (This was unusual, as many of the other Auto Innovators comments were handled very carefully in the Response to Comment document). [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

In this rulemaking alone, new criteria pollutant controls are expected to reduce direct PM2.5 emissions from gasoline vehicles by roughly 90%, so those same PM2.5 control benefits should not also be counted as benefits of the CO2 standards and BEVs. Auto Innovators suggests the EPA focus on the potential benefits of a successful transformation to electric vehicles rather than incremental benefits of adding additional PM control beyond the California ACC II requirements. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

Second, EPA is correct that, once BEVs are produced and sold in 2027-2032, they will be recharged for up to 30 years as they are used by motorists, and the grid may become cleaner over that time frame. However, Auto Innovators is concerned that the analytic baseline in the DRIA takes a highly optimistic stance regarding how fast the grid will become clean over the next several decades. Obviously, if the grid becomes less carbon intensive due to more renewables, BEVs will be environmentally cleaner, but the agency should not engage in wishful thinking. The agency assumes, without support from a peer-reviewed analysis, that the Inflation Reduction Act will reduce CO2 emissions from the electricity sector by 70% over the lifetimes of the affected vehicles. Since the average lifetime of an electric powerplant is roughly twice as long (30 vs 15 years) as a passenger vehicle, it seems highly unlikely that the electrical grid will turn over so fast that it will become dramatically cleaner during the lifetimes of model year 2027-2032 vehicles. Nor is there a good evidence-based foundation for the claim that the Inflation Reduction Act, which provides only subsidies for clean electricity, will make the electricity sector dramatically cleaner in the next decade or two. The big need is for large new transmission lines to bring renewable energy to markets where it can be used. What is holding back those transmission lines and renewables is not capital, but cumbersome permitting processes. Indeed, several recent studies suggest that the clean-electricity subsidies in the IRA, without meaningful permitting reform, will have minimal impact on the carbon-intensity of the grid for the foreseeable future (e.g., Sud and Patnaik, 2022; Sud, Patnaik, Glicksman, 2023; Rosetti, 2022; 2023). The optimistic studies which find that the IRA will make the grid dramatically cleaner simply assume that renewable energy resources, and the needed transmissions lines, will obtain permits in a timely manner. The recent debt-limit deal in Congress did include some limited permitting reform, but it did not address the transmission-line reforms that are crucial to a rapid expansion of renewable sources of electricity. [EPA-HQ-OAR-2022-0829-0701, pp. 289-290]

4. Philip Rossetti. Written Testimony for the Hearing on "Tax Incentives in the Inflation Reduction Act: Jobs and Investment in Energy Communities." Committee on Finance. United States Senate. Washington, DC. May 18, 2023. [EPA-HQ-OAR-2022-0829-0701, pp. 289-290]

The economics of renewables versus natural gas are also not as solid as the agency suggests.

The agency is correct that the prices of wind and solar continue to decline, but the agency does not mention that natural gas prices have risen significantly due to the Russian invasion of Ukraine and Europe's campaign to reduce its dependence on Russian gas. If the conflict ends in the next 5-10 years, natural gas prices in the U.S. could return to pre-invasion levels, which would complicate the accelerated deployment of renewables that the agency is forecasting. The agency's IPM modeling ignores the possibility of a sustained decline in natural gas prices. Moreover, a dramatic expansion in wind and solar can occur only with breakthroughs in the economics of grid-scale energy storage technologies. Moreover, the only plausible pathway for rapid expansion of renewable energy sources is to couple them with new energy storage technologies that make use of lithium ion batteries. (Wind and solar are not reliable sources of electricity without energy storage). The agency makes a speculative claim that grid-scale storage could be accomplished without lithium-ion batteries, but the agency provides no evidence that those storage technologies are commercially feasible and cost effective. If the agency is serious about this optimistic claim, they should provide a modeling forecast of grid-scale storage and expose it to independent peer review. Relatedly, Auto Innovators is concerned that the agency's analysis of the adequacy of supplies of raw materials for BEVs does not assume a rapid expansion of grid-scale energy storage between now and 2035. It may not be feasible to expand BEVs rapidly if scarce lithium ion batteries are used to support energy storage in the utility sector in the pre-2035 time frame. The agency's modeling of battery prices needs to be modified if there is a rapid increase in demand from U.S. utilities for lithium ion batteries. [EPA-HQ-OAR-2022-0829-0701, pp. 290-291]

Third, as mentioned earlier, the EV deployment induced by the EPA rule will occur predominantly in non-ZEV states while the EPA rule will have little incremental effect on EV deployment in the ZEV states (which account for 30-40% of the new vehicle population). The ICCT study that EPA cites reports that, in 2019, the California grid produced only 225 g/kWh CO2 while the U.S. average grid (even accounting for a gradually cleaner grid from 2021 to 2038) produces 357 g/kWh. Thus, the grids in the non-ZEV states are associated with much larger emissions than the grids in the ZEV states. Funke et al. (2023, p. 43 and Figure B3, Appendix B) make the same point with information on the grids in all ZEV states (not just California). To avoid exaggerating the climate benefits of the rule, the agency should assume that most of the BEVs deployed due to the role will be in non-ZEV states that, today, have more carbon-intensive electricity sectors. [EPA-HQ-OAR-2022-0829-0701, pp. 291-292]

Organization: Alliance for Vehicle Efficiency (AVE)

Many of the estimates for future compliance in the Proposal assume that within four years, all the following requirements will be in place: that significant quantities of critical minerals and materials will be available, that the nation's electrical grid will be reliable (and cleaner), that new supply chains will be established, and that all the necessary technology and components needed for zero-emission vehicles (ZEVs) will be mass produced. [EPA-HQ-OAR-2022-0829-0631, pp. 2-4]

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

Electricity Grids Will Need Substantial Upgrades Before They Can Support Widespread Electrification

Even if adequate charging stations could be established in the numbers and at the locations needed across the United States, providing those stations with the massive amounts of electricity required would pose another likely insuperable obstacle on the proposed rule's timeline. [EPA-HQ-OAR-2022-0829-0683, pp. 47-48]

Compliance with EPA's rule would require chargers to power more than two-thirds of the Nation's light-duty vehicles and nearly one-half of the Na-tion's medium-duty vehicles. Powering those numbers of light-and medium-duty vehicles would require an exponential increases in electricity-generation capacity. One study found that, if half of new passenger cars and light trucks in 2030 were "zero-emission vehicles," the "annual demand for electricity to charge them would surge from 11 billion kilowatt-hours (kWh) now to 230 bil-lion kWh in 2030." Kampshoff, Building Electric-Vehicle Charging Infrastructure. [EPA-HQ-OAR-2022-0829-0683, pp. 47-48]

Meeting that more than 20-fold increase in demand for electricity to charge electric vehicles in such a short period would seriously strain the Nation's gen-eration capabilities—particularly during peak-charging periods, when demand could reach extraordinary levels. For example, under stringent state standards like those in New York and Massachusetts, more than a quarter of highway stations could require 5 megawatts to meet peak demand (the same capacity needed for an outdoor professional sports stadium) by 2030, and some could require 40 megawatts (the same capacity needed for a major industrial site) by 2045. See Gideon Katsh et al., Electric Highways: Accelerating and Optimizing Fast-Charging Deployment for Carbon Free Transportation, Nat'l Grid, at 2 ("Electric Highways") (2022). Utilities would likely struggle to address such surging de-mands. See Kampshoff, Building Electric-Vehicle Charging Infrastructure at 15 (not-ing that few utilities "can deliver large amounts of electricity to many EVs at high rates at the same time"). One report shows that, in the City of Palo Alto— an area with high rates of electric-vehicle adoption—"[a] cluster of uncoordi-nated [Level 2] charging could create an excessive peak load that would over-load or blow out a transformer." Robert N. Charette, Can Power Grids Cope with Millions of EVs?, IEEE Spectrum (Nov. 28, 2022) ("Can Power Grids Cope"), https://tinyurl.com/3ybx8st7. The Director of the Center for Distributed En-ergy at Georgia Tech similarly asserts that, in residential areas, multiple Level 2 chargers on one distribution transformer can reduce its life from an expected 30 to 40 years to only 3. See id. And Xcel Energy, an electric utility, told the Minneapolis Star Tribute "that four or five families buying EVs noticeably af-fects the transformer load in a neighborhood, with a family buying an EV 'add-ing another half of their house.'" Id. [EPA-HQ-OAR-2022-0829-0683, pp. 47-48]

The proposed rule thus would require not only a massive expansion of charging points, but also significant upgrades of electricity-grid infrastructure and distribution technologies. See Kampshoff, Building Electric-Vehicle Charging Infrastructure at 15. Those upgrades would be costly. One study found that, even if only 15 percent of light-duty vehicles were electric by 2030 and used moder-ately optimized charging patterns, a typical utility would "need to make cumu-lative transmission and distribution investments of $2.8 billion through 2030, for an estimated grid capacity upgrade cost of $2,600 per EV." Anshuman Sa-hoo et al., The Costs of Revving Up the Grid for Electric Vehicles, Bos. Consulting Grp. (Dec. 20, 2019) ("Cost of Revving Up"), https://tinyurl.com/2vrye6ua. Ac-cording to the authors, that is a "meaningful sum" given that a typical utility "tends to spend about $1 billion annually on transmission and distribution cap-ital expenditures." Id. EPA's proposal—which anticipates that 67 percent of light-duty and 46 percent of medium-duty vehicles will be electric by 2032— would necessarily entail even more substantial costs. Another study reports that "for a single public direct-current fast-charging (DCFC) station consisting of four DC 150-kW chargers, the cost of upgrading the grid and the site could be more than $150,000." Kampshoff, Building Electric-Vehicle Charging Infrastructure at 15. And recent reports note that "[s]upplies for distribution transformers are low," causing prices to "skyrocket[]" from a range of $3,000-$4,000 to $20,000 each. Charette, Can Power Grids Cope. [EPA-HQ-OAR-2022-0829-0683, pp. 48-49]

Some necessary upgrades will also take a substantial amount of time. For example, in places with highway charging, a single fast-charging station can quickly exceed the peak-load capacity of a typical feeder-circuit transformer, which in turn means establishing a transmission interconnection. Katsh, Electric Highways at 6. That project can take as long as eight years to complete—if it can be done at all. See id. at 4, 34 ("It may not be feasible to extend the trans-mission network to every site, particularly in locations where there would be impacts to local residents and the environment."). And Palo Alto, which is considering investing $150 million toward modernizing its distribution system to support electric-vehicle charging, states that it will "take two to three years of planning, as well as another three to four years or more to perform all the necessary work"—and perhaps longer if the utility cannot "get the engineering and management staff, which continues to be in short supply there and at other utilities across the country." Charette, Can Power Grids Cope. [EPA-HQ-OAR-2022-0829-0683, pp. 48-49]

EPA asserts that other measures could be taken to mitigate the problems associated with peak charging demands, such as: scheduling vehicles to charge at off-peak hours; developing new electric utility tariffs; using on-site battery storage; and implementing vehicle-to-grid technology (which allows electricity to be drawn from vehicles that are plugged in) and other vehicle-grid integration systems (which allow utilities to manage vehicle charging time). See 88 Fed. Reg. at 29,311–12; Draft RIA at 5-37–39. Those mitigating measures, however, may not be effective for a variety of reasons. For example, off-peak charging will not fully solve the peak-load problem because transformers are designed to be cooled at night; adding even a few electric-vehicles using Level 2 chargers during those hours could cause transformers to run hot when they are supposed to be cooling down. Charette, Can Power Grids Cope. Moreover, spreading peak charging loads will itself require investment in "better transformers and smart metering systems," and utilities will need to obtain "regulatory permission to change electricity-rate structures to encourage off-peak charging." Id. In addi-tion, before vehicle-to-grid technology can be implemented, “[n]umerous issues need to be addressed, such as the updating of millions of household electrical panels and smart meters,” creating “agreed-upon national technical standards for the information exchange needed between EVs and local utilities,” devel-oping “[vehicle-to-grid] regulatory policies” and “residential and commercial business models, including fair compensation for utilizing an EV’s stored en-ergy.” Id. As a result, one energy expert explained that “vehicle-to-grid is not really a thing” today, and it will not become a viable option “for quite some time” until the industry “solve[s] a lot of problems at various utility commis-sions, state by state, rate by rate.” Id. [EPA-HQ-OAR-2022-0829-0683, pp. 49-51]

EPA does not address these problems or meaningfully assess the obstacles that utilities and station operators would face in the wake of its proposed rule. Instead, although observing that grid upgrades and mitigation strategies will be necessary, the agency ultimately concludes that there is too much “uncertainty” with “future distribution upgrade needs” and the “uptake” of mitigation tech-nologies to “model them directly as part of [its] infrastructure cost analysis.” 88 Fed. Reg. at 29,311. Elsewhere, the agency noted that “there is little experience to assess the impacts of significant PEV use on U.S. electric grid reliability and resiliency” and asserted that it will be the responsibility of electric utilities and transmission system operators to plan for the increase in electric-vehicle charg-ing—and how that increase will intersect with other factors affecting the grid, such as extreme weather events and the greater use of variable supply technol-ogies. Draft RIA at 11-14. Once again, EPA’s regulate-first, confront-practical-impediments-later approach is backwards and exceedingly problematic in this context. As EPA itself notes, “[a] reliable and resilient electricity sector is cru-cial for the U.S.’s national security” and supports “many other types of critical infrastructure,” including “water systems, oil, natural gas, communications, in-formation technology, and financial services.” Id. at 11-13–11-14. It is irrational to press forward without robust analysis of the changes that are likely to be necessary; if EPA concludes that reliable analysis is impossible, it should stay its hand or pursue a different approach. At a minimum, the acknowledged un-certainty about the potentially massive burdens that grid improvements might necessitate provides further doubt on the proposed rule’s feasibility and more reason for caution. [EPA-HQ-OAR-2022-0829-0683, pp. 49-51]

Organization: American Fuel & Petrochemical Manufacturers

There is significant doubt that the U.S. electric grid can reliably support the proposal. Demand for electric vehicle charging will place significant stress on generation, transmission, distribution, and consumer charging systems, that are unlikely to meet increased demand in such a short timeframe. EPA should better assess grid impacts from a regional basis, particularly in the Southwest where the grid is already under significant stress. [EPA-HQ-OAR-2022-0829-0733, p. 3]

I. EPA’s Proposal Does Not Comprehensively Address Cross-Cutting Issues

EPA’s desire to remake the automotive sector creates significant energy and national security concerns and stresses an aging electrical grid subject to increasing demand. In glossing over these issues, EPA fails to adequately consider the mineral, metal, electricity generation, transmission, distribution, and charging infrastructure requirements necessary for the Proposed Rule to be feasible. This is alarming and undermines our energy security. We lack the supply of domestically sourced minerals and metals needed to build batteries and transmission lines and, contrary to the legislative intent of U.S. laws such as the Bipartisan Infrastructure Law (“BIL”) and Inflation Reduction Act ("IRA"), we will have to rely on foreign countries to fulfill the Proposed Rule's mandate. [EPA-HQ-OAR-2022-0829-0733, p. 4]

Even if we could import vast quantities of mineral resources, EPA's electrification mandate is unobtainable. We face a limited supply of copper, which is a critical mineral needed to build out the transmission grid to supply electricity to charging stations. We also do not have near the vehicle charging infrastructure necessary to power the mandated number of ZEVs. Rather than conducting a clear-eyed assessment of these challenges, EPA erroneously assumes that all the necessary conditions to enable its proposal will happen on its aggressive timeline. This conclusion dismisses or outright ignores a multitude of evidence to the contrary. [EPA-HQ-OAR-2022-0829-0733, p. 4]

B. The United States Lacks Copper and Aluminum Production Required for Grid Expansion

Beyond the ZEV itself, electricity networks need a large amount of copper and aluminum.23 The need for grid expansion that would result from this rapid increase in electricity demand underpins a doubling of annual demand for copper and aluminum.24 Most supply of these materials will come from overseas, as the United States lacks current production capacity or the ability to increase such capacity in time to meet the demands of the Proposed Rule. [EPA-HQ-OAR-2022-0829-0733, pp. 11-12]

23 IEA Report 2022.

24 Id.

The United States does not supply much of the world's aluminum. Instead, China, Russia, and India lead global production with an estimated 45 million metric tons per year. China possesses more than half of the entire world's aluminum smelting capacity and produces by far the most aluminum of any country at over 36 million tons per year.25 The United States, by contrast, produces approximately 1 million tons per year. Similarly, countries supplying the most copper are Chile, Peru, China, and the Democratic Republic of the Congo. These countries supply ten times the amount produced domestically. [EPA-HQ-OAR-2022-0829-0733, pp. 11-12]

25 Andy Home, "Global aluminum production pendulum swings back to China" (June 21, 2022) available at https://www.mining.com/web/column-global-aluminum-production-pendulum-swings-back-to-china/.

Experts predict our demand for these materials will rise dramatically, but we lack the ability to source them domestically. The latest data concludes sourcing copper for electric infrastructure (e.g., charging stations and storage) needed to accommodate increased electrical demand will be challenging.26 Copper demand is expected to rise by 53 percent, while supply is expected to rise by only 16 percent.27 U.S. import dependency for copper has grown from 10 percent in 1995 to 40 percent in 2020, with projections of copper import dependency reaching between 55 percent and 67 percent between 2020 and 2040.28 Other estimates predict that by 2030 supply from existing mines and projects under construction is estimated to meet only 80 percent of copper needs by 203029—not considering the anticipated increase in ZEV production anticipated by EPA's Proposed Rule. [EPA-HQ-OAR-2022-0829-0733, pp. 11-12]

C. The Proposal’s Deployment Timeline is Impracticable

EPA’s emissions standards rely on the unsubstantiated assumption that the U.S. electricity and transmission grid and ZEV charging infrastructure will be available to charge the massive numbers of ZEVs that will enter the market. As outlined below, available data supports the Alliance for Automotive Innovation’s conclusion that the timeline for EPA’s standard is infeasible.36 [EPA-HQ-OAR-2022-0829-0733, p. 13]

36 Alliance for Automotive Innovation, Comments to the Environmental Protection Agency, Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, Proposed Rule, Docket No. EPA-HQ-OAR-2022-0829 (hereinafter AAI Comments) at iv.

1. There is Significant Doubt that the U.S. Electrical Grid and Transmission Grid Can Reliably Support this Proposal.

The Proposal will further strain our nation’s electricity system as global electricity demand could increase 47 percent by 2050 based on 2021 projections of population and economic growth, alone.37 In the U.S., the estimated increase in energy consumption is 15 percent by 2050, without consideration of EPA’s Proposal. Notably, this value is likely much higher considering the anticipated increase of between 900 and 2,000 percent electricity purchased for transportation by 2050 with the increased adoption of EVs.38 The Department of Energy concluded that transmission systems must expand by 60 percent by 2030 and triple that capacity by 2050 to meet the Administration’s emissions goals.39 An author of the Princeton University’s Net-Zero America Project40 said “The current power grid took 150 years to build. Now, to get to net-zero emissions by 2050, we have to build that amount of transmission again in the next 15 years and then build that much more again in the 15 years after that. It’s a huge amount of change.”41 [EPA-HQ-OAR-2022-0829-0733, p. 13]

Accessed 28 June 2023.

Yet, our electricity generation and transmission system are increasingly challenged to keep up with current demand. As shown in Figure 5, the North American Electric Reliability Corporation's ("NERC") recent summer assessment shows roughly two-thirds of the U.S. faces increased resource adequacy risk in the summer of 2023.42 [EPA-HQ-OAR-2022-0829-0733, p. 13]

42 NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION, "2023 Summer Reliability Assessment" (May 2023).

43 NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION, "2023 Summer Energy Market and Electric Reliability Assessment" (May 18, 2023), available at https://www.ferc.gov/news-events/news/presentation-report-2023-summer-energy-market-and-electric-reliability-assessment

Depending on where you are, the long-term reliability assessment is not much better. NERC's 2022 Long-Term Reliability Assessment of the U.S. analyzed the electrical grid and the entities delivering power to the continental United States during 2023-2032.44 Regional operators of the power grid—Regional Transmission Organizations ("RTOs") or Independent System Operators ("ISO")—are responsible for transmission, but also balancing a regional power system to ensure that supply constantly matches demand. The grids in some RTOs are already under various degrees of stress. Several operating regions are still at-risk during periods of peak demand, including the Midcontinent ISO (which will face challenges in meeting above-normal peak demand), the SERC – Central area (where, compared to the summer of 2022, forecasted peak demand has risen by over 950 MW while growth in anticipated resources has remained flat) and the Southwest Power Pool (where reserve margins have fallen as a result of increasing peak demand and declining anticipated resources).45 [EPA-HQ-OAR-2022-0829-0733, pp. 14-15]

44 NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION, "2022 Long Term Reliability Assessment" (December 2022), available at https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2022.pdf.

45 NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION, "2023 Summer Reliability Assessment" (May 2023) at 23, available at https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_SRA_2023.pdf.

Future electricity demand is expected to grow due to government policies for EV adoption and energy transition programs. The California Energy Commission staff estimates that by 2030, an additional 5,500 MW of demand at midnight and 4,600 MW of demand at 10:00 a.m. on a typical weekday will be needed for plug-in EV charging.46 This is an increase of 25 and 20 percent, respectively, at those times. State and local policies for transitioning appliances and heating systems, such as banning natural gas stoves, can also affect projections of electricity demand and daily load shapes.47 Moreover, as global temperatures rise, increased use of air conditioning will draw a greater load from the grid. As recently reported, "two-thirds of North America is at risk of energy shortfalls this summer during periods of extreme demand."48 [EPA-HQ-OAR-2022-0829-0733, pp. 14-15]

48 https://www.cnn.com/2023/06/26/business/heat-wave-power-blackout/index.html

Although EPA projects ZEV sales on a national basis, the ability to charge the vehicles is driven by the ability of the RTOs and ISOs to manage regional or local power grids to supply electricity on demand. EPA's national data thus disguise important problems that increasing ZEV penetration will cause. By 2022, more than 50 percent of ZEVs were concentrated in California (WECC-CA/MX), Florida (SERC), and Texas (ERCOT).49 The distribution of the ZEV fleet across RTOs can be seen in Figure 6, in which state shares of ZEV registrations are allocated across RTOs.50 [EPA-HQ-OAR-2022-0829-0733, pp. 15-16]

49 S&P GLOBAL MOBILITY, "EV Chargers: How Many Do We Need?" (Jan. 9, 2023), available at press.spglobal.com/2023-01-09-EV-Chargers-How-many-do-we-need.

50 There are several states which are covered by more than one RTO. For this high-level assessment, the Turner Mason Report allocates state EV sales by roughly the geographic footprint of each RTO within the state.

SEE ORIGINAL COMMENT FOR EV Fleet is Heavily Concentrated in California. Figure 6: ZEV registrations by RTO51 [EPA-HQ-OAR-2022-0829-0733, pp. 15-16]

51 Turner Mason Report.

As seen in Figure 7, the greatest stress is not in California (although it is significant in California), but rather in the southwestern U.S. [EPA-HQ-OAR-2022-0829-0733, pp. 15-16]

SEE ORIGINAL COMMENT FOR Power Grid Serving Southwestern U.S. has Greatest Risk of Not Being Able to Support Growing EV Fleet. Figure 7: EV Power Requirement by RTO52 [EPA-HQ-OAR-2022-0829-0733, pp. 15-16]

In the southwestern U.S., for example, electricity demand from EV charging is expected to completely consume the 2023 reserve margin for the WECC-SW grid, leaving no reserve margin to address emergency conditions. This is based on EPA's estimate of ZEV electricity demand in 2032, allocated to RTOs, assuming no reserve capacity is added over the next eight years. For an RTO to fill incremental ZEV electricity demand and maintain its reserve margin, the required capacity investment will vary depending on the source of generation and that source's availability (i.e., expected load factor) specific to that region. For the U.S. the total investment would be significant; the Brattle Group estimated an additional $75 to $125 billion total investment across the power sector at a ZEV penetration rate lower than EPA proposes.53 [EPA-HQ-OAR-2022-0829-0733, pp. 15-16]

53 Michael Hagerty, et al., "Opportunities for the Electricity Industry in Preparing for an EV Future" (June 2020).

The "major questions doctrine" holds that Congress must "speak clearly when authorizing an agency to exercise [such] powers" of "vast economic and political significance."61 And as EPA is aware, this doctrine applies in the context of environmental regulation. Last year, in West Virginia v. EPA, the Supreme Court relied on the major questions doctrine in holding that the EPA exceeded its statutory authority in adopting its Clean Power Plan. That regulation sought to impose caps on GHG emissions by requiring utilities and other providers to shift electricity production from coal-fired power to natural gas and then to renewable energy in place of imposing source-specific requirements reflective of the application of state-of-the-art emission reduction technologies.62 [EPA-HQ-OAR-2022-0829-0733, p. 18]

61 Nat'l Fed. Of Indep. Bus. v. Dep't of Labor, 142 S. Ct. 661,665 (2022); see also Ala. Assoc. of Realtors v. Dep't of Health & Human Servs., 141 S. Ct. 2485, 2489 (2021); Utility Air Regulatory Group v. EPA, 573 U.S. 302, 324 (2014); U.S. Telecom Assoc. v. FCC, 855 F.3d 381, 419-21 (D.C. Cir. 2017) (Kavanaugh, J., dissenting from denial of rehearing en banc) (explaining provenance of "major rules doctrine").

62 West Virginia v. EPA, 142 S. Ct. 2587 (2022).

As noted by the Court, EPA "announc[ed] what the market share of coal, natural gas, wind, and solar must be, and then require[d] plants to reduce operations or subsidize their competitors to get there."63 EPA's attempt to devise GHG emissions caps based on a generation-shifting approach would have had major economic and political significance impacting vast swaths of American life and substantially restructured the American energy market; however, EPA's purported authority was only based on a "vague statutory grant" within Section 111(d) of the Clean Air Act—far from the "clear authorization required by [Supreme Court] precedents."64 The need for clear congressional authorization for such sweeping regulatory programs is nothing new – just last week the Supreme Court reaffirmed the major questions doctrine "as an identifiable body of law that has developed over a series of significant cases spanning decades."65 [EPA-HQ-OAR-2022-0829-0733, p. 18]

65 Biden v. Nebraska, No. 22-506, slip op. at 23 (June 30, 2023) (internal quotations omitted) (applying major questions doctrine to strike down student loan repayment program that will cost taxpayers approximately $500 billion and affects nearly every student loan borrower). Just as the trade-offs inherent in a mass debt cancelation program are ones that Congress would likely have reserved for itself, id., slip op. at 25, so too are those that must be considered for the mass adoption of electric vehicles.

EPA likewise assumes that the IRA and the BIL funds will be adequate to build the necessary electrification infrastructure. It is uncertain that (1) critical minerals will be available to manufacture ZEV batteries (see Section I.A.1); (2) consumers will buy EVs at the rate assumed by EPA (see Section IV.B.2); and (3) there will be ample electricity to power these vehicles (see Sections I.B and IV.B.3).127 What is certain is that the Proposal's timeline is unachievable and completely detached from reality.128 EPA also improperly relied on the general characterization of recent years of the light-duty and medium-duty market as supplemented by incentives in the BIL and IRA to support its proposition that there will be a rapid increase in ZEV market penetration. Setting aside the laws of supply and demand and the fact that the future availability of ZEVs is insufficient to meet the ZEV adoption requirements proposed by EPA (as discussed further below), EPA improperly relies on the number of models currently available on the free market as a surrogate for the number of actual units sold and in use. The underlying reality is that without federal regulation requiring vastly increased ZEV penetration, providing automakers certainty for long-term planning, automakers could not financially justify long-term investment in a technology with tepid consumer demand. The referenced electrification projections may be a function of OEMs striving to create certainty and minimize risk as they attempt to comply with forthcoming regulations. Indeed, the CEO of the Alliance for Automotive Innovation recently questioned the feasibility of the Proposed Rule – stating that the proposal was too aggressive and could benefit China: [EPA-HQ-OAR-2022-0829-0733, pp. 29-30]

127 Id.

128 Id.

I’ve said the EPA proposal wasn’t feasible without certain public policies and in light of today’s market and supply chain conditions .. . . There’s not enough charging and uncertain utility and grid capacity. Here’s the big one – and where China looms largest – essentially no domestic or allied supply of battery critical minerals, processing, and components until 2025 (and even then, nowhere near enough to supply what’s needed).129 [EPA-HQ-OAR-2022-0829-0733, pp. 29-30]

EV charging infrastructure, range, and charging time remain top concerns for nearly half of U.S. customers.139 OEMs expect that ZEV penetration will not be uniform across markets, with larger impact in markets with more low carbon intensity electricity and greater electrical grid reliability.140 Toyota announced that regional energy variation is the reason Toyota will provide a diversified range of carbon neutral options to meet the needs and circumstances in every country and region.141 Toyota believes optionality facilitates the ability to adapt to change, while selecting a single option is an attempt to predict the future in uncertain times.142 [EPA-HQ-OAR-2022-0829-0733, pp. 31-32]

142 Id.

Grid resiliency is at risk of further deterioration due to increasing power demand from electrification, not just in transportation. EPA overlooks this issue in another example of the agency’s failure to address a major aspect of the Proposal. Notably absent from EPA’s analysis is any demonstration that sufficient utilities and other infrastructure needed to support accelerated ZEV implementation will be available by MY27. Focusing solely on ZEV themselves, EPA has not adequately evaluated or grasped the time and resources required to permit, construct, and operate the necessary infrastructure to power these vehicles, while maintaining reliable and affordable electricity for all other power consumers. This is particularly concerning in light of the very real risk that the electric grid will not be able to meet the increased demand anticipated by the Proposed Rule.159 [EPA-HQ-OAR-2022-0829-0733, pp. 34-35]

159 North American Electric Reliability Corporation, 2022 Long-Term Reliability Assessment (Dec. 2022), 21, available at https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2022.pdf (indicating that increased demand projections may lead to reliability concerns for the electric grid, especially as dual-peaking or seasonal peaking times change with increased electrification).

Power generation using traditional fuels has an advantage in that capacity is located near demand centers. Except for nuclear, any low-carbon power generation capacity must be located at the energy source (e.g., where the wind blows, water flows, sun shines). Supplying low-carbon electricity to charge EVs also needs to resolve the transmission of that power to the demand center. Installation of transmission capacity in a timely manner is not guaranteed, or even likely. The Bureau of Land Management recently issued its record of decision for the SunZia Southwest Transmission Project more than 15 years after the project was proposed.160 Once this incremental power is transmitted from supply location to a load center, there are potentially additional distribution constraints before the electrons reach charging stations and homes. Just to get a sense of the burden that charging will have on the electrical grid, One ZEV supercharger equals the launch of 70 air-conditioning units at once. Such an instant change in the power demand profile is a significant problem for the local distribution grid, requiring innumerable upgrades, such as replacement of nearly every distribution system transformer with a larger transformer, the costs of which are borne by all electric ratepayers. EV chargers typically used in a home (Level 2) can increase a home's peak load by 40 percent to 100 percent, which stress neighborhood transformers and compromise reliability.161 [EPA-HQ-OAR-2022-0829-0733, pp. 34-35]

160 Emma Peterson, INSIDE CLIMATE NEWS, "SunZia Southwest Transmission Project Receives Final Federal Approval" (May 29, 2023) available at https://insideclimatenews.org/news/29052023/sunzia-transmission-project-approval/.

161 Matt Egan, "Extreme heat means two-thirds of North America could suffer blackouts this summer," Jan 26, 2023 (two-thirds of North America is at risk of energy shortfalls this summer during periods of extreme demand caused by air conditioning use). See also Gilleran, Madeline & Bonnema, Eric & Woods, Jason & Mishra, Partha & Doebber, Ian & Hunter, Chad & Mitchell, Matt & Mann, Margaret. (2021). Impact of electric vehicle charging on the power demand of retail buildings. Advances in Applied Energy. 4 ("[A]n electric vehicle station has the potential to dwarf a big box building's power demand if behind the same meter, increasing monthly peak power demand at the site by over 250%. Cold-climate areas paired with rate structures incorporating high demand charges are most susceptible for significant changes to the annual electricity bill, with increases as high as 88%."). As discussed in Section IV.B.2, charging time will decrease dramatically with DCFC chargers, but the trade-off is they require vastly more electricity.

The intensity is further complicated in that the capacity factor (percentage of time a plant is likely to be available for generation) of thermal and photovoltaic solar (ranging from 7-32 percent) and wind (ranging from 23-46 percent) plants is so much lower than dispatchable (e.g., nuclear 93 percent) generation capacity.162 [EPA-HQ-OAR-2022-0829-0733, pp. 34-35]

162 ENERGY INFORMATION ADMINISTRATION "Electric Power Monthly" (June 27, 2023).

Therefore, it is not sufficient to evaluate total grid capacity; EPA must consider the ability of RTOs to supply power safely and reliably to all users during peak demand conditions and the impact of commercial charging on local grids, and work with other federal entities to ensure the growth in power demand stemming from an expanding ZEV fleet in the Proposed Rule can be safely and reliably supplied. Beyond the normal approximately four-year lead time for OEMs to make incremental changes to their production needed to meet emissions standard, the typical duration of an electricity transmission system capital project timeline is approximately ten years, meaning the additional electricity generation and distribution required by the Proposed Rule is unlikely to be available in the period covered by the Proposal. large-scale electric generation and storage projects are increasingly backlogged year-on-year due to long lead times for permitting and approvals, supply chain shortages, and shortage of skilled workers. While government programs have recently been put in place to help overcome some of these hurdles, it will take time for the grid to be upgraded quickly enough to overcome the constraints above.163 [EPA-HQ-OAR-2022-0829-0733, pp. 34-35]

163 Gracie Brown, et al., MCKINSEY AND COMPANY, "Upgrade the grid: Speed is of the essence in the energy transition" (Feb. 1, 2022) available at https://www.mckinsey.com/capabilities/operations/our-insights/global-infrastructure-initiative/voices/upgrade-the-grid-speed-is-of-the-essence-in-the-energy-transitionl; DELOITTE, "2023 power and utilities industry outlook" available https://www2.deloitte.com/content/dam/Deloitte/us/Documents/energy-resources/us-eri-power-utilities-outlook-2023.pdf.

Regardless of whether OEMs even could comply with the Proposed Rule, they would likely be left in a position where there is no consumer demand, and fleet turnover declines because the infrastructure necessary to support the new ZEVs is either at capacity or nonexistent. Indeed, at least one study to date has concluded that, upon ZEVs becoming the norm in California, it could push the total demand for electricity beyond the existing capacity of the state's grid—turning ZEVs into zero electricity vehicles.164 Even more important, meeting the electricity demand will require construction of new power plants, or electricity purchases from neighboring states, which require increased transmission and distribution capabilities.165 Or, in the short term, electricity may come from fossil-fuel fired generators, in which case it makes more sense to leave the ICE in the car rather than beside it. [EPA-HQ-OAR-2022-0829-0733, p. 36]

164 Beth Daley, THE CONVERSATION, "Switching to electric vehicles could save the US billions, but timing is everything" (Dec. 4, 2018), available at https://theconversation.com/switching-to-electric-vehicles-could-save-the-us-billions-but-timing-is-everything-106227.

165 Id.

EPA ignores these constraints, relying on the hope that a massive expansion of renewable electricity generation and the transmission grid will occur in time to service EVs produced during MY 2027-2032. The Agency's expectations are unrealistic. While the Lawrence Berkley National Laboratory reports strong interest in clean energy, increasing delays in studying, building, and connecting new energy projects to the grid means that "much of this proposed capacity will not ultimately be built."166 The high-rate project withdrawal is reflected in the fact that only 21 percent of the projects (representing 14 percent of capacity) seeking connection from 2000 to 2017 were constructed as of the end of 2022.167 Other challenges cited by the Berkeley National Lab that prevent timely operation of new renewable energy projects include increased interconnection wait times, reaching agreements with landowners and communities, power purchasers, supply chain constraints, and financing.168 EPA's refusal to examine the costs associated with grid updates required by the rule is another example of the agency's biased evaluation, resulting in an arbitrary and capricious regulatory decision. [EPA-HQ-OAR-2022-0829-0733, p. 36]

168 Id.

EPA assumes the power sector is expected to shift over time to using significantly more wind/solar generation and electricity storage (i.e., batteries), but ignores the environmental impacts of the overall increase in critical minerals demand for electrical grid storage and how that compounds the stress on critical minerals for the ZEVs themselves. But the expansion of electrical grids—even ignoring the Proposed Rule's increased demand—requires a large amount of earth minerals and metals. Copper and aluminum, which are both needed for ZEVs, are also the two main materials in wires and cables and, as described above, higher prices could have a major impact on future grid investments and EV costs.205 The need for expanded grid capabilities simultaneous to expanded ZEV production places a more pressing demand on materials like copper and aluminum thereby increasing extraction and refining efforts throughout the global market. [EPA-HQ-OAR-2022-0829-0733, pp. 44-45]

205 IEA Report 2022.

EPA also ignores the GHG emissions associated with manufacturing more, less dense, remotely located intermittent generation sources and battery back-up, plus the need for more natural gas peaking capacity and massive transmission, substation, and transformer investment to integrate these technologies into the power grid. Those emissions are significant and may offset or eliminate the benefits that EPA calculates. [EPA-HQ-OAR-2022-0829-0733, p. 45]

207 EPA, "2020 National Emissions Inventory (NEI) Data," available at https://www.epa.gov/air-emissions- inventories/2020-national-emissions-inventory-nei-data.

The U.S. needs to invest an estimated $4.5 trillion to fully transition the U.S. power grid to renewables during the next 10-20 years.261 The cost of grid upgrade projects needed to support the incremental electricity demand growth from transportation is significant and can be quite variable. A particular case study of Northern California illustrated in IOP Science notes: "[T]he total cost of these upgrades will be at least $1 billion and potentially more than $10 billion" for a service area of 4.8 million electricity customers.262 These costs need to be taken into consideration with expected demand growth, within detailed rate base calculations, and in concert with appliance upgrade costs to fully understand their ultimate impact on annual ratepayer expenditures. We agree with and support the Proposed Rule's acknowledgement that "a recent study found power needs as low as 200 kW could trigger a requirement to install a distribution transformer."263 Other anecdotal evidence discussed within an RMI report highlights the expensive mistakes that can emerge from insufficient planning and engagement in details.264 [EPA-HQ-OAR-2022-0829-0733, p. 57]

v. Costs to upgrade electricity generation, transmission, and distribution

For EPA to achieve its GHG reduction aspirations in this Proposed Rule, all three of these challenges must be met: (1) sufficient materials to manufacture the required EVs, chargers, and grid upgrades, (2) consumer willingness to substitute ZEVs for ICEVs currently for sale, and (3) a low-carbon power generation grid capable of reliably supplying energy for this mode of transportation. Combined with other issues, such as a disorderly transformation of the generation base as conventional units are replaced with intermittent resources, raises questions of the grid's ability to reliably meet consumer demand on a regional basis. Despite these challenges, EPA incredibly assumes no increase in the cost of electricity to consumers (whether EV owners or others) associated with the proposed rulemaking. EPA underestimates the cost of electricity to all consumers, including EV owners, and omits the cost of grid upgrades and distributed energy resources have been excluded from these estimates.260 [EPA-HQ-OAR-2022-0829-0733, pp. 56-57]

260 U.S. Department of Energy, National Renewable Energy Laboratory, "The 2030 National Charging Network: Estimating U.S. Light-Duty Demand for Electric Vehicle Charging Infrastructure." June 2023. https://driveelectric.gov/files/2030-charging-network.pdf.

EPA incorrectly assumes that ZEV owners will pay the national average residential electricity price to charge their vehicles. EPA fails to consider that the majority of ZEVs in the U.S. are located in utility service territories with some of the highest electricity rates in the country and that the average EV owner currently pays a much higher price to charge their ZEV at home than the national average residential electricity rate. Given that EV penetration has varied widely across the U.S., it would be arbitrary to assume that EVs will, unlike in the past, penetrate uniformly across the U.S. and thus that the average electricity price would be representative of the actual cost electricity. For example, California, which has roughly 40 percent of all registered ZEVs in the U.S., has a residential electricity rate that is roughly double the national average. Considering that EPA is modeling its rule after a California-like approach to mandate ZEVs, it would be more appropriate for EPA to assume similar real-world costs (at a minimum, given California's temperate climate). Moreover, EPA fails to consider that mandating such a high ZEV sales rate will necessarily require exponential increases in commercial ZEV charging at rates that are currently three, four or five times higher than the current national average residential electricity rate, depending on location and charging speed. Those customers who are not homeowners and not able to install their own charging stations and take advantage of charging at low-cost times will be adversely impacted. Instead, EPA uses a residential rate for electricity and does not consider peak power or time of use charges. California electric prices rose 42 percent -78 percent between 2010 and 2020 and are projected to rise an additional 50 percent by 2030 as shown in Figure 9. [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

SEE ORIGINAL COMMENT FOR Historic and Forecasted Residential Average Rates Based on Most Recent 5-year Average Rate Increase. Figure 9: [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

Source: Michael Shellenberger, Twitter (citing California Public Advocate's Office data), April 27, 2021). [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

Heaping additional demand for EV charging into this market could exacerbate already high electricity prices. This will be especially impactful to lower-income homeowners who may not be able to install dedicated charging units, forcing them to pay more out of pocket for charging during peak demand periods.265 [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

265 Hardman, Scott, et al., "A Perspective on Equity in the Transition to Electric Vehicles." MIT Science Policy Review, (Aug. 20 2021), available at https://sciencepolicyreview.org/2021/08/equity-transition-electric-vehicles/ (accessed June 29, 2023).

EPA must revise its analysis to account for realistic electricity prices. The proposed ZEV mandate will require an enormous investment in power generation and distribution, resulting in nationwide increases in electricity bills that EPA has not considered. Of course, considering the additional trillions of dollars in costs would paint a clear picture that the costs of forced electrification far exceed even the inflated benefits EPA presented in the Proposed Rule. [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

EPA also did not include any cost of power distribution upgrade needed for EVSE installation, citing large uncertainty. While uncertainty may exist, EPA cannot assume there is no cost associated with this required upgrade. The National Renewable Energy Laboratory ("NREL") published new estimates of the need for ZEV charging infrastructure investment that finds: [EPA-HQ-OAR-2022-0829-0733, pp. 59-60]

"A cumulative national capital investment of $53–$127 billion in charging infrastructure is needed by 2030 (including private residential charging) to support 33 million PEVs. The large range of potential capital costs found in this study is a result of variable and evolving equipment and installation costs observed within the industry across charging networks, locations, and site designs. The estimated cumulative capital investment includes: [EPA-HQ-OAR-2022-0829-0733, pp. 59-60]

-$22–$72 billion for privately accessible Level 1 and Level 2 charging ports

-$27–$44 billion for publicly accessible fast charging ports

-$5–$11 billion for publicly accessible Level 2 charging ports.274 [EPA-HQ-OAR-2022-0829-0733, pp. 59-60]

274 National Renewable Energy Laboratory, The 2030 National Charging Network: Estimating U.S. Light-Duty Demand for Electric Vehicle Charging Infrastructure, June 26, 2023, at vii. Available at https://www.nrel.gov/docs/fy23osti/85654.pdf.

Clearly, these cost estimates are vastly higher than the $7 billion in costs that EPA claims is needed over an even longer time frame. Given a general linear relationship between ZEV charging infrastructure costs and the number of registered ZEVs, it is reasonable to estimate (using the DOE numbers) a cost adder for charging infrastructure to each ZEV of (at least) $1,606 to $3,848. These costs are not shown by EPA and EPA's failure to account for them is arbitrary and unreasonable. Moreover, note that DOE's estimate excludes "the cost of grid upgrades and distributed energy resources."275 [EPA-HQ-OAR-2022-0829-0733, pp. 59-60]

275 Id.

The BIL provides up to $7.5 billion to install 500,000 public chargers nationwide by 2030. "However, even the addition of half a million public chargers could be far from enough. In a scenario in which half of all vehicles sold are ZEVs by 2030—in line with federal targets—McKinsey estimates that America would require 1.2 million public EV chargers and 28 million private EV chargers by that year.276 All told, the country would need almost 20 times more chargers than it has now."277 EPA must address charger investment and reliability by more than just referencing EV subsidies in recent legislation. [EPA-HQ-OAR-2022-0829-0733, pp. 59-60]

277 Id.

However, building more charging stations is not enough. “Electricity purchased at a public charger can cost five to ten times more than electricity at a private one.”278 Lower-income consumers cannot afford to install solar photovoltaics, which proponents claim will allow ZEVs to be charged at home with emissions-free electricity.279 Those who cannot afford private charging will end up paying vastly more for a re-charge than the wealthy. For those who simply cannot afford the upfront costs for a new EV or pay higher public charging rates, they may end up retaining older ICEVs for longer. [EPA-HQ-OAR-2022-0829-0733, p. 60]

Moreover, a recent ATRI study found that electrification of the entire U.S. vehicle fleet would consume 40.3% of the current electricity demand, yet our aging national grid can hardly sustain its current needs.5 [EPA-HQ-OAR-2022-0829-0696, pp. 4-5]

5 Charging Infrastructure Challenges for the U.S. Electric Vehicle Fleet, American Transportation Research Institute, December 2022. https://truckingresearch.org/2022/12/charging-infrastructure-challenges-for-the-u-s-electric-vehicle-fleet/

Organization: American Petroleum Institute (API)

2. The electricity grid and charging.

In the DRIA, EPA estimates that by 2050, the proposed rule would drive annual electricity demand higher by 430 terawatt hours (TWh). This number represents 10% of today’s electricity demand. EPA makes the claim that it is relatively small in the context of total electricity demand in 2050 (4.4%). EPA does not include in its assessment a clear explanation on how this estimate was obtained and, accordingly, has not provided meaningful opportunity for the public to comment. API requests further clarification on the assessment of electricity demand projections by EPA. The past two decades have seen an annual growth in energy generation (i.e., total electricity consumption, or load, and system losses) averaging 30 TWh.40 Historically, the U.S. electric power system has evolved over time to accommodate new energy demand. However, the rapid pace at which BEVs will have to be in the market to comply with the proposed rule, in addition to the HD GHG Phase 3 rule proposed ZEV deployment, poses several potential challenges at the distribution level that warrant further analysis 41: [EPA-HQ-OAR-2022-0829-0641, pp. 15-16]

40 Energy Information Administration. “Monthly Energy Review.” Total Energy. June 2023. https://www.eia.gov/totalenergy/data/monthly/.

41 USDRIVE. “Summary Report on EVs at Scale and the U.S. Electric Power System.” November 2019. https://www.energy.gov/eere/vehicles/articles/summary-report-evs-scale-and-us-electric-power-system-2019.

• Distribution capacity expansion could present additional costs. Areas that should be assessed are: (a) high power charging of light-duty EVs (at 150kW and above), (b) high-power charging of medium-and heavy-duty vehicles (potentially at over 1 MW), (c) legacy infrastructure constraints in dense urban areas, and (d) low-power charging of light-duty EVs on distribution systems. [EPA-HQ-OAR-2022-0829-0641, pp. 15-16]

• Transmission constraints must be assessed. Transmission expansions must be deliberate as these investments in the U.S. power system are costly and time consuming. [EPA-HQ-OAR-2022-0829-0641, pp. 15-16]

• Ramping up capabilities of the generating fleet of the bulk power system should be considered for BEVs at scale. [EPA-HQ-OAR-2022-0829-0641, pp. 15-16]

• Analysis of medium-and heavy-duty EV market growth scenarios are needed to assess the impact on energy generation and generation capacity. [EPA-HQ-OAR-2022-0829-0641, pp. 15-16]

Additional factors such as utilities' readiness for the installation of new capacity, sufficient utility labor, capital, land use, other environmental regulations, reliability requirements, and the policy environment must be taken into consideration.42 [EPA-HQ-OAR-2022-0829-0641, pp. 15-16]

42 Ibid.

BEV impact on the order of 2-4% increased electricity demand may appear "modest" in an aggregate sense, but EPA has failed to include in their assessment that grid supply-demand strain is a localized phenomenon (both spatially and temporally). Add on the increased demand from electrification ambitions and the system becomes more tenuous and requires additional consideration. While the light-duty and medium-duty NPRM 43 notes "vehicle-to-grid software and systems that allow management of vehicle charging time and rate have been found to create value for electric vehicle drivers, electric grid operators, and ratepayers;" however, we submit that vehicle to grid (V2G) technology is still a topic of active research and development activity and early pilot demonstrations and will take years44 for effective widespread deployment to help with load-balancing. Depending on the time of day and the extent of renewable electricity in the grid mix for a given location, it should be noted that the carbon intensity of the electricity that gets consumed by these vehicles may also fluctuate depending upon fluctuation of renewable energy availability.45,46 [EPA-HQ-OAR-2022-0829-0641, pp. 16-17]

Upgrades to the typical duration of an electricity transmission system capital project timeline would need to be accelerated from roughly 10-year timelines to have a chance to support the proposed ZEV demand, while current large-scale electric generation and storage projects are increasingly facing backlogs year-on-year due to long lead times for permitting and approvals, supply chain shortages, and shortage of skilled workers. While government programs have recently been put in place to help overcome some of these hurdles, they will take time for the benefits of those programs to be realized.47,48,49 [EPA-HQ-OAR-2022-0829-0641, pp. 16-17]

49 Rocky Mountain Institute. "Increasing Equitable EV Access and Charging: A Path Forward for States." 2022. https://rmi.org/insight/increasing-equitable-ev-access-charging/.

EPA's proposal indicates that by 2035, the "power sector modeling results showed that non-hydroelectric renewables (primarily wind and solar) will be the largest source of electric generation (approximately 46 percent of total generation), and they would account for more than 70 percent of generation by 2050." This will primarily be driven by the incentives included in the IRA. If these projections become a reality, further analysis and consideration should be given to the intermittency of a grid primarily powered by these sources of energies. As indicated by a study50 conducted by the National Renewable Energy Laboratory (NREL), dramatically accelerating electrification of sectors such as transportation, may make it more difficult to decarbonize the electricity system due to the higher rate of generation and transmission capacity additions needed. Wood Mackenzie's51 forecasts for BEV sales includes the projection that charging will account for about 4% of total U.S. retail electricity sales in the early 2030s. Faster growth in BEV sales would likewise result in greater demands on the grid, and at a time when the power industry is also under pressure to cut its own greenhouse gas emissions. [EPA-HQ-OAR-2022-0829-0641, pp. 16-17]

50 Denholm, Paul, Patrick Brown, Wesley Cole, et al. 2022. "Examining Supply-Side Options to Achieve 100% Clean Electricity by 2035." National Renewable Energy Laboratory. NREL/TP-6A40-81644. https://www.nrel.gov/docs/fy22osti/81644.pdf.

51 Crooks, E. April 13, 2023. "The EPA plans to rev up US EV sales." Wood Mackenzie. https://www.woodmac.com/news/opinion/the-epa-plans-to-rev-up-us-ev-sales/.

Another critical aspect to be considered is that normal BEV charging behavior will put extra load pressure52 on the grid, especially at peak hours. As a general practice, a passenger BEV user will charge the vehicle during the evening, which is also the time that electricity demand from the residential sector generally peaks. EV charging at peak hours is anticipated to be more expensive, as additional generation capacity may be required. Moreover, the current consumer trend toward acquiring larger vehicles, which typically have lower battery efficiency and further charging requirements, suggests increasing energy consumption per mile. We believe that electricity demand from BEVs should not cause additional burden to other electricity users, especially during emergencies. However, EPA has not provided an adequate analysis of the feasibility of the proposed regulation given the significant increase of charging infrastructure, electrical generation and transmission and distribution infrastructure that would be required to support a significant shift in the national fleet from ICEVs to BEVs. Furthermore, in its cost-benefit analysis of the proposed standards, EPA has failed to account for the full costs associated with the charging infrastructure and grid infrastructure upgrades that would be necessary. It is also important to note that increased use of high-capacity battery storage and high-voltage upgrades to the grid's electrical distribution and transmission infrastructure may lead to increased risk of wildfires in certain areas of the country, which would have an impact on fire response and other emergency services. [EPA-HQ-OAR-2022-0829-0641, p. 18]

52 United Nations Industrial Development Organization. "Best Practices in Electric Mobility." Discussion Paper. 2019. https://www.unido.org/sites/default/files/files/2019-09/EMG%20Discussion%20Paper.pdf.

EPA has failed to adequately address the major impacts of the proposed rule on the electricity grid and charging infrastructure. It would be arbitrary and capricious for EPA not to adjust its analysis to take into account these factors. [EPA-HQ-OAR-2022-0829-0641, p. 18]

e. API Supports Consumer Choice for Vehicles.

API 53 supports the concept that different vehicle technologies that reduce greenhouse gas emissions should be allowed to compete equally for consumer and market acceptance and growth. However, API has concerns with regards to the EPA's approach and its effect on consumer choice. [EPA-HQ-OAR-2022-0829-0641, pp. 18-19]

53 https://www.api.org/news-policy-and-issues/blog/2021/05/18/us-consumers-need-balance-choice-in-transportation-policy.

The stringency of the proposed standard is essentially forcing electrification of the transportation sector and is not in alignment with most Americans that, according to a Pew Center survey,54 favor "using a mix of energy sources to meet the country's needs" and a majority of survey respondents oppose phasing out gasoline powered vehicles by 2035. Concerns with charging availability55 could be relieved with vehicle technologies (e.g., PHEVs56) where the length of an average daily trip is approximately 30 miles.57 [EPA-HQ-OAR-2022-0829-0641, pp. 18-19]

Fueling the BEVs

Section 5 of the DRIA discusses the electrical infrastructure impacts of the regulation forcing 67% BEV market share for new vehicles by 2032.128 [EPA-HQ-OAR-2022-0829-0641, pp. 50-51]

128 Draft Regulatory Impact Analysis EPA-420-D-23-003 April 2023, Table 5-13.

Table 5-13: IPM results for net export of electricity into the contiguous United States for the proposal. [EPA-HQ-OAR-2022-0829-0641, pp. 50-51]

2028 2030 2035 2040 2045 2050

Net US Exports (GWh) -28,312 -23,879 -24,877 -8,809 -4,453 -22

US Electricity Demand (GWh) 4,403,327 4,545,283 4,971,619 5,371,913 5,753,443 6,117,592

Net US Exports as a Percentage of Total Demand (%) -0.64% -0.53% -0.50% -0.16% -0.08% 0.00% [EPA-HQ-OAR-2022-0829-0641, pp. 50-51]

Table Notes: [EPA-HQ-OAR-2022-0829-0641, pp. 50-51]

Negative net exports represent imports of electricity

International dispatch to the contiguous United States occurred over the U.S.-Canada border. [EPA-HQ-OAR-2022-0829-0641, pp. 50-51]

This table shows an increase in power generation capacity of 968,586 GWh per year by 2040 due to the impact of the proposed rulemaking. However, this section does not consider the additional costs to the power generation market as a result of this regulation, merely the net increase in total power generation. The agency states: [EPA-HQ-OAR-2022-0829-0641, pp. 50-51]

- "However, as the expected increase in electricity generation associated with the proposal relative to a no-action case is relatively small – approximately 4.4 percent increase in 2050 – we do not expect the U.S. electric power distribution system to be adversely affected by the projected additional number of charging electric vehicles." [EPA-HQ-OAR-2022-0829-0641, pp. 50-51]

Since the proposed rule now requires BEVs as part of the assumed technology needed to meet the proposed standards, the agency should also now account for the additional costs borne by the power generation market to meet the requirements of the standard. Ignoring the costs is not valid since the proposed rule forces market penetrations higher than would otherwise be natural. [EPA-HQ-OAR-2022-0829-0641, pp. 50-51]

Based on publicly available information129 and the agency's assumed path of new power generation sources from wind and solar, the average cost of building the infrastructure required to support the assumed BEVs in operation by 2040 is ~$1,800/kWh. This means that there could be ~$200B of infrastructure cost that is ignored by the agency as "relatively small." The financial burden placed on the power generation industry is not small and should be accounted for accurately in the final regulatory impact analysis. [EPA-HQ-OAR-2022-0829-0641, pp. 50-51]

129 https://proest.com/construction/cost-estimates/power-plants/.

Organization: Anonymous

EPA should conduct a rigorous study on the full environmental impacts of a dramatic shift to BEV with respect to other environmental media (i.e., non-air pollutants/contaminants), since the proposed rule is designed to more or less force transition to that vehicle technology. The European Environmental Agency (EEA) issued a report in 2018 that reveals the far higher "Human Toxicity Potential" of BEVs, largely from mining the mineral requirements for EV manufacturing (https://www.eea.europa.eu/publications/electric-vehicles-from-life-cycle). Note especially Figure 6.2 on page 58 that even if BEVs are charged with 100% RE (i.e., eliminating the "In-use phase" segments of the BEV bars in the graph), human toxicity impacts are still over twice as high. Ecotoxicity is also higher even if BEVs are charged with 100% RE (Figure 6.3). This is supported by a publically-available European LCA model "carculator" (https://carculator.psi.ch/). Damages to environmental media other than air should also be taken into account when a shift to a substantially different vehicle technology is expected, even if some of that contamination currently is non-domestic. [EPA-HQ-OAR-2022-0829-0490, pp. 1-2]

A peer-reviewed study in 2018 (https://onlinelibrary.wiley.com/doi/10.1111/jiec.12862, Figure 1) also demonstrated the far higher human toxicity impacts of BEV. Even in extremely clean future electric grid scenarios (denoted by dotted lines (generally corresponding to the RCP2.6 scenario in the IPCC AR5)), "Human Toxicity" remains ~3 times higher for BEV in the same electric grid mix scenario. Note also that "Particle matter formation" is higher for BEV than ICEV in all but the cleanest future grid mix scenarios, disputing the BEV air quality benefits claims. [EPA-HQ-OAR-2022-0829-0490, pp. 1-2]

The 2023 study in California concludes that "…our results indicate that the CVRP [clean vehicle rebate project] has displaced emissions from vehicle tailpipes to electric generating units, leading to a net increase in primary PM2.5 emissions across the state of California…. [EPA-HQ-OAR-2022-0829-0490, pp. 2-3]

…Of particular concern for environmental justice and public health is the finding that Disadvantaged Communities, as defined according to CalEnviroScreen 4.0, are disproportionately more likely to experience either larger net increases or smaller net reductions in primary PM2.5, NOX, and SO2 emissions as a result of the CVRP…." That's considering California's current electric grid, which is among the cleanest in the U.S. This is counter to the stated goals of the proposed regulation. [EPA-HQ-OAR-2022-0829-0490, pp. 2-3]

These studies come on the heels of a 2010 study by the National Academy of Sciences (National Research Council -https://www.nationalacademies.org/news/2009/10/report-examines-hidden-costs-of-energy-production-and-use), which concluded... "Electric vehicles and grid-dependent (plug-in) hybrid vehicles showed somewhat higher nonclimate damages than many other technologies for both 2005 and 2030." According to Figure 3-7b in the full report, BEV is projected to be more damaging than most of the ICEV technologies/fuel pathways in 2030. Even if the NRC committee underestimated the pace of the decline in coal-generated electricity, some ICEV technologies/fuel pathways would still be less damaging than BEV or FCV, even in much cleaner grids, most notably diesel/biodiesel and CNG ICEV. [EPA-HQ-OAR-2022-0829-0490, pp. 2-3]

Environmental regulations should be technology neutral with respect to compliance with the goals of the regulations. Forcing a transition to 100% BEV will almost certainly result in much higher contamination of toxic substances, both carcinogenic and non-carcinogenic, in ground water, surface water, and soils near mining sites. BEVs will likely play a prominent role in the future vehicle mix regardless, but categorically excluding ICE vehicle technologies via regulation is a mistake and potentially counterproductive. [EPA-HQ-OAR-2022-0829-0490, pp. 2-3]

Organization: Anonymous

EPA should conduct a rigorous study on the full environmental impacts of a dramatic shift to BEV with respect to other environmental media (i.e., non-air pollutants/contaminants), since the proposed rule is designed to more or less force transition to that vehicle technology. The European Environmental Agency (EEA) issued a report in 2018 that reveals the far higher "Human Toxicity Potential" of BEVs, largely from mining the mineral requirements for EV manufacturing (https://www.eea.europa.eu/publications/electric-vehicles-from-life-cycle). Note especially Figure 6.2 on page 58 that even if BEVs are charged with 100% RE (i.e., eliminating the "In-use phase" segments of the BEV bars in the graph), human toxicity impacts are still over twice as high. Ecotoxicity is also higher even if BEVs are charged with 100% RE (Figure 6.3). This is supported by a publically-available European LCA model "carculator" (https://carculator.psi.ch/). Damages to environmental media other than air should also be taken into account when a shift to a substantially different vehicle technology is expected, even if some of that contamination currently is non-domestic. [EPA-HQ-OAR-2022-0829-0490, pp. 1-2]

A peer-reviewed study in 2018 (https://onlinelibrary.wiley.com/doi/10.1111/jiec.12862, Figure 1) also demonstrated the far higher human toxicity impacts of BEV. Even in extremely clean future electric grid scenarios (denoted by dotted lines (generally corresponding to the RCP2.6 scenario in the IPCC AR5)), "Human Toxicity" remains ~3 times higher for BEV in the same electric grid mix scenario. Note also that "Particle matter formation" is higher for BEV than ICEV in all but the cleanest future grid mix scenarios, disputing the BEV air quality benefits claims. [EPA-HQ-OAR-2022-0829-0490, pp. 1-2]

The 2023 study in California concludes that "…our results indicate that the CVRP [clean vehicle rebate project] has displaced emissions from vehicle tailpipes to electric generating units, leading to a net increase in primary PM2.5 emissions across the state of California…. [EPA-HQ-OAR-2022-0829-0490, pp. 2-3]

…Of particular concern for environmental justice and public health is the finding that Disadvantaged Communities, as defined according to CalEnviroScreen 4.0, are disproportionately more likely to experience either larger net increases or smaller net reductions in primary PM2.5, NOX, and SO2 emissions as a result of the CVRP…." That's considering California's current electric grid, which is among the cleanest in the U.S. This is counter to the stated goals of the proposed regulation. [EPA-HQ-OAR-2022-0829-0490, pp. 2-3]

These studies come on the heels of a 2010 study by the National Academy of Sciences (National Research Council -https://www.nationalacademies.org/news/2009/10/report-examines-hidden-costs-of-energy-production-and-use), which concluded... Organization: Arizona State Legislature

EPA's proposed rule for light-duty and medium-duty vehicles will cost jobs, increase the price of goods, hurt families, threaten our electric grid's reliability, and endanger our national security. We are both elected representatives of the people of Arizona, and citizens of Arizona who purchase and operate vehicles and participate in the Arizona economy on the same footing as other Arizonans. In both capacities, we have grave concerns about this reckless proposed rule. EPA should reject the proposed rule for at least the ten reasons set forth in this comment. [EPA-HQ-OAR-2022-0829-0537, p. 2]

9. The proposed rule makes erroneous estimates about grid reliability. Current grid-reliability issues and estimates of electricity needs contradict EPA's view that the proposed rule will only cause a "modest increase in electricity demand." [EPA-HQ-OAR-2022-0829-0537, p. 3]

IX. The proposed rule is arbitrary and capricious because of erroneous estimates about grid reliability.

EPA estimates that the additional electricity generation needed to meet the demand of battery electric vehicles is "relatively modest." 88 Fed. Reg. 29,311. According to EPA's estimates, "the proposal is estimated to increase electric power end use by electric vehicles by between 0.1% (2028) and 4.2% (2055)." Id. EPA argues that the electric grid supported adoption of air conditioners and data processing centers successfully. Id. EPA concludes that "the expected increase in electric power demand attributable to vehicle electrification is not expected to adversely affect grid reliability due to the modest increase in electricity demand associated with electric vehicle charging." Id. [EPA-HQ-OAR-2022-0829-0537, p. 27]

The electric grid is already stretched to the breaking point before implementing the proposed rule. According to the North American Electric Reliability Corporation's 2023 Summer Reliability Assessment, numerous sectors of the electric grid face shortfalls during peak demand this summer: [EPA-HQ-OAR-2022-0829-0537, pp. 27-28]

-Midcontinent ISO (MISO): "MISO can face challenges in meeting above-normal peak demand if wind generator energy output is lower than expected. Furthermore, the need for external (non-firm) supply assistance during more extreme demand levels will depend largely on wind energy output."39 [EPA-HQ-OAR-2022-0829-0537, pp. 27-28]

39 North American Electric Reliability Corporation, 2023 Summer Reliability Assessment, May 2023, 5, available at https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_SRA_2023.pdf.

-NPCC-New England: “Operating procedures for obtaining emergency resources or non-firm supplies from neighboring areas are likely to be needed during more extreme demand or low resource conditions.”40 [EPA-HQ-OAR-2022-0829-0537, pp. 27-28]

40 Id.

-SERC-Central: “Compared to the summer of 2022, forecasted peak demand has risen by over 950 MW while growth in anticipated resources has been flat. The assessment area is expected to have sufficient supply for normal peak demand while demand-side management or other operating mitigations can be expected for above-normal demand or high generator-outage conditions.”41 [EPA-HQ-OAR-2022-0829-0537, pp. 27-28]

41 Id.

-Southwest Power Pool (SPP): “Reserve margins have also fallen in SPP as a result of increasing peak demand and declining anticipated resources. Like MISO, the energy output of SPP’s wind generators during periods of high demand is a key factor in determining whether there is sufficient electricity supply on the system.”42 [EPA-HQ-OAR-2022-0829-0537, pp. 27-28]

42 Id.

-Texas (ERCOT): “Resources are adequate for peak demand of the average summer; however, dispatchable generation may not be sufficient to meet reserves during an extreme heat-wave that is accompanied by low winds.”43 [EPA-HQ-OAR-2022-0829-0537, pp. 27-28]

43 Id.

-U.S. Western Interconnection: “However, wide-area heat events can expose the WECC assessment areas of California/Mexico (CA/MX), Northwest (NW), and Southwest (SW) to risk of energy supply shortfall as each area relies on regional transfers to meet demand at peak and the late afternoon to evening hours when energy output from the area’s vast solar PV resources are diminished.” [EPA-HQ-OAR-2022-0829-0537, pp. 27-28]

44 Id.

Almost all of these sectors are projected to have fewer resources than demand during extreme heat conditions.45 Power outages reached an all-time high in 2020, and the average person went seven hours without power in 2021.46 [EPA-HQ-OAR-2022-0829-0537, p. 28]

Other observers recognize significant issues with the current electric grid’s reliability. A commissioner to the Federal Energy Regulatory Commission recently testified to a U.S. Senate committee, “The United States is heading for a reliability crisis.”47 Another commissioner echoed this warning, testifying, “We know that there is a looming resource adequacy crisis.” The commissioner predicted that “there will be, in time, a catastrophic reliability event.” [EPA-HQ-OAR-2022-0829-0537, p. 28]

EPA has only exacerbated the threats to grid reliability by proposing new carbon pollution standards for coal and natural-gas fired power plants in May 2023.50 The National Rural Electric Cooperative Association is "concerned the proposal could disrupt domestic energy security, force critical, always-available power plants into early retirement and make new natural gas plants exceedingly difficult to permit, site and build."51 This is consistent with a FERC commissioner's concern that "[t]he problem generally is not the addition of intermittent resources, primarily wind and solar, but the far too rapid subtraction of dispatchable resources, especially coal and gas."52 As the Electric Power Supply Association observed upon release of the proposed power plant rule, "For the EPA to issue proposed rules that are likely to drive power plant retirements while simultaneously undertaking separate actions to significantly increase demand for electricity due to electrification of the nation's vehicle fleet creates the conditions for a reliability failure We are not slow walking into a reliability crisis – if this rule is finalized, we will be choosing to run toward that outcome."53 [EPA-HQ-OAR-2022-0829-0537, p. 29]

50 U.S. EPA, "EPA Proposes New Carbon Pollution Standards for Fossil Fuel-Fired Power Plants to Tackle the Climate Crisis and Protect Public Health," May 11, 2023, available at https://www.epa.gov/newsreleases/epa-proposes-new-carbon-pollution-standards-fossil-fuel-fired-power-plants-tackle.

51 National Rural Electric Cooperative Association, "Electric Co-ops: EPA's Power Plant Proposal Would Further Jeopardize Reliability," May 11, 2023, available at https://www.electric.coop/electric-co-ops-epas-power-plant-proposal-would-further-jeopardize-reliability.

53 Electric Power Supply Association, "Proposed EPA Power Plant Rules Could Intensify Reliability Challenges," May 11, 2023, available at https://epsa.org/proposed-epa-power-plant-rule-could-intensify-reliability-challenges/.

Into the face of these EPA-exacerbated grid reliability issues come EPA's electric vehicle rules, and many electricity requirement estimates are far less optimistic than EPA's. Before the electric vehicle rules, the U.S. Energy Information Administration was forecasting that "electricity consumption by the transportation sector will increase by more than a factor of 12 between 2021 and 2050 (from 12 billion kWh in 2021 to more than 145 billion kWh in 2050)."54 The American Research Transportation Institute estimates that full electrification of the country's passenger cars and trucks will require a 26.3 percent increase in existing electricity generation.55 When combined with the needs for electricity generation for freight trucks, which EPA is separately proposing, the country needs to increase its existing electricity generation by more than 40%.56 California needs to increase its existing electricity generation by more than 57%.57 [EPA-HQ-OAR-2022-0829-0537, p. 29]

EPA's mandate could require automobile manufacturers to sell 10-12 million electric vehicles in calendar year 2035 alone.58 Millions more would be sold in the years before that. According to a study conducted for the Department of Energy that modeled grid impacts in 2028 from electric vehicles, "The results indicated that the first issues would occur between 30 and 37 million EVs, at which point load could not be reliably met."59 [EPA-HQ-OAR-2022-0829-0537, pp. 29-30]

59 M. Kintner-Meyer et al., Electric Vehicles at Scale – Phase I Analysis: High EV Adoption Impacts on the Western U.S. Power Grid, PNNL Report 29894, July 2020, available at https://www.pnnl.gov/sites/default/files/media/file/EV-AT-SCALE_1_IMPACTS_final.pdf.

EPA has failed to consider the significant grid reliability issues caused by its interconnected proposals that increase electricity demand while decreasing electricity supply. [EPA-HQ-OAR-2022-0829-0537, pp. 29-30]

Conclusion

EPA's proposed rule will hurt Arizona families and workers by forcing them to buy vehicles they cannot afford, increasing the cost of goods they need, costing them jobs, decreasing the reliability of the electricity they depend on, and weakening our national security by making us dependent on China. EPA's green dream will be a nightmare for Arizona. EPA should reject the proposed rule and begin acting in the best interests of Arizonans and Americans. [EPA-HQ-OAR-2022-0829-0537, p. 32]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Vehicle-to-Infrastructure Integration

As the infrastructure for BEVs expands and becomes more standardized, vehicles themselves have a role in providing a reliable, consistent, and convenient charging experience for consumers. BEVs also have the unique opportunity to support grid stability in the future through "vehicle-to-grid" systems. However, to broadly realize these consumer and grid service benefits, vehicles must be able to communicate with the chargers themselves, known as electric vehicle supply equipment (EVSE), in a standardized way. [EPA-HQ-OAR-2022-0829-0780, pp. 43-44]

International Organization for Standardization (ISO) 15118 is a set of communication and charging management standards intended for use between vehicles and EVSE, including a customer convenience feature referred to as Plug & Charge. To help ensure consistent and successful use of charging infrastructure, CARB recommends that U.S. EPA require manufacturers to integrate these industry-developed standards into the design of future BEVs. CARB notes that several automakers have already introduced or will introduce U.S. vehicles that can support some portions of these standards, especially the Plug & Charge feature, including Audi, BMW, Daimler, Porsche, Lucid, Volkswagen, 60 and Ford. 61 Standardized deployment of vehicle-to-infrastructure communication across the industry will reduce barriers to BEV adoption and maximize benefits. [EPA-HQ-OAR-2022-0829-0780, pp. 43-44]

60 In a joint comment to the California Public Utilities Commission on its February 2018 Staff Report on the Vehicle-Grid Integration (VGI) Communication Protocol Working Group, Audi, BMW, Daimler, Lucid, Porsche, and VW stated their intention to implement ISO 15118 on their future vehicles, including the Plug & Charge feature. https://www.cpuc.ca.gov/-/media/cpuc-website/files/legacyfiles/o/6442457082-oems-final-comments-vgi-wg-draft-report-correction-v2.pdf

61 Ford. “Charging Your Mustang Mach-E.” https://www.ford.com/mustang/ev-charging/mache/. Accessed June 15, 2023.

Specifically, CARB recommends that, for future BEVs, U.S. EPA require manufacturers to: [EPA-HQ-OAR-2022-0829-0780, pp. 43-44]

- Implement and conform to ISO 15118-3 Vehicle to grid communication interface – Part 3: physical and data link layer requirements, 62 [EPA-HQ-OAR-2022-0829-0780, pp. 43-44]

- Implement and conform to ISO 15118-2 Vehicle to grid communication interface – Part 2: Network and application protocol requirements 63 and ISO 15118-20 Vehicle to grid communication interface: Part 20: 2nd generation network layer and application layer requirements, 64 and [EPA-HQ-OAR-2022-0829-0780, pp. 43-44]

- Demonstrate successful results for each certified vehicle configuration with ISO 15118-4 Vehicle to grid communication interface – Part 4: Network and application protocol conformance test 65 and ISO 15118-5 Vehicle to grid communication interface – Part 5: Physical layer and data link layer conformance test. 66 [EPA-HQ-OAR-2022-0829-0780, pp. 43-44]

62 ISO 15118-3:2015.

63 ISO 15118-2:2014.

64 ISO 15118-20:2022.

65 ISO 15118-4:2018.

66 ISO 15118-5:2018.

CARB notes several important benefits associated with widespread deployment of harmonized communication standards between the vehicle and the charging infrastructure. First, drivers will see the benefit of a simplified public charging user experience. Plug & Charge allows drivers to establish their electric charging preferences and input payment information once, providing a more seamless charging experience. With widespread implementation of Plug & Charge, drivers charging their vehicle at a compatible public EVSE will be able to simply plug in their vehicle and walk away while the vehicle and the EVSE communicate and manage the charging session accordingly. [EPA-HQ-OAR-2022-0829-0780, pp. 44-45]

Second, vehicle-to-grid connectivity could enable BEVs to provide important grid services. Implementation of the communications protocols outlined in the suite of ISO 15118 standards is a key step to enable this functionality by ensuring that the vehicle and the EVSE are coordinated on the bi-directional flow of electricity during grid support services. CARB agrees with U.S. EPA's findings that grid reliability is not expected to be adversely affected by the modest increase in electricity demand associated with electric vehicle charging. 67 California's grid has historically expanded and evolved as consumer demand for electricity services has grown, including with the recent emergence of electric vehicles. This trend is reflected in the historical expansion of the national grid as noted in U.S. EPA's proposal. However, BEVs can further support grid resilience with their unique ability to fuel on a flexible schedule depending on the driver's and the grid's needs. Drivers with access to residential charging could also realize greater opportunities to reduce their total cost of ownership by potentially selling electricity back to the grid or powering their homes during peak times. Furthermore, BEVs have already been demonstrated to be able to function as back-up power devices during emergencies, and standardized implementation of this protocol could make such activities even more seamless in the future. [EPA-HQ-OAR-2022-0829-0780, pp. 44-45]

67 CARB. Response to Comments on the Draft Environmental Analysis Prepared for the Advanced Clean Cars II Program. August 2022. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/accii/acciirtc1.pdf.

Third, requiring implementation of these communication standards on the vehicle aligns with—and maximizes the benefits from—recent infrastructure planning and funding. The federal government is making unprecedented investments in charging infrastructure through the Infrastructure Investment Jobs Act. The law set aside $5 billion to build a National Electric Vehicle Infrastructure (NEVI) network that will enable widespread travel across the nation. 68 As part of deploying the NEVI funds, the Joint Office of Transportation and Energy set minimum requirements that NEVI-funded EVSE must meet including minimum payment standards, minimum power, minimum number of ports, and collection of reliability metrics. One of these requirements is the implementation of Plug & Charge on direct current fast chargers (DCFC), utilizing the ISO 15118 suite of standards outlined above. 69 The California Energy Commission is also taking steps in this direction by requiring public chargers it partially or fully funds to install EVSE designed to be compatible with the ISO 15118 suite of standards. 70 Matching vehicle requirements with NEVI implementation will harmonize communication flow between vehicles and charging stations, reducing the number of potential points of failure to communicate in the charging ecosystem. [EPA-HQ-OAR-2022-0829-0780, pp. 44-45]

68 Public Law No. 117-58. Available at: https://www.congress.gov/117/plaws/publ58/PLAW-117publ58.pdf. Accessed June 15, 2023.

In addition to individual cost savings and broader economic growth, U.S. EPA's proposal will provide economic benefits for the nation's energy systems. For example, increased ZEV deployment will reduce our reliance on foreign oil, providing economic resilience to global fuel supply chain disruptions and price shocks. With the integration of emerging vehicle-to-grid communication strategies, as CARB recommends, vehicles will be able to promote grid resilience through enabling demand response load management strategies, providing backup power during blackouts, and supporting storage of renewable energy. [EPA-HQ-OAR-2022-0829-0780, pp. 66-67]

Organization: California Attorney General's Office, et al.

These state and local actors are also at the forefront of innovative and emerging solutions to managing grid load, including through EVs, such as “vehicle-to-grid” (“V2G”) technology,151 demand response and distributed energy resource programs,152 and vehicle-integrated microgrids.153 For example, the California PUC is actively investing in V2G technologies, which allow electric vehicles to supply power back to the grid and thereby promote reliability.154 One 2019 study estimated potential benefits to ratepayers from these ancillary services at $670 million to $1.02 billion per year from V2G services.155 [EPA-HQ-OAR-2022-0829-0746, pp. 25]

Second, state and local agencies are implementing ambitious programs to ready power grids and charging infrastructure for the increased adoption of electric vehicles and the associated increase in electricity demand, which further supports EPA’s feasibility analysis. [EPA-HQ-OAR-2022-0829-0746, p. 33]

2. State and Local Actions Are Facilitating the Necessary Generation, Transmission, and Charging Infrastructure to Support the Projected Compliance Pathway

While EPA only needs to consider the costs of regulatory compliance incurred within the allotted lead time, Coalition for Responsible Regulation, 684 F.3d at 128, EPA also considers the demands on the power sector from projected compliance with the proposed and alternative standards. 88 Fed. Reg. 29,309-312. We agree with EPA’s assessment that the projected modest increase in electricity demand (0.04 to 2% over the course of the regulated model years) is more than manageable. This is especially true when compared to other historical and current examples of rapid demand increases that the power sector successfully met, see 88 Fed. Reg. at 29,311 (noting widespread adoption of air conditioning in 1960s and 1970s and 21st-century growth of data centers and server farms),188 and given Congress's significant investments in transmission, generation, and charging infrastructure in the Bipartisan Infrastructure Law's NEVI Formula Program and the Inflation Reduction Act. Draft RIA, at 5-14 (Tables 5-2 & 5-3); 88 Fed. Reg. at 29,307-08. Part D.2 of the Background section, supra at 21-25, provides examples of some of the actions our States and Cities are taking, including under the NEVI Formula Program, to ensure there is sufficient charging infrastructure to support the projected electric vehicle penetration rate. [EPA-HQ-OAR-2022-0829-0746, p. 35]

188 See also White House Office of Science and Technology Policy, Climate and Energy Implications of Crypto-Assets in the United States (Sep. 2022), at 14-15, available at https://www.whitehouse.gov/wp-content/uploads/2022/09/09-2022-Crypto-Assets-and-Climate-Report.pdf (estimating U.S.-based cryptocurrency mining operations for Bitcoin alone to consume "33 to 55 billion kWh per year, or 0.9% to 1.4% of total U.S. electricity usage in 2021").

In addition to the federal agencies that ensure the safety and reliability of U.S. power grids, EPA properly recognizes that many of the decisions that affect the power sector's response to widespread electric vehicle adoption will be made by non-federal entities. States, RTOs/ISOs, public utility commissions, and public and private utilities have the responsibility to ensure adequate supply, transmission capacity, and grid resiliency. 88 Fed. Reg. at 29,311; see 16 U.S.C. §§ 824(a), (b)(1), and are at the forefront of developing vehicle-to-grid applications and other grid management solutions. Part D.2 of the Background section, supra at 21-25, details many of the initiatives that states and other non-federal actors are taking to meet the transition. [EPA-HQ-OAR-2022-0829-0746, p. 35]

Organization: Charles Forsberg

Impact on the electricity grid. Fossil fuels provide two services to the electricity grid: energy and energy storage. Fossil fuel energy storage is on the scale of millions of gigawatt hours. Moving off liquid hydrocarbon fuels to electricity implies moving to the most expensive energy source to produce, store and transport. Replacing the hourly to seasonal storage function in the electricity system with batteries has cost estimates of tens of trillions of dollars. Because of the cost difference in energy storage and transport by liquid fuels versus electricity, there is a massive functional and cost difference between hybrid plug-in electric vehicles and all-electric vehicles. All electric vehicles force hourly to seasonal storage onto the electricity grid whereas hybrid plug-in electric vehicles enable use of liquid hydrocarbons to provide these storage and transport functions when the electricity grid is stressed. Plug-in hybrid vehicles can be "good citizen" electricity customers by buying electricity when generating capacity is available and the electricity grid is not overloaded because they have liquid hydrocarbon fuel backup. Battery electric vehicles raise electricity rates because need very expensive upgrades to assure recharging on an hourly to seasonal basis. The paper below goes into these energy storage cost challenges. [EPA-HQ-OAR-2022-0829-0738, pp. 2-3]

C. Forsberg, "Addressing the Low-Carbon Million Gigawatt-Hour Energy Storage Challenge", The Electricity Journal, December 2021. https://doi.org/10.1016/j.tej.2021.107042 [EPA-HQ-OAR-2022-0829-0738, pp. 2-3]

Recommended action for EPA. Conduct a detailed analysis on impacts of different electric vehicle options on U.S. electricity prices-including separate analysis of the effects of full-deployment plug-in hybrid versus all electric vehicles. This must include multi-year hourly analysis to include seasonal and more extreme events that only occur every few years. This far, nobody has done such an analysis. There are radically different outcomes in terms of electricity prices for everyone from the use of hybrid/plug-in hybrid versus all-electric vehicles that is not recognized by EPA. Such analysis will likely make the case that the U.S. should not provide any regulatory or financial incentives to all-electric vehicles because of the resulting increases in U.S. electricity prices. [EPA-HQ-OAR-2022-0829-0738, pp. 2-3]

Organization: Chevron

4. Feasibility and implementation.

Chevron is concerned that the rapid increases in forecasted BEV sales rate are optimistic and may overstate the benefits of the proposals. The proposals may limit choices and increase costs for consumers, including those in economically disadvantaged groups and smaller businesses. [EPA-HQ-OAR-2022-0829-0553, p. 6]

BEV sales forecasts may rely on optimistic expectations for increased electricity generation and charging infrastructure. EPA should conduct an assessment to account for the costs and timing associated with upgrades to the nation's grid infrastructure, including new and upgraded generation, transmission, and distribution, and the costs associated with the installation of public and private electric vehicle chargers. If it is not feasible to complete expansion and improvements for the current grid, it may not be possible to meet the additional demand created by the proposed regulation. [EPA-HQ-OAR-2022-0829-0553, p. 6]

Organization: Clean Fuels Development Coalition et al.

These aggregate costs include: [EPA-HQ-OAR-2022-0829-0712, pp. 5-6]

-Electric power costs. Researchers estimate that the 350 million electric vehicles required to decarbonize the U.S. fleet by 2050 could use as much as half of U.S. national electricity demand. See Thea Riofrancos et al., Achieving Zero Emissions with More Mobility and Less Mining, U.C. Davis Climate+ Community Project (Jan. 2023), https://subscriber.politicopro.com/eenews/f/eenews/?id=00000185-e562-de44-a7bf-ed7751a00000. The proposal would hence amount to a complete transformation of the electric power sector, requiring substantially more generation, transmission, and distribution, which in turn would result in higher power prices not just for those using electrified vehicles, but for all users. [EPA-HQ-OAR-2022-0829-0712, pp. 5-6]

-Air quality effects. These include the air quality and health impacts from significant increases in tire wear from electric vehicles, as well as the increases in CO_2 emissions that will result from manufacturing more electric generation infrastructure, transmission, distribution, and charging equipment, and the manufacturing of electric vehicles themselves, which produce far more upstream emissions than their internal combustion engine counterparts. [EPA-HQ-OAR-2022-0829-0712, pp. 6-7]

-Taxpayer subsidies: Taxpayers subsidize the sales of electric vehicles, charging infrastructure, roads, and the electricity generation, transmission, and distribution required to power these vehicles. The proposal currently ignores these costs, counting them instead as "transfers."5 88 Fed. Reg. 29,369. [EPA-HQ-OAR-2022-0829-0712, pp. 6-7]

5 As described below, the many direct subsidies (federal and state electric vehicle credits, charging credits, etc.) and regulatory subsidies (EPA multiplier credits, NHTSA multiplier credits, state ZEV credits, etc.) result in real costs to taxpayers and the consumers of the many products that cross-subsidize these "preferred" products. These costs cannot be treated as "transfers" that are cost-free, and they absolutely cannot be treated as "transfers" to circumvent the economic significance prong of the major questions doctrine.

F. The proposed rule neglects the impact of EPA's many other proposed rules on these rules.

Problems with critical minerals and charging infrastructure are made worse when coupled with EPA's proposed heavy-duty vehicle rule, which will compete with the light-and medium-duty market for minerals, batteries, charging infrastructure, and more. EPA has entirely ignored this. See DRIA 5-30 n.107 ("Estimates above do not include PEV charging demand for medium-duty or heavy-duty vehicles."). EPA must account for how these parallel standards will increase the demand for the above and thus raise prices or provide other barriers. [EPA-HQ-OAR-2022-0829-0712, pp. 31-32]

EPA has also failed to confront the interaction of its proposed standards with its standards for electricity generating units—critical to powering electric vehicles— and how these standards and a surge of electric vehicles will interact with an increasingly unreliable grid. EPA has proposed new carbon pollution standards for coal and natural gas-fired power plants. "New Source Performance Standards for Greenhouse Gas Emissions From New, Modified, and Reconstructed Fossil Fuel-Fired Electric Generating Units; Emission Guidelines for Greenhouse Gas Emissions From Existing Fossil Fuel-Fired Electric Generating Units; and Repeal of the Affordable Clean Energy Rule," 88 Fed. Reg. 33,240 (May 23, 2023). Among other things, this proposal assumes it would cause all coal facilities to close by 2040 or implement—largely unproven—carbon capture and storage technology with at least a 90 percent capture rate. The proposal would also require the use of hydrogen blending or carbon capture in all natural gas plants. [EPA-HQ-OAR-2022-0829-0712, pp. 31-32]

These new rules will drive up electricity costs—by adding large new expenses to the coal and gas the currently provides a majority of our nation's electricity—and reduce grid reliability by driving offline the large thermal generation sources that provide most of our electric grid's reliable power. Grid reliability is a serious concern. A decline in steady thermal sources like coal makes our grid susceptible to the "fatal trifecta": "overreliance on weather-dependent solar and wind, just-in-time natural-gas backstops, and imports of electricity from neighboring states." Michael Buschbacher & Taylor Myers, FERC Gaslights America, American Conservative (Sep. 6, 2022), https://www.theamericanconservative.com/ferc-gaslights-america/. [EPA-HQ-OAR-2022-0829-0712, pp. 31-32]

The effects of decreasing baseload power are already being felt. The North American Electric Reliability Corporation's ("NERC") most recent Long-Term Risk Assessment found that found that most of the country is already at elevated risk of blackouts, with some regions being at high-risk during even normal peak conditions. 2022 Long-Term Reliability Assessment, North American Electric Reliability Corporation (Dec. 2022), https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2022.pdf. These problems are exacerbated by rules like EPA's proposed power plant rule because those rules drive the adoption of less reliable intermittent resources like solar and wind. NERC explained that "[a]s solar decreases as sunset approaches, the total of all available resources can fall short of the demand, especially [during] higher demand levels." Id. [EPA-HQ-OAR-2022-0829-0712, p. 32]

Reliability concerns are also exacerbated by the increasing penetration of electric vehicles in the nation's automotive fleet. A recent NERC report explained that when upticks in electrical vehicle charging coincide with increasingly frequent grid disturbances in the bulk power system. Electric Vehicle Dynamic Charging Performance Characteristics during Bulk Power System Disturbances, North American Electric Reliability Corporation (Apr. 10, 2023), https://www.nerc.com/comm/RSTC/Documents/Grid_Friendly_EV_Charging_Recommendations.pdf. When these events coincide they could "have catastrophic consequences for grid reliability if left un checked (i.e., cascading blackouts and widespread power interruptions)." Id. [EPA-HQ-OAR-2022-0829-0712, p. 32]

The proposal fails to confront these issues and instead waves away concerns about grid reliability by explaining that "U.S. electric power utilities routinely up-grade the nation's electric power system to improve grid reliability and to meet new electric power demand." 88 Fed. Reg. 29,311. This explanation is inadequate. If the Biden Administration is going to adopt a "whole of government" approach to environmental rulemaking, it must consider the interaction of all of those rules. [EPA-HQ-OAR-2022-0829-0712, p. 32]

Even by its own logic, EPA's rule fails because it fails to account for decreased energy security owing to an increased demand for natural gas, which currently makes up 40 percent of our grid's electricity generation. This share—or at least the volume of energy generated—will need to grow dramatically to make up for the increased electricity demand.19 [EPA-HQ-OAR-2022-0829-0712, p. 36]

19 Of course, "[t]he United States is [also] the leading producer of natural gas," and so increasing reliance on natural gas does little to move the needle on energy security. C. Boyden Gray, American Energy, Chinese Ambition, and Climate Realism, 5 American Affairs Journal (Winter 2021), https://americanaffairsjournal.org/2021/11/american-energy-chinese-ambition-and-climate-realism/. But if the proposal intends to count decreases in petroleum in its favor it is completely unreasonable to ignore the concomitant increases in natural gas consumption.

Organization: Consumer Energy Alliance (CEA)

By requiring up to two-thirds of new vehicles sold in the United States to be electric by 2032, over 48 billion kWh of electricity consumption would be added every year to replace only light duty vehicles. Ultimately, seeing two-thirds of the current ICE-powered vehicle fleet transition to EV's would increase electricity consumption by 899.5 billion kWh. As a result, the U.S. EPA needs to ask itself from where this generation is going to come? [EPA-HQ-OAR-2022-0829-0788, p. 2]

In addition to increased electric generation capacity, what kind of improvements to electric transmission and distribution infrastructure will be required to serve this increased electricity demand? Who pays for these upgrades -including the electric vehicle charging infrastructure necessary to serve the additional of 9.3 million EVs every year reliably and affordably? [EPA-HQ-OAR-2022-0829-0788, p. 2]

Organization: Daniel Hellebuyck

Aside from the well publicized drawbacks of electric vehicles (EVs) such as range anxiety, long charging times, purchase costs, lack of available and operating charging stations, and replacement of fuel taxes, there are several other issues to consider: [EPA-HQ-OAR-2022-0829-0526, p. 1]

Strained Electrical Grid: While China is developing EVs on a large scale, they are also building up to two coal-powered generating plants a week to ensure there will be enough power to reliably charge the vehicles. Compare this to the dismantling of coal-powered power plants in the United States. There is no assurance that renewable energy sources will be feasible or sufficient enough to replace all the lost coal-based generating capacity in this nation. Already we are seeing rolling blackouts and brownouts in states like California as more EVs hit the grid. [EPA-HQ-OAR-2022-0829-0526, p. 1]

Organization: Delek US Holdings, Inc.

EPA also assumes the power sector is expected to become cleaner over time using wind/solar generation and electricity storage (i.e., batteries), but ignores the environmental impacts of the overall increase in critical minerals demand for electrical grid storage and how that compounds the stress on critical minerals for the ZEVs themselves. However, the expansion of electrical grids—even ignoring the Proposed Rule's increased demand—requires a large amount of earth minerals and metals. Indeed, copper and aluminum—both needed for ZEVs—are also the two main materials in wires and cables and, as described above, higher prices could have a major impact on future grid investments.45 The need for expanded grid capabilities simultaneous to expanded ZEV production places a more pressing demand on materials like copper and aluminum thereby increasing extraction and refining efforts throughout the global market. [EPA-HQ-OAR-2022-0829-0527, pp. 9-10]

45 International Energy Agency, The Role of Critical Minerals in Clean Energy Transitions (Mar. 2022), 77–80, available at https://iea.blob.core.windows.net/assets/ffd2a83b-8c30-4e9d-980a-52b6d9a86fdc/TheRoleofCriticalMineralsinCleanEnergyTransitions.pdf.

Organization: Dylan Ondek

Dear Environmental Protection Agency, I am writing to express my anger at what you are doing for the environment. Going to electric cars is not the way to go. How are we powering the chargers for these electric vehicles? How are you going to stop every single person in the world from stopping driving? It is not going to happen. [EPA-HQ-OAR-2022-0829-5089]

I do agree with some of the things that the EPA is doing. But going to all electric vehicles is not the right move. [EPA-HQ-OAR-2022-0829-5089]

Organization: Edison Electric Institute (EEI)

A. Electric companies can accommodate increased energy demand.

As EPA notes, the electric power sector has a long history of accommodating growth in electricity demand from the adoption of new technologies, including electric home appliances, residential and commercial air conditioning, and data centers. See id. At 25,983. Electricity use from EVs today is modest. Argonne National Lab estimates the approximately 2.3 million EVs on the road as of the end of 2021 consumed 6.1 terawatt-hours of electricity in that year, or about 0.16 percent of the total electric sales to U.S. customers in that year.18 As EPA also notes, the increase in electricity use resulting from the Proposed Rule also will be modest, increasing electricity end-use by less than 3 percent in 2055. See id. On a macro-level, meeting the increased energy usage from electric truck adoption as contemplated in the Proposed Rule will not be a significant challenge for the electric power sector. Meeting the location-specific power needs of large electric vehicle (EV) charging facilities can be a more pressing challenge. [EPA-HQ-OAR-2022-0829-0708, pp. 7-9]

However, this is a challenge that can be addressed with deliberate effort and collaboration among electric companies, fleet operators, and stakeholders.

18 See Gohlke, et al., Assessment of Light-Duty Plug-in Electric Vehicles in the United States, 2010 – 2021, https://publications.anl.gov/anlpubs/2022/11/178584.pdf and U.S. Energy Information Administration, Electric Power Monthly

Electric companies can accommodate localized power needs at the pace of customer demand, provided appropriate customer engagement and enabling policies are in place. The power required by a customer is essential when considering the infrastructure needed at the facility level, because the capacity of the local distribution circuit is sized to meet the peak power requirements of customers on that circuit. Some large EV charging facilities have power requirements in the tens of megawatts (MW). Electric companies are well accustomed to serving facilities with those types of power needs, but large fleet customers differ from traditional electric customers (e.g., commercial or industrial buildings) in several important aspects. These aspects include, but are not limited to: [EPA-HQ-OAR-2022-0829-0708, pp. 7-9]

- Construction timelines: A new, large commercial building with a multi-MW power demand, for example, will typically have a multi-year construction timeline, giving the local electric company time to plan and make appropriate upgrades to the electric distribution system serving that customer. A fleet operator, in contrast, may be able to procure vehicles and complete construction on a multi-MW charging facility in a matter of months. This creates a potential misalignment between the fleet operators' timeline to procure vehicles and charging equipment and the electric company's timeline for making the necessary system upgrades to provide power to that facility. [EPA-HQ-OAR-2022-0829-0708, pp. 7-9]

- Customer familiarity with procuring electric power: Commercial and industrial electric customers are used to working with electric companies for the operation of their facilities as part of their normal course of business, including working with electric companies as part of the construction process for launching new facilities. In particular, national corporate customers often have long-standing relationships with the electric companies that serve them. Electric companies typically assign these customers an account manager, given their scale and complexity. A fleet operator, in contrast, is used to procuring diesel to operate its vehicles, and may consider procuring electricity in the same paradigm. Fleet operators may be small electricity users today and thus that division may not yet be considered a managed account for the electric company. However, EEI members have identified this issue and are expanding their working relationship with these customers. [EPA-HQ-OAR-2022-0829-0708, pp. 7-9]

• Uncertain and dynamic load profiles: The power usage throughout the day, known as the "load profile," of typical commercial and industrial buildings is well understood (e.g., large retail store, data center, or manufacturing facility). Typical load profiles for electric fleet customers are not yet well understood and often hypothetical given the early stage of electric truck commercialization. A fleet charging load profile is the product of many factors, including the routes of the vehicles, the state of charge of the EV when returning to the facility, the number of operating shifts, etc. Unlike a typical commercial building, the load profile of a fleet facility could also drastically change with a change in vehicle operations (e.g., changing from a one-shift to two-shift operation). This uncertainty adds complexity for electric companies when determining how best to serve the power requirements of a fleet customer. [EPA-HQ-OAR-2022-0829-0708, pp. 7-9]

These factors could result in misalignment between expectations and reality regarding the timing, cost, and complexity of procuring electric power for fleet charging. Electric companies are taking a multi-pronged approach to remedy this potential misalignment, as discussed in the following sections. [EPA-HQ-OAR-2022-0829-0708, pp. 7-9]

B. Earlier customer engagement through education and coordination will alleviate infrastructure delays.

Early engagement between the relevant fleet customer and electric company is important as it allows planning for the infrastructure to support EV charging to occur much earlier and accommodate longer lead-times. In 2020, EEI began a collaboration with a large, national corporate customer that was planning to electrify a significant portion of its fleet operation. EEI facilitated meetings for this customer to share its conceptual plans with EEI's members and establish points of contact at the customer and each electric company. Over the course of more than a year, the customer identified the locations within each member's territory where it planned to deploy EVs and developed a five-year forecast to inform the electric company how the power demand would increase at each location over time. This unprecedented level of collaboration has resulted in this customer deploying thousands of electric vehicles to date. This includes alternative locations that were identified by the electric company after consulting with the customer. [EPA-HQ-OAR-2022-0829-0708, pp. 9-10]

The extent of collaboration described in this example may not be feasible, or necessary, for every fleet customer. But it does provide a helpful template for how early engagement and planning can streamline fleet electrification. The Electric Power Research Institute (EPRI) is developing a data-sharing platform as part of its EVs2Scale2030 initiative that will formalize and expand this model by allowing fleet customers to upload their forward-looking fleet electrification plans to a common database.19 Electric companies will then be able to access this data to visualize where on its system upgrades will be needed to accommodate growing power needs from fleet customers. [EPA-HQ-OAR-2022-0829-0708, pp. 9-10]

19 See Electric Power Research Institute, EVs2Scale2030, https://www.epri.com/research/products/000000003002025622.

Many electric companies are developing tools and resources to assist fleet customers. These include, but are not limited to: [EPA-HQ-OAR-2022-0829-0708, pp. 10-11]

• Grid capacity evaluation tools: Several electric companies have launched capacity hosting maps that are available on public websites that illustrate local grid capacity in their service territory.20 These maps can be helpful early indicators for fleet customers when considering the level of upgrades that may be required at a particular facility. These maps have limitations, as they are a snapshot in time and do not substitute for a formal engineering study. Even if they have not published such a capacity map, many electric companies have the ability to assist fleet customers by providing an early screen for local grid capacity by location directly. In either case, the outcome is the same: for customers that have the ability to consider multiple locations for their EV deployment plans, pre-screening the local distribution system capacity at these locations allows the fleet to factor grid upgrade timelines into their deployment plans. [EPA-HQ-OAR-2022-0829-0708, pp. 10-11]

• Fleet assessments and advisory services: Many electric companies have launched programs to provide in-depth consulting services to fleets that are considering electrification, including elements like feasibility studies based on total cost of ownership.21 These programs also may include dedicated staff resources to guide customers through the fleet electrification journey, including choosing the appropriate charging strategy and charging infrastructure to meet their operational needs. These programs help to educate fleet customers about the nuances of procuring power for their fleet operations and allow electric companies to learn more about the expected operations of electric fleets. [EPA-HQ-OAR-2022-0829-0708, pp. 10-11]

20 Examples include: AVANGRID (United Illuminating, NYSEG, Rochester Gas & Electric), Ameren Illinois, Con Edison, Dominion Energy, Eversource, Exelon (Atlantic City Electric, Delmarva Power, Pepco, Comed, PECO), Jersey Central Power & Light, National Grid, Orange & Rockland, Public Service Electric & Gas, San Diego Gas & Electric, and Southern California Edison.

21 See Alliance for Transportation Electrification, Fleet Advisory Services (FAS) for Fleet Electrification: Meet Customer Needs and Provide Grid Benefits, https://evtransportationalliance.org/wp-content/uploads/2023/02/PRESS-ATE-EC-White-Paper.pdf, which includes case studies from DTE Energy, Exelon, Portland General Electric, Southern California Edison, and Xcel Energy.

These and other resources being developed and deployed today by electric companies are essential to ensuring that infrastructure plans and efforts are matched to forthcoming electrification efforts from fleets and other operators. [EPA-HQ-OAR-2022-0829-0708, pp. 10-11]

C. Electric companies are planning for fleet electrification.

Investor-owned electric companies are regulated by state commissions, which approve electric company capital plans to maintain and upgrade the electric grid. While policies vary by state commission, two generally applicable principles have important implications for fleet electrification. First, the “used and useful” standard means that regulators will only approve the electric company to build infrastructure that will be utilized and provide value. The onus is on electric companies to provide evidence that their capital plans will meet this standard. Second is the principle that the customer that incurs the cost must pay for the cost. Typically, a customer seeking new or upgraded electric service must submit a formal service request to the electric company, which prompts the electric company to perform an engineering study to determine the cost of the upgrades needed to provide that service. [EPA-HQ-OAR-2022-0829-0708, pp. 11-13]

The implication for fleet electrification, a potentially fast-growing source of significant new demand on the electric system, is that electric companies are not authorized to upgrade the electric system in anticipation of new demand without robust evidence that those upgrades will be "used and useful." Only when a fleet customer submits a service request is the electric company permitted to make the upgrades necessary to serve that customer. Electric company forecasts for load growth, including that due to electrification, are typically at a system level, not the local distribution system level for individual fleet facilities. Given the nascent commercialization of fleet electrification, there is a lack of visibility into how, where, and when fleet electrification will appear on the system sufficient evidence to give electric companies (and their regulators) confidence to build for it. [EPA-HQ-OAR-2022-0829-0708, pp. 11-13]

Importantly, electric companies are recognizing the risks of this approach and are getting ahead of the need. Given the long lead times to make distribution upgrades, particularly if the upgrades are significant to extend further upstream to the substation and transmission level, it will increasingly be unacceptable to customers to wait for the customer service request-driven process. There is a risk that fleet customers, facing increased regulatory pressure to electrify their fleets, will be unable to plan their businesses around these infrastructure lead times and fail to meet their electrification goals. Electric companies must find mechanisms to plan and build for these increased loads now, so that the power is available when the customer needs them. [EPA-HQ-OAR-2022-0829-0708, pp. 11-13]

In California, the investor-owned electric companies use the California Energy Commission's Integrated Energy Policy Report (IEPR) as their base forecast. Southern California Edison (SCE) in its recent General Rate Case found a significant gap between the electric transportation load growth in the IEPR forecast and that expected due to the state's policies, specifically the California Air Resources Board's Advanced Clean Cars II, Advanced Clean Trucks, and Advanced Clean Fleets rules.22 SCE developed a Transportation Electrification Grid Readiness (TEGR) analysis to account for this gap in its General Rate Case that will set the electric company's grid investments for the next several years. SCE used a top-down methodology to apply this higher forecast to the circuit level for electric transportation loads, as well as a bottom-up methodology for certain high growth areas. [EPA-HQ-OAR-2022-0829-0708, pp. 13-14]

22 See Southern California Edison, 2025 General Rate Case, WP SCE-02, Vol. 07 Bk. A, TEGR Forecast Development Workpaper.

SCE has deployed a variety of new methods to account for HDV development and deployment, including the Power Service Availability (PSA) initiative to support transportation electrification. The PSA initiative, working in concert with the TEGR analysis, focuses on improving SCE's internal processes to streamline interconnection, engaging fleet operators to better understand their plans for electrification, improving their ability to forecast and assess the impacts of load growth from electrification, and leveraging new technologies as grid infrastructure solutions. Because some projects will require more time than others to build, SCE actively encourages fleet owners to engage with them early in the process so that SCE can better understand and plan for their needs. For grid upgrades that require a longer construction schedule, SCE is developing temporary solutions that can deploy quickly while those upgrades are being built. These solutions may include mobile battery storage or a mobile substation brought in on a semi tractor-trailer. [EPA-HQ-OAR-2022-0829-0708, pp. 13-14]

In New York, the Public Service Commission opened a proceeding in April to address barriers to medium-and heavy-duty electric vehicle infrastructure. In particular, the order recognizes that "proactive planning for the grid infrastructure needed to serve future electrification load must anticipate the location and magnitude of future demand" and notes an analogy to previous policies in which the commission directed the electric companies in New York to "develop proactive planning processes to anticipate the need for local transmission and distribution system upgrades to enable the renewable interconnections required to achieve the State's renewable energy goals."23 [EPA-HQ-OAR-2022-0829-0708, pp. 14-15]

23 State of New York Public Service Commission, Case 23-E-0070, Proceeding on Motion of the Commission to Address Barriers to Medium-and Heavy-Duty Electric Vehicle Charging Infrastructure.

EPA's assessment that "there is sufficient time for the infrastructure, especially for depot charging, to gradually increase over the remainder of this decade to levels that support the stringency of the proposed standards for the timeframe they would apply" is accurate. 88 Fed. Reg. 25,999. As seen above, EEI members actively are planning for and deploying infrastructure today. However, the increased deployment of this infrastructure over the next decade and beyond will not happen on its own. Proactive planning processes, whether initiated by the relevant electric company or state regulatory commission, will be critical to accommodate fleet electrification to meet customer expectations and planning requirements, while also providing affordable and reliable service. [EPA-HQ-OAR-2022-0829-0708, pp. 14-15]

EPA specifically requests comment on "whether there are additional stakeholders EPA should work with during implementation of the Phase 3 standards." 88 Fed. Reg. 26,000. EPA, states, engine and truck manufacturers, and fleet operators should work with electric companies on a regional or state level to glean additional insight into their planning processes and help bolster proactive planning and infrastructure investments. As discussed above, electric companies and their regulators benefit from the confidence that fleet electrification load will materialize through additional forward planning and outreach, which also provides visibility into where and when that load will materialize on the system. Final adoption of the Proposed Rule will help provide confidence that fleet electrification will occur through the period of the rule, but at a national level. [EPA-HQ-OAR-2022-0829-0708, p. 15]

Additionally, the States, Congress, EPA, and other federal partners should work with the electric power industry to ensure policies are aligned across the federal government to reduce the cost and timelines associated with building infrastructure to support increased electrification. This includes but is not limited to: [EPA-HQ-OAR-2022-0829-0708, p. 15]

- Investing in domestic manufacturing of critical electrical infrastructure, including efforts to alleviate the labor pool shortage limiting domestic manufacturing of critical electrical infrastructure and provide loan or purchase guarantees to manufacturers. [EPA-HQ-OAR-2022-0829-0708, p. 15]

- Not exacerbating the supply shortage of distribution transformers with unsupported efficiency rules. The U.S. Department of Energy should choose an efficiency standard for transformers that does not require switching to a new type of steel or make a determination that no new standard is needed.24 [EPA-HQ-OAR-2022-0829-0708, p. 15]

- Reforming permitting, both at the bulk power level with respect to building electricity generation and transmission, and at the state and local levels with respect to building distribution infrastructure. [EPA-HQ-OAR-2022-0829-0708, p. 15]

24 EEI's comments are attached as Appendix A.

EEI and its members stand ready to work with our regulatory and legislative partners to ensure these challenges are appropriately addressed. [EPA-HQ-OAR-2022-0829-0708, p. 15]

IV. Electric Company Policies and Programs Can Help Reduce Capital and Operational Costs for Fleet Electrification Customers.

Many EEI members over the last decade have sought regulatory approval from their state regulatory commissions to accelerate transportation electrification by reducing customer barriers to adoption. As of March 2023, and as mentioned supra, electric transportation filings from 62 electric companies in 35 states and Washington, D.C. have totaled more than $4.2 billion. The majority of these investments support the deployment of EV charging infrastructure at customer locations, and a significant portion is targeted to fleet customers. These programs can help reduce the cost that the customer would otherwise pay for the installation of EV charging infrastructure, which is a commonly cited barrier to EV charging infrastructure deployment.25 Further, electric companies can work with fleet customers to help manage their EV charging to occur at non-peak times. This can reduce operational costs for the fleet customer and improve utilization of the electric system, which puts downward pressure on rates for all customers.26 [EPA-HQ-OAR-2022-0829-0708, pp. 16-17]

25 An oft cited barrier to adoption for some customers is the low utilization of EV charging stations. Traditional electric rates for commercial customers include a demand component designed to recover the fixed costs of delivery electricity. With low utilization (such as a public EV charging station or some fleet charging use cases), the effective electric price can be higher than a customer with the same demand but higher utilization. Many electric companies offer or are exploring commercial rates or other programs that reduce some of the demand charge exposure for these low utilization customers. See Cappers, et al., A Snapshot of EV-Specific Rate Designs Among U.S. Investor-Owned Electric Utilities, https://emp.lbl.gov/publications/snapshot-ev-specific-rate-designs.

26 See, e.g., Metz, et al., Distribution System Investments to Enable Medium-and Heavy-Duty Vehicle Electrification – A Case Study of New York, https://www.edf.org/media/worth-investment-report-finds-utilities-fleet-owners-consumers-benefit-when-utilities-cover.

EPA notes that “there is considerable uncertainty associated with future distribution upgrade needs, and in many cases, some costs may be borne by utilities rather than directly incurred by BEV or fleet owners” in explaining why it models these costs as part of the infrastructure cost analysis. 88 Fed. Reg. 25,983. In general, the upgrades to the local electric system needed to bring sufficient power to the site may be known as “electric company-side make-ready” or “front-of-the-meter” infrastructure and includes but is not limited to poles, vaults, service drops, transformers, mounting pads, trenching, conduit, wire, cables, meters, other equipment as necessary, and associated engineering and civil construction work. Front-of-the-meter infrastructure is distinct from infrastructure on the customer side of the meter (“behind-the-meter”), which includes the supply infrastructure (conduit and wiring to bring power from the service connection to the charging station, and the associated installation costs, sometimes known as “customer-side make-ready”) and the charging equipment, sometimes known as Electric Vehicle Supply Equipment (EVSE). [EPA-HQ-OAR-2022-0829-0708, pp. 16-17]

Front-of-the-meter infrastructure is generally installed, owned, and operated by the electric company. However, the costs associated with front-of-the-meter infrastructure may be borne by the site host customer in full or in part if the costs exceed an allowance as determined by the electric company’s line-extension and/or service extension policy. These costs may also be known as “contributions in aid of construction.” [EPA-HQ-OAR-2022-0829-0708, pp. 17-20]

Modeling these front-of-the-meter infrastructure costs is inappropriate for the following reasons. First, estimating distribution upgrade costs may be beyond the scope of EPA's analysis, as it is not clear that a similar scope of analysis is applied to traditional liquid fuels. For example, the analogous cost comparison for internal combustion engine vehicle would include cost considerations for fleet operators either 1) installing refueling stations at their own facilities, or 2) the embedded cost of fuel retailers' business operations in the cost of diesel or gasoline. [EPA-HQ-OAR-2022-0829-0708, pp. 17-20]

Second, as described above, distribution upgrades are highly location specific. The costs associated with these upgrades are also highly variable, depending on the upgrade requested by the customer and the local distribution capacity. As stated in EEI's Preparing to Plug In Your Fleet guide, "the grid can expand as needed to accommodate the needs of any customer, but the time and resources needed to make the required upgrades are highly dependent on the specific facility and the circuit that serves it."27 [EPA-HQ-OAR-2022-0829-0708, pp. 17-20]

27 See EEI, Preparing To Plug In Your Fleet – 10 Things to Consider, https://www.eei.org/-/media/Project/EEI/Documents/Issues-and-Policy/Electric-Transportation/PreparingToPlugInYourFleet.pdf.

Third, the share of any distribution costs that the customer may bear varies as a matter of policy. Some electric companies have or are seeking approval for line extension allowances to cover some or all of these costs for serving EV charging infrastructure. In California, for example, legislation required electric companies in the state to file tariffs that would authorize them to "design and deploy all electrical distribution infrastructure on the utility side of the customer's meter for all customers installing separately metered infrastructure to support charging stations, other than those in single-family residences." This policy prompted tariffs from EEI members Pacific Gas & Electric (PG&E), San Diego Gas & Electric (SDG&E), and SCE that essentially allow electric companies to invest in more of the electric company-side infrastructure costs as part of the standard distribution system investment. [EPA-HQ-OAR-2022-0829-0708, pp. 17-20]

Fourth, EEI expects that the majority of fleets to electrify in the next several years will be those with return-to-base operations, which enables depot charging that is owned and operated by the fleet itself. Public charging, analogous to the existing gas station model, will be needed to serve long-haul electric trucks, but that opportunity will be limited in the near-term by battery capabilities. However, there are many new refueling models emerging, including but not limited to: fleet charging facilities owned by third parties and accessed by fleet operators through a reservation or subscription system; charging-as-a-service companies that disintermediate the fleet operator from the electric company, owning and operating the charging equipment at a customer facility and assessing the fleet operator a fully-bundled, flat charging fee (e.g., $/kWh); and transportation-as-a-service companies that provide the vehicle and charging to a fleet operator, such that the fleet operator pays a fully-bunded, flat service feel (e.g., $/mile). In all of these models, the fleet operator itself is not exposed to the front-of-the-meter infrastructure costs, but rather these costs are borne by a third party that then recoups all of its costs through their charging or service fees. [EPA-HQ-OAR-2022-0829-0708, pp. 17-20]

In conclusion, EPA is justified in not modeling front-of-the meter costs because doing so would result in an apples-to-oranges comparison to liquid fuels, those costs are site-specific and variable, the recovery mechanism of those costs depends upon state-specific policies, and fleet-operators may not always bear those costs. [EPA-HQ-OAR-2022-0829-0708, pp. 17-20]

Organization: Electric Drive Transportation Association (EDTA)

Across the private sector, vehicle manufacturers, materials and components suppliers, utilities, charging companies and other organizations are making investments in the EV supply chain that parallel these critical essential policy drivers. [EPA-HQ-OAR-2022-0829-0589, p. 1]

In the United States, the EV ecosystem is growing. 3.8 million plug-in electric vehicles have been sold since 2010. There are 87 plug-in electric models available today – and automakers have announced an additional 58 models to be rolled out by 2027. [EPA-HQ-OAR-2022-0829-0589, p. 1]

We would also urge the agency to revisit modeling assumptions regarding the proposed plug-in hybrid (PHEV) utility curve to reflect next-generation PHEVs, whose electric range will be significantly larger than those modelled. New PHEVs' driving range increased 8.5% in 2021 and that trend is expected to continue. The increase in all-electric operation capability will change consumer use patterns over the regulated period and the rule for 2027-2032 should reflect that in an updated utility factor. [EPA-HQ-OAR-2022-0829-0589, p. 2]

Achieving the penetration rates envisioned in the proposed scenarios will also require an equally aggressive expansion of charging and refueling infrastructure, and modernization of the electricity grid. [EPA-HQ-OAR-2022-0829-0589, p. 2]

A comprehensive approach to electric transportation will also require updates to the electricity grid, with demand management and V-2-G technologies, which can optimize the use of EV as a mobile load and distributed energy source while building a more secure, efficient, and resilient grid. [EPA-HQ-OAR-2022-0829-0589, p. 2]

These challenges are all addressable and offer opportunities for creating jobs, a more efficient energy sector and more resilient supply chains. They also present as significant variables that may alter the market trajectories undergirding the proposed Multi-Pollutant Emissions standards. [EPA-HQ-OAR-2022-0829-0589, p. 2]

Organization: Elizabeth Boynton

Even if I did want to wait that time, even at home, the grid infrastructure for such increased demand for such a fairly quick jump in EV demand is not there. According to a May 2023 report from The North American Electric Reliability Corporation (NERC), two-thirds of North America could face power shortages this summer during periods of extreme heat. This, combined with this quote from Federal Energy Regulatory Commission member Mark Christie during a May Senate hearing, "I'm afraid to say it, but I think the United States is heading towards a catastrophic situation." [EPA-HQ-OAR-2022-0829-0568, p. 1]

Organization: Energy Innovation

V. The modern electric grid can support widespread transportation electrification of LDVs and MDVs over time. [EPA-HQ-OAR-2022-0829-0561, p. 2]

Fortunately, the Inflation Reduction Act (IRA) and the Bipartisan Infrastructure Law (BIL) helped tip the scale in favor of climate-oriented investments and the adoption of zero-emission technologies,[ii] particularly battery electric vehicles (BEVs), and also hydrogen fuel cell electric vehicles (FCEVs).[iii] [EPA-HQ-OAR-2022-0829-0561, pp. 4-5]

ii This includes technologies that eliminate tailpipe GHG emissions and other pollutants, namely battery electric vehicles (BEVs) for LDVs and MDVs.

iii Based on our analysis and current market trends, we do not anticipate FCEVs will play a sizable role in the LDV and MDV market for the foreseeable future. However, we recognize the value of technology-neutral standards.

Energy Innovation's modeling reveals that the IRA's transportation electrification incentives (combined with infrastructure investments in the BIL) can jump-start transportation decarbonization this decade. However, these federal policies are insufficient to cut the sector's GHG emissions at the pace needed to achieve the U.S. nationally determined contribution (NDC) and to align with the Paris Agreement to limit global warming and achieve net zero by 2050. Mitigating the transportation sector's (especially LDVs and MDVs) impact on the climate and public health will require additional policy and regulatory action in the next decade, including stronger federal tailpipe emissions standards. Our modeling shows that widespread deployment of clean vehicles, powered by a clean grid, can help reduce GHG emissions to meet the U.S. NDC.8 See Figures 1 and 2. [EPA-HQ-OAR-2022-0829-0561, pp. 4-5]

Other research from the University of California, Berkeley, Grid Lab, and Energy Innovation, 2035 2.0: Plummeting Costs and Dramatic Improvements in Batteries Can Accelerate Our Clean Transportation Future (April 2021), evaluated the technical and economic feasibility (and associated impacts and benefits) of achieving a future scenario where electric vehicles make up 100 percent of new sales of all vehicles by 2035, combined with a 90 percent clean grid (called the DRIVE Clean Scenario).[iv] Compared with the No New Policy scenario (which was pre-IRA and BIL), the total transportation sector pollutant[v] and carbon dioxide emissions reductions in the DRIVE Clean Scenario would reduce ground transportation sector CO_2 emissions by 60 percent in 2035 and by 93 percent in 2050, relative to 2020 levels.9 See Figure 3. The DRIVE Clean Scenario would also avoid approximately 150,000 premature deaths and generate nearly $1.3 trillion in health and environmental savings through 2050.10 Compared to the No New Policy, the DRIVE Clean Scenario would also result in approximately $2.7 trillion in consumer savings through 2050 compared—a household savings of about $1000 per year on average over 30 years.11 [EPA-HQ-OAR-2022-0829-0561, pp. 5-6]

[EPA-HQ-OAR-2022-0829-0561, pp. 5-6]

V. THE MODERN ELECTRIC GRID CAN SUPPORT WIDESPREAD TRANSPORTATION ELECTRIFICATION OVER TIME.

As part of its analysis, the EPA modeled "changes to power generation due to the increased electricity demand anticipated in the proposal as part of our upstream analysis. [It] project[s] the additional generation needed to meet the demand of the light-and medium-duty BEVs in the proposal to be relatively modest compared to the No Action case, ranging from less than 0.4 percent in 2030 to approximately 4 percent in 2050 (as shown in Figure 23 [below]). The U.S. electricity end use between the years 1992 and 2021 increased by around 25% without any adverse effects on electric grid reliability or electricity generation capacity shortages. As the proposal is estimated to increase electric power end use by electric vehicles by between 0.1% (2028) and 4.2% (2055) – approximately 18% of the increase that occurred between 1995 and 2021—grid reliability is not expected to be adversely affected by the modest increase in electricity demand associated with electric vehicle charging."63 We concur with this finding. [EPA-HQ-OAR-2022-0829-0561, pp. 24-27]

63 U.S. EPA, "Proposed Rules," May 5, 2023, 29311.

[See original attachment for graph described below] [EPA-HQ-OAR-2022-0829-0561, pp. 24-27]

A similar analysis in the 2035 2.0 study found that the DRIVE Clean Scenario resulted in demand growth from increased electrification averages about 2 percent per year, a growth rate slower than that achieved between 1975 and 2005. See Figure 20. To meet this demand with a 90 percent clean grid (analyzed as part of the DRIVE Clean Scenario), the U.S. would need to install on average 105 GW of new wind and solar and 30 GW of new battery storage each year—nearly four times the current deployment rate.64 See Figure 21. [EPA-HQ-OAR-2022-0829-0561, pp. 24-27]

64 Phadke et al., "2035 2.0: Plummeting Costs and Dramatic Improvements in Batteries Can Accelerate Our Clean Transportation Future."

Even with additional electric loads in the DRIVE Clean Scenario, grid modeling found a 90 percent clean grid would be dependable without coal plants or new natural gas plants by 2035. The grid model also found that during normal periods of generation and demand, wind, solar, and batteries provide 72 percent of total annual generation, while hydropower and nuclear provide 16 percent. During periods of high demand and/or low renewable generation, existing natural gas plants (primarily combined-cycle plants) cost-effectively compensate for remaining mismatches between demand and renewables-plus-battery generation—accounting for about 10 percent of total annual electricity generation. The increased electrification and renewable energy and battery storage deployments require investments mainly in new transmission spurs connecting renewable generation to existing high-capacity transmission, rather than new investments in bulk transmission.65 Of note, the rates of LDV/MDV EV adoption envisioned in the DRIVE Clean Scenario are considerably higher than the adoption rates in the proposed rule, even if a more stringent alternative is finalized. [EPA-HQ-OAR-2022-0829-0561, pp. 24-27]

65 "Transitioning to All-Electric Cars and Trucks Won't Crash the Power Grid," 2035 2.0, https://www.2035report.com/transportation/evsthe-power-grid/.

[See original attachment for graph described below] [EPA-HQ-OAR-2022-0829-0561, pp. 24-27]

The examples the EPA provides in its proposed rule offer useful reminders that increased electric demand from new technologies has, throughout recent history, been met with commensurate increases in investments, grid upgrades, and reinforcements to comply with grid reliability standards. Examples include the rapid adoption of air conditioners in the 1960s and 1970s and the rapid growth of power-intensive data centers and server farms over the past two decades.66 As noted in the proposed rule, the U.S. electric power utilities have already successfully designed and built the distribution system infrastructure required for 1.4 million BEVs and have successfully integrated 46.1 GW of new utility-scale electric generating capacity into the grid between 2020 and 2021.67 The challenges posed by the prospect of gradual growth in ZEVs in the HDV sector over the next decade can be addressed with the continued adoption of policies, regulations, planning, and prudent investments. [EPA-HQ-OAR-2022-0829-0561, pp. 24-27]

Numerous reports articulate what's needed to support a highly electrified transportation future, including Accelerating Clean, Electrified Transportation by 2035: Policy Priorities: A 2035 2.0 Companion Report and the ACEEE State Transportation Electrification Scorecard.68 [EPA-HQ-OAR-2022-0829-0561, pp. 24-27]

68 Peter Huether et al., "2023 Transportation Electrification Scorecard" (American Council for an Energy-Efficient Economy, June 2023), https://www.aceee.org/research-report/t2301.

Finally, more nascent vehicle-to-grid (V2G) technologies, vehicle grid integration (VGI), and managed charging programs have the potential to be game changers for transportation electrification and the electric grid. Certain vehicles are especially well suited to deliver on the promise of V2G, given how they are used and where they are located. V2G can help vehicle and fleet owners recoup energy costs while also meeting power needs during grid constraints. For example, a fleet of electric-powered school buses in El Cajon can send electricity back to California's grid, thanks to V2G technology developed by a San Diego company and a partnership with San Diego Gas & Electric.69 More utilities are working with original equipment manufacturers, fleets, and government officials to adopt V2G technologies and develop V2G programs, and the IRA and BIL both contain funding to support pilots and next-generation R&D.70 The EPA points to several other entities engaged in VGI research.71 [EPA-HQ-OAR-2022-0829-0561, pp. 24-27]

71 U.S. EPA, "Proposed Rules," May 5, 2023, 29311.

Based on other analyses and continued advancements in technologies, we agree strongly with the EPA's finding that the increase in electric power demand attributable to vehicle electrification is not expected to adversely affect grid reliability due to the modest increase in electricity demand associated with EV charging. [EPA-HQ-OAR-2022-0829-0561, pp. 24-27]

Organization: Energy Strategy Coalition

Members of this coalition are already engaging in long-term planning to meet the increased demand for electricity attributable to vehicle electrification, and the LMDV Proposal will provide a regulatory backstop supporting further investments in electrification and grid reliability. Demand for electricity will increase under both the LMDV Proposal and the recently-proposed Phase 3 Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles ("HDV

Proposed Rule”),4 but the electricity grid is capable of planning for and accommodating such demand growth and has previously experienced periods of significant and sustained growth. Moreover, historic growth in demand and generation resources does not reflect the investments that will be made under the Infrastructure Investment and Jobs Act (“IIJA”) and the Inflation Reduction Act (“IRA”) to support the deployment of new renewable and zero-carbon generation resources, energy storage and charging infrastructure. Coalition members are already making investments in the resources and infrastructure needed to support transportation electrification and realize the benefits that integration of EVs can provide to the electricity grid. The Coalition encourages EPA to work closely with state and local partners and other federal agencies to ensure that deployment of this infrastructure occurs on the pace and scale needed to achieve the EV penetration-rates contemplated by these proposals, while ensuring grid reliability. [EPA-HQ-OAR-2022-0829-0610, pp. 1-2]

4 Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles—Phase 3, 88 Fed. Reg. 25,926 (published April 27, 2023).

II. The proposed rule supports long-term planning and investment

Long-term planning and investment for vehicle electrification is a business imperative for the Coalition’s members and a necessary element of their efforts to provide affordable, clean, and reliable power to their customers. By setting a clear trajectory for vehicle electrification that complements existing regulatory and market forces, EPA’s LMDV and HDV proposals facilitate further investment in the generation and charging infrastructure needed to meet increased demand associated with electrification of the vehicle fleet. [EPA-HQ-OAR-2022-0829-0610, pp. 1-2]

Even before the LMDV and HDV proposals, market forces and government incentives were projected to greatly increase the rate of vehicle electrification. As EPA notes, “virtually every major manufacturer of light-duty vehicles is already planning to introduce widespread electrification across their global fleets in the coming years.” 5The IRA is now providing significant incentivies for automakers to accelerate these commitments through generous subsidies for EV purchases. These include up to $7,500 in tax credits for new EVs,6 $4,000 for used EVs,7 as well as incentives for the commercial purchase of light-and medium-duty vehicles.8 The IIJA also provides significant incentives to support vehicle electrification, including $7.5 billion in funding for installation of public charging and other alternative fueling infrastructure,9 and funding for the Department of Energy’s (“DOE”) Building a Better Grid Initiative, which allocates $2.5 billion to support the development of nationally significant transmission lines, $2.3 billion to strengthen and modernize the power grid against wildfires and other extreme weather exacerbated by climate change, and $10.5 billion to improve grid resilience and grid flexibility (including by supporting transmission and distribution infrastructure).10 [EPA-HQ-OAR-2022-0829-0610, pp. 1-2]

8 See 26 U.S. Code § 45W.

9 88 Fed. Reg. at 29,195.

10 See, e.g., Building a Better Grid Initiative, GRID DEPLOYMENT OFFICE, DEPARTMENT OF ENERGY https://www.energy.gov/gdo/building-better-grid-initiative.

Expectations for electrification of the vehicle fleet are already being incorporated into long-term planning decisions of electric utilities, regional transmission organizations and independent system operators. For example, National Grid co-authored a November 2022 study to "support utility long-term capital planning,"19 which assumed that the two states in its service territory (New York and Massachusetts) reached 100% sales of zero-emission passenger vehicles by 2035 and complied with California's Advanced Clean Trucks regulation.20 By providing regulatory certainty needed for long-term resource planning and investment decisions, the proposed LDMV and HDV rules will help ensure that the necessary resources are deployed to accommodate anticipated growth in demand due to electrification of the vehicle fleet. Indeed, such long-term planning has previously made it possible for the electricity grid to accommodate periods of significant and sustained growth,21 including relatively recently.22 Moreover, these historical periods do not reflect the pace and scale of generation growth anticipated as a result of implementation of the IRA and IIJA. [EPA-HQ-OAR-2022-0829-0610, p. 4]

20 Id. at 5.

21 From 1960 to 1980, net generation in the electric power sector increased a remarkable 5.7% per year, with net generation more than tripling from just 756 GWh to 2,286 GWh. See ENERGY INFO. ADMIN., MONTHLY ENERGY REVIEW 134 tbl. 7.2b (May 2023), https://www.eia.gov/totalenergy/data/monthly/pdf/mer.pdf.

22 Between 1995 and 2007, average nationwide generation demand grew approximately 1.9% per year. See id. (noting an increase from 3,194 GWh to 4,005 GWh over this 13-year period).

III. Coalition members are investing in EV charging infrastructure

Members of this Coalition have begun making significant investments in the charging infrastructure for electric passenger cars and trucks: [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

-National Grid recently received approval for a $206 million initiative to enable up to 32,000 additional charging ports in Massachusetts.23

-The New York Power Authority will have up to 400 fast chargers installed or in construction through its EVolve NY program by the end of 2025.24 [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

-The Pacific Gas and Electric Company ("PG&E") has successfully installed through March 2023 over 5,700 charging ports through its EV Charge Network, EV Fleet, EV Fast Charge and EV Schools programs.25 To aid with equity efforts to expand EV charging, PG&E recently launched its Empower EV program, which offers income-eligible households up to $2,500 in financial incentives for the installation of a Level-2 charger and any necessary service panel upgrades,26 as well as its Multifamily Housing and Small Business EV Charger program, which will install Level 1 and Level 2 EV chargers at multifamily housing units, not-for-profit organizations and small businesses, at no cost for sites located in a priority community.27 [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

-Austin Energy provides rebates of up to $1,200 and $4,000 for customers installing Level 2 charging stations at their homes and workplaces respectively.28 [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

-The Sacramento Municipal Utility District ("SMUD") offers up to $1,000 toward residential charging equipment and installation costs through its Charge@Home program.29 [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

-Constellation Energy Corporation's venture arm (Constellation Technology Ventures, or "CTV") has invested in portfolio companies focused on EV and charging infrastructure.30 [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

Footntoe 30: For instance, CTV invested in Qnovo, which offers a solution suite that uses advanced computation to optimize the chemical reactions within lithium-ion batteries, resulting in faster charging, increased daily run times, and longer battery lifetimes. See Constellation Technology Ventures, https://www.constellationenergy.com/our-work/innovation-and-advancement/technology-ventures.html. [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

Coalition members are making these investments in part because of the benefits that EVs can provide to grid reliability. EVs' primary near-term grid benefits stem from their enablement of load shifting—whether from periods of higher load demand to periods of lower load demand, or from periods of more carbon-intensive power generation to periods where more renewable energy is available.31 Load shifting can involve both deferral (to avoid charging during periods of peak load) and more targeted scheduling (to take advantage of periods of excess energy supply).32 In addition to enhancing grid reliability, load shifting can also reduce customer electricity rates, increase the value of renewable energy investments (by maximizing usage of excess solar energy produced during the day), and mitigate the need for equipment upgrades (e.g., increased storage capacity to accommodate excess solar energy).33 [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

For example, PG&E has partnered with the BMW Group to explore ways to incentivize EV drivers to shift their charging times to support grid reliability.34 This program—called ChargeForward— first kicked off in 2015 and moved into its third phase in 2021.35 Building on the success of the first two phases, phase three expanded the program's scope to 3,000 EV drivers (from prior pilots of 100 and 400 drivers in phases one and two).36 Phase two of ChargeForward demonstrated the ability to shift nearly 20% of charging from a particular hour to another time and to shift up to 30% of charging to a particular hour.37 SMUD is also engaged in a managed charging pilot program with BMW, Ford, and GM, and is planning to add Tesla vehicles to the pilot as well, targeting participation of around 2,000 vehicles through 2024.38 [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

Coalition members are also exploring Vehicle-to-Grid ("V2G") technology, through which EVs can send power back to load sources (e.g., homes) and the grid from their batteries. While still in the early stages of development, V2G technology can offer reliability benefits by serving as a grid resource during periods of peak demand.39 PG&E and BMW recently extended their ChargeForward partnership until March 2026 and, as part of that program, will conduct a field trial of V2G-enabled vehicles in order to explore their potential to increase grid reliability.40 In addition, PG&E has announced vehicle-grid integration ("VGI") pilot programs with Ford41 and General Motors to test the ability of EVs to provide backup power to homes.42 SMUD is also in the process of conducting an electric school bus V2G demonstration project with the Twin Rivers Unified School District.43 SMUD is planning to expand the program to additional school districts and is also pursuing other projects to explore V2G capabilities for light-duty EVs.44 [EPA-HQ-OAR-2022-0829-0610, pp. 4-7]

44 Id.

IV. EPA should work closely with state and local partners to ensure deployment of the resources and infrastructure needed to accelerate transportation electrification while maintaining grid reliability [EPA-HQ-OAR-2022-0829-0610, pp. 13-14]

EPA's LMDV Proposal will help support deployment of the charging and generation resources needed to meet anticipated demand from vehicle electrification. Yet effective and efficient deployment of these resources will require coordination among electric utilities, state public utility commissions, and local governments to factor load from EVs into long-range resource planning and to permit the distribution and transmission system upgrades and new generation and storage resources needed to serve that load. To ensure these resources are deployed on the pace and scale needed to support vehicle electrification and grid reliability, EPA should coordinate closely with federal, state and local agenices to remove deployment barriers and emphasize the benefits that vehicle electrification can provide to the electricity grid, public health, and the climate. [EPA-HQ-OAR-2022-0829-0610, pp. 13-14]

Organization: Environmental. and Public Health Organizations

G. Comparison of Utility Impacts

ERM's results also point to the potential for net revenue (revenue in excess of the costs of serving PEV load) from PEV charging to reduce utility bills for all customers (see Figure V G-1). Since most PEV charging can be accomplished when there is spare capacity on the grid, charging can spread the costs of maintaining the system over a greater volume of electricity sales, reducing the per-kilowatt-hour price of electricity to the benefit of all customers. Public utility regulations require additional revenues in excess of authorized revenue to be returned to all utility customers in the form of reduced rates and bills. [EPA-HQ-OAR-2022-0829-0759, p. 33]

Electrifying L/MD vehicles (especially at the levels projected under an Alternative 1+ approach) could lead to between $7.7 to $11.3 billion in net utility revenue, which could reduce electricity rates by 2.1% to 3.1% ($0.004/kWh to $0.006/kWh). This could save the average U.S. household $35 to $60 per year and the average commercial customer $253 to $428 per year on their electricity bills. This phenomenon has already been observed in the real world. PEV drivers have already contributed $1.7 billion in net revenue that has been returned to all utility customers in the form of rates and bills that are lower than they otherwise would have been.115 [EPA-HQ-OAR-2022-0829-0759, p. 33]

115 Synapse Energy. 2022. "Electric Vehicles Are Driving Electric Rates Down." https://www.nrdc.org/sites/default/files/media-uploads/ev_impacts_december_2022_0.pdf.

SEE ORIGINAL COMMENT FOR Figure V.G-1: Incremental Reduced Utility Bills from L/MDV Charging116

116 Id. at 14.

This analysis looks at all of the costs associated with providing and distributing electricity, as well as any revenue based on the identified utility rate from the Energy Information Administration (which is approximately 10.4 cents per kilowatt hour for commercial customers and 12.7 cents per kilowatt hour for residential customers).117 [EPA-HQ-OAR-2022-0829-0759, p. 34]

117 These electricity rates come from EIA's Annual Electric Power Industry Report (Form EIA-861 for 2021), using the State data tab and adding all Sales (MWh) divided by the Revenues (Thousand $) to obtain the average price ($/kWh) for both Residential and Commercial customers. https://www.eia.gov/electricity/data/eia861/

1. Electric system impacts will be gradual and within the range of historical growth.

When considering infrastructure buildout, it is important to remember that L/MD PEVs will enter the total on-road L/MD fleet gradually and in volumes that will remain below in-use L/MD combustion vehicles for the foreseeable future. EPA's data show that the Proposed Standards, if finalized, would likely result in PEVs comprising just 5% of the total on-road L/MD fleet by 2027, gradually reaching 20% in 2032 and 43% in 2040. Similarly, under the more stringent standards we recommend in this comment letter, the transition of the on-road L/MD fleet to PEVs would be gradual, reaching 22% in 2032 and 49% in 2040 (Table XVII.G-1). In other words, a relatively small portion of the L/MD fleet will be tapping into charging and grid infrastructure over the next decade, and even by 2040, L/MD PEVs would comprise less than half of the on-road fleet under this rulemaking. Infrastructure needs for L/MD PEVs will accordingly grow gradually over time. [EPA-HQ-OAR-2022-0829-0759, p. 121]

Table XVII.G-1: L/MD PEVs as a Share of Total On-Road L/MD Fleet, 2026-2040

[See original attachment for Table XVII.G-1]. [EPA-HQ-OAR-2022-0829-0759, pp. 121-122]

Additionally, projected growth in electricity demand over the coming years, including demand related to PEV deployment in line with strengthened L/MD standards as well as additional economy-wide load growth, is well within the range of past historical load growth. EPA provides estimates of system-wide demand, including L/MD PEVs, under both No Action (i.e., baseline) and the Proposed Standards. DRIA at 5-14. These values show that system-wide increases in demand, including both increased demand from the Proposed Standards (assuming EPA finalizes the stringency levels it has proposed) and projected economy-wide load growth, is projected to average 1.6% per year between 2028 and 2040. Furthermore, based on analysis conducted by ERM (see Section V above), it is expected that incremental annual average electricity demand growth associated with PEV penetration in line with Alternative 1+, as compared to EPA's Proposed Standards, would be minimal—i.e., around or less than one tenth of a percentage point. [EPA-HQ-OAR-2022-0829-0759, p. 122]

Maintaining reliable and safe electric power delivery through this level of demand growth, as well as higher levels of growth resulting from more stringent standards, is within electric utility standard practice as demonstrated through the electric power sector's strong track record of reliability and resiliency. These annual generation increases are well within the range of contemporary, normal operations for the U.S. electric sector (see Figure XVII.G-1 below). According to data reported to the Energy Information Administration in Form 861, in the 31 years from 1990 to 2021, average annual national growth in electricity sales was 1.1%. In 15 of those years, growth was 1.5% or higher, and in ten years it exceeded 2%. The U.S. has also seen previous periods of sustained high demand growth across most states; for example, 1995 to 2007 saw average nationwide growth of approximately 1.9% per year. [EPA-HQ-OAR-2022-0829-0759, pp. 122-123]

Many states saw much higher, sustained levels of growth. In the two decades from 1999 to 2018, North Dakota electric sales more than doubled. Year over year growth averaged nearly 5%, and in 2014 electric sales were 14% higher than the previous year alone. In Nevada between 1992 and 2007, annual electric sales growth averaged 4.9% and fell below 1.5% only once. More recently, Virginia has seen strong annual sales growth, with sales increasing 12.3% in the five years from 2016 to 2021, or 3% on average per year, even accounting for a pandemic dip. [EPA-HQ-OAR-2022-0829-0759, p. 123]

This analysis draws similar conclusions to those of the researchers at the Electrification Futures Study, a multi-year research project to explore potential widespread electrification in the future energy system of the United States. In a report developing an integrated understanding of how the potential for electrification might impact the demand side in all major sectors of the U.S. energy system—transportation, residential and commercial buildings, and industry—this study concluded that "[e]lectrification has the potential to significantly increase overall demand for electricity, although even in the High scenario, compound annual electricity consumption growth rates are below long-term historical growth rates."338 And costs associated with integrating PEV charging onto the grid can also be minimized with effective load management programs, as described immediately below. [EPA-HQ-OAR-2022-0829-0759, p. 123]

338 Trieu Mai et al., NREL, Electrification Futures Study: Scenarios of Electric Technology Adoption and Power Consumption for the United States (2018), https://www.nrel.gov/docs/fy18osti/71500.pdf.

Figure XVII.G-1: Projected Demand Growth Rates Under Proposed Standards Compared to U.S. Historic Rates

[See original attachment for Figure XVII.G-1]. [EPA-HQ-OAR-2022-0829-0759, p. 124]

2. Time-of-use electric rates are extremely effective at pushing PEV charging to hours of the day when there is plenty of spare grid capacity.

Real-world data from hundreds of thousands of PEVs reveals that time-of-use (TOU) electricity rates work. At the time the data described below was collected, SCE estimated there were 329,940 PEVs in its service territory (through December 31, 2021).339 Figure XVII.G-2 shows the load profile of households in SCE territory with EVs, with a readily discernible uptick in electricity demand after 9PM (when the on-peak period ends on the time-of-use rates) as a result of PEV charging that increases until just before midnight and trails off in the early morning hours as those PEVs complete their charging. [EPA-HQ-OAR-2022-0829-0759, p. 125]

339 S. Cal. Edison Co., San Diego Gas & Elec. Co. & Pac. Gas & Elec. Co., Joint IOU Electric Vehicle Load Research and Charging Infrastructure Cost Report 10th Report Sec. VI Att. 2 - SCE (Mar. 31, 2022), https://www.cpuc.ca.gov/-/media/cpuc-website/divisions/energy-division/documents/transportation-electrification/1 0th-joint-iou-ev-load-report-mar-2022.pdf.

Figure XVII.G-2. Load Profile of Households with PEVs on a TOU Rate in SCE Territory340

[See original attachment for Figure XVII.G-2]. [EPA-HQ-OAR-2022-0829-0759, p. 126]

340 Id. at 59.

The impact of TOU rates is even more self-evident in Figure XVII.G-3, which isolates PEVs on separate meters, demonstrating that PEVs charge almost exclusively after 9 PM on that TOU rate. [EPA-HQ-OAR-2022-0829-0759, p. 125]

Figure XVII.G-3: Load Profile of PEVs on a Separately Metered TOU Rate in SCE Territory341 [EPA-HQ-OAR-2022-0829-0759, p. 125]

341 Id. at 60.

[See original attachment for XVII.G-3:]. [EPA-HQ-OAR-2022-0829-0759, p. 126]

The figures above represent real-world data collected from hundreds of thousands of households with PEVs. There is no need to test the proposition that simple TOU rates designed for PEVs work. [EPA-HQ-OAR-2022-0829-0759, p. 126]

The combination of TOU rates and more active means of managing PEV charging can yield even greater benefits. Researchers from NRDC, Lawrence Berkeley National Laboratory, and Pacific Gas & Electric found that well-designed TOU rates could allow the utility's system to accommodate universal light-duty BEV adoption with minimal associated costs.342 This peer-reviewed study used real-world data on the distribution grid and BEVs to simulate what would happen if every household in a major metro area had a BEV, and found that more comprehensive load management could essentially prevent all otherwise necessary grid upgrades.343 [EPA-HQ-OAR-2022-0829-0759, p. 126]

Organization: Fermata Energy

II. Why EPA should enable V2G (bidirectional vehicle-to-grid) technologies in the final rulemaking and ensure that warranty and durability requirements adequately consider and do not hinder frequent use of V2G services. [EPA-HQ-OAR-2022-0829-0710, pp. 3-4]

There are numerous reasons for the EPA to encourage the adoption of V2G technology and support our detailed recommendations below. We feel strongly that the EPA has a unique opportunity to make a major difference in the commercialization of V2X technology. If the EPA were to provide incentives or regulations on V2X, as we are recommending, it could provide market confidence for vehicle manufacturers and V2X charging equipment providers, and accelerate V2X by providing a positive value to consumers, including low-and moderate-income consumers. EPA action to unlock the full potential of V2X could help mitigate the emerging generation shortage because with V2X, EVs become grid assets.3 For example, PG&E CEO Patti Poppe recently noted that EVs on the road in "PG&E's service area today have 6,700 MW of capacity," which equals "three Diablo Canyon nuclear power plants. It's on the road today, and we are not using it as a power source. We're only using it as a power draw."4 EPA action on V2X could also help address the duck curve, evening ramp, and summertime "needle" peaks in many generation and distribution grids. More importantly V2G, as a storage asset, unlocks and enables the large GHG benefits of the on-going, large-scale transition to intermittent renewable energy. EPA action to help commercialize V2X could create a low-cost, cleaner alternative to the zero-emission portable gensets required by California Air Resources Board's (CARB) recent Small Off-Road Engines (SORE) regulation and replace dirty portable gensets in other states. Finally, Fermata Energy encourages the EPA to support all connectors, protocols, and EVSE sizes in any V2X recommendations for incentives or regulation in order to foster competition and encourage lower cost solutions. [EPA-HQ-OAR-2022-0829-0710, pp. 3-4]

3 Decommissioning of Diablo Canyon and lack of hydropower in drought years. https://www.utilitydive.com/news/california-drought-could-halve-summer-hydropower-share-leading-to-more-nat/624489/https://www.utilitydive.com/news/california-grid-reliability-2022-2023-summer/609261/

4 https://www.latimes.com/environment/newsletter/2021-10-14/as-california-fires-burn-pge-ceo-promises-fixes-boiling-point

BNEF data (Figures 1 and 2) show over 10 million battery-powered EVs on the road globally at the end of 2020, with a combined 296-gigawatt hours of lithium-ion batteries installed in them. That's a lot of batteries driving around – 8 times more than the number of stationary grid-scale batteries installed globally.5,6 [EPA-HQ-OAR-2022-0829-0710, pp. 3-4]

5 More EVs Are Being Designed to Push Power to The Electrical Grid -Bloomberg (Link: https://www.bloomberg.com/news/newsletters/2021-04-27/more-evs-are-being-designed-to-push-power-to-the-electrical-grid)

6 https://news.bloomberglaw.com/environment-and-energy/electric-vehicles-to-drive-massive-battery-demand-bnef-chart

[See original attachment for Figures 1 and 2: Energy storage onboard EVs is much greater than in stationary battery resources]7 [EPA-HQ-OAR-2022-0829-0710, pp. 3-4]

7 Electric Vehicles to Drive Massive Battery Demand, BNEF, 2021 (Link: https://news.bloomberglaw.com/environment-and-energy/electric-vehicles-to-drive-massive-battery-demand-bnef-chart)

In addition, a May 2022 presentation by the World Resources Institute using Bloomberg NEF and Energy Information Administration (EIA) data projected that in 2030, the power capacity onboard EVs will be 10 to 20 times more than the 2030 power capacity of stationary storage.8 While these numbers are for light-duty EVs, electrified trucks can also contribute and some fleets (e.g., school buses, municipal trucks, trucks in one-shift operations) are expected to be early adopters. [EPA-HQ-OAR-2022-0829-0710, pp. 3-4]

8 See slide 5 at https://www.slideshare.net/emmaline742/building-resiliency-with-v2g-in-residential-homes-by-camron-gorguinpour

V2X bidirectional charging is a win-win-win investment: many benefits accrue:

• Achieves EPA's environmental goals. Just like stationary storage, V2X bidirectional charging platforms can reduce carbon and criteria pollutant emissions from generators by shifting electricity consumption to the cleanest hours of the day and removing the need for dirty thermal peaker electricity generation. However, V2X is more cost-effective than stationary storage, as ratepayers don't have to pay for purchase of the EV battery and can accelerate the renewable transition. [EPA-HQ-OAR-2022-0829-0710, pp. 4-6]

• Provides grid services. With V2X bidirectional charging, utilities gain a low-cost energy storage resource to help integrate renewable energy into the electric grid by shifting energy, providing resource adequacy, and ancillary services (Figure 3). For example, modeling by the CPUC currently projects 14,700 MW of new energy storage is needed in CA by 2032 to support the integration of renewables but only 2,185 MW is operational today.9,10 V2X, with supportive policies, can provide many thousands of MW by 2030. [EPA-HQ-OAR-2022-0829-0710, pp. 4-6]

• Lower vehicle ownership costs. EV owners can earn money by selling electricity back to the grid, significantly cutting the cost of vehicle ownership. Offsetting the cost of owning and maintaining an EV supports equitable access to EVs, particularly those EVs in the used car market, such as the low-income EV driving community. [EPA-HQ-OAR-2022-0829-0710, pp. 4-6]

• Increased resiliency. Unidirectional charging is a grid load. V2X bidirectional charging cost-effectively supports grid resilience. During blackouts and extreme weather events, such as Public Safety Power Shutoffs (PSPS) in CA, EV owners can power their homes, businesses, and critical infrastructure. [EPA-HQ-OAR-2022-0829-0710, pp. 4-6]

• Ratepayer benefits. EV adoption has already been shown to significantly benefit utility ratepayers and V2X technology can further those benefits.12 For example, a 2018 CEC study projects $1 billion in annual ratepayer benefits if 50% of chargers were V2X capable.13 V2X technology also improves driver economics which would likely drive further EV adoption and even greater ratepayer benefits. [EPA-HQ-OAR-2022-0829-0710, pp. 4-6]

III. Recommendations regarding V2G in EPA rules and EPA's Proposed Battery Durability Monitoring and Warranty Requirements for Light-and Medium-Duty Electric Vehicles

Any eventual battery durability requirements set by EPA should account for frequent bidirectional charging (e.g. such as vehicle-to-grid) activities [EPA-HQ-OAR-2022-0829-0710, pp. 6-7]

We recognize that the EPA is proposing battery durability and warranty requirements that are less than those in Advanced Clean Cars II and we appreciate that.. However, the EPA made no mention of the need for V2G technology in light-and medium-duty BEVs and PHEVs in the proposed rule. [EPA-HQ-OAR-2022-0829-0710, pp. 6-7]

Battery degradation is an inherently complex topic; battery chemistry, temperature, use cases, the EV duty cycle, and other factors all impact battery degradation. Some V2X activities, especially those utilizing bidirectional charging capabilities, will require additional battery cycling that will impact long-term battery durability. While the exact level of cycling will depend on the specific V2X use case and could vary based on customer behavior, it is reasonable to expect that in the future most EVs could experience some incremental level of degradation due to V2X activities. [EPA-HQ-OAR-2022-0829-0710, pp. 6-7]

Given the extensive public and private benefits that V2X can offer, as detailed above, it is paramount that any battery durability and warranty requirements EPA establishes for EVs not inadvertently foreclose V2X activities, and especially V2G opportunities. Setting overly-stringent durability requirements that limit V2X activities – whether intentionally or not – conflicts with the EPA's larger mission of reducing emissions and accelerating EV adoption. [EPA-HQ-OAR-2022-0829-0710, pp. 6-7]

Final battery warranty and battery durability requirements should include a thorough understanding of the impact on V2G in light-and medium-duty vehicles so as to not discourage V2G. At a minimum, the EPA should lower the warranty requirement to account for frequent bidirectional charging and allow automakers to exclude vehicles that have done V2X from the pool of vehicles in the durability test sample. [EPA-HQ-OAR-2022-0829-0710, pp. 6-7]

We do not see any consideration of frequent use of V2G in this proposal. V2G technology is emerging in light-duty and medium-duty vehicles, and attractive use cases exist (e.g. EVs that spend many hours connected to a charger or EVSE in a fleet or for personal use, such as school buses). The concern is that overly restrictive warranty or durability requirements by the EPA could place arbitrary restrictions on V2X activities. Fermata Energy appreciates the EPA's intent to ensure consumer protection and customer satisfaction with EV ownership through robust standards and to meet the useful life requirements in the Clean Air Act. However, overly stringent requirements that constrain battery cycling could also constrain the novel set of value propositions that V2X offers and that would otherwise spur EV adoption (e.g., home backup power, payment for grid services, customer bill management, etc.). Overly stringent battery durability requirements could drive OEMs to limit the range, performance, and/or state of charge of EV batteries, or take other measures to provide for sufficient degradation margin in later years. As such, Fermata Energy believes that the EPA should consider an approach to durability and warranty requirements that balances competing factors and specifically considers the GHG benefits of V2G as a storage technology which unlocks and enables a faster, more cost-effective transition to renewable energy. [EPA-HQ-OAR-2022-0829-0710, pp. 7-8]

Furthermore, we note there are ongoing efforts by the Informal Working Group on Electric Vehicles and the Environment under the United Nations Economic Commission for Europe (UN ECE) to develop minimum performance requirements for EV batteries that include V2X considerations. This Working Group is chaired by the US Environmental Protection Agency (EPA) and includes the European Commission, individual European and Asian countries, as well as industry stakeholders from around the world. In order to account for VGI activities, the Working Group is also considering a "virtual km" mechanism, in which the energy discharged by the EV battery in bidirectional mode is converted to a km-equivalent via a predetermined formula.14 The total mileage used for confirming the compliance with the performance requirements would consist of the sum of the km driven and the virtual km. While Fermata Energy is not necessarily endorsing this specific approach or methodology, we believe that the EPA should seriously consider an agreed upon method to account for V2G battery degradation such as the UN Global Technical Regulation "virtual miles" before adopting a final regulation with durability or warranty requirements. [EPA-HQ-OAR-2022-0829-0710, pp. 7-8]

14 For example, see the following presentation on V2X virtual mileage at the 50th EVE IWG meeting: https://wiki.unece.org/download/attachments/128420289/Input%20on%20V2X%20virtual%20mileage.pptx?api=v2

In the absence of an agreed upon method to account for V2G battery degradation, OEMs may choose to reach individual battery warranty agreements with V2X services providers to approve specific equipment for use with their bidirectionally-enabled vehicles. In September 2022, Nissan approved the Fermata Energy bidirectional charger as the first bidirectional charging system for use with its all-electric LEAF vehicle in the US.15 While these sorts of battery warranty approvals are a very important development for the bidirectional charging industry, OEM approval processes can be slow. It may take years for other OEMs to negotiate these sorts of agreements with V2X charger manufacturers and service providers. An agreed-upon methodology for accounting for V2G battery degradation would be the more expedient approach to ensuring battery durability, instead of relying on individual OEM to EVSE agreements, which could take years. [EPA-HQ-OAR-2022-0829-0710, pp. 7-8]

15 https://usa.nissannews.com/en-US/releases/release-5078281d19ed36853371357c4a1a8244-nissan-approves-first-bi-directional-charger-for-use-with-nissan-leaf-in-the-us

Regarding battery warranties, Fermata Energy recommends that the EPA 1) either delay adopting battery warranty requirements to a future rulemaking when more data on V2X is available or 2) reduce the battery warranty requirement in the final regulation to account for and assume frequent vehicle-to-grid charging by battery EVs and plug-in hybrid EVs. We also recommend that the EPA explicitly state that automakers may exclude those vehicles that have done vehicle-to-building or vehicle to grid charging from the pool of vehicles in the battery durability test sample. The Advanced Clean Cars II regulation took this approach, and we recommend the EPA do the same. [EPA-HQ-OAR-2022-0829-0710, p. 8]

The EPA should add in the final regulation a small multiplier credit for vehicles that have on-board AC bidirectional chargers or are integrated with multiple DC off-board chargers. [EPA-HQ-OAR-2022-0829-0710, p. 8]

The promise of bidirectional charging (AC or DC) to address air pollution, GHG emissions, and challenges to the electric grid is very significant with BEVs and PHEVS in medium-and light-duty vehicles. While we understand the desire by the EPA to simplify the regulation and reduce the use of bonus multiplier credits, we believe a small bonus credit in this regulation is justified and needed to unlock this technology because of the large emissions reduction benefits and other grid services enabled by bidirectional charging as described in Section II above. The EPA has a long history of providing multiplier credits to emerging technologies and we strongly encourage the EPA to adopt in the final regulation a modest multiplier credit for light-duty and medium-duty passenger vehicles that appropriately phases out over time. This multiplier should apply to automakers with vehicles that have on-board AC inverters for bidirectional charging and for vehicles that can show they have integrated with many brands of off-board DC fast chargers. This approach will not only will help enable the emerging V2G industry, but it will also help consumers achieve lower operating costs,16 reduce GHG and traditional pollutants from fossil fueled power plants by shifting electricity use to renewable energy in the cleanest hours of the day, and reduce the need for high-emitting peaker plants. V2G also provides a zero-emission, lower cost alternative to high-emitting portable back-up generators, and saves utility ratepayers money with a low-cost resource as compared to battery stationary storage. [EPA-HQ-OAR-2022-0829-0710, p. 8]

16 See footnote 11

By implementing our recommendations, the EPA has a unique opportunity to help the emerging V2G industry, consumers, and the power generation and transportation industries. Fermata Energy appreciates the opportunity to provide these comments and welcomes a more in-depth dialogue on this and offers itself as a resource on V2X topics for EPA. [EPA-HQ-OAR-2022-0829-0710, p. 8]

Organization: Ford Motor Company

To achieve the 2032MY goals EPA has proposed and Ford supports, the final regulation must have the following elements. First, regarding the stringency of the GHG standards, the EPA should finalize the Alternative 3 standards with minor adjustments to the utility allowance inherent in the truck curves and provide a phase-out for refrigerant credits (rather than eliminate all at once). The Alternative 3 standards effectively draw a straight line from 2026 to 2032; that is, they would require roughly equal reductions in absolute grams-per-mile targets over the duration of the program. Alternative 3 reaches the same endpoint in 2032 as the EPA's main proposal, and therefore would achieve the primary goal shared by Ford and EPA—widespread adoption of ZEVs. In contrast, EPA's main proposal, Alternative 1, and Alternative 2 each would require precipitous reductions in 2027 – 2029; this is not feasible and does not align with the anticipated scaling of the EV supply chain and manufacturing base. Similarly, the EPA's proposal to end refrigerant credits altogether in 2027 would be abrupt and have the effect of standards being even more strict; EPA should phase these credits out over time. Lastly, EPA's final regulations must continue to recognize the utility provided by trucks. Although electrified vehicles hold promise for all vehicles classes, ICE-powered trucks will continue to provide unique capability and utility for many years. The EPA proposal (and Alternative 3) would reduce the existing truck utility allowance too severely. [EPA-HQ-OAR-2022-0829-0605, p. 3]

Second, to ensure the final rule does not go too far and too fast, especially in 2027 – 2029, the EPA should adjust two aspects of the proposal regarding criteria emissions: fuel enrichment and particulate matter testing obligations. Although fuel enrichment can lead to higher emissions during brief and infrequent conditions which are disclosed to the EPA, fuel enrichment has been critical for overall emissions reductions. The practice enables automakers to downsize engines while also meeting consumer needs for some of the toughest jobs, without compromising powertrain durability. Removing fuel enrichment, as EPA has proposed, will directly impact customers' acceptance of new products, especially trucks, and they may keep their existing vehicle longer or opt for a larger (i.e., higher emitting) vehicle to be sure they can get the job done. Major powertrain redesigns would be needed to recover this lost utility, and these are not possible within the timeframe defined by the enrichment phase-out proposed by EPA. Next, although Ford supports aspects of EPA's proposed particulate matter (PM) standards which will necessitate the use of gasoline particulate filters, the proposed PM standard will challenge current laboratory equipment and procedures. Ford requests that the EPA eliminate the need to measure PM on the -7°C FTP for vehicles that are equipped with gasoline particulate filters. [EPA-HQ-OAR-2022-0829-0605, p. 3]

Car vs. Truck Stringency

Ford appreciates EPA's efforts to develop a data-driven, analytical basis for determining the appropriate relative stringency between the car and truck footprint curves. It is essential to full-line OEMs that the utility provided by trucks—particularly large pickup trucks—continue to be appropriately credited in the footprint-based standards. Any changes should made cautiously and gradually, with awareness of the broader context of the other sweeping changes that automakers are managing during the timeframe of this rule. [EPA-HQ-OAR-2022-0829-0605, pp. 5-6]

Ford believes the following modifications to the EPA's truck utility methodology are appropriate: [EPA-HQ-OAR-2022-0829-0605, pp. 5-6]

-Increase the 9 g CO2/mile per 1000 lbs of incremental towing to 11 g CO2/mile to account for increased road loads on highly capable towing vehicles (e.g., losses from larger brakes, axles, and engine parasitics).

-Increase the sales weighted towing delta from 7000 lbs to 8500 lbs to better capture the full range of towing capabilities for full size pickup trucks.

-Decrease the expected EV penetration rate from 50% to 35% for the harder-to-electrify full-size pickup truck market. [EPA-HQ-OAR-2022-0829-0605, pp. 5-6]

These refinements would result in an approximately 40 g CO2/mile difference between the Car and Truck curves by 2032MY utilizing the maximum footprint of 70 ft2, as shown in the graph below. Ford would like to continue to work with EPA to fully explain our rational and recommendations. [EPA-HQ-OAR-2022-0829-0605, pp. 5-6]

[See original comment for Graph 1: Vehicle Utility vs Truck Footprint Curves] [EPA-HQ-OAR-2022-0829-0605, pp. 5-6]

Limits on EV Growth

Ford is already delivering electrified light-and medium-duty EVs at scale. While we remain optimistic that EVs will constitute a steadily growing portion of new vehicle sales in the US, we are also mindful of the considerable challenges and uncertainties that will affect the rate of growth. The pace of electrification has been and may continue to be limited by many factors and forces, many of which are outside the control of vehicle manufacturers. A few deserve mention here. [EPA-HQ-OAR-2022-0829-0605, pp. 6-7]

Consumer preference is difficult to predict out to 2032. While EV adoption is growing quickly, and we are seeing enthusiasm for EVs among the early adopters, we cannot assume the same enthusiasm from the early majority let alone the late majority. Market studies suggest many people are interested in purchasing an EV, but not at any cost and not while charging infrastructure remains at a nascent stage. [EPA-HQ-OAR-2022-0829-0605, pp. 6-7]

Plug-In Hybrid Vehicle Utility Factor

Ford does not support the proposed update to the Plug-In Hybrid (PHEV) utility factor (UF). We do not believe it is appropriate to recalibrate the PHEV compliance benefit at the same time the EPA is proposing other sweeping changes and historically stringent standards. Product planning lead time and uncertainty in EV market growth requires that all electrification options be available with stable and predictable compliance benefits. Ford would support an EPA program designed to gather additional data for use in a future rulemaking which would yield a robust basis for a UF update and prevent disruption to EV product compliance plans. [EPA-HQ-OAR-2022-0829-0605, p. 8]

Light-and Medium-Duty Fuel Enrichment

EPA is proposing to eliminate commanded enrichment for ICE-powered vehicles for power and component protection. Fuel enrichment protects engine components during infrequent and/or short duration high-power demand events, such as freeway on-ramps or towing on steep grades. The ability to employ limited commanded enrichment has allowed downsized engines to meet customer performance demands across a broad range of real-world driving condition, resulting in considerable CO2 savings. If left unmitigated, the elimination of commanded enrichment would result in performance degradations that would be unacceptable to most customers, forcing many to retain older models or to upgrade to larger, more capable vehicle classes. Either result would run counter to EPA's intention to reduce on-road emissions. [EPA-HQ-OAR-2022-0829-0605, pp. 12-13]

In order to meet customer needs without enrichment, Ford will need to implement expensive, long-lead time engine development actions, such as increasing component sizes (turbos and heat exchangers) and adding more expensive engine and manifold materials. Under the EPA proposal, this would need to be accomplished and during a timeframe when we are already stretching our capital and engineering resources to their limits in order to transition to electrification. The proposal would also not provide the lead-time needed to undertake such engine redesign programs. For these reasons, Ford does not consider the proposed phase-in for the enrichment prohibition to be feasible. For recommends that EPA shift the phase-in requirements to at least 2029MY for vehicles below 6,000lb GVWR. [EPA-HQ-OAR-2022-0829-0605, pp. 12-13]

[See original comment for Table 2: Ford Recommended Enrichment Phase-in] [EPA-HQ-OAR-2022-0829-0605, pp. 12-13]

Regarding EPA's proposed enrichment exception allowances under 40 CFR 86.1811-17(d)(2), Ford requests that EPA include the following additional conditions to account for sporadic pre-ignition and other potential future technologies that may be deemed acceptable for agency approval through the AECD review process: [EPA-HQ-OAR-2022-0829-0605, pp. 12-13]

-Temporary and infrequent enrichment following sporadic pre-ignition events (used to prevent follow-on events which are prone to causing engine damage),

-Enrichment conditions substantially demonstrated during emissions testing, or

-Enrichment conditions otherwise approved by the EPA. [EPA-HQ-OAR-2022-0829-0605, pp. 12-13]

Organization: Fred Reitman

Electric grid cannot support this. The electric grid is remarkable engineering. But there is little reserve capacity and the grid is overtaxed. EV charging will stress the grid and is sure to result in brownouts and blackouts, which are dangerous during winter when power is needed for heating homes. Brownouts and Blackouts are already a problem in some states. This rule if finalized would only make the problem worse. [EPA-HQ-OAR-2022-0829-0432, p. 1]

Organization: Fuel Freedom Foundation

Battery electric vehicles are an attractive option for many households. However, they are not yet on par with internal combustion engine (ICE) vehicles in affordability and/or convenience for the majority of American drivers. Moreover, the electric grid needs vast improvement before achieving the necessary capacity, carbon intensity, and reliability for a fully electrified transportation system. GHG reductions should not wait for uncertainties to resolve or for the technology and market to evolve. [EPA-HQ-OAR-2022-0829-0711, pp. 1-2]

Organization: GROWMARK, Inc.

Furthermore, the electric grid is ill-equipped to handle a rapid increase in the number of EVs. According to the North American Electric Reliability Corporation, two-thirds of North America risk energy shortfalls this summer.3 Increasing the number of EVs at the rate mandated by these standards will only exacerbate these issues, especially in rural areas where infrastructure is most vulnerable. This puts the lives and livelihoods of farmers and all rural Americans at risk. [EPA-HQ-OAR-2022-0829-0560, p. 2]

3 North American Electric Reliability Corporation (2023, May 17). Two-thirds of North America Faces reliability challenges in the event of widespread heatwaves. https://www.nerc.com/news/Headlines%20DL/Summer%20Reliability%20Assessment%20Announcement%20May%202023.pdf

Organization: Growth Energy

In contrast, it is not as simple to convert to EV technology. Doing so at scale requires massive investments in both charging infrastructure and the electric power sufficient to support massive new electricity demand. Developing sufficient charging infrastructure can be difficult in rural areas and in locations where there are competing land uses. And developing additional electric power faces multiple challenges—the country will need significantly more electric capacity and, for EVs to have their intended GHG reduction benefits, that additional electric generation will need to be relatively low-carbon. For example, converting vehicles used in the Appalachian region rapidly to EVs and powering them by increasing loads on existing coal-fired power plants would not have the significant benefits claimed by the proposed rule. [EPA-HQ-OAR-2022-0829-0580, p. 6]

The zero grams/mile compliance value for EVs … does not reflect the increase in upstream GHG emissions associated with the electricity used by EVs compared to the upstream GHG emissions associated with the gasoline or diesel fuel used by conventional vehicles. For example, based on GHG emissions from today’s national average electricity generation (including GHG emissions associated with feedstock extraction, processing, and transportation) and other key assumptions related to vehicle electricity consumption, vehicle charging losses, and grid transmission losses, a midsize EV might have an upstream GHG emissions of about 180 grams/mile, compared to the upstream GHG emissions of a typical midsize gasoline car of about 60 grams/mile. Thus, the EV would cause a net upstream GHG emissions increase of about 120 grams/mile (in general, the net upstream GHG increase would be less for a smaller EV and more for a larger EV). [EPA-HQ-OAR-2022-0829-0580, pp. 6-7]

75 Fed. Reg. 25,324.

And that estimate of 120 grams/mile for EVs’ upstream emissions does not even account for emissions associated with production of batteries. Recent research has increasingly revealed that there are significant GHG emissions associated with the mining of materials for production of batteries used in EVs.6 For example, mining nickel alone requires both significant fossil energy expenditures and GHG emissions associated with land use, including the clear-cutting of rainforest in Indonesia.7 When compared to production of an ICE vehicle on a cradle-to-grave basis, those emissions represent another source of emissions from EVs that are not addressed in EPA’s assumption that EVs produce zero grams per mile of GHGs. [EPA-HQ-OAR-2022-0829-0580, pp. 6-7]

6 See, e.g., Catherine Early, The new 'gold rush' for green lithium, BBC News (Nov. 24, 2020) https://www.bbc.com/future/article/20201124-how-geothermal-lithium-could-revolutionise-green-energy.

7 Jon Emont, EV Makers Confront the ‘Nickel Pickle’, Wall Street Journal, June 4, 2023.

Indeed, a recent National Academy of Sciences (“NAS”) assessment explained that an approach like EPA’s fails to “fully capture” emissions from “the total light-duty vehicle system.”8 NAS noted that one issue of that type of non-system-based analysis is that it would lead to inaccurate comparisons between vehicles using different fuels.9 And NAS further opined that: [EPA-HQ-OAR-2022-0829-0580, pp. 6-7]

9 Id.

[I]f deep GHG emissions reduction is a goal, then there will need to be consideration of not only onboard vehicle emissions, but also the emissions from related sectors, like electricity (for vehicle charging), and manufacturing (of vehicles and their materials and components). This motivates the need for life cycle thinking.10 [EPA-HQ-OAR-2022-0829-0580, pp. 6-7]

Organization: Illinois Corn Growers Association

Enormous advances have been made in electric vehicle technology in the last two decades and there is strong auto industry commitment to eventually replace internal combustion engine powered vehicles with electric ones. There are, however, still technological and economic challenges in creating products that meet consumer expectations. In addition, there are many things that must happen to support electric vehicles, many of which are outside the control of automakers. [EPA-HQ-OAR-2022-0829-0756, p. 3]

These include: [EPA-HQ-OAR-2022-0829-0756, p. 3]

-Increasing the electrical generating capacity in the U.S to provide the power to replace the energy now supplied by gasoline. [EPA-HQ-OAR-2022-0829-0756, p. 3]

-Switching the source of energy used to generate this electricity from fossil fuels to zero-carbon sources such as wind, solar, nuclear and hydroelectric. [EPA-HQ-OAR-2022-0829-0756, p. 3]

-Upgrading the electrical grid to move this additional power from the point of generation to

the point of vehicle recharging. [EPA-HQ-OAR-2022-0829-0756, p. 3]

-Installing recharging stations in nearly every home with an electric vehicle and enough public charging stations to give electric vehicles the same utility as the gasoline powered vehicles they are intended to replace. [EPA-HQ-OAR-2022-0829-0756, p. 3]

-Securing enough raw materials to build the large batery packs needed to give electric vehicles the range consumers demand. [EPA-HQ-OAR-2022-0829-0756, p. 3]

-Upgrading the nation's roads, bridges and parking structures to ensure they can absorb the extra weight of inherently heavier electric vehicles. [EPA-HQ-OAR-2022-0829-0756, p. 3]

Thus, even if in the next eight years automakers, suppliers and retailers can retool their businesses to supply an estimated 7.5 million new vehicles in 2032 and beyond, it is far from assured that: [EPA-HQ-OAR-2022-0829-0756, p. 3]

-The marketplace is willing to buy that many vehicles in spite of their higher purchase cost, charging requirements, limited utility and extremely high batery replacement costs. [EPA-HQ-OAR-2022-0829-0756, p. 3]

-The mines can extract enough raw materials to build the bateries necessary to build these vehicles, especially since it is expected that electric utilities will be buying huge bateries made of the same materials to deal with the intermit nature of wind and solar energy. [EPA-HQ-OAR-2022-0829-0756, p. 3]

-The electric utilities can provide enough electricity. [EPA-HQ-OAR-2022-0829-0756, p. 3]

-The electric grid has been upgraded to handle the new demand, again considering that not only vehicles but residential and commercial heating systems, railroads and even ships will be converting from fossil fuels to electricity. [EPA-HQ-OAR-2022-0829-0756, p. 3]

Given the uncertainty that automakers can meet the proposed Multi-Pollutant Emissions Standards through electric vehicles alone, what other new technologies are available for compliance? [EPA-HQ-OAR-2022-0829-0756, p. 3]

Organization: International Council on Clean Transportation (ICCT)

In addition to all this industry investment in EV manufacturing, battery production, and the battery material supply chain, substantial investments are underway in the electric power sector. From 2012 through mid 2022, about $3.6 billion in utility transportation electrification investment plans have been approved across the country.18 These investments include upgrades in grid capacity, safety, resilience, and managed charging. The U.S. already has enough power generation and transmission capacity to fuel the EV expansion over the next few years.19 Meeting the 2050 demand requires about 1% per year growth in electricity production, well below the 3.2% average annual growth rate for the electricity generation over the past 70 years.20 [EPA-HQ-OAR-2022-0829-0569, p. 9]

Organization: International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

Short Summary

The UAW fully supports the transition to a cleaner auto industry, and it must be done in a way that protects both good union jobs and the environment. We urge the EPA to reach a consensus-based standard for light-and medium-duty greenhouse gas emissions that avoids allowing the burden of compliance to fall heaviest on the workers who currently build ICE vehicles and those who will build ZEVs in the future. [EPA-HQ-OAR-2022-0829-0614, p. 1]

Regulations that push the industry to adopt cleaner technologies are important to creating a strong domestic union manufacturing base. We also know that the US auto industry does not have a perfect track record in keeping up with consumer interest. In the 1980s, we saw the decimation of US auto market share and with it of good union auto jobs in this country, in part due to the companies' misjudging the consumer market and failing to adapt. We cannot allow this pattern to repeat in the 21st century in case the existing US automakers fail to keep up with rising EV demand, further sacrificing market share to foreign, non-union, and low-road employers. There is a risk of US automakers focusing on short-term profit while non-union employers capture future generations of market share, with disastrous outcomes for the industry labor standards and union workers. [EPA-HQ-OAR-2022-0829-0614, p. 1]

However, we are also concerned the proposed standards do not adequately address the projected impact on an industry that balances ICE jobs with the quality of new EV jobs. Nor does it properly account for the role that the sale of ICE vehicles will play in the transition or the availability of charging infrastructure. The EPA must involve stakeholders to reach a mutual agreement. [EPA-HQ-OAR-2022-0829-0614, p. 1]

Organization: John Graham

The IPM modeling assumes that the carbon intensity of the electrical grid will decline by 70 percent over the lifetimes of 2032 vehicles, as renewables replace most fossil fuels throughout the United States. The reader is led to believe that the subsidies for renewables in the Inflation Reduction Act will cause this rapid transformation of the US utility industry. However, the Inflation Reduction Act does not include the permitting reforms that are required for the large new transmission lines necessary to bring renewable energy to the markets where they are needed. Recent reports from both Brookings and the R Street Institute show that, without permitting reform, the monies in the Inflation Reduction Act are likely to have minimal impact on the expansion of renewables in the utility sector.95 The IPM modeling also ignores the massive expansion of grid-scale energy storage that would be required to achieve reliability with renewables. That energy storage, which would likely require large numbers of lithium ion batteries, is not included in the agency's assessment of battery prices, electricity prices, or material supply requirements. For these reasons, it is unrealistic to expect that the electricity currently provided by fossil fuels will be provided by renewables within the average lifetime of the model year 2032 vehicle. Thus, the upstream emissions from BEVs will be significantly larger than the agency assumes. Without this bias, HEVs would look much better in comparison to BEVs, as we illustrate in the simulation below. [EPA-HQ-OAR-2022-0829-0585, pp. 33-34]

> 95 Rayan Sud, Sanjay Patnaik. How Does Permitting for Clean Energy Work? Brookings Institution. Washington, DC. September 28, 2022; Rayan Sud, Sanjay Patnaik, Robert L. Glicksman. Federal Permitting to Accelerate Clean Energy Infrastructure: A Nonpartisan Way Forward. Brookings Institution. Washington, DC. February 14, 2023; Philip Rosetti. Potential Effects of the Inflation Reduction Act on Greenhouse Gas Emissions. R Street. Washington, DC. September 27, 2022; Philip Rossetti. Written Testimony for the Hearing on "Tax Incentives in the Inflation Reduction Act: Jobs and Investment in Energy Communities." Committee on Finance. United States Senate. Washington, DC. May 18, 2023.

The attached Table 1 calculates lifecycle and tailpipe emissions for ICEVs, HEVs, and BEVs for 2021 and 2030. Model years 2021 and 2030 are used because it begins with ICCT's calculation of 101 g/km CO2 for life cycle emissions of a 2021 model year BEV car in ICCT's 2021 lifecycle emission study.96 The 101 g/km CO2 is composed of 60 g/km due to operation from the U.S. national electric grid at 357 g/kWh CO2 and 41 g/km due to manufacturing and maintenance emissions. These are converted into g/mi CO2 in Table 1. BEV emissions with the

CA grid at 225 g/kWh CO_2 are also shown for 2021. [EPA-HQ-OAR-2022-0829-0585, pp. 33-34]

96 George Bieker, International Council on Clean Transportation, "A Global Comparison of the Life-Cycle Greenhouse Gas Emissions of Combustion Engine and Electric Passenger Cars", July 2021, Figure 4.1. https://theicct.org/sites/default/files/publications/Global-LCA-passenger-cars-jul2021_0.pdf

The ICCT lifecycle study also calculates ICEV life cycle emissions for cars of 252 g/km CO_2 for model year 2021, comprised of 55 g/km from upstream fuel production, 31 g/km due to manufacturing and maintenance, and 166 g/km for tailpipe emissions (also converted into g/mi). [EPA-HQ-OAR-2022-0829-0585, p. 34]

Second, the electric utility industry works on longer time scales (about 30 years for a powerplant) than the auto industry (about 15 years for a vehicle). Thus, the decarbonization of the electric power sector will take longer than a transition to BEVs in the transportation sector. Pushing the transport sector to BEVs faster than the utility sector can decarbonize is wasteful of scarce battery resources that will likely be needed for grid-scale energy storage systems in the utility industry. Moreover, it will take many years to site, approve and build new renewables plus the additional years to build grid-scale energy storage and the long-range transmission lines necessary to transport wind and solar energy to markets where it is needed. [EPA-HQ-OAR-2022-0829-0585, p. 9]

Organization: Kentucky Office of the Attorney General et al.

C. The Proposed Rule ignores significant hurdles to the industry transformation that the rule requires.

EPA is pushing forward with this proposal at a breakneck pace and in circumstances ill-suited to the aggressive industry transformations that the Agency demands. The electrical grids are neither stable nor safe enough to handle EPA's proposal. The country will be more energy dependent and less secure because of it. Automakers will be left without the materials they need to comply. And all the while, consumers—our citizens—will have to deal with empty government promises about vehicle pricing, utilization, and safety. In short, the Proposed Rule ignores too many aspects of this too-important issue. [EPA-HQ-OAR-2022-0829-0649, p. 10]

1. The American power grids are not ready for the Proposed Rule.

As with other areas of concern, the Proposed Rule minimizes the damage it is poised to inflict on the power grids. EPA says utility upgrades to "improve grid reliability and … meet new electric power demands" are "routine[]." 88 Fed. Reg. at 29,311. And the Agency projects that increased demand from a greater number of EVs in the market will be "relatively modest" and have no adverse effect on grid reliability. Id. But converting the majority of the automobile market to EVs is not so simple. The Proposed Rule would forcibly phase out an entire fueling and service infrastructure, built over a century, and replace it with one that is still in its infancy. EPA has not accounted for all the problems that will cause. [EPA-HQ-OAR-2022-0829-0649, pp. 10-11]

For starters, the Proposed Rule will send a surge of EV demand to a power grid that is "running on an antiquated delivery system established several decades ago," Gina S. Warren, Hotboxing the Polar Bear: The Energy and Climate Impacts of Indoor Marijuana Cultivation, 101 [EPA-HQ-OAR-2022-0829-0649, pp. 10-11]

B.U. L. Rev. 979, 982 (2021), and “already strained” by the uptick in renewable energy “share and the challenge of more intermittent energy supply.” Luis Avelar, The Road to an EV Future Still Has a Few Potholes. Here’s How To Fix Them, World Econ. Forum (Jan. 31, 2022), http://bit.ly/3gEVgRj. [EPA-HQ-OAR-2022-0829-0649, pp. 10-11]

One need only look to California—a State the Proposed Rule showcases as an example of a State’s “demonstrated . . . ability” to handle the increased charging loads of EVs, 88 Fed. Reg. at 29,312—to see how this plays out in real time. Just days after California officials “voted in favor of banning the sale of new gas-powered vehicles in the state by 2035,” Simrin Singh, California bans the sale of new gas-powered vehicles by 2035, CBS News (Aug. 25, 2022), https://bit.ly/3P5d1s8, California faced a heat wave that triggered calls for residents to avoid charging their EVs during evening hours to “conserve power” as the “aging electricity grid struggle[d]” to keep up, Flex Alert extended to Saturday; EV owners asked to not charge vehicles during peak hours, CBS News (Sept. 2, 2022), https://cbsn.ws/3N4CqQa. As “[a]ll states . . . rethink electricity pricing structures as their EV charging needs increase and their grid changes,” California should serve as a warning, not a model. Mark Golden, Charging cars at home at night is not the way to go, Stanford study finds, Stanford News Service (Sept. 22, 2022) https://bit.ly/46a3qqm; see James Downing, Federal Funding Will Speed Up Grid Modernization, Utility Officials Say, CQ Roll Call (Oct. 12, 2022), 2022 WL 6905896 (predicting Texas will add “nearly a quarter of its peak demand” to its overall load in the coming years). [EPA-HQ-OAR-2022-0829-0649, pp. 10-11]

The beginnings of needed grid upgrades will not be easy, fast, or cheap. Some experts estimate that it will cost between $1 and $2.4 trillion by 2050 to make the necessary changes, including replacing countless miles of transmission lines. See Tim McLaughlin, Creaky U.S. power grid threatens progress on renewables, EVs, Reuters (May 12, 2022), https://bit.ly/43Unta3. Even before the Proposed Rule was announced, experts predicted that a $125 billion share of that price tag would need to be spent just to “allow [the grids] to handle electric vehicles.” Will Englund, Plug-In Cars Are The Future. The Grid Isn’t Ready, Wash. Post (Oct. 13, 2021), http://bit.ly/3SEDPhk. [EPA-HQ-OAR-2022-0829-0649, pp. 10-11]

On top of that, the Proposed Rule is just one part of EPA’s full-court press to transform the very energy sector the grids support. The corollary proposal for tailpipe emissions from heavy-duty vehicles, the Coal Combustion Residuals Rule, new methane restrictions, new GHG regulations under Section 111 of the Clean Air Act, the tighter Mercury and Air Toxics Standards, the recent update to the Good Neighbor Plan for ozone—this comprehensive suite of regulations adds even greater strain to existing baseload capacity. The Proposed Rule flouts the reality of existing infrastructure even considered in a vacuum. The Agency has not explained how pursuing all of these measures together—that is, how the Proposed Rule would operate in the actual context in which EPA plans to promulgate it—only adds to the impossibility of achieving EPA’s vision. In short, these near-simultaneous responses to President Biden’s pledge to “end fossil fuel” and “generate all electricity from carbon-free sources in just over a decade”—by, in part, “shut[ting] down” American coal plants—will “have tangible consequences for grid reliability and security” that the Proposed Rule does not address. WV Amicus Brief at 20-24. [EPA-HQ-OAR-2022-0829-0649, pp. 10-11]

Another serious problem is that power grids present “a massive to-do list” that “belongs to no one in particular.” McLaughlin, supra. Neither of the country’s top electricity regulators “has the authority to fix or upgrade the U.S. grid problems to match Washington’s green-energy ambitions.” Id. Similarly, while “[a]ppropriate permits may be required from the local building and permitting authorities” for new “[c]harging equipment installations,” the “state and local regulators” “have little independent power” to modernize the grids themselves. Charging Electric Vehicles at Home, U.S. Department of Energy Alternative Fuels Data Center, https://bit.ly/42y0f8L. EPA’s claim that the Proposed Rule has “no[] . . . federalism implications” is thus puzzling. 88 Fed. Reg. at 29,405. Basing a massive proposal on anticipated grid expansions when “none of the[] players individually [even] have the power or the responsibility to maintain the U.S. grid in the national interest,” McLaughlin, supra, is too speculative for responsible regulation. And trying to move forward without accounting for the role of the States at all—who at least are “responsibl[e] for grid maintenance, upgrades and inter-regional connections” in their own spheres—only increases the Proposed Rule’s head-in-the-sand approach. [EPA-HQ-OAR-2022-0829-0649, pp. 11-12]

These are just some of the power-grid-related problems the Proposed Rule triggers without a solution. The grids not only lack the capacity to accommodate the Proposed Rule’s new demands on them, but are also nowhere near secure enough to take them on. This security piece cannot be overstated; the Agency’s failure to sufficiently account for it is another red flag. Within the grids themselves, the EV ecosystem is still “emerging.” Mohammad Sayed, Ribal Atallah, Chadi Assi, Mourad Debbabi, Electric vehicle attack impact on power grid operation, 137 Int’l J. of Electrical Power & Energy Systems 107,784 (2022), https://bit.ly/3qFk2WI. The “special nature of EV loads” means that “EVs now present a new cyber-physical attack vector . . . against the power grid” that was “previously not possible.” Id. So every charging station in the country is becoming a potential “entry point[] for cyberattacks directed at the American energy grid.” Karoline Gore, Could electric vehicles present a Cybersecurity risk to the grid?, AT&T Cybersecurity (Dec. 7, 2020), https://bit.ly/3X1L0DW. The increased number of EVs presents new challenges, too. Because “[a]n electric vehicle has far more hardware chips and software components than an internal combustion engine,” manufacturers and consumers alike must “be more careful around security in general.” Paul Seredynski, SAE WCX 2022: EV Cybersecurity threats, SAE International (Apr. 14, 2022), https://bit.ly/3oYJk1q. More cause for caution and concern that, again, the Proposed Rule does not resolve. [EPA-HQ-OAR-2022-0829-0649, pp. 11-12]

At bottom, the Proposed Rule’s high “pressure to achieve rapid expansion” will be “a great hindrance to the secure deployment of the EV infrastructure.” Sayed, et al., at 107,784. And because “[o]perators and manufacturers often forgo security measures to achieve faster and cheaper deployment of their equipment,” id., the Proposed Rule only promises to increase the risk that grid security will falter in the very years it would be called on to take up massive new loads. The logical result, then, is that these “[p]oorly implemented electric vehicle . . . systems could be a significant risk to EV adoption because the political, social, and financial impact of cyberattacks—or public perception of such—would ripple across the industry and produce lasting effects.” Jay Johnson, et al., Cybersecurity for Electric Vehicle Charging Infrastructure, Sandia National Laboratories (July 1, 2022), https://www.osti.gov/servlets/purl/1877784. And with “no comprehensive []cybersecurity approach and limited best practices” in the market to date, id., the Proposed Rule must do much better to explain how those risks will not become reality. [EPA-HQ-OAR-2022-0829-0649, pp. 11-12]

The Proposed Rule somewhat attempts to deal with this concern by predicting that sales will increase as consumers become more familiar with EVs as they see broader “charging infrastructure” and more electric cars “on the road.” 88 Fed. Reg. at 29,189. But that raises another buyer-focused concern that makes it even less likely consumers will change their purchasing habits to the extreme degree EPA predicts. For people who “rely on street parking,” park in a garage over 25 feet from a power source, or own a condo where the building association is not willing to “pay for upgrading the electrical panel or service,” where and how to charge a new electric car is a real concern. Rachel Kurzius, Considering an electric vehicle? Here’s how to prep your home for one, Wash. Post (Sept. 26, 2022), https://bit.ly/3N4Y3zZ. Even for the slowest and most basic “Level 1” charging option, potential EV customers are out of luck; their “home probably can’t accommodate” an EV. Id. And those who are able to upgrade their home parking situations may find themselves in a long line as the need for more complex and expensive charging mechanisms grows at a fast clip. See EV Chargers: How many do we need?, S&P Global (Jan. 9, 2023), https://bit.ly/3X1xFeM (predicting that the EV population uptick will require “about 700,000 Level 2 and 70,000 Level 3 chargers deployed, including both public and restricted-use facilities,” 1.2 million and 109,000 nationally by 2027, and 2.13 million and 172,000 by 2030, “all in addition to the units that consumers put in their own garages”). [EPA-HQ-OAR-2022-0829-0649, pp. 15-16]

Even those who already own EVs may be in for some unpleasant surprises. A recent study concluded, for example, that “[t]he vast majority of electric vehicle owners [who] charge their cars at home in the evening or overnight” are “doing it wrong” and should instead “move to daytime charging at work or public charging stations” so as to not overwhelm the grids. Golden, supra. But standard electricity pricing “charg[es] commercial and industrial customers big fees based on their peak electricity use.” Id. “This can disincentivize employers from installing chargers, especially once half or more of their employees have EVs.” Id. Some of these vehicle owners may thus be left in a vehicle-charging no-man’s land. [EPA-HQ-OAR-2022-0829-0649, pp. 15-16]

Finally, many consumers may not be able to afford electric cars even if they want them. The average new car now costs nearly $50,000. Average New Car Price Tops $49,500, Kelly Blue Book (January 11, 2023) https://bit.ly/3PcSkKT. The typical new car payment is now nearly $800 a month. New Vehicle Affordability Worse Than Ever, Kelly Blue Book (June 18, 2023) https://bit.ly/3X3F8Kt. EPA admits that the Proposed Rule “will result in a rise in the average purchase price for consumers” from even these rates. 88 Fed. Reg. at 29,364. The Agency estimates increased costs for vehicle manufacturers at $7.5 billion annually by 2027. Id. By 2032, the Proposed Rule will cost manufacturers at least $1,200 per vehicle, which they will no doubt pass to consumers. Id. at 29,201. Prices for used cars will rise as well. Id. at 29,364. [EPA-HQ-OAR-2022-0829-0649, p. 17]

The Agency argues that the benefits of EV ownership will offset these costs. Specifically, EPA insists that “projected vehicle technology costs are offset by the savings in reduced operating costs, including fuel savings and reduced maintenance and repair costs.” 88 Fed. Reg. at 29,364. EPA’s reasoning is flawed. [EPA-HQ-OAR-2022-0829-0649, p. 17]

The alleged savings for reduced fuel consumption are based on layers of speculation. The shift to EVs is projected to "reduce liquid fuel consumption (gasoline and diesel) while simultaneously increasing electricity consumption." 88 Fed. Reg. at 29,365. EPA is correct to consider the net result of these effects when analyzing the costs and benefits of the Proposed Rule. But a necessary part of that analysis relies on correctly forecasting electricity prices over the coming decades. Simultaneous with the forced electrification of vehicles, EPA is attempting to dramatically restructure America's power-generating portfolio. Whether such a transformation is possible given resource limitations, geopolitical factors, permitting issues, land-use debates, jurisdictional policy differences, and litigation is still to be determined. Even if it is possible, EPA cannot predict with any accuracy the costs to the retail ratepayer for completing such a drastic transition. In short, no one knows with enough certainty to justify massive regulatory shifts whether charging an EV will be more cost-effective than refueling a gasoline engine. [EPA-HQ-OAR-2022-0829-0649, p. 17]

Moreover, low-income consumers will not be able to afford an EV. Despite the Agency's best efforts to present EVs as increasingly affordable, at the end of 2022 the average new EV sold for $61,448. Average New Car Price Tops $49,500, supra. This is why the Agency acknowledges "low-income households are more likely to buy used vehicles and own older vehicles." 88 Fed. Reg. at 29,344. But used EVs offer little savings if the buyer has to replace the battery. According to the Department of Energy's National Renewable Energy Laboratory, advanced batteries "wear out eventually," and today's batteries last only 8 to 15 years. Electric Vehicle Benefits and Considerations, U.S. Department of Energy Alternate Fuels Data Center, https://bit.ly/3PcOn9i. Replacing an EV battery costs anywhere from $5,000 to more than $15,000. Electric Car Battery Replacement Costs, Edmunds (May 2, 2023) https://bit.ly/3NutoNS. Such substantial expenses hardly qualify as "reduced repair and maintenance costs." 88 Fed. Reg. at 29,364. [EPA-HQ-OAR-2022-0829-0649, pp. 17-18]

All of this comes at a time of record inflation, historic gasoline prices, and high utility bills. Since President Biden took office, food prices are up over 18%, and energy prices are up over 37%. Introducing the 'Presidential Inflation Rate': Biden trails only Carter, Roll Call (March 15, 2023) https://bit.ly/3qH63jd. Home prices have also surged. In the first quarter of 2023, the average home price in the United States was $516,500, Average Sales Price of Houses Sold for the United States, Federal Reserve Economic Data, https://bit.ly/3p4BenX—an increase of 27% in less than three years. Agencies cannot ignore context when weighing the costs and benefits of a proposed rule. Here, the broader economic landscape is another strong mark against the Proposed Rule. [EPA-HQ-OAR-2022-0829-0649, pp. 17-18]

Organization: Lucid Group, Inc.

The Zero Emission Transportation Association (ZETA) and its members have found that electricity providers and grid-readiness will keep pace with the transition to zero-emission vehicles. In 2021, the U.S. fleet of electric vehicles used 6.1 terawatt hours (TWhs) of electricity, accounting for 0.15% of the total national energy generation that year.2, 3 It's estimated that an additional 15-27 TWh of annual new power generation will be needed to service EVs and related technologies. In the past, nearly 100 TWh have been added in a single year, demonstrating that such an increase is accomplishable.4 [EPA-HQ-OAR-2022-0829-0664, pp. 2-3]

2 “Assessment of Light-Duty Plug-in Electric Vehicles in the United States, 2010–2021,” Argonne National Lab, November 2022, available at https://publications.anl.gov/anlpubs/2022/11/178584.pdf.

3 “Monthly Energy Review May 2023,” EIA, available at https://www.eia.gov/totalenergy/data/monthly/pdf/sec7_3.pdf.

4 “Summary Report on EVs at Scale and the U.S. Electric Power System,” US Drive https://www.energy.gov/eere/vehicles/articles/summary-report-evs-scale-and-us-electric-power-system-2019.

Transmission of the energy generated is another key component, and one that this Administration has begun to address. This year, the Administration published its plan to decrease permitting timelines, including those for new transmission projects.5 Additionally, the U.S. Department of Energy proposed a rule on designating National Interest Electric Transmission Corridors.6 The Federal government is demonstrating its intent to bolster grid resilience, which in part will ensure electricity demand is met. [EPA-HQ-OAR-2022-0829-0664, pp. 2-3]

5 “FACT SHEET: Biden-Harris Administration Outlines Priorities for Building America’s Energy Infrastructure Faster, Safer, and Cleaner,” (May 2023) available at https://www.whitehouse.gov/briefing-room/statements-releases/2023/05/10/fact-sheet-biden-harris-administration-outlines-priorities-for-building-americas-energy-infrastructure-faster-safer-and-cleaner/.

6 Notice of Intent and Request for Information: Designation of National Interest Electric Transmission Corridors, 88 FR 30956 (May 15, 2023).

Organization: Mayor Becky Daggett, City of Flagstaff, Arizona et al.

Throughout the rulemaking process, EPA should also recognize and consider investments from the recently enacted Infrastructure Investment and Jobs Act (IIJA) and Inflation Reduction Act (IRA). [EPA-HQ-OAR-2022-0829-0732, pp. 1-2]

Together, these two laws are expected to reduce adoption costs for ZEVs by providing at least $245 billion in federal funds—through tax credits, loans, and grants—to support ZEV charging infrastructure, manufacturing, and purchasing. Long-term regulatory certainty will push domestic manufacturers to take full advantage of these investments. [EPA-HQ-OAR-2022-0829-0732, pp. 1-2]

Organization: MEMA, The Vehicle Suppliers Associated

Infrastructure

To achieve the ambitious vision for U.S. charging infrastructure needed to rapidly electrify a high proportion of new vehicles, as noted above, EPA must work closely with other U.S. government agencies to help ensure that the dozens of programs in the Inflation Reduction Act (IRA) and Bipartisan Infrastructure Law (BIL), and others still needed to support the transition, are effectively deployed by the federal government. While it is true that agencies are -so far - rolling out these programs expeditiously, strong coordination of these initiatives is needed to realize nationwide transportation transformation. [EPA-HQ-OAR-2022-0829-0644, p. 11]

V2G bidirectional charging technologies can provide a transformational opportunity to help address the nation's energy crisis while also decarbonizing the transportation sector. The use of bidirectional charging installations, for fleet and private vehicles, can help stabilize local grid activity and balance load versus demand.9 Besides grid load balancing, the use of vehicle batteries as energy sources can also offset local energy production demands and further improve grid resiliency and national security. [EPA-HQ-OAR-2022-0829-0644, p. 11]

9 This notice is one example of "grid services vehicles can provide" according to the US DOE https://content.govdelivery.com/accounts/USEERE/bulletins/3594aae

Organization: Mercedes-Benz AG

Section IV: Batteries

V2X applications such as vehicle-to-grid, vehicle-to-load, and vehicle-to-home are increasingly considered key features that will support the shift to electrification. For instance, the California legislature is currently considering a mandate for all new vehicles in the state to have bidirectional charging capability starting in 2030 MY. Regardless of California's law or separate OEM efforts to advance V2G, inclusion of the parameter, "virtual distance", is fundamental to the transparent deployment of V2G technology. As such, we would like EPA to add virtual distance to the regulatory language in both the durability and warranty mileage calculation. [EPA-HQ-OAR-2022-0829-0623, pp. 15-16]

Organization: Minnesota Pollution Control Agency (MPCA)

-The Minnesota Public Utilities Commission has found that EVs are both an opportunity and a challenge for the electric power sector and has therefore directed Minnesota's investor-owned utilities to take steps to encourage cost-effective integration of EVs and plan for their adoption. Minnesota's utilities have developed and begun implementing a variety of programs to support EV adoption, including home charging and rate design, as well as public charging investments.6 [EPA-HQ-OAR-2022-0829-0557, pp. 3-4]

6 Minnesota Public Utilities Commission, Electric vehicles, https://mn.gov/puc/activities/economic-analysis/electric-vehicles/ (accessed 6/15/2023).

Organization: Missouri Corn Growers Association (MCGA)

Coincidentally, there is no similar proposal to upgrade the power grid to support this rule. Researchers estimate the 350 million electric vehicles required to decarbonize the U.S. fleet by 2050 could use as much as half of the U.S. national electricity demand. Therefore, EPA's proposal would require a complete transformation of the electric power sector, requiring substantially more generation, transmission, and distribution, resulting in higher emissions and power prices not only for those using electrified vehicles, but for all consumers. [EPA-HQ-OAR-2022-0829-0578, p. 2]

Alongside this rule, EPA should be warning Americans of the higher energy costs and increased electrical blackouts that may accompany the forced BEV adoption rates. EPA should also prepare consumers for a future of increasingly expensive vehicles that many lower to middle-class families can't afford, along with coinciding increases in the cost of used vehicles. [EPA-HQ-OAR-2022-0829-0578, p. 2]

Organization: Missouri Farm Bureau (MOFB)

Further, MOFB is greatly concerned that the proposed rule contains zero language regarding what impact it will have on the country's severely aged and inadequate electric grid. In 2020, the U.S. experienced 180 major electrical disruptions, up from fewer than two dozen in 2000.8 [EPA-HQ-OAR-2022-0829-0590, pp. 2-3]

8 America's Power Grid Is Increasingly Unreliable -WSJ, (Link: https://www.wsj.com/articles/americas-power-grid-is-increasingly-unreliable-11645196772) accessed June 14, 2023.

EPA's proposed rule fails to illustrate how electricity will actually be delivered to thousands of new charging stations that will be needed to accommodate this mandate, and what impact it will have upon every other aspect of our lives, much of which relies on the uninterrupted delivery of electricity. EPA should be warning Americans about the higher energy costs and increased electrical shortages and blackouts that could accompany the massive EV rate of adoption mandated by its proposed rule. [EPA-HQ-OAR-2022-0829-0590, pp. 2-3]

As stated in our HD rule comments, MOFB is especially concerned with the future buildout of electric transmission lines that will be needed to carry the proposed rule's mandates into fruition. Unfortunately, and all too often, farmers and ranchers hear others say that their land is needed for the "public's benefit." Government agencies and renewable energy advocates often forget that farmers and ranchers are part of the "public" as well, and need to be fairly compensated for the continued buildout of transmission lines through their private property, which will take away the critical farm and ranch land necessary to run their businesses for generations to come. [EPA-HQ-OAR-2022-0829-0590, pp. 2-3]

Organization: National Association of Convenience Stores (NACS) et al.

iii. Transmission Capacity is Severely Lacking

Another substantial challenge is the generation and supply of electricity to charging stations. Every market participant that our membership communicates with is extraordinarily skeptical that electricity providers will be able to increase generation and transmission activity to service the kind of load necessary to provide charging infrastructure for the volume and type of Level 3 or DCFCs needed to accommodate travelers or those without access to home charging, which is likely to be a majority of future EV drivers—and within the next seven to nine years. A recent analysis of grid upgrades necessary for electrification found that a single highway fast-charging site, which would offer services to light-, medium-, and heavy-duty vehicles, will require the same amount of electricity as a sports stadium or a small town.26 This will require the development of dedicated substations and significant energy resources behind the meter. The Proposed Rule largely assumes that, with an increase in EV production, there will be a sufficient increase in electricity generation and transmission to meet those EV needs. Even when charging sites are financed, lead times for commercial charging infrastructure can range from six months to two or more years.27 [EPA-HQ-OAR-2022-0829-0648, p. 9]

26 Gideon Katsh, et al., CALSTART ET AL., "Electric Highways: Accelerating and Optimizing Fast-Charging Deployment for Carbon-Free Transportation" (Nov. 11, 2022) available at https://calstart.org/electric-highways-study/.

27 SPARKCHARGE, "Commercial EV Charging Station Installation Timeline" (2023) available at https://www.sparkcharge.io/blogs/leadthecharge/commercial-ev-charging-station-installation-timeline.

EPA cannot ignore that the infrastructure and electricity supply needed for the Proposed Rule do not exist in a vacuum; the effects of EPA's Proposal is only further compounded by its simultaneous proposal mandating the electrification of heavy-duty trucks.28 [EPA-HQ-OAR-2022-0829-0648, p. 9]

28 88 Fed. Reg. 25,926 (Apr. 27, 2023) (Proposed Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles— Phase 3).

c. Supply Chain and Market-Related Barriers to EV Adoption

Various other barriers to EV adoption exist beyond public charging, including consumer skepticism toward new technology, higher costs than internal combustion engine ("ICE") vehicles, limited range, lack of convenient public charging infrastructure, uncertain battery aging and resale value, dismissive or deceptive car dealerships, lack of available models, and other supply constraints.29 [EPA-HQ-OAR-2022-0829-0648, p. 9]

29 Matteo Muratori et al., PROG. ENERGY 3 022002 "The rise of electric vehicles—2020 status and future expectations" (Mar. 25, 2021) available at https://doi.org/10.1088/2516-1083/abe0ad.

EPA acknowledges, though does not meaningfully address, many of the barriers to EV adoption.30 If the Agency is interested in electrifying light-duty transportation in the United States, it should proactively redress these obstacles rather than assume they will dissipate on their own under the full weight of unachievable mandates. [EPA-HQ-OAR-2022-0829-0648, p. 9]

30 Proposed Rule at 29,311.

Further, the Proposed Rule overlooks the emissions impacts from the substantial expansion of the electrical grid. While EPA credits emissions reductions from assuming the power sector will become cleaner over time using renewable generation and electricity storage (e.g., batteries), it ignores the impacts of building out that associated infrastructure. New power generation, renewable power generation, and energy storage require the same critical minerals necessary for manufacturing EV batteries. Increased electricity demand will only further compound the stress on critical minerals. Indeed, copper and aluminum—both needed for EVs—are also the two main materials in wires and cables. Battery storage equipment for solar and other renewable energy sources rely on similar battery chemistries as EVs.39 Again, EVs may be the most environmentally compelling solution, but it does neither the climate nor American consumers any favors for the Agency to pretend the solution is more compelling or achievable than it actually is. [EPA-HQ-OAR-2022-0829-0648, pp. 10-12]

39 And, as described above, higher prices on these materials could have a major impact on future grid investments. INTERNATIONAL ENERGY AGENCY, The Role of Critical Minerals in Clean Energy Transitions (Mar. 2022), 77–80, available at https://iea.blob.core.windows.net/assets/ffd2a83b-8c30-4e9d-980a-52b6d9a86fdc/TheRoleofCriticalMineralsinCleanEnergyTransitions.pdf.

The simultaneous spike in demand for materials such as copper and aluminum for both the grid and EV manufacturing will increase extraction and refining efforts globally, potentially exacerbating consequences on a regional level.40 By failing to consider geographic electricity generation differences and the potential benefits of a non-homogenized vehicle population, the Proposal misses the opportunity to most effectively respond to emissions concerns and, more importantly, could indirectly lead to increased emissions in certain regions. A full accounting of the relative advantages and disadvantages of the different vehicle technologies is necessary to ensure the Proposal harnesses the benefits of competition among different current and potential future vehicle technologies. [EPA-HQ-OAR-2022-0829-0648, pp. 10-12]

40 The U.S. is almost entirely dependent on other countries, especially China, for materials essential to manufacturing EVs, meaning the Proposal may potentially raise national security concerns.

Organization: National Propane Gas Association (NPGA)

The EPA's efforts will promote additional demand for electricity for zero-emission vehicles at a time when the electric grid is suffering from a reliability crisis. The North American Electric Reliability Corporation's most recent long-term reliability assessment shows more than 50% of the United States is in high risk or elevated risk of shortfalls in electricity supply.5 This assessment is based on existing demand, and show that the grid needs significant improvements to meet rising demand, and extreme conditions. Specifically, the Assessment calls on industry and policymakers to "consider the impact that electrification of transportation, space heating, and other sectors may have on future electricity demand and infrastructure."6 The EPA has failed to present its consideration of the impact of its proposal on grid reliability, and consequently, failed to answer any questions about such necessary analysis.7 Prior to adding additional demand, the EPA should urge its partner, the DOE and the Federal Energy Regulatory Commission, to heed the guidance of the Government Accountability Office and analyze options for grid resilience, so as to avoid enhanced strain without a demand management or supply plan.8 Further, the EPA would benefit particularly in this review by reviewing analysis of grid strain during extreme weather events, which have called for enhanced storage, transmission, and generation enhancement of 35-70 gigawatts of power.9 The EPA's efforts will only exacerbate the strain on the grid, risking consumer blackouts and brownouts, as well as vehicles being unable to charge, which could have fatal follow-on effects when considering the essential role light-and medium-duty vehicles play in the economy. [EPA-HQ-OAR-2022-0829-0634, p. 2]

Organization: National Rural Electric Cooperative Association (NRECA)

Critical Role of Electric Cooperatives as Light-and Medium-Duty Vehicles are Electrified

Electrification of the transportation sector creates both opportunities and challenges for the electric sector, and electric cooperatives will play a critical role in the success of the transformation now underway. As such, electric cooperatives welcome the opportunity to partner with state and local entities on implementing the programs dedicated to building out the nation's electric vehicle (EV) charging network in the bipartisan infrastructure law (BIL) and through other opportunities. The funding in the BIL is an important down payment in the federal support required to electrify the transportation sector, particularly in rural areas that could otherwise be left behind. [EPA-HQ-OAR-2022-0829-0575, pp. 1-2]

To support the electrification of light-and medium-duty vehicles as laid out in EPA's proposed rule, electric cooperatives and other utilities must be involved from the very beginning of planning for the charging infrastructure these vehicles will require. There are already examples of 1 MW charging stations being built to support vehicle fleets. Electric cooperatives and other utilities need to be integrated at the very beginning of planning for such facilities by the project developers, or other relevant planning authorities where applicable, to avoid unintended consequences. [EPA-HQ-OAR-2022-0829-0575, pp. 1-2]

EPA Should Account for Grid-side Investments in Proposed Rule's Analysis

Bearing these realities in mind, we write to express our significant concern that EPA has failed to adequately account for the costs associated with serving the new load that will be created via light-and medium-duty vehicle (LDV and MDV) electrification as outlined in this proposed rule. While EPA accounts for the cost to purchasers for the hardware and installation of charging equipment, EPA fails to include the electric grid-side upgrades that will likely be needed, if not now, certainly in the future as electrification spreads and this could have serious negative consequences to American consumers. [EPA-HQ-OAR-2022-0829-0575, p. 2]

Specifically, within the proposed rule section on PEV Charging Infrastructure Considerations, EPA states:1 "there may be additional infrastructure needs and costs beyond those associated with charging equipment itself. While planning for additional electricity demand is a standard practice for utilities and not specific to PEV charging, the buildout of public and private charging stations (particularly those with multiple high-powered DC fast charging units) could in some cases require upgrades to local distribution systems…However, there is considerable uncertainty associated with…future distribution upgrade needs, and we do not model them directly as part of our infrastructure cost analysis." [EPA-HQ-OAR-2022-0829-0575, p. 2]

1 Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, 88 Fed. Reg. 29,311 (May 5, 2023).

It is important for EPA to correct this failure in the proposed rule stage by updating its analysis with inclusion of a range of expected costs associated with serving the new load from the LDV and MDV fleets created by EPA's proposal. Failure to do so will likely result in unrealistic expectations on the part of consumers and fleet operators and possibly delay plans for electrification as they learn of the full costs that will be required to serve this new load from their electric cooperatives or other electric utilities. Neither these consumers/operators, nor the EPA, should expect that electric cooperatives can bear the burden of these new costs alone, particularly when these costs will ultimately need to be passed on to the end of the line consumer-members of the cooperative. [EPA-HQ-OAR-2022-0829-0575, p. 2]

Overall, it is important for EPA to recognize that electrification of the transportation sector, and the increased flexibility of this newly electrified demand, will require substantial distribution infrastructure investment over time to meet increased average local electric demand and to meet increased demand in new locations (e.g., EV charging stations). Significant transmission infrastructure investment may also be required to meet increased average electric demand and changes in the spatial distribution of electric demand among load centers. According to the

National Academy of Sciences, to transition the transportation sector through increased electrification, electric utilities will need to increase generation by up to 170% and see a three-fold expansion of the transmission grid by 2050. Over time, electrification of the transportation sector will require additional generation investment to ensure resource and energy adequacy to meet increased average electric demand and changing consumption profiles. Unfortunately, this investment challenge is becoming more complex due to several recent EPA actions that are jeopardizing flexible, dispatchable always available generation resources.2 These actions would require increased reliance on intermittent energy sources. Particular attention will be needed to ensure that generation investment is adequate in amount and in operational characteristics to meet the demands of electrification while ensuring grid stability, security, and reliability. [EPA-HQ-OAR-2022-0829-0575, pp. 2-3]

2 These actions include: Supplemental Effluent Limitations Guidelines and Standards for the Steam Electric Power Generating Point Source Category, 88 FR 18824 (March 29, 2023); National Emission Standards for Hazardous Air Pollutants: Coal-and Oil-Fired Electric Utility Steam Generating Units Review of the Residual Risk and Technology Review, 88 FR 24854 (April 24, 2023); Hazardous and Solid Waste Management System: Disposal of Coal Combustion Residuals From Electric Utilities; Legacy CCR Surface Impoundments, 88 FR 31982 (May 18, 2023); New Source Performance Standards for Greenhouse Gas Emissions From New, Modified, and Reconstructed Fossil Fuel-Fired Electric Generating Units; Emission Guidelines for Greenhouse Gas Emissions From Existing Fossil Fuel-Fired Electric Generating Units; and Repeal of the Affordable Clean Energy Rule, 88 FR 33240 (May 23, 2023); and Federal Good Neighbor Plan for the 2015 Ozone National Ambient Air Quality Standards, 88 FR 36654 (June 5, 2023).

Specific Costs for EPA to Consider Incorporating in the Proposed Rule’s Analysis

Again, we urge EPA to update its analysis to account for the costs needed to make updates to the grid to support transportation electrification as envisioned in this proposal. Grid upgrade costs for EV charging will vary by region, neighborhood, cooperative, circuit, and feeder. However, to illustrate the types and ranges of costs that EPA should account for, we provide the following costs sourced from four different cooperative regions, broken down by charge level: [EPA-HQ-OAR-2022-0829-0575, pp. 3-4]

-Residential (Level 1 and Level 2): One out of three households will need an expanded electric panel to accommodate 240 V Breakers. If a household purchases two electric vehicles, then four slots on a breaker will be needed to accommodate this load. The average cost will be approximately $4,000 for a Level 2 residential charger with a panel upgrade.

--Upgrading panel (20% of panels must be upgraded) – can start around $600

--Transformer upgrades -$2,600 and climbing

--Service wire gauge upgrades to accommodate higher amperage -$3,000

- Public (Level 2 and DC Fast Charging (DCFC)): For commercial sites, transformer upgrade needs will vary. Most sites will already have three-phase power available; however, in very rural locations single-phase power will need to be upgraded to three-phase. If transformers do need to be upgraded on a three-phase line, then three transformers will need to be upgraded.

--Level 2 charger including panel -approx. $4,000 on average

--National EV Infrastructure Program (NEVI)-Compliant DCFC -approx. $25,000-

$150,000

-Transformer -$25,000 -$40,000 (reflects current prices for three transformers)

-Service entrance -$3,000-$4,000

-Metering package (including instrumentation, voltage transformers (PT) and current transformers (CT) -$2,000

-Line extension, if required (site dependent) -$50,000 -$75,000

[EPA-HQ-OAR-2022-0829-0575, pp. 3-4]

Circumstances vary across cooperatives, but some of these costs will be borne directly by the consumer-members and others will be paid for by the cooperative. Regardless, these costs help to illustrate more accurately the investment it will take to implement on EPA's proposed rule. [EPA-HQ-OAR-2022-0829-0575, pp. 3-4]

We note that these costs reflect a snapshot estimate in time and are likely to increase, particularly due to the significant challenges and delays utilities are facing in their supply chains, which are contributing to an unprecedented shortage of the most basic machinery and components essential to ensure the continued reliability of the electric grid. Electric cooperatives are waiting a year, on average, to receive distribution transformers. Additionally, lead times for large power transformers have grown to more than three years. And orders for electrical conduit have been delayed five-fold to 20 weeks with costs ballooning by 200 percent year-over-year. As a result, new projects are being deferred or canceled, and electric cooperatives are concerned about their ability to respond to major storms due to depleted stockpiles. We expect these supply chain challenges to persist with the increased demand for electrification projects being incentivized by the U.S. federal government. All these delays will likely impact the cost and timing of charging infrastructure buildout needed to support the transportation. [EPA-HQ-OAR-2022-0829-0575, pp. 3-4]

EPA should update its analysis in the proposed rule to account for the significant grid investments that may be needed to support transportation electrification as laid out in the proposal. As detailed above, these costs may be significant and should not be shouldered by the electric cooperatives serving this new load. Again, electric cooperatives are consumer-owned and operate at cost on a not-for-profit basis. They also serve 92% of the nation's persistent poverty counties. Affordability is critical to electric cooperatives and the consumer-members they serve, and any new costs imposed on an electric cooperative are ultimately borne by the consumers at the end of the line. EPA should update its analysis to ensure it more accurately represents the costs associated with electrifying both LDVs and MDVs, which could be significant across the country. [EPA-HQ-OAR-2022-0829-0575, p. 4]

[EPA-HQ-OAR-2022-0829-0575, p. 4]

Organization: National Tribal Air Association (NTAA)

Electrified Vehicles

As noted in the announcement of the proposed standards, "EPA's proposal builds upon a proliferation of announcements by automakers that collectively signal a rapidly growing shift…toward zero-emission technologies, including electrification"5. This anticipated reliance on hybrid, plug-in hybrid, and fully electric power trains may be disproportionately burdensome and costly in Indian country. Far too many homes on many reservations lack access to an electric grid. Further, vehicle reliance on centralized or individual battery charging sites as anticipated in the proposed regulations presents a huge challenge. [EPA-HQ-OAR-2022-0829-0504, p. 3]

5 Biden-Harris Administration Proposes Strongest-Ever Pollution Standards for cars and trucks to Accelerate Transition to a Clean – Transportation Future, USEPA News Release, April 12, 2023

The NTAA is well aware of many initiatives to enhance the deployment of renewable energy technologies to support the nation's electricity demand. We actively participate in meetings, webinars, forums, etc. as programs emerge under the Bipartisan Infrastructure Law, Inflation Reduction Act, and other climate change – related initiatives. The NTAA continues to formally comment on EPA proposals that emerge which have the potential to impact Indian country. NTAA remains concerned about realistic access to funding and other resources that are essential to advance renewable energy in Tribal communities and are necessary to transition vehicle fleets as anticipated by the proposed light-duty and medium-duty vehicle emissions standards. [EPA-HQ-OAR-2022-0829-0504, p. 3]

Organization: Nebraska Corn Board (NCB) and Nebraska Corn Growers Association

According to the North American Electric Reliability Corporation (NERC), two-thirds of the country could experience rolling blackouts this summer. The current power grid is unable to handle the added light-duty vehicles and does not include adding heavy-duty electric fleets requiring larger amounts of electricity. Not only does the infrastructure need updating, but it will take a large amount of public investment to meet this goal. [EPA-HQ-OAR-2022-0829-0583, p. 1]

Further, EVs are not a zero emissions product as 60% of the U.S. power grid is requires coal and natural gas along with the mining of rare earth minerals. Aside from not being a zero emissions vehicle, Americans will face rolling blackouts and weakened energy security with EVs depending on the electrical grid. Current energy infrastructure cannot support this proposal. [EPA-HQ-OAR-2022-0829-0583, p. 1]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC)

Like ZEV sales regulations, the shared ambition memorialized in these multi-state agreements sends strong and consistent signals to industry and investors and promotes public and private investment in zero-emission technologies and infrastructure. For example, the public utility commissions in the U.S. signatories to the 2022 MOU have already approved more than $2 billion dollars of utility funding for medium-and heavy-duty ZEV infrastructure planning and deployment.22 [EPA-HQ-OAR-2022-0829-0584, pp. 5-6]

Organization: Paul Bonifas and Tim Considine

EVSE Port Costs & Grid Upgrades: The EPA purposefully ignores a fundamental truth about EV charging. The EPA's study does NOT include the massive costs to upgrade the electrical grid to accommodate EV charging, as they consider it outside of the scope of their Rule. However, these mandatory grid upgrades must be included in the analysis as they will be a large cost burden for every consumer of electricity in the country. Including these grid upgrade costs results in a more realistic cost of $330 billion, a $210 billion cost increase from the EPA's calculations. [EPA-HQ-OAR-2022-0829-0551, p. 3]

This rule is like the Clean Power Plan proposed by the Biden Administration. The US Energy Information Administration conducted a study of the Clean Power Plan and found that average retail electricity rates would increase upwards of 3-7%.13 Taking the mid-range of this price increase, or 5%, the proposed rule would raise the previous electric rate increase of 55% to 58% and increase electricity costs for EV charging from EPA's estimate of $460 billion to $728 billion. [EPA-HQ-OAR-2022-0829-0551, p. 5]

13 https://www.eia.gov/analysis/requests/powerplants/cleanplan/

This $728 billion in higher electricity expenditures more than offsets the savings in reduced liquid fuel spending of $620. On balance, the fuel cost savings are a NEGATIVE $108 billion in contrast to EPA's estimated pre-tax fuel savings of $890 billion. This is a nearly $1 trillion difference. So, under rather conservative but realistic assumptions and elementary economic analysis, the proposed EV rule will not save consumers money but instead will lead to higher electricity costs, especially for poor and lower to middle class households living in rental units. [EPA-HQ-OAR-2022-0829-0551, p. 5]

There is also another concern related to timing. The electrical grid may not be ready to accommodate the additional load from this head long rush to force consumers to buy EVs. Electricity supply is like a backwards "L," with low marginal costs for generation levels up to capacity constraints. Once demand reaches those capacity constraints, the supply curve is vertical, and prices can reach extraordinary heights until demand falls or new capacity is available. We have witnessed this phenomenon in Texas and other regional electricity markets due to weather events. The EPA's proposed EV rule is a similar demand shock, however, it would be persistent unlike transitory weather demand shocks and unless electricity providers respond in a timely manner, rates could increase much more than 58%. [EPA-HQ-OAR-2022-0829-0551, p. 5]

EVSE Port Costs & Grid Upgrades

EPA Claimed Costs: $120 billion

Realistic Costs: $330 billion

[EPA-HQ-OAR-2022-0829-0551, p. 5]

This cost category purposefully ignores a fundamental truth about EV charging. Simply put, the EPA's study does NOT include the colossal costs to upgrade the electrical grid to accommodate EV charging. When the EPA discusses Electric Vehicle Supply Equipment (EVSE), they only consider the costs to install the physical "plugs" or "ports" that provide electricity to a vehicle and charges its battery, a measly $120 billion cost (present value at 3 percent discount rate). [EPA-HQ-OAR-2022-0829-0551, pp. 8-9]

In their RIA, the EPA states: [EPA-HQ-OAR-2022-0829-0551, pp. 8-9]

"Charging infrastructure is different from the electric power utility distribution system infrastructure, which is comprised of distribution feeder circuits, switches, protective equipment, primary circuits, distribution transformers, secondaries, service drops, etc."29 [2] [EPA-HQ-OAR-2022-0829-0551, pp. 8-9]

29 Page 364 of EPA's Draft Regulatory Impact Analysis - https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf

and in the EPA rule, they state: [EPA-HQ-OAR-2022-0829-0551, pp. 8-9]

"The buildout of public and private charging stations (particularly those with multiple high-powered DC fast charging units) could in some cases require upgrades to local distribution systems. For example, a recent study found power needs as low as 200 kW could trigger a requirement to install a distribution transformer…. there is considerable uncertainty associated with the uptake of these technologies as well as with future distribution upgrade needs, and we do not model them directly as part of our infrastructure cost analysis".30 [EPA-HQ-OAR-2022-0829-0551, pp. 8-9]

30 Page 128 of EPA's Rule -https://www.govinfo.gov/content/pkg/FR-2023-05-05/pdf/2023-07974.pdf

However, these mandatory grid upgrades made by utility companies MUST be included in the analysis as they will be a large cost burden on consumers of electricity, even for those that do not own EVs. [EPA-HQ-OAR-2022-0829-0551, pp. 8-9]

As of 2021, the department of transportation reported more than 272 million vehicles (cars, buses, and trucks) were registered in the US31. Using the EPA's "EV Penetration Rates" as a proxy for eventual nationwide EV adoption, their rule would force the ownership of 76 million more EVs by 2032 compared to the "no change" scenario 32. [EPA-HQ-OAR-2022-0829-0551, p. 9]

32 Pages 668 & 670 of EPA's Draft Regulatory Impact Analysis - https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf

The Boston Consulting Group estimates that: [EPA-HQ-OAR-2022-0829-0551, p. 9]

"Depending on charging patterns, [a utility] will need to invest between $1,700 and $5,800 in grid upgrades per electric vehicle (EV) through 2030"33. [EPA-HQ-OAR-2022-0829-0551, p. 9]

33 https://www.bcg.com/publications/2019/costs-revving-up-the-grid-for-electric-vehicles

The midpoint of that cost range ($3,750 per EV) yields an incremental electric grid upgrade cost of $286 billion for the eventual 76 million additional EVs. These costs would be in addition to the $120 billion the EPA estimates solely for EVSE ports. [EPA-HQ-OAR-2022-0829-0551, p. 9]

Another study by the Brattle Group, estimates $60 billion in electric grid upgrades (generation, storage, transmission, and distribution) for every $40 billion in EVSE port costs34. Therefore, since the EPA is estimating three times (3X) the EVSE port costs that Brattle is showing, this would result in an electric grid upgrade cost of $180 billion to accommodate the EV charging. This would be in addition to the $120 billion in costs the EPA estimates solely for EVSE ports. [EPA-HQ-OAR-2022-0829-0551, p. 9]

34 https://www.brattle.com/insights-events/publications/electric-power-sector-investments-of-75-125-billion-needed-to-support-projected-20-million-evs-by-2030-according-to-brattle-economists/

Assuming the costs are evenly spread out over the next 8 years, using an average of the Boston Consulting Group's and Brattle's data for grid upgrades ($233 billion avg, $210 billion PV3), the resulting combined PV3 costs for EVSE ports and electric grid upgrades is $330 billion, a 175% increase from the EPA figure of $120 billion. [EPA-HQ-OAR-2022-0829-0551, p. 9]
